10.12.6 The LHAPDF data block

The data block holds the incoming flavor (which has to be proton, pion, or photon), the corresponding pointer to the global access data (1, 2, or 3), the flag `invert` which is set for an antiproton, the bounds as returned by LHAPDF for the specified set, and a mask that determines which partons will be actually in use.

```

10.12.7 The LHAPDF object

The `lhpdf_t` data type is a $1 \rightarrow 2$ interaction which describes the splitting of an (anti)proton into a parton and a beam remnant. We stay in the strict forward-splitting limit, but allow some invariant mass for the beam remnant such that the outgoing parton is exactly massless. For a real event, we would replace this by a parton cascade, where the outgoing partons have virtuality as dictated by parton-shower kinematics, and transverse momentum is generated.

This is the LHAPDF object which holds input data together with the interaction. We also store the x momentum fraction and the scale, since kinematics and function value are requested at different times.

The PDF application is a $1 \rightarrow 2$ splitting process, where the particles are ordered as (hadron, remnant, parton).

Polarization is ignored completely. The beam particle is colorless, while partons and beam remnant carry color. The remnant gets a special flavor code.

10.12.8 Structure function

For the PDFs, we separate kinematics from dynamics. We first generate appropriate x values, independent of flavor and scale. This allows us to determine the momenta that initiate the hard scattering. Only when the hard process has been computed, we can be sure about the scattering scale and compute the structure function values.

For the x values, we can only apply a simple mapping that eliminates the $1/x$ singularity, i.e., we generate x on a logarithmic scale. This produces a Jacobian factor that we store along with the generated x value. The boundaries are used as returned by the LHAPDF library for the chosen PDF set.

```

<LHAPDF: procedures>+≡
subroutine generate_x (x, f, r, lhpdf_data)
    real(default), intent(out) :: x, f
    real(default), intent(in) :: r
    type(lhpdf_data_t), intent(in) :: lhpdf_data
    real(default) :: lg
    x = r
    f = 1
!    lg = log (lhpdf_data% xmax / lhpdf_data% xmin)
!    x = lhpdf_data% xmin * exp (r * lg)
!    f = x * lg
end subroutine generate_x

```

The previous routine is called here, so we can compute the complete kinematics.

(There is no mapping involved [see above], otherwise we should take and respect a `no_map` flag.)

```

<LHAPDF: public>+≡
public :: interaction_set_kinematics_lhpdf

<LHAPDF: procedures>+≡
subroutine interaction_set_kinematics_lhpdf (int, x, f, s, r, lhpdf_data)
    type(interaction_t), intent(inout) :: int
    real(default), intent(out) :: x, f, s
    real(default), intent(in) :: r
    type(lhpdf_data_t), intent(in) :: lhpdf_data
    type(vector4_t) :: k
    type(splitting_data_t) :: sd
    call generate_x (x, f, r, lhpdf_data)
    k = interaction_get_momentum (int, 1)
    s = k**2
    sd = new_splitting_data (k, s, 0._default, 0._default)
    call splitting_set_t_bounds (sd, x, 1 - x)
    call splitting_set_collinear (sd)
    call interaction_set_momenta &
        (int, split_momentum (k, sd), outgoing=.true.)

```

```
end subroutine interaction_set_kinematics_lhapdf
```

Once the scale is also known, we can actually call the library and set the values. If the scale is out of bounds, we reset it to the boundary. Account for the Jacobian.

We have to cast the LHAPDF arguments to/from double precision (possibly from/to quadruple precision), if necessary. Furthermore, some structure functions can yield negative results (sea quarks close to $x = 1$). We set these unphysical values to zero.

```

10.12.9 Strong Coupling

Since the PDF codes provide a function for computing the running α_s value, we make this available as an implementation of the abstract `alpha_qcd_t` type, which is used for matrix element evaluation.

```
<SF lhpdf: public>+≡
    public :: alpha_qcd_lhapdf_t

<SF lhpdf: types>+≡
    type, extends (alpha_qcd_t) :: alpha_qcd_lhapdf_t
        type(string_t) :: pdfset_dir
        type(string_t) :: pdfset_file
        integer :: pdfset_member = -1
    contains
        <SF lhpdf: alpha qcd: TBP>
    end type alpha_qcd_lhapdf_t
```

Output. As in earlier versions we leave the LHAPDF path out.

```
<SF lhpdf: alpha qcd: TBP>≡
    procedure :: write => alpha_qcd_lhapdf_write

<SF lhpdf: procedures>+≡
    subroutine alpha_qcd_lhapdf_write (object, unit)
        class(alpha_qcd_lhapdf_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit)
        write (u, "(3x,A)") "QCD parameters (lhpdf):"
        write (u, "(5x,A,A)") "PDF set      = ", char (object%pdfset_file)
        write (u, "(5x,A,I0)") "PDF member = ", object%pdfset_member
    end subroutine alpha_qcd_lhapdf_write
```

Calculation: the numeric member ID selects the correct PDF set, which must be properly initialized.

```
<SF lhpdf: interfaces>+≡
    interface
        double precision function alphasPDF (Q)
            double precision, intent(in) :: Q
        end function alphasPDF
    end interface

<SF lhpdf: alpha qcd: TBP>+≡
    procedure :: get => alpha_qcd_lhapdf_get

<SF lhpdf: procedures>+≡

10.13.3 The PDF object

The PDF $1 \rightarrow 2$ interaction which describes the splitting of an (anti)proton into a parton and a beam remnant. We stay in the strict forward-splitting limit, but allow some invariant mass for the beam remnant such that the outgoing parton

is exactly massless. For a real event, we would replace this by a parton cascade, where the outgoing partons have virtuality as dictated by parton-shower kinematics, and transverse momentum is generated.

The PDF application is a $1 \rightarrow 2$ splitting process, where the particles are ordered as (hadron, remnant, parton).

Polarization is ignored completely. The beam particle is colorless, while partons and beam remnant carry color. The remnant gets a special flavor code.

```

10.13.4 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

⟨SF pdf builtin: pdf builtin: TBP⟩+≡
    procedure :: complete_kinematics => pdf_builtin_complete_kinematics

⟨SF pdf builtin: procedures⟩+≡
    subroutine pdf_builtin_complete_kinematics (sf_int, x, f, r, map)

10.14.3 The interaction

We fill the interaction by looking up the table of states using the interface functions.

For particles which have a known flavor (as indicated by the mask), we compute the mass squared, so we can use it for the invariant mass of the particle objects.

```

<SF user: user: TBP>≡
  procedure :: init => user_init

10.14.4 The user structure function

For maximal flexibility, user structure functions separate kinematics from dynamics just as the PDF interface does. (JRR: Ok, I guess this now done for all structure functions, right?) We create `c_prt_t` particle objects from the incoming momenta (all other quantum numbers are irrelevant) and call the user-supplied kinematics function to compute the outgoing momenta, along with other variables that will be needed for matrix element evaluation. If known, we use the mass squared computed above. !!! JRR: WK please check I don't know actually whether this really fits into the setup done by WK.

```

<SF user: types>+≡
  !!! JRR: WK please check
  type, extends (sf_int_t) :: user_t

```

10.14.5 Kinematics

Set kinematics. If *map* is unset, the *r* and *x* values coincide, and the Jacobian $f(r)$ is trivial.

If *map* is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

10.15.1 The structure functions type

Definition

This contains the specific structure function data, much of which depends on the type. An extensible type would be appropriate. As long as this is not available in general, we emulate it by allocating the requested data explicitly.

⟨Strfun: types⟩≡

```

!! !! type :: strfun_t
!! !!     private
!! !!     integer :: type = STRF_NONE
!! !!     type(string_t) :: name
!! !!     type(interaction_t) :: int
!! !!     type(lhapdf_data_t), dimension(:), allocatable :: lhpdf_data
!! !!     type(pdf_builtin_data_t), dimension(:), allocatable :: pdf_builtin_data
!! !!     type(isr_data_t), dimension(:), allocatable :: isr_data
!! !!     type(epa_data_t), dimension(:), allocatable :: epa_data
!! !!     type(ewa_data_t), dimension(:), allocatable :: ewa_data
!! !!     type(circe1_data_t), dimension(:), allocatable :: circe1_data
!! !!     type(circe2_data_t), dimension(:), allocatable :: circe2_data
!! !!     type(escan_data_t), dimension(:), allocatable :: escan_data
!! !!     type(beam_events_data_t), dimension(:), allocatable :: beam_events_data
!! !!     type(sf_user_data_t), dimension(:), allocatable :: user_data
!! !!     real(default) :: x = 0, f = 1, s = 0
!! !!     real(default), dimension(:), allocatable :: user_xval
!! !!     real(default) :: scale = 0
!! !! end type strfun_t

```

The list of structure function codes:

⟨Strfun: parameters⟩≡

```

integer, parameter, public :: STRF_NONE = 0

```

```

integer, parameter, public :: STRF_LHAPDF = 1, STRF_ISR = 2, &
    STRF_EPA = 3, STRF_EWA = 4, STRF_CIRCE1 = 5, STRF_CIRCE2 = 6, &
    STRF_ESCAN = 7, STRF_BEVT = 8, STRF_PDF_BUILTIN = 9
integer, parameter, public :: STRF_USER = 99

```

The initializer assigns specific data and tags the interaction. The data block(s) have to be known already.

<Strfun: interfaces>≡

  end select
end subroutine strfun_apply

```

10.15.2 Mappings

Definition

Mappings for single structure functions may be defined in the individual sections, but pairwise mappings belong here. We define a mapping type that applies to an array of x parameters identified by their indices. The individual mapping

types are identified by a `type` parameter. A mapping may depend on a set on real parameters.

```

(Strfun: parameters)+≡
  integer, parameter, public :: SFM_NONE = 0
  integer, parameter, public :: SFM_PAIR = 1
  integer, parameter, public :: SFM_PAIR_RESONANCE = 2

(Strfun: types)+≡
  type :: strfun_mapping_t
  private
  integer, dimension(:), allocatable :: index
  integer :: type = SFM_NONE
  real(default) :: p = 0
  real(default) :: m2 = 0, mg = 0, s = 0
  real(default) :: a1 = 0, a2 = 0, a3 = 0
end type strfun_mapping_t

```

Initialization:

```

(Strfun: procedures)+≡
  subroutine strfun_mapping_init (sf_mapping, index, type, par)
    type(strfun_mapping_t), intent(out) :: sf_mapping
    integer, dimension(:), intent(in) :: index
    integer, intent(in) :: type
    real(default), dimension(:), intent(in) :: par
    real(default) :: s, m2, mg
    allocate (sf_mapping%index (size (index)))
    sf_mapping%index = index
    sf_mapping%type = type
    select case (type)
    case (SFM_PAIR)
      sf_mapping%p = par(1)
    case (SFM_PAIR_RESONANCE)
      s = par(1)**2
      m2 = par(2)**2
      mg = par(2) * par(3)
      sf_mapping%s = s
      sf_mapping%m2 = m2
      sf_mapping%mg = mg
      sf_mapping%a1 = atan (- m2 / mg)
      sf_mapping%a2 = atan ((s - m2) / mg)
      sf_mapping%a3 = (sf_mapping%a2 - sf_mapping%a1) * mg / s
    end select
  end subroutine strfun_mapping_init

```

Output

```

(Strfun: procedures)+≡
  subroutine strfun_mapping_write (sf_mapping, unit)
    type(strfun_mapping_t), intent(in) :: sf_mapping
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit); if (u < 0) return
    write (u, "(1x,A)", advance="no") "Strfun mapping for indices: "
    write (u, "(10(1x,I0))") sf_mapping%index

```

```

write (u, "(1x,A,1x,I0)") "mapping type =", sf_mapping%type
write (u, "(1x,A)", advance="no") "mapping pars ="
select case (sf_mapping%type)
case (SFM_NONE)
  write (u, *) "[none]"
case (SFM_PAIR)
  write (u, *) sf_mapping%p
case (SFM_PAIR_RESONANCE)
  write (u, *) sf_mapping%s, sf_mapping%m2, sf_mapping%mg
end select
end subroutine strfun_mapping_write

```

Evaluation

(*Strfun: procedures*) +=

```

subroutine strfun_mapping_apply (sf_mapping, x, factor)
  type(strfun_mapping_t), intent(in) :: sf_mapping
  real(default), dimension(:), intent(inout) :: x
  real(default), intent(out) :: factor

    x2 = x(sf_mapping%index)
    call map_unit_square (x2, factor, sf_mapping%p)
    x(sf_mapping%index) = x2
  case (SFM_PAIR_RESONANCE)
    x2 = x(sf_mapping%index)
    call map_resonance (x2(1), f2, &
      sf_mapping%s, sf_mapping%m2, sf_mapping%mg, &
      sf_mapping%a1, sf_mapping%a2, sf_mapping%a3)
    call map_unit_square (x2, f1)
    x(sf_mapping%index) = x2
    factor = f1 * f2
  case default
    factor = 1
  end select
end subroutine strfun_mapping_apply

subroutine strfun_mapping_apply_inverse (sf_mapping, x, factor)
  type(strfun_mapping_t), intent(in) :: sf_mapping
  real(default), dimension(:), intent(inout) :: x
  real(default), intent(out) :: factor
  real(default) :: f1, f2
  real(default), dimension(2) :: x2
  select case (sf_mapping%type)
  case (SFM_PAIR)
    x2 = x(sf_mapping%index)
    call map_unit_square_inverse (x2, factor, sf_mapping%p)
    x(sf_mapping%index) = x2
  case (SFM_PAIR_RESONANCE)
    x2 = x(sf_mapping%index)
    call map_unit_square_inverse (x2, f1)

```

```

      call map_resonance_inverse (x2(1), f2, &
        sf_mapping%s, sf_mapping%m2, sf_mapping%mg, &
        sf_mapping%a1, sf_mapping%a2, sf_mapping%a3)
      x(sf_mapping%index) = x2
      factor = f1 * f2
    case default
      factor = 1
    end select
  end subroutine strfun_mapping_apply_inverse

```

This mapping of the unit square is appropriate in particular for structure functions which are concentrated at the lower end. Instead of a rectangular grid, one set of grid lines corresponds to constant parton c.m. energy. The other set is chosen such that the jacobian is only mildly singular ($\ln x$ which is zero at $x = 1$), corresponding to an initial concentration of sampling points at the maximum energy. If **power** is greater than one (the default), points are also concentrated at the lower end.

<Strfun: procedures>+≡

```

subroutine map_unit_square (x, factor, power)
  real(kind=default), dimension(2), intent(inout) :: x
  real(kind=default), intent(out) :: factor
  real(kind=default), intent(in), optional :: power
  real(kind=default) :: xx, yy
  factor = 1
  xx = x(1)
  yy = x(2)
  if (present(power)) then
    if (x(1) > 0 .and. power > 1) then
      xx = x(1)**power
      factor = factor * power * xx / x(1)
    end if
  end if
  if (xx /= 0) then
    x(1) = xx ** yy
    x(2) = xx / x(1)
    factor = factor * abs (log (xx))
  else
    x = 0
  end if
end subroutine map_unit_square

```

This is the inverse mapping.

<Strfun: procedures>+≡

```

subroutine map_unit_square_inverse (x, factor, power)
  real(kind=default), dimension(2), intent(inout) :: x
  real(kind=default), intent(out) :: factor
  real(kind=default), intent(in), optional :: power
  real(kind=default) :: lg, xx, yy
  factor = 1
  xx = x(1) * x(2)
  if (xx /= 0) then
    lg = log (xx)

```

```

      yy = log (x(1)) / lg
      x(2) = yy
      factor = factor * abs (lg)
      if (present(power)) then
        x(1) = xx**(1._default/power)
        factor = factor * power * xx / x(1)
      else
        x(1) = xx
      end if
    else
      x = 0
    end if
  end subroutine map_unit_square_inverse

```

This is the usual mapping of a Lorentz peak. Since the x range maps the energy range $0 \dots \sqrt{s}$ to $0 \dots 1$, the position of the peak is m^2/s , the width is given by $m\Gamma/s$.

```

    t = (x * s - m2) / mg
    x = (atan (t) - a1) / (a2 - a1)
    factor = a3 * (1 + t**2)
  end subroutine map_resonance_inverse

```

10.15.3 Structure function chains

Definition

The structure function chain contains an array of structure functions, where each one has one or more free parameters. For each structure function there is an interaction, an image of the interaction within the **strfun** object, which is needed when quantum numbers are reduced. Furthermore, an array of evaluators which cumulatively multiply the structure functions. The last evaluator is connected to the hard matrix element.

The `last_strfun` and `out_index` index (pairs) identify, for each beam, the last structure function and the outgoing particle. The `coll_index` (pair) identifies the outgoing particles in the last evaluator.

For a decay, this structure is also used, but normally there are no structure functions besides the “beam” object.

```

<Strfun: public>≡
    public :: strfun_chain_t

This procedure links a new structure function to the existing chain. *i* is the overall structure function counter. *line* indicates the beam(s) to which the structure function applies; 0 is for both beams. The last two arguments are the indices of the incoming and outgoing particle(s) within the current structure function. For a single-beam (double-beam) structure function, these arrays are of length 1 (2), respectively.

The connections of outgoing/incoming particles are recorded as links in the new structure-function entry `sfchain%strfun(i)`.

Chapter 11

Phase space and hard matrix elements

These modules contain the internal representation and evaluation of phase space and the interface to (hard-)process evaluation.

mappings Generate invariant masses and decay angles from given random numbers (or the inverse operation). Each mapping pertains to a particular node in a phase-space tree. Different mappings account for uniform distributions, resonances, zero-mass behavior, and so on.

phs_trees Phase space parameterizations for scattering processes are defined recursively as if there was an initial particle decaying. This module sets up a representation in terms of abstract trees, where each node gets a unique binary number. Each tree is stored as an array of branches, where integers indicate the connections. This emulates pointers in a transparent way. Real pointers would also be possible, but seem to be less efficient for this particular case.

phs_forests The type defined by this module collects the decay trees corresponding to a given process and the applicable mappings. To set this up, a file is read which is either written by the user or by the **cascades** module functions. The module also contains the routines that evaluate phase space, i.e., generate momenta from random numbers and back.

cascades This module is a Feynman diagram generator with the particular purpose of finding the phase space parameterizations best suited for a given process. It uses a model file to set up the possible vertices, generates all possible diagrams, identifies resonances and singularities, and simplifies the list by merging equivalent diagrams and dropping irrelevant ones. This process can be controlled at several points by user-defined parameters. Note that it depends on the particular values of particle masses, so it cannot be done before reading the input file.

11.1 Process data block

We define a simple transparent type that contains universal constant process data. We will reference objects of this type for the phase-space setup, for interfacing with process libraries, for implementing matrix-element generation, and in the master process-handling module.

```
<process_constants.f90>≡  
  <File header>
```

```
  module process_constants
```

```
    <Use kinds>
```

```
    <Use strings>
```

```
    <Standard module head>
```

```
    <Process constants: public>
```

```
    <Process constants: types>
```

```
  end module process_constants
```

The data type is just a block of public objects, only elementary types, no type-bound procedures.

```
<Process constants: public>≡  
  public :: process_constants_t  
  
<Process constants: types>≡  
  type :: process_constants_t  
    type(string_t) :: id  
    type(string_t) :: model_name  
    character(32) :: md5sum = ""  
    logical :: openmp_supported = .false.  
    integer :: n_in = 0  
    integer :: n_out = 0  
    integer :: n_flv = 0  
    integer :: n_hel = 0  
    integer :: n_col = 0  
    integer :: n_cin = 0  
    integer :: n_cf = 0  
    integer, dimension(:,:), allocatable :: flv_state  
    integer, dimension(:,:), allocatable :: hel_state  
    integer, dimension(:,:), allocatable :: col_state  
    logical, dimension(:,:), allocatable :: ghost_flag  
    complex(default), dimension(:), allocatable :: color_factors  
    integer, dimension(:,:), allocatable :: cf_index  
  end type process_constants_t
```

11.2 Abstract phase-space module

In this module we define an abstract base type (and a trivial test implementation) for multi-channel phase-space parameterizations.

```
<phs_base.f90>≡  
<File header>  
  
module phs_base  
  
  <Use kinds>  
  <Use strings>  
  <Use file utils>  
  use constants !NODEP!  
  use diagnostics !NODEP!  
  use lorentz !NODEP!  
  use unit_tests  
  use os_interface  
  use md5  
  use variables  
  use models  
  use flavors  
  use process_constants  
  use sf_mappings  
  use sf_base  
  
  <Standard module head>  
  
  <PHS base: public>  
  
  <PHS base: types>  
  
  <PHS base: interfaces>  
  
  <PHS base: test types>  
  
  contains  
  
  <PHS base: procedures>  
  
  <PHS base: tests>  
  
end module phs_base
```

11.2.1 Phase-space channels

The kinematics configuration may generate multiple parameterizations of phase space. Some of those have specific properties, such as a resonance in the s channel.

This is the abstract type for the channel properties.

```
<PHS base: types>≡  
  type, abstract :: channel_prop_t  
  contains  
    procedure (channel_prop_to_string), deferred :: to_string
```

```
end type channel_prop_t
```

```
⟨PHS base: interfaces⟩≡
  abstract interface
    function channel_prop_to_string (object) result (string)
      import
      class(channel_prop_t), intent(in) :: object
      type(string_t) :: string
    end function channel_prop_to_string
  end interface
```

This type describes an equivalence. The current channel is equivalent to channel c. The equivalence involves a permutation **perm** of integration dimensions and, within each integration dimension, a mapping **mode**.

```
⟨PHS base: types⟩+≡
  type :: phs_equivalence_t
    integer :: c = 0
    integer, dimension(:), allocatable :: perm
    integer, dimension(:), allocatable :: mode
  contains
    ⟨PHS base: phs equivalence: TBP⟩
  end type phs_equivalence_t
```

The mapping modes are

```
⟨PHS base: types⟩+≡
  integer, parameter, public :: &
    EQ_IDENTITY = 0, EQ_INVERT = 1, EQ_SYMMETRIC = 2, EQ_INVARIANT = 3
```

In particular, if a channel is equivalent to itself in the EQ_SYMMETRIC mode, the integrand can be assumed to be symmetric w.r.t. a reflection $x \rightarrow 1 - x$ of the corresponding integration variable.

These are the associated tags, for output:

```
⟨PHS base: types⟩+≡
  character, dimension(0:3), parameter :: TAG = ["+", "-", ":", "x"]
```

Write an equivalence.

```
⟨PHS base: phs equivalence: TBP⟩≡
  procedure :: write => phs_equivalence_write

⟨PHS base: procedures⟩≡
  subroutine phs_equivalence_write (object, unit)
    class(phs_equivalence_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, j
    u = output_unit (unit)
    write (u, "(5x,'=',1x,I0,1x)", advance = "no") object%c
    if (allocated (object%perm)) then
      write (u, "(A)", advance = "no") "("
      do j = 1, size (object%perm)
        if (j > 1) write (u, "(1x)", advance = "no")
        write (u, "(I0,A1)", advance = "no") &
```

```

            object%perm(j), TAG(object%mode(j))
        end do
        write (u, "(A)" " ")
    else
        write (u, "(A)")
    end if
end subroutine phs_equivalence_write

```

Initialize an equivalence. This allocates the `perm` and `mode` arrays with equal size.

```

<PHS base: phs equivalence: TBP>+=
    procedure :: init => phs_equivalence_init

<PHS base: procedures>+=
    subroutine phs_equivalence_init (eq, n_dim)
        class(phs_equivalence_t), intent(out) :: eq
        integer, intent(in) :: n_dim
        allocate (eq%perm (n_dim), source = 0)
        allocate (eq%mode (n_dim), source = EQ_IDENTITY)
    end subroutine phs_equivalence_init

```

The channel entry holds (optionally) specific properties.

`sf_channel` is the structure-function channel that corresponds to this phase-space channel. The structure-function channel may be set up with a specific mapping that depends on the phase-space channel properties. (The default setting is to leave the properties empty.)

```

<PHS base: public>=
    public :: phs_channel_t

<PHS base: types>+=
    type :: phs_channel_t
        class(channel_prop_t), allocatable :: prop
        integer :: sf_channel = 1
        type(phs_equivalence_t), dimension(:), allocatable :: eq
    contains
        <PHS base: phs channel: TBP>
    end type phs_channel_t

```

Output.

```

<PHS base: phs channel: TBP>=
    procedure :: write => phs_channel_write

<PHS base: procedures>+=
    subroutine phs_channel_write (object, unit)
        class(phs_channel_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, j
        u = output_unit (unit)
        write (u, "(1x,I0)", advance="no") object%sf_channel
        if (allocated (object%prop)) then
            write (u, "(1x,A)" char (object%prop%to_string ()))
        else
            write (u, *)
        end if
    end subroutine phs_channel_write

```

```

end if
if (allocated (object%eq)) then
  do j = 1, size (object%eq)
    call object%eq(j)%write (u)
  end do
end if
end subroutine phs_channel_write

```

11.2.2 Kinematics configuration

Here, we store the universal information that is specifically relevant for phase-space generation. It is a subset of the process data, supplemented by basic information on phase-space parameterization channels.

A concrete implementation will contain more data, that describe the phase space in detail.

```

<PHS base: public>+≡
  public :: phs_config_t

<PHS base: types>+≡
  type, abstract :: phs_config_t
  !
    private
      type(string_t) :: id
      integer :: n_in = 0
      integer :: n_out = 0
      integer :: n_tot = 0
      integer :: n_state = 0
      integer :: n_par = 0
      integer :: n_channel = 0
      real(default) :: sqrts = 0
      logical :: sqrts_fixed = .true.
      logical :: cm_frame = .true.
      logical :: azimuthal_dependence = .false.
      integer, dimension(:), allocatable :: dim_flat
      logical :: provides_equivalences = .false.
      logical :: provides_chains = .false.
      integer, dimension(:), allocatable :: chain
      type(model_t), pointer :: model => null ()
      type(flavor_t), dimension(:, :), allocatable :: flv
      type(phs_channel_t), dimension(:), allocatable :: channel
      character(32) :: md5sum_process = ""
      character(32) :: md5sum_model_par = ""
      character(32) :: md5sum_phs_config = ""
    contains
      <PHS base: phs config: TBP>
  end type phs_config_t

```

Finalizer, deferred.

```

<PHS base: phs config: TBP>≡
  procedure (phs_config_final), deferred :: final

```

```

<PHS base: interfaces>+=
  abstract interface
    subroutine phs_config_final (object)
      import
      class(phs_config_t), intent(inout) :: object
    end subroutine phs_config_final
  end interface

```

Output. We provide an implementation for the output of the base-type contents and an interface for the actual write method.

