## **Abstract**

We present an new implementation of the classic Vegas algorithm for adaptive multi-dimensional Monte Carlo integration in Fortran95. This implementation improves the performance for a large class of integrands, supporting stratified sampling in higher dimensions through automatic identification of the directions of largest variation. This implementation also supports multi channel sampling with individual adaptive grids. Sampling can be performed in parallel on workstation clusters and other parallel hardware.

## *Program Summary:*

- **Title of program:** VAMP, Version 1.0 (October 1999)
- **Program obtainable** by anonymous `ftp` from the host `crunch.ikp.physik.th-darmstadt.de` in the directory `pub/ohl/vamp`.
- **Licensing provisions:** Free software under the GNU General Public License.
- **Programming language used:** Fortran95 [8] (Fortran90 [7] and F [13] versions available as well)
- **Number of program lines in distributed program, including test data, etc.:**  $\approx 4300$  (excluding comments)
- **Computer/Operating System:** Any with a Fortran95 (or Fortran90 or F) programming environment.
- **Memory required to execute with typical data:** Negligible on the scale of typical applications calling the library.
- **Typical running time:** A small fraction (typically a few percent) of the running time of applications calling the library.
- **Purpose of program:**
- **Nature of physical problem:**
- **Method of solution:**
- **Keywords:** adaptive integration, event generation, parallel processing

# —1— INTRODUCTION

We present a reimplementation of the classic Vegas [1, 2] algorithm for adaptive multi-dimensional integration in Fortran95 [8, 12]<sup>1</sup>. The purpose of this reimplementation is two-fold: for pedagogical reasons it is useful to employ Fortran95 features (in particular the array language) together with literate programming [4] for expressing the algorithm more concisely and more transparently. On the other hand we use a Fortran95 abstract type to separate the state from the functions. This allows multiple instances of Vegas with different adaptions to run in parallel and in paves the road for a more parallelizable implementation.

The variable names are more in line with [1] than with [2] or with [16, 17, 18], which is almost identical to [2].

## —2— ALGORITHMS

 The notation has to be synchronized with [3]!

We establish some notation to allow a concise discussion. Notation:

$$\text{expectation: } E(f) = \frac{1}{|\mathcal{D}|} \int_{\mathcal{D}} dx f(x) \quad (2.1a)$$

$$\text{variance: } V(f) = E(f^2) - (E(f))^2 \quad (2.1b)$$

$$\text{estimate of expectation (average): } \langle X|f \rangle = \frac{1}{|X|} \sum_{x \in X} f(x) \quad (2.1c)$$

$$\text{estimate of variance: } \sigma_X^2(f) = \frac{1}{|X|-1} (\langle X|f^2 \rangle - \langle X|f \rangle^2) \quad (2.1d)$$

Where  $|X|$  is the size of the point set and  $|\mathcal{D}| = \int_{\mathcal{D}} dx$  the size of the integration region. If  $\mathcal{E}(\langle f \rangle)$  denotes the ensemble average of  $\langle X|f \rangle$  over random point sets  $X$  with  $|X| = N$ , we have for expectation and variance

$$\mathcal{E}(\langle f \rangle) = E(f) \quad (2.2a)$$

$$\mathcal{E}(\sigma^2(f)) = V(f) \quad (2.2b)$$

and the ensemble variance of the expectation is also given by the variance

$$\mathcal{V}(\langle f \rangle) = \frac{1}{N} V(f) \quad (2.2c)$$

Therefore, it can be estimated from  $\sigma_X^2(f)$ . Below, we will also use the notation  $\mathcal{E}_g$  for the ensemble average over random point sets  $X_g$  with probability distribution  $g$ . We will write  $E_g(f) = E(fg)$  as well.

## 2.1 Importance Sampling

If, instead of uniformly distributed points  $X$ , we use points  $X_g$  distributed according to a probability density  $g$ , we can easily keep the expectation constant

$$\mathcal{E}_g(\langle f \rangle) = E_g\left(\frac{f}{g}\right) = E(f) \quad (2.3)$$

while the variance transforms non-trivially

$$\mathcal{V}_g(\langle f \rangle) = \frac{1}{N} V_g\left(\frac{f}{g}\right) = \frac{1}{N} \left( E_g\left(\frac{f^2}{g^2}\right) - \left(E_g\left(\frac{f}{g}\right)\right)^2 \right) \quad (2.4)$$

and the error is minimized when  $f/g$  is constant, i.e.  $g$  is a good approximation of  $f$ . The non-trivial problem is to find a  $g$  that can be generated efficiently and is a good approximation at the same time.

One of the more popular approaches is to use a mapping  $\phi$  of the integration domain

$$\begin{aligned} \phi : \mathcal{D} &\rightarrow \Delta \\ x &\mapsto \xi = \phi(x) \end{aligned} \quad (2.5)$$

In the new coordinates, the distribution is multiplied by the Jacobian of the inverse map  $\phi^{-1}$ :

$$\int_{\mathcal{D}} dx f(\phi(x)) = \int_{\Delta} d\xi J_{\phi^{-1}}(\xi) f(\xi) \quad (2.6)$$

A familiar example is given by the map

$$\begin{aligned} \phi : [0, 1] &\rightarrow \mathbf{R} \\ x &\mapsto \xi = x^0 + a \cdot \tan\left(\left(x - \frac{1}{2}\right)\pi\right) \end{aligned} \quad (2.7)$$

with the inverse  $\phi^{-1}(\xi) = \text{atan}((\xi - x_0)/a)/\pi + 1/2$  and the corresponding Jacobian reproducing a resonance

$$J_{\phi^{-1}}(\xi) = \frac{d\phi^{-1}(\xi)}{d\xi} = \frac{a}{\pi} \frac{1}{(\xi - x^0)^2 + a^2} \quad (2.8)$$

Obviously, this works only for a few special distributions. Fortunately, we can combine several of these mappings to build efficient integration algorithms, as will be explained in section 2.4 below. Another approach is to construct the approximation numerically, by appropriate binning of the integration domain (cf. [1, 2, 19]). The most popular technique for this will be discussed below in section 2.3.

## 2.2 Stratified Sampling

The technique of importance sampling concentrates the sampling points in the region where the contribution to the integrand is largest. Alternatively we can also concentrate the sampling points in the region where the contribution to the variance is largest.

If we divide the sampling region  $\mathcal{D}$  into  $n$  disjoint subregions  $\mathcal{D}^i$

$$\mathcal{D} = \bigcup_{i=1}^n \mathcal{D}^i, \quad \mathcal{D}^i \cap \mathcal{D}^j = \emptyset \quad (i \neq j) \quad (2.9)$$

a new estimator is

 Bzzzt! Wrong. These multi-channel formulae are incorrect for partitions and must be fixed.

$$\overline{\langle X | f \rangle} = \sum_{i=1}^n \frac{N_i}{N} \langle X_{\theta_i} | f \rangle \quad (2.10)$$

where

$$\theta_i(x) = \begin{cases} 1 & \text{for } x \in \mathcal{D}^i \\ 0 & \text{for } x \notin \mathcal{D}^i \end{cases} \quad (2.11)$$

and

$$\sum_{i=1}^n N_i = N \quad (2.12)$$

since the expectation is linear

$$\mathcal{E}(\overline{\langle f \rangle}) = \sum_{i=1}^n \frac{N_i}{N} \mathcal{E}_{\theta_i}(\langle f \rangle) = \sum_{i=1}^n \frac{N_i}{N} E_{\theta_i}(f) = \sum_{i=1}^n \frac{N_i}{N} E(f \theta_i) = E(f) \quad (2.13)$$

On the other hand, the variance of the estimator  $\overline{\langle X | f \rangle}$  is

$$\mathcal{V}(\overline{\langle f \rangle}) = \sum_{i=1}^n \frac{N_i}{N} \mathcal{V}_{\theta_i}(\langle f \rangle) \quad (2.14)$$

This is minimized for

$$N_i \propto \sqrt{V(f \cdot \theta_{\mathcal{D}^i})} \quad (2.15)$$

as a simple variation of  $\mathcal{V}(\overline{\langle f \rangle})$  shows.

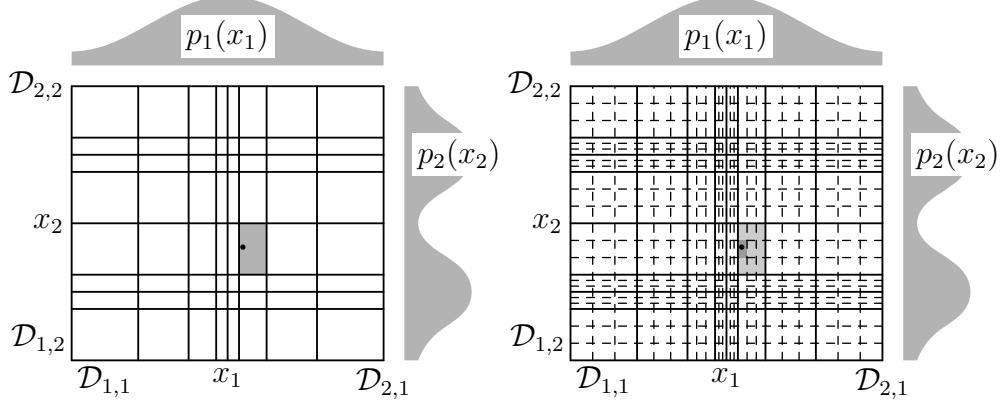

Figure 2.1: `vegas` grid structure for non-stratified sampling (left) and for genuinely stratified sampling (right), which is used in low dimensions. N.B.: the grid and the weight functions  $p_{1,2}$  are only in qualitative agreement.

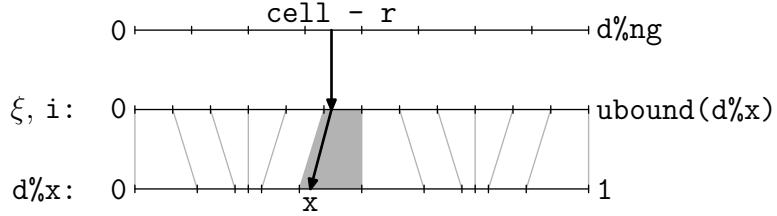

Figure 2.2: One-dimensional illustration of the `vegas` grid structure for pseudo stratified sampling, which is used in high dimensions.

## 2.3 Vegas

Under construction!

### 2.3.1 Vegas' Inflexibility

The classic implementation of the Vegas algorithm [1, 2] treats all dimensions alike. This constraint allows a very concise FORTRAN77-style coding of the algorithm, but there is no theoretical reason for having the same number of divisions in each direction. On the contrary, under these circumstances, even a dimension in which the integrand is rather smooth will contribute to the exponential blow-up of cells for stratified sampling. It is obviously beneficial to use a finer grid in those directions in which the fluctuations are stronger, while a coarser grid will suffice in the other directions.

One small step along this line is implemented in Version 5.0 of the package BASES/SPRING [19], where one set of “wild” variables is separated from “smooth” variables [20].

The present reimplementation of the Vegas algorithm allows the application to choose the number of divisions in each direction freely. The routines that reshape the grid accept an integer array with the number of divisions as an optional argument `num_div`. It is easy to construct examples in which the careful use of this feature reduces the variance significantly.

Currently, no attempt is made for automatic optimization of the number of divisions. One reasonable approach is to monitor Vegas’ grid adjustments and to increase the number of division in those directions where Vegas’ keeps adjusting because of fluctuations. For each direction, a numerical measure of these fluctuations is given by the spread in the  $m_i$ . The total number of cells can be kept constant by reducing the number of divisions in the other directions appropriately. Thus

$$n_{\text{div},j} \rightarrow \frac{Q_j n_{\text{div},j}}{\left(\prod_j Q_j\right)^{1/n_{\text{dim}}}} \quad (2.16)$$

where we have used the damped standard deviation

$$Q_j = \left( \sqrt{\text{Var}(\{m\}_j)} \right)^\alpha \quad (2.17)$$

instead of the spread.

### 2.3.2 Vegas’ Dark Side

Under construction!

A partial solution of this problem will be presented in section 2.5.

## 2.4 Multi Channel Sampling

Even if Vegas performs well for a large class of integrands, many important applications do not lead to a factorizable distribution. The class of integrands that can be integrated efficiently by Vegas can be enlarged substantially by using multi channel methods. The new class will include almost all integrals appearing in high energy physics simulations.

The first version of this section is now obsolete. Consult [3] instead.

## 2.5 Revolving

 Under construction!

## 2.6 Parallelization

Traditionally, parallel processing has not played a large rôle in simulations for high energy physics. A natural and trivial method of utilizing many processors will run many instances of the same (serial) program with different values of the input parameters in parallel. Typical matrix elements and phase space integrals offer few opportunities for small scale parallelization.

On the other hand, parameter fitting has become possible recently for observables involving a phase space integration. In this case, fast evaluation of the integral is essential and parallel execution becomes an interesting option.

A different approach to parallelizing Vegas has been presented recently [21].

### 2.6.1 Multilinear Structure of the Sampling Algorithm

In order to discuss the problems with parallelizing adaptive integration algorithms and to present solutions, it helps to introduce some mathematical notation. A sampling  $S$  is a map from the space  $\pi$  of point sets and the space  $F$  of functions to the real (or complex) numbers

$$\begin{aligned} S : \pi \times F &\rightarrow \mathbf{R} \\ (p, f) &\mapsto I = S(p, f) \end{aligned}$$

For our purposes, we have to be more specific about the nature of the point set. In general, the point set will be characterized by a sequence of pseudo random numbers  $\rho \in R$  and by one or more grids  $G \in \Gamma$  used for importance or stratified sampling. A simple sampling

$$\begin{aligned} S_0 : R \times \Gamma \times A \times F \times \mathbf{R} \times \mathbf{R} &\rightarrow R \times \Gamma \times A \times F \times \mathbf{R} \times \mathbf{R} \\ (\rho, G, a, f, \mu_1, \mu_2) &\mapsto (\rho', G, a', f, \mu'_1, \mu'_2) = S_0(\rho, G, a, f, \mu_1, \mu_2) \end{aligned} \tag{2.18}$$

estimates the  $n$ -th moments  $\mu'_n \in \mathbf{R}$  of the function  $f \in F$ . The integral and its standard deviation can be derived easily from the moments

$$I = \mu_1 \tag{2.19a}$$

$$\sigma^2 = \frac{1}{N-1} (\mu_2 - \mu_1^2) \tag{2.19b}$$

while the latter are more convenient for the following discussion. In addition,  $S_0$  collects auxiliary information to be used in the grid refinement, denoted by  $a \in A$ . The unchanged arguments  $G$  and  $f$  have been added to the result of  $S_0$  in (2.18), so that  $S_0$  has identical domain and codomain and can therefore be iterated. Previous estimates  $\mu_n$  may be used in the estimation of  $\mu'_n$ , but a particular  $S_0$  is free to ignore them as well. Using a little notational freedom, we augment  $\mathbf{R}$  and  $A$  with a special value  $\cdot$ , which will always be discarded by  $S_0$ .

In an adaptive integration algorithm, there is also a refinement operation  $r : \Gamma \times A \rightarrow \Gamma$  that can be extended naturally to the codomain of  $S_0$

$$\begin{aligned} r : R \times \Gamma \times A \times F \times \mathbf{R} \times \mathbf{R} &\rightarrow R \times \Gamma \times A \times F \times \mathbf{R} \times \mathbf{R} \\ (\rho, G, a, f, \mu_1, \mu_2) &\mapsto (\rho, G', a, f, \mu_1, \mu_2) = r(\rho, G, a, f, \mu_1, \mu_2) \end{aligned} \quad (2.20)$$

so that  $S = rS_0$  is well defined and we can specify  $n$ -step adaptive sampling as

$$S_n = S_0(rS_0)^n \quad (2.21)$$

Since, in a typical application, only the estimate of the integral and the standard deviation are used, a projection can be applied to the result of  $S_n$ :

$$\begin{aligned} P : R \times \Gamma \times A \times F \times \mathbf{R} \times \mathbf{R} &\rightarrow \mathbf{R} \times \mathbf{R} \\ (\rho, G, a, f, \mu_1, \mu_2) &\mapsto (I, \sigma) \end{aligned} \quad (2.22)$$

Then

$$(I, \sigma) = PS_0(rS_0)^n(\rho, G_0, \cdot, f, \cdot, \cdot) \quad (2.23)$$

and a good refinement prescription  $r$ , such as Vegas, will minimize the  $\sigma$ .

For parallelization, it is crucial to find a division of  $S_n$  or any part of it into *independent* pieces that can be evaluated in parallel. In order to be effective,  $r$  has to be applied to *all* of  $a$  and therefore a synchronization of  $G$  before and after  $r$  is appropriately. Furthermore,  $r$  usually uses only a tiny fraction of the CPU time and it makes little sense to invest a lot of effort into parallelizing it beyond what the Fortran compiler can infer from array notation. On the other hand,  $S_0$  can be parallelized naturally, because all operations are linear, including the computation of  $a$ . We only have to make sure that the cost of communicating the results of  $S_0$  and  $r$  back and forth during the computation of  $S_n$  do not offset any performance gain from parallel processing.

When we construct a decomposition of  $S_0$  and proof that it does not change the results, i.e.

$$S_0 = \iota S_0 \phi \quad (2.24)$$

where  $\phi$  is a forking operation and  $\iota$  is a joining operation, we are faced with the technical problem of a parallel random number source  $\rho$ . As made explicit in (2.18),  $S_0$  changes the state of the random number general  $\rho$ , demanding *identical* results therefore imposes a strict ordering on the operations and defeats parallelization. It is possible to devise implementations of  $S_0$  and  $\rho$  that circumvent this problem by distributing subsequences of  $\rho$  in such a way among processes that results do not depend on the number of parallel processes.

However, a reordering of the random number sequence will only change the result by the statistical error, as long as the scale of the allowed reorderings is *bounded* and much smaller than the period of the random number generator <sup>1</sup>. Below, we will therefore use the notation  $x \approx y$  for “equal for an appropriate finite reordering of the  $\rho$  used in calculating  $x$  and  $y$ ”. For our purposes, the relation  $x \approx y$  is strong enough and allows simple and efficient implementations.

Since  $S_0$  is essentially a summation, it is natural to expect a linear structure

$$\bigoplus_i S_0(\rho_i, G_i, a_i, f, \mu_{1,i}, \mu_{2,i}) \approx S_0(\rho, G, a, f, \mu_1, \mu_2) \quad (2.25a)$$

where

$$\rho = \bigoplus_i \rho_i \quad (2.25b)$$

$$G = \bigoplus_i G_i \quad (2.25c)$$

$$a = \bigoplus_i a_i \quad (2.25d)$$

$$\mu_n = \bigoplus_i \mu_{n,i} \quad (2.25e)$$

for appropriate definitions of “ $\oplus$ ”. For the moments, we have standard addition

$$\mu_{n,1} \oplus \mu_{n,2} = \mu_{n,1} + \mu_{n,2} \quad (2.26)$$

and since we only demand equality up to reordering, we only need that the  $\rho_i$  are statistically independent. This leaves us with  $G$  and  $a$  and we have to discuss importance sampling and stratified sampling separately.

---

<sup>1</sup>Arbitrary reorderings on the scale of the period of the random number generators could select constant sequences and have to be forbidden.

### *Importance Sampling*

In the case of naive Monte Carlo and importance sampling the natural decomposition of  $G$  is to take  $j$  copies of the same grid  $G/j$  which is identical to  $G$ , each with one  $j$ -th of the total sampling points. As long as the  $a$  are linear themselves, we can add them up just like the moments

$$a_1 \oplus a_2 = a_1 + a_2 \quad (2.27)$$

and we have found a decomposition (2.25). In the case of Vegas, the  $a_i$  are sums of function values at the sampling points. Thus they are obviously linear and this approach is applicable to Vegas in the importance sampling mode.

### *Stratified Sampling*

The situation is more complicated in the case of stratified sampling. The first complication is that in pure stratified sampling there are only two sampling points per cell. Splitting the grid in two pieces as above provide only a very limited amount of parallelization. The second complication is that the  $a$  are no longer linear, since they correspond to a sampling of the variance per cell and no longer of function values themselves.

However, as long as the samplings contribute to disjoint bins only, we can still “add” the variances by combining bins. The solution is therefore to divide the grid into disjoint bins along the divisions of the stratification grid and to assign a set of bins to each processor.

Finer decompositions will incur higher communications costs and other resource utilization. An implementation based on PVM is described in [21], which minimizes the overhead by running identical copies of the grid  $G$  on each processor. Since most of the time is usually spent in function evaluations, it makes sense to run a full  $S_0$  on each processor, skipping function evaluations everywhere but in the region assigned to the processor. This is a neat trick, which is unfortunately tied to the computational model of message passing systems such as PVM and MPI [11]. More general paradigms can not be supported since the separation of the state for the processors is not explicit (it is implicit in the separated address space of the PVM or MPI processes).

However, it is possible to implement (2.25) directly in an efficient manner. This is based on the observation that the grid  $G$  used by Vegas is factorized into divisions  $D^j$  for each dimension

$$G = \bigotimes_{j=1}^{n_{\text{dim}}} D^j \quad (2.28)$$

and decompositions of the  $D^j$  induce decompositions of  $G$

$$\begin{aligned} G_1 \oplus G_2 &= \left( \bigotimes_{j=1}^{i-1} D^j \otimes D_1^i \otimes \bigotimes_{i=j+1}^{n_{\text{dim}}} D^j \right) \oplus \left( \bigotimes_{j=1}^{i-1} D^j \otimes D_2^i \otimes \bigotimes_{i=j+1}^{n_{\text{dim}}} D^j \right) \\ &= \bigotimes_{j=1}^{i-1} D^j \otimes (D_1^i \oplus D_2^i) \otimes \bigotimes_{j=i+1}^{n_{\text{dim}}} D^j \end{aligned} \quad (2.29)$$

We can translate (2.29) directly to code that performs the decomposition  $D^i = D_1^i \oplus D_2^i$  discussed below and simply duplicates the other divisions  $D^{j \neq i}$ . A decomposition along multiple dimensions is implemented by a recursive application of (2.29).

In Vegas, the auxiliary information  $a$  inherits a factorization similar to the grid (2.28)

$$a = (d^1, \dots, d^{n_{\text{dim}}}) \quad (2.30)$$

but not a multilinear structure. Instead, *as long as the decomposition respects the stratification grid*, we find the in place of (2.29)

$$a_1 \oplus a_2 = (d_1^1 + d_2^1, \dots, d_1^i \oplus d_2^i, \dots, d_1^{n_{\text{dim}}} + d_2^{n_{\text{dim}}}) \quad (2.31)$$

with “+” denoting the standard addition of the bin contents and “ $\oplus$ ” denoting the aggregation of disjoint bins. If the decomposition of the division would break up cells of the stratification grid (2.31) would be incorrect, because, as discussed above, the variance is not linear.