```

<PHS base: phs config: TBP>+=
  procedure (phs_config_write), deferred :: write
  procedure :: base_write => phs_config_write

<PHS base: procedures>+=
  subroutine phs_config_write (object, unit)
    class(phs_config_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i, j
    u = output_unit (unit)
    write (u, "(3x,A,A,A)") "ID          = ", char (object%id), ""
    write (u, "(3x,A,I0)")  "n_in       = ", object%n_in
    write (u, "(3x,A,I0)")  "n_out      = ", object%n_out
    write (u, "(3x,A,I0)")  "n_tot      = ", object%n_tot
    write (u, "(3x,A,I0)")  "n_state    = ", object%n_state

    write (u, "(3x,A,L1)")  "azim.dep. = ", object%azimuthal_dependence
    if (allocated (object%dim_flat)) then
      write (u, "(3x,A,I0)")  "flat dim. = ", object%dim_flat
    end if
    write (u, "(1x,A)")  "Flavor combinations:"
    do i = 1, object%n_state
      write (u, "(3x,I0,':')", advance="no") i
      do j = 1, object%n_tot
        write (u, "(1x,A)", advance="no") &
          char (flavor_get_name (object%flv(j,i)))
      end do
      write (u, *)
    end do
    if (allocated (object%channel)) then
      write (u, "(1x,A)")  "Phase-space / structure-function channels:"
      do i = 1, object%n_channel
        write (u, "(3x,I0,':')", advance="no") i
        call object%channel(i)%write (u)
      end do
    end if
    if (object%md5sum_process /= "") then
      write (u, "(3x,A,A,A)") "MD5 sum (process)    = ", &
        object%md5sum_process, ""
    end if

```

```

    if (object%md5sum_model_par /= "") then
        write (u, "(3x,A,A,A)") "MD5 sum (model par) = ', &
            object%md5sum_model_par, "'"
    end if
    if (object%md5sum_phs_config /= "") then
        write (u, "(3x,A,A,A)") "MD5 sum (phs config) = ', &
            object%md5sum_phs_config, "'"
    end if
end subroutine phs_config_write

```

Similarly, a basic initializer and an interface. The model pointer is taken as an argument; we may verify that this has the expected model name.

The intent is `inout`. We want to be able to set parameters in advance.

(PHS base: phs config: TBP)+≡

```

    procedure :: init => phs_config_init

```

(PHS base: procedures)+≡

```

subroutine phs_config_init (phs_config, data, model)
    class(phs_config_t), intent(inout) :: phs_config
    type(process_constants_t), intent(in) :: data
    type(model_t), intent(in), target :: model
    integer :: i, j
    phs_config%id = data%id
    phs_config%n_in = data%n_in
    phs_config%n_out = data%n_out
    phs_config%n_tot = data%n_in + data%n_out
    phs_config%n_state = data%n_flv
    if (data%model_name == model_get_name (model)) then
        phs_config%model => model
    else
        call msg_bug ("phs_config_init: model name mismatch")
    end if
    allocate (phs_config%flv (phs_config%n_tot, phs_config%n_state))
    do i = 1, phs_config%n_state
        do j = 1, phs_config%n_tot
            call flavor_init (phs_config%flv(j,i), data%flv_state(j,i), &
                phs_config%model)
        end do
    end do
    phs_config%md5sum_process = data%md5sum
end subroutine phs_config_init

```

This procedure should complete the phase-space configuration. We need the `sqrts` value as overall scale, which is known only after the beams have been defined. The procedure should determine the number of channels, their properties (if any), and allocate and fill the `channel` array accordingly.

(PHS base: phs config: TBP)+≡

```

    procedure (phs_config_configure), deferred :: configure

```

(PHS base: interfaces)+≡

```

abstract interface
    subroutine phs_config_configure (phs_config, sqrts, &
        sqrts_fixed, cm_frame, azimuthal_dependence, rebuild)

```

```

import
class(phs_config_t), intent(inout) :: phs_config
real(default), intent(in) :: sqrts
logical, intent(in), optional :: sqrts_fixed
logical, intent(in), optional :: cm_frame
logical, intent(in), optional :: azimuthal_dependence
logical, intent(in), optional :: rebuild
end subroutine phs_config_configure
end interface

```

Compute the MD5 sum. We abuse the `write` method. In type implementations, `write` should only display information that is relevant for the MD5 sum. The data include the process MD5 sum which is taken from the process constants, and the MD5 sum of the model parameters. This may change, so it is computed here.

```

<PHS base: phs config: TBP>+≡
  procedure :: compute_md5sum => phs_config_compute_md5sum

<PHS base: procedures>+≡
  subroutine phs_config_compute_md5sum (phs_config)
    class(phs_config_t), intent(inout) :: phs_config
    integer :: u
    phs_config%md5sum_model_par = model_get_parameters_md5sum (phs_config%model)
    phs_config%md5sum_phs_config = ""
    u = free_unit ()
    open (u, status = "scratch", action = "readwrite")
    call phs_config%write (u)
    rewind (u)
    phs_config%md5sum_phs_config = md5sum (u)
    close (u)
  end subroutine phs_config_compute_md5sum

```

Print an informative message after phase-space configuration.

```

<PHS base: phs config: TBP>+≡
  procedure (phs_startup_message), deferred :: startup_message
  procedure :: base_startup_message => phs_startup_message

<PHS base: procedures>+≡
  subroutine phs_startup_message (phs_config, unit)
    class(phs_config_t), intent(in) :: phs_config
    integer, intent(in), optional :: unit
    write (msg_buffer, "(A,3(1x,I0,1x,A))") &
      "Phase space:", &
      phs_config%n_channel, "channels,", &
      phs_config%n_par, "dimensions"
    call msg_message (unit = unit)
  end subroutine phs_startup_message

```

This procedure should assign structure-function channels to the phase-space channels. The assignment will depend on the phase-space channel properties (which are known at this point) and on the available structure-function channels or mappings.

For the actual implementation, this procedure has to apply heuristics as to which structure-function mappings are appropriate for which phase-space structure. The mappings have to be prepared in advance. This requires extracting information (e.g., about resonance parameters) from the configured phase space.

```

<PHS base: phs config: TBP>+≡
  procedure (phs_config_match_channels), deferred :: match_channels

<PHS base: interfaces>+≡
  abstract interface
    subroutine phs_config_match_channels (phs_config, sf, sf_channel)
      import
      class(phs_config_t), intent(inout) :: phs_config
      type(sf_config_t), dimension(:), intent(in), allocatable :: sf
      type(sf_channel_t), dimension(:), intent(in), allocatable :: sf_channel
    end subroutine phs_config_match_channels
  end interface

```

This procedure should be implemented such that the phase-space configuration object allocates a phase-space instance of matching type.

```

<PHS base: phs config: TBP>+≡
  procedure (phs_config_allocate_instance), nopass, deferred :: &
    allocate_instance

<PHS base: interfaces>+≡
  abstract interface
    subroutine phs_config_allocate_instance (phs)
      import
      class(phs_t), intent(inout), pointer :: phs
    end subroutine phs_config_allocate_instance
  end interface

```

11.2.3 Extract data

Return the number of MC input parameters.

```

<PHS base: phs config: TBP>+≡
  procedure :: get_n_par => phs_config_get_n_par

<PHS base: procedures>+≡
  function phs_config_get_n_par (phs_config) result (n)
    class(phs_config_t), intent(in) :: phs_config
    integer :: n
    n = phs_config%n_par
  end function phs_config_get_n_par

```

Return dimensions (parameter indices) for which the phase-space dimension is flat, so integration and event generation can be simplified.

```

<PHS base: phs config: TBP>+≡
  procedure :: get_flat_dimensions => phs_config_get_flat_dimensions

```

```

(PHS base: procedures)+≡
function phs_config_get_flat_dimensions (phs_config) result (dim_flat)

  integer, dimension(:), allocatable :: dim_flat
  if (allocated (phs_config%dim_flat)) then
    allocate (dim_flat (size (phs_config%dim_flat)))
    dim_flat = phs_config%dim_flat
  else
    allocate (dim_flat (0))
  end if
end function phs_config_get_flat_dimensions

```

Return the number of phase-space channels.

```

(PHS base: phs config: TBP)+≡
  procedure :: get_n_channel => phs_config_get_n_channel

(PHS base: procedures)+≡
function phs_config_get_n_channel (phs_config) result (n)
  class(phs_config_t), intent(in) :: phs_config
  integer :: n
  n = phs_config%n_channel
end function phs_config_get_n_channel

```

Return the structure-function channel that corresponds to the phase-space channel *c*. If the channel array is not allocated (which happens if there is no structure function), return zero.

```

(PHS base: phs config: TBP)+≡
  procedure :: get_sf_channel => phs_config_get_sf_channel

(PHS base: procedures)+≡
function phs_config_get_sf_channel (phs_config, c) result (c_sf)
  class(phs_config_t), intent(in) :: phs_config
  integer, intent(in) :: c
  integer :: c_sf
  if (allocated (phs_config%channel)) then
    c_sf = phs_config%channel(c)%sf_channel
  else
    c_sf = 0
  end if
end function phs_config_get_sf_channel

```

Return the mass(es) of the incoming particle(s). We take the first flavor combination in the array, assuming that masses must be degenerate among flavors.

```

(PHS base: phs config: TBP)+≡
  procedure :: get_masses_in => phs_config_get_masses_in

(PHS base: procedures)+≡
subroutine phs_config_get_masses_in (phs_config, m)
  class(phs_config_t), intent(in) :: phs_config
  real(default), dimension(:), intent(out) :: m
  integer :: i
  do i = 1, phs_config%n_in
    m(i) = flavor_get_mass (phs_config%flv(i,1))
  end do
end subroutine phs_config_get_masses_in

```

```

    end do
end subroutine phs_config_get_masses_in

```

Return the MD5 sum of the configuration.

```

<PHS base: phs config: TBP>+≡
  procedure :: get_md5sum => phs_config_get_md5sum

<PHS base: procedures>+≡
  function phs_config_get_md5sum (phs_config) result (md5sum)
    class(phs_config_t), intent(in) :: phs_config
    character(32) :: md5sum
    md5sum = phs_config%md5sum_phs_config
  end function phs_config_get_md5sum

```

11.2.4 Phase-space point instance

The `phs_t` object holds the workspace for phase-space generation. In the base object, we have the MC input parameters `r` and the Jacobian factor `f`, for each channel, and the incoming and outgoing momenta.

Note: The `active_channel` array is not used yet, all elements are initialized with `.true.`. It should be touched by the integrator if it decides to drop irrelevant channels.

```

<PHS base: public>+≡
  public :: phs_t

<PHS base: types>+≡
  type, abstract :: phs_t
    class(phs_config_t), pointer :: config => null ()
    logical :: r_defined = .false.
    integer :: selected_channel = 0
    logical, dimension(:), allocatable :: active_channel
    real(default), dimension(:,:), allocatable :: r
    real(default), dimension(:), allocatable :: f
    real(default), dimension(:), allocatable :: m_in
    real(default), dimension(:), allocatable :: m_out
    real(default) :: flux = 0
    real(default) :: volume = 0
    type(lorentz_transformation_t) :: lt_cm_to_lab
    logical :: p_defined = .false.
    real(default) :: sqrts_hat = 0
    type(vector4_t), dimension(:), allocatable :: p
    logical :: q_defined = .false.
    type(vector4_t), dimension(:), allocatable :: q
  contains
    <PHS base: phs: TBP>
  end type phs_t

```

Output. Since phase space may get complicated, we include a `verbose` option for the abstract `write` procedure.

```

<PHS base: phs: TBP>≡
  procedure (phs_write), deferred :: write

```

```

<PHS base: interfaces>+=
  abstract interface
    subroutine phs_write (object, unit, verbose)
      import
      class(phs_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose
    end subroutine phs_write
  end interface

```

This procedure can be called to print the contents of the base type.

```

<PHS base: phs: TBP>+=
  procedure :: base_write => phs_base_write

<PHS base: procedures>+=

class(phs_t), intent(inout), pointer :: phs
allocate (phs_test_t :: phs)
end subroutine phs_test_config_allocate_instance

```

Test kinematics implementation

This implementation of kinematics generates a simple two-particle configuration from the incoming momenta. The incoming momenta must be in the c.m. system, all masses equal.

There are two channels: one generates $\cos\theta$ and ϕ uniformly, in the other channel we map the r_1 parameter which belongs to $\cos\theta$.

We should store the mass parameter that we need.

```

<PHS base: public>+≡
public :: phs_test_t

Uniform angular distribution

These procedures implement the uniform angular distribution, generated from two parameters x_1 and x_2 :

$$\cos \theta = 1 - 2x_1, \quad \phi = 2\pi x_2 \quad (11.1)$$

We generate a rotation (Lorentz transformation) which rotates the positive z axis into this point on the unit sphere. This rotation is applied to the incoming momenta, which are assumed to be back-to-back and on-shell.

We do not compute a Jacobian (constant). The uniform distribution is assumed to be normalized.

```

<PHS base: public>+≡
    public :: compute_kinematics_solid_angle

<PHS base: tests>+≡
    subroutine compute_kinematics_solid_angle (p, q, x)
        type(vector4_t), dimension(2), intent(in) :: p
        type(vector4_t), dimension(2), intent(out) :: q
        real(default), dimension(2), intent(in) :: x
        real(default) :: ct, st, phi
        type(lorentz_transformation_t) :: rot
        integer :: i
        ct = 1 - 2*x(1)
        st = sqrt (1 - ct**2)
        phi = twopi * x(2)
        rot = rotation (phi, 3) * rotation (ct, st, 2)
        do i = 1, 2
            q(i) = rot * p(i)
        end do
    end subroutine compute_kinematics_solid_angle

```

This is the inverse transformation. We assume that the outgoing momenta are rotated versions of the incoming momenta, back-to-back. Thus, we determine the angles from $q(1)$ alone. p is unused.

```

11.3 Single-particle phase space

This module implements the phase space for a single particle, i.e., the solid angle, in a straightforward parameterization with a single channel. The phase-space implementation may be used either for $1 \rightarrow 2$ decays or for $2 \rightarrow 2$ scattering processes, so the number of incoming particles is the only free parameter in the configuration. In the latter case, we should restrict its use to non-resonant s-channel processes, because there is no mapping of the scattering angle.

(We might extend this later to account for generic $2 \rightarrow 2$ situations, e.g., account for a Coulomb singularity or detect an s-channel resonance structure that requires matching structure-function mappings.)

This is derived from the `phs_test` implementation in the `phs_base` module above, even more simplified, but intended for actual use.

```

```

The finalizer is empty.

```

<PHS single: phs single: TBP>+≡
  procedure :: final => phs_single_final

<PHS single: procedures>+≡
  subroutine phs_single_final (object)
    class(phs_single_t), intent(inout) :: object
  end subroutine phs_single_final

```

Initialization. We allocate arrays (`base_init`) and adjust the phase-space volume. The massless two-particle phase space volume is

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.55294034614 \times 10^{-5} \quad (11.2)$$

For a decay with nonvanishing masses (m_3, m_4), there is a correction factor

$$\Phi_2(m)/\Phi_2(0) = \frac{1}{\hat{s}} \lambda^{1/2}(\hat{s}, m_3^2, m_4^2). \quad (11.3)$$

For a scattering process with nonvanishing masses, the correction factor is

$$\Phi_2(m)/\Phi_2(0) = \frac{1}{\hat{s}^2} \lambda^{1/2}(\hat{s}, m_1^2, m_2^2) \lambda^{1/2}(\hat{s}, m_3^2, m_4^2). \quad (11.4)$$

If the energy is fixed, this is constant. Otherwise, we have to account for varying \hat{s} .

```

<PHS single: phs single: TBP>+≡
  procedure :: init => phs_single_init
<PHS single: procedures>+≡
  subroutine phs_single_init (phs, phs_config)
    class(phs_single_t), intent(out) :: phs
    class(phs_config_t), intent(in), target :: phs_config
    call phs%base_init (phs_config)
    phs%volume = 1 / (4 * twopi5)
    call phs%compute_factor ()
  end subroutine phs_single_init

```

Compute the correction factor for nonzero masses. We do this during initialization (when the incoming momenta \mathbf{p} are undefined), unless `sqrts` is variable. We do this again once for each phase-space point, but then we skip the calculation if `sqrts` is fixed.

```

11.4 Mappings

Mappings are objects that encode the transformation of the interval $(0,1)$ to a physical variable m^2 or $\cos\theta$ (and back), as it is used in the phase space parameterization. The mapping objects contain fixed parameters, the associated methods implement the mapping and inverse mapping operations, including the computation of the Jacobian (phase space factor).

```
<mappings.f90>≡  
  <File header>  
  
  module mappings  
  
    <Use kinds>  
    use kinds, only: TC !NODEP!  
    <Use strings>  
    use constants, only: pi !NODEP!  
    <Use file utils>  
    use diagnostics !NODEP!  
    use md5  
    use models  
    use flavors  
  
    <Standard module head>

```

11.4.2 The Mapping type

Each mapping has a type (e.g., s-channel, infrared), a binary code (redundant, but useful for debugging), and a reference particle. The flavor code of this par-

ticle is stored for bookkeeping reasons, what matters are the mass and width of this particle. Furthermore, depending on the type, various mapping parameters can be set and used.

The parameters **a1** to **a3** (for m^2 mappings) and **b1** to **b3** (for $\cos \theta$ mappings) are values that are stored once to speed up the calculation, if **variable_limits** is false. The exact meaning of these parameters depends on the mapping type. The limits are fixed if there is a fixed c.m. energy.

```

<Mappings: public>+≡
    public :: mapping_t

<Mappings: types>+≡
    type :: mapping_t
    private
    integer :: type = NO_MAPPING
    integer(TC) :: bincode

      end select
    end if
  end if
end if
1 format (1x,A,3ES19.12)
end subroutine mapping_write

```

11.4.4 Define a mapping

The initialization routine sets the mapping type and the particle (binary code and flavor code) for which the mapping applies (e.g., a Z resonance in branch #3). We only need the absolute value of the flavor code.

<Mappings: public>+≡

public :: mapping_init

<Mappings: procedures>+≡

```

subroutine mapping_init (mapping, bincode, type, f, model)
  type(mapping_t), intent(inout) :: mapping
  integer(TC), intent(in) :: bincode
  type(string_t), intent(in) :: type
  integer, intent(in), optional :: f
  type(model_t), intent(in), optional, target :: model
  mapping%bincode = bincode
  select case (char (type))
  case ("s_channel"); mapping%type = S_CHANNEL
  case ("collinear"); mapping%type = COLLINEAR
  case ("infrared"); mapping%type = INFRARED

```

```

case ("radiation"); mapping%type = RADIATION
case ("t_channel"); mapping%type = T_CHANNEL
case ("u_channel"); mapping%type = U_CHANNEL
case ("step_exp"); mapping%type = STEP_MAPPING_E
case ("step_hyp"); mapping%type = STEP_MAPPING_H
end select
if (present (f) .and. present (model)) &
    call flavor_init (mapping%flv, abs (f), model)
end subroutine mapping_init

```

This sets the actual mass and width, using a parameter set. Since the auxiliary parameters will only be determined when the mapping is first called, they are marked as unknown.

```

<Mappings: public>+≡
    public :: mapping_set_parameters

<Mappings: procedures>+≡
    subroutine mapping_set_parameters (map, mapping_defaults, variable_limits)
        type(mapping_t), intent(inout) :: map
        type(mapping_defaults_t), intent(in) :: mapping_defaults
        logical, intent(in) :: variable_limits
        if (map%type /= NO_MAPPING) then
            map%mass = flavor_get_mass (map%flv)
            map%width = flavor_get_width (map%flv)
            map%variable_limits = variable_limits
            map%a_unknown = .true.
            map%b_unknown = .true.
            select case (map%type)
            case (S_CHANNEL)
                if (map%mass <= 0) then
                    call mapping_write (map)
                    call msg_fatal &
                        & (" S-channel resonance must have positive mass")
                else if (map%width <= 0) then
                    call mapping_write (map)
                    call msg_fatal &
                        & (" S-channel resonance must have positive width")
                end if
            case (RADIATION)
                map%width = max (map%width, mapping_defaults%energy_scale)
            case (INFRARED, COLLINEAR)
                map%mass = max (map%mass, mapping_defaults%invariant_mass_scale)
            case (T_CHANNEL, U_CHANNEL)
                map%mass = max (map%mass, mapping_defaults%momentum_transfer_scale)
            end select
        end if
    end subroutine mapping_set_parameters

```

For a step mapping the mass and width are set directly, instead of being determined from the flavor parameter (which is meaningless here). They correspond to the effective upper bound of phase space due to a resonance, as opposed to the absolute upper bound.

```

<Mappings: public>+≡

```

```

    public :: mapping_set_step_mapping_parameters
<Mappings: procedures>+≡
    subroutine mapping_set_step_mapping_parameters (map, &
        mass, width, variable_limits)
        type(mapping_t), intent(inout) :: map
        real(default), intent(in) :: mass, width
        logical, intent(in) :: variable_limits
        select case (map%type)
        case (STEP_MAPPING_E, STEP_MAPPING_H)
            map%variable_limits = variable_limits
            map%a_unknown = .true.
            map%b_unknown = .true.
            map%mass = mass
            map%width = width
        end select
    end subroutine mapping_set_step_mapping_parameters

```

11.4.5 Retrieve contents

    if (m1%type == m2%type) then
      select case (m1%type)
        case (NO_MAPPING)
          equal = .true.
        case (S_CHANNEL, RADIATION, STEP_MAPPING_E, STEP_MAPPING_H)
          equal = (m1%mass == m2%mass) .and. (m1%width == m2%width)
        case default
          equal = (m1%mass == m2%mass)
      end select
    else
      equal = .false.
    end if
  end function mapping_equal

```

11.4.7 Mappings of the invariant mass

Inserting an x value between 0 and 1, we want to compute the corresponding invariant mass $m^2(x)$ and the jacobian, aka phase space factor $f(x)$. We also need the reverse operation.

In general, the phase space factor f is defined by

$$\frac{1}{s} \int_{m_{\min}^2}^{m_{\max}^2} dm^2 g(m^2) = \int_0^1 dx \frac{1}{s} \frac{dm^2}{dx} g(m^2(x)) = \int_0^1 dx f(x) g(x), \quad (11.5)$$

where thus

$$f(x) = \frac{1}{s} \frac{dm^2}{dx}. \quad (11.6)$$

With this mapping, a function of the form

$$g(m^2) = c \frac{dx(m^2)}{dm^2} \quad (11.7)$$

is mapped to a constant:

$$\frac{1}{s} \int_{m_{\min}^2}^{m_{\max}^2} dm^2 g(m^2) = \int_0^1 dx f(x) g(m^2(x)) = \int_0^1 dx \frac{c}{s}. \quad (11.8)$$

Here is the mapping routine. Input are the available energy squared s , the limits for m^2 , and the x value. Output are the m^2 value and the phase space factor f .

```

Trivial mapping

We simply map the boundaries of the interval (m_{\min}, m_{\max}) to $(0, 1)$:

$$m^2 = (1 - x)m_{\min}^2 + xm_{\max}^2; \quad (11.9)$$

the inverse is

$$x = \frac{m^2 - m_{\min}^2}{m_{\max}^2 - m_{\min}^2}. \quad (11.10)$$

Hence

$$f(x) = \frac{m_{\max}^2 - m_{\min}^2}{s}, \quad (11.11)$$

and we have, as required,

$$f(x) \frac{dx}{dm^2} = \frac{1}{s}. \quad (11.12)$$

We store the constant parameters the first time the mapping is called – or, if limits vary, recompute them each time.

<Constants for trivial msq mapping>≡

```

if (map%variable_limits .or. map%a_unknown) then
  map%a1 = 0
  map%a2 = msq_max - msq_min
  map%a3 = map%a2 / s
  map%a_unknown = .false.
end if

⟨Apply trivial msq mapping⟩≡
  msq = (1-x) * msq_min + x * msq_max
  f = map%a3

```

```

⟨Apply inverse trivial msq mapping⟩≡
  if (map%a2 /= 0) then
    x = (msq - msq_min) / map%a2
  else
    x = 0
  end if
  f = map%a3

```

Resonance or step mapping does not make much sense if the resonance mass is outside the kinematical bounds. If this is the case, revert to `NO_MAPPING`. This is possible even if the kinematical bounds vary from event to event.

```

⟨Modify mapping type if necessary⟩≡
  select case (type)
  case (S_CHANNEL, STEP_MAPPING_E, STEP_MAPPING_H)
    msq0 = map%mass**2
    if (msq0 < msq_min .or. msq0 > msq_max) type = NO_MAPPING
  end select

```

Breit-Wigner mapping

A Breit-Wigner resonance with mass M and width Γ is flattened by the following mapping:

This mapping does not make much sense if the resonance mass is too low. If this is the case, revert to `NO_MAPPING`. There is a tricky point with this if the mass is too high: `msq_max` is not a constant if structure functions are around. However, switching the type depending on the overall energy does not change the integral, it is just another branching point.

$$m^2 = M(M + t\Gamma), \quad (11.13)$$

where

$$t = \tan \left[(1-x) \arctan \frac{m_{\min}^2 - M^2}{M\Gamma} + x \arctan \frac{m_{\max}^2 - M^2}{M\Gamma} \right]. \quad (11.14)$$

The inverse:

$$x = \frac{\arctan \frac{m^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma}}{\arctan \frac{m_{\max}^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma}} \quad (11.15)$$

The phase-space factor of this transformation is

$$f(x) = \frac{M\Gamma}{s} \left(\arctan \frac{m_{\max}^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma} \right) (1 + t^2). \quad (11.16)$$

This maps any function proportional to

$$g(m^2) = \frac{M\Gamma}{(m^2 - M^2)^2 + M^2\Gamma^2} \quad (11.17)$$

to a constant times $1/s$.

  f = map%a3 * (1 + tmp**2)

```

Mapping for massless splittings

This mapping accounts for approximately scale-invariant behavior where $\ln M^2$ is evenly distributed.

$$m^2 = m_{\min}^2 + M^2 (\exp(xL) - 1) \quad (11.18)$$

where

$$L = \ln \left(\frac{m_{\max}^2 - m_{\min}^2}{M^2} + 1 \right). \quad (11.19)$$

The inverse:

$$x = \frac{1}{L} \ln \left(\frac{m^2 - m_{\min}^2}{M^2} + 1 \right) \quad (11.20)$$

The constant M is a characteristic scale. Above this scale ($m^2 - m_{\min}^2 \gg M^2$), this mapping behaves like $x \propto \ln m^2$, while below the scale it reverts to a linear mapping.

The phase-space factor is

$$f(x) = \frac{M^2}{s} \exp(xL) L. \quad (11.21)$$

A function proportional to

$$g(m^2) = \frac{1}{(m^2 - m_{\min}^2) + M^2} \quad (11.22)$$

is mapped to a constant, i.e., a simple pole near m_{\min} with a regulator mass M .

This type of mapping is useful for massless collinear and infrared singularities, where the scale is stored as the mass parameter. In the radiation case (IR radiation off massive particle), the heavy particle width is the characteristic scale.

```

  x = log (msq1 / map%a1) / map%a2
  f = map%a3 * msq1

```

Mapping for t-channel poles

This is also approximately scale-invariant, and we use the same type of mapping as before. However, we map $1/x$ singularities at both ends of the interval; again, the mapping becomes linear when the distance is less than M^2 :

$$m^2 = \begin{cases} m_{\min}^2 + M^2 (\exp(xL) - 1) & \text{for } 0 < x < \frac{1}{2} \\ m_{\max}^2 - M^2 (\exp((1-x)L) - 1) & \text{for } \frac{1}{2} \leq x < 1 \end{cases} \quad (11.23)$$

where

$$L = 2 \ln \left(\frac{m_{\max}^2 - m_{\min}^2}{2M^2} + 1 \right). \quad (11.24)$$

The inverse:

$$x = \begin{cases} \frac{1}{L} \ln \left(\frac{m^2 - m_{\min}^2}{M^2} + 1 \right) & \text{for } m^2 < (m_{\max}^2 - m_{\min}^2)/2 \\ 1 - \frac{1}{L} \ln \left(\frac{m_{\max}^2 - m^2}{M^2} + 1 \right) & \text{for } m^2 \geq (m_{\max}^2 - m_{\min}^2)/2 \end{cases} \quad (11.25)$$

The phase-space factor is

$$f(x) = \begin{cases} \frac{M^2}{s} \exp(xL) L. & \text{for } 0 < x < \frac{1}{2} \\ \frac{M^2}{s} \exp((1-x)L) L. & \text{for } \frac{1}{2} \leq x < 1 \end{cases} \quad (11.26)$$

A (continuous) function proportional to

$$g(m^2) = \begin{cases} 1/(m^2 - m_{\min}^2) + M^2 & \text{for } m^2 < (m_{\max}^2 - m_{\min}^2)/2 \\ 1/((m_{\max}^2 - m^2) + M^2) & \text{for } m^2 \geq (m_{\max}^2 - m_{\min}^2)/2 \end{cases} \quad (11.27)$$

is mapped to a constant by this mapping, i.e., poles near both ends of the interval.