Now it remains to find a decomposition

$$D^i = D_1^i \oplus D_2^i \quad (2.32)$$

for both the pure stratification mode and the pseudo stratification mode of vegas (cf. figure 2.1). In the pure stratification mode, the stratification grid is strictly finer than the adaptive grid and we can decompose along either of them immediately. Technically, a decomposition along the coarser of the two is straightforward. Since the adaptive grid already has more than 25 bins, a decomposition along the stratification grid makes no practical sense and the decomposition along the adaptive grid has been implemented. The sampling algorithm  $S_0$  can be applied *unchanged* to the individual grids resulting from the decomposition.

For pseudo stratified sampling (cf. figure 2.2), the situation is more complicated, because the adaptive and the stratification grid do not share bin boundaries. Since Vegas does *not* use the variance in this mode, it would be theoretically possible to decompose along the adaptive grid and to mimic the

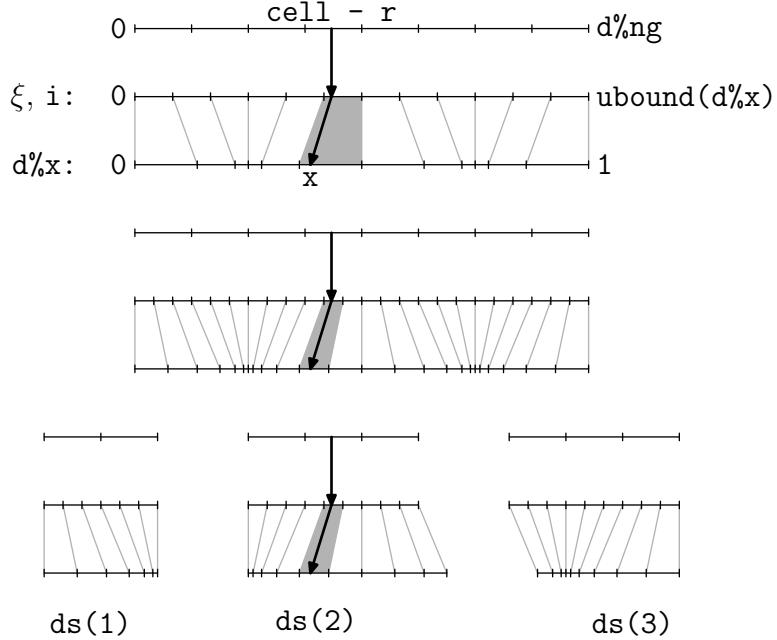

Figure 2.3: Forking one dimension  $d$  of a grid into three parts  $ds(1)$ ,  $ds(2)$ , and  $ds(3)$ . The picture illustrates the most complex case of pseudo stratified sampling (cf. fig. 2.2).

incomplete bins of the stratification grid in the sampling algorithm. However, this would be a technical complication, destroying the universality of  $S_0$ . Therefore, the adaptive grid is subdivided in a first step in

$$\text{lcm} \left( \frac{\text{lcm}(n_f, n_g)}{n_f}, n_x \right) \quad (2.33)$$

bins,<sup>2</sup> such that the adaptive grid is strictly finer than the stratification grid. This procedure is shown in figure 2.3.

## 2.6.2 State and Message Passing

## 2.6.3 Random Numbers

In the parallel example sitting on top of MPI [11] takes advantage of the ability of Knuth's generator [15] to generate statistically independent subse-

---

<sup>2</sup>The coarsest grid covering the division of  $n_g$  bins into  $n_f$  forks has  $n_g / \text{gcd}(n_f, n_g) = \text{lcm}(n_f, n_g) / n_f$  bins per fork.

quences. However, since the state of the random number generator is explicit in all procedure calls, other means of obtaining subsequences can be implemented in a trivial wrapper.

The results of the parallel example will depend on the number of processors, because this effects the subsequences being used. Of course, the variation will be compatible with the statistical error. It must be stressed that the results are deterministic for a given number of processors and a given set of random number generator seeds. Since parallel computing environments allow to fix the number of processors, debugging of exceptional conditions is possible.

#### 2.6.4 Practice

In this section we show three implementations of  $S_n$ : one serial, and two parallel, based on HPF [9, 10, 14] and MPI [11], respectively. From these examples, it should be obvious how to adapt VAMP to other parallel computing paradigms.

##### *Serial*

Here is a bare bones serial version of  $S_n$ , for comparison with the parallel versions below. The real implementation of `vamp_sample_grid` in the module `vamp` includes some error handling, diagnostics and the projection  $P$  (cf. (2.22)):

14 ⟨Serial implementation of  $S_n = S_0(rS_0)^n$  14⟩≡

```

subroutine vamp_sample_grid (rng, g, iterations, func)
    type(tao_random_state), intent(inout) :: rng
    type(vamp_grid), intent(inout) :: g
    integer, intent(in) :: iterations
    <Interface declaration for func 22>
    integer :: iteration
    iterate: do iteration = 1, iterations
        call vamp_sample_grid0 (rng, g, func)
        call vamp_refine_grid (g)
    end do iterate
end subroutine vamp_sample_grid

```

##### *HPF*

The HPF version of  $S_n$  is based on decomposing the grid `g` as described in section 2.6.1 and lining up the components in an array `gs`. The elements of `gs` can then be processed in parallel. This version can be compiled with any

Fortran compiler and a more complete version of this procedure (including error handling, diagnostics and the projection  $P$ ) is included with VAMP as `vamp_sample_grid_parallel` in the module `vamp`. This way, the algorithm can be tested on a serial machine, but there will obviously be no performance gain.

Instead of one random number generator state `rng`, it takes an array consisting of one state per processor. These `rng(:)` are assumed to be initialized, such that the resulting sequences are statistically independent. For this purpose, Knuth's random number generator [15] is most convenient and is included with VAMP (see the example on page 16). Before each  $S_0$ , the procedure `vamp_distribute_work` determines a good decomposition of the grid `d` into `size(rng)` pieces. This decomposition is encoded in the array `d` where `d(1,:)` holds the dimensions along which to split the grid and `d(2,:)` holds the corresponding number of divisions. Using this information, the grid is decomposed by `vamp_fork_grid`. The HPF compiler will then distribute the `!hpfs` independent loop among the processors. Finally, `vamp_join_grid` gathers the results.

15 *(Parallel implementation of  $S_n = S_0(rS_0)^n$  (HPF) 15)≡*

```

subroutine vamp_sample_grid_hpf (rng, g, iterations, func)
    type(tao_random_state), dimension(:), intent(inout) :: rng
    type(vamp_grid), intent(inout) :: g
    integer, intent(in) :: iterations
    <Interface declaration for func 22>
    type(vamp_grid), dimension(:), allocatable :: gs, gx
    !hpfs processors p(number_of_processors())
    !hpfs distribute gs(cyclic(1)) onto p
    integer, dimension(:, :, ), pointer :: d
    integer :: iteration, num_workers
    iterate: do iteration = 1, iterations
        call vamp_distribute_work (size (rng), vamp_rigid_divisions (g), d)
        num_workers = max (1, product (d(2,:)))
        if (num_workers > 1) then
            allocate (gs(num_workers), gx(vamp_fork_grid_joints (d)))
            call vamp_create_empty_grid (gs)
            call vamp_fork_grid (g, gs, gx, d)
            !hpfs independent
            do i = 1, num_workers
                call vamp_sample_grid0 (rng(i), gs(i), func)
            end do
            call vamp_join_grid (g, gs, gx, d)
            call vamp_delete_grid (gs)
            deallocate (gs, gx)
        end if
    end iterate

```

```

    else
        call vamp_sample_grid0 (rng(1), g, func)
    end if
    call vamp_refine_grid (g)
end do iterate
end subroutine vamp_sample_grid_hp

```

Since `vamp_sample_grid0` performs the bulk of the computation, an almost linear speedup with the number of processors can be achieved, if `vamp_distribute_work` finds a good decomposition of the grid. The version of `vamp_distribute_work` distributed with VAMP does a good job in most cases, but will not be able to use all processors if their number is a prime number larger than the number of divisions in the stratification grid. Therefore it can be beneficial to tune `vamp_distribute_work` to specific hardware. Furthermore, using a finer stratification grid can improve performance.

For definiteness, here is an example of how to set up the array of random number generators for HPF. Note that this simple seeding procedure only guarantees statistically independent sequences with Knuth's random number generator [15] and will fail with other approaches.

16 <Parallel usage of  $S_n = S_0(rS_0)^n$  (HPF) 16>≡

```

type(tao_random_state), dimension(:), allocatable :: rngs
!hpfs$ processors p(number_of_processors())
!hpfs$ distribute gs(cyclic(1)) onto p
integer :: i, seed
! ...
allocate (rngs(number_of_processors()))
seed = 42 ! can be read from a file, of course ...
!hpfs$ independent
do i = 1, size (rngs)
    call tao_random_create (rngs(i), seed + i)
end do
! ...
call vamp_sample_grid_hp (rngs, g, 6, func)
! ...

```

### *MPI*

The MPI version is more low level, because we have to keep track of message passing ourselves. Note that we have made this synchronization points explicit with three `if ... then ... else ... end if` blocks: forking, sampling, and joining. These blocks could be merged (without any performance gain) at the expense of readability. We assume that `rng` has been initialized

in each process such that the sequences are again statistically independent.

**17** *(Parallel implementation of  $S_n = S_0(rS_0)^n$  (MPI) 17)*≡

```

subroutine vamp_sample_grid_mpi (rng, g, iterations, func)
    type(tao_random_state), dimension(:), intent(inout) :: rng
    type(vamp_grid), intent(inout) :: g
    integer, intent(in) :: iterations
    <Interface declaration for func 22>
    type(vamp_grid), dimension(:), allocatable :: gs, gx
    integer, dimension(:, :, ), pointer :: d
    integer :: num_proc, proc_id, iteration, num_workers
    call mpi90_size (num_proc)
    call mpi90_rank (proc_id)
    iterate: do iteration = 1, iterations
        if (proc_id == 0) then
            call vamp_distribute_work (num_proc, vamp_rigid_divisions (g), d)
            num_workers = max (1, product (d(2,:)))
        end if
        call mpi90_broadcast (num_workers, 0)
        if (proc_id == 0) then
            allocate (gs(num_workers), gx(vamp_fork_grid_joints (d)))
            call vamp_create_empty_grid (gs)
            call vamp_fork_grid (g, gs, gx, d)
            do i = 2, num_workers
                call vamp_send_grid (gs(i), i-1, 0)
            end do
        else if (proc_id < num_workers) then
            call vamp_receive_grid (g, 0, 0)
        end if
        if (proc_id == 0) then
            if (num_workers > 1) then
                call vamp_sample_grid0 (rng, gs(1), func)
            else
                call vamp_sample_grid0 (rng, g, func)
            end if
        else if (proc_id < num_workers) then
            call vamp_sample_grid0 (rng, g, func)
        end if
        if (proc_id == 0) then
            do i = 2, num_workers
                call vamp_receive_grid (gs(i), i-1, 0)
            end do
            call vamp_join_grid (g, gs, gx, d)
            call vamp_delete_grid (gs)
        end if
    end do
end subroutine

```

```
    deallocate (gs, gx)
    call vamp_refine_grid (g)
    else if (proc_id < num_workers) then
        call vamp_send_grid (g, 0, 0)
    end if
end do iterate
end subroutine vamp_sample_grid_mpi
```

A more complete version of this procedure is included with VAMP as well, this time as `vamp_sample_grid` in the MPI support module `vampi`.

## —3— DESIGN TRADE OFFS

There have been three competing design goals for vegas, that are not fully compatible and had to be reconciled with compromises:

- *Ease-Of-Use*: few procedures, few arguments.
- *Parallelizability*: statelessness
- *Performance and Flexibility*: rich interface, functionality.

In fact, parallelizability and ease-of-use are complementary. A parallelizable implementation has to expose *all* the internal state. In our case, this includes the state of the random number generator and the adaptive grid. A simple interface would hide such details from the user.

The modern language features introduced to Fortran in 1990 [7] allows to reconcile these competing goals. Two abstract data types `vamp_state` and `tao_random_state` hide the details of the implementation from the user and encapsulate the two states in just two variables.

Another problem with parallelizability arised from the lack of a general exception mechanism in Fortran. The Fortran90 standard [8] forbids *any* input/output (even to the terminal) as well as `stop` statements in parallelizable (`pure`) procedures. This precludes simple approaches to monitoring and error handling. In Vegas we use a simple hand crafted exception mechanism (see chapter B) for communicating error conditions to the out layers of the applications. Unfortunately this requires the explicit passing of state in argument lists.

An unfortunate consequence of the similar approach to monitoring is that monitoring is *not* possible during execution. Instead, intermediate results can only be examined after a parallelized section of code has completed.

### *3.1 Programming Language*

We have chosen to implement VAMP in Fortran90/95, which some might consider a questionable choice today. Nevertheless, we are convinced that Fortran90/95 (with all its weaknesses) is, by a wide margin, the right tool for the job.

Let us consider the alternatives

- FORTRAN77 is still the dominant language in high energy physics and all running experiment's software environments are based on it. However, the standard [6] is obsolete now and the successors [7, 8] have added many desirable features, while retaining almost all of FORTRAN77 as a subset.
- C/C++ appears to be the most popular programming language in industry and among young high energy physicists. Large experiments have taken a bold move and are basing their software environment on C++.
- Typed higher order functional programming languages (ML, Haskell, etc.) are a very promising development. Unfortunately, there is not yet enough industry support for high performance optimizing compilers. While the performance penalty of these languages is not as high as commonly believed (research compilers, which do not perform extensive processor specific optimizations, result in code that runs by a factor of two or three slower than equivalent Fortran code), it is relevant for long running, computing intensive applications. In addition, these languages are syntactically and idiomatically very different from Fortran and C. Another implementation of VAMP in ML will be undertaken for research purposes to investigate new algorithms that can only be expressed awkwardly in Fortran, but we do not expect it to gain immediate popularity.

## —4— USAGE

### 4.1 Basic Usage

```
type(vamp_grid)

subroutine vamp_create_grid (g, domain [, num_calls] [, exc])
    Create a fresh grid for the integration domain
    
$$\mathcal{D} = [D_{1,1}, D_{2,1}] \times [D_{1,2}, D_{2,2}] \times \dots \times [D_{1,n}, D_{2,n}] \quad (4.1)$$

    dropping all accumulated results. This function must not be called twice on the first argument, without an intervening vamp_delete_grid. If the variable num_calls is given, it will be the number of sampling points per iteration for the call to vamp_sample_grid.
```

```
subroutine vamp_delete_grid (g [, exc])
subroutine vamp_discard_integral (g [, num_calls] [, exc])
    Keep the current optimized grid, but drop the accumulated results for the integral (value and errors). If the variable num_calls is given, it will be the new number of sampling points per iteration for the calls to vamp_sample_grid.
```

```
subroutine vamp_reshape_grid (g [, num_calls] [, exc])
    Keep the current optimized grid and the accumulated results for the integral (value and errors). The variable num_calls is the new number of sampling points per iteration for the calls to vamp_sample_grid.
```

```
subroutine vamp_sample_grid (rng, g, func, iterations
    [, integral] [, std_dev] [, avg_chi2] [, exc] [, history])
```

Sample the function `func` using the grid `g` for `iterations` iterations and optimize the grid after each iteration. The results are returned in `integral`, `std_dev` and `avg_chi2`. The random number generator uses and updates the state stored in `rng`. The explicit random number state is inconvenient, but required for parallelizability.

```
subroutine vamp_integrate (rng, g, func, calls [, integral]
[, std_dev] [, avg_chi2] [, exc] [, history])
```

This is a wrapper around the above routines, that is steered by a `integer, dimension(2,:)` array `calls`. For each `i`, there will be `calls(1,i)` iterations with `calls(2,i)` sampling points.

```
subroutine vamp_integrate (rng, domain, func, calls
[, integral] [, std_dev] [, avg_chi2] [, exc] [, history])
```

A second specific form of `vamp_integrate`. This one keeps a private grid and provides the shortest—and most inflexible—calling sequence.

**22** *⟨Interface declaration for func 22⟩*≡

```
interface
    pure function func (xi, prc_index, weights, channel, grids) result (f)
        use kinds
        use vamp_grid_type !NODEP!
        real(kind=default), dimension(:), intent(in) :: xi
        integer, intent(in) :: prc_index
        real(kind=default), dimension(:), intent(in), optional :: weights
        integer, intent(in), optional :: channel
        type(vamp_grid), dimension(:), intent(in), optional :: grids
        real(kind=default) :: f
    end function func
end interface
```

#### 4.1.1 Basic Example

In Fortran95, the function to be sampled *must* be `pure`, i.e. have no side effects to allow parallelization. The optional arguments `weights` and `channel` *must* be declared to allow the compiler to verify the interface, but they are ignored during basic use. Their use for multi channel sampling will be explained below. Here's a Gaussian

$$f(x) = e^{-\frac{1}{2} \sum_i x_i^2} \quad (4.2)$$

```

23a <basic.f90 23a>≡
  module basic_fct
    use kinds
    implicit none
    private
    public :: fct
  contains
    function fct (x, weights, channel) result (f_x)
      real(kind=default), dimension(:), intent(in) :: x
      real(kind=default), dimension(:), intent(in), optional :: weights
      integer, intent(in), optional :: channel
      real(kind=default) :: f_x
      f_x = exp (-0.5 * sum (x*x))
    end function fct
  end module basic_fct

```

In the main program, we need to import five modules. The customary module `kinds` defines `double` as the kind for double precision floating point numbers. The module `exceptions` provides simple error handling support (parallelizable routines are not allowed to issue error messages themselves, but must pass them along). The module `tao_random_numbers` hosts the random number generator used and `vamp` is the adaptive interation module proper. Finally, the application module `basic_fct` has to be imported as well.

```

23b <basic.f90 23a>+≡
  program basic
    use kinds
    use exceptions
    use tao_random_numbers
    use vamp
    use basic_fct
    implicit none

```

Then we define four variables for an error message, the random number generator state and the adaptive integration grid. We also declare a variable for holding the integration domain and variables for returning the result. In this case we integrate the 7-dimensional hypercube.

```

23c <basic.f90 23a>+≡
  type(exception) :: exc
  type(tao_random_state) :: rng
  type(vamp_grid) :: grid
  real(kind=default), dimension(2,7) :: domain
  real(kind=default) :: integral, error, chi2
  domain(1,:) = -1.0
  domain(2,:) = 1.0

```

Initialize and seed the random number generator. Initialize the grid for 10 000 sampling points.

24a `<basic.f90 23a>+≡`

```
call tao_random_create (rng, seed=0)
call clear_exception (exc)
call vamp_create_grid (grid, domain, num_calls=10000, exc=exc)
call handle_exception (exc)
```

Warm up the grid in six low statistics iterations. Clear the error status before and check it after the sampling.

24b `<basic.f90 23a>+≡`

```
call clear_exception (exc)
call vamp_sample_grid (rng, grid, fct, 6, exc=exc)
call handle_exception (exc)
```

Throw away the intermediate results and reshape the grid for 100 000 sampling points—keeping the adapted grid—and do four iterations of a higher statistics integration

24c `<basic.f90 23a>+≡`

```
call clear_exception (exc)
call vamp_discard_integral (grid, num_calls=100000, exc=exc)
call handle_exception (exc)
call clear_exception (exc)
call vamp_sample_grid (rng, grid, fct, 4, integral, error, chi2, exc=exc)
call handle_exception (exc)
print *, "integral = ", integral, "+/-", error, " (chi^2 = ", chi2, ")"
end program basic
```

Since this is the most common use, there is a convenience routine available and the following code snippet is equivalent:

24d `(Alternative to basic.f90 24d)≡`

```
integer, dimension(2,2) :: calls
calls(:,1) = (/ 6, 10000 /)
calls(:,2) = (/ 4, 100000 /)
call clear_exception (exc)
call vamp_integrate (rng, domain, fct, calls, integral, error, chi2, exc=exc)
call handle_exception (exc)
```

## 4.2 Advanced Usage

Caveat emptor: no magic of literate programming can guarantee that the following remains in sync with the implementation. This has to be maintained manually.

All `real` variables are declared as `real(kind=default)` in the source and the variable `double` is imported from the module `kinds` (see appendix A.1). The representation of real numbers can therefore be changed by changing `double` in `kinds`.

#### 4.2.1 Types

```
type(vamp_grid)
type(vamp_grids)
type(vamp_history)
type(exception)
  (from module exceptions)
```

#### 4.2.2 Shared Arguments

Arguments keep their name across procedures, in order to make the Fortran90 keyword interface consistent.

`real, intent(in) :: accuracy`

Terminate  $S_n$  after  $n' < n$  iterations, if relative error is smaller than `accuracy`. Specifically, the terminatio condition is

$$\frac{\text{std\_dev}}{\text{integral}} < \text{accuracy} \quad (4.3)$$

`real, intent(out) :: avg_chi2`

The average  $\chi^2$  of the iterations.

`integer, intent(in) :: channel`

Call `func` with this optional argument. Multi channel sampling uses this to emulate arrays of functions

`logical, intent(in) :: covariance`

Collect covariance data.

`type(exception), intent(inout) :: exc`

Exceptional conditions are reported in `exc`.

`type(vamp_grid), intent(inout) :: g`

Unless otherwise noted, `g` denotes the active sampling grid in the documentation below.

```
type(vamp_histories), dimension(:), intent(inout) ::  
    histories
```

Diagnostic information for multi channel sampling.

```
type(vamp_history), dimension(:), intent(inout) ::  
    history
```

Diagnostic information for single channel sampling or summary of multi channel sampling.

```
real, intent(out) :: integral
```

The current best estimate of the integral.

```
integer, intent(in) :: iterations
```

```
real, dimension(:, :, :), intent(in) :: map
```

```
integer, intent(in) :: num_calls
```

The number of sampling points.

```
integer, dimension(:), intent(in) :: num_div
```

Number of divisions of the adaptive grid in each dimension.

```
logical, intent(in) :: quadrupole
```

Allow “quadrupole oscillations” of the sampling grid (cf. section 2.3.1).

```
type(tao_random_state), intent(inout) :: rng
```

Unless otherwise noted, `rng` denotes the source of random numbers used for sampling in the documentation below.

```
real, intent(out) :: std_dev
```

The current best estimate of the error on the integral.

```
logical, intent(in) :: stratified
```

Try to use stratified sampling.

```
real(kind=default), dimension(:), intent(in) :: weights
```

...

#### 4.2.3 Single Channel Procedures

```
subroutine vamp_create_grid (g, domain, num_calls
    [, quadrupole] [, stratified] [, covariance] [, map] [, exc])
    real, dimension(:, :, :), intent(in) :: domain

subroutine vamp_create_empty_grid (g)

subroutine vamp_discard_integral (g [, num_calls]
    [, stratified] [, quadrupole] [, covariance] [, exc])

subroutine vamp_reshape_grid (g [, num_calls] [, num_div]
    [, stratified] [, quadrupole] [, covariance] [, exc])

subroutine vamp_sample_grid (rng, g, func, iterations
    [, integral] [, std_dev] [, avg_chi2] [, accuracy] [, channel]
    [, weights] [, exc] [, history])

    func

 $S_n$  with  $n = \text{iterations}$ 

subroutine vamp_sample_grid0 (rng, g, func, [, channel]
    [, weights] [, exc])

    func

 $S_0$ 

subroutine vamp_refine_grid (g, [, exc])
    r

subroutine vamp_average_iterations (g, iteration, integral,
    std_dev, avg_chi2)

    integer, intent(in) :: iteration
    Number of iterations so far (needed for  $\chi^2$ ).

subroutine vamp_integrate (g, func, calls [, integral]
    [, std_dev] [, avg_chi2] [, accuracy] [, covariance])

    type(vamp_grid), intent(inout) :: g
    func
```

```

integer, dimension(:, :, ), intent(in) :: calls

subroutine vamp_integratex (region, func, calls [, integral]
[, std_dev] [, avg_chi2] [, stratified] [, accuracy] [, pancake]
[, cigar])

real, dimension(:, :, ), intent(in) :: region
func

integer, dimension(:, :, ), intent(in) :: calls
integer, intent(in) :: pancake
integer, intent(in) :: cigar

subroutine vamp_copy_grid (lhs, rhs)

type(vamp_grid), intent(inout) :: lhs
type(vamp_grid), intent(in) :: rhs

subroutine vamp_delete_grid (g)

type(vamp_grid), intent(inout) :: g

```

#### *4.2.4 Inout/Output and Marshling*

```

subroutine vamp_write_grid (g, [, ...])

type(vamp_grid), intent(inout) :: g

subroutine vamp_read_grid (g, [, ...])

type(vamp_grid), intent(inout) :: g

subroutine vamp_write_grids (g, [, ...])

type(vamp_grids), intent(inout) :: g

subroutine vamp_read_grids (g, [, ...])

type(vamp_grids), intent(inout) :: g

pure subroutine vamp_marshall_grid (g, integer_buffer,
double_buffer)

```

```

type(vamp_grid), intent(in) :: g
integer, dimension(:), intent(inout) :::
integer_buffer
real(kind=default), dimension(:), intent(inout)
:: double_buffer

```

Marshal the grid `g` in the integer array `integer_buffer` and the real array `double_buffer`, which must have at least the sizes obtained from call `vamp_marshal_grid_size (g, integer_size, double_size)`.

 Note that we can not use the `transfer` intrinsic function for marshalling types that contain pointers that substitute for allocatable array components. `transfer` would copy the pointers in this case and not where they point to!

```

pure subroutine vamp_marshal_grid_size (g, integer_size,
double_size)

type(vamp_grid), intent(in) :: g
integer :: words

```

Compute the sizes of the arrays required for marshaling the grid `g`.

```

pure subroutine vamp_unmarshal_grid (g, integer_buffer,
double_buffer)

type(vamp_grid), intent(inout) :: g
integer, dimension(:), intent(in) :::
integer_buffer
real(kind=default), dimension(:), intent(in) :::
double_buffer

```

Marshaling and unmarshaling need to use two separate buffers for integers and floating point numbers. In a homogeneous network, the intrinsic procedure `transfer` could be used to store the floating point numbers in the integer array. In a heterogeneous network this will fail. However, message passing environments provide methods for sending floating point numbers. For example, here's how to send a grid from process 0 to process 1 in MPI [11]

29 ⟨MPI communication example 29⟩≡  
call `vamp_marshal_grid_size (g, isize, dsize)`

```

allocate (ibuf(isize), dbuf(dsize))
call mpi_comm_rank (MPI_COMM_WORLD, proc_id, errno)
select case (proc_id)
  case (0)
    call vamp_marshal_grid (g, ibuf, dbuf)
    call mpi_send (ibuf, size (ibuf), MPI_INTEGER, &
                  1, 1, MPI_COMM_WORLD, errno)
    call mpi_send (dbuf, size (dbuf), MPI_DOUBLE_PRECISION, &
                  1, 2, MPI_COMM_WORLD, errno)
  case (1)
    call mpi_recv (ibuf, size (ibuf), MPI_INTEGER, &
                  0, 1, MPI_COMM_WORLD, status, errno)
    call mpi_recv (dbuf, size (dbuf), MPI_DOUBLE_PRECISION, &
                  0, 2, MPI_COMM_WORLD, status, errno)
    call vamp_unmarshal_grid (g, ibuf, dbuf)
end select

```

assuming that `double` is such that `MPI_DOUBLE_PRECISION` corresponds to `real(kind=default)`. The module `vampi` provides two high level functions `vamp_send_grid` and `vamp_receive_grid` that handle the low level details:

30    *<MPI communication example' 30>*

```

call mpi_comm_rank (MPI_COMM_WORLD, proc_id, errno)
select case (proc_id)
  case (0)
    call vamp_send_grid (g, 1, 0)
  case (1)
    call vamp_receive_grid (g, 0, 0)
end select

subroutine vamp_marshal_history_size (g, [, ...])
  type(vamp_grid), intent(inout) :: g

subroutine vamp_marshal_history (g, [, ...])
  type(vamp_grid), intent(inout) :: g

subroutine vamp_unmarshal_history (g, [, ...])
  type(vamp_grid), intent(inout) :: g

```

#### 4.2.5 Multi Channel Procedures

$$g \circ \phi_i = \left| \frac{\partial \phi_i}{\partial x} \right|^{-1} \left( \alpha_i g_i + \sum_{\substack{j=1 \\ j \neq i}}^{N_c} \alpha_j (g_j \circ \pi_{ij}) \left| \frac{\partial \pi_{ij}}{\partial x} \right| \right). \quad (4.4)$$

31a *(Interface declaration for phi 31a)≡*

```
interface

```

Genuinely stratified sampling will superimpose an equidistant grid on the adaptive grid, as shown in figure 5.2. Obviously, this is only possible when the number of cells of the stratification grid is large enough, specifically when  $n_g \geq n_{\text{div}}^{\min} = n_{\text{div}}^{\max}/2 = 25$ . This condition can be met by a high number of sampling points or by a low dimensionality of the integration region (cf. table 5.1).

For a low number of sampling points and high dimensions, genuinely stratified sampling is impossible, because we would have to reduce the number  $n_{\text{div}}$  of adaptive divisions too far. Instead, we keep **stratified** false which will tell the integration routine not to concentrate the grid in the regions where

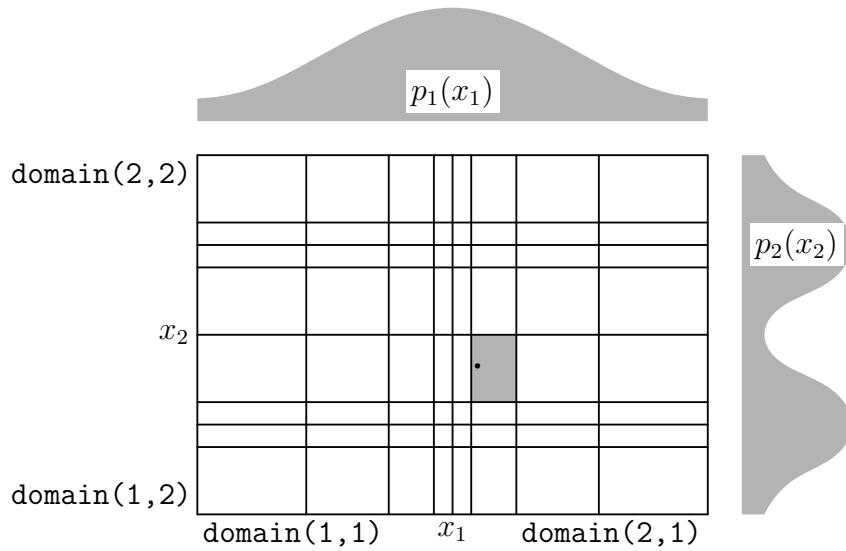

Figure 5.1: `vegas` grid structure for non-stratified sampling. N.B.: the grid and the weight functions  $p_{1,2}$  are only in qualitative agreement.

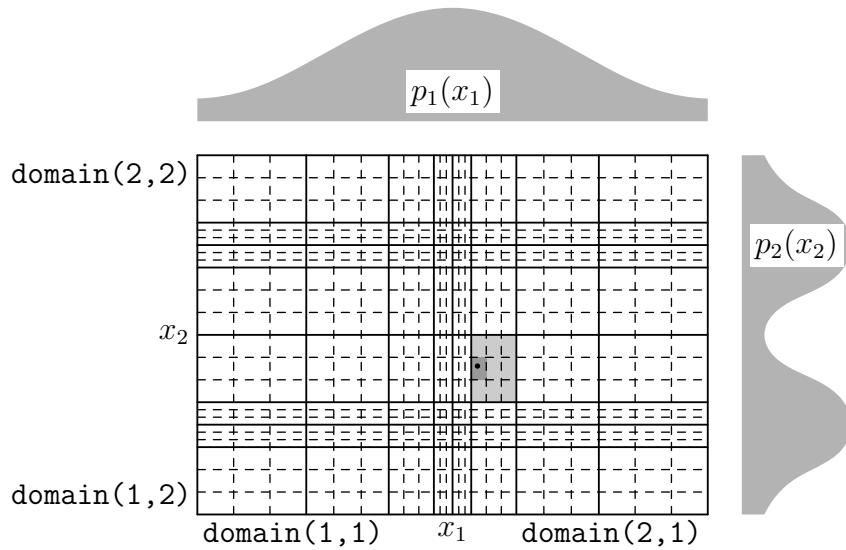

Figure 5.2: `vegas` grid structure for genuinely stratified sampling, which is used in low dimensions. N.B.: the grid and the weight functions  $p_{1,2}$  are only in qualitative agreement.

$n_{\text{dim}}$	$N_{\text{calls}}^{\max}(n_g = 25)$
2	$1 \cdot 10^3$
3	$3 \cdot 10^4$
4	$8 \cdot 10^5$
5	$2 \cdot 10^7$
6	$5 \cdot 10^8$

Table 5.1: To stratify or not to stratify.

the contribution to the error is largest, but to use importance sampling, i. e. concentrating the grid in the regions where the contribution to the value is largest.

In this case, the rigid grid is much coarser than the adaptive grid and furthermore, the boundaries of the cells overlap in general. The interplay of the two grids during the sampling process is shown in figure 5.3.

First we determine the (integer) number  $k$  of equidistant divisions of an adaptive cell for at most  $n_{\text{div}}^{\max}$  divisions of the adaptive grid

$$k = \left\lfloor \frac{n_g}{n_{\text{div}}^{\max}} \right\rfloor + 1 \quad (5.2a)$$

and the corresponding number  $n_{\text{div}}$  of adaptive divisions

$$n_{\text{div}} = \left\lfloor \frac{n_g}{k} \right\rfloor \quad (5.2b)$$

Finally, adjust  $n_g$  to an exact multiple of  $n_{\text{div}}$

$$n_g = k \cdot n_{\text{div}} \quad (5.2c)$$

```
42  <Initialize stratified sampling 42>≡
    if (d%ng >= max_num_div / 2) then
        d%stratified = .true.
        equ_per_adap = d%ng / max_num_div + 1
        num_div = d%ng / equ_per_adap
        if (num_div < 2) then
            d%stratified = .false.
            num_div = 2
            d%ng = 1
        else if (mod (num_div,2) == 1) then
            num_div = num_div - 1
            d%ng = equ_per_adap * num_div
        else
```

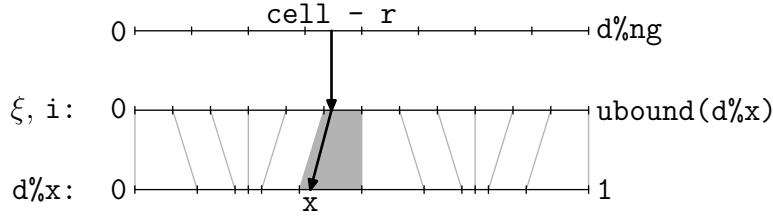

Figure 5.3: One-dimensional illustration of the `vegas` grid structure for pseudo stratified sampling, which is used in high dimensions.

```

d%ng = equ_per_adap * num_div
end if
else
  d%stratified = .false.
  num_div = max_num_div
  d%ng = 1
end if

```

Figure 5.3 on page 43 is a one-dimensional illustration of the sampling algorithm. In each cell of the rigid equidistant grid, two random points are selected (or  $N_{\text{calls}}$  in the not stratified case). For each point, the corresponding cell and relative coordinate in the adaptive grid is found, *as if the adaptive grid was equidistant* (upper arrow). Then this point is mapped according to the adapted grid (lower arrow) and the proper Jacobians are applied to the weight.

$$\prod_{j=1}^n (x_i^j - x_{i-1}^j) \cdot N^n = \text{Vol}(\text{cell}') \cdot \frac{1}{\text{Vol}(\text{cell})} = \frac{1}{p(x_i^j)} \quad (5.3)$$

```

Smooth the  $d_i = \bar{f}_i \Delta x_i$

$$\begin{aligned}
d_1 &\rightarrow \frac{1}{2}(d_1 + d_2) \\
d_2 &\rightarrow \frac{1}{3}(d_1 + d_2 + d_3) \\
&\dots \\
d_{n-1} &\rightarrow \frac{1}{3}(d_{n-2} + d_{n-1} + d_n) \\
d_n &\rightarrow \frac{1}{2}(d_{n-1} + d_n)
\end{aligned} \tag{5.4}$$

As long as the initial `num_div`  $\geq 6$ , we know that `num_div`  $\geq 3$ .

46a *(Variables in divisions 46a)* $\equiv$   
`integer, private, parameter :: MIN_NUM_DIV = 3`

Here the Fortran90 array notation really shines, but we have to handle the cases `nd`  $\leq 2$  specially, because the `quadrupole` option can lead to small `nd`s. The equivalent Fortran77 code [2] is orders of magnitude less obvious<sup>1</sup>. Also protect against vanishing  $d_i$  that will blow up the logarithm.

$$m_i = \left( \frac{\sum_j \bar{f}_j \Delta x_j}{\ln \left( \frac{\sum_j \bar{f}_j \Delta x_j}{\sum_j \bar{f}_j \Delta x_j} \right)} - 1 \right)^\alpha \tag{5.5}$$

46b *(Implementation of divisions procedures 38b)* $\equiv$   
`pure function rebinning_weights (d) result (m)`  
`real(kind=default), dimension(:), intent(in) :: d`  
`real(kind=default), dimension(size(d)) :: m`  
`real(kind=default), dimension(size(d)) :: smooth_d`  
`real(kind=default), parameter :: ALPHA = 1.5`  
`integer :: nd`  
*(Bail out if any (d == NaN) 47b)*  
`nd = size (d)`  
`if (nd > 2) then`  
`smooth_d(1) = (d(1) + d(2)) / 2.0`  
`smooth_d(2:nd-1) = (d(1:nd-2) + d(2:nd-1) + d(3:nd)) / 3.0`  
`smooth_d(nd) = (d(nd-1) + d(nd)) / 2.0`  
`else`  
`smooth_d = d`  
`end if`  
`if (all (smooth_d < tiny (1.0_default))) then`

---

<sup>1</sup>Some old timers call this a feature, however.

```

    m = 1.0_default
else
    smooth_d = smooth_d / sum (smooth_d)
    where (smooth_d < tiny (1.0_default))
        smooth_d = tiny (1.0_default)
    end where
    where (smooth_d /= 1._default)
        m = ((smooth_d - 1.0) / (log (smooth_d)))**ALPHA
    elsewhere
        m = 1.0_default
    endwhere
end if
end function rebinning_weights

```

47a ⟨Declaration of divisions procedures 38a⟩+≡  
private :: rebinning\_weights

 The NaN test is probably not portable:

47b ⟨Bail out if any (d == NaN) 47b⟩≡  
if (any (d /= d)) then  
 m = 1.0  
 return  
end if

Take a binning  $x$  and return a new binning with  $\text{num\_div}$  bins with the  $m$  homogeneously distributed:

47c ⟨Implementation of divisions procedures 38b⟩+≡  
pure function rebin (m, x, num\_div) result (x\_new)

        end if
    end do bracket
else
    p = 0
end if
end function probability

```

### 5.1.4 Quadrupole

49a *(Declaration of divisions procedures 38a)* +≡

```
public :: quadrupole_division
```

49b *(Implementation of divisions procedures 38b)* +≡

```
elemental function quadrupole_division (d) result (q)
    type(division_t), intent(in) :: d
    real(kind=default) :: q
    !!!   q = value_spread_percent (rebinning_weights (d%variance))
    q = standard_deviation_percent (rebinning_weights (d%variance))
end function quadrupole_division
```

### 5.1.5 Forking and Joining

The goal is to split a division in such a way, that we can later sample the pieces separately and combine the results.

49c *(Declaration of divisions procedures 38a)* +≡

```
public :: fork_division, join_division, sum_division
```

 Caveat emptor: splitting divisions can lead to `num_div < 3` and the application *must not* try to refine such grids before merging them again!

50a *Implementation of divisions procedures 38b* +≡

```

pure subroutine fork_division (d, ds, sum_calls, num_calls, exc)
    type/division_t/, intent(in) :: d
    type/division_t/, dimension(:), intent(inout) :: ds
    integer, intent(in) :: sum_calls
    integer, dimension(:), intent(inout) :: num_calls
    type(exception), intent(inout), optional :: exc
    character(len=*), parameter :: FN = "fork_division"
    integer, dimension(size(ds)) :: n0, n1
    integer, dimension(0:size(ds)) :: n, ds_ng
    integer :: i, j, num_div, num_forks, nx
    real(kind=default), dimension(:, allocatable :: d_x, d_integral, d_variance
! real(kind=default), dimension(:, allocatable :: d_efficiency
    num_div = ubound(d%x, dim=1)
    num_forks = size(ds)
    if (d%ng == 1) then
        <Fork an importance sampling division 51a>
    else if (num_div >= num_forks) then
        if (modulo(d%ng, num_div) == 0) then
            <Fork a pure stratified sampling division 52b>
        else
            <Fork a pseudo stratified sampling division 54a>
        end if
    else
        if (present(exc)) then
            call raise_exception (exc, EXC_FATAL, FN, "internal error")
        end if
        num_calls = 0
    end if
end subroutine fork_division

```

50b *Implementation of divisions procedures 38b* +≡

```

pure subroutine join_division (d, ds, exc)
    type/division_t/, intent(inout) :: d
    type/division_t/, dimension(:, intent(in) :: ds
    type(exception), intent(inout), optional :: exc
    character(len=*), parameter :: FN = "join_division"
    integer, dimension(size(ds)) :: n0, n1
    integer, dimension(0:size(ds)) :: n, ds_ng
    integer :: i, j, num_div, num_forks, nx
    real(kind=default), dimension(:, allocatable :: d_x, d_integral, d_variance

```

```

! real(kind=default), dimension(:), allocatable :: d_efficiency
num_div = ubound(d%x, dim=1)
num_forks = size(ds)
if (d%ng == 1) then
    <Join importance sampling divisions 51b>
else if (num_div >= num_forks) then
    if (modulo(d%ng, num_div) == 0) then
        <Join pure stratified sampling divisions 52c>
    else
        <Join pseudo stratified sampling divisions 54b>
    end if
else
    if (present(exc)) then
        call raise_exception(exc, EXC_FATAL, FN, "internal error")
    end if
end if
end subroutine join_division

```

### *Importance Sampling*

Importance sampling ( $d\%ng == 1$ ) is trivial, since we can just sample `size(ds)` copies of the same grid with (almost) the same number of points

51a  $\langle$  Fork an importance sampling division 51a  $\rangle \equiv$

```

if (d%stratified) then
    call raise_exception(exc, EXC_FATAL, FN, &
                        "ng == 1 incompatible w/ stratification")
else
    call copy_division(ds, d)
    num_calls(2:) = ceiling(real(sum_calls) / num_forks)
    num_calls(1) = sum_calls - sum(num_calls(2:))
end if

```

and sum up the results in the end:

51b  $\langle$  Join importance sampling divisions 51b  $\rangle \equiv$

```

call sum_division(d, ds)

```

Note, however, that this is only legitimate as long as  $d\%ng == 1$  implies `d%stratified == .false.`, because otherwise the sampling code would be incorrect (cf. `var_f` on page 88).

### *Stratified Sampling*

For stratified sampling, we have to work a little harder, because there are just two points per cell and we have to slice along the lines of the stratification

grid. Actually, we are slicing along the adaptive grid, since it has a reasonable size. Slicing along the stratification grid could be done using the method below. However, in this case *very* large adaptive grids would be shipped from one process to the other and the communication costs will outweigh the gains from parallel processing.

```

52a <Setup to fork a pure stratified sampling division 52a>≡
      n = (num_div * (/ (j, j=0,num_forks) /)) / num_forks
      n0(1:num_forks) = n(0:num_forks-1)
      n1(1:num_forks) = n(1:num_forks)

52b <Fork a pure stratified sampling division 52b>≡
      <Setup to fork a pure stratified sampling division 52a>
      do i = 1, num_forks
          call copy_array_pointer (ds(i)%x, d%x(n0(i):n1(i)), lb = 0)
          call copy_array_pointer (ds(i)%integral, d%integral(n0(i)+1:n1(i)))
          call copy_array_pointer (ds(i)%variance, d%variance(n0(i)+1:n1(i)))
!       call copy_array_pointer (ds(i)%efficiency, d%efficiency(n0(i)+1:n1(i)))
          ds(i)%x = (ds(i)%x - ds(i)%x(0)) / (d%x(n1(i)) - d%x(n0(i)))
      end do
      ds%x_min = d%x_min + d%dx * d%x(n0)
      ds%x_max = d%x_min + d%dx * d%x(n1)
      ds%dx = ds%x_max - ds%x_min
      ds%x_min_true = d%x_min_true
      ds%x_max_true = d%x_max_true
      ds%stratified = d%stratified
      ds%ng = (d%ng * (n1 - n0)) / num_div
      num_calls = sum_calls ! this is a misnomer, it remains “calls per cell” here
      ds%dxg = real (n1 - n0, kind=default) / ds%ng

Joining is the exact inverse, but we’re only interested in d%integral and
d%variance for the grid refinement:

52c <Join pure stratified sampling divisions 52c>≡
      <Setup to fork a pure stratified sampling division 52a>
      do i = 1, num_forks
          d%integral(n0(i)+1:n1(i)) = ds(i)%integral
          d%variance(n0(i)+1:n1(i)) = ds(i)%variance
!       d%efficiency(n0(i)+1:n1(i)) = ds(i)%efficiency
      end do

```

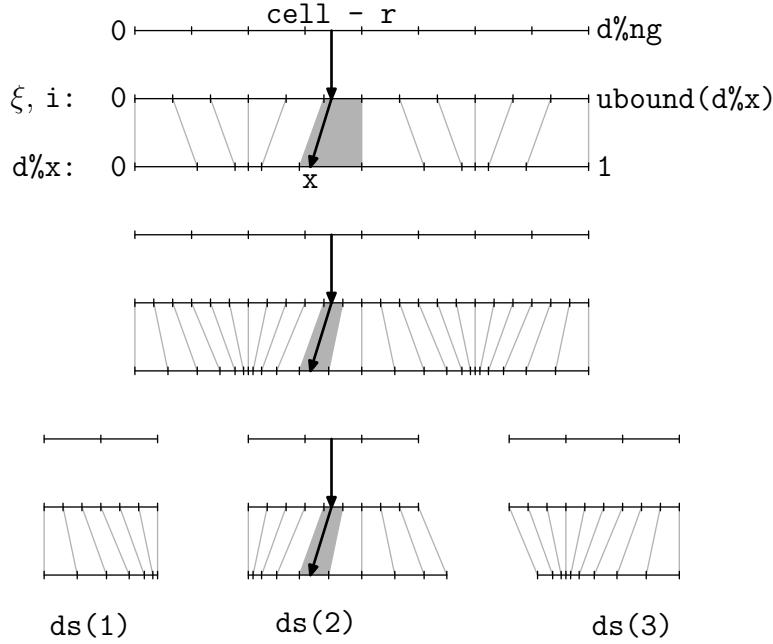

Figure 5.5: Forking one dimension  $d$  of a grid into three parts  $ds(1)$ ,  $ds(2)$ , and  $ds(3)$ . The picture illustrates the most complex case of pseudo stratified sampling (cf. fig. 5.3).