```

⟨Constants for t-channel pole mapping⟩≡

    x = 1 - log (msq1/map%a1) / map%a2
  end if
  f = map%a3 * msq1

```

11.4.8 Step mapping

Step mapping is useful when the allowed range for a squared-mass variable is large, but only a fraction at the lower end is populated because the particle in question is an (off-shell) decay product of a narrow resonance. I.e., if the resonance was forced to be on-shell, the upper end of the range would be the resonance mass, minus the effective (real or resonance) mass of the particle(s) in the sibling branch of the decay.

The edge of this phase space section has a width which is determined by the width of the parent, plus the width of the sibling branch. (The widths might be added in quadrature, but this precision is probably not important.)

Fermi function

A possible mapping is derived from the Fermi function which has precisely this behavior. The Fermi function is given by

$$f(x) = \frac{1}{1 + \exp \frac{x-\mu}{\gamma}} \quad (11.28)$$

where x is taken as the invariant mass squared, μ is the invariant mass squared of the edge, and γ is the effective width which is given by the widths of the

parent and the sibling branch. (Widths might be added in quadrature, but we do not require this level of precision.)

$$x = \frac{m^2 - m_{\min}^2}{\Delta m^2} \quad (11.29)$$

$$\mu = \frac{m_{\max, \text{eff}}^2 - m_{\min}^2}{\Delta m^2} \quad (11.30)$$

$$\gamma = \frac{2m_{\max, \text{eff}}\Gamma}{\Delta m^2} \quad (11.31)$$

with

$$\Delta m^2 = m_{\max}^2 - m_{\min}^2 \quad (11.32)$$

m^2 is thus given by

$$m^2(x) = xm_{\max}^2 + (1-x)m_{\min}^2 \quad (11.33)$$

For the mapping, we compute the integral $g(x)$ of the Fermi function, normalized such that $g(0) = 0$ and $g(1) = 1$. We introduce the abbreviations

$$\alpha = 1 - \gamma \ln \frac{1 + \beta e^{1/\gamma}}{1 + \beta} \quad (11.34)$$

$$\beta = e^{-\mu/\gamma} \quad (11.35)$$

and obtain

$$g(x) = \frac{1}{\alpha} \left(x - \gamma \ln \frac{1 + \beta e^{x/\gamma}}{1 + \beta} \right) \quad (11.36)$$

The actual mapping is the inverse function $h(y) = g^{-1}(y)$,

$$h(y) = -\gamma \ln \left(e^{-\alpha y/\gamma} (1 + \beta) - \beta \right) \quad (11.37)$$

The Jacobian is

$$\frac{dh}{dy} = \alpha \left(1 - e^{\alpha y/\gamma} \frac{\beta}{1 + \beta} \right)^{-1} \quad (11.38)$$

which is equal to $1/(dg/dx)$, namely

$$\frac{dg}{dx} = \frac{1}{\alpha} \frac{1}{1 + \beta e^{x/\gamma}} \quad (11.39)$$

The final result is

$$\int_{m_{\min}^2}^{m_{\max}^2} dm^2 F(m^2) = \Delta m^2 \int_0^1 dx F(m^2(x)) \quad (11.40)$$

$$= \Delta m^2 \int_0^1 dy F(m^2(h(y))) \frac{dh}{dy} \quad (11.41)$$

Here is the implementation. We fill **a1**, **a2**, **a3** with α, β, γ , respectively.

```

⟨Constants for exponential step mapping⟩≡
  if (map%variable_limits .or. map%a_unknown) then
    map%a3 = max (2 * map%mass * map%width / (msq_max - msq_min), 0.01_default)
    map%a2 = exp (- (map%mass**2 - msq_min) / (msq_max - msq_min) &
                  / map%a3)

  msq = z * msq_max + (1 - z) * msq_min
  f = map%a1 / (1 - map%a2 / tmp) * (msq_max - msq_min) / s

⟨Apply inverse exponential step mapping⟩≡
  z = (msq - msq_min) / (msq_max - msq_min)
  tmp = 1 + map%a2 * exp (z / map%a3)
  x = (z - map%a3 * log (tmp / (1 + map%a2))) &
    / map%a1
  f = map%a1 * tmp * (msq_max - msq_min) / s

```

Hyperbolic mapping

The Fermi function has the drawback that it decreases exponentially. It might be preferable to take a function with a power-law decrease, such that the high-mass region is not completely depopulated.

Here, we start with the actual mapping which we take as

$$h(y) = \frac{b}{a-y} - \frac{b}{a} + \mu y \quad (11.42)$$

with the abbreviation

$$a = \frac{1}{2} \left(1 + \sqrt{1 + \frac{4b}{1-\mu}} \right) \quad (11.43)$$

This is a hyperbola in the xy plane. The derivative is

$$\frac{dh}{dy} = \frac{b}{(a-y)^2} + \mu \quad (11.44)$$

The constants correspond to

$$\mu = \frac{m_{\text{max,eff}}^2 - m_{\text{min}}^2}{\Delta m^2} \quad (11.45)$$

$$b = \frac{1}{\mu} \left(\frac{2m_{\text{max,eff}}\Gamma}{\Delta m^2} \right)^2 \quad (11.46)$$

The inverse function is the solution of a quadratic equation,

$$g(x) = \frac{1}{2} \left[\left(a + \frac{x}{\mu} + \frac{b}{a\mu} \right) - \sqrt{\left(a - \frac{x}{\mu} \right)^2 + 2\frac{b}{a\mu} \left(a + \frac{x}{\mu} \right) + \left(\frac{b}{a\mu} \right)^2} \right] \quad (11.47)$$

The constants $a_{1,2,3}$ are identified with a, b, μ .

```

⟨Constants for hyperbolic step mapping⟩≡

  tmp = map%a2 / (map%a1 * map%a3)
  x = ((map%a1 + z / map%a3 + tmp) &
        - sqrt((map%a1 - z / map%a3)**2 + 2 * tmp * (map%a1 + z / map%a3) &
              + tmp**2)) / 2
  f = (map%a2 / (map%a1 - x)**2 + map%a3) * (msq_max - msq_min) / s

```

11.4.9 Mappings of the polar angle

The other type of singularity, a simple pole just outside the integration region, can occur in the integration over $\cos\theta$. This applies to exchange of massless (or light) particles.

Double poles (Coulomb scattering) are also possible, but only in certain cases. These are also handled by the single-pole mapping.

The mapping is analogous to the previous m^2 pole mapping, but with a different normalization and notation of variables:

$$\frac{1}{2} \int_{-1}^1 d\cos\theta g(\theta) = \int_0^1 dx \frac{d\cos\theta}{dx} g(\theta(x)) = \int_0^1 dx f(x) g(x), \quad (11.48)$$

where thus

$$f(x) = \frac{1}{2} \frac{d\cos\theta}{dx}. \quad (11.49)$$

With this mapping, a function of the form

$$g(\theta) = c \frac{dx(\cos\theta)}{d\cos\theta} \quad (11.50)$$

is mapped to a constant:

$$\int_{-1}^1 d\cos\theta g(\theta) = \int_0^1 dx f(x) g(\theta(x)) = \int_0^1 dx c. \quad (11.51)$$

```

```

Trivial mapping

This is just the mapping of the interval $(-1, 1)$ to $(0, 1)$:

$$\cos \theta = -1 + 2x \quad (11.52)$$

and

$$f(x) = 1 \quad (11.53)$$

with the inverse

$$x = \frac{1 + \cos \theta}{2} \quad (11.54)$$

```

<Apply trivial ct mapping>≡
    tmp = 2 * (1-x)
    ct = 1 - tmp
    st = sqrt (tmp * (2-tmp))
    f = 1

<Apply inverse trivial ct mapping>≡
    x = (ct + 1) / 2
    f = 1

```

Pole mapping

As above for m^2 , we simultaneously map poles at both ends of the $\cos \theta$ interval. The formulae are completely analogous:

$$\cos \theta = \begin{cases} \frac{M^2}{s} [\exp(xL) - 1] - 1 & \text{for } x < \frac{1}{2} \\ -\frac{M^2}{s} [\exp((1-x)L) - 1] + 1 & \text{for } x \geq \frac{1}{2} \end{cases} \quad (11.55)$$

where

$$L = 2 \ln \frac{M^2 + s}{M^2}. \quad (11.56)$$

Inverse:

$$x = \begin{cases} \frac{1}{2L} \ln \frac{1 + \cos \theta + M^2/s}{M^2/s} & \text{for } \cos \theta < 0 \\ 1 - \frac{1}{2L} \ln \frac{1 - \cos \theta + M^2/s}{M^2/s} & \text{for } \cos \theta \geq 0 \end{cases} \quad (11.57)$$

The phase-space factor:

$$f(x) = \begin{cases} \frac{M^2}{s} \exp(xL) L & \text{for } x < \frac{1}{2} \\ \frac{M^2}{s} \exp((1-x)L) L & \text{for } x \geq \frac{1}{2} \end{cases} \quad (11.58)$$

```

```

11.5 Phase-space trees

The phase space evaluation is organized in terms of trees, where each branch corresponds to three integrations: m^2 , $\cos\theta$, and ϕ . The complete tree thus makes up a specific parameterization of the multidimensional phase-space integral. For the multi-channel integration, the phase-space tree is a single channel.

The trees imply mappings of formal Feynman tree graphs into arrays of integer numbers: Each branch, corresponding to a particular line in the graph, is assigned an integer code c (with kind value $\text{TC} = \text{tree code}$).

In this integer, each bit determines whether a particular external momentum flows through the line. The external branches therefore have codes 1, 2, 4, 8, ... An internal branch has those bits ORed corresponding to the momenta flowing through it. For example, a branch with momentum $p_1 + p_4$ has code $2^0 + 2^3 = 1 + 8 = 9$.

There is a two-fold ambiguity: Momentum conservation implies that the branch with code

$$c_0 = \sum_{i=1}^{n(\text{ext})} 2^{i-1} \quad (11.59)$$

i.e. the branch with momentum $p_1 + p_2 + \dots p_n$ has momentum zero, which is equivalent to tree code 0 by definition. Correspondingly,

$$c \quad \text{and} \quad c_0 - c = c \text{ XOR } c_0 \quad (11.60)$$

are equivalent. E.g., if there are five externals with codes $c = 1, 2, 4, 8, 16$, then $c = 9$ and $\bar{c} = 31 - 9 = 22$ are equivalent.

This ambiguity may be used to assign a direction to the line: If all momenta are understood as outgoing, $c = 9$ in the example above means $p_1 + p_4$, but $c = 22$ means $p_2 + p_3 + p_5 = -(p_1 + p_4)$.

Here we make use of the ambiguity in a slightly different way. First, the initial particles are singled out as those externals with the highest bits, the IN-bits. (Here: 8 and 16 for a $2 \rightarrow 3$ scattering process, 16 only for a $1 \rightarrow 4$ decay.) Then we invert those codes where all IN-bits are set. For a decay process this maps each tree of an equivalence class onto a unique representative (that one with the smallest integer codes). For a scattering process we proceed further:

The ambiguity remains in all branches where only one IN-bit is set, including the initial particles. If there are only externals with this property, we have an s -channel graph which we leave as it is. In all other cases, an internal with only one IN-bit is a t -channel line, which for phase space integration should be associated with one of the initial momenta as a reference axis. We take that one whose bit is set in the current tree code. (E.g., for branch $c = 9$ we use the initial particle $c = 8$ as reference axis, whereas for the same branch we would take $c = 16$ if it had been assigned $\bar{c} = 31 - 9 = 22$ as tree code.) Thus, different ways of coding the same t -channel graph imply different phase space parameterizations.

s -channel graphs have a unique parameterization. The same sets of parameterizations are used for t -channel graphs, except for the reference frames of their angular parts. We map each t -channel graph onto an s -channel graph as follows:

Working in ascending order, for each t -channel line (whose code has exactly one IN-bit set) the attached initial line is flipped upstream, while the outgoing

line is flipped downstream. (This works only if t -channel graphs are always parameterized beginning at their outer vertices, which we require as a restriction.) After all possible flips have been applied, we have an s -channel graph. We only have to remember the initial particle a vertex was originally attached to.

11.5.2 The phase-space tree type

Definition

In the concrete implementation, each branch c may have two *daughters* c_1 and c_2 such that $c_1 + c_2 = c$, a *sibling* c_s and a *mother* c_m such that $c + c_s = c_m$, and a *friend* which is kept during flips, such that it can indicate a fixed reference frame. Absent entries are set $c = 0$.

First, declare the branch type. There is some need to have this public. Give initializations for all components, so no `init` routine is necessary. The branch has some information about the associated coordinates and about connections.

```

<PHS trees: types>+≡
type :: phs_branch_t
  private
  logical :: set = .false.
  logical :: inverted_decay = .false.
  logical :: inverted_axis = .false.
  integer(TC) :: mother = 0
  integer(TC) :: sibling = 0
  integer(TC) :: friend = 0
  integer(TC) :: origin = 0
  integer(TC), dimension(2) :: daughter = 0
  integer :: firstborn = 0

```

```

        logical :: has_children = .false.
        logical :: has_friend = .false.
    end type phs_branch_t

```

The tree type: No initialization, this is done by `phs_tree_init`. In addition to the branch array which

The branches are collected in an array which holds all possible branches, of which only a few are set. After flips have been applied, the branch $c_M = \sum_{i=1}^{n(\text{fin})} 2^{i-1}$ must be there, indicating the mother of all decay products. In addition, we should check for consistency at the beginning.

`n_branches` is the number of those actually set. `n externals` defines the number of significant bit, and `mask` is a code where all bits are set. Analogous: `n_in` and `mask_in` for the incoming particles.

The mapping array contains the mappings associated to the branches (corresponding indices). The array `mass_sum` contains the sum of the real masses of the external final-state particles associated to the branch. During phase-space evaluation, this determines the boundaries.

```

<PHS trees: public>+≡
    public :: phs_tree_t

<PHS trees: types>+≡
    type :: phs_tree_t
        private
        integer :: n_branches, n externals, n_in, n_msq, n_angles
        integer(TC) :: n_branches_tot, n_branches_out
        integer(TC) :: mask, mask_in, mask_out
        type(phs_branch_t), dimension(:), allocatable :: branch
        type(mapping_t), dimension(:), allocatable :: mapping
        real(default), dimension(:), allocatable :: mass_sum
        real(default), dimension(:), allocatable :: effective_mass
        real(default), dimension(:), allocatable :: effective_width
    end type phs_tree_t

```

The maximum number of external particles that can be represented is related to the bit size of the integer that stores binary codes. With the default integer of 32 bit on common machines, this is more than enough space. If TC is actually the default integer kind, there is no need to keep it separate, but doing so marks this as a special type of integer. So, just state that the maximum number is 32:

```

<Limits: public parameters>+≡
    integer, parameter, public :: MAX_EXTERNAL = 32

```

Constructor and destructor

Allocate memory for a phase-space tree with given number of externals and incoming. The number of allocated branches can easily become large, but appears manageable for realistic cases, e.g., for `n_in=2` and `n_out=8` we get $2^{10} - 1 = 1023$.

```

<PHS trees: public>+≡
    public :: phs_tree_init
    public :: phs_tree_final

```

Here we set the masks for incoming and for all externals.

```

<PHS trees: procedures>+≡
  elemental subroutine phs_tree_init (tree, n_in, n_out, n_masses, n_angles)
    type(phs_tree_t), intent(inout) :: tree
    integer, intent(in) :: n_in, n_out, n_masses, n_angles
    integer(TC) :: i
    tree%n_externals = n_in + n_out
    tree%n_branches_tot = 2**(n_in+n_out) - 1
    tree%n_branches_out = 2**n_out - 1
    tree%mask = 0

```

11.5.3 PHS tree setup

Transformation into an array of branch codes and back

Assume that the tree/array has been created before with the appropriate length and is empty.

```

<PHS trees: public>+≡
    public :: phs_tree_from_array

<PHS trees: procedures>+≡
    subroutine phs_tree_from_array (tree, a)
        type(phs_tree_t), intent(inout) :: tree
        integer(TC), dimension(:), intent(in) :: a
        integer :: i
        integer(TC) :: k
        <Set branches from array a>
        <Set external branches if necessary>
        <Check number of branches>
        <Determine the connections>
    contains
        <Subroutine: set relatives>
    end subroutine phs_tree_from_array

```

First, set all branches specified by the user. If all IN-bits are set, we invert the branch code.

```

<Set branches from array a>≡
    do i=1, size(a)
        k = a(i)
        if (iand(k, tree%mask_in) == tree%mask_in) k = ieor(tree%mask, k)
        tree%branch(k)%set = .true.
        tree%n_branches = tree%n_branches+1
    end do

```

The external branches are understood, so set them now if not yet done. In all cases ensure that the representative with one bit set is used, except for decays where the in-particle is represented by all OUT-bits set instead.

```

<Set external branches if necessary>≡
do i=0, tree%n_externals-1
  k = ibset(0,i)
  if (iand(k, tree%mask_in) == tree%mask_in) k = ieor(tree%mask, k)
  if (tree%branch(ieor(tree%mask, k))%set) then
    tree%branch(ieor(tree%mask, k))%set = .false.
    tree%branch(k)%set = .true.
  else if (.not.tree%branch(k)%set) then
    tree%branch(k)%set = .true.
    tree%n_branches = tree%n_branches+1
  end if
end do

```

Now the number of branches set can be checked. Here we assume that the tree is binary. For three externals there are three branches in total, and for each additional external branch we get another internal one.

```

<Check number of branches>≡
if (tree%n_branches /= tree%n_externals*2-3) then
  call phs_tree_write (tree)
  call msg_bug &
    & (" Wrong number of branches set in phase space tree")
end if

```

For all branches that are set, except for the externals, we try to find the daughter branches:

```

<Determine the connections>≡
do k=1, size (tree%branch)
  if (tree%branch(k)%set .and. tc_decay_level (k) /= 1) then
    call branch_set_relatives(k)
  end if
end do

```

To this end, we scan all codes less than the current code, whether we can find two branches which are set and which together give the current code. After that, the tree may still not be connected, but at least we know if a branch does not have daughters: This indicates some inconsistency.

The algorithm ensures that, at this stage, the first daughter has a smaller code value than the second one.

```

<Subroutine: set relatives>≡
subroutine branch_set_relatives (k)
  integer(TC), intent(in) :: k
  integer(TC) :: m,n
  do m=1, k-1
    if(iand(k,m)==m) then
      n = ieor(k,m)
      if ( tree%branch(m)%set .and. tree%branch(n)%set ) then
        tree%branch(k)%daughter(1) = m; tree%branch(k)%daughter(2) = n
        tree%branch(m)%mother      = k; tree%branch(n)%mother      = k
        tree%branch(m)%sibling      = n; tree%branch(n)%sibling      = m
        tree%branch(k)%has_children = .true.
      return
    end if
  end do
end subroutine

```

```

        end if
    end if
end do
call phs_tree_write (tree)
call msg_bug &
    & (" Missing daughter branch(es) in phase space tree")
end subroutine branch_set_relatives

```

The inverse: this is trivial, fortunately.

Flip t -channel into s -channel

Flipping the tree is done upwards, beginning from the decay products. First we select a t -channel branch k : one which is set, which does have an IN-bit, and which is not an external particle.

Next, we determine the adjacent in-particle (called the 'friend' f here, since it will provide the reference axis for the angular integration). In addition, we look for the 'mother' and 'sibling' of this particle. If the latter field is empty, we select the (unique) other out-particle which has no mother, calling the internal subroutine `find_orphan`.

The flip is done as follows: We assume that the first daughter d is an s -channel line, which is true if the daughters are sorted. This will stay the first daughter. The second one is a t -channel line; it is exchanged with the 'sibling' s . The new line which replaces the branch k is just the sum of s and d . In addition, we have to rearrange the relatives of s and d , as well of f .

Finally, we flip 'sibling' and 'friend' and set the new s -channel branch n which replaces the t -channel branch k . After this is complete, we are ready to execute another flip.

[Although the friend is not needed for the final flip, since it would be an initial particle anyway, we need to know whether we have t - or u -channel.]

(PHS trees: public)+≡

```
public :: phs_tree_flip_t_to_s_channel
```

(PHS trees: procedures)+≡

```

subroutine phs_tree_flip_t_to_s_channel (tree)
    type(phs_tree_t), intent(inout) :: tree
    integer(TC) :: k, f, m, n, d, s
    if (tree%n_in == 2) then
        FLIP: do k=3, tree%mask-1
            if (.not. tree%branch(k)%set) cycle FLIP
            f = iand(k,tree%mask_in)
            if (f==0 .or. f==k) cycle FLIP
            m = tree%branch(k)%mother
            s = tree%branch(k)%sibling
            if (s==0) call find_orphan(s)
            d = tree%branch(k)%daughter(1)
            n = ior(d,s)
            tree%branch(k)%set = .false.
            tree%branch(n)%set = .true.
            tree%branch(n)%origin = k
            tree%branch(n)%daughter(1) = d; tree%branch(d)%mother = n
            tree%branch(n)%daughter(2) = s; tree%branch(s)%mother = n
        end do
    end if
end subroutine

```

```

        tree%branch(n)%has_children = .true.
        tree%branch(d)%sibling = s; tree%branch(s)%sibling = d

end subroutine phs_tree_flip_t_to_s_channel

```

After the tree has been flipped, one may need to determine what has become of a particular t -channel branch. This function gives the bincode of the flipped tree. If the original bincode does not contain IN-bits, we leave it as it is.

(PHS trees: procedures)+≡

```

function tc_flipped (tree, kt) result (ks)
    type(phs_tree_t), intent(in) :: tree
    integer(TC), intent(in) :: kt
    integer(TC) :: ks
    if (iand (kt, tree%mask_in) == 0) then
        ks = kt
    else
        ks = tree%branch(iand (kt, tree%mask_out))%mother
    end if
end function tc_flipped

```

Scan a tree and make sure that the first daughter has always a smaller code than the second one. Furthermore, delete any `friend` entry in the root branch – this branching has the incoming particle direction as axis anyway. Keep track of reordering by updating `inverted_axis`, `inverted_decay` and `firstborn`.

    type(mapping_t), intent(out) :: mapping
    mapping = tree%mapping(tree%mask_out)
  end subroutine phs_tree_assign_s_mapping

```

Kinematics

Fill the mass sum array, starting from the external particles and working down to the tree root. For each bincode k we scan the bits in k ; if only one is set, we take the physical mass of the corresponding external particle; if more than one is set, we sum up the two masses (which we know have already been set).

```

<PHS trees: public>+≡
  public :: phs_tree_set_mass_sum

<PHS trees: procedures>+≡
  subroutine phs_tree_set_mass_sum (tree, flv)
    type(phs_tree_t), intent(inout) :: tree
    type(flavor_t), dimension(:), intent(in) :: flv

              tree%mass_sum(ibclr(k,i)) + tree%mass_sum(ibset(0,i))
          end if
        end if
      end do
    end do
  end subroutine phs_tree_set_mass_sum

```

```

        end do
    end do
end subroutine phs_tree_set_mass_sum

```

Set the effective masses and widths. For each non-resonant branch in a tree, the effective mass is equal to the sum of the effective masses of the children (and analogous for the width). External particles have their real mass and width zero. For resonant branches, we insert mass and width from the corresponding mapping.

This routine has `phs_tree_set_mass_sum` and `phs_tree_set_mapping_parameters` as prerequisites.

(PHS trees: public)+≡

```

public :: phs_tree_set_effective_masses

```

(PHS trees: procedures)+≡

```

        end if
    end subroutine set_masses_x
end subroutine phs_tree_set_effective_masses

```

Define step mappings, recursively, for the decay products of all intermediate resonances. Step mappings account for the fact that a branch may originate from a resonance, which almost replaces the upper limit on the possible invariant mass. The step mapping implements a smooth cutoff that interpolates between the resonance and the real kinematic limit. The mapping width determines the sharpness of the cutoff.

Step mappings are inserted only for branches that are not mapped otherwise.

At each branch, we record the mass that is effectively available for phase space, by taking the previous limit and subtracting the effective mass of the sibling branch. Widths are added, not subtracted.

If we encounter a resonance decay, we discard the previous limit and replace it by the mass and width of the resonance, also subtracting the sibling branch.

Initially, the limit is zero, so it becomes negative at any branch. Only if there is a resonance, the limit becomes positive. Whenever the limit is positive, and the current branch decays, we activate a step mapping for the current branch.

As a result, step mappings are implemented for all internal lines that originate from an intermediate resonance decay.

The flag `variable_limits` applies to the ultimate limit from the available energy, not to the intermediate resonances whose masses are always fixed.

This routine requires `phs_tree_set_effective_masses`

```

Structural comparison

This function allows to check whether one tree is the permutation of another one. The permutation is applied to the second tree in the argument list. We do not make up a temporary permuted tree, but compare the two trees directly. The branches are scanned recursively, where for each daughter we check the friend and the mapping as well. Once a discrepancy is found, the recursion is exited immediately.

```

Determine momenta

This is done in two steps: First the masses are determined. This step may fail, in which case `ok` is set to `false`. If successful, we generate angles and the actual momenta. The array `decay_p` serves for transferring the individual three-momenta of the daughter particles in their mother rest frame from the mass generation to the momentum generation step.

```

<PHS trees: public>+≡
    public :: phs_tree_compute_momenta_from_x

<PHS trees: procedures>+≡
    subroutine phs_tree_compute_momenta_from_x &
        (tree, prt, factor, volume, sqrts, x, ok)
        type(phs_tree_t), intent(inout) :: tree
        type(phs_prt_t), dimension(:), intent(inout) :: prt

    end subroutine phs_tree_compute_momenta_from_x

```

Mass generation is done recursively. The `ok` flag causes the filled tree to be discarded if set to `.false.`. This happens if a three-momentum turns out to be imaginary, indicating impossible kinematics. The index `ix` tells us how far we have used up the input array `x`.

```

The heart of phase space generation: Now we have the invariant masses, let us generate angles. At each branch, we take a Lorentz transformation and augment it by a boost to the current particle rest frame, and by rotations ϕ and θ around the z and y axis, respectively. This transformation is passed down to the daughter particles, if present.

```

This subroutine is the most time-critical part of the whole program. Therefore, we do not exactly parallel the angle generation routine above but make sure that things get evaluated only if they are really needed, at the expense of readability. Particularly important is to have as few multiplications of Lorentz transformations as possible.

11.6 The phase-space forest

Simply stated, a phase-space forest is a collection of phase-space trees. More precisely, a `phs_forest` object contains all parameterizations of phase space that `WHIZARD` will use for a single hard process, prepared in the form of `phs_tree` objects. This is suitable for evaluation by the `VAMP` integration package: each parameterization (tree) is a valid channel in the multi-channel adaptive integration, and each variable in a tree corresponds to an integration dimension, defined by an appropriate mapping of the $(0, 1)$ interval to the allowed range of the integration variable.

The trees are grouped in groves. The trees (integration channels) within a grove share a common weight, assuming that they are related by some approximate symmetry.

Trees/channels that are related by an exact symmetry are connected by an array of equivalences; each equivalence object holds the data that relate one channel to another.

The phase-space setup, i.e., the detailed structure of trees and forest, are read from a file. Therefore, this module also contains the syntax definition and the parser needed for interpreting this file.

11.6.1 Phase-space setup parameters

This transparent container holds the parameters that the algorithm needs for phase-space setup, with reasonable defaults.