### Pseudo Stratified Sampling

The coarsest grid covering the division of  $n_g$  bins into  $n_f$  forks has  $n_g / \gcd(n_f, n_g) = \text{lcm}(n_f, n_g) / n_f$  bins per fork. Therefore, we need

$$\text{lcm} \left( \frac{\text{lcm}(n_f, n_g)}{n_f}, n_x \right) \quad (5.8)$$

divisions of the adaptive grid (if  $n_x$  is the number of bins in the original adaptive grid).

Life would be much easier, if we knew that  $n_f$  divides  $n_g$ . However, this is hard to maintain in real life applications. We can try to achieve this if possible, but the algorithms must be prepared to handle the general case.

53  $\langle$ Setup to fork a pseudo stratified sampling division 53 $\rangle \equiv$

```

nx = lcm (d%ng / gcd (num_forks, d%ng), num_div)
ds_ng = (d%ng * (/ (j, j=0,num_forks) /)) / num_forks
n = (nx * ds_ng) / d%ng
n0(1:num_forks) = n(0:num_forks-1)
n1(1:num_forks) = n(1:num_forks)

```

## 5.2 The Abstract Datatype *vamp\_grid*

70c <*vamp.f90* 70c>≡

```
! vamp.f90 --
⟨Copyleft notice 1⟩
```

⌚ NAG f95 requires this split. Check with the Fortran community, if it is really necessary, or a bug! The problem is that this split forces us to expose the components of `vamp_grid`.

**NB:** with the introduction of `vamp_equivaleces`, this question has (probably) become academic.

71a ⟨vamp.f90 70c⟩+≡

N.B.: In Fortran95 we will be able to give default initializations to components of the type. In particular, we can use the `null()` intrinsic to initialize the pointers to a disassociated state. Until then, the user *must* call the initializer `vamp_create_grid` himself or herself, because we can't check for the allocation status of the pointers in Fortran90 or F.

 Augment this datatype by `real(kind=default), dimension(2) :: mu_plus,`  
`mu_minus` to record positive and negative weight separately, so that we  
can estimate the efficiency for reweighting from indefinite weights to  
 $\{+1, -1\}$ .

76b <*Declaration of vamp\_grid\_type types 76b*>≡

```

type, public :: vamp_grid

    call create_division (g%div, x_min, x_max, x_min_true, x_max_true)
else
    nullify (g%map)
    call create_division (g%div, x_min, x_max)
end if
g%num_calls = num_calls
if (present (num_div)) then
    g%num_div = num_div
else
    g%num_div = NUM_DIV_DEFAULT
end if
g%stratified = .true.
g%quadrupole = .false.
g%independent = .true.
g%equivalent_to_ch = 0
g%multiplicity = 1
nullify (g%mu_x, g%mu_xx, g%sum_mu_x, g%sum_mu_xx)
call vamp_discard_integral &
    (g, num_calls, num_div, stratified, quadrupole, covariance, exc)
end subroutine vamp_create_grid

```

Below, we assume that  $\text{NUM\_DIV\_DEFAULT} \geq 6$ , but we will never go that low anyway.

78a *(Variables in vamp 78a)≡*

```
integer, private, parameter :: NUM_DIV_DEFAULT = 20
```

Given a linear map  $M$ , find a domain  $\mathcal{D}_0$  such that

$$\mathcal{D} \subset M\mathcal{D}_0 \quad (5.10)$$

78b *(Declaration of vamp procedures 77a)++≡*

```
private :: map_domain
```

If we can assume that  $M$  is orthogonal  $M^{-1} = M^T$ , then we just have to rotate  $\mathcal{D}$  and determine the maximal and minimal extension of the corners:

$$\mathcal{D}_0^T = \overline{\mathcal{D}^T M} \quad (5.11)$$

The corners are just the powerset of the maximal and minimal extension in each coordinate. It is determined most easily with binary counting:

79a *(Implementation of vamp procedures 77c)*+≡

```

end subroutine vamp_reshape_grid

```

`vegas` operates in three different modes, which are chosen according to explicit user requests and to the relation of the requested number of sampling points to the dimensionality of the integration domain.

The simplest case is when the user has overwritten the default of stratified sampling with the optional argument `stratified` in the call to `vamp_create_grid`. Then sample points will be chosen randomly with equal probability in each cell of the adaptive grid, as displayed in figure 5.1.

The implementation is actually shared with the stratified case described below, by pretending that there is just a single stratification cell. The number

of divisions for the adaptive grid is set to a compile time maximum value.

If the user has agreed on stratified sampling then there are two cases, depending on the dimensionality of the integration region and the number of sample points. First we determine the number of divisions  $n_g$  (i.e. `ng`) of the rigid grid such that there will be two sampling points per cell.

$$N_{\text{calls}} = 2 \cdot (n_g)^{n_{\text{dim}}} \quad (5.12)$$

The additional optional argument  $\hat{n}_g$  specifies an anisotropy in the shape

$$n_{g,j} = \frac{\hat{n}_{g,j}}{\left(\prod_j \hat{n}_{g,j}\right)^{1/n_{\text{dim}}}} \left(\frac{N}{2}\right)^{1/n_{\text{dim}}} \quad (5.13)$$

NB:

$$\prod_j n_{g,j} = \frac{N}{2} \quad (5.14)$$

```

86c <*Local variables in vamp\_sample\_grid0 86c*>≡

```

real(kind=default), parameter :: &
  eps = tiny (1._default) / epsilon (1._default)

```

```

    character(len=6) :: buffer
87a  <Local variables in vamp_sample_grid0 86c>+≡
      integer :: j, k
      integer, dimension(size(g%div)) :: cell
87b  <Sample calls_per_cell points in the current cell 87b>≡
      sum_f = 0.0
      sum_f2 = 0.0
      do k = 1, g%calls_per_cell
        <Get x in the current cell 87c>
        <f = wgt * func (x, weights, channel), iff x inside true_domain 87d>
        <Collect integration and grid optimization data for x from f 88a>
      end do

```

We are using the generic procedure `tao_random_number` from the `tao_random_numbers` module for generating an array of uniform deviates. A better alternative would be to pass the random number generator as an argument to `vamp_sample_grid`. Unfortunately, it is not possible to pass *generic* procedures in Fortran90, Fortran95, or F. While we could export a specific procedure from `tao_random_numbers`, a more serious problem is that we have to pass the state `rng` of the random number generator as a `tao_random_state` anyway and we have to hardcode the random number generator anyway.

```

87c  <Get x in the current cell 87c>≡
      call tao_random_number (rng, r)
      call inject_division (g%div, real (r, kind=default), &
                           cell, x, x_mid, ia, wgts)
      wgt = g%jacobi * product (wgts)
      if (associated (g%map)) then
        x = matmul (g%map, x)
      end if

```

This somewhat contorted nested `if` constructs allow to minimize the number of calls to `func`. This is useful, since `func` is the most expensive part of real world applications. Also `func` might be singular outside of `true_domain`.

The original `vegas` used to call `f = wgt * func (x, wgt)` below to allow `func` to use `wgt` (i.e.  $1/p(x)$ ) for integrating another function at the same time. This form of “parallelism” relies on side effects and is therefore impossible with pure functions. Consequently, it is not supported in the current implementation.

```

87d  <f = wgt * func (x, weights, channel), iff x inside true_domain 87d>≡
      if (associated (g%map)) then

```
interface vamp_average_iterations
    module procedure vamp_average_iterations_grid
end interface
```

Lepage suggests [1] to reweight the contributions as in the following improved

formulae, which we might implement as an option later.

$$\bar{I} = \frac{1}{\left(\sum_i \frac{I_i^2}{\sigma_i^2}\right)^2} \sum_i I_i \frac{I_i^2}{\sigma_i^2} \quad (5.22a)$$

$$\frac{1}{\sigma_I^2} = \frac{1}{(\bar{I})^2} \sum_i \frac{I_i^2}{\sigma_i^2} \quad (5.22b)$$

$$\chi^2 = \sum_i \frac{(I_i - \bar{I})^2}{(\bar{I})^2} \frac{I_i^2}{\sigma_i^2} \quad (5.22c)$$

Iff possible, copy the result to the caller's variables:

```
95a <Copy results of vamp_sample_grid to dummy variables 95a>≡
    if (present (integral)) then
        integral = local_integral
    end if
    if (present (std_dev)) then
        std_dev = local_std_dev
    end if
    if (present (avg_chi2)) then
        avg_chi2 = local_avg_chi2
    end if

95b <Exit iterate if accuracy has been reached 95b>≡
    if (present (accuracy)) then
        if (local_std_dev <= accuracy * local_integral) then
            call raise_exception (exc, EXC_INFO, FN, &
                "requested accuracy reached")
            exit iterate
        end if
    end if
```

### 5.2.3 Forking and Joining

```
95c <Declaration of vamp procedures 77a>+≡
    public :: vamp_fork_grid
    private :: vamp_fork_grid_single, vamp_fork_grid_multi
    public :: vamp_join_grid
    private :: vamp_join_grid_single, vamp_join_grid_multi

95d <Interfaces of vamp procedures 94c>+≡
    interface vamp_fork_grid
        module procedure vamp_fork_grid_single, vamp_fork_grid_multi
    end interface
```

```

interface vamp_join_grid
    module procedure vamp_join_grid_single, vamp_join_grid_multi
end interface

```

Caveat emptor: splitting divisions can lead to `num_div < 3` an the application must not try to refine such grids before merging them again! `d == 0` is special.

96a *<Implementation of vamp procedures 77c>*+≡

```

pure subroutine vamp_fork_grid_single (g, gs, d, exc)
    type(vamp_grid), intent(in) :: g

gs%f_max = g%f_max * (gs%jacobi * gs%calls) / (g%jacobi * g%calls)

```

This could be self-explaining, if the standard would allow .... Note that we can get away with copying just the pointers, because `fork_division` does the dirty work for the memory management.

97d *(call fork\_division (g%div(j), gs%div(j), g%calls\_per\_cell, ...)* 97d) ≡  
`allocate (d_tmp(num_grids))`  
`do i = 1, num_grids`  
 `d_tmp(i) = gs(i)%div(j)`

```

    end do
    call fork_division (g%div(j), d_tmp, g%calls_per_cell, gs%calls_per_cell, exc)
    do i = 1, num_grids
        gs(i)%div(j) = d_tmp(i)
    end do
    deallocate (d_tmp)
    <Bail out if exception exc raised 98a>

98a  <Bail out if exception exc raised 98a>≡
      if (present (exc)) then
          if (exc%level > EXC_WARN) then
              return
          end if
      end if

We have to do a deep copy ( $gs(i)\%div(j) = g\%div(j)$  does not suffice),
because copy_division handles the memory management.

98b  <call copy_division (gs%div(j), g%div(j)) 98b>≡

    end if

```

The following is made a little bit hairy by the fact that `vamp_fork_grid` can't join grids onto a non-existing grid<sup>2</sup> therefore we have to keep a tree of joints. Maybe it would be the right thing to handle this tree of joints as a tree with pointers, but since we need the leaves flattened anyway (as food for multiple `vamp_sample_grid`) we use a similar storage layout for the joints.

100a *(Idioms 100a)≡*

```
type(vamp_grid), dimension(:), allocatable :: gx
integer, dimension(:, :, ), allocatable :: dim
...
allocate (gx(vamp_fork_grid_joints (dim)))

[22]

$$g(x) = \sum_i \alpha_i g_i(x) \quad (5.25a)$$

$$w(x) = \frac{f(x)}{g(x)} \quad (5.25b)$$

We want to minimize the variance  $W(\alpha)$  with the subsidiary condition  $\sum_i \alpha_i = 1$ . We introduce a Lagrange multiplier  $\lambda$ :

$$\tilde{W}(\alpha) = W(\alpha) + \lambda \left( \sum_i \alpha_i - 1 \right) \quad (5.26)$$

Therefore...

$$W_i(\alpha) = -\frac{\partial}{\partial \alpha_i} W(\alpha) = \int dx g_i(x)(w(x))^2 \approx \left\langle \frac{g_i(x)}{g(x)} (w(x))^2 \right\rangle \quad (5.27)$$

 Here it *really* hurts that **Fortran** has no *first-class* functions. The following can be expressed much more elegantly in a functional programming language with *first-class* functions, currying and closures. **Fortran** makes it extra painful since not even procedure pointers are supported. This puts extra burden on the users of this library.

Note that the components of **vamp\_grids** are not protected. However, this is not a license for application programs to access it. Only Other libraries (e.g. for parallel processing, like **vampi**) should do so.

The rules for optional arguments forces us to handle special cases, because we can't just pass a array section of an optional array as an actual argument (cf. 12.4.1.5(4) in [8]) even if the dummy argument is optional itself.

$$N = \sum_c N_c \quad (5.30c)$$

where (5.30b) is actually

$$\sigma^2 = \frac{1}{N} (\mu_2 - \mu_1^2) = \frac{1}{N} \left( \frac{1}{N} \sum_c N_c \mu_{2,c} - I^2 \right) = \frac{1}{N} \left( \frac{1}{N} \sum_c (N_c^2 \sigma_c^2 + N_c I_c^2) - I^2 \right)$$

but the latter form suffers from numerical instability and (5.30b) is thus preferred.

### 5.2.7 Mapping

 This section is still under construction. The basic algorithm is in place, but the heuristics have not been developed yet.

The most naive approach is to use the rotation matrix  $R$  that diagonalizes the covariance  $C$ :

$$R_{ij} = (v_j)_i \quad (5.32)$$

where

$$Cv_j = \lambda_j v_j \quad (5.33)$$

with the eigenvalues  $\{\lambda_j\}$  and eigenvectors  $\{v_j\}$ . Then

$$R^T C R = \text{diag}(\lambda_1, \dots) \quad (5.34)$$

After call `diagonalize_real_symmetric (cov, evals, evecs)`, we have `evals(j) = λ_j` and `evecs(:,j) = v_j`. This is equivalent with `evecs(i,j) = R_ij`.

This approach will not work in high dimensions, however. In general,  $R$  will *not* leave most of the axes invariant, even if the covariance matrix is almost isotropic in these directions. In this case the benefit from the rotation is rather small and offset by the negative effects from the misalignment of the integration region.

A better strategy is to find the axis of the original coordinate system around which a rotation is most beneficial. There are two extreme cases:

- “pancake”: one eigenvalue much smaller than the others
- “cigar”: one eigenvalue much larger than the others

Actually, instead of rotating around a specific axis, we can as well diagonalize in a subspace. Empirically, rotation around an axis is better than diagonalizing in a two-dimensional subspace, but diagonalizing in a three-dimensional subspace can be even better.

125a *(Declaration of vamp procedures 77a)* +≡

```

In both cases, we can rotate in the plane  $P_{ij}$  closest to eigenvector corresponding to the the singled out eigenvalue. This plane is given by

$$\max_{i \neq i'} \sqrt{(v_j)_i^2 + (v_j)_{i'}^2} \quad (5.35)$$

which is simply found by looking for the two largest  $|(v_j)_i|$ :<sup>3</sup>

127a *(Set i(1), i(2) to the axes of the optimal plane 127a)*≡

```
abs_evec = abs (evecs(:,iv))
i(1) = sum (maxloc (abs_evec))
abs_evec(i(1)) = -1.0
i(2) = sum (maxloc (abs_evec))
```

The following is cute, but unfortunately broken, since it fails for degenerate eigenvalues:

127b *(Set i(1), i(2) to the axes of the optimal plane (broken!) 127b)*≡

```
abs_evec = abs (evecs(:,iv))
i(1) = sum (maxloc (abs_evec))
i(2) = sum (maxloc (abs_evec, mask = abs_evec < abs_evec(i(1))))
```

127c *(Set i(1), i(2) to the axes of the optimal plane 127a)*+≡

```
print *, iv, evals(iv), " => ", evecs(:,iv)
print *, i(1), abs_evec(i(1)), " ", " , i(2), abs_evec(i(2))
print *, i(1), evecs(i(1),iv), " ", " , i(2), evecs(i(2),iv)
```

127d *(Get cos θ and sin θ from evecs 127d)*≡

```

### *Condensing Eigenvalues*

In order to decide whether we have a “pancake” or a “cigar”, we have to classify the eigenvalues of the covariance matrix. We do this by condensing the  $n_{\text{dim}}$  eigenvalues into  $n_{\text{cl}} \ll n_{\text{dim}}$  clusters.

130    *(Declaration of vamp procedures 77a)* +≡

```

! private :: condense
public :: condense

```

The rough description is as follows: in each step, combine the nearest neighbours (according to an appropriate metric) to form a smaller set. This is an extremely simplified, discretized modeling of molecules condensing under the influence of some potential.

 If there’s not a clean separation, this algorithm is certainly chaotic and we need to apply some form of damping!

131a  $\langle$ Initialize clusters 131a $\rangle \equiv$

```
cl_pos = x
cl_num = size (cl_pos)
cl = spread ((/ (i, i=1,cl_num) /), dim = 2, ncopies = 2)
```

It appears that the logarithmic metric

$$d_0(x, y) = \left| \log \left( \frac{x}{y} \right) \right| \quad (5.37a)$$

performs better than the linear metric

$$d_1(x, y) = |x - y| \quad (5.37b)$$

since the latter won't separate very small eigenvalues from the bulk. Another option is

$$d_\alpha(x, y) = |x^\alpha - y^\alpha| \quad (5.37c)$$

with  $\alpha \neq 1$ , in particular  $\alpha \approx -1$ . I haven't studied it yet, though.

 but I should perform more empirical studies to determine whether the logarithmic or the linear metric is more appropriate in realistic cases.

131b  $\langle$ Join closest clusters 131b $\rangle \equiv$

```
if (linear_metric) then
    gap = sum (minloc (cl_pos(2:cl_num) - cl_pos(1:cl_num-1)))
else
    gap = sum (minloc (cl_pos(2:cl_num) / cl_pos(1:cl_num-1)))
end if
wgt0 = cl(gap,2) - cl(gap,1) + 1
wgt1 = cl(gap+1,2) - cl(gap+1,1) + 1
cl_pos(gap) = (wgt0 * cl_pos(gap) + wgt1 * cl_pos(gap+1)) / (wgt0 + wgt1)
cl(gap,2) = cl(gap+1,2)
```

### 5.2.8 Event Generation

Automagically adaptive tools are not always appropriate for unweighted event generation, but we can give it a try.

133a *(Declaration of vamp procedures 77a)*+≡

```
public :: vamp_next_event
```

133b *(Interfaces of vamp procedures 94c)*+≡

```
interface vamp_next_event
    module procedure vamp_next_event_single, vamp_next_event_multi
end interface
```

133c *(Declaration of vamp procedures 77a)*+≡

```
private :: vamp_next_event_single, vamp_next_event_multi
```

Both event generation routines operate in two modes, depending on whether the optional argument **weight** is present.

133d *(Implementation of vamp procedures 77c)*+≡

```

pure subroutine vamp_next_event_single &
    (x, rng, g, func, prc_index, &
     weight, channel, weights, grids, exc)
    real(kind=default), dimension(:), intent(out) :: x
    type(tao_random_state), intent(inout) :: rng
    type(vamp_grid), intent(inout) :: g
    real(kind=default), intent(out), optional :: weight
    integer, intent(in) :: prc_index
    integer, intent(in), optional :: channel
    real(kind=default), dimension(:), intent(in), optional :: weights
    type(vamp_grid), dimension(:), intent(in), optional :: grids
    type(exception), intent(inout), optional :: exc
    <Interface declaration for func 22>
    character(len=*), parameter :: FN = "vamp_next_event_single"
    real(kind=default), dimension(size(g%div)):: wgts
    real(kind=default), dimension(size(g%div)):: r
    integer, dimension(size(g%div)):: ia
    real(kind=default) :: f, wgt
    real(kind=default) :: r0
    rejection: do
        <Choose a x and calculate f(x) 134a>
        if (present (weight)) then
            <Unconditionally accept weighted event 134b>
        else
            <Maybe accept unweighted event 134c>
        end if
    end do rejection
end subroutine vamp_next_event_single

```

134a <Choose a x and calculate f(x) 134a>≡  
 call tao\_random\_number (rng, r)  
 call inject\_division\_short (g%div, real(r, kind=default), x, ia, wgts)  
 wgt = g%jacobi \* product (wgts)  
 wgt = g%calls \* wgt ! the calling procedure will divide by #calls  
 if (associated (g%map)) then  
 x = matmul (g%map, x)  
 end if  
 <f = wgt \* func (x, weights, channel), iff x inside true\_domain 87d>  
 ! call record\_efficiency (g%div, ia, f/g%f\_max)

134b <Unconditionally accept weighted event 134b>≡  
 weight = f  
 exit rejection

134c <Maybe accept unweighted event 134c>≡

```

if (f > g%f_max) then
    g%f_max = f
    call raise_exception (exc, EXC_WARN, FN, "weight > 1")
    exit rejection
end if
call tao_random_number (rng, r0)
if (r0 * g%f_max <= f) then
    exit rejection
end if

```

We know that `g%weights` are normalized: `sum (g%weights) == 1.0`. The basic formula for multi channel sampling is

$$f(x) = \sum_i \alpha_i g_i(x) w(x) \quad (5.39)$$

with  $w(x) = f(x)/g(x) = f(x)/\sum_i \alpha_i g_i(x)$  and  $\sum_i \alpha_i = 1$ . The non-trivial problem is that the adaptive grid is different in each channel, so we can't just reject on  $w(x)$ .

**135** *<Implementation of vamp procedures 77c>+≡*

```

pure subroutine vamp_next_event_multi &
    (x, rng, g, func, prc_index, phi, weight, excess, exc)
    real(kind=default), dimension(:), intent(out) :: x
    type(tao_random_state), intent(inout) :: rng
    type(vamp_grids), intent(inout) :: g
    integer, intent(in) :: prc_index
    real(kind=default), intent(out), optional :: weight
    real(kind=default), intent(out), optional :: excess
    type(exception), intent(inout), optional :: exc
    <Interface declaration for func 22>
    <Interface declaration for phi 31a>
    character(len=*), parameter :: FN = "vamp_next_event_multi"
    real(kind=default), dimension(size(x)) :: xi
    real(kind=default) :: r, wgt
    real(kind=default), dimension(size(g%weights)) :: weights
    integer :: channel
    <weights:  $\alpha_i \rightarrow w_{\max,i} \alpha_i$  136a>
    rejection: do
        <Select channel from weights 136b>
        call vamp_next_event_single &
            (xi, rng, g%grids(channel), func, prc_index, wgt, &
            channel, g%weights, g%grids, exc)
        if (present (weight)) then
            <Unconditionally accept weighted multi channel event 136c>

```

```

    else
        (Maybe accept unweighted multi channel event 136d)
    end if
end do rejection
x = phi (xi, channel)
end subroutine vamp_next_event_multi

```

We can either reject with the weights

$$\frac{w_i(x)}{\max_i \max_x w_i(x)} \quad (5.40)$$

after using the apriori weights  $\alpha_i$  to select a channel  $i$  or we can reject with the weights

$$\frac{w_i(x)}{\max_x w_i(x)} \quad (5.41)$$

after using the apriori weights  $\alpha_i(\max_x w_i(x)) / (\max_i \max_x w_i(x))$ . The latter method is more efficient if the  $\max_x w_i(x)$  have a wide spread.

- 136a *{weights:  $\alpha_i \rightarrow w_{\max,i} \alpha_i$  136a}*≡
 

```

        if (any (g%grids%f_max > 0)) then

```

137a *⟨Maybe accept unweighted multi channel event (old version) 137a⟩*≡

```

if (wgt > g%grids(channel)%f_max) then
  g%grids(channel)%f_max = wgt
  ⟨weights:  $\alpha_i \rightarrow w_{\max,i}\alpha_i$  136a⟩
  call raise_exception (exc, EXC_WARN, FN, "weight > 1")
  exit rejection
end if
call tao_random_number (rng, r)
if (r * g%grids(channel)%f_max <= wgt) then
  exit rejection
end if

```

Using `vamp_sample_grid (g, ...)` to warm up the grid `g` has a somewhat subtle problem: the minimum and maximum weights `g%f_min` and `g%f_max` refer to the grid *before* the final refinement. One could require an additional `vamp_sample_grid0 (g, ...)`, but users are likely to forget such technical details. A better solution is a wrapper `vamp_warmup_grid (g, ...)` that drops the final refinement transparently.

### 5.3 Interface to MPI

The module `vamp` makes no specific assumptions about the hardware and software supporting parallel execution. In this section, we present a specific example of a parallel implementation of multi channel sampling using the message passing paradigm.

The modules `vamp_serial_mpi` and `vamp_parallel_mpi` are not intended to be used directly by application programs. For this purpose, the module `vampi` is provided. `vamp_serial_mpi` is identical to `vamp`, but some types, procedures and variables are renamed so that `vamp_parallel_mpi` can redefine them:

165b *<vampi.f90 165b>*≡

```

! vampi.f90 --
<Copyleft notice 1>
module vamp_serial_mpi
    use vamp, &
        <vamp0_* => vamp_* 166c>
        VAMPO_RCS_ID => VAMP_RCS_ID
    public
end module vamp_serial_mpi

```

`vamp_parallel_mpi` contains the non trivial MPI code and will be discussed in detail below.

165c *<vampi.f90 165b>*+≡

```

module vamp_parallel_mpi
    use kinds
    use utils
    use tao_random_numbers
    use exceptions
    use mpi90
    use divisions
    use vamp_serial_mpi !NODEP!
    use iso_fortran_env

```

```

implicit none
private
<Declaration of vampi procedures 166b>
<Interfaces of vampi procedures 170d>
<Parameters in vampi 167a>
<Declaration of vampi types 171b>
character(len=*), public, parameter :: VAMPI_RCS_ID = &
    "$Id: vampi.nw 314 2010-04-17 20:32:33Z ohl $"
contains
    <Implementation of vampi procedures 166d>
end module vamp_parallel_mpi

```

vampi is now a plug-in replacement for vamp and *must not* be used together with vamp:

166a <vampi.f90 165b>+≡

```

module vampi
    use vamp_serial_mpi !NODEP!
    use vamp_parallel_mpi !NODEP!
    public
end module vampi

```

if (distribute_complete_grids) then
    call mpi90_broadcast (g%proc, VAMP_ROOT)
end if
iterate: do iteration = 1, iterations
    if (distribute_complete_grids) then
        call vamp_broadcast_grid (g%g0%grids, VAMP_ROOT)
        <Distribute complete grids among processes 175b>
    else
        <Distribute each grid among processes 179b>
    end if
    <Exit iterate if accuracy has been reached (MPI) 178a>
end do iterate

```

```

    <Copy results of vamp_sample_grids to dummy variables 177e>
end subroutine vamp_sample_grids

```

Setting VAMP\_MAX\_WASTE to 1 disables the splitting of grids, which doesn't work yet.

175a <Parameters in vampi 167a>+≡  
`real(kind=default), private, parameter :: VAMP_MAX_WASTE = 1.0  
! real(kind=default), private, parameter :: VAMP_MAX_WASTE = 0.3`

175b <Distribute complete grids among processes 175b>≡  
`do ch = 1, nch  
 if (g%active(ch)) then  
 if (proc_id == g%proc(ch)) then  
 call vamp0_discard_integral (g%g0%grids(ch))  
 <Sample g%g0%grids(ch) 175d>  
 end if  
 else  
 call vamp_nullify_variance (g%g0%grids(ch))  
 call vamp_nullify_covariance (g%g0%grids(ch))  
 end if  
end do`

Refine the grids after *all* grids have been sampled:

175c <Distribute complete grids among processes 175b>+≡  
`do ch = 1, nch  
 if (g%active(ch) .and. (proc_id == g%proc(ch))) then  
 call vamp_refine_grid (g%g0%grids(ch))  
 if (proc_id /= VAMP_ROOT) then  
 <Ship the result for channel #ch back to the root 176c>  
 end if  
 end if  
end do`

therefore we use `vamp_sample_grid0` instead of `vamp0_sample_grid`:

175d <Sample g%g0%grids(ch) 175d>≡  
`call vamp_sample_grid0 &  
 (rng, g%g0%grids(ch), func, ch, weights, g%g0%grids, exc)  
call vamp_average_iterations &  
 (g%g0%grids(ch), iteration, g%integrals(ch), g%std_devs(ch), local_avg_chi2)  
if (present (histories)) then  
 if (iteration <= ubound (histories, dim=1)) then  
 call vamp_get_history &  
 (histories(iteration,ch), g%g0%grids(ch), &  
 g%integrals(ch), g%std_devs(ch), local_avg_chi2)  
 else`

```

        call raise_exception (exc, EXC_WARN, FN, "history too short")
    end if
    call vamp_terminate_history (histories(iteration+1:,ch))
end if

176a <Distribute complete grids among processes 175b>+≡
if (proc_id == VAMP_ROOT) then
    do ch = 1, nch
        if (g%active(ch) .and. (g%proc(ch) /= proc_id)) then
            (Receive the result for channel #ch at the root 177a)
        end if
    end do
call vamp_reduce_channels (g%g0, g%integrals, g%std_devs, g%active)
call vamp_average_iterations &
    (g%g0, iteration, local_integral, local_std_dev, local_avg_chi2)
if (present (history)) then
    if (iteration <= size (history)) then
        call vamp_get_history &
            (history(iteration), g%g0, local_integral, local_std_dev, &
            local_avg_chi2)
    else
        call raise_exception (exc, EXC_WARN, FN, "history too short")
    end if
    call vamp_terminate_history (history(iteration+1:))
end if
end if

```

This would be cheaper than `vamp_broadcast_grid`, but we need the latter to support the adaptive multi channel sampling:

```

176b <Ship g%g0%grids from the root to the assigned processor 176b>≡
do ch = 1, nch
    if (g%active(ch) .and. (g%proc(ch) /= VAMP_ROOT)) then
        if (proc_id == VAMP_ROOT) then
            call vamp_send_grid &
                (g%g0%grids(ch), g%proc(ch), object (ch, TAG_GRID))
        else if (proc_id == g%proc(ch)) then
            call vamp_receive_grid &
                (g%g0%grids(ch), VAMP_ROOT, object (ch, TAG_GRID))
        end if
    end if
end do

176c <Ship the result for channel #ch back to the root 176c>≡
call mpi90_send (g%integrals(ch), VAMP_ROOT, object (ch, TAG_INTEGRAL))
call mpi90_send (g%std_devs(ch), VAMP_ROOT, object (ch, TAG_STD_DEV))

```

```

call vamp_send_grid (g%g0%grids(ch), VAMP_ROOT, object (ch, TAG_GRID))
if (present (histories)) then
    call vamp_send_history &
        (histories(iteration,ch), VAMP_ROOT, object (ch, TAG_HISTORY))
end if

177a <Receive the result for channel #ch at the root 177a>≡

        call raise_exception (exc, EXC_INFO, FN, &
            "requested accuracy reached")
        exit iterate
    end if
end if

```

A very simple minded scheduler: maximizes processor utilization and, does not pay attention to communication costs.

178b *(Declaration of vmpi procedures 166b)*+≡

```

private :: schedule

```

We disfavor the root process a little bit (by starting up with a fake filling ratio of 10%) so that it is likely to be ready to answer all communication requests.

178c *(Implementation of vmpi procedures 166d)*+≡

```

pure subroutine schedule (jobs, num_procs, assign, waste)
    real(kind=default), dimension(:), intent(in) :: jobs
    integer, intent(in) :: num_procs
    integer, dimension(:), intent(out) :: assign
    real(kind=default), intent(out), optional :: waste
    integer, dimension(size(jobs)) :: idx
    real(kind=default), dimension(size(jobs)) :: sjobs
    real(kind=default), dimension(num_procs) :: fill
    integer :: job, proc
    sjobs = jobs / sum (jobs) * num_procs
    idx = (/ (job, job = 1, size(jobs)) /)
    call sort (sjobs, idx, reverse = .true.)
    fill = 0.0
    fill(VAMP_ROOT+1) = 0.1
    do job = 1, size (sjobs)
        proc = sum (minloc (fill))
        fill(proc) = fill(proc) + sjobs(job)
        assign(idx(job)) = proc - 1
    end do
    <Estimate waste of processor time 179a>
end subroutine schedule

```

Assuming equivalent processors and uniform computation costs, the waste is

given by the fraction of the time that it spent by the other processors waiting for the processor with the biggest assignment:

179a *(Estimate waste of processor time 179a)*≡  
 if (present (waste)) then  
     waste = 1.0 - sum (fill) / (num\_procs \* maxval (fill))  
 end if

Accordingly, if the waste caused by distributing only complete grids, we switch to splitting the grids, just like in single channel sampling. This is *not* the default, because the communication costs are measurably higher for many grids and many processors.

 This version is broken!

179b *(Distribute each grid among processes 179b)*≡  
 do ch = 1, size (g%g0%grids)

### 5.3.4 Communicating Grids

184d *(Declaration of vampi procedures 166b)*+≡

```

public :: vamp_send_grid

```

```

public :: vamp_receive_grid
public :: vamp_broadcast_grid
public :: vamp_broadcast_grids

```

-  The next two are still kludged. Nicer implementations with one message less per call below, but MPICH does funny things during `mpi_get_count`, which is called by `mpi90_receive_pointer`.

Caveat: this `vamp_send_grid` uses *three* tags: `tag`, `tag+1` and `tag+2`:

185a *<Implementation of vampi procedures 166d>+≡*

```

subroutine vamp_send_grid (g, target, tag, domain, error)
    type(vamp_grid), intent(in) :: g
    integer, intent(in) :: target, tag
    integer, intent(in), optional :: domain
    integer, intent(out), optional :: error
    integer, dimension(2) :: words
    integer, dimension(:), allocatable :: ibuf
    real(kind=default), dimension(:), allocatable :: dbuf
    call vamp_marshal_grid_size (g, words(1), words(2))
    allocate (ibuf(words(1)), dbuf(words(2)))
    call vamp_marshal_grid (g, ibuf, dbuf)
    call mpi90_send (words, target, tag, domain, error)
    call mpi90_send (ibuf, target, tag+1, domain, error)
    call mpi90_send (dbuf, target, tag+2, domain, error)
    deallocate (ibuf, dbuf)
end subroutine vamp_send_grid

```

185b *<Implementation of vampi procedures 166d>+≡*

```

subroutine vamp_receive_grid (g, source, tag, domain, status, error)
    type(vamp_grid), intent(inout) :: g
    integer, intent(in) :: source, tag
    integer, intent(in), optional :: domain
    type(mpi90_status), intent(out), optional :: status
    integer, intent(out), optional :: error
    integer, dimension(2) :: words
    integer, dimension(:), allocatable :: ibuf
    real(kind=default), dimension(:), allocatable :: dbuf
    call mpi90_receive (words, source, tag, domain, status, error)
    allocate (ibuf(words(1)), dbuf(words(2)))
    call mpi90_receive (ibuf, source, tag+1, domain, status, error)
    call mpi90_receive (dbuf, source, tag+2, domain, status, error)
    call vamp_unmarshal_grid (g, ibuf, dbuf)
    deallocate (ibuf, dbuf)

```

```
end subroutine vamp_receive_grid
```

Caveat: the real `vamp_send_grid` uses *two* tags: `tag` and `tag+1`:

186a *(Implementation of vampi procedures (doesn't work with MPICH yet) 186a)*≡  
  subroutine vamp\_send\_grid (g, target, tag, domain, error)  
    type(vamp\_grid), intent(in) :: g  
    integer, intent(in) :: target, tag  
    integer, intent(in), optional :: domain  
    integer, intent(out), optional :: error  
    integer :: iwords, dwords  
    integer, dimension(:), allocatable :: ibuf  
    real(kind=default), dimension(:), allocatable :: dbuf  
    call vamp\_marshal\_grid\_size (g, iwords, dwords)  
    allocate (ibuf(iwords), dbuf(dwords))  
    call vamp\_marshal\_grid (g, ibuf, dbuf)  
    call mpi90\_send (ibuf, target, tag, domain, error)  
    call mpi90\_send (dbuf, target, tag+1, domain, error)  
    deallocate (ibuf, dbuf)  
  end subroutine vamp\_send\_grid

⌚ There's something wrong with MPICH: if I call `mpi90_receive_pointer` in the opposite order, the low level call to `mpi_get_count` bombs for no apparent reason!

⌚ There are also funky things going on with tag: `mpi90_receive_pointer` should leave it alone, but ...

186b *(Implementation of vampi procedures (doesn't work with MPICH yet) 186a)*+≡  
  subroutine vamp\_receive\_grid (g, source, tag, domain, status, error)  
    type(vamp\_grid), intent(inout) :: g  
    integer, intent(in) :: source, tag  
    integer, intent(in), optional :: domain  
    type(mpi90\_status), intent(out), optional :: status  
    integer, intent(out), optional :: error  
    integer, dimension(:), pointer :: ibuf  
    real(kind=default), dimension(:), pointer :: dbuf  
    nullify (ibuf, dbuf)  
    call mpi90\_receive\_pointer (dbuf, source, tag+1, domain, status, error)  
    call mpi90\_receive\_pointer (ibuf, source, tag, domain, status, error)  
    call vamp\_unmarshal\_grid (g, ibuf, dbuf)  
    deallocate (ibuf, dbuf)  
  end subroutine vamp\_receive\_grid

This if not a good idea, with respect to communication costs. For SMP machines, it appears to be negligible however.

# —6—

## SELF TEST

### 6.1 No Mapping Mode

In this chapter we perform a test of the major features of Vamp. A function with many peaks is integrated with the traditional Vegas algorithm, using a multi-channel approach and in parallel. The function is constructed to have a known analytical integral (which is chosen to be one) in order to be able to gauge the accuracy of the result and error estimate.

#### 6.1.1 Serial Test

### 6.1.3 Output

202a ⟨vamp\_test.out 202a⟩≡

## 6.2 Mapped Mode

In this chapter we perform a test of the major features of Vamp. A function with many peaks is integrated with the traditional Vegas algorithm, using a multi-channel approach and in parallel. The function is constructed to have a known analytical integral (which is chosen to be one) in order to be able to gauge the accuracy of the result and error estimate.

### 6.2.1 Serial Test

202b ⟨vamp\_test0.f90 202b⟩≡  
! vamp\_test0.f90 --  
⟨Copyleft notice 1⟩  
⟨Module vamp\_test0\_functions 203⟩

### Single Channel

The functions to be integrated are shared by the serial and the parallel incarnation of the code.

```
203 <Module vamp_test0_functions 203>≡
  module vamp_test0_functions
    use kinds
    use vamp, only: vamp_grid, vamp_multi_channel0
    implicit none
    private
    public :: f, g, phi, w
    public :: create_sample, delete_sample
    private :: f0, psi, g0, f_norm
    real(kind=default), dimension(:), allocatable, private :: c, x_min, x_max
    real(kind=default), dimension(:,:,:,:), allocatable, public :: x0, gamma
    contains
      <Implementation of vamp_test0_functions procedures 204a>
  end module vamp_test0_functions
```

We start from a model of  $n_p$  interfering resonances in one variable (cf. section ??)

$$f_0(x|x_{\min}, x_{\max}, x_0, \gamma) = \frac{1}{N(x_{\min}, x_{\max}, x_0, \gamma)} \left| \sum_{p=1}^{n_p} \frac{1}{x - x_{0,p} + i\gamma_p} \right|^2 \quad (6.3)$$

where

$$N(x_{\min}, x_{\max}, x_0, \gamma) = \int_{x_{\min}}^{x_{\max}} dx \left| \sum_{p=1}^{n_p} \frac{1}{x - x_{0,p} + i\gamma_p} \right|^2 \quad (6.4)$$

such that

$$\int_{x_{\min}}^{x_{\max}} dx f_0(x|x_{\min}, x_{\max}, x_0, \gamma) = 1 \quad (6.5)$$

NB: the  $N(x_{\min}, x_{\max}, x_0, \gamma)$  should be calculated once and tabulated to save processing time, but we are lazy here.

$$\begin{aligned} N(x_{\min}, x_{\max}, x_0, \gamma) &= \sum_{p=1}^{n_p} \int_{x_{\min}}^{x_{\max}} dx \left| \frac{1}{x - x_{0,p} + i\gamma_p} \right|^2 \\ &\quad + 2 \operatorname{Re} \sum_{p=1}^{n_p} \sum_{q=1}^{n_p} \int_{x_{\min}}^{x_{\max}} dx \frac{1}{x - x_{0,p} + i\gamma_p} \frac{1}{x - x_{0,q} - i\gamma_q} \end{aligned} \quad (6.6)$$

204a *(Implementation of vamp\_test0\_functions procedures 204a)*≡

```

    end do
    end do
    f_x = amp * conjg (amp) / norm
end function f0

```

$$\int_{x_{\min}}^{x_{\max}} dx \frac{1}{x - x_{0,p} + i\gamma_p} \frac{1}{x - x_{0,q} - i\gamma_q} = \frac{1}{x_{0,p} - x_{0,q} - i\gamma_p - i\gamma_q} \left( \ln \left( \frac{x_{\max} - x_{0,p} + i\gamma_p}{x_{\min} - x_{0,p} + i\gamma_p} \right) - \ln \left( \frac{x_{\max} - x_{0,q} - i\gamma_q}{x_{\min} - x_{0,q} - i\gamma_q} \right) \right) \quad (6.7)$$

Don't even think of merging the logarithms: it will screw up the Riemann sheet.

204b *(Implementation of vamp\_test0\_functions procedures 204a)*+≡

```

pure function f_norm (x_min, x_max, x0p, gp, x0q, gq) &
    result (norm)
    real(kind=default), intent(in) :: x_min, x_max, x0p, gp, x0q, gq
    real(kind=default) :: norm
    norm = real (( log ( cmplx (x_max - x0p, gp, kind=default) &
                           / cmplx (x_min - x0p, gp, kind=default)) &
                  - log ( cmplx (x_max - x0q, - gq, kind=default) &
                           / cmplx (x_min - x0q, - gq, kind=default))) &
                  / cmplx (x0p - x0q, - gp - gq, kind=default), &
                  kind=default)
end function f_norm

```

Since we want to be able to do the integral of  $f$  analytically, it is most

convenient to take a weighted sum of products:

$$f(x_1, \dots, x_{n_d} | x_{\min}, x_{\max}, x_0, \gamma) = \frac{1}{\sum_{i=1}^{n_c} c_i} \sum_{i=1}^{n_c} c_i \prod_{j=1}^{n_d} f_0(x_j | x_{\min,j}, x_{\max,j}, x_{0,ij}, \gamma_{ij}) \quad (6.8)$$

Each summand is factorized and therefore very easily integrated by Vegas. A non-trivial sum is more realistic in this respect.

end subroutine create_sample

```

### *Multi Channel*

We start from the usual mapping for Lorentzian peaks

$$\begin{aligned} \psi(x_{\min}, x_{\max}, x_0, \gamma) : [x_{\min}, x_{\max}] &\rightarrow [x_{\min}, x_{\max}] \\ \xi \mapsto x = \psi(\xi | x_{\min}, x_{\max}, x_0, \gamma) \end{aligned} \quad (6.9)$$

where

$$\begin{aligned} \psi(\xi | x_{\min}, x_{\max}, x_0, \gamma) = x_0 + \\ \gamma \cdot \tan \left( \frac{\xi - x_{\min}}{x_{\max} - x_{\min}} \cdot \atan \frac{x_{\max} - x_0}{\gamma} - \frac{x_{\max} - \xi}{x_{\max} - x_{\min}} \cdot \atan \frac{x_0 - x_{\min}}{\gamma} \right) \end{aligned} \quad (6.10)$$

206    *Implementation of vamp\_test0\_functions procedures 204a>+≡*  

```

pure function psi (xi, x_min, x_max, x0, gamma) result (x)
    real(kind=default), intent(in) :: xi, x_min, x_max, x0, gamma
    real(kind=default) :: x
    x = x0 + gamma &
        * tan (((xi - x_min) * atan ((x_max - x0) / gamma) &
        - (x_max - xi) * atan ((x0 - x_min) / gamma)) &
        / (x_max - x_min))
end function psi

```

The inverse mapping is

$$\begin{aligned} \psi^{-1}(x_{\min}, x_{\max}, x_0, \gamma) : [x_{\min}, x_{\max}] &\rightarrow [x_{\min}, x_{\max}] \\ x \mapsto \xi = \psi^{-1}(x | x_{\min}, x_{\max}, x_0, \gamma) \end{aligned} \quad (6.11)$$

with

$$\begin{aligned} \psi^{-1}(x | x_{\min}, x_{\max}, x_0, \gamma) = \\ \frac{x_{\max}(\atan \frac{x_0 - x_{\min}}{\gamma} + \atan \frac{x - x_0}{\gamma}) + x_{\min}(\atan \frac{x_{\max} - x_0}{\gamma} + \atan \frac{x_0 - x}{\gamma})}{\atan \frac{x_{\max} - x_0}{\gamma} + \atan \frac{x_0 - x_{\min}}{\gamma}} \end{aligned} \quad (6.12)$$

with Jacobian

$$\frac{d(\psi^{-1}(x|x_{\min}, x_{\max}, x_0, \gamma))}{dx} = \frac{x_{\max} - x_{\min}}{\tan \frac{x_{\max} - x_0}{\gamma} + \tan \frac{x_0 - x_{\min}}{\gamma}} \frac{\gamma}{(x - x_0)^2 + \gamma^2} \quad (6.13)$$

207a *(Implementation of vamp\_test0\_functions procedures 204a) +≡*

```
pure function g0 (x, x_min, x_max, x0, gamma) result (g_x)
    real(kind=default), intent(in) :: x, x_min, x_max, x0, gamma
    real(kind=default) :: g_x
    g_x = gamma / (atan ((x_max - x0) / gamma) - atan ((x_min - x0) / gamma)) &
        * (x_max - x_min) / ((x - x0)**2 + gamma**2)
end function g0
```

The function  $f$  has  $n_c n_p^{n_d}$  peaks and we need a channel for each one, plus a constant function for the background. We encode the position on the grid linearly:

207b *(Decode channel into ch and p(:) 207b) +≡*

```
ch = channel - 1
do j = 1, size (x)
    p(j) = 1 + modulo (ch, np)
    ch = ch / np
end do
ch = ch + 1
```

The map  $\phi$  is the direct product of  $\psi$ s:

207c *(Implementation of vamp\_test0\_functions procedures 204a) +≡*

```
pure function phi (xi, channel) result (x)
    real(kind=default), dimension(:, intent(in) :: xi
    integer, intent(in) :: channel
    real(kind=default), dimension(size(xi)) :: x
    integer, dimension(size(xi)) :: p
    integer :: j, ch, np, nch, nd, channels
    np = size (x0, dim = 1)
    nch = size (x0, dim = 2)
    nd = size (x0, dim = 3)
    channels = nch * np**nd
    if (channel >= 1 .and. channel <= channels) then
        <Decode channel into ch and p(:) 207b>
        do j = 1, size (xi)
            if (all (gamma(:,ch,j) > 0)) then
                x(j) = psi (xi(j), x_min(j), x_max(j), &
                    x0(p(j),ch,j), gamma(p(j),ch,j))
            else
                x = xi
            end if
        end do
    else
        x = xi
    end if
end function phi
```

```

        end if
    end do
else if (channel == channels + 1) then
    x = xi
else
    x = 0
end if
end function phi

```

similarly for the Jacobians:

# —A— CONSTANTS

## A.1 Kinds

This borders on overkill, but it is the most portable way to get double precision in standard Fortran without relying on `kind (1.0D0)`. Currently, it is possible to change `double` to any other supported real kind. The MPI interface is a potential trouble source for such things, however.