The threshold mass (for considering a particle as effectively massless) is specified separately for s- and t-channel. The default is to treat W and Z bosons as massive in the s-channel, but as massless in the t-channel. The b -quark is treated always massless, the t -quark always massive.

```
⟨PHS forests: public⟩≡
```

```
public :: phs_parameters_t
```

```
⟨PHS forests: types⟩≡
```

```
type :: phs_parameters_t

```

11.6.2 Equivalences

This type holds information about equivalences between phase-space trees. We make a linked list, where each node contains the two trees which are equivalent and the corresponding permutation of external particles. Two more arrays are

to be filled: The permutation of mass variables and the permutation of angular variables, where the signature indicates a necessary exchange of daughter branches.

```

(PHS forests: types)+≡
  type :: equivalence_t
  private
    integer :: left, right
    type(permutation_t) :: perm
    type(permutation_t) :: msq_perm, angle_perm
    logical, dimension(:), allocatable :: angle_sig
    type(equivalence_t), pointer :: next => null ()
  end type equivalence_t

```

```

(PHS forests: types)+≡
  type :: equivalence_list_t
  private
    integer :: length = 0
    type(equivalence_t), pointer :: first => null ()
    type(equivalence_t), pointer :: last => null ()
  end type equivalence_list_t

```

Append an equivalence to the list

```

(PHS forests: procedures)+≡
  subroutine equivalence_list_add (eql, left, right, perm)
    type(equivalence_list_t), intent(inout) :: eql
    integer, intent(in) :: left, right
    type(permutation_t), intent(in) :: perm
    type(equivalence_t), pointer :: eq
    allocate (eq)
    eq%left = left
    eq%right = right
    eq%perm = perm
    if (associated (eql%last)) then

    else
      write (u, "(1x,A)", advance="no") "-"
    end if
  end do
  write (u, *)
  if (associated (eq%next)) call equivalence_write_rec (eq%next, u)
end subroutine equivalence_write_rec
end subroutine equivalence_list_write

```

11.6.3 Groves

A grove is a group of trees (phase-space channels) that share a common weight in the integration. Within a grove, channels can be declared equivalent, so they also share their integration grids (up to symmetries). The grove contains a list of equivalences. The `tree_count_offset` is the total number of trees of the preceding groves; when the trees are counted per forest (integration channels), the offset has to be added to all tree indices.

```

<PHS forests: types>+≡
  type :: phs_grove_t
  private
  integer :: tree_count_offset
  type(phs_tree_t), dimension(:), allocatable :: tree
  type(equivalence_list_t) :: equivalence_list
end type phs_grove_t

```

Call `phs_tree_init` which is also elemental:

```

<PHS forests: procedures>+≡
  elemental subroutine phs_grove_init &
    (grove, n_trees, n_in, n_out, n_masses, n_angles)
  type(phs_grove_t), intent(inout) :: grove
  integer, intent(in) :: n_trees, n_in, n_out, n_masses, n_angles
  grove%tree_count_offset = 0
  allocate (grove%tree (n_trees))
  call phs_tree_init (grove%tree, n_in, n_out, n_masses, n_angles)

```

```
end subroutine phs_grove_init
```

The trees do not have pointer components, thus no call to `phs_tree_final`:

```
(PHS forests: procedures)+≡
  elemental subroutine phs_grove_final (grove)
    type(phs_grove_t), intent(inout) :: grove
    deallocate (grove%tree)
    call equivalence_list_final (grove%equivalence_list)
  end subroutine phs_grove_final
```

Deep copy.

```
(PHS forests: interfaces)+≡
  interface assignment(=)
    module procedure phs_grove_assign0
    module procedure phs_grove_assign1
  end interface

(PHS forests: procedures)+≡
  subroutine phs_grove_assign0 (grove_out, grove_in)
    type(phs_grove_t), intent(out) :: grove_out
    type(phs_grove_t), intent(in) :: grove_in
    grove_out%tree_count_offset = grove_in%tree_count_offset
    if (allocated (grove_in%tree)) then
      allocate (grove_out%tree (size (grove_in%tree)))
      grove_out%tree = grove_in%tree
    end if
    grove_out%equivalence_list = grove_in%equivalence_list
  end subroutine phs_grove_assign0

  subroutine phs_grove_assign1 (grove_out, grove_in)
    type(phs_grove_t), dimension(:), intent(out) :: grove_out
    type(phs_grove_t), dimension(:), intent(in) :: grove_in
    integer :: i
    do i = 1, size (grove_in)
      call phs_grove_assign0 (grove_out(i), grove_in(i))
    end do
  end subroutine phs_grove_assign1
```

Get the global (s-channel) mappings. Implemented as a subroutine which returns an array (slice).

```
(PHS forests: procedures)+≡
  subroutine phs_grove_assign_s_mappings (grove, mapping)
    type(phs_grove_t), intent(in) :: grove
    type(mapping_t), dimension(:), intent(out) :: mapping
    integer :: i
    if (size (mapping) == size (grove%tree)) then
      do i = 1, size (mapping)
        call phs_tree_assign_s_mapping (grove%tree(i), mapping(i))
      end do
    else
      call msg_bug ("phs_grove_assign_s_mappings: array size mismatch")
    end if
```

```
end subroutine phs_grove_assign_s_mappings
```

11.6.4 The forest type

This is a collection of trees and associated particles. In a given tree, each branch code corresponds to a particle in the `prt` array. Furthermore, we have an array of mass sums which is independent of the decay tree and of the particular event. The mappings directly correspond to the decay trees, and the decay groves collect the trees in classes. The permutation list consists of all permutations of outgoing particles that map the decay forest onto itself.

The particle codes `flv` (one for each external particle) are needed for determining masses and such. The trees and associated information are collected in the `grove` array, together with a lookup table that associates tree indices to groves. Finally, the `prt` array serves as workspace for phase-space evaluation.

The `prt_combination` is a list of index pairs, namely the particle momenta pairs that need to be combined in order to provide all momentum combinations that the phase-space trees need to know.

```
<PHS forests: public>+≡
  public :: phs_forest_t

<PHS forests: types>+≡
  type :: phs_forest_t
    private
    integer :: n_in, n_out, n_tot
    integer :: n_masses, n_angles, n_dimensions
    integer :: n_trees, n_equivalences
    type(flavor_t), dimension(:), allocatable :: flv
    type(phs_grove_t), dimension(:), allocatable :: grove
    integer, dimension(:), allocatable :: grove_lookup
    type(phs_prt_t), dimension(:), allocatable :: prt_in
    type(phs_prt_t), dimension(:), allocatable :: prt_out
    type(phs_prt_t), dimension(:), allocatable :: prt
    integer(TC), dimension(:,:), allocatable :: prt_combination
    type(mapping_t), dimension(:), allocatable :: s_mapping
  contains
    <PHS forests: phs forest: TBP>
  end type phs_forest_t
```

The initialization merely allocates memory. We have to know how many trees there are in each grove, so we can initialize everything. The number of groves is the size of the `n_tree` array.

In the `grove_lookup` table we store the grove index that belongs to each absolute tree index. The difference between the absolute index and the relative (to the grove) index is stored, for each grove, as `tree_count_offset`.

The particle array is allocated according to the total number of branches each tree has, but not filled.

```
<PHS forests: public>+≡
  public :: phs_forest_init
```

(PHS forests: procedures)+≡

```

subroutine phs_forest_init (forest, n_tree, n_in, n_out)
  type(phs_forest_t), intent(inout) :: forest
  integer, dimension(:), intent(in) :: n_tree
  integer, intent(in) :: n_in, n_out
  integer :: g, count, k_root
  forest%n_in = n_in
  forest%n_out = n_out
  forest%n_tot = n_in + n_out
  forest%n_masses = max (n_out - 2, 0)
  forest%n_angles = max (2*n_out - 2, 0)
  forest%n_dimensions = forest%n_masses + forest%n_angles
  forest%n_trees = sum (n_tree)
  forest%n_equivalences = 0
  allocate (forest%grove (size (n_tree)))
  call phs_grove_init &
    (forest%grove, n_tree, n_in, n_out, forest%n_masses, forest%n_angles)
  allocate (forest%grove_lookup (forest%n_trees))
  count = 0
  do g = 1, size (forest%grove)
    forest%grove(g)%tree_count_offset = count
    forest%grove_lookup (count+1:count+n_tree(g)) = g
    count = count + n_tree(g)
  end do
  allocate (forest%prt_in (n_in))
  allocate (forest%prt_out (n_out))
  k_root = 2**forest%n_tot - 1
  allocate (forest%prt (k_root))
  allocate (forest%prt_combination (2, k_root))
  allocate (forest%s_mapping (forest%n_trees))
end subroutine phs_forest_init

```

Assign the global (s-channel) mappings.

(PHS forests: public)+≡

```

public :: phs_forest_set_s_mappings

```

(PHS forests: procedures)+≡

```

subroutine phs_forest_set_s_mappings (forest)
  type(phs_forest_t), intent(inout) :: forest
  integer :: g, i0, i1, n
  do g = 1, size (forest%grove)
    call phs_forest_get_grove_bounds (forest, g, i0, i1, n)
    call phs_grove_assign_s_mappings &
      (forest%grove(g), forest%s_mapping(i0:i1))
  end do
end subroutine phs_forest_set_s_mappings

```

The grove finalizer is called because it contains the equivalence list:

(PHS forests: public)+≡

```

public :: phs_forest_final

```

(PHS forests: procedures)+≡

```

subroutine phs_forest_final (forest)
  type(phs_forest_t), intent(inout) :: forest

```

```

    if (allocated (forest%grove)) then
        call phs_grove_final (forest%grove)
        deallocate (forest%grove)
    end if
    if (allocated (forest%grove_lookup)) deallocate (forest%grove_lookup)
    if (allocated (forest%prt)) deallocate (forest%prt)
    if (allocated (forest%s_mapping)) deallocate (forest%s_mapping)
end subroutine phs_forest_final

```

11.6.5 Screen output

Write the particles that are non-null, then the trees which point to them:

```

<PHS forests: public>+=
    public :: phs_forest_write

11.6.7 Read the phase space setup from file

The phase space setup is stored in a file. The file may be generated by the `cascades` module below, or by other means. This file has to be read and parsed to create the PHS forest as the internal phase-space representation.

Create lexer and syntax:

```

<PHS forests: procedures>+≡
subroutine define_phs_forest_syntax (ifile)
    type(ifile_t) :: ifile
    call ifile_append (ifile, "SEQ phase_space_list = process_phase_space*")
    call ifile_append (ifile, "SEQ process_phase_space = " &
        // "process_def process_header phase_space")
    call ifile_append (ifile, "SEQ process_def = process process_list")
    call ifile_append (ifile, "KEY process")
    call ifile_append (ifile, "LIS process_list = process_tag*")
    call ifile_append (ifile, "IDE process_tag")
    call ifile_append (ifile, "SEQ process_header = " &
        // "md5sum_process = md5sum " &
        // "md5sum_model_par = md5sum " &
        // "md5sum_phs_config = md5sum " &
        // "sqrts = real " &
        // "m_threshold_s = real " &
        // "m_threshold_t = real " &
        // "off_shell = integer " &
        // "t_channel = integer " &
        // "keep_nonresonant = logical")
    call ifile_append (ifile, "KEY '='")
    call ifile_append (ifile, "KEY md5sum_process")
    call ifile_append (ifile, "KEY md5sum_model_par")
    call ifile_append (ifile, "KEY md5sum_phs_config")
    call ifile_append (ifile, "KEY sqrts")
    call ifile_append (ifile, "KEY m_threshold_s")
    call ifile_append (ifile, "KEY m_threshold_t")
    call ifile_append (ifile, "KEY off_shell")
    call ifile_append (ifile, "KEY t_channel")
    call ifile_append (ifile, "KEY keep_nonresonant")
    call ifile_append (ifile, "QUO md5sum = '""' ... '""'")
    call ifile_append (ifile, "REA real")
    call ifile_append (ifile, "INT integer")
    call ifile_append (ifile, "IDE logical")
    call ifile_append (ifile, "SEQ phase_space = grove_def+")

```

```

call ifile_append (ifile, "SEQ grove_def = grove tree_def+")
call ifile_append (ifile, "KEY grove")
call ifile_append (ifile, "SEQ tree_def = tree bincodes mapping*")
call ifile_append (ifile, "KEY tree")
call ifile_append (ifile, "SEQ bincodes = bincodes+")
call ifile_append (ifile, "INT bincodes")
call ifile_append (ifile, "SEQ mapping = map bincodes channel pdg")
call ifile_append (ifile, "KEY map")
call ifile_append (ifile, "ALT channel = s_channel | t_channel | u_channel | collinear | infrared")
call ifile_append (ifile, "KEY s_channel")
! call ifile_append (ifile, "KEY t_channel")
call ifile_append (ifile, "KEY u_channel")
call ifile_append (ifile, "KEY collinear")
call ifile_append (ifile, "KEY infrared")
call ifile_append (ifile, "KEY radiation")
call ifile_append (ifile, "INT pdg")
end subroutine define_phs_forest_syntax

```

The model-file syntax and lexer are fixed, therefore stored as module variables:

```

<PHS forests: variables>≡
  type(syntax_t), target, save :: syntax_phs_forest

        integer, intent(in), optional :: unit
        call syntax_write (syntax_phs_forest, unit)
    end subroutine syntax_phs_forest_write

```

The concrete parser and interpreter. Generate an input stream for the external `unit`, read the parse tree (with given `syntax` and `lexer`) from this stream, and transfer the contents of the parse tree to the PHS forest.

We look for the matching `process` tag, count groves and trees for initializing the `forest`, and fill the trees.

If the optional parameters are set, compare the parameters stored in the file to those. Set `match` true if everything agrees.

```

(PHS forests: public)+≡
    public :: phs_forest_read

```

11.6.8 Preparation

The trees that we read from file do not carry flavor information. This is set separately:

The flavor list must be unique for a unique set of masses; if a given particle can have different flavor, the mass must be degenerate, so we can choose one of the possible flavor combinations.

```

<PHS forests: public>+≡
public :: phs_forest_set_flavors

<PHS forests: procedures>+≡
subroutine phs_forest_set_flavors (forest, flv)
type(phs_forest_t), intent(inout) :: forest
type(flavor_t), dimension(:), intent(in) :: flv
allocate (forest%flv (size (flv)))
forest%flv = flv
end subroutine phs_forest_set_flavors

```

Once the parameter set is fixed, the masses and the widths of the particles are known and the `mass_sum` arrays as well as the mapping parameters can be computed. Note that order is important: we first compute the mass sums, then the ordinary mappings. The resonances obtained here determine the effective masses, which in turn are used to implement step mappings for resonance decay products that are not mapped otherwise.

```

<PHS forests: public>+≡

end subroutine phs_forest_set_parameters

```

Generate the particle combination table. Scan all trees and merge their individual combination tables. At the end, valid entries are non-zero, and they indicate the indices of a pair of particles to be combined to a new particle. If a particle is accessible by more than one tree (this is usual), only keep the first possibility.

```

11.6.10 Find equivalences among phase-space trees

Scan phase space for equivalences. We generate the complete set of unique permutations for the given list of outgoing particles, and use this for scanning equivalences within each grove. We scan all pairs of trees, using all permutations. This implies that trivial equivalences are included, and equivalences between different trees are recorded twice. This is intentional.

(PHS forests: procedures)+≡

```

end do
end do
end subroutine phs_forest_get_equivalences

```

Obsolete:

Transform the equivalence lists into a `vamp_equivalence_list` object. The additional information that we need is: the number of extra integration dimensions (associated to structure functions), which ones of those correspond to external event generators (so that the binning must not be adapted), and whether there is any dependence on the first azimuthal angle (so its binning may be adapted or fixed).

The permutations of masses and angles are translated into permutations of integration dimensions, where the correct mapping modes are important: `msq` values are always mapped 1:1 while azimuthal angles may need an offset by 1/2 and polar angles may need an inversion. The first azimuthal angle should not be adapted to since the dependence of the matrix element is (usually) trivial.

11.7 Finding phase space parameterizations

If the phase space configuration is not found in the appropriate file, we should generate one.

The idea is to construct all Feynman diagrams subject to certain constraints which eliminate everything that is probably irrelevant for the integration. These Feynman diagrams (cascades) are grouped in groves by finding equivalence classes related by symmetry and ordered with respect to their importance (resonances). Finally, the result (or part of it) is written to file and used for the integration.

This module may eventually disappear and be replaced by CAML code. In particular, we need here a set of Feynman rules (vertices with particle codes, but not the factors). Thus, the module works for the Standard Model only.

Note that this module is stand-alone, it communicates to the main program only via the generated ASCII phase-space configuration file.

```

<cascades.f90>≡
  <File header>

  module cascades

    <Use kinds>
    use kinds, only: TC, i8, i32 !NODEP!

```

11.7.1 The mapping modes

The valid mapping modes, to be used below. We will make use of the convention that mappings of internal particles have a positive value. Only for positive values, the flavor code is propagated when combining cascades.

```
<Mapping modes>≡
  integer, parameter :: &
    & EXTERNAL_PRT = -1, &
    & NO_MAPPING = 0, S_CHANNEL = 1, T_CHANNEL = 2, U_CHANNEL = 3, &
    & RADIATION = 4, COLLINEAR = 5, INFRARED = 6, &
    & STEP_MAPPING_E = 11, STEP_MAPPING_H = 12

<Cascades: parameters>≡
  <Mapping modes>
```

11.7.2 The cascade type

A cascade is essentially the same as a decay tree (both definitions may be merged in a later version). It contains a linked tree of nodes, each of which representing an internal particle. In contrast to decay trees, each node has a definite particle code. These nodes need not be modified, therefore we can use pointers and do not have to copy them. Thus, physically each cascades has only a single node, the mother particle. However, to be able to compare trees quickly, we store in addition an array of binary codes which is always sorted in ascending order. This is accompanied by a corresponding list of particle codes. The index is the location of the corresponding cascade in the cascade set, this may be used to access the daughters directly.

The real mass is the particle mass belonging to the particle code. The minimal mass is the sum of the real masses of all its daughters; this is the kinematical cutoff. The effective mass may be zero if the particle mass is below a certain threshold; it may be the real mass if the particle is resonant; or it may be some other value.

The logical `t_channel` is set if this a *t*-channel line, while `initial` is true only for an initial particle. Note that both initial particles are also `t_channel` by definition, and that they are distinguished by the direction of the tree: One of them decays and is the root of the tree, while the other one is one of the leaves.

The cascade is a list of nodes (particles) which are linked via the `daughter` entries. The node is the mother particle of the decay cascade. Much of the information in the nodes is repeated in arrays, to be accessible more easily. The arrays will be kept sorted by binary codes.

The counter `n_off_shell` is increased for each internal line that is neither resonant nor log-enhanced. It is set to zero if the current line is resonant, since this implies on-shell particle production and subsequent decay.

The counter `n_t_channel` is non-negative once an initial particle is included in the tree: then, it counts the number of t -channel lines.

The `multiplicity` is the number of branchings to follow until all daughters are on-shell. A resonant or non-decaying particle has multiplicity one. Merging nodes, the multiplicities add unless the mother is a resonance. An initial or final node has multiplicity zero.

The arrays correspond to the subnode tree `tree` of the current cascade. PDG codes are stored only for those positions which are resonant, with the exception of the last entry, i.e., the current node. Other positions, in particular external legs, are assigned undefined PDG code.

A cascade is uniquely identified by its tree, the tree of PDG codes, and the tree of mappings. The tree of resonances is kept only to mask the PDG tree as described above.

$\langle \text{Cascades: types} \rangle \equiv$

```

11.7.3 Creating new cascades

This initializes a single-particle cascade (external, final state). The PDG entry in the tree is set undefined because the cascade is not resonant. However, the flavor entry is set, so the cascade flavor is identified nevertheless.

(Cascades: procedures)+≡

```

subroutine cascade_init_outgoing (cascade, flv, pos, m_thr)
    type(cascade_t), intent(out) :: cascade
    type(flavor_t), intent(in) :: flv
    integer, intent(in) :: pos
    real(default), intent(in) :: m_thr
    call cascade_init (cascade, 1)
    cascade%bincode = ibset (0_TC, pos-1)
    cascade%flv = flv
    cascade%pdg = abs (flavor_get_pdg (cascade%flv))
    cascade%is_vector = flavor_get_spin_type (flv) == VECTOR
    cascade%m_min = flavor_get_mass (flv)
    cascade%m_rea = cascade%m_min
    if (cascade%m_rea >= m_thr) then
        cascade%m_eff = cascade%m_rea
    end if
    cascade%on_shell = .true.
    cascade%multiplicity = 1
    cascade%tree(1) = cascade%bincode
    cascade%tree_pdg(1) = cascade%pdg

```

```

        cascade%tree_mapping(1) = EXTERNAL_PRT
        cascade%tree_resonant(1) = .false.
    end subroutine cascade_init_outgoing

```

The same for an incoming line:

```

<Cascades: procedures>+=
    subroutine cascade_init_incoming (cascade, flv, pos, m_thr)
        type(cascade_t), intent(out) :: cascade
        type(flavor_t), intent(in) :: flv
        integer, intent(in) :: pos
        real(default), intent(in) :: m_thr
        call cascade_init (cascade, 1)
        cascade%incoming = .true.
        cascade%bincode = ibset (0_TC, pos-1)
        cascade%flv = flavor_anti (flv)
        cascade%pdg = abs (flavor_get_pdg (flv))
        cascade%is_vector = flavor_get_spin_type (flv) == VECTOR
        cascade%m_min = flavor_get_mass (flv)
        cascade%m_rea = cascade%m_min
        if (cascade%m_rea >= m_thr) then
            cascade%m_eff = cascade%m_rea
        end if
        cascade%on_shell = .true.
        cascade%n_t_channel = 0
        cascade%n_off_shell = 0
        cascade%tree(1) = cascade%bincode
        cascade%tree_pdg(1) = cascade%pdg
        cascade%tree_mapping(1) = EXTERNAL_PRT
        cascade%tree_resonant(1) = .false.
    end subroutine cascade_init_incoming

```

11.7.4 Tools

This function returns true if the two cascades share no common external particle. This is a requirement for joining them.

```

<Cascades: interfaces>=
    interface operator(.disjunct.)
        module procedure cascade_disjunct
    end interface

<Cascades: procedures>+=
    function cascade_disjunct (cascade1, cascade2) result (flag)
        logical :: flag
        type(cascade_t), intent(in) :: cascade1, cascade2
        flag = iand (cascade1%bincode, cascade2%bincode) == 0
    end function cascade_disjunct

```

Compute a hash code for the resonance pattern of a cascade. We count the number of times each particle appears as a resonance.

We pack the PDG codes of the resonances in two arrays (s-channel and t-channel), sort them both, concatenate the results, transfer to i8 integers, and compute the hash code from this byte stream.

```

<Cascades: procedures>+=
  subroutine cascade_assign_resonance_hash (cascade)
    type(cascade_t), intent(inout) :: cascade
    integer(i8), dimension(1) :: mold
    cascade%res_hash = hash (transfer &
      (concat (sort (pack (cascade%tree_pdg, &
        cascade%tree_resonant)), &
        sort (pack (cascade%tree_pdg, &
          cascade%tree_mapping == T_CHANNEL .or. &
          cascade%tree_mapping == U_CHANNEL))), &
        mold))
  end subroutine cascade_assign_resonance_hash

```

11.7.5 Hash entries for cascades

We will set up a hash array which contains keys of and pointers to cascades. We hold a list of cascade (pointers) within each bucket. This is not for collision resolution, but for keeping similar, but unequal cascades together.

```

<Cascades: types>+=
  type :: cascade_p
    type(cascade_t), pointer :: cascade => null ()
    type(cascade_p), pointer :: next => null ()
  end type cascade_p

```

Here is the bucket or hash entry type:

```

<Cascades: types>+=
  type :: hash_entry_t
    integer(i32) :: hashval = 0
    integer(i8), dimension(:), allocatable :: key
    type(cascade_p), pointer :: first => null ()
    type(cascade_p), pointer :: last => null ()
  end type hash_entry_t

```

Finalize: just deallocate the list; the contents are just pointers.

```

<Cascades: procedures>+=
  subroutine hash_entry_final (hash_entry)
    type(hash_entry_t), intent(inout) :: hash_entry
    type(cascade_p), pointer :: current
    do while (associated (hash_entry%first))
      current => hash_entry%first
      hash_entry%first => current%next
      deallocate (current)
    end do
  end subroutine hash_entry_final

```

Output: concise format for debugging, just list cascade indices.

```

(Cascades: procedures)+≡
subroutine hash_entry_write (hash_entry, unit)
  type(hash_entry_t), intent(in) :: hash_entry
  integer, intent(in), optional :: unit
  type(cascade_p), pointer :: current
  integer :: u, i
  u = output_unit (unit); if (u < 0) return
  write (u, "(1x,A)", advance="no") "Entry:"
  do i = 1, size (hash_entry%key)
    write (u, "(1x,I0)", advance="no") hash_entry%key(i)
  end do
  write (u, "(1x,A)", advance="no") "->"
  current => hash_entry%first
  do while (associated (current))
    write (u, "(1x,I7)", advance="no") current%cascade%index
    current => current%next
  end do
  write (u, *)
end subroutine hash_entry_write

```

This function adds a cascade pointer to the bucket. If ok is present, check first if it is already there and return failure if yes. If `cascade_ptr` is also present, set it to the current cascade if successful. If not, set it to the cascade that is already there.

```

(Cascades: procedures)+≡
subroutine hash_entry_add_cascade_ptr (hash_entry, cascade, ok, cascade_ptr)
  type(hash_entry_t), intent(inout) :: hash_entry
  type(cascade_t), intent(in), target :: cascade
  logical, intent(out), optional :: ok
  type(cascade_t), optional, pointer :: cascade_ptr
  type(cascade_p), pointer :: current
  if (present (ok)) then
    call hash_entry_check_cascade (hash_entry, cascade, ok, cascade_ptr)
    if (.not. ok) return
  end if
  allocate (current)
  current%cascade => cascade
  if (associated (hash_entry%last)) then
    hash_entry%last%next => current
  else
    hash_entry%first => current
  end if
  hash_entry%last => current
end subroutine hash_entry_add_cascade_ptr

```

This function checks whether a cascade is already in the bucket. For incomplete cascades, we look for an exact match. It should suffice to verify the tree, the PDG codes, and the mapping modes. This is the information that is written to the phase space file.

For complete cascades, we ignore the PDG code at positions with mappings infrared, collinear, or t/u-channel. Thus a cascade which is distinguished only by

PDG code at such places, is flagged existent. If the convention is followed that light particles come before heavier ones (in the model definition), this ensures that the lightest particle is kept in the appropriate place, corresponding to the strongest peak.

For external cascades (incoming/outgoing) we take the PDG code into account even though it is zeroed in the PDG-code tree.

```

<Cascades: procedures>+=
  subroutine hash_entry_check_cascade (hash_entry, cascade, ok, cascade_ptr)
    type(hash_entry_t), intent(in), target :: hash_entry
    type(cascade_t), intent(in), target :: cascade
    logical, intent(out) :: ok
    type(cascade_t), optional, pointer :: cascade_ptr
    type(cascade_p), pointer :: current
    integer, dimension(:), allocatable :: tree_pdg
    ok = .true.
    allocate (tree_pdg (size (cascade%tree_pdg)))
    if (cascade%complete) then
      where (cascade%tree_mapping == INFRARED .or. &
            cascade%tree_mapping == COLLINEAR .or. &
            cascade%tree_mapping == T_CHANNEL .or. &
            cascade%tree_mapping == U_CHANNEL)
        tree_pdg = 0
      elsewhere
        tree_pdg = cascade%tree_pdg
      end where
    else
      tree_pdg = cascade%tree_pdg
    end if
    current => hash_entry%first
    do while (associated (current))
      if (current%cascade%depth == cascade%depth) then
        if (all (current%cascade%tree == cascade%tree)) then
          if (all (current%cascade%tree_mapping == cascade%tree_mapping)) &
            then
              if (all (current%cascade%tree_pdg .match. tree_pdg)) then
                if (present (cascade_ptr)) cascade_ptr => current%cascade
                ok = .false.; return
              end if
            end if
          end if
        end if
      end if
      current => current%next
    end do
    if (present (cascade_ptr)) cascade_ptr => cascade
  end subroutine hash_entry_check_cascade

```

For PDG codes, we specify that the undefined code matches any code. This is already defined for flavor objects, but here we need it for the codes themselves.

```

<Cascades: interfaces>+=
  interface operator(.match.)
    module procedure pdg_match
  end interface

```

```

<Cascades: procedures>+=
  elemental function pdg_match (pdg1, pdg2) result (flag)
    logical :: flag
    integer(TC), intent(in) :: pdg1, pdg2
    select case (pdg1)
    case (0)
      flag = .true.
    case default
      select case (pdg2)
      case (0)
        flag = .true.
      case default
        flag = pdg1 == pdg2
      end select
    end select
  end function pdg_match

```

11.7.6 The cascade set

The cascade set will later be transformed into the decay forest. It is set up as a linked list. In addition to the usual **first** and **last** pointers, there is a **first_t** pointer which points to the first t-channel cascade (after all s-channel cascades), and a **first_k** pointer which points to the first final cascade (with a keystone).

As an auxiliary device, the object contains a hash array with associated parameters where an additional pointer is stored for each cascade. The keys are made from the relevant cascade data. This hash is used for fast detection (and thus avoidance) of double entries in the cascade list.

```

<Cascades: public>≡
  public :: cascade_set_t

<Cascades: types>+=
  type :: cascade_set_t
    private
    type(model_t), pointer :: model
    integer :: n_in, n_out, n_tot
    type(flavor_t), dimension(:, :), allocatable :: flv
    integer :: depth_out, depth_tot
    real(default) :: sqrts = 0
    real(default) :: m_threshold_s = 0
    real(default) :: m_threshold_t = 0
    integer :: off_shell = 0
    integer :: t_channel = 0
    logical :: keep_nonresonant
    integer :: n_groves = 0
    ! The cascade list
    type(cascade_t), pointer :: first => null ()
    type(cascade_t), pointer :: last => null ()
    type(cascade_t), pointer :: first_t => null ()
    type(cascade_t), pointer :: first_k => null ()
    ! The hashtable
    integer :: n_entries = 0
    real :: fill_ratio = 0

```

```

integer :: n_entries_max = 0
integer(i32) :: mask = 0
logical :: fatal_beam_decay = .true.
type(hash_entry_t), dimension(:), allocatable :: entry
end type cascade_set_t

```

Return true if there are cascades which are active and complete, so the phase space file would be nonempty.

```

<Cascades: public>+≡
public :: cascade_set_is_valid

<Cascades: procedures>+≡
function cascade_set_is_valid (cascade_set) result (flag)
logical :: flag
type(cascade_set_t), intent(in) :: cascade_set
type(cascade_t), pointer :: cascade
flag = .false.
cascade => cascade_set%first_k
do while (associated (cascade))
    if (cascade%active .and. cascade%complete) then
        flag = .true.
        return
    end if
    cascade => cascade%next
end do
end function cascade_set_is_valid

```

The initializer sets up the hash table with some initial size guessed by looking at the number of external particles. We choose 256 for 3 external particles and a factor of 4 for each additional particle, limited at $2^{30}=1\text{G}$.

```

<Limits: public parameters>+≡
real, parameter, public :: CASCADE_SET_FILL_RATIO = 0.1

11.7.7 Adding cascades

Add a deep copy of a cascade to the set. The copy has all content of the original, but the pointers are nullified. We do not care whether insertion was successful or not. The pointer argument, if present, is assigned to the input cascade, or to the hash entry if it is already present.

The procedure is recursive: any daughter or mother entries are also deep-copied and added to the cascade set before the current copy is added.

(Cascades: procedures)+≡

```
recursive subroutine cascade_set_add_copy &
```

```

        (cascade_set, cascade_in, cascade_ptr)
type(cascade_set_t), intent(inout), target :: cascade_set
type(cascade_t), intent(in) :: cascade_in
type(cascade_t), optional, pointer :: cascade_ptr
type(cascade_t), pointer :: cascade
logical :: ok
allocate (cascade)
cascade = cascade_in
if (associated (cascade_in%daughter1)) call cascade_set_add_copy &
    (cascade_set, cascade_in%daughter1, cascade%daughter1)
if (associated (cascade_in%daughter2)) call cascade_set_add_copy &
    (cascade_set, cascade_in%daughter2, cascade%daughter2)
if (associated (cascade_in%mother)) call cascade_set_add_copy &
    (cascade_set, cascade_in%mother, cascade%mother)
cascade%next => null ()
call cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
end subroutine cascade_set_add_copy

```

Add a cascade to the set. This does not deep-copy. We first try to insert it in the hash array. If successful, add it to the list. Failure indicates that it is already present, and we drop it.

The hash key is built solely from the tree array, so neither particle codes nor resonances count, just topology.

Technically, hash and list receive only pointers, so the cascade can be considered as being in either of both. We treat it as part of the list.

<Cascades: procedures>+≡

```

subroutine cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
type(cascade_set_t), intent(inout), target :: cascade_set
type(cascade_t), intent(in), target :: cascade
logical, intent(out) :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i8), dimension(1) :: mold
call cascade_set_hash_insert &
    (cascade_set, transfer (cascade%tree, mold), cascade, ok, cascade_ptr)
if (ok) call cascade_set_list_add (cascade_set, cascade)
end subroutine cascade_set_add

```

Add a new cascade to the list:

<Cascades: procedures>+≡

```

subroutine cascade_set_list_add (cascade_set, cascade)
type(cascade_set_t), intent(inout) :: cascade_set
type(cascade_t), intent(in), target :: cascade
if (associated (cascade_set%last)) then
    cascade_set%last%next => cascade
else
    cascade_set%first => cascade
end if
cascade_set%last => cascade
end subroutine cascade_set_list_add

```

Add a cascade entry to the hash array:

<Cascades: procedures>+≡

```

subroutine cascade_set_hash_insert &
    (cascade_set, key, cascade, ok, cascade_ptr)
    type(cascade_set_t), intent(inout), target :: cascade_set
    integer(i8), dimension(:), intent(in) :: key
    type(cascade_t), intent(in), target :: cascade
    logical, intent(out) :: ok
    type(cascade_ptr), optional, pointer :: cascade_ptr
    integer(i32) :: h
    if (cascade_set%n_entries >= cascade_set%n_entries_max) &
        call cascade_set_hash_expand (cascade_set)
    h = hash (key)
    call cascade_set_hash_insert_rec &
        (cascade_set, h, h, key, cascade, ok, cascade_ptr)
end subroutine cascade_set_hash_insert

```

Double the hashtable size when necessary:

```

<Cascades: procedures>+≡
subroutine cascade_set_hash_expand (cascade_set)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(hash_entry_t), dimension(:), allocatable, target :: table_tmp
    type(cascade_p), pointer :: current
    integer :: i, s
    allocate (table_tmp (0:cascade_set%mask))
    table_tmp = cascade_set%entry
    deallocate (cascade_set%entry)
    s = 2 * size (table_tmp)
    cascade_set%n_entries = 0
    cascade_set%n_entries_max = s * cascade_set%fill_ratio
    cascade_set%mask = s - 1
    allocate (cascade_set%entry (0:cascade_set%mask))
    do i = 0, ubound (table_tmp, 1)
        current => table_tmp(i)%first
        do while (associated (current))
            call cascade_set_hash_insert_rec &
                (cascade_set, table_tmp(i)%hashval, table_tmp(i)%hashval, &
                    table_tmp(i)%key, current%cascade)
            current => current%next
        end do
    end do
end subroutine cascade_set_hash_expand

```

Insert the cascade at the bucket determined by the hash value. If the bucket is filled, check first for a collision (unequal keys). In that case, choose the following bucket and repeat. Otherwise, add the cascade to the bucket.

If the bucket is empty, record the hash value, allocate and store the key, and then add the cascade to the bucket.

If ok is present, before insertion we check whether the cascade is already stored, and return failure if yes.

```

<Cascades: procedures>+≡
recursive subroutine cascade_set_hash_insert_rec &
    (cascade_set, h, hashval, key, cascade, ok, cascade_ptr)
    type(cascade_set_t), intent(inout) :: cascade_set

```

```

integer(i32), intent(in) :: h, hashval
integer(i8), dimension(:), intent(in) :: key
type(cascade_t), intent(in), target :: cascade
logical, intent(out), optional :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i32) :: i
i = iand (h, cascade_set%mask)
if (allocated (cascade_set%entry(i)%key)) then
  if (size (cascade_set%entry(i)%key) /= size (key)) then
    call cascade_set_hash_insert_rec &
      (cascade_set, h + 1, hashval, key, cascade, ok, cascade_ptr)
  else if (any (cascade_set%entry(i)%key /= key)) then
    call cascade_set_hash_insert_rec &
      (cascade_set, h + 1, hashval, key, cascade, ok, cascade_ptr)
  else
    call hash_entry_add_cascade_ptr &
      (cascade_set%entry(i), cascade, ok, cascade_ptr)
  end if
else
  cascade_set%entry(i)%hashval = hashval
  allocate (cascade_set%entry(i)%key (size (key)))
  cascade_set%entry(i)%key = key
  call hash_entry_add_cascade_ptr &
    (cascade_set%entry(i), cascade, ok, cascade_ptr)
  cascade_set%n_entries = cascade_set%n_entries + 1
end if
end subroutine cascade_set_hash_insert_rec

```

11.7.8 External particles

We want to initialize the cascade set with the outgoing particles. In case of multiple processes, initial cascades are prepared for all of them. The hash array check ensures that no particle appears more than once at the same place.

<Cascades: interfaces>+≡

```

interface cascade_set_add_outgoing
  module procedure cascade_set_add_outgoing1
  module procedure cascade_set_add_outgoing2
end interface

```

<Cascades: procedures>+≡

```

subroutine cascade_set_add_outgoing2 (cascade_set, flv)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(flavor_t), dimension(:,:), intent(in) :: flv
  integer :: pos, prc, n_out, n_prc
  type(cascade_t), pointer :: cascade
  logical :: ok
  n_out = size (flv, dim=1)
  n_prc = size (flv, dim=2)
  do prc = 1, n_prc
    do pos = 1, n_out
      allocate (cascade)
      call cascade_init_outgoing &

```

```

        (cascade, flv(pos,prc), pos, cascade_set%m_threshold_s)
    call cascade_set_add (cascade_set, cascade, ok)
    if (.not. ok) then
        deallocate (cascade)
    end if
end do
end do
end subroutine cascade_set_add_outgoing2

subroutine cascade_set_add_outgoing1 (cascade_set, flv)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(flavor_t), dimension(:), intent(in) :: flv
    integer :: pos, n_out
    type(cascade_t), pointer :: cascade
    logical :: ok
    n_out = size (flv, dim=1)
    do pos = 1, n_out
        allocate (cascade)
        call cascade_init_outgoing &
            (cascade, flv(pos), pos, cascade_set%m_threshold_s)
        call cascade_set_add (cascade_set, cascade, ok)
        if (.not. ok) then
            deallocate (cascade)
        end if
    end do
end subroutine cascade_set_add_outgoing1

```

The incoming particles are added one at a time. Nevertheless, we may have several processes which are looped over. At the first opportunity, we set the pointer `first_t` in the cascade set which should point to the first t-channel cascade.

Return the indices of the first and last cascade generated.

(Cascades: interfaces)+≡

```

interface cascade_set_add_incoming
    module procedure cascade_set_add_incoming0
    module procedure cascade_set_add_incoming1
end interface

```

(Cascades: procedures)+≡

```

subroutine cascade_set_add_incoming1 (cascade_set, n1, n2, pos, flv)

11.7.9 Cascade combination I: flavor assignment

We have two disjunct cascades, now use the vertex table to determine the possible flavors of the combination cascade. For each possibility, try to generate a new cascade. The total cascade depth has to be one less than the limit, because this is reached by setting the keystone.

(Cascades: procedures) +=

```

subroutine cascade_match_pair (cascade_set, cascade1, cascade2, s_channel)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(cascade_t), intent(in), target :: cascade1, cascade2
    logical, intent(in) :: s_channel
    integer, dimension(:), allocatable :: pdg3
    integer :: i, depth_max
    type(flavor_t) :: flv

```

```

if (s_channel) then
  depth_max = cascade_set%depth_out
else
  depth_max = cascade_set%depth_tot
end if
if (cascade1%depth + cascade2%depth < depth_max) then
  call model_match_vertex (cascade_set%model, &
    flavor_get_pdg (cascade1%flv), &
    flavor_get_pdg (cascade2%flv), &
    pdg3)
  do i = 1, size (pdg3)
    call flavor_init (flv, pdg3(i), cascade_set%model)
    if (s_channel) then
      call cascade_combine_s (cascade_set, cascade1, cascade2, flv)
    else
      call cascade_combine_t (cascade_set, cascade1, cascade2, flv)
    end if
  end do
  deallocate (pdg3)
end if
end subroutine cascade_match_pair

```

The triplet version takes a third cascade, and we check whether this triplet has a matching vertex in the database. If yes, we make a keystone cascade.

(Cascades: procedures) +=

```

subroutine cascade_match_triplet &
  (cascade_set, cascade1, cascade2, cascade3, s_channel)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in), target :: cascade1, cascade2, cascade3
  logical, intent(in) :: s_channel
  integer :: depth_max
  depth_max = cascade_set%depth_tot
  if (cascade1%depth + cascade2%depth + cascade3%depth == depth_max) then
    if (model_check_vertex (cascade_set%model, &
      flavor_get_pdg (cascade1%flv), &
      flavor_get_pdg (cascade2%flv), &
      flavor_get_pdg (cascade3%flv))) then
      call cascade_combine_keystone &
        (cascade_set, cascade1, cascade2, cascade3, s_channel)
    end if
  end if
end subroutine cascade_match_triplet

```

11.7.10 Cascade combination II: kinematics setup and check

Having three matching flavors, we start constructing the combination cascade. We look at the mass hierarchies and determine whether the cascade is to be kept. In passing we set mapping modes, resonance properties and such.

If successful, the cascade is finalized. For a resonant cascade, we prepare in addition a copy without the resonance.

(Cascades: procedures) +=

```

Here we complete a decay cascade. The third input is the single-particle cascade for the initial particle. There is no resonance or mapping assignment. The only condition for keeping the cascade is the mass sum of the final state, which must be less than the available energy.

Two modifications are necessary for scattering cascades: a pure s-channel diagram (cascade1 is the incoming particle) do not have a logarithmic mapping

at top-level. And in a t-channel diagram, the last line exchanged is mapped t-channel, not u-channel. In both cases we register a new cascade with the modified mapping.

```

11.7.11 Cascade combination III: node connections and tree fusion

Here we assign global tree properties. If the allowed number of off-shell lines is exceeded, discard the new cascade. Otherwise, assign the trees, sort them, and assign connections. Finally, append the cascade to the list. This may fail (because in the hash array there is already an equivalent cascade). On failure, discard the cascade.

```

    resonant(i) = resonant_tmp (pos(1))
    tree_tmp(pos(1)) = 0
  end do
end subroutine tree_sort

```

11.7.12 Cascade set generation

These procedures loop over cascades and build up the cascade set. After each iteration of the innermost loop, we set a breakpoint.

s-channel: We use a nested scan to combine all cascades with all other cascades.

(Cascades: procedures)+≡

```

subroutine cascade_set_generate_s (cascade_set)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), pointer :: cascade1, cascade2
  cascade1 => cascade_set%first
  LOOP1: do while (associated (cascade1))
    cascade2 => cascade_set%first
    LOOP2: do while (associated (cascade2))
      if (cascade2%index >= cascade1%index) exit LOOP2
      if (cascade1 .disjunct. cascade2) then
        call cascade_match_pair (cascade_set, cascade1, cascade2, .true.)
      end if
      call terminate_now_if_signal ()
      cascade2 => cascade2%next
    end do LOOP2
    cascade1 => cascade1%next
  end do LOOP1
end subroutine cascade_set_generate_s

```

The t-channel cascades are directed and have a seed (one of the incoming particles) and a target (the other one). We loop over all possible seeds and targets. Inside this, we loop over all t-channel cascades (`cascade1`) and s-channel cascades (`cascade2`) and try to combine them.

```

(Cascades: procedures)+=
  subroutine cascade_set_generate_t (cascade_set, pos_seed, pos_target)
    type(cascade_set_t), intent(inout), target :: cascade_set
    integer, intent(in) :: pos_seed, pos_target
    type(cascade_t), pointer :: cascade_seed, cascade_target
    type(cascade_t), pointer :: cascade1, cascade2
    integer(TC) :: bc_seed, bc_target
    bc_seed = ibset (0_TC, pos_seed-1)
    bc_target = ibset (0_TC, pos_target-1)
    cascade_seed => cascade_set%first_t
    LOOP_SEED: do while (associated (cascade_seed))
      if (cascade_seed%bincode == bc_seed) then
        cascade_target => cascade_set%first_t
        LOOP_TARGET: do while (associated (cascade_target))
          if (cascade_target%bincode == bc_target) then
            cascade1 => cascade_set%first_t
            LOOP_T: do while (associated (cascade1))
              if ((cascade1 .disjunct. cascade_target) &
                  .and. .not. (cascade1 .disjunct. cascade_seed)) then

end do LOOP_SEED
end subroutine cascade_set_generate_scattering

```

11.7.13 Groves

Before assigning groves, assign hashcodes to the resonance patterns, so they can easily be compared.

(Cascades: procedures)+≡

```

subroutine cascade_set_assign_resonance_hash (cascade_set)
    type(cascade_set_t), intent(inout) :: cascade_set
    type(cascade_t), pointer :: cascade
    cascade => cascade_set%first_k
    do while (associated (cascade))
        call cascade_assign_resonance_hash (cascade)
        cascade => cascade%next
    end do
end subroutine cascade_set_assign_resonance_hash

```

After all cascades are recorded, we group the complete cascades in groves. A grove consists of cascades with identical multiplicity, number of resonances, log-enhanced, t-channel lines, and resonance flavors.

(Cascades: procedures)+≡

```

subroutine cascade_set_assign_groves (cascade_set)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(cascade_t), pointer :: cascade1, cascade2
    integer :: multiplicity
    integer :: n_resonances, n_log_enhanced, n_t_channel, n_off_shell
    integer :: res_hash

```

```

integer :: grove
grove = 0
cascade1 => cascade_set%first_k
do while (associated (cascade1))
  if (cascade1%active .and. cascade1%complete &
      .and. cascade1%grove == 0) then
    grove = grove + 1
    cascade1%grove = grove
    multiplicity = cascade1%multiplicity
    n_resonances = cascade1%n_resonances
    n_log_enhanced = cascade1%n_log_enhanced
    n_off_shell = cascade1%n_off_shell
    n_t_channel = cascade1%n_t_channel
    res_hash = cascade1%res_hash
    cascade2 => cascade1%next
    do while (associated (cascade2))
      if (cascade2%grove == 0) then
        if (cascade2%multiplicity == multiplicity &
            .and. cascade2%n_resonances == n_resonances &
            .and. cascade2%n_log_enhanced == n_log_enhanced &
            .and. cascade2%n_off_shell == n_off_shell &
            .and. cascade2%n_t_channel == n_t_channel &
            .and. cascade2%res_hash == res_hash) then
          cascade2%grove = grove
        end if
      end if
      call terminate_now_if_signal ()
      cascade2 => cascade2%next
    end do
  end if
  call terminate_now_if_signal ()
  cascade1 => cascade1%next
end do
cascade_set%n_groves = grove
end subroutine cascade_set_assign_groves

```

11.7.14 Generate the phase space file

Generate a complete phase space configuration.

For each flavor assignment: First, all s-channel graphs that can be built up from the outgoing particles. Then we distinguish (1) decay, where we complete the s-channel graphs by connecting to the input line, and (2) scattering, where we now generate t-channel graphs by introducing an incoming particle, and complete this by connecting to the other incoming particle.

After all cascade sets have been generated, merge them into a common set. This eliminates redundancies between flavor assignments.

```

<Cascades: public>+=
  public :: cascade_set_generate

<Cascades: procedures>+=
  subroutine cascade_set_generate &
    (cascade_set, model, n_in, n_out, flv, phs_par, fatal_beam_decay)

```

```

type(cascade_set_t), intent(out) :: cascade_set
type(model_t), intent(in), target :: model
integer, intent(in) :: n_in, n_out
type(flavor_t), dimension(:,:), intent(in) :: flv
type(phs_parameters_t), intent(in) :: phs_par
logical, intent(in) :: fatal_beam_decay
type(cascade_set_t), dimension(:), allocatable :: cset
type(cascade_t), pointer :: cascade
integer :: i
if (phase_space_vanishes (phs_par%sqrts, n_in, flv)) return
call cascade_set_init (cascade_set, model, n_in, n_out, phs_par, &
    fatal_beam_decay, flv)
allocate (cset (size (flv, 2)))
do i = 1, size (cset)
    call cascade_set_generate_single (cset(i), &
        model, n_in, n_out, flv(:,i), phs_par, fatal_beam_decay)
    cascade => cset(i)%first_k
    do while (associated (cascade))
        if (cascade%active .and. cascade%complete) then
            call cascade_set_add_copy (cascade_set, cascade)
        end if
        cascade => cascade%next
    end do
    call cascade_set_final (cset(i))
end do
cascade_set%first_k => cascade_set%first
call cascade_set_assign_resonance_hash (cascade_set)
call cascade_set_assign_groves (cascade_set)
end subroutine cascade_set_generate

```

This generates phase space for a single channel, without assigning groves.

(Cascades: procedures)+≡

```

subroutine cascade_set_generate_single (cascade_set, &

11.8 WOOD phase space

This is the module that interfaces the `phs_forests` phase-space treatment and the `cascades` module for generating phase-space channels. As an extension of the `phs_base` abstract type, the phase-space configuration and instance implement the standard API.

(Currently, this is the only generic phase-space implementation of `WHIZARD`. For trivial two-particle phase space, there is `phs_wood` as an alternative.)

`<phs_wood.f90>`≡
<File header>

```

module phs_wood

  <Use kinds>
  <Use strings>
  <Use file utils>
  use diagnostics !NODEP!
  use unit_tests
  use os_interface

```

```

use md5
use constants !NODEP!
use lorentz !NODEP!
use variables
use models
use flavors
use process_constants
use sf_mappings
use sf_base
use phs_base
use mappings
use phs_forests
use cascades

```

```

The MD5 sum of the forest is computed in addition to the MD5 sum of the configuration. The reason is that the forest may depend on a user-provided external file. On the other hand, this MD5 sum encodes all information that is relevant for further processing. Therefore, the `get_md5sum` method returns this result, once it is available.

```

<PHS wood: phs wood config: TBP>+≡

  end subroutine phs_wood_init

```

11.8.5 Evaluation

We compute the outgoing momenta from the incoming momenta and the input parameter set `r_in` in channel `r_in`. We also compute the `r` parameters and Jacobians `f` for all other channels.

We do *not* need to apply a transformation from/to the c.m. frame, because in `phs_base` the momenta are already boosted to the c.m. frame before assigning them in the `phs` object, and inversely boosted when extracting them.

Note: We should postpone computation of the complete **r** and **f** arrays until after cut evaluation. This was done in the previous WHIZARD version, to save computing time for events which fail cut evaluation.

```

Chapter 12

Random Number Generation

The integration and event generation modules need a random-number generator. Here, we provide an abstract interface for a random-number generator and a concrete implementation.

Module rng_base: Abstract type for interfacing or implementing a r.n.g.

Module rng_tao: Implementation as an interface to the TAO random number generator which the VAMP package provides.

12.1 Generic Random-Number Generator

```
<rng_base.f90>≡  
<File header>  
  
module rng_base  
  
    use kinds !NODEP!  
<Use file utils>  
    use unit_tests  
  
<Standard module head>  
  
<RNG base: public>  
  
<RNG base: types>  
  
<RNG base: interfaces>  
  
<RNG base: test types>  
  
contains  
  
<RNG base: procedures>  
  
<RNG base: tests>
```

```
end module rng_base
```

12.1.1 Generator type

The `rng` object is actually the state of the random-number generator. The methods `initialize/reset` and `call` the generator for this state.

```
<RNG base: public>≡
  public :: rng_t

<RNG base: types>≡
  type, abstract :: rng_t
  contains
    <RNG base: rng: TBP>
  end type rng_t
```

The `init` method initializes the generator and sets a seed. We should implement the interface such that a single integer is sufficient for a seed.

The seed may be omitted. The behavior without seed is not defined, however.

```
<RNG base: rng: TBP>≡
  procedure (rng_init), deferred :: init

<RNG base: interfaces>≡
  abstract interface
    subroutine rng_init (rng, seed)
      import
        class(rng_t), intent(out) :: rng
        integer, intent(in), optional :: seed
    end subroutine rng_init
  end interface
```

The `final` method deallocates memory where necessary and allows for another call of `init` to reset the generator.

```
<RNG base: rng: TBP>+≡
  procedure (rng_final), deferred :: final

<RNG base: interfaces>+≡
  abstract interface
    subroutine rng_final (rng)
      import
        class(rng_t), intent(inout) :: rng
    end subroutine rng_final
  end interface
```

Output. We should, at least, identify the generator.

```
<RNG base: rng: TBP>+≡
  procedure (rng_write), deferred :: write

<RNG base: interfaces>+≡
  abstract interface
    subroutine rng_write (rng, unit)
      import
        class(rng_t), intent(in) :: rng
```

```

        integer, intent(in), optional :: unit
    end subroutine rng_write
end interface

```

These routines generate a single and an array of default-precision random numbers, respectively.

```

<RNG base: rng: TBP>+≡
    generic :: generate => generate_single, generate_array
    procedure (rng_generate_single), deferred :: generate_single
    procedure (rng_generate_array), deferred :: generate_array

<RNG base: interfaces>+≡
    abstract interface
        subroutine rng_generate_single (rng, x)
            import
            class(rng_t), intent(inout) :: rng
            real(default), intent(out) :: x
        end subroutine rng_generate_single
    end interface

    abstract interface
        subroutine rng_generate_array (rng, x)
            import
            class(rng_t), intent(inout) :: rng
            real(default), dimension(:), intent(out) :: x
        end subroutine rng_generate_array
    end interface

```

12.1.2 Unit tests

```

<RNG base: public>+≡
    public :: rng_base_test

<RNG base: tests>≡
    subroutine rng_base_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <RNG base: execute tests>
    end subroutine rng_base_test

```

Test generator

The test 'mock' random generator generates a repeating series with the numbers 0.1, 0.3, 0.5, 0.7, 0.9. It has an integer stored as state. The integer must be one of 1, 3, 5, 7, 9.

```

<RNG base: public>+≡
    public :: rng_test_t

```

```

<RNG base: test types>≡
type, extends (rng_t) :: rng_test_t
  integer :: state = 1
contains
  procedure :: write => rng_test_write
  procedure :: init => rng_test_init
  procedure :: final => rng_test_final
  procedure :: generate_single => rng_test_generate_single
  procedure :: generate_array => rng_test_generate_array
end type rng_test_t

```

Output. The state is a single number, so print it.

```

<RNG base: tests>+≡
subroutine rng_test_write (rng, unit)
  class(rng_test_t), intent(in) :: rng
  integer, intent(in), optional :: unit
  integer :: u
  u = output_unit (unit)
  write (u, "(1x,A,I0,A)") "Random-number generator: &
    &test (state = ", rng%state, ")"
end subroutine rng_test_write

```

The default seed is 1.

```

<RNG base: tests>+≡
subroutine rng_test_init (rng, seed)
  class(rng_test_t), intent(out) :: rng
  integer, intent(in), optional :: seed
  if (present (seed)) rng%state = seed
end subroutine rng_test_init

```

Nothing to finalize:

```

<RNG base: tests>+≡
subroutine rng_test_final (rng)
  class(rng_test_t), intent(inout) :: rng
end subroutine rng_test_final

```

Generate a single number and advance the state.

```

<RNG base: tests>+≡
subroutine rng_test_generate_single (rng, x)
  class(rng_test_t), intent(inout) :: rng
  real(default), intent(out) :: x
  x = rng%state / 10._default
  rng%state = mod (rng%state + 2, 10)
end subroutine rng_test_generate_single

```

The array generator calls the single-item generator multiple times.

```

<RNG base: tests>+≡
subroutine rng_test_generate_array (rng, x)
  class(rng_test_t), intent(inout) :: rng
  real(default), dimension(:), intent(out) :: x
  integer :: i

```

```

do i = 1, size (x)
  call rng%generate (x(i))
end do
end subroutine rng_test_generate_array

```

Generator check

Initialize the generator and draw random numbers.

```

(RNG base: execute tests)≡
  call test (rng_base_1, "rng_base_1", &
    "rng initialization and call", &
    u, results)

(RNG base: tests)+≡
  subroutine rng_base_1 (u)
    integer, intent(in) :: u
    class(rng_t), allocatable, target :: rng

    real(default) :: x
    real(default), dimension(2) :: x2

    write (u, "(A)")  "* Test output: rng_base_1"
    write (u, "(A)")  "* Purpose: initialize and call a test random-number &
      &generator"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize generator"
    write (u, "(A)")

    allocate (rng_test_t :: rng)
    call rng%init (3)

    call rng%write (u)

    write (u, "(A)")
    write (u, "(A)")  "* Get random number"
    write (u, "(A)")

    call rng%generate (x)
    write (u, "(A,2(1x,F9.7))")  "x =", x

    write (u, "(A)")
    write (u, "(A)")  "* Get random number pair"
    write (u, "(A)")

    call rng%generate (x2)
    write (u, "(A,2(1x,F9.7))")  "x =", x2

    write (u, "(A)")
    write (u, "(A)")  "* Cleanup"

    call rng%final ()

```

```

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: rng_base_1"

    end subroutine rng_base_1

```

12.2 TAO Random-Number Generator

This module provides an implementation for the generic random-number generator. Actually, we interface the TAO random-number generator which is available via the VAMP package.

```

⟨rng_tao.f90⟩≡
  ⟨File header⟩

  module rng_tao

    use kinds !NODEP!
    ⟨Use file utils⟩
    use unit_tests
    use tao_random_numbers !NODEP!

    use rng_base

    ⟨Standard module head⟩

    ⟨RNG tao: public⟩

    ⟨RNG tao: types⟩

    contains

    ⟨RNG tao: procedures⟩

    ⟨RNG tao: tests⟩

  end module rng_tao

```

12.2.1 Generator type

The rng object is actually the state of the random-number generator. The methods initialize/reset and call the generator for this state.

We keep the seed, in case we want to recover it later, and count the number of calls since seeding.

```

⟨RNG tao: public⟩≡
  public :: rng_tao_t

⟨RNG tao: types⟩≡
  type, extends (rng_t) :: rng_tao_t
    integer :: seed = 0
    integer :: n_calls = 0
    type(tao_random_state) :: state
  contains

```

```

    <RNG tao: rng tao: TBP>
end type rng_tao_t

```

Output: Display seed and number of calls.

```

<RNG tao: rng tao: TBP>≡
    procedure :: write => rng_tao_write

<RNG tao: procedures>≡
    subroutine rng_tao_write (rng, unit)
        class(rng_tao_t), intent(in) :: rng
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit)
        write (u, "(1x,A)") "TAO random-number generator:"
        write (u, "(3x,A,I0)") "seed = ", rng%seed
        write (u, "(3x,A,I0)") "calls = ", rng%n_calls
    end subroutine rng_tao_write

```

The `init` method initializes the generator and sets a seed. We should implement the interface such that a single integer is sufficient for a seed.