```
243a <vamp_kinds.f90 243a>≡
      ! vamp_kinds.f90 --
      <Copyleft notice 1>
      module kinds
          implicit none
          integer, parameter, private :: single = &
              & selected_real_kind (precision(1.0), range(1.0))
          integer, parameter, private :: double = &
              & selected_real_kind (precision(1.0_single) + 1, range(1.0_single) + 1)
          integer, parameter, private :: quadruple = &
              & selected_real_kind (precision (1.0_double) + 1, range (1.0_double))
          integer, parameter, public :: default = double
          character(len=*), public, parameter :: KINDS_RCS_ID = &
              "$Id: kinds.nw 314 2010-04-17 20:32:33Z ohl $"

```

## —B— ERRORS AND EXCEPTIONS

Fortran95 does not allow *any* I/O in pure and elemental procedures, not even output to the unit \*. A stop statement is verboten as well. Therefore we have to use condition codes

```
245a <exceptions.f90 245a>≡

            end if
        end if
    end subroutine handle_exception

246d  <Declaration of exceptions procedures 246b>+≡
    public :: raise_exception, clear_exception, gather_exceptions

Raise an exception, but don't overwrite the messages in exc if it holds a more
severe exception. This way we can accumulate error codes across procedure
calls. We have exc optional to simplify life for the calling procedures, which
might have it optional themselves.

246e  <Implementation of exceptions procedures 246c>+≡
    elemental subroutine raise_exception (exc, level, origin, message)

```

```

type(exception), intent(inout), optional :: exc
integer, intent(in), optional :: level
character(len=*), intent(in), optional :: origin, message
integer :: local_level
if (present (exc)) then
    if (present (level)) then
        local_level = level
    else
        local_level = EXC_DEFAULT
    end if
    if (exc%level < local_level) then
        exc%level = local_level
        if (present (origin)) then
            exc%origin = origin
        else
            exc%origin = "[vamp]"
        end if
        if (present (message)) then
            exc%message = message
        else
            exc%message = "[vamp]"
        end if
    end if
end if
end subroutine raise_exception

```

247a ⟨Implementation of exceptions procedures 246c⟩+≡

```

elemental subroutine clear_exception (exc)
    type(exception), intent(inout) :: exc
    exc%level = 0
    exc%message = ""
    exc%origin = ""
end subroutine clear_exception

```

247b ⟨Implementation of exceptions procedures 246c⟩+≡

```

pure subroutine gather_exceptions (exc, excs)
    type(exception), intent(inout) :: exc
    type(exception), dimension(:), intent(in) :: excs
    integer :: i
    i = sum (maxloc (excs%level))
    if (exc%level < excs(i)%level) then
        call raise_exception (exc, excs(i)%level, excs(i)%origin, &
                             excs(i)%message)
    end if
end subroutine gather_exceptions

```

Here's how to use `gather_exceptions`. `elemental_procedure`

248 *⟨Idioms 100a⟩+≡*

```
call clear_exception (excs)
call elemental_procedure_1 (y, x, excs)
call elemental_procedure_2 (b, a, excs)
if (any (excs%level > 0)) then
    call gather_exceptions (exc, excs)
    return
end if
```

# —C— THE ART OF RANDOM NUMBERS

Volume two of Donald E. Knuth’ *The Art of Computer Programming* [15] has always been celebrated as the prime reference for random number generation. Recently, the third edition has been published and it contains a gem of a *portable* random number generator. It generates 30-bit integers with the following desirable properties

- they pass all the tests from George Marsaglia’s “diehard” suite of tests for random number generators [23] (but see [15] for a caveat regarding the “birthday-spacing” test)
- they can be generated with portable signed 32-bit arithmetic (Fortran can’t do unsigned arithmetic)
- it is faster than other lagged Fibonacci generators
- it can create at least  $2^{30} - 2$  independent sequences

## C.1 Application Program Interface

A function returning single reals and integers. Note that the static version without the `tao_random_state` argument does not require initialization. It will behave as if `call tao_random_seed(0)` had been executed. On the other hand, the parallelizable version with the explicit `tao_random_state` will fail if none of the `tao_random_create` have been called for the state. (This is a deficiency of Fortran90 that can be fixed in Fortran95).

<sup>249</sup> `<API documentation 249>`≡  
`call tao_random_number (r)`  
`call tao_random_number (s, r)`

The state of the random number generator comes in two variaties: buffered and raw. The former is much more efficient, but it can be beneficial to flush the buffers and to pass only the raw state in order to save of interprocess communication (IPC) costs.

250a *<API documentation 249>+≡*  
    *type(tao\_random\_state) :: s*  
    *type(tao\_random\_raw\_state) :: rs*

Subroutines filling arrays of reals and integers:

250b *<API documentation 249>+≡*  
    *call tao\_random\_number (a, num = n)*  
    *call tao\_random\_number (s, a, num = n)*

Subroutine for changing the seed:

250c *<API documentation 249>+≡*  
    *call tao\_random\_seed (seed = seed)*  
    *call tao\_random\_seed (s, seed = seed)*

Subroutine for changing the luxury. Per default, use all random numbers:

250d *<API documentation 249>+≡*  
    *call tao\_random\_luxury ()*  
    *call tao\_random\_luxury (s)*

With an integer argument, use the first *n* of each fill of the buffer:

250e *<API documentation 249>+≡*  
    *call tao\_random\_luxury (n)*  
    *call tao\_random\_luxury (s, n)*

With a floating point argument, use that fraction of each fill of the buffer:

250f *<API documentation 249>+≡*  
    *call tao\_random\_luxury (x)*  
    *call tao\_random\_luxury (s, x)*

Create a *tao\_random\_state*

250g *<API documentation 249>+≡*  
    *call tao\_random\_create (s, seed, buffer\_size = buffer\_size)*  
    *call tao\_random\_create (s, raw\_state, buffer\_size = buffer\_size)*  
    *call tao\_random\_create (s, state)*

Create a *tao\_random\_raw\_state*

250h *<API documentation 249>+≡*  
    *call tao\_random\_create (rs, seed)*  
    *call tao\_random\_create (rs, raw\_state)*  
    *call tao\_random\_create (rs, state)*

Destroy a *tao\_random\_state* or *tao\_random\_raw\_state*

250i *<API documentation 249>+≡*  
    *call tao\_random\_destroy (s)*

Copy `tao_random_state` and `tao_random_raw_state` in all four combinations

251a *(API documentation 249)*+≡  
call `tao_random_copy` (`lhs`, `rhs`)  
`lhs` = `rhs`

251b *(API documentation 249)*+≡  
call `tao_random_flush` (`s`)

251c *(API documentation 249)*+≡  
call `tao_random_read` (`s`, `unit`)  
call `tao_random_write` (`s`, `unit`)

251d *(API documentation 249)*+≡  
call `tao_random_test` (`name` = `name`)

Here is a sample application of random number states:

251e *(API documentation 249)*+≡  
subroutine `threads` (`args`, `y`, `state`)  
    real, dimension(:), intent(in) :: `args`  
    real, dimension(:), intent(out) :: `y`  
    type(`tao_random_state`) :: `state`  
    integer :: `seed`  
    type(`tao_random_raw_state`), dimension(size(`y`)) :: `states`  
    integer :: `s`  
    call `tao_random_number` (`state`, `seed`)  
    call `tao_random_create` (`states`, (/ (`s`, `s=seed`, size(`y`)-1) /))  
    `y` = `thread` (`args`, `states`)  
end function `thread`

In this example, we could equivalently pass an integer seed, instead of `raw_state`. But in more complicated cases it can be beneficial to have the option of reusing `raw_state` in the calling routine.

251f *(API documentation 249)*+≡  
elemental function `thread` (`arg`, `raw_state`) result (`y`)  
    real, dimension, intent(in) :: `arg`  
    type(`tao_random_raw_state`) :: `raw_state`  
    real :: `y`  
    type(`tao_random_state`) :: `state`  
    real :: `r`  
    call `tao_random_create` (`state`, `raw_state`)  
    do  
        ...  
        call `tao_random_number` (`state`, `r`)  
        ...  
    end do

```
end function thread
```

## C.2 Low Level Routines

Here the low level routines are *much* more interesting than the high level routines. The latter contain a lot of duplication (made necessary by Fortran's lack of parametric polymorphism) and consist mostly of bookkeeping. We will therefore start with the former.

### C.2.1 Generation of 30-bit Random Numbers

The generator is a subtractive lagged Fibonacci

$$X_j = (X_{j-K} - X_{j-L}) \mod 2^{30} \quad (\text{C.1})$$

with lags  $K = 100$  and  $L = 37$ .

252a *⟨Parameters in tao\_random\_numbers 252a⟩≡*

```
integer, parameter, private :: K = 100, L = 37
```

Other good choices for  $K$  and  $L$  are (cf. [15], table 1 in section 3.2.2, p. 29)

252b *⟨Parameters in tao\_random\_numbers (alternatives) 252b⟩≡*

```
integer, parameter, private :: K = 55, L = 24
integer, parameter, private :: K = 89, L = 38
integer, parameter, private :: K = 100, L = 37
integer, parameter, private :: K = 127, L = 30
integer, parameter, private :: K = 258, L = 83
integer, parameter, private :: K = 378, L = 107
integer, parameter, private :: K = 607, L = 273
```

A modulus of  $2^{30}$  is the largest we can handle in *portable* (i.e. *signed*) 32-bit arithmetic

252c *⟨Variables in 30-bit tao\_random\_numbers 252c⟩≡*

```
integer(kind=tao_i32), parameter, private :: M = 2**30
```

generate fills the array  $a_1, \dots, a_n$  with random integers  $0 \leq a_i < 2^{30}$ . We *must* have at least  $n \geq K$ . Higher values don't change the results, but make generate more efficient (about a factor of two, asymptotically). For  $K = 100$ , DEK recommends  $n \geq 1000$ . Best results are obtained using the first 100 random numbers out of 1009. Let's therefore use 1009 as a default buffer size. The user can call `tao_random_luxury (100)` him/herself:

252d *⟨Parameters in tao\_random\_numbers 252a⟩+≡*

```
integer, parameter, private :: DEFAULT_BUFFER_SIZE = 1009
```

Since users are not expected to call `generate` directly, we do *not* check for  $n \geq K$  and assume that the caller knows what (s)he's doing ...

253a *(Implementation of 30-bit tao\_random\_numbers 253a)*≡  

```
pure subroutine generate (a, state)
    integer(kind=tao_i32), dimension(:), intent(inout) :: a, state
    integer :: j, n
    n = size (a)
    <Load a and refresh state 253c>
end subroutine generate
```

253b *(Declaration of tao\_random\_numbers 253b)*≡  

```
private :: generate
state(1:K) is already set up properly:
```

253c *(Load a and refresh state 253c)*≡  

```
a(1:K) = state(1:K)
```

The remaining  $n - K$  random numbers can be gotten directly from the recursion (C.1). Note that Fortran90's new `modulo` intrinsic does the right thing, since it guarantees (unlike Fortran77's `mod`) that  $0 \leq \text{modulo}(a, m) < a$  if  $m > 0$ ):

253d *(Load a and refresh state 253c)+*≡  

```
do j = K+1, n
    a(j) = modulo (a(j-K) - a(j-L), M)
end do
```

Do the recursion (C.1)  $K$  more times to prepare `state(1:K)` for the next invocation of `generate`.

253e *(Load a and refresh state 253c)+*≡  

```
state(1:L) = modulo (a(n+1-K:n+L-K) - a(n+1-L:n), M)
do j = L+1, K
    state(j) = modulo (a(n+j-K) - state(j-L), M)
end do
```

### C.2.2 Initialization of 30-bit Random Numbers

The non-trivial and most beautiful part is the algorithm to initialize the random number generator state `state` with the first  $K$  numbers. I haven't studied algebra over finite fields in sufficient depth to consider the mathematics behind it straightforward. The commentary below is rather verbose and reflects my understanding of DEK's rather terse remarks (solution to exercise 3.6-9 [15]).

253f *(Implementation of tao\_random\_numbers 253f)*≡  

```
subroutine seed_static (seed)
```

```

    integer, optional, intent(in) :: seed
    call seed_stateless (s_state, seed)
    s_virginal = .false.
    s_last = size (s_buffer)
end subroutine seed_static

```

The static version of tao\_random\_raw\_state:

- 254a *<Variables in 30-bit tao\_random\_numbers 252c>*+≡
- ```

    integer(kind=tao_i32), dimension(K), save, private :: s_state
    logical, save, private :: s_virginal = .true.

```
- 254b *<Implementation of tao\_random\_numbers 253f>*+≡
- ```

    elemental subroutine seed_raw_state (s, seed)
        type(tao_random_raw_state), intent(inout) :: s
        integer, optional, intent(in) :: seed
        call seed_stateless (s%x, seed)
    end subroutine seed_raw_state

```
- 254c *<Implementation of tao\_random\_numbers 253f>*+≡
- ```

    elemental subroutine seed_state (s, seed)
        type(tao_random_state), intent(inout) :: s
        integer, optional, intent(in) :: seed
        call seed_raw_state (s%state, seed)
        s%last = size (s%buffer)
    end subroutine seed_state

```

This incarnation of the procedure is pure.

- 254d *<Implementation of 30-bit tao\_random\_numbers 253a>*+≡
- ```

    pure subroutine seed_stateless (state, seed)
        integer(kind=tao_i32), dimension(:), intent(out) :: state
        integer, optional, intent(in) :: seed
        <Parameters local to tao_random_seed 255a>
        integer :: seed_value, j, s, t
        integer(kind=tao_i32), dimension(2*K-1) :: x
        <Set up seed_value from seed or DEFAULT_SEED 255c>
        <Bootstrap the x buffer 255d>
        <Set up s and t 255f>
        do
            <p(z) → p(z)2 (modulo 2 and zK + zL + 1) 256a>
            <p(z) → zp(z) (modulo 2 and zK + zL + 1) 257a>
            <Shift s or t and exit if t ≤ 0 257b>
        end do
        <Fill state from x 257c>
    end subroutine seed_stateless

```

Any default will do

255a *<Parameters local to tao\_random\_seed 255a>*  
 integer, parameter :: DEFAULT\_SEED = 0

These must not be changed:

255b *<Parameters local to tao\_random\_seed 255a>+≡*  
 integer, parameter :: MAX\_SEED = 2\*\*30 - 3  
 integer, parameter :: TT = 70

255c *<Set up seed\_value from seed or DEFAULT\_SEED 255c>*  
 if (present (seed)) then  
     seed\_value = seed  
 else  
     seed\_value = DEFAULT\_SEED  
 end if  
 if (seed\_value < 0 .or. seed\_value > MAX\_SEED) then  
     !!! print \*, "tao\_random\_seed: seed (", seed\_value, &  
     !!!         ") not in [ 0, ", MAX\_SEED, "]!"  
     seed\_value = modulo (abs (seed\_value), MAX\_SEED + 1)  
     !!! print \*, "tao\_random\_seed: seed set to ", seed\_value, "!"  
 end if

Fill the array  $x_1, \dots, x_K$  with even integers, shifted cyclically by 29 bits.

255d *<Bootstrap the x buffer 255d>*  
 s = seed\_value - modulo (seed\_value, 2) + 2  
 do j = 1, K  
     x(j) = s  
     s = 2\*s  
     if (s >= M) then  
         s = s - M + 2  
     end if  
 end do  
 x(K+1:2\*K-1) = 0

Make  $x_2$  (and only  $x_2$ ) odd:

255e *<Bootstrap the x buffer 255d>+≡*  
 x(2) = x(2) + 1

255f *<Set up s and t 255f>*  
 s = seed\_value  
 t = TT - 1

Consider the polynomial

$$p(z) = \sum_{n=1}^K x_n z^{n-1} = x_K z^{K-1} + \dots + x_2 z + x_1 \quad (\text{C.2})$$

We have  $p(z)^2 = p(z^2) \bmod 2$  because cross terms have an even coefficient and  $x_n^2 = x_n \bmod 2$ . Therefore we can square the polynomial by shifting the coefficients. The coefficients for  $n > K$  will be reduced  $\bmod 2$  below.

$$256a \quad \langle p(z) \rightarrow p(z)^2 \text{ (modulo 2 and } z^K + z^L + 1) \rangle \equiv \\ x(3:2*K-1:2) = x(2:K)$$

The coefficients of the odd powers (those with the even indices) have not been changed yet. Set them to a flipped version of the other coefficients with the least significant bit set to 0.

$$\begin{aligned} x_2 &\leftarrow \text{even } x_{2K-1} \\ x_4 &\leftarrow \text{even } x_{2K-3} \\ &\dots \\ x_{K+L-1} &\leftarrow \text{even } x_{K-L+2} \end{aligned} \tag{C.3}$$

Note that the array notation is unambiguous because  $2K - 1$  is odd and source and destination are therefore interleaved:

$$256b \quad \langle p(z) \rightarrow p(z)^2 \text{ (modulo 2 and } z^K + z^L + 1) \rangle \equiv \\ x(2:K+L-1:2) = x(2*K-1:K-L+2:-2) - \text{modulo}(x(2*K-1:K-L+2:-2), 2\_tao_i32)$$

The Fortran program in [15] reads

$$256c \quad \langle p(z) \rightarrow p(z)^2 \text{ (modulo 2 and } z^K + z^L + 1) \text{ (DEK, Fortran)} \rangle \equiv \\ \text{do } j = 2*K-1, K-L+1, -2 \\ \quad x(2*K+1-j) = x(j) - \text{mod}(x(j), 2) \\ \text{end do}$$

i.e.

$$256d \quad \langle p(z) \rightarrow p(z)^2 \text{ (modulo 2 and } z^K + z^L + 1) \text{ (alternative)} \rangle \equiv \\ x(2:K+L:2) = x(2*K-1:K-L+1:-2) - \text{modulo}(x(2*K-1:K-L+1:-2), 2)$$

which is equivalent, as long as  $K + L$  is odd. This is the case most of the time. The version used above is the direct translation of the C version

$$256e \quad \langle p(z) \rightarrow p(z)^2 \text{ (modulo 2 and } z^K + z^L + 1) \text{ (DEK, C)} \rangle \equiv \\ \text{for } (j = 2*K-2; j > K-L; j == 2) \\ \quad x[2*K-1-j] = \text{evenize}(x[j]);$$

 I should decide from theoretical considerations whether the difference matters and if so, which is the correct version. At least I should inform DEK of the inconsistency.

Let's return to the coefficients for  $n > K$  generated by the shifting above. Subtract  $z^n(z^K + z^L + 1) = z^n z^K (1 + z^{-(K-L)} + z^{-K})$  iff the coefficient of  $z^n z^K$  doesn't vanish  $\bmod 2$  after squaring. The coefficient of  $z^n z^K$  is left alone, because it doesn't belong to  $p(z)$  anyway.

256f  $\langle p(z) \rightarrow p(z)^2 \text{ (modulo } 2 \text{ and } z^K + z^L + 1) \text{ 256a} \rangle + \equiv$   
     do j= 2\*K-1, K+1, -1  
         if (modulo (x(j), int(2, tao\_i32)) == 1) then  
             x(j-(K-L)) = modulo (x(j-(K-L)) - x(j), M)  
             x(j-K) = modulo (x(j-K) - x(j), M)  
         end if  
     end do

257a  $\langle p(z) \rightarrow zp(z) \text{ (modulo } 2 \text{ and } z^K + z^L + 1) \text{ 257a} \rangle \equiv$   
     if (modulo (s, 2) == 1) then  
         x(2:K+1) = x(1:K)  
         x(1) = x(K+1)  
         if (modulo (x(K+1), 2\_tao\_i32) == 1) then  
             x(L+1) = modulo (x(L+1) - x(K+1), M)  
         end if  
     end if

257b  $\langle \text{Shift s or t and exit if t} \leq 0 \text{ 257b} \rangle \equiv$   
     if (s /= 0) then  
         s = s / 2  
     else  
         t = t - 1  
     end if  
     if (t <= 0) then  
         exit  
     end if

257c  $\langle \text{Fill state from x 257c} \rangle \equiv$   
     state(K-L+1:K) = x(1:L)  
     state(1:K-L) = x(L+1:K)

257d  $\langle \text{Interfaces of tao_random_numbers 257d} \rangle \equiv$   
     interface tao\_random\_seed  
         module procedure  $\langle \text{Specific procedures for tao_random_seed 257f} \rangle$   
     end interface

257e  $\langle \text{Declaration of tao_random_numbers 253b} \rangle + \equiv$   
     private ::  $\langle \text{Specific procedures for tao_random_seed 257f} \rangle$

257f  $\langle \text{Specific procedures for tao_random_seed 257f} \rangle \equiv$   
     seed\_static, seed\_state, seed\_raw\_state

### C.2.3 Generation of 52-bit Random Numbers

$$X_j = (X_{j-K} + X_{j-L}) \mod 1 \quad (\text{C.4})$$

257g  $\langle \text{Variables in 52-bit tao_random_numbers 257g} \rangle \equiv$   
     real(kind=tao\_r64), parameter, private :: M = 1.0\_tao\_r64

The state of the internal routines

258a *(Variables in 52-bit tao\_random\_numbers 257g)*+≡  
real(kind=tao\_r64), dimension(K), save, private :: s\_state  
logical, save, private :: s\_virginal = .true.

258b *(Implementation of 52-bit tao\_random\_numbers 258b)*≡  
pure subroutine generate (a, state)  
real(kind=tao\_r64), dimension(:), intent(inout) :: a  
real(kind=tao\_r64), dimension(:), intent(inout) :: state  
integer :: j, n  
n = size (a)  
*<Load 52-bit a and refresh state 258c>*  
end subroutine generate

That's almost identical to the 30-bit version, except that the relative sign is flipped:

258c *(Load 52-bit a and refresh state 258c)*≡  
a(1:K) = state(1:K)  
do j = K+1, n  
a(j) = modulo (a(j-K) + a(j-L), M)  
end do  
state(1:L) = modulo (a(n+1-K:n+L-K) + a(n+1-L:n), M)  
do j = L+1, K  
state(j) = modulo (a(n+j-K) + state(j-L), M)  
end do

#### C.2.4 Initialization of 52-bit Random Numbers

This incarnation of the procedure is pure.

258d *(Implementation of 52-bit tao\_random\_numbers 258b)*+≡  
pure subroutine seed\_stateless (state, seed)  
real(kind=tao\_r64), dimension(:), intent(out) :: state  
integer, optional, intent(in) :: seed

### C.3.1 Creation

261a *<Interfaces of tao\_random\_numbers 257d>+≡*  
 interface tao\_random\_create  
     module procedure *<Specific procedures for tao\_random\_create 261c>*  
 end interface

261b *<Declaration of tao\_random\_numbers 253b>+≡*  
 private :: *<Specific procedures for tao\_random\_create 261c>*

261c *<Specific procedures for tao\_random\_create 261c>≡*  
 create\_state\_from\_seed, create\_raw\_state\_from\_seed, &  
 create\_state\_from\_state, create\_raw\_state\_from\_state, &  
 create\_state\_from\_raw\_state, create\_raw\_state\_from\_raw\_st

There are no procedures for copying the state of the static generator to or from an explicit tao\_random\_state. Users needing this functionality can be expected to handle explicit states anyway. Since the direction of the copying can not be obvious from the type of the argument, such functions would spoil the simplicity of the generic procedure interface.

261d *<Implementation of tao\_random\_numbers 253f>+≡*  
 elemental subroutine create\_state\_from\_seed (s, seed, buffer\_size)

### C.4.1 Single Random Numbers

A random integer  $r$  with  $0 \leq r < 2^{30} = 1073741824$ :

274a *⟨Implementation of 30-bit tao\_random\_numbers 253a⟩+≡*  
`pure subroutine integer_stateless &
 (state, buffer, buffer_end, last, r)
 integer(kind=tao_i32), dimension(:), intent(inout) :: state, buffer
 integer, intent(in) :: buffer_end
 integer, intent(inout) :: last
 integer, intent(out) :: r
 integer, parameter :: NORM = 1
 ⟨Body of tao_random_* 274b⟩
end subroutine integer_stateless`

274b *⟨Body of tao\_random\_\* 274b⟩≡*  
*⟨Step last and reload buffer iff necessary 274d⟩*  
`r = NORM * buffer(last)`

The low level routine `generate` will fill an array  $a_1, \dots, a_n$ , which will be consumed and refilled like an input buffer. We need at least  $n \geq K$  for the call to `generate`.

274c *⟨Variables in 30-bit tao\_random\_numbers 252c⟩+≡*  
`integer(kind=tao_i32), dimension(DEFAULT_BUFFER_SIZE), save, private :: s_buffer
integer, save, private :: s_buffer_end = size (s_buffer)
integer, save, private :: s_last = size (s_buffer)`

Increment the index `last` and reload the array `buffer`, iff this buffer is exhausted. Throughout these routines, `last` will point to random number that has just been consumed. For the array filling routines below, this is simpler than pointing to the next waiting number.

274d *⟨Step last and reload buffer iff necessary 274d⟩≡*  
`last = last + 1
if (last > buffer_end) then
 call generate (buffer, state)
 last = 1
end if`

A random real  $r \in [0, 1]$ . This is almost identical to `tao_random_integer`, but we duplicate the code to avoid the function call overhead for speed.

274e *⟨Implementation of 30-bit tao\_random\_numbers 253a⟩+≡*  
`pure subroutine real_stateless (state, buffer, buffer_end, last, r)
 integer(kind=tao_i32), dimension(:), intent(inout) :: state, buffer
 integer, intent(in) :: buffer_end
 integer, intent(inout) :: last
 real(kind=default), intent(out) :: r`