The seed may be omitted. The default seed is 0.

```

<RNG tao: rng tao: TBP>+≡
    procedure :: init => rng_tao_init

<RNG tao: procedures>+≡
    subroutine rng_tao_init (rng, seed)
        class(rng_tao_t), intent(out) :: rng
        integer, intent(in), optional :: seed
        if (present (seed)) rng%seed = seed
        call tao_random_create (rng%state, rng%seed)
    end subroutine rng_tao_init

```

The `final` method deallocates memory where necessary and allows for another call of `init` to reset the generator.

```

<RNG tao: rng tao: TBP>+≡
    procedure :: final => rng_tao_final

<RNG tao: procedures>+≡
    subroutine rng_tao_final (rng)
        class(rng_tao_t), intent(inout) :: rng
        call tao_random_destroy (rng%state)
    end subroutine rng_tao_final

```

These routines generate a single and an array of default-precision random numbers, respectively.

We have to convert from explicit double to abstract default precision. Under normal conditions, both are equivalent, however. Unless, someone decides to do single precision, there is always an interface for `tao_random_numbers`.

```

<RNG tao: rng tao: TBP>+≡
    procedure :: generate_single => rng_tao_generate_single
    procedure :: generate_array => rng_tao_generate_array

```

```

<RNG tao: procedures>+=
  subroutine rng_tao_generate_single (rng, x)
    class(rng_tao_t), intent(inout) :: rng
    real(default), intent(out) :: x
    real(default) :: r
    call tao_random_number (rng%state, r)
    x = r
    rng%n_calls = rng%n_calls + 1
  end subroutine rng_tao_generate_single

  subroutine rng_tao_generate_array (rng, x)
    class(rng_tao_t), intent(inout) :: rng
    real(default), dimension(:), intent(out) :: x
    real(default) :: r
    integer :: i
    do i = 1, size (x)
      call tao_random_number (rng%state, r)
      x(i) = r
    end do
    rng%n_calls = rng%n_calls + size (x)
  end subroutine rng_tao_generate_array

```

12.2.2 Unit tests

```

<RNG tao: public>+=
  public :: rng_tao_test

<RNG tao: tests>=
  subroutine rng_tao_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <RNG tao: execute tests>
  end subroutine rng_tao_test

```

Generator check

Initialize the generator and draw random numbers.

```

<RNG tao: execute tests>=
  call test (rng_tao_1, "rng_tao_1", &
    "rng initialization and call", &
    u, results)

<RNG tao: tests>+=
  subroutine rng_tao_1 (u)
    integer, intent(in) :: u
    class(rng_t), allocatable, target :: rng

    real(default) :: x
    real(default), dimension(2) :: x2

    write (u, "(A)")  "* Test output: rng_tao_1"
    write (u, "(A)")  "* Purpose: initialize and call the TAO random-number &

```

```

        &generator"
write (u, "(A)")

write (u, "(A)")  "* Initialize generator (default seed)"
write (u, "(A)")

allocate (rng_tao_t :: rng)
call rng%init ()

call rng%write (u)

write (u, "(A)")
write (u, "(A)")  "* Get random number"
write (u, "(A)")

call rng%generate (x)
write (u, "(A,2(1x,F9.7))")  "x =", x

write (u, "(A)")
write (u, "(A)")  "* Get random number pair"
write (u, "(A)")

call rng%generate (x2)
write (u, "(A,2(1x,F9.7))")  "x =", x2

write (u, "(A)")
call rng%write (u)

write (u, "(A)")
write (u, "(A)")  "* Cleanup"

call rng%final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: rng_tao_1"

end subroutine rng_tao_1

```

Chapter 13

Multi-Channel Integration

In this chapter we provide a generic module for handling multi-channel phase space and concrete implementations.

Module mci_base: The abstract types and their methods. It provides a test integrator that is referenced in later unit tests.

Module mci_midpoint: A simple integrator that uses the midpoint rule to sample the integrand uniformly over the unit hypercube. There is only one integration channel, so this can be matched only to single-channel phase space.

Module mci_vamp: Interface for the VAMP package. (not implemented yet)

13.1 Generic Integrator

This module provides a multi-channel integrator (MCI) base type, a corresponding configuration type, and methods for integration and event generation.

```
<mci_base.f90>≡  
<File header>  
  
module mci_base  
  
    use kinds !NODEP!  
<Use strings>  
<Use file utils>  
    use diagnostics !NODEP!  
    use unit_tests  
  
    use phs_base  
    use rng_base  
  
<Standard module head>  
  
<MCI base: public>  
  
<MCI base: types>
```

⟨MCI base: interfaces⟩

⟨MCI base: test types⟩

contains

⟨MCI base: procedures⟩

⟨MCI base: tests⟩

end module mci_base

13.1.1 MCI: integrator

The MCI object contains the methods for integration and event generation. For the actual work and data storage, it spawns an MCI instance object.

The base object contains the number of integration dimensions and the number of channels as configuration data. Further configuration data are stored in the concrete extensions.

The MCI sum contains all relevant information about the integrand. It can be used for comparing the current configuration against a previous one. If they match, we can skip an actual integration. (Implemented only for the VAMP version.)

There is a random-number generator (its state with associated methods) available as **rng**. It may or may not be used for integration. It will be used for event generation.

⟨MCI base: public⟩≡

public :: mci_t

⟨MCI base: types⟩≡

```
type, abstract :: mci_t
  integer :: n_dim = 0
  integer :: n_channel = 0
  integer :: n_chain = 0
  integer, dimension(:), allocatable :: chain
  character(32) :: md5sum = ""
  logical :: integral_known = .false.
  logical :: error_known = .false.
  logical :: efficiency_known = .false.
  real(default) :: integral = 0
  real(default) :: error = 0
  real(default) :: efficiency = 0
  class(rng_t), allocatable :: rng
contains
  ⟨MCI base: mci: TBP⟩
end type mci_t
```

Finalizer: the random-number generator may need one.

⟨MCI base: mci: TBP⟩≡

```
procedure :: base_final => mci_final
procedure (mci_final), deferred :: final
```

```

<MCI base: procedures>+=
  subroutine mci_final (object)
    class(mci_t), intent(inout) :: object
    if (allocated (object%rng)) call object%rng%final ()
  end subroutine mci_final

```

Output: basic and extended output.

```

<MCI base: mci: TBP>+=
  procedure :: base_write => mci_write
  procedure (mci_write), deferred :: write

<MCI base: procedures>+=
  subroutine mci_write (object, unit)
    class(mci_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i, j
    u = output_unit (unit)
    if (object%integral_known) then
      write (u, "(3x,A,ES17.10)") "Integral" = ", object%integral
    end if
    if (object%error_known) then
      write (u, "(3x,A,ES17.10)") "Error" = ", object%error
    end if
    if (object%efficiency_known) then
      write (u, "(3x,A,ES17.10)") "Efficiency" = ", object%efficiency
    end if
    write (u, "(3x,A,I0)") "Number of channels" = ", object%n_channel
    write (u, "(3x,A,I0)") "Number of dimensions" = ", object%n_dim
    if (object%n_chain > 0) then
      write (u, "(3x,A,I0)") "Number of chains" = ", object%n_chain
      write (u, "(3x,A)") "Chains:"
      do i = 1, object%n_chain
        write (u, "(5x,I0,':')", advance = "no") i
        do j = 1, object%n_channel
          if (object%chain(j) == i) &
            write (u, "(1x,I0)", advance = "no") j
          end do
        write (u, "(A)")
      end do
    end if
  end subroutine mci_write

```

Print an informative message when starting integration.

```

<MCI base: mci: TBP>+=
  procedure (mci_startup_message), deferred :: startup_message
  procedure :: base_startup_message => mci_startup_message

<MCI base: procedures>+=
  subroutine mci_startup_message (mci, unit)
    class(mci_t), intent(in) :: mci
    integer, intent(in), optional :: unit
    if (mci%n_chain > 0) then
      write (msg_buffer, "(A,3(1x,I0,1x,A))" &
        "Integrator:", mci%n_chain, "chains,", &

```

```

        mci%n_channel, "channels,", &
        mci%n_dim, "dimensions"
    else
        write (msg_buffer, "(A,3(1x,I0,1x,A))") &
            "Integrator:", &
            mci%n_channel, "channels,", &
            mci%n_dim, "dimensions"
    end if
    call msg_message (unit = unit)
end subroutine mci_startup_message

```

There is no Initializer for the abstract type, but a generic setter for the number of channels and dimensions. We make two aliases available, to be able to override it.

```

<MCI base: mci: TBP>+=
    procedure :: set_dimensions => mci_set_dimensions
    procedure :: base_set_dimensions => mci_set_dimensions

<MCI base: procedures>+=
    subroutine mci_set_dimensions (mci, n_dim, n_channel)
        class(mci_t), intent(inout) :: mci
        integer, intent(in) :: n_dim
        integer, intent(in) :: n_channel
        mci%n_dim = n_dim
        mci%n_channel = n_channel
    end subroutine mci_set_dimensions

```

Declare particular dimensions as flat. This information can be used to simplify integration. When generating events, the flat dimensions should be sampled with uniform and uncorrelated distribution. It depends on the integrator what to do with that information.

```

<MCI base: mci: TBP>+=
    procedure (mci_declare_flat_dimensions), deferred :: declare_flat_dimensions

<MCI base: interfaces>=
    abstract interface
        subroutine mci_declare_flat_dimensions (mci, dim_flat)
            import
            class(mci_t), intent(inout) :: mci
            integer, dimension(:), intent(in) :: dim_flat
        end subroutine mci_declare_flat_dimensions
    end interface

```

Declare particular channels as equivalent, possibly allowing for permutations or reflections of dimensions. We use the information stored in the `phs_channel_t` object array that the phase-space module provides.

(We do not test this here, deferring the unit test to the `mci_vamp` implementation where we actually use this feature.)

```

<MCI base: mci: TBP>+=
    procedure (mci_declare_equivalences), deferred :: declare_equivalences

```

```

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_declare_equivalences (mci, channel, dim_offset)
      import
      class(mci_t), intent(inout) :: mci
      type(php_channel_t), dimension(:), intent(in) :: channel
      integer, intent(in) :: dim_offset
    end subroutine mci_declare_equivalences
  end interface

```

Declare particular channels as chained together. The implementation may use this array for keeping their weights equal to each other, etc.

The chain array is an array sized by the number of channels. For each channel, there is an integer entry that indicates the corresponding chains. The total number of chains is the maximum value of this entry.

```

<MCI base: mci: TBP>+≡
  procedure :: declare_chains => mci_declare_chains

<MCI base: procedures>+≡
  subroutine mci_declare_chains (mci, chain)
    class(mci_t), intent(inout) :: mci
    integer, dimension(:), intent(in) :: chain
    allocate (mci%chain (size (chain)))
    mci%n_chain = maxval (chain)
    mci%chain = chain
  end subroutine mci_declare_chains

```

Set the MD5 sum, independent of initialization.

```

<MCI base: mci: TBP>+≡
  procedure :: set_md5sum => mci_set_md5sum

<MCI base: procedures>+≡
  subroutine mci_set_md5sum (mci, md5sum)
    class(mci_t), intent(inout) :: mci
    character(32), intent(in) :: md5sum
    mci%md5sum = md5sum
  end subroutine mci_set_md5sum

```

Initialize a new integration pass. This is not necessarily meaningful, so we provide an empty base method. The mci_vamp implementation overrides this.

```

<MCI base: mci: TBP>+≡
  procedure :: add_pass => mci_add_pass

<MCI base: procedures>+≡
  subroutine mci_add_pass (mci, adapt_grids, adapt_weights)
    class(mci_t), intent(inout) :: mci
    logical, intent(in), optional :: adapt_grids
    logical, intent(in), optional :: adapt_weights
  end subroutine mci_add_pass

```

Allocate an instance with matching type. This must be deferred.

```

<MCI base: mci: TBP>+≡
  procedure (mci_allocate_instance), deferred :: allocate_instance

```

```

<MCI base: interfaces>+=
  abstract interface
    subroutine mci_allocate_instance (mci, mci_instance)
      import
      class(mci_t), intent(in) :: mci
      class(mci_instance_t), intent(out), pointer :: mci_instance
    end subroutine mci_allocate_instance
  end interface

```

Import a random-number generator. We transfer the allocation of an existing generator state into the object. The generator state may already be initialized, or we can reset it by its `init` method.

```

<MCI base: mci: TBP>+=
  procedure :: import_rng => mci_import_rng

<MCI base: procedures>+=
  subroutine mci_import_rng (mci, rng)
    class(mci_t), intent(inout) :: mci
    class(rng_t), intent(inout), allocatable :: rng
    call move_alloc (rng, mci%rng)
  end subroutine mci_import_rng

```

Integrate: this depends on the implementation.

```

<MCI base: mci: TBP>+=
  procedure (mci_integrate), deferred :: integrate

<MCI base: interfaces>+=
  abstract interface
    subroutine mci_integrate (mci, instance, sampler, n_it, n_calls, results)
      import
      class(mci_t), intent(inout) :: mci
      class(mci_instance_t), intent(inout) :: instance
      class(mci_sampler_t), intent(inout) :: sampler
      integer, intent(in) :: n_it
      integer, intent(in) :: n_calls
      class(mci_results_t), intent(inout), optional :: results
    end subroutine mci_integrate
  end interface

```

Analogously: event generation. Depending on the implementation, event generation may or may not require a previous integration pass.

Instead of a black-box `simulate` method, we require an initializer, a finalizer, and procedures for generating a single event. This allows us to interface simulation event by event from the outside, and it facilitates the further processing of an event after successful generation. For integration, this is not necessary.

The initializer has `intent(inout)` for the `mci` passed object. The reason is that the initializer can read integration results and grids from file, where the results can modify the `mci` record.

```

<MCI base: mci: TBP>+=
  procedure (mci_init_simulation), deferred :: init_simulation
  procedure (mci_final_simulation), deferred :: final_simulation

```

```

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_init_simulation (mci, instance)
      import
      class(mci_t), intent(inout) :: mci
      class(mci_instance_t), intent(inout) :: instance
    end subroutine mci_init_simulation
  end interface

  abstract interface
    subroutine mci_final_simulation (mci, instance)
      import
      class(mci_t), intent(in) :: mci
      class(mci_instance_t), intent(inout) :: instance
    end subroutine mci_final_simulation
  end interface

```

The generated event will reside in in the **instance** object (overall results and weight) and in the **sampler** object (detailed data). In the real application, we can subsequently call methods of the **sampler** in order to further process the generated event.

The **target** attributes are required by the VAMP implementation, which uses pointers to refer to the instance and sampler objects from within the integration function.

```

<MCI base: mci: TBP>+≡
  procedure (mci_generate), deferred :: generate_weighted_event
  procedure (mci_generate), deferred :: generate_unweighted_event

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_generate (mci, instance, sampler)
      import
      class(mci_t), intent(inout) :: mci
      class(mci_instance_t), intent(inout), target :: instance
      class(mci_sampler_t), intent(inout), target :: sampler
    end subroutine mci_generate
  end interface

```

This is analogous, but we rebuild the event from the information stored in **state** instead of generating it.

```

<MCI base: mci: TBP>+≡
  procedure (mci_rebuild), deferred :: rebuild_event

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_rebuild (mci, instance, sampler, state)
      import
      class(mci_t), intent(inout) :: mci
      class(mci_instance_t), intent(inout) :: instance
      class(mci_sampler_t), intent(inout) :: sampler
      class(mci_state_t), intent(in) :: state
    end subroutine mci_rebuild
  end interface

```

Return the value of the integral, error, and efficiency.

```
<MCI base: mci: TBP>+≡
  procedure :: get_integral => mci_get_integral
  procedure :: get_error => mci_get_error
  procedure :: get_efficiency => mci_get_efficiency

<MCI base: procedures>+≡
  function mci_get_integral (mci) result (integral)
    class(mci_t), intent(in) :: mci
    real(default) :: integral
    if (mci%integral_known) then
      integral = mci%integral
    else
      ! error?
      integral = 0
    end if
  end function mci_get_integral

  function mci_get_error (mci) result (error)
    class(mci_t), intent(in) :: mci
    real(default) :: error
    if (mci%error_known) then
      error = mci%error
    else
      ! error?
      error = 0
    end if
  end function mci_get_error

  function mci_get_efficiency (mci) result (efficiency)
    class(mci_t), intent(in) :: mci
    real(default) :: efficiency
    if (mci%efficiency_known) then
      efficiency = mci%efficiency
    else
      ! error?
      efficiency = 0
    end if
  end function mci_get_efficiency
```

Return the MD5 sum of the configuration. This may be overridden in an extension, to return a different MD5 sum.

```
<MCI base: mci: TBP>+≡
  procedure :: get_md5sum => mci_get_md5sum

<MCI base: procedures>+≡
  function mci_get_md5sum (mci) result (md5sum)
    class(mci_t), intent(in) :: mci
    character(32) :: md5sum
    md5sum = mci%md5sum
  end function mci_get_md5sum
```

13.1.2 MCI instance

The base type contains an array of channel weights. The value `mci_weight` is the combined MCI weight that corresponds to a particular sampling point.

For convenience, we also store the `x` and Jacobian values for this sampling point.

```

<MCI base: public>+≡
  public :: mci_instance_t

<MCI base: types>+≡
  type, abstract :: mci_instance_t
    real(default), dimension(:), allocatable :: w
    real(default), dimension(:), allocatable :: f
    real(default), dimension(:,:), allocatable :: x
    integer :: selected_channel = 0
    real(default) :: mci_weight = 0
    real(default) :: integrand = 0
  contains
    <MCI base: mci instance: TBP>
  end type mci_instance_t

```

Output: deferred

```

<MCI base: mci instance: TBP>≡
  procedure (mci_instance_write), deferred :: write

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_instance_write (object, unit)
      import
      class(mci_instance_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine mci_instance_write
  end interface

```

A finalizer, just in case.

```

<MCI base: mci instance: TBP>+≡
  procedure (mci_instance_final), deferred :: final

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_instance_final (object)
      import
      class(mci_instance_t), intent(inout) :: object
    end subroutine mci_instance_final
  end interface

```

Init: basic initializer for the arrays, otherwise deferred. Assigning the `mci` object is also deferred, because it depends on the concrete type.

The weights are initialized with an uniform normalized value.

```

<MCI base: mci instance: TBP>+≡
  procedure (mci_instance_base_init), deferred :: init
  procedure :: base_init => mci_instance_base_init

```

```

<MCI base: procedures>+≡
  subroutine mci_instance_base_init (mci_instance, mci)
    class(mci_instance_t), intent(out) :: mci_instance
    class(mci_t), intent(in), target :: mci
    allocate (mci_instance%w (mci%n_channel))
    allocate (mci_instance%f (mci%n_channel))
    allocate (mci_instance%x (mci%n_dim, mci%n_channel))
    if (size (mci_instance%w) /= 0) then
      mci_instance%w = 1._default / size (mci_instance%w)
    end if
    mci_instance%f = 0
    mci_instance%x = 0
  end subroutine mci_instance_base_init

```

Compute the overall weight factor for a configuration of x values and Jacobians f . The x values come in `n_channel` rows with `n_dim` entries each. The f factors constitute an array with `n_channel` entries.

We assume that the x and f arrays are already stored inside the MC instance. The result is also stored there.

```

<MCI base: mci instance: TBP>+≡
  procedure (mci_instance_compute_weight), deferred :: compute_weight

```

```

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_instance_compute_weight (mci, c)
      import
      class(mci_instance_t), intent(inout) :: mci
      integer, intent(in) :: c
    end subroutine mci_instance_compute_weight
  end interface

```

Record the integrand as returned by the sampler. Depending on the implementation, this may merely copy the value, or do more complicated things.

We may need the MCI weight for the actual computations, so this should be called after the previous routine.

```

<MCI base: mci instance: TBP>+≡
  procedure (mci_instance_record_integrand), deferred :: record_integrand

```

```

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_instance_record_integrand (mci, integrand)
      import
      class(mci_instance_t), intent(inout) :: mci
      real(default), intent(in) :: integrand
    end subroutine mci_instance_record_integrand
  end interface

```

Sample a point directly: evaluate the sampler, then compute the weight and the weighted integrand. Finally, record the integrand within the MCI instance.

```

<MCI base: mci instance: TBP>+≡
  procedure :: evaluate => mci_instance_evaluate

```

```

<MCI base: procedures>+≡
  subroutine mci_instance_evaluate (mci, sampler, c, x)
    class(mci_instance_t), intent(inout) :: mci
    class(mci_sampler_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x
    real(default) :: val
    call sampler%evaluate (c, x, val, mci%x, mci%f)
    call mci%compute_weight (c)
    call mci%record_integrand (val)
  end subroutine mci_instance_evaluate

```

Assuming that the sampler is in a completely defined state, just extract the data that `evaluate` would compute. Also record the integrand.

```

<MCI base: mci instance: TBP>+≡
  procedure :: fetch => mci_instance_fetch

<MCI base: procedures>+≡
  subroutine mci_instance_fetch (mci, sampler, c)
    class(mci_instance_t), intent(inout) :: mci
    class(mci_sampler_t), intent(in) :: sampler
    integer, intent(in) :: c
    real(default) :: val
    call sampler%fetch (val, mci%x, mci%f)
    call mci%compute_weight (c)
    call mci%record_integrand (val)
  end subroutine mci_instance_fetch

```

The value, i.e., the weighted integrand, is the integrand (which should be taken as-is from the sampler) multiplied by the MCI weight.

```

<MCI base: mci instance: TBP>+≡
  procedure :: get_value => mci_instance_get_value

<MCI base: procedures>+≡
  function mci_instance_get_value (mci) result (value)
    class(mci_instance_t), intent(in) :: mci
    real(default) :: value
    value = mci%integrand * mci%weight
  end function mci_instance_get_value

```

This is an extra routine. By default, the event weight is equal to the value returned by the previous routine. However, if we select a channel for event generation not just based on the channel weights, the event weight has to account for this bias, so the event weight that applies to event generation is different. In that case, we should override the default routine.

```

<MCI base: mci instance: TBP>+≡
  procedure :: get_event_weight => mci_instance_get_value

```

13.1.3 MCI state

This object can hold the relevant information that allows us to reconstruct the MCI instance without re-evaluating the sampler completely.

We store the `x_in` MC input parameter set, which coincides with the section of the complete `x` array that belongs to a particular channel. We also store the MC function value. When we want to reconstruct the state, we can use the input array to recover the complete `x` and `f` arrays (i.e., the kinematics), but do not need to recompute the MC function value (the dynamics).

The `mci_state_t` may be extended, to allow storing/recalling more information. In that case, we would override the type-bound procedures. However, the base type is also a concrete type and self-contained.

```

<MCI base: public>+≡
  public :: mci_state_t

<MCI base: types>+≡
  type :: mci_state_t
    integer :: selected_channel = 0
    real(default), dimension(:), allocatable :: x_in
    real(default) :: val
  contains
    <MCI base: mci state: TBP>
  end type mci_state_t

```

Output:

```

<MCI base: mci state: TBP>≡
  procedure :: write => mci_state_write

<MCI base: procedures>+≡
  subroutine mci_state_write (object, unit)
    class(mci_state_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(1x,A)") "MCI state:"
    write (u, "(3x,A,I0)") "Channel   = ", object%selected_channel
    write (u, "(3x,A,999(1x,F12.10))") "x (in)   =", object%x_in
    write (u, "(3x,A,ES19.12)") "Integrand = ", object%val
  end subroutine mci_state_write

```

To store the object, we take the relevant section of the `x` array. The channel used for storing data is taken from the `instance` object, but it could be arbitrary in principle.

```

<MCI base: mci instance: TBP>+≡
  procedure :: store => mci_instance_store

<MCI base: procedures>+≡
  subroutine mci_instance_store (mci, state)
    class(mci_instance_t), intent(in) :: mci
    class(mci_state_t), intent(out) :: state
    state%selected_channel = mci%selected_channel
    allocate (state%x_in (size (mci%x, 1)))
    state%x_in = mci%x(:,mci%selected_channel)
    state%val = mci%integrand
  end subroutine mci_instance_store

```

Recalling the state, we must consult the sampler in order to fully reconstruct the \mathbf{x} and \mathbf{f} arrays. The integrand value is known, and we also give it to the sampler, bypassing evaluation.

The final steps are equivalent to the `evaluate` method above.

```

<MCI base: mci instance: TBP>+≡
  procedure :: recall => mci_instance_recall

<MCI base: procedures>+≡
  subroutine mci_instance_recall (mci, sampler, state)
    class(mci_instance_t), intent(inout) :: mci
    class(mci_sampler_t), intent(inout) :: sampler
    class(mci_state_t), intent(in) :: state
    if (size (state%x_in) == size (mci%x, 1) &
        .and. state%selected_channel <= size (mci%x, 2)) then
      call sampler%rebuild (state%selected_channel, &
        state%x_in, state%val, mci%x, mci%f)
      call mci%compute_weight (state%selected_channel)
      call mci%record_integrand (state%val)
    else
      call msg_fatal ("Recalling event: mismatch in channel or dimension")
    end if
  end subroutine mci_instance_recall

```

13.1.4 MCI sampler

A sampler is an object that implements a multi-channel parameterization of the unit hypercube. Specifically, it is able to compute, given a channel and a set of x MC parameter values, a the complete set of x values and associated Jacobian factors f for all channels.

Furthermore, the sampler should return a single real value, the integrand, for the given point in the hypercube.

It must implement a method `evaluate` for performing the above computations.

```

<MCI base: public>+≡
  public :: mci_sampler_t

<MCI base: types>+≡
  type, abstract :: mci_sampler_t
  contains
    <MCI base: mci sampler: TBP>
  end type mci_sampler_t

```

Output, deferred to the implementation.

```

<MCI base: mci sampler: TBP>≡
  procedure (mci_sampler_write), deferred :: write

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_sampler_write (object, unit)
      import
      class(mci_sampler_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine mci_sampler_write
  end interface

```

```

        end subroutine mci_sampler_write
    end interface

```

The evaluation routine. Input is the channel index `c` and the one-dimensional parameter array `x_in`. Output are the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

```

<MCI base: mci_sampler: TBP>+≡
    procedure (mci_sampler_evaluate), deferred :: evaluate

<MCI base: interfaces>+≡
    abstract interface
        subroutine mci_sampler_evaluate (sampler, c, x_in, val, x, f)
            import
            class(mci_sampler_t), intent(inout) :: sampler
            integer, intent(in) :: c
            real(default), dimension(:), intent(in) :: x_in
            real(default), intent(out) :: val
            real(default), dimension(:, :), intent(out) :: x
            real(default), dimension(:), intent(out) :: f
        end subroutine mci_sampler_evaluate
    end interface

```

The shortcut. Again, the channel index `c` and the parameter array `x_in` are input. However, we also provide the integrand value `val`, and we just require that the complete parameter array `x` and Jacobian array `f` are recovered.

```

<MCI base: mci_sampler: TBP>+≡
    procedure (mci_sampler_rebuild), deferred :: rebuild

<MCI base: interfaces>+≡
    abstract interface
        subroutine mci_sampler_rebuild (sampler, c, x_in, val, x, f)
            import
            class(mci_sampler_t), intent(inout) :: sampler
            integer, intent(in) :: c
            real(default), dimension(:), intent(in) :: x_in
            real(default), intent(in) :: val
            real(default), dimension(:, :), intent(out) :: x
            real(default), dimension(:), intent(out) :: f
        end subroutine mci_sampler_rebuild
    end interface

```

This routine should extract the important data from a sampler that has been filled by other means. We fetch the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

```

<MCI base: mci_sampler: TBP>+≡
    procedure (mci_sampler_fetch), deferred :: fetch

<MCI base: interfaces>+≡
    abstract interface
        subroutine mci_sampler_fetch (sampler, val, x, f)
            import
            class(mci_sampler_t), intent(in) :: sampler
            real(default), intent(out) :: val

```

```

        real(default), dimension(:,:), intent(out) :: x
        real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_fetch
end interface

```

13.1.5 Results record

This is an abstract type which allows us to implement callback: each integration results can optionally be recorded to an instance of this object. The actual object may store a new result, average results, etc. It may also display a result on-line or otherwise, whenever the `record` method is called.

```

<MCI base: public>+≡
    public :: mci_results_t
<MCI base: types>+≡
    type, abstract :: mci_results_t
    contains
    <MCI base: mci results: TBP>
end type mci_results_t

```

The output routine is deferred. We provide an extra `verbose` flag, which could serve any purpose.

```

<MCI base: mci results: TBP>≡
    procedure (mci_results_write), deferred :: write
<MCI base: interfaces>+≡
    abstract interface
        subroutine mci_results_write (object, unit, verbose)
            import
            class(mci_results_t), intent(in) :: object
            integer, intent(in), optional :: unit
            logical, intent(in), optional :: verbose
        end subroutine mci_results_write
    end interface

```

This is the `record` method, which can be called directly from the integrator.

```

<MCI base: mci results: TBP>+≡
    procedure (mci_results_record), deferred :: record
<MCI base: interfaces>+≡
    abstract interface
        subroutine mci_results_record &
            (object, n_it, n_calls, integral, error, efficiency)
            import
            class(mci_results_t), intent(inout) :: object
            integer, intent(in) :: n_it
            integer, intent(in) :: n_calls
            real(default), intent(in) :: integral
            real(default), intent(in) :: error
            real(default), intent(in) :: efficiency
        end subroutine mci_results_record
    end interface

```

13.1.6 Unit tests

```
<MCI base: public>+≡
  public :: mci_base_test

<MCI base: tests>≡
  subroutine mci_base_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <MCI base: execute tests>
  end subroutine mci_base_test
```

Test implementation of the configuration type

The concrete type contains the number of requested calls and the integral result, to be determined.

The `max_factor` entry is set for the actual test integration, where the integrand is not unity but some other constant value. This value should be set here, such that the actual maximum of the integrand is known when vetoing unweighted events.

```
<MCI base: public>+≡
  public :: mci_test_t

<MCI base: test types>≡
  type, extends (mci_t) :: mci_test_t
    integer :: divisions = 0
    integer :: tries = 0
    real(default) :: max_factor = 1
  contains
    procedure :: final => mci_test_final
    procedure :: write => mci_test_write
    procedure :: startup_message => mci_test_startup_message
    procedure :: declare_flat_dimensions => mci_test_ignore_flat_dimensions
    procedure :: declare_equivalences => mci_test_ignore_equivalences
    procedure :: set_divisions => mci_test_set_divisions
    procedure :: set_max_factor => mci_test_set_max_factor
    procedure :: allocate_instance => mci_test_allocate_instance
    procedure :: integrate => mci_test_integrate
    procedure :: init_simulation => mci_test_ignore_init_simulation
    procedure :: final_simulation => mci_test_ignore_final_simulation
    procedure :: generate_weighted_event => mci_test_generate_weighted_event
    procedure :: generate_unweighted_event => &
      mci_test_generate_unweighted_event
    procedure :: rebuild_event => mci_test_rebuild_event
  end type mci_test_t
```

Finalizer: base version is sufficient

```
<MCI base: tests>+≡
  subroutine mci_test_final (object)
    class(mci_test_t), intent(inout) :: object
    call object%base_final ()
  end subroutine mci_test_final
```

Output: trivial

```
<MCI base: tests>+≡
subroutine mci_test_write (object, unit)

```

Integrate: sample at the midpoints of uniform bits and add the results. We implement this for one and for two dimensions. In the latter case, we scan over two channels and multiply with the channel weights.

The arguments `n_it` and `n_calls` are ignored in this implementations.

The test integrator does not set error or efficiency, so those will remain undefined.

```

    type is (mci_test_instance_t)
        call instance%recall (sampler, state)
    end select
end subroutine mci_test_rebuild_event

```

Instance of the test MCI type

This instance type simulates the VAMP approach. We implement the VAMP multi-channel formula, but keep the channel-specific probability functions g_i smooth and fixed. We also keep the weights fixed.

The setup is as follows: we have n mappings of the unit hypercube

$$x = x(x^{(k)}) \quad \text{where } x = (x_1, \dots). \quad (13.1)$$

The Jacobian factors are the determinants

$$f^{(k)}(x^{(k)}) = \left| \frac{\partial x}{\partial x^{(k)}} \right| \quad (13.2)$$

We introduce arbitrary probability functions

$$g^{(k)}(x^{(k)}) \quad \text{with} \quad \int dx^{(k)} g^{(k)}(x^{(k)}) = 1 \quad (13.3)$$

and weights

$$w_k \quad \text{with} \quad \sum_k w_k = 1 \quad (13.4)$$

and construct the joint probability function

$$g(x) = \sum_k w_k \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \quad (13.5)$$

which also satisfies

$$\int g(x) dx = 1. \quad (13.6)$$

The algorithm implements a resolution of unity as follows

$$\begin{aligned} 1 &= \int dx = \int \frac{g(x)}{g(x)} dx \\ &= \sum_k w_k \int \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \frac{dx}{g(x)} \\ &= \sum_k w_k \int g^{(k)}(x^{(k)}) \frac{dx^{(k)}}{g(x^{(k)})} \end{aligned} \quad (13.7)$$

where each of the integrals in the sum is evaluated using the channel-specific variables $x^{(k)}$.

We provide two examples: (1) trivial with one channel, one dimension, and all functions unity and (2) two channels and two dimensions with

$$\begin{aligned} x(x^{(1)}) &= (x_1^{(1)}, x_2^{(1)}) \\ x(x^{(2)}) &= (x_1^{(2)2}, x_2^{(2)}) \end{aligned} \quad (13.8)$$

hence

$$f^{(1)} \equiv 1, \quad f^{(2)}(x^{(2)}) = 2x_1^{(2)} \quad (13.9)$$

The probability functions are

$$g^{(1)} \equiv 1, \quad g^{(2)}(x^{(2)}) = 2x_2^{(2)} \quad (13.10)$$

In the concrete implementation of the integrator instance we store values for the channel probabilities g_i and the accumulated probability g .

We also store the result (product of integrand and MCI weight), the expected maximum for the result in each channel.

```

Test sampler

The test sampler implements a fixed configuration, either trivial (one-channel, one-dimension), or slightly nontrivial (two-channel, two-dimension). In the second channel, the first parameter is mapped according to $x_1 = x_1^{(2)2}$, so we have $f^{(2)}(x^{(2)}) = 2x_1^{(2)}$.

For display purposes, we store the return values inside the object. This is not strictly necessary.

13.2 Simple midpoint integration

This is a most simple implementation of an integrator. The algorithm is the straightforward multi-dimensional midpoint rule, i.e., the integration hypercube is binned uniformly, the integrand is evaluated at the midpoints of each bin, and the result is the average. The binning is equivalent for all integration dimensions.

This rule is accurate to the order h^2 , where h is the bin width. Given that $h = N^{-1/d}$, where d is the integration dimension and N is the total number of sampling points, we get a relative error of order $N^{-2/d}$. This is superior to MC integration if $d < 4$, and equivalent if $d = 4$. It is not worse than higher-order formulas (such as Gauss integration) if the integrand is not smooth, e.g., if it contains cuts.

The integrator is specifically single-channel. However, we do not limit the dimension.

13.2.1 Integrator

The object contains the methods for integration and event generation. For the actual work and data storage, it spawns an instance object.

After an integration pass, we update the `max` parameter to indicate the maximum absolute value of the integrand that the integrator encountered. This is required for event generation.

Integrate. The number of dimensions is arbitrary. We make sure that the number of calls is evenly distributed among the dimensions. The actual number of calls will typically be smaller than the requested number, but never smaller than 1.

The sampling over a variable number of dimensions implies a variable number of nested loops. We implement this by a recursive subroutine, one loop in each recursion level.

The number of iterations `n_it` is ignored. Also, the error is set to zero in the current implementation.

For unweighted events, we generate weighted events and apply a simple rejection step to the relative event weight, until an event passes.

Note that we use the `max_abs` value stored in the configuration record, not the one stored in the instance. The latter may change during event generation. After an event generation pass is over, we may update the value for a subsequent pass.

```

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

This is the function $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

Mimicking the behavior of a process object, we store the argument and result inside the sampler, so we can `fetch` results.

```

<MCI midpoint: test types>≡
type, extends (mci_sampler_t) :: test_sampler_1_t
    real(default), dimension(:), allocatable :: x
    real(default) :: val
contains
    <MCI midpoint: test sampler 1: TBP>
end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

13.3 VAMP interface

The standard method for integration is VAMP: the multi-channel version of the VEGAS algorithm. Each parameterization (channel) of the hypercube is binned in each dimension. The binning is equally equidistant, but an iteration of the integration procedure, the binning is updated for each dimension, according to the variance distribution of the integrand, summed over all other dimension. In the next iteration, the binning approximates (hopefully) follows the integrand

more closely, and the accuracy of the result is increased. Furthermore, the relative weight of the individual channels is also updated after an iteration.

The bin distribution is denoted as the grid for a channel, which we can write to file and reuse later.

In our implementation we specify the generic VAMP algorithm more tightly: the number of bins is equal for all dimensions, the initial weights are all equal. The user controls whether to update bins and/or weights after each iteration. The integration is organized in passes, each one consisting of several iterations with a common number of calls to the integrand. The first passes are intended as warmup, so the results are displayed but otherwise discarded. In the final pass, the integration estimates for the individual iterations are averaged for the final result.

```

Integrate. Perform a new integration pass (possibly reusing previous results), which may consist of several iterations.

Note: we record the integral once per iteration. The integral stored in the `mci` record itself is the last integral of the current iteration, no averaging done. The `results` record may average results.

Note: recording the efficiency is not supported yet.

13.3.4 Sampler as Workspace

In the full setup, the sampling function requires the process instance object as workspace. We implement this by (i) implementing the process instance as a type extension of the abstract `sampler_t` object used by the MCI implementation and (ii) providing such an object as an extra argument to the sampling function that VAMP can call. To minimize cross-package dependencies, we use an abstract type `vamp_workspace` that VAMP declares and extend this by including a pointer to the `sampler` and `instance` objects. In the body of the sampling function, we dereference this pointer and can then work with the contents.

```

<MCI vamp: types>+≡
    type, extends (vamp_data_t) :: mci_workspace_t
        class(mci_sampler_t), pointer :: sampler => null ()
        class(mci_vamp_instance_t), pointer :: instance => null ()

```

```
end type mci_workspace_t

Integration: sample the VAMP grids. The number of calls etc. are already stored inside the grids. We provide the random-number generator, the sampling function, and a link to the workspace object, which happens to contain a pointer to the sampler object. The sampler object thus becomes the workspace of the sampling function.

Note: in the current implementation, the random-number generator must be the TAO generator. This explicit dependence should be removed from the VAMP implementation.

13.3.6 Sampling function

The VAMP sampling function has a well-defined interface which we have to implement. The `data` argument allows us to pass pointers to the `sampler` and `instance` objects, so we can access configuration data and fill point-dependent contents within these objects.

The `weights` and `channel` argument must be present in the call.

Note: we would normally declare the `instance` pointer with the concrete type, or just use the `data` component directly. Unfortunately, gfortran 4.6 forgets the inherited base-type methods in that case.

(MCI vamp: procedures)+≡

```

function vamp_sampling_function (xi, data, weights, channel, grids) result (f)
  real(default) :: f
  real(default), dimension(:), intent(in) :: xi
  class(vamp_data_t), intent(in) :: data
  real(default), dimension(:), intent(in), optional :: weights
  integer, intent(in), optional :: channel
  type(vamp_grid), dimension(:), intent(in), optional :: grids
  class(mci_instance_t), pointer :: instance
  select type (data)

```

```

type is (mci_workspace_t)
  instance => data%instance
  select type (instance)
    class is (mci_vamp_instance_t)
      instance%calls = instance%calls + 1
    end select
    call instance%evaluate (data%sampler, channel, xi)
    f = instance%get_value ()
  end select
end function vamp_sampling_function

```

This is supposed to be the mapping between integration channels. The VAMP event generating procedures technically require it, but it is meaningless in our setup where all transformations happen inside the sampler object. So, this implementation is trivial:

```

⟨MCI vamp: procedures⟩+=≡
function phi_trivial (xi, channel_dummy) result (x)
  real(default), dimension(:), intent(in) :: xi
  integer, intent(in) :: channel_dummy
  real(default), dimension(size(xi)) :: x
  x = xi
end function phi_trivial

```

13.3.7 Integrator instance: evaluation

Here, we compute the multi-channel reweighting factor for the current channel, that accounts for the Jacobians of the transformations from/to all other channels.

The computation of the VAMP probabilities may consume considerable time, therefore we enable parallel evaluation. (Collecting the contributions to `mci%g` is a reduction, which we should also implement via OpenMP.)

Note: inactive channels not implemented yet.

```

⟨MCI vamp: mci vamp instance: TBP⟩+=≡
  procedure :: compute_weight => mci_vamp_instance_compute_weight

⟨MCI vamp: procedures⟩+=≡
subroutine mci_vamp_instance_compute_weight (mci, c)
  class(mci_vamp_instance_t), intent(inout) :: mci
  integer, intent(in) :: c
  integer :: i
  mci%selected_channel = c
  !$OMP PARALLEL PRIVATE(i) SHARED(mci)
  !$OMP DO
  do i = 1, mci%mci%n_channel
    mci%gi(i) = vamp_probability (mci%grids%grids(i), mci%x(:,i))
  end do
  !$OMP END DO
  !$OMP END PARALLEL
  mci%g = 0
  do i = 1, mci%mci%n_channel
    mci%g = mci%g + mci%w(i) * mci%gi(i) / mci%f(i)
  end do

```

```

    if (mci%g /= 0) then
        mci%mci_weight = mci%gi(c) / mci%g
    else
        mci%mci_weight = 0
    end if
end subroutine mci_vamp_instance_compute_weight

```

Record the integrand. Apply the Jacobian weight to get the absolute value. Divide by the channel maximum and by any overall factor to get the value relative to the maximum.

```

<MCI vamp: mci vamp instance: TBP>+≡
    procedure :: record_integrand => mci_vamp_instance_record_integrand

<MCI vamp: procedures>+≡
    subroutine mci_vamp_instance_record_integrand (mci, integrand)
        class(mci_vamp_instance_t), intent(inout) :: mci
        real(default), intent(in) :: integrand
        mci%integrand = integrand
    end subroutine mci_vamp_instance_record_integrand

```

Get the event weight. The default routine returns the same value that we would use for integration. This is correct if we select the integration channel according to the channel weight. *vamp_next_event* does differently, so we should rather rely on the weight that VAMP returns. This is the value stored in *vamp_weight*. We override the default TBP accordingly.

```

    <MCI vamp: execute tests>
    end subroutine mci_vamp_test

```

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is $11x^{10}$, also with integral 1.

```

(MCI vamp: test types)≡
  type, extends (mci_sampler_t) :: test_sampler_1_t
    real(default), dimension(:), allocatable :: x
    real(default) :: val
    integer :: mode = 1
  contains
    (MCI vamp: test sampler 1: TBP)
  end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

(MCI vamp: test sampler 1: TBP)≡
  procedure :: write => test_sampler_1_write

(MCI vamp: tests)+≡

Two-channel, one dimension test sampler

This sampler implements the function

$$f(x, y) = a * 5x^4 + b * 5(1 - x)^4 \quad (13.15)$$

Each term contributes 1 to the integral, multiplied by a or b , respectively. The first term is peaked at $x = 1$, the second one at $x = 0$.

We implement the two mappings

$$x = u^{1/5} \quad \text{and} \quad x = 1 - v^{1/5}, \quad (13.16)$$

with Jacobians

$$\frac{\partial(x)}{\partial(u)} = u^{-4/5}/5 \quad \text{and} \quad v^{-4/5}/5, \quad (13.17)$$

respectively. The first mapping concentrates points near $x = 1$, the second one near $x = 0$.

One-dimensional integration

Construct an integrator and use it for a one-dimensional sampler.

Note: We would like to check the precise contents of the grid allocated during integration, but the output format for reals is very long (for good reasons), so the last digits in the grid content display are numerical noise. So, we just check the integration results.

```

select type (mci)
type is (mci_vamp_t)
  call mci%update_from_ref (mci_ref, success)
end select

```

```

write (u, "(1x,A,L1)") "success = ", success
write (u, "(A)")
call mci%write (u)

write (u, "(A)")
write (u, "(A)")  "* Cleanup"

call mci%final ()
call mci_ref%final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: mci_vamp_13"

end subroutine mci_vamp_13

```

Chapter 14

Process Libraries

This chapter consists of two modules which organize and interface the interaction matrix elements for a variety of elementary processes.

prclib_interfaces This module deals with matrix-element code which is accessible via external libraries (Fortran libraries or generic C-compatible libraries) and must either be generated by the program or provided by the user explicitly.

The module defines and uses an abstract type `prc_writer_t` and two abstract extensions, one for a Fortran module and one for a C-compatible library. The implementation provides the specific methods for writing the appropriate parts in external matrix element code.

prc_core_def This module defines the abstract types `prc_core_def_t` and `prc_driver_t`. The implementation of the former provides the configuration for processes of a certain class, while the latter accesses the corresponding matrix element, in particular those generated by the appropriate `prc_writer_t` object.

process_libraries This module combines the functionality of the previous module with the means for holding processes definitions (the internal counterpart of appropriate declarations in the user interface), for handling matrix elements which do not need external code, and for accessing the matrix elements by the procedures for matrix-element evaluation, integration and event generation.

test_me This module provides a test implementation for the abstract types in the `prc_core_def` module. The implementation is intended for self-tests of several later modules. The implementation is internal, i.e., no external code has is generated.

All data structures which are specific for a particular way of generating code or evaluating matrix element are kept abstract and thus generic. Later modules such as `prc_omega` provide implementations, in the form of type extensions for the various abstract types.

14.1 Process library interface

The module `prclib_interfaces` handles external matrix-element code.

14.1.1 Overview

The top-level data structure is the `prclib_driver_t` data type. The associated type-bound procedures deal with the generation of external code, compilation and linking, and accessing the active external library.

An object of type `prclib_driver_t` consists of the following parts:

1. Metadata that identify name and status of the library driver, etc.
2. An array of process records (`prclib_driver_record_t`), one for each external matrix element.
3. A record of type `dlaccess_t` which handles the operating-system part of linking a dynamically loadable library.
4. A collection of procedure pointers which have a counterpart in the external library interface. Given the unique identifier of a matrix element, the procedures retrieve generic matrix-element information such as the particle content and helicity combination tables. There is also a procedure which returns pointers to the more specific procedures that a matrix element provides, called *features*.

The process records of type `prclib_driver_record_t` handle the individual matrix elements. Each record identifies a process by name (`id`), names the physics model to be loaded for this process, lists the features that the associated matrix-element code provides, and holds a `writer` object which handles all operations that depend on the process type. The numbering of process records is identical to the numbering of matrix-element codes in the external library.

The writer object is of abstract type `prc_writer_t`. The module defines two basic, also abstract, extensions: `prc_writer_f_module_t` and `prc_writer_c_lib_t`. The first version is for matrix-element code that is available in form of Fortran modules. The writer contains type-bound procedures which create appropriate `use` directives and C-compatible wrapper functions for the given set of Fortran modules and their features. The second version is for matrix-element code that is available in form of a C-compatible library (this includes Fortran libraries with proper C bindings). The writer needs not write wrapper function, but explicit interface blocks for the matrix-element features.

Each matrix-element variant is encoded in an appropriate extension of `prc_writer_t`. For instance, `O'MEGA` matrix elements provide an implementation `omega_writer_t` which extends `prc_writer_f_module_t`.

14.1.2 Workflow

We expect that the functionality provided by this module is called in the following order:

1. The caller initializes the `prclib_driver_t` object and fills the array of `prclib_record_t` entries with the appropriate process data and process-specific writer objects.

2. It calls the `generate_makefile` method to set up an appropriate makefile in the current directory. The makefile will handle source generation, compilation and linking both for the individual matrix elements (unless this has to be done manually) and for the common external driver code which interfaces those matrix element.
3. The `generate_driver_code` writes the common driver as source code to file.
4. The methods `make_source`, `make_compile`, and `make_link` individually perform the corresponding steps in building the library. Wherever possible, they simply use the generated makefile. By calling `make`, we make sure that we can avoid unnecessary recompilation. For the compilation and linking steps, the makefile will employ `libtool`.
5. The `load` method loads the library procedures into the corresponding procedure pointers, using the `dlopen` mechanism via the `dlaccess` subobject.

14.1.3 The module

```

<prclib_interfaces.f90>≡
  <File header>

  module prclib_interfaces

    use iso_c_binding !NODEP!
    use kinds !NODEP!
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use limits, only: TAB !NODEP!
    use unit_tests
    use os_interface

    <Standard module head>

    <Prclib interfaces: public>

    <Prclib interfaces: types>

    <Prclib interfaces: interfaces>

    <Prclib interfaces: test types>

    contains

    <Prclib interfaces: procedures>

    <Prclib interfaces: tests>

  end module prclib_interfaces

```

14.1.4 Writers

External matrix element code provides externally visible procedures, which we denote as *features*. The features consist of informational subroutines and functions which are mandatory (universal features) and matrix-element specific subroutines and functions (specific features). The driver interfaces the generic features directly, while it returns the specific features in form of `bind(C)` procedure pointers to the caller. For instance, function `n_in` is generic, while the matrix matrix-element value itself is specific.

To implement these tasks, the driver needs `use` directives for Fortran module procedures, interface blocks for other external stuff, wrapper code, and Makefile snippets.

Generic writer

In the `prc_writer_t` data type, we collect the procedures which implement the writing tasks. The type is abstract. The concrete implementations are defined by an extension which is specific for the process type.

The MD5 sum stored here should be the MD5 checksum of the current process component, which can be calculated once the process is configured completely. It can be used by implementations which work with external files, such as O'MEGA.

```
<Prclib interfaces: public>≡
  public :: prc_writer_t

<Prclib interfaces: types>≡
  type, abstract :: prc_writer_t
    character(32) :: md5sum = ""
    contains
    <Prclib interfaces: prc writer: TBP>
  end type prc_writer_t
```

In any case, it is useful to have a string representation of the writer type. This must be implemented by all extensions.

```
<Prclib interfaces: prc writer: TBP>≡
  procedure(get_const_string), nopass, deferred :: type_name

<Prclib interfaces: interfaces>≡
  abstract interface
    function get_const_string () result (string)
      import
      type(string_t) :: string
    end function get_const_string
  end interface
```

Return the name of a procedure that implements a given feature, as it is provided by the external matrix-element code. For a reasonable default, we take the feature name unchanged.

```
<Prclib interfaces: prc writer: TBP>+≡
  procedure, nopass :: get_procname => prc_writer_get_procname
```

```

<Prclib interfaces: procedures>≡
function prc_writer_get_procname (feature) result (name)
    type(string_t) :: name
    type(string_t), intent(in) :: feature
    name = feature
end function prc_writer_get_procname

```

Return the name of a procedure that implements a given feature with the bind(C) property, so it can be accessed via a C procedure pointer and handled by dlopen. We need this for all special features of a matrix element, since the interface has to return a C function pointer for it. For a default implementation, we prefix the external procedure name by the process ID.

```

<Prclib interfaces: prc writer: TBP>+≡
    procedure :: get_c_procname => prc_writer_get_c_procname

<Prclib interfaces: procedures>+≡
function prc_writer_get_c_procname (writer, id, feature) result (name)
    class(prc_writer_t), intent(in) :: writer
    type(string_t), intent(in) :: id, feature
    type(string_t) :: name
    name = id // "_" // feature
end function prc_writer_get_c_procname

```

Common signature of code-writing procedures. The procedure may use the process ID, and the feature name. (Not necessarily all of them.)

```

<Prclib interfaces: interfaces>+≡
    abstract interface
        subroutine write_code_file (writer, id)
            import
            class(prc_writer_t), intent(in) :: writer
            type(string_t), intent(in) :: id
        end subroutine write_code_file
    end interface

    abstract interface
        subroutine write_code (writer, unit, id)
            import
            class(prc_writer_t), intent(in) :: writer
            integer, intent(in) :: unit
            type(string_t), intent(in) :: id
        end subroutine write_code
    end interface

    abstract interface
        subroutine write_code_os (writer, unit, id, os_data)
            import
            class(prc_writer_t), intent(in) :: writer
            integer, intent(in) :: unit
            type(string_t), intent(in) :: id
            type(os_data_t), intent(in) :: os_data
        end subroutine write_code_os
    end interface

```

```

abstract interface
  subroutine write_feature_code (writer, unit, id, feature)
    import
    class(prc_writer_t), intent(in) :: writer
    integer, intent(in) :: unit
    type(string_t), intent(in) :: id, feature
  end subroutine write_feature_code
end interface

```

There must be a procedure which writes an interface block for a given feature. If the external matrix element is implemented as a Fortran module, this is required only for the specific features which are returned as procedure pointers.

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure(write_feature_code), deferred :: write_interface

```

There must also be a procedure which writes Makefile code which is specific for the current process, but not the feature.

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure(write_code_os), deferred :: write_makefile_code

```

This procedure writes code process-specific source-code file (which need not be Fortran). It may be a no-op, if the source code is generated by Make instead.

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure(write_code_file), deferred :: write_source_code

```

Writer for Fortran-module matrix elements

If the matrix element is available as a Fortran module, we have specific requirements: (i) the features are imported via `use` directives, (ii) the specific features require `bind(C)` wrappers.

The type is still abstract, all methods must be implemented explicitly for a specific matrix-element variant.

```

<Prclib interfaces: public>+≡
  public :: prc_writer_f_module_t

<Prclib interfaces: types>+≡
  type, extends (prc_writer_t), abstract :: prc_writer_f_module_t
  contains
    <Prclib interfaces: prc writer f module: TBP>
  end type prc_writer_f_module_t

```

Return the name of the Fortran module. As a default implementation, we take the process ID unchanged.

```

<Prclib interfaces: prc writer f module: TBP>≡
  procedure, nopass :: get_module_name => prc_writer_get_module_name

<Prclib interfaces: procedures>+≡
  function prc_writer_get_module_name (id) result (name)
    type(string_t) :: name
    type(string_t), intent(in) :: id
    name = id
  end function prc_writer_get_module_name

```

Write a `use` directive that associates the driver reference with the procedure in the matrix element code. By default, we use the C name for this.

```

<Prclib interfaces: prc writer f module: TBP>+≡
  procedure :: write_use_line => prc_writer_write_use_line

<Prclib interfaces: procedures>+≡
  subroutine prc_writer_write_use_line (writer, unit, id, feature)
    class(prc_writer_f_module_t), intent(in) :: writer
    integer, intent(in) :: unit
    type(string_t) :: id, feature
    write (unit, "(2x,9A)") "use ", char (writer%get_module_name (id)), &
      ", only: ", char (writer%get_c_procname (id, feature)), &
      " => ", char (writer%get_procname (feature))
  end subroutine prc_writer_write_use_line

```

Write a wrapper routine for a feature. This also associates a C name the module procedure. The details depend on the writer variant.

```

<Prclib interfaces: prc writer f module: TBP>+≡
  procedure(prc_write_wrapper), deferred :: write_wrapper

<Prclib interfaces: interfaces>+≡
  abstract interface
    subroutine prc_write_wrapper (writer, unit, id, feature)
      import
      class(prc_writer_f_module_t), intent(in) :: writer
      integer, intent(in) :: unit
      type(string_t), intent(in) :: id, feature
    end subroutine prc_write_wrapper
  end interface

```

This is used for testing only: initialize the writer with a specific MD5 sum string.

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure :: init_test => prc_writer_init_test

<Prclib interfaces: procedures>+≡
  subroutine prc_writer_init_test (writer)
    class(prc_writer_t), intent(out) :: writer
    writer%md5sum = "1234567890abcdef1234567890abcdef"
  end subroutine prc_writer_init_test

```

Writer for C-library matrix elements

This applies if the matrix element is available as a C library or a Fortran library with `bind(C)` compatible interface. We can use the basic version.

The type is still abstract, all methods must be implemented explicitly for a specific matrix-element variant.

```

<Prclib interfaces: types>+≡
  type, extends (prc_writer_t), abstract :: prc_writer_c_lib_t
  contains
    <Prclib interfaces: prc writer c lib: TBP>
  end type prc_writer_c_lib_t

```

14.1.5 Process records in the library driver

A process record holds the process (component) ID, the physics `model_name`, and the array of `features` that are implemented by the corresponding matrix element code.