```

    real(kind=default), parameter :: NORM = 1.0_default / M
    <Body of tao_random_* 274b>
end subroutine real_stateless

```

A random real  $r \in [0, 1]$ .

275a *<Implementation of 52-bit tao\_random\_numbers 258b>*+≡

```

pure subroutine real_stateless (state, buffer, buffer_end, last, r)
    real(kind=tao_r64), dimension(:), intent(inout) :: state, buffer
    integer, intent(in) :: buffer_end
    integer, intent(inout) :: last
    real(kind=default), intent(out) :: r
    integer, parameter :: NORM = 1
    <Body of tao_random_* 274b>
end subroutine real_stateless

```

The low level routine `generate` will fill an array  $a_1, \dots, a_N$ , which will be consumed and refilled like an input buffer.

275b *<Variables in 52-bit tao\_random\_numbers 257g>*+≡

```

real(kind=tao_r64), dimension(DEFAULT_BUFFER_SIZE), save, private :: s_buffer
integer, save, private :: s_buffer_end = size (s_buffer)
integer, save, private :: s_last = size (s_buffer)

```

#### C.4.2 Arrays of Random Numbers

Fill the array  $j_1, \dots, j_\nu$  with random integers  $0 \leq j_i < 2^{30} = 1073741824$ . This has to be done such that the underlying array length in `generate` is transparent to the user. At the same time we want to avoid the overhead of calling `tao_random_real`  $\nu$  times.

275c *<Implementation of 30-bit tao\_random\_numbers 253a>*+≡

```

pure subroutine integer_array_stateless &
    (state, buffer, buffer_end, last, v, num)
    integer(kind=tao_i32), dimension(:), intent(inout) :: state, buffer
    integer, intent(in) :: buffer_end
    integer, intent(inout) :: last
    integer, dimension(:), intent(out) :: v
    integer, optional, intent(in) :: num
    integer, parameter :: NORM = 1
    <Body of tao_random_*_array 275d>
end subroutine integer_array_stateless

```

275d *<Body of tao\_random\_\*\_array 275d>*≡

```

integer :: nu, done, todo, chunk
<Set nu to num or size(v) 276a>
<Prepare array buffer and done, todo, chunk 276b>

```

```

v(1:chunk) = NORM * buffer(last+1:last+chunk)
do
  ⟨Update last, done and todo and set new chunk 276c⟩
  ⟨Reload buffer or exit 276d⟩
  v(done+1:done+chunk) = NORM * buffer(1:chunk)
end do

276a ⟨Set nu to num or size(v) 276a⟩≡
  if (present (num)) then
    nu = num
  else
    nu = size (v)
  end if

last is used as an offset into the buffer buffer, as usual. done is an offset
into the target. We still have to process all nu numbers. The first chunk can
only use what's left in the buffer.

276b ⟨Prepare array buffer and done, todo, chunk 276b⟩≡
  if (last >= buffer_end) then
    call generate (buffer, state)
    last = 0
  end if
  done = 0
  todo = nu
  chunk = min (todo, buffer_end - last)

This logic is a bit weird, but after the first chunk, todo will either vanish
(in which case we're done) or we have consumed all of the buffer and must
reload. In any case we can pretend that the next chunk can use the whole
buffer.

276c ⟨Update last, done and todo and set new chunk 276c⟩≡
  last = last + chunk
  done = done + chunk
  todo = todo - chunk
  chunk = min (todo, buffer_end)

276d ⟨Reload buffer or exit 276d⟩≡
  if (chunk <= 0) then
    exit
  end if
  call generate (buffer, state)
  last = 0

276e ⟨Implementation of 30-bit tao_random_numbers 253a⟩+≡
  pure subroutine real_array_stateless &
    (state, buffer, buffer_end, last, v, num)

```

```

integer(kind=tao_i32), dimension(:), intent(inout) :: state, buffer
integer, intent(in) :: buffer_end
integer, intent(inout) :: last
real(kind=default), dimension(:), intent(out) :: v
integer, optional, intent(in) :: num
real(kind=default), parameter :: NORM = 1.0_default / M
<Body of tao_random_*_array 275d>
end subroutine real_array_stateless

```

Fill the array  $v_1, \dots, v_v$  with uniform deviates  $v_i \in [0, 1]$ .

277a *<Implementation of 52-bit tao\_random\_numbers 258b>+≡*

```

pure subroutine real_array_stateless &
    (state, buffer, buffer_end, last, v, num)
    real(kind=tao_r64), dimension(:), intent(inout) :: state, buffer
    integer, intent(in) :: buffer_end
    integer, intent(inout) :: last
    real(kind=default), dimension(:), intent(out) :: v
    integer, optional, intent(in) :: num
    integer, parameter :: NORM = 1
    <Body of tao_random_*_array 275d>
end subroutine real_array_stateless

```

#### C.4.3 Procedures With Explicit *tao\_random\_state*

Unfortunately, this is very boring, but Fortran's lack of parametric polymorphism forces this duplication on us:

277b *<Implementation of 30-bit tao\_random\_numbers 253a>+≡*

```

elemental subroutine integer_state (s, r)
    type(tao_random_state), intent(inout) :: s
    integer, intent(out) :: r
    call integer_stateless (s%state%x, s%buffer, s%buffer_end, s%last, r)
end subroutine integer_state

277c <Implementation of 30-bit tao_random_numbers 253a>+≡

```

elemental subroutine real_state (s, r)
    type(tao_random_state), intent(inout) :: s
    real(kind=default), intent(out) :: r
    call real_stateless (s%state%x, s%buffer, s%buffer_end, s%last, r)
end subroutine real_state

277d <Implementation of 52-bit tao_random_numbers 258b>+≡

```

elemental subroutine real_state (s, r)
    type(tao_random_state), intent(inout) :: s
    real(kind=default), intent(out) :: r

```

```

```

```

        call real_stateless (s%state%x, s%buffer, s%buffer_end, s%last, r)
end subroutine real_state

278a <Implementation of 30-bit tao_random_numbers 253a>+≡
pure subroutine integer_array_state (s, v, num)
    type(tao_random_state), intent(inout) :: s
    integer, dimension(:), intent(out) :: v
    integer, optional, intent(in) :: num
    call integer_array_stateless &
        (s%state%x, s%buffer, s%buffer_end, s%last, v, num)
end subroutine integer_array_state

278b <Implementation of 30-bit tao_random_numbers 253a>+≡
pure subroutine real_array_state (s, v, num)
    type(tao_random_state), intent(inout) :: s
    real(kind=default), dimension(:), intent(out) :: v
    integer, optional, intent(in) :: num
    call real_array_stateless &
        (s%state%x, s%buffer, s%buffer_end, s%last, v, num)
end subroutine real_array_state

278c <Implementation of 52-bit tao_random_numbers 258b>+≡
pure subroutine real_array_state (s, v, num)
    type(tao_random_state), intent(inout) :: s
    real(kind=default), dimension(:), intent(out) :: v
    integer, optional, intent(in) :: num
    call real_array_stateless &
        (s%state%x, s%buffer, s%buffer_end, s%last, v, num)
end subroutine real_array_state

```

#### C.4.4 Static Procedures

First make sure that `tao_random_seed` has been called to initialize the generator state:

```

278d <Initialize a virginal random number generator 278d>≡
if (s_virginal) then
    call tao_random_seed ()
end if

278e <Implementation of 30-bit tao_random_numbers 253a>+≡
subroutine integer_static (r)
    integer, intent(out) :: r
    <Initialize a virginal random number generator 278d>
    call integer_stateless (s_state, s_buffer, s_buffer_end, s_last, r)
end subroutine integer_static

```

279a *Implementation of 30-bit tao\_random\_numbers 253a* +≡  
 subroutine real\_static (r)  
   real(kind=default), intent(out) :: r  
   *Initialize a virginal random number generator 278d*  
   call real\_stateless (s\_state, s\_buffer, s\_buffer\_end, s\_last, r)  
 end subroutine real\_static

279b *Implementation of 52-bit tao\_random\_numbers 258b* +≡  
 subroutine real\_static (r)  
   real(kind=default), intent(out) :: r  
   *Initialize a virginal random number generator 278d*  
   call real\_stateless (s\_state, s\_buffer, s\_buffer\_end, s\_last, r)  
 end subroutine real\_static

279c *Implementation of 30-bit tao\_random\_numbers 253a* +≡  
 subroutine integer\_array\_static (v, num)  
   integer, dimension(:), intent(out) :: v  
   integer, optional, intent(in) :: num  
   *Initialize a virginal random number generator 278d*  
   call integer\_array\_stateless &  
     (s\_state, s\_buffer, s\_buffer\_end, s\_last, v, num)  
 end subroutine integer\_array\_static

279d *Implementation of 30-bit tao\_random\_numbers 253a* +≡  
 subroutine real\_array\_static (v, num)  
   real(kind=default), dimension(:), intent(out) :: v  
   integer, optional, intent(in) :: num  
   *Initialize a virginal random number generator 278d*  
   call real\_array\_stateless &  
     (s\_state, s\_buffer, s\_buffer\_end, s\_last, v, num)  
 end subroutine real\_array\_static

279e *Implementation of 52-bit tao\_random\_numbers 258b* +≡  
 subroutine real\_array\_static (v, num)  
   real(kind=default), dimension(:), intent(out) :: v  
   integer, optional, intent(in) :: num  
   *Initialize a virginal random number generator 278d*  
   call real\_array\_stateless &  
     (s\_state, s\_buffer, s\_buffer\_end, s\_last, v, num)  
 end subroutine real\_array\_static

#### C.4.5 Generic Procedures

279f *Interfaces of 30-bit tao\_random\_numbers 279f* ≡  
 interface tao\_random\_number

```

        module procedure <Specific procedures for 30-bit tao_random_number 280a>
    end interface

280a  <Specific procedures for 30-bit tao_random_number 280a>≡
        integer_static, integer_state, &
        integer_array_static, integer_array_state, &
        real_static, real_state, real_array_static, real_array_state
These are not exported

280b  <Declaration of 30-bit tao_random_numbers 266d>+≡
        private :: &
            integer_stateless, integer_array_stateless, &
            real_stateless, real_array_stateless

280c  <Declaration of 30-bit tao_random_numbers 266d>+≡

## C.5 Testing

### C.5.1 30-bit

282d <Implementation of 30-bit tao\_random\_numbers 253a>+≡  
     subroutine tao\_random\_test (name)  
         character(len=\*), optional, intent(in) :: name  
         character (len = \*), parameter :: &  
             OK = "(1x,i10,' is ok.')", &  
             NOT\_OK = "(1x,i10,' is not ok, (expected ',i10,')')"  
         <Parameters in tao\_random\_test 282e>  
         integer, parameter :: &  
             A\_2027082 = 461390032  
         integer, dimension(N) :: a  
         type(tao\_random\_state) :: s, t  
         integer, dimension(:,), allocatable :: ibuf  
         real(kind=tao\_r64), dimension(:,), allocatable :: dbuf  
         integer :: i, ibuf\_size, dbuf\_size  
         print \*, TAO\_RANDOM\_NUMBERS\_RCS\_ID  
         print \*, "testing the 30-bit tao\_random\_numbers ..."  
         <Perform simple tests of tao\_random\_numbers 283a>  
         <Perform more tests of tao\_random\_numbers 283d>  
     end subroutine tao\_random\_test  
  
 282e <Parameters in tao\_random\_test 282e>≡  
     integer, parameter :: &  
         SEED = 310952, &  
         N = 2009, M = 1009, &  
         N\_SHORT = 1984

DEK's "official" test expects  $a_{1009 \cdot 2009+1} = a_{2027082} = 461390032$ :

283a  $\langle$ Perform simple tests of tao\_random\_numbers 283a $\rangle \equiv$   
    ! call tao\_random\_luxury ()  
    call tao\_random\_seed (SEED)  
    do i = 1, N+1  
        call tao\_random\_number (a, M)  
    end do  
     $\langle$ Test a(1) = A\_2027082 283b $\rangle$

283b  $\langle$ Test a(1) = A\_2027082 283b $\rangle \equiv$   
    if (a(1) == A\_2027082) then  
        print OK, a(1)  
    else  
        print NOT\_OK, a(1), A\_2027082  
    end if

Deja vu all over again, but 2027081 is factored the other way around this time

283c  $\langle$ Perform simple tests of tao\_random\_numbers 283a $\rangle + \equiv$   
    call tao\_random\_seed (SEED)  
    do i = 1, M+1  
        call tao\_random\_number (a)  
    end do  
     $\langle$ Test a(1) = A\_2027082 283b $\rangle$

Now checkpoint the random number generator after  $N_{\text{short}} \cdot M$  numbers

283d  $\langle$ Perform more tests of tao\_random\_numbers 283d $\rangle \equiv$   
    print \*, "testing the stateless stuff ..."  
    call tao\_random\_create (s, SEED)  
    do i = 1, N\_SHORT  
        call tao\_random\_number (s, a, M)  
    end do  
    call tao\_random\_create (t, s)  
    do i = 1, N+1 - N\_SHORT  
        call tao\_random\_number (s, a, M)  
    end do  
     $\langle$ Test a(1) = A\_2027082 283b $\rangle$

and restart the saved generator

283e  $\langle$ Perform more tests of tao\_random\_numbers 283d $\rangle + \equiv$   
    do i = 1, N+1 - N\_SHORT  
        call tao\_random\_number (t, a, M)  
    end do  
     $\langle$ Test a(1) = A\_2027082 283b $\rangle$

The same story again, but this time saving the copy to a file

284a *⟨Perform more tests of tao\_random\_numbers 283d⟩+≡*

```
if (present (name)) then
    print *, "testing I/O ..."
    call tao_random_seed (s, SEED)
    do i = 1, N_SHORT
        call tao_random_number (s, a, M)
    end do
    call tao_random_write (s, name)
    do i = 1, N+1 - N_SHORT
        call tao_random_number (s, a, M)
    end do
    ⟨Test a(1) = A_2027082 283b⟩
    call tao_random_read (s, name)
    do i = 1, N+1 - N_SHORT
        call tao_random_number (s, a, M)
    end do
    ⟨Test a(1) = A_2027082 283b⟩
end if
```

And finally using marshaling/unmarshaling:

284b *⟨Perform more tests of tao\_random\_numbers 283d⟩+≡*

```
print *, "testing marshaling/unmarshaling ..."
call tao_random_seed (s, SEED)
do i = 1, N_SHORT
    call tao_random_number (s, a, M)
end do
call tao_random_marshal_size (s, ibuf_size, dbuf_size)
allocate (ibuf(ibuf_size), dbuf(dbuf_size))
call tao_random_marshal (s, ibuf, dbuf)
do i = 1, N+1 - N_SHORT
    call tao_random_number (s, a, M)
end do
⟨Test a(1) = A_2027082 283b⟩
call tao_random_unmarshal (s, ibuf, dbuf)
do i = 1, N+1 - N_SHORT
    call tao_random_number (s, a, M)
end do
⟨Test a(1) = A_2027082 283b⟩
```

### C.5.2 52-bit

    call test52 ("tmp.tao")
end program tao_test

```

# —D— SPECIAL FUNCTIONS

```

286a <specfun.f90 286a>≡
    ! specfun.f90 --
    <Copyleft notice 1>
    module specfun
        use kinds
    ! use constants
        implicit none
    private
        <Declaration of specfun procedures 286b>
        character(len=*), public, parameter :: SPECFUN_RCS_ID = &
            "$Id: specfun.nw 314 2010-04-17 20:32:33Z ohl $"
        !WK:
        real(kind=default), public, parameter :: &
            PI = 3.1415926535897932384626433832795028841972_default
    contains
        <Implementation of specfun procedures 287c>
    end module specfun

```

The algorithm is stolen from the FORTRAN version in routine C303 of the CERN library [24]. It has an accuracy which is approximately one digit less than machine precision.

286b <Declaration of specfun procedures 286b>≡  
`public :: gamma`

The so-called reflection formula is used for negative arguments:

$$\Gamma(x)\Gamma(1-x) = \frac{\pi}{\sin \pi x} \quad (\text{D.1})$$

Here's the identity transformation that pulls the argument of  $\Gamma$  into [3, 4]:

$$\Gamma(u) = \begin{cases} (u-1)\Gamma(u-1) & \text{for } u > 4 \\ \frac{1}{u}\Gamma(u+1) & \text{for } u < 3 \end{cases} \quad (\text{D.2})$$

287a *(Pull u into the intervall [3, 4] 287a)*≡

```
f = 1
if (u < 3) then
    do i = 1, int (4 - u)
        f = f / u
        u = u + 1
    end do
else
    do i = 1, int (u - 3)
        u = u - 1
        f = f * u
    end do
end if
```

A Chebyshev approximation for  $\Gamma(x)$  is used after mapping  $x \in [3, 4]$  linearly to  $h \in [-1, 1]$ . The series is evaluated by Clenshaw's recurrence formula:

$$\begin{aligned} d_m &= d_{m+1} = 0 \\ d_j &= 2xd_{j+1} - d_{j+2} + c_j \text{ for } 0 < j < m-1 \\ f(x) &= d_0 = xd_1 - d_2 + \frac{1}{2}c_0 \end{aligned} \quad (\text{D.3})$$

287b *(Clenshaw's recurrence formula 287b)*≡

```
alpha = 2*g
b1 = 0
b2 = 0
do i = 15, 0, -1
    b0 = c(i) + alpha * b1 - b2
    b2 = b1
    b1 = b0
end do
g = f * (b0 - g * b2)
```

Note that we're assuming that  $c(0)$  is in fact  $c_0/2$ . This is for compatibility with the CERN library routines.

287c *(Implementation of specfun procedures 287c)*≡

```
pure function gamma (x) result (g)
    real(kind=default), intent(in) :: x
    real(kind=default) :: g

end interface
```

### G.3 Mathematics

310b *<Declaration of utils procedures 304b>+≡*

```
public :: outer_product
```

Admittedly, one has to get used to this notation for the tensor product:

310c *<Implementation of utils procedures 305c>+≡*

```
pure function outer_product (x, y) result (xy)
    real(kind=default), dimension(:,), intent(in) :: x, y
    real(kind=default), dimension(size(x),size(y)) :: xy
    xy = spread (x, dim=2, ncopies=size(y)) &
          * spread (y, dim=1, ncopies=size(x))
end function outer_product
```

Greatest common divisor and least common multiple

310d *<Declaration of utils procedures 304b>+≡*

```
public :: factorize, gcd, lcm
private :: gcd_internal
```

For our purposes, a straightforward implementation of Euclid's algorithm suffices:

310e *<Implementation of utils procedures 305c>+≡*

```
pure recursive function gcd_internal (m, n) result (gcd_m_n)
    integer, intent(in) :: m, n
    integer :: gcd_m_n
    if (n <= 0) then
        gcd_m_n = m
    else
        gcd_m_n = gcd_internal (n, modulo (m, n))
    end if
end function gcd_internal
```

Wrap an elemental procedure around the recursive procedure:

310f *<Implementation of utils procedures 305c>+≡*

```
elemental function gcd (m, n) result (gcd_m_n)
    integer, intent(in) :: m, n
    integer :: gcd_m_n
```

```

    gcd_m_n = gcd_internal (m, n)
end function gcd

```

As long as  $m \cdot n$  does not overflow, we can use  $\text{gcd}(m, n) \text{lcm}(m, n) = mn$ :

311a *(Implementation of utils procedures 305c)* $\equiv$

```

elemental function lcm (m, n) result (lcm_m_n)
    integer, intent(in) :: m, n
    integer :: lcm_m_n
    lcm_m_n = (m * n) / gcd (m, n)
end function lcm

```

A very simple minded factorization procedure, that is not fool proof at all. It maintains  $n == \text{product}(\text{factors}(1:i))$ , however, and will work in all cases of practical relevance.

311b *(Implementation of utils procedures 305c)* $\equiv$

```

pure subroutine factorize (n, factors, i)
    integer, intent(in) :: n
    integer, dimension(:), intent(out) :: factors
    integer, intent(out) :: i
    integer :: nn, p
    nn = n
    i = 0
    do p = 1, size (PRIMES)
        try: do
            if (modulo (nn, PRIMES(p)) == 0) then
                i = i + 1
                factors(i) = PRIMES(p)
                nn = nn / PRIMES(p)
                if (i >= size (factors)) then
                    factors(i) = nn
                    return
                end if
            else
                exit try
            end if
        end do try
        if (nn == 1) then
            return
        end if
    end do
end subroutine factorize

```

311c *(Parameters in utils 311c)* $\equiv$

```

integer, dimension(13), parameter, private :: &
    PRIMES = (/ 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41 /)

```

    contains
        <Implementation of linalg procedures 314>
    end module linalg

```

## *H.1 LU Decomposition*

```

313b <Declaration of linalg procedures 313b>≡
    public :: lu_decompose

```

$$A = LU \tag{H.1a}$$

In more detail

$$\begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{pmatrix} = \begin{pmatrix} 1 & 0 & \dots & 0 \\ l_{21} & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ l_{n1} & l_{n2} & \dots & 1 \end{pmatrix} \begin{pmatrix} u_{11} & u_{12} & \dots & u_{1n} \\ 0 & u_{22} & \dots & u_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \dots & u_{nn} \end{pmatrix} \tag{H.1b}$$

Rewriting (H.1) in block matrix notation

$$\begin{pmatrix} a_{11} & a_{1\cdot} \\ a_{\cdot 1} & A \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ l_{\cdot 1} & L \end{pmatrix} \begin{pmatrix} u_{11} & u_{1\cdot} \\ 0 & U \end{pmatrix} = \begin{pmatrix} u_{11} & u_{1\cdot} \\ l_{\cdot 1}u_{11} & l_{\cdot 1} \otimes u_{1\cdot} + LU \end{pmatrix} \quad (\text{H.2})$$

we can solve it easily

$$u_{11} = a_{11} \quad (\text{H.3a})$$

$$u_{1\cdot} = a_{1\cdot} \quad (\text{H.3b})$$

$$l_{\cdot 1} = \frac{a_{\cdot 1}}{a_{11}} \quad (\text{H.3c})$$

$$LU = A - \frac{a_{\cdot 1} \otimes a_{1\cdot}}{a_{11}} \quad (\text{H.3d})$$

and (H.3c) and (H.3d) define a simple iterative algorithm if we work from the outside in. It just remains to add pivoting.

314 *Implementation of linalg procedures 314*≡

```
pure subroutine lu_decompose (a, pivots, eps, l, u)
    real(kind=default), dimension(:, :, ), intent(inout) :: a

 do i = 1, size (a, dim = 1)  
 det = det \* lu(i,i)  
 end do  
 end subroutine determinant

## H.3 Diagonalization

The code is an implementation of the algorithm presented in [16, 17], but independent from the code presented in [18] to avoid legal problems.

A Jacobi rotation around the angle  $\phi$  in row  $p$  and column  $q$

$$P(\phi; p, q) = \begin{pmatrix} 1 & & & & \\ & \ddots & & & \\ & & \cos \phi & \cdots & \sin \phi \\ & & \vdots & 1 & \vdots \\ & & -\sin \phi & \cdots & \cos \phi \\ & & & & \ddots \\ & & & & 1 \end{pmatrix} \quad (\text{H.4})$$

results in

$$A' = P^T(\phi; p, q) \cdot A \cdot P(\phi; p, q) = \begin{pmatrix} & A'_{1p} & A'_{1q} \\ & \vdots & \vdots \\ A'_{p1} & \cdots & A'_{pq} & \cdots & A'_{pq} & \cdots & A'_{pn} \\ & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ A'_{q1} & \cdots & A'_{qp} & \cdots & A'_{qq} & \cdots & A'_{qn} \\ & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ & A'_{np} & & A'_{nq} & & & \end{pmatrix} \quad (\text{H.5})$$

317a *(Declaration of linalg procedures 313b)* +≡  
 public :: diagonalize\_real\_symmetric

317b *(Implementation of linalg procedures 314)* +≡  
 pure subroutine diagonalize\_real\_symmetric (a, eval, evec, num\_rot)

 spread (one\_to\_ndim, dim=1, ncopies=ndim) &  
 > spread (one\_to\_ndim, dim=2, ncopies=ndim)  
 aa = a  
 call unit (evec)  
*(Initialize num\_rot 320e)*  
 sweeps: do sweep = 1, MAX\_SWEEPS  
 off\_diagonal\_norm = sum (abs (aa), mask=upper\_triangle)  
 if (off\_diagonal\_norm == 0.0) then  
 eval = diag (aa)  
 return  
 end if  
 if (sweep < 4) then  
 threshold = 0.2 \* off\_diagonal\_norm / ndim\*\*2  
 else

```

        threshold = 0.0
    end if
    do p = 1, ndim - 1
        do q = p + 1, ndim
            <Perform the Jacobi rotation resulting in  $A'_{pq} = 0$  318>
        end do
    end do
end do sweeps
if (present (num_rot)) then
    num_rot = -1
end if
!!! print *, "linalg::diagonalize_real_symmetric: exceeded sweep count"
end subroutine diagonalize_real_symmetric

318 <Perform the Jacobi rotation resulting in  $A'_{pq} = 0$  318>≡
g = 100 * abs (aa (p,q))
if ((sweep > 4) &
    .and. (g <= min (spacing (aa(p,p)), spacing (aa(q,q))))) then
    aa(p,q) = 0.0
else if (abs (aa(p,q)) > threshold) then
    <Determine  $\phi$  for the Jacobi rotation  $P(\phi; p, q)$  with  $A'_{pq} = 0$  319a>
    < $A' = P^T(\phi; p, q) \cdot A \cdot P(\phi; p, q)$  319c>
    < $V' = V \cdot P(\phi; p, q)$  320d>
    <Update num_rot 320f>
end if

```

We want

$$A'_{pq} = (c^2 - s^2)A_{pq} + sc(A_{pp} - A_{qq}) = 0 \quad (\text{H.6})$$

and therefore

$$\cot 2\phi = \frac{1 - \tan^2 \phi}{2 \tan \phi} = \frac{\cos^2 \phi - \sin^2 \phi}{2 \sin \phi \cos \phi} = \frac{A_{pp} - A_{qq}}{2A_{pq}} \quad (\text{H.7})$$

i.e. with  $t = \tan \phi = s/c$

$$t^2 + 2t \cot 2\phi - 1 = 0 \quad (\text{H.8})$$

This quadratic equation has the roots

$$t = -\cot 2\phi \pm \sqrt{1 + \cot^2 2\phi} = \frac{\epsilon(\cot 2\phi)}{|\cot 2\phi| \pm \epsilon(\cot 2\phi)\sqrt{1 + \cot^2 2\phi}} \quad (\text{H.9})$$

and the smaller in magnitude of these is

$$t = \frac{\epsilon(\cot 2\phi)}{|\cot 2\phi| + \sqrt{1 + \cot^2 2\phi}} \quad (\text{H.10})$$

and since  $|t| \leq 1$ , it corresponds to  $|\phi| \leq \pi/4$ . For very large  $\cot 2\phi$  we will use

$$t = \frac{1}{2 \cot 2\phi} = \frac{A_{pq}}{A_{pp} - A_{qq}} \quad (\text{H.11})$$

$$h = A_{qq} - A_{pp} \quad (\text{H.12})$$

319a  $\langle$  Determine  $\phi$  for the Jacobi rotation  $P(\phi; p, q)$  with  $A'_{pq} = 0$  319a  $\rangle \equiv$

```

h = aa(q,q) - aa(p,p)
if (g <= spacing (h)) then
    t = aa(p,q) / h
else
    cot_2phi = 0.5 * h / aa(p,q)
    t = sign (1.0_default, cot_2phi) &
        / (abs (cot_2phi) + sqrt (1.0 + cot_2phi**2))
end if

```

Trivia

$$\cos^2 \phi = \frac{\cos^2 \phi}{\cos^2 \phi + \sin^2 \phi} = \frac{1}{1 + \tan^2 \phi} \quad (\text{H.13a})$$

$$\sin \phi = \tan \phi \cos \phi \quad (\text{H.13b})$$

$$\tau \sin \phi = \frac{\sin^2}{1 + \cos \phi} = \frac{1 - \cos^2}{1 + \cos \phi} = 1 - \cos \phi \quad (\text{H.13c})$$

319b  $\langle$  Determine  $\phi$  for the Jacobi rotation  $P(\phi; p, q)$  with  $A'_{pq} = 0$  319a  $\rangle + \equiv$

```

c = 1.0 / sqrt (1.0 + t**2)
s = t * c
tau = s / (1.0 + c)
A'_{pp} = c^2 A_{pp} + s^2 A_{qq} - 2scA_{pq} = A_{pp} - tA_{pq}
A'_{qq} = s^2 A_{pp} + c^2 A_{qq} + 2scA_{pq} = A_{qq} + tA_{pq}
A'_{pq} = (c^2 - s^2)A_{pq} + sc(A_{pp} - A_{qq})

```

319c  $\langle A' = P^T(\phi; p, q) \cdot A \cdot P(\phi; p, q)$  319c  $\rangle \equiv$

```

aa(p,p) = aa(p,p) - t * aa(p,q)
aa(q,q) = aa(q,q) + t * aa(p,q)
aa(p,q) = 0.0

```

$$\begin{aligned}
r \neq p < q \neq r : A'_{rp} &= cA_{rp} - sA_{rq} \\
A'_{rq} &= sA_{rp} + cA_{rq}
\end{aligned} \quad (\text{H.15})$$

Here's how we cover the upper triangular region using array notation:

$$\begin{pmatrix} & a(1:p-1,p) & & a(1:p-1,q) & \\ \dots & A_{pq} & a(p,p+1:q-1) & A_{pq} & a(p,q+1:ndim) \\ & \vdots & & a(p+1:q-1,q) & \\ \dots & A_{qp} & \dots & A_{qq} & a(q,q+1:ndim) \\ & \vdots & & \vdots & \end{pmatrix} \quad (\text{H.16})$$

320a  $\langle A' = P^T(\phi; p, q) \cdot A \cdot P(\phi; p, q) \text{ 319c} \rangle + \equiv$   
 call jacobi\_rotation (s, tau, aa(1:p-1,p), aa(1:p-1,q))  
 call jacobi\_rotation (s, tau, aa(p,p+1:q-1), aa(p+1:q-1,q))  
 call jacobi\_rotation (s, tau, aa(p,q+1:ndim), aa(q,q+1:ndim))

Using (H.13c), we can write the rotation as a perturbation:

$$\begin{aligned} V'_p &= cV_p - sV_q = V_p - s(V_q + \tau V_p) \\ V'_q &= sV_p + cV_q = V_q + s(V_p - \tau V_q) \end{aligned} \quad (\text{H.17})$$

end interface

```

Boost a four vector  $p$  to the inertial frame moving with the velocity  $\beta$ :

$$p'_0 = \gamma \left( p_0 - \vec{\beta} \vec{p} \right) \quad (\text{J.1a})$$

$$\vec{p}' = \gamma \left( \vec{p}_{\parallel} - \vec{\beta} p_0 \right) + \vec{p}_{\perp} \quad (\text{J.1b})$$

with  $\gamma = 1/\sqrt{1 - \vec{\beta}^2}$ ,  $\vec{p}_{\parallel} = \vec{\beta}(\vec{\beta} \vec{p})/\vec{\beta}^2$  and  $\vec{p}_{\perp} = \vec{p} - \vec{p}_{\parallel}$ . Using  $1/\vec{\beta}^2 = \gamma^2/(\gamma + 1) \cdot 1/(\gamma - 1)$  and  $\vec{b} = \gamma \vec{\beta}$  this can be rewritten as

$$p'_0 = \gamma p_0 - \vec{b} \vec{p} \quad (\text{J.2a})$$

$$\vec{p}' = \vec{p} + \left( \frac{\vec{b} \vec{p}}{\gamma + 1} - p_0 \right) \vec{b} \quad (\text{J.2b})$$

## *J.4 Massless n-Particle Phase Space: RAMBO*

332c *(Declaration of kinematics procedures 324b)*+≡

```
public :: massless_isotropic_decay
```

The massless RAMBO algorithm [25]:

332d *(Implementation of kinematics procedures 325a)*+≡

```
pure function massless_isotropic_decay (roots, ran) result (p)
    real (kind=default), intent(in) :: roots
    real (kind=default), dimension(:, :, :), intent(in) :: ran
    real (kind=default), dimension(size(ran, dim=1), 0:3) :: p
    real (kind=default), dimension(size(ran, dim=1), 0:3) :: q
    real (kind=default), dimension(0:3) :: qsum
    real (kind=default) :: cos_theta, sin_theta, phi, qabs, x, r, z
    integer :: k
    <Generate isotropic null vectors 332e>
    <Boost and rescale the vectors 333a>
end function massless_isotropic_decay
```

Generate a  $xe^{-x}$  distribution for  $q(k, 0)$

332e *(Generate isotropic null vectors 332e)*≡

```
do k = 1, size (p, dim = 1)
    q(k,0) = - log (ran(k,1) * ran(k,2))
    cos_theta = 2 * ran(k,3) - 1
    sin_theta = sqrt (1 - cos_theta**2)
    phi = 2 * PI * ran(k,4)
    q(k,1) = q(k,0) * sin_theta * cos (phi)
    q(k,2) = q(k,0) * sin_theta * sin (phi)
    q(k,3) = q(k,0) * cos_theta
enddo
```

The proof that the Jacobian of the transformation vanishes can be found in [25]. The transformation is really a Lorentz boost (as can be seen easily).

333a *(Boost and rescale the vectors 333a)* $\equiv$

```

qsum = sum (q, dim = 1)
qabs = sqrt (dot (qsum, qsum))
x = roots / qabs
do k = 1, size (p, dim = 1)
    r = dot (q(k,:), qsum) / qabs
    z = (q(k,0) + r) / (qsum(0) + qabs)
    p(k,1:3) = x * (q(k,1:3) - qsum(1:3) * z)
    p(k,0) = x * r
enddo

```

333b *(Declaration of kinematics procedures 324b)* $\equiv$

```
public :: phase_space_volume
```

$$V_n(s) = \frac{1}{8\pi} \frac{n-1}{(\Gamma(n))^2} \left( \frac{s}{16\pi^2} \right)^{n-2} \quad (\text{J.11})$$

333c *(Implementation of kinematics procedures 325a)* $\equiv$

```

pure function phase_space_volume (n, roots) result (volume)
    integer, intent(in) :: n
    real (kind=default), intent(in) :: roots
    real (kind=default) :: volume
    real (kind=default) :: nd
    nd = n
    volume = (nd - 1) / (8*PI * (gamma (nd))**2) * (roots / (4*PI))**(2*n-4)
end function phase_space_volume

```

```

### *K.1 Angular Spherical Coordinates*

$$\begin{aligned}
 x_n &= r \cos \theta_{n-2} \\
 x_{n-1} &= r \sin \theta_{n-2} \cos \theta_{n-3} \\
 &\dots \\
 x_3 &= r \sin \theta_{n-2} \sin \theta_{n-3} \cdots \cos \theta_1 \\
 x_2 &= r \sin \theta_{n-2} \sin \theta_{n-3} \cdots \sin \theta_1 \cos \phi \\
 x_1 &= r \sin \theta_{n-2} \sin \theta_{n-3} \cdots \sin \theta_1 \sin \phi
 \end{aligned} \tag{K.1}$$

and

$$J = r^{n-1} \prod_{i=1}^{n-2} (\sin \theta_i)^i \tag{K.2}$$

We can minimize the number of multiplications by computing the products

$$P_j = \prod_{i=j}^{n-2} \sin \theta_i \quad (\text{K.3})$$

Then

$$\begin{aligned} x_n &= r \cos \theta_{n-2} \\ x_{n-1} &= r P_{n-2} \cos \theta_{n-3} \\ &\dots \\ x_3 &= r P_2 \cos \theta_1 \\ x_2 &= r P_1 \cos \phi \\ x_1 &= r P_1 \sin \phi \end{aligned} \quad (\text{K.4})$$

and

$$J = r^{n-1} \prod_{i=1}^{n-2} P_i \quad (\text{K.5})$$

Note that  $\theta_i \in [0, \pi]$  and  $\phi \in [0, 2\pi]$  or  $\phi \in [-\pi, \pi]$ . Therefore  $\sin \theta_i \geq 0$  and

$$\sin \theta_i = \sqrt{1 - \cos^2 \theta_i} \quad (\text{K.6})$$

which is not true for  $\phi$ . Since `sqrt` is typically much faster than `sin` and `cos`, we use (K.6) where ever possible.

**337a** *(Declaration of coordinates procedures 337a)*≡  
**337b** *(Implementation of coordinates procedures 337b)*≡

```

public :: spherical_to_cartesian_2, &
         spherical_to_cartesian, spherical_to_cartesian_j

divert' dnl

```

## M.2 Miscellaneous Utilities

- 358a *<Implementation of utils procedures 305c>+≡*  
`_begin_f90`
- 358b *<Declaration of utils procedures 304b>+≡*  
`_begin_f90`  
`private :: swap_integer_array, swap_real_array`  
`_end_f90`
- 358c *<Interfaces of utils procedures 304c>+≡*  
`_begin_f90`  
`interface swap`  
 `module procedure swap_integer_array, swap_real_array`  
`end interface`  
`_end_f90`
- 358d *<Implementation of utils procedures 305c>+≡*  
`pure subroutine swap_integer_array (a, b)`  
 `integer, dimension(:), intent(inout) :: a, b`  
 `integer, dimension(max(size(a),size(b))) :: tmp`  
 `tmp = a`  
 `a = b`  
 `b = tmp`  
`end subroutine swap_integer_array`
- 358e *<Implementation of utils procedures 305c>+≡*  
`pure subroutine swap_real_array (a, b)`  
 `real(kind=default), dimension(:), intent(inout) :: a, b`  
 `real(kind=default), dimension(max(size(a),size(b))) :: tmp`  
 `tmp = a`  
 `a = b`  
 `b = tmp`  
`end subroutine swap_real_array`
- 358f *<Declaration of utils procedures 304b>+≡*  
`_specific_sva(gcd)`  
`_specific_sva(lcm)`

359a *<Interfaces of utils procedures 304c>+≡*  
  `_interface_sva(gcd)`  
  `_interface_sva(lcm)`

359b *<Implementation of utils procedures 305c>+≡*  
`pure function gcd_v (m, n) result (gcd_m_n)`  
  `integer, dimension(:,), intent(in) :: m, n`  
  `integer, dimension(size(m)) :: gcd_m_n`  
  `integer :: i`  
  `do i = 1, size (m)`  
    `gcd_m_n(i) = gcd (m(i), n(i))`  
  `end do`  
`end function gcd_v`

359c *<Implementation of utils procedures 305c>+≡*  
`pure function lcm_v (m, n) result (lcm_m_n)`  
  `integer, dimension(:,), intent(in) :: m, n`  
  `integer, dimension(size(m)) :: lcm_m_n`  
  `integer :: i`  
  `do i = 1, size (m)`  
    `lcm_m_n(i) = lcm (m(i), n(i))`  
  `end do`  
`end function lcm_v`

This abuses the `_a` suffix, which is used elsewhere for two-dimensional arrays:

359d *<Implementation of utils procedures 305c>+≡*  
`pure function gcd_a (m, n) result (gcd_m_n)`

## —N— IDEAS

### *N.1 Toolbox for Interactive Optimization*

*Idea:* Provide a OpenGL interface to visualize the grid optimization.

*Motivation:* Would help multi channel developers.

*Implementation:* Coding is straightforward, but interface design is hard.

### *N.2 Partially Non-Factorized Importance Sampling*

*Idea:* Allow non-factorized grid optimization in two- or three-dimensional subspaces.

*Motivation:* Handle nastiest subspaces. Non-factorized approaches are impossible in higher than three dimensions (and probably only realistic in two dimensions), but there are cases that are best handled by including non-factorized optimization in two dimensions.

*Implementation:* The problem is that the present `vamp_sample_grid0` can't accomodate this, because other auxiliary information has to be collected, but a generalization is straightforward. Work has to start from an extended `divisions` module.

### *N.3 Correlated Importance Sampling (?)*

*Idea:* Is it possible to include *some* correlations in a mainly factorized context?

*Motivation:* Would be nice ...

*Implementation:* First, I have to think about the maths ...

#### *N.4 Align Coordinate System (i.e. the grid) with Singularities (or the hot region)*

*Idea:* Solve `vegas`' nastiest problem by finding the direction(s) along which singularities are aligned.

*Motivation:* Automatically choose proper coordinate system in generator generators and separate wild and smooth directions.

*Implementation:* Diagonalize the covariance matrix  $\text{cov}(x_i x_j)$  to find better axes. Caveats:

- damp rotations (rotate only if eigenvalues are spread out sufficiently).
- be careful about blow up of the integration volume, which is  $V' = V d^{d/2}$  in the worst case for hypercubes and can be even worse for stretched cubes. (An adaptive grid can help, since we will have more smooth directions!)

*Maybe* try non-linear transformations as well.

#### *N.5 Automagic Multi Channel*

*Idea:* Find and extract one singularity after the other.

*Motivation:* Obvious.

*Implementation:* Either use multiple of `vegas`'  $p(x)$  for importance sampling. Or find hot region(s) and split the integration region (á la signal/background).