The `writer` component holds procedures. The procedures write source code for the current record, either for the driver or for the Makefile.

```
<Prclib interfaces: types>+≡
  type :: prclib_driver_record_t
    type(string_t) :: id
    type(string_t) :: model_name
    type(string_t), dimension(:), allocatable :: feature
    class(prc_writer_t), pointer :: writer => null ()
  contains
    <Prclib interfaces: prclib driver record: TBP>
  end type prclib_driver_record_t
```

Output routine. We indent the output, so it smoothly integrates into the output routine for the whole driver.

Note: the pointer `writer` is introduced as a workaround for a NAG compiler bug.

```
<Prclib interfaces: prclib driver record: TBP>≡
  procedure :: write => prclib_driver_record_write

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_record_write (object, unit)
    class(prclib_driver_record_t), intent(in) :: object
    integer, intent(in) :: unit
    integer :: j
    class(prc_writer_t), pointer :: writer
    write (unit, "(3x,A,2x,['',A,']')") &
      char (object%id), char (object%model_name)
    if (allocated (object%feature)) then
      writer => object%writer
      write (unit, "(5x,A,A)", advance="no") &
        char (writer%type_name ()), ":"
      do j = 1, size (object%feature)
        write (unit, "(1x,A)", advance="no") &
          char (object%feature(j))
      end do
      write (unit, *)
    end if
  end subroutine prclib_driver_record_write
```

Get the C procedure name for a feature.

```
<Prclib interfaces: prclib driver record: TBP>+≡
  procedure :: get_c_procname => prclib_driver_record_get_c_procname

<Prclib interfaces: procedures>+≡
  function prclib_driver_record_get_c_procname (record, feature) result (name)
    type(string_t) :: name
    class(prclib_driver_record_t), intent(in) :: record
    type(string_t), intent(in) :: feature
```

```

        name = record%writer%get_c_procname (record%id, feature)
    end function prclib_driver_record_get_c_procname

```

Write a USE directive for a given feature. Applies only if the record corresponds to a Fortran module.

```

<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_use_line => prclib_driver_record_write_use_line
<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_record_write_use_line (record, unit, feature)
        class(prclib_driver_record_t), intent(in) :: record
        integer, intent(in) :: unit
        type(string_t), intent(in) :: feature
        select type (writer => record%writer)
            class is (prc_writer_f_module_t)
                call writer%write_use_line (unit, record%id, feature)
            end select
    end subroutine prclib_driver_record_write_use_line

```

The alternative: write an interface block for a given feature, unless the record corresponds to a Fortran module.

```

<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_interface => prclib_driver_record_write_interface
<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_record_write_interface (record, unit, feature)
        class(prclib_driver_record_t), intent(in) :: record
        integer, intent(in) :: unit
        type(string_t), intent(in) :: feature
        select type (writer => record%writer)
            class is (prc_writer_f_module_t)
                class default
                    call writer%write_interface (unit, record%id, feature)
                end select
        end select
    end subroutine prclib_driver_record_write_interface

```

Write all special feature interfaces for the current record. Do this for all process variants.

```

<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_interfaces => prclib_driver_record_write_interfaces
<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_record_write_interfaces (record, unit)
        class(prclib_driver_record_t), intent(in) :: record
        integer, intent(in) :: unit
        integer :: i
        do i = 1, size (record%feature)
            call record%writer%write_interface (unit, record%id, record%feature(i))
        end do
    end subroutine prclib_driver_record_write_interfaces

```

Write the wrapper routines for this record, if it corresponds to a Fortran module.

```

<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_wrappers => prclib_driver_record_write_wrappers

```

```

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_record_write_wrappers (record, unit)
    class(prclib_driver_record_t), intent(in) :: record
    integer, intent(in) :: unit
    integer :: i
    select type (writer => record%writer)
    class is (prc_writer_f_module_t)
      do i = 1, size (record%feature)
        call writer%write_wrapper (unit, record%id, record%feature(i))
      end do
    end select
  end subroutine prclib_driver_record_write_wrappers

```

Write the Makefile code for this record.

```

<Prclib interfaces: prclib driver record: TBP>+≡
  procedure :: write_makefile_code => prclib_driver_record_write_makefile_code

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_record_write_makefile_code (record, unit, os_data)
    class(prclib_driver_record_t), intent(in) :: record
    integer, intent(in) :: unit
    type(os_data_t), intent(in) :: os_data
    call record%writer%write_makefile_code (unit, record%id, os_data)
  end subroutine prclib_driver_record_write_makefile_code

```

Write source-code files for this record. (Does nothing if the source code is handled by Makefile rules.)

```

<Prclib interfaces: prclib driver record: TBP>+≡
  procedure :: write_source_code => prclib_driver_record_write_source_code

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_record_write_source_code (record)
    class(prclib_driver_record_t), intent(in) :: record
    call record%writer%write_source_code (record%id)
  end subroutine prclib_driver_record_write_source_code

```

14.1.6 The process library driver object

A `prclib_driver_t` object provides the interface to external matrix element code. The code is provided by an external library which is either statically or dynamically linked.

The `basename` identifies the library, both by file names and by Fortran variable names.

The `static` flag tells whether the external library is statically or dynamically linked.

The `loaded` flag becomes true once all procedure pointers to the matrix element have been assigned.

For a dynamical external library, the communication proceeds via a `dlaccess` object.

`n_processes` is the number of external process code components that are referenced by this library. The code is addressed by index (`i_lib` in the process

library entry above). This number should be equal to the number returned by `get_n_prc`.

For each external process, there is a separate **record** which holds the data that are needed for the driver parts which are specific for a given process component. The actual pointers for the loaded library will be assigned elsewhere.

The remainder is a collection of procedure pointers, which can be assigned once all external code has been compiled and linked. The procedure pointers all take a process component code index as an argument. Most return information about the process component that should match the process definition. The `get_fptr` procedures return a function pointer, which is the actual means to compute matrix elements or retrieve associated data.

Finally, the `unload_hook` and `reload_hook` pointers allow for the insertion of additional code when a library is loaded.

```

<Prclib interfaces: public>+≡
    public :: prclib_driver_t

<Prclib interfaces: types>+≡
    type :: prclib_driver_t
        type(string_t) :: basename
        character(32) :: md5sum = ""
        logical :: static = .false.
        logical :: loaded = .false.
        type(string_t) :: libname
        type(dlaccess_t) :: dlaccess
        integer :: n_processes = 0
        type(prclib_driver_record_t), dimension(:), allocatable :: record
        procedure(prc_get_n_processes), nopass, pointer :: &
            get_n_processes => null ()
        procedure(prc_get_stringptr), nopass, pointer :: &
            get_process_id_ptr => null ()
        procedure(prc_get_stringptr), nopass, pointer :: &
            get_model_name_ptr => null ()
        procedure(prc_get_stringptr), nopass, pointer :: &
            get_md5sum_ptr => null ()
        procedure(prc_get_log), nopass, pointer :: &
            get_omp_status => null ()
        procedure(prc_get_int), nopass, pointer :: get_n_in => null ()
        procedure(prc_get_int), nopass, pointer :: get_n_out => null ()
        procedure(prc_get_int), nopass, pointer :: get_n_flv => null ()
        procedure(prc_get_int), nopass, pointer :: get_n_hel => null ()
        procedure(prc_get_int), nopass, pointer :: get_n_col => null ()
        procedure(prc_get_int), nopass, pointer :: get_n_cin => null ()
        procedure(prc_get_int), nopass, pointer :: get_n_cf => null ()
        procedure(prc_set_int_tab1), nopass, pointer :: &
            set_flv_state_ptr => null ()
        procedure(prc_set_int_tab1), nopass, pointer :: &
            set_hel_state_ptr => null ()
        procedure(prc_set_col_state), nopass, pointer :: &
            set_col_state_ptr => null ()
        procedure(prc_set_color_factors), nopass, pointer :: &
            set_color_factors_ptr => null ()
        procedure(prc_get_fptr), nopass, pointer :: get_fptr => null ()
!       procedure(prclib_unload_hook), nopass, pointer :: unload_hook => null ()

```

```

!      procedure(prclib_reload_hook), nopass, pointer :: reload_hook => null ()
contains
  <Prclib interfaces: prclib driver: TBP>
end type prclib_driver_t

```

Print just the metadata. Procedure pointers cannot be printed.

```

<Prclib interfaces: prclib driver: TBP>≡
  procedure :: write => prclib_driver_write

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_write (object, unit)
    class(prclib_driver_t), intent(in) :: object
    integer, intent(in) :: unit
    integer :: i
    write (unit, "(1x,A,A)") &

14.1.8 Write driver file

This procedure writes the process library driver source code to the specified output unit. The individual routines for writing source-code procedures are

given below.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: generate_driver_code => prclib_driver_generate_code

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_generate_code (driver, unit)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: unit
    type(string_t) :: prefix
    integer :: i

    prefix = driver%basename // "_"

    write (unit, "(A)")  "! WHIZARD matrix-element code interface"
    write (unit, "(A)")  "!"
    write (unit, "(A)")  "! Automatically generated file, do not edit"
    call driver%write_lib_md5sum_fun (unit, prefix)
    call driver%write_get_n_processes_fun (unit, prefix)
    call driver%write_get_process_id_fun (unit, prefix)
    call driver%write_get_model_name_fun (unit, prefix)
!   call write_get_restrictions_fun ()
!   call write_get_omega_flags_fun ()
    call driver%write_get_md5sum_fun (unit, prefix)
    call driver%write_string_to_array_fun (unit, prefix)
    call driver%write_get_openmp_status_fun (unit, prefix)
    call driver%write_get_int_fun (unit, prefix, var_str ("n_in"))
    call driver%write_get_int_fun (unit, prefix, var_str ("n_out"))
    call driver%write_get_int_fun (unit, prefix, var_str ("n_flv"))
    call driver%write_get_int_fun (unit, prefix, var_str ("n_hel"))
    call driver%write_get_int_fun (unit, prefix, var_str ("n_col"))
    call driver%write_get_int_fun (unit, prefix, var_str ("n_cin"))
    call driver%write_get_int_fun (unit, prefix, var_str ("n_cf"))
    call driver%write_set_int_sub (unit, prefix, var_str ("flv_state"))
    call driver%write_set_int_sub (unit, prefix, var_str ("hel_state"))
    call driver%write_set_col_state_sub (unit, prefix)
    call driver%write_set_color_factors_sub (unit, prefix)
    call driver%write_get_fptr_sub (unit, prefix)
    do i = 1, driver%n_processes
      call driver%record(i)%write_wrappers (unit)
    end do
  end subroutine prclib_driver_generate_code

```

This function provides the overall library MD5sum. The function is for internal use (therefore not bind(C)), the external interface is via the `get_md5sum_ptr` procedure with index 0.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: write_lib_md5sum_fun => prclib_driver_write_lib_md5sum_fun

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_write_lib_md5sum_fun (driver, unit, prefix)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    write (unit, "(A)")  ""

```

```

write (unit, "(A)")  "! The MD5 sum of the library"
write (unit, "(A)")  "function " // char (prefix) &
// "md5sum () result (md5sum)"
write (unit, "(A)")  "  implicit none"
write (unit, "(A)")  "  character(32) :: md5sum"
write (unit, "(A)")  "  md5sum = ' " // driver%md5sum // "' "
write (unit, "(A)")  "end function " // char (prefix) // "md5sum"
end subroutine prclib_driver_write_lib_md5sum_fun

```

14.1.9 Interface bodies for informational functions

These interfaces implement the communication between WHIZARD (the main program) and the process-library driver. The procedures are all BIND(C), so they can safely be exposed by the library and handled by the `dlopen` mechanism, which apparently understands only C calling conventions.

In the sections below, for each procedure, we provide both the interface itself and a procedure that writes the corresponding procedure as source code to the process library driver.

Process count

Return the number of processes contained in the library.

```

<Prclib interfaces: public>+≡
public :: prc_get_n_processes

<Prclib interfaces: interfaces>+≡
abstract interface
  function prc_get_n_processes () result (n) bind(C)
  import
  integer(c_int) :: n
end function prc_get_n_processes
end interface

```

Here is the code.

```

<Prclib interfaces: prclib driver: TBP>+≡
procedure :: write_get_n_processes_fun

<Prclib interfaces: procedures>+≡
subroutine write_get_n_processes_fun (driver, unit, prefix)
  class(prclib_driver_t), intent(in) :: driver
  integer, intent(in) :: unit
  type(string_t), intent(in) :: prefix
  write (unit, "(A)")  ""
  write (unit, "(A)")  "! Return the number of processes in this library"
  write (unit, "(A)")  "function " // char (prefix) &
// "get_n_processes () result (n) bind(C)"
  write (unit, "(A)")  "  use iso_c_binding"
  write (unit, "(A)")  "  implicit none"
  write (unit, "(A)")  "  integer(c_int) :: n"
  write (unit, "(A,I0)")  "  n = ", driver%n_processes
  write (unit, "(A)")  "end function " // char (prefix) &
// "get_n_processes"
end subroutine write_get_n_processes_fun

```

Informational string functions

These functions return constant information about the matrix-element code.

The following procedures have to return strings. With the BIND(C) constraint, we choose to return the C pointer to a string, and its length, so the procedures implement this interface. They are actually subroutines.

```
(Prclib interfaces: public)+≡
    public :: prc_get_stringptr

(Prclib interfaces: interfaces)+≡
    abstract interface
        subroutine prc_get_stringptr (i, cptr, len) bind(C)
            import
            integer(c_int), intent(in) :: i
            type(c_ptr), intent(out) :: cptr
            integer(c_int), intent(out) :: len
        end subroutine prc_get_stringptr
    end interface
```

To hide this complication, we introduce a subroutine that converts the returned C pointer to a **string_t** object. As a side effect, we deallocate the original after conversion – otherwise, we might have a memory leak.

For the conversion, we first pointer-convert the C pointer to a Fortran character array pointer, length 1 and size **len**. Using argument association and an internal subroutine, we convert this to a character array with length **len** and size 1. Using ordinary assignment, we finally convert this to **string_t**.

The function takes the pointer-returning function as an argument. The index **i** identifies the process in the library.

```
(Prclib interfaces: procedures)+≡
    subroutine get_string_via_cptr (string, i, get_stringptr)
        type(string_t), intent(out) :: string
        integer, intent(in) :: i
        procedure(prc_get_stringptr) :: get_stringptr
        type(c_ptr) :: cptr
        integer(c_int) :: pid, len
        character(kind=c_char), dimension(:), pointer :: c_array
        pid = i
        call get_stringptr (pid, cptr, len)
        if (c_associated (cptr)) then
            call c_f_pointer (cptr, c_array, shape = [len])
            call set_string (c_array)
            call get_stringptr (0_c_int, cptr, len)
        else
            string = ""
        end if
    contains
        subroutine set_string (buffer)
            character(len, kind=c_char), dimension(1), intent(in) :: buffer
            string = buffer(1)
        end subroutine set_string
    end subroutine get_string_via_cptr
```

Since the module procedures return Fortran strings, we have to convert them. This is the necessary auxiliary routine. The routine is not BIND(C), it is not accessed from outside.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure, nopass :: write_string_to_array_fun

<Prclib interfaces: procedures>+≡
  subroutine write_string_to_array_fun (unit, prefix)
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    write (unit, "(A)") ""
    write (unit, "(A)") "! Auxiliary: convert character string &
      &to array pointer"
    write (unit, "(A)") "subroutine " // char (prefix) &
      // "string_to_array (string, a)"
    write (unit, "(A)") "  use iso_c_binding"
    write (unit, "(A)") "  implicit none"
    write (unit, "(A)") "  character(*), intent(in) :: string"
    write (unit, "(A)") "  character(kind=c_char), dimension(:), &
      &allocatable, intent(out) :: a"
    write (unit, "(A)") "  integer :: i"
    write (unit, "(A)") "  allocate (a (len (string)))"
    write (unit, "(A)") "  do i = 1, size (a)"
    write (unit, "(A)") "    a(i) = string(i:i)"
    write (unit, "(A)") "  end do"
    write (unit, "(A)") "end subroutine " // char (prefix) &
      // "string_to_array"
  end subroutine write_string_to_array_fun

```

The above routine is called by other functions. It is not in a module, so they need its interface explicitly.

```

<Prclib interfaces: procedures>+≡
  subroutine write_string_to_array_interface (unit, prefix)
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    write (unit, "(2x,A)") "interface"
    write (unit, "(2x,A)") "  subroutine " // char (prefix) &
      // "string_to_array (string, a)"
    write (unit, "(2x,A)") "    use iso_c_binding"
    write (unit, "(2x,A)") "    implicit none"
    write (unit, "(2x,A)") "    character(*), intent(in) :: string"
    write (unit, "(2x,A)") "    character(kind=c_char), dimension(:), &
      &allocatable, intent(out) :: a"
    write (unit, "(2x,A)") "  end subroutine " // char (prefix) &
      // "string_to_array"
    write (unit, "(2x,A)") "end interface"
  end subroutine write_string_to_array_interface

```

Here are the info functions which return strings, implementing the interface `prc_get_stringptr`.

Return the process ID for each process.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: write_get_process_id_fun

```

<Prclib interfaces: procedures>+≡

```

subroutine write_get_process_id_fun (driver, unit, prefix)
  class(prclib_driver_t), intent(in) :: driver
  integer, intent(in) :: unit

write (unit, "(A)") " end if"
write (unit, "(A)") "end subroutine " // char (prefix) &
// "get_model_name_ptr"
end subroutine write_get_model_name_fun

```

Call the MD5 sum function for the process. The function calls the corresponding function of the matrix-element code, and it returns the C address of a character array with length 32.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: write_get_md5sum_fun

<Prclib interfaces: procedures>+≡
  subroutine write_get_md5sum_fun (driver, unit, prefix)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    integer :: i
    write (unit, "(A)") ""
    write (unit, "(A)") " ! Return the MD5 sum for the process configuration &
      &(as a C pointer to a character array)"
    write (unit, "(A)") "subroutine " // char (prefix) &
      // "get_md5sum_ptr (i, cptr, len) bind(C)"
    write (unit, "(A)") " use iso_c_binding"
    call driver%write_interfaces (unit, var_str ("md5sum"))
    write (unit, "(A)") " interface"
    write (unit, "(A)") "   function " // char (prefix) &
      // "md5sum () result (md5sum)"
    write (unit, "(A)") "     character(32) :: md5sum"
    write (unit, "(A)") "   end function " // char (prefix) // "md5sum"
    write (unit, "(A)") " end interface"
    write (unit, "(A)") " integer(c_int), intent(in) :: i"
    write (unit, "(A)") " type(c_ptr), intent(out) :: cptr"

```

```

write (unit, "(A)") " integer(c_int), intent(out) :: len"
write (unit, "(A)") " character(kind=c_char), dimension(32), &
    &target, save :: md5sum"
write (unit, "(A)") " select case (i)"
write (unit, "(A)") " case (0)"
write (unit, "(A)") " call copy (" // char (prefix) // "md5sum ())"
write (unit, "(A)") " cptr = c_loc (md5sum)"
do i = 1, driver%n_processes
    write (unit, "(A,I0,A)") " case (" , i, ")"
    call driver%record(i)%write_md5sum_call (unit)
end do
write (unit, "(A)") " case default"
write (unit, "(A)") " cptr = c_null_ptr"
write (unit, "(A)") " end select"
write (unit, "(A)") " len = 32"
write (unit, "(A)") "contains"
write (unit, "(A)") " subroutine copy (md5sum_tmp)"
write (unit, "(A)") " character, dimension(32), intent(in) :: &
    &md5sum_tmp"
write (unit, "(A)") " md5sum = md5sum_tmp"
write (unit, "(A)") " end subroutine copy"
write (unit, "(A)") "end subroutine " // char (prefix) &
    // "get_md5sum_ptr"
end subroutine write_get_md5sum_fun

```

The actual call depends on the type of matrix element.

```

<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_md5sum_call => prclib_driver_record_write_md5sum_call

<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_record_write_md5sum_call (record, unit)
        class(prclib_driver_record_t), intent(in) :: record
        integer, intent(in) :: unit
        call record%writer%write_md5sum_call (unit, record%id)
    end subroutine prclib_driver_record_write_md5sum_call

```

The interface goes into the writer base type:

```

<Prclib interfaces: prc writer: TBP>+≡
    procedure(write_code), deferred :: write_md5sum_call

In the Fortran module case, we take a detour. The string returned by the
Fortran function is copied into a fixed-size array. The copy routine is an internal
subroutine of get_md5sum_ptr. We return the C address of the target array.

<Prclib interfaces: prc writer f module: TBP>+≡
    procedure :: write_md5sum_call => prc_writer_f_module_write_md5sum_call

<Prclib interfaces: procedures>+≡
    subroutine prc_writer_f_module_write_md5sum_call (writer, unit, id)
        class(prc_writer_f_module_t), intent(in) :: writer
        integer, intent(in) :: unit
        type(string_t), intent(in) :: id
        write (unit, "(5x,9A)") "call copy (" , &
            char (writer%get_c_procname (id, var_str ("md5sum"))), " ()"
        write (unit, "(5x,9A)") "cptr = c_loc (md5sum)"

```

```
end subroutine prc_writer_f_module_write_md5sum_call
```

In the C library case, the library function returns a C pointer, which we can just copy.

```
<Prclib interfaces: prc writer c lib: TBP>≡
  procedure :: write_md5sum_call => prc_writer_c_lib_write_md5sum_call

<Prclib interfaces: procedures>+≡
  subroutine prc_writer_c_lib_write_md5sum_call (writer, unit, id)
    class(prc_writer_c_lib_t), intent(in) :: writer
    integer, intent(in) :: unit
    type(string_t), intent(in) :: id
    write (unit, "(5x,9A)") &
      "cptr = ", &
      char (writer%get_c_procname (id, var_str ("get_md5sum"))), " ()"
  end subroutine prc_writer_c_lib_write_md5sum_call
```

Actual references to the info functions

The string-valued info functions return C character arrays. For the API of the library driver, we provide convenience functions which (re)convert those arrays into `string_t` objects.

```
<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: get_process_id => prclib_driver_get_process_id
  procedure :: get_model_name => prclib_driver_get_model_name
  procedure :: get_md5sum => prclib_driver_get_md5sum

<Prclib interfaces: procedures>+≡
  function prclib_driver_get_process_id (driver, i) result (string)
    type(string_t) :: string
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    call get_string_via_cptr (string, i, driver%get_process_id_ptr)
  end function prclib_driver_get_process_id

  function prclib_driver_get_model_name (driver, i) result (string)
    type(string_t) :: string
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    call get_string_via_cptr (string, i, driver%get_model_name_ptr)
  end function prclib_driver_get_model_name

  function prclib_driver_get_md5sum (driver, i) result (string)
    type(string_t) :: string
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    call get_string_via_cptr (string, i, driver%get_md5sum_ptr)
  end function prclib_driver_get_md5sum
```

Informational logical functions

When returning a logical value, we use the C boolean type, which may differ from Fortran.

```
<Prclib interfaces: public>+≡
    public :: prc_get_log

<Prclib interfaces: interfaces>+≡
    abstract interface
        function prc_get_log (pid) result (l) bind(C)
            import
            integer(c_int), intent(in) :: pid
            logical(c_bool) :: l
        end function prc_get_log
    end interface
```

Return a logical flag which tells whether OpenMP is supported for a specific process code.

```
<Prclib interfaces: prclib driver: TBP>+≡
    procedure :: write_get_openmp_status_fun

<Prclib interfaces: procedures>+≡
    subroutine write_get_openmp_status_fun (driver, unit, prefix)
        class(prclib_driver_t), intent(in) :: driver
        integer, intent(in) :: unit
        type(string_t), intent(in) :: prefix
        integer :: i
        write (unit, "(A)") ""
        write (unit, "(A)") "! Return the OpenMP support status"
        write (unit, "(A)") "function " // char (prefix) &
            // "get_openmp_status (i) result (openmp_status) bind(C)"
        write (unit, "(A)") " use iso_c_binding"
        call driver%write_interfaces (unit, var_str ("openmp_supported"))
        write (unit, "(A)") " integer(c_int), intent(in) :: i"
        write (unit, "(A)") " logical(c_bool) :: openmp_status"
        write (unit, "(A)") " select case (i)"
        do i = 1, driver%n_processes
            write (unit, "(A,I0,9A)") " case (" , i, "); ", &
                "openmp_status = ", &
                char (driver%record(i)%get_c_procname &
                    (var_str ("openmp_supported"))), " ()"
        end do
        write (unit, "(A)") " end select"
        write (unit, "(A)") "end function " // char (prefix) &
            // "get_openmp_status"
    end subroutine write_get_openmp_status_fun
```

Informational integer functions

Various process metadata are integer values. We can use a single interface for all of them.

```
<Prclib interfaces: public>+≡
    public :: prc_get_int
```

```

<Prclib interfaces: interfaces>+≡
abstract interface
  function prc_get_int (pid) result (n) bind(C)
  import
    integer(c_int), intent(in) :: pid
    integer(c_int) :: n
  end function prc_get_int
end interface

```

This function returns any data of type integer, for each process.

```

<Prclib interfaces: prclib driver: TBP>+≡
procedure :: write_get_int_fun

<Prclib interfaces: procedures>+≡
subroutine write_get_int_fun (driver, unit, prefix, feature)
  class(prclib_driver_t), intent(in) :: driver
  integer, intent(in) :: unit
  type(string_t), intent(in) :: prefix
  type(string_t), intent(in) :: feature
  integer :: i
  write (unit, "(A)") ""
  write (unit, "(9A)") "! Return the value of ", char (feature)
  write (unit, "(9A)") "function ", char (prefix), &
    "get_", char (feature), " (pid)", &
    " result (", char (feature), ") bind(C)"
  write (unit, "(9A)") " use iso_c_binding"
  call driver%write_interfaces (unit, feature)
  write (unit, "(9A)") " integer(c_int), intent(in) :: pid"
  write (unit, "(9A)") " integer(c_int) :: ", char (feature)
  write (unit, "(9A)") " select case (pid)"
  do i = 1, driver%n_processes
    write (unit, "(2x,A,I0,9A)") "case (", i, "); ", &
      char (feature), " = ", &
      char (driver%record(i)%get_c_procname (feature)), &
      " ()"
  end do
  write (unit, "(9A)") " end select"
  write (unit, "(9A)") "end function ", char (prefix), &
    "get_", char (feature)
end subroutine write_get_int_fun

```

Write a case line that assigns the value of the external function to the current return value.

```

<Prclib interfaces: procedures>+≡
subroutine write_case_int_fun (record, unit, i, feature)
  class(prclib_driver_record_t), intent(in) :: record
  integer, intent(in) :: unit
  integer, intent(in) :: i
  type(string_t), intent(in) :: feature
  write (unit, "(5x,A,I0,9A)") "case (", i, "); ", &
    char (feature), " = ", char (record%get_c_procname (feature))
end subroutine write_case_int_fun

```

Flavor and helicity tables

Transferring tables is more complicated. First, a two-dimensional array.

```
<Prclib interfaces: public>+≡
    public :: prc_set_int_tab1

<Prclib interfaces: interfaces>+≡
    abstract interface
        subroutine prc_set_int_tab1 (pid, cptr, shape) bind(C)
            import
            integer(c_int), intent(in) :: pid
            integer(c_int), dimension(*), intent(in) :: cptr
            integer(c_int), dimension(2), intent(in) :: shape
        end subroutine prc_set_int_tab1
    end interface
```

This subroutine returns a table of integers.

```
<Prclib interfaces: prclib driver: TBP>+≡
    procedure :: write_set_int_sub

<Prclib interfaces: procedures>+≡
    subroutine write_set_int_sub (driver, unit, prefix, feature)
        class(prclib_driver_t), intent(in) :: driver
        integer, intent(in) :: unit
        type(string_t), intent(in) :: prefix
        type(string_t), intent(in) :: feature
        integer :: i
        write (unit, "(A)") ""
        write (unit, "(9A)") "! Set table: ", char (feature)
        write (unit, "(9A)") "subroutine ", char (prefix), &
            "set_", char (feature), "_ptr (pid, ", char (feature), &
            ", shape) bind(C)"
        write (unit, "(9A)") " use iso_c_binding"
        call driver%write_interfaces (unit, feature)
        write (unit, "(9A)") " integer(c_int), intent(in) :: pid"
        write (unit, "(9A)") " integer(c_int), dimension(*), intent(out) :: ", &
            char (feature)
        write (unit, "(9A)") " integer(c_int), dimension(2), intent(in) :: shape"
        write (unit, "(9A)") " integer, dimension(:,:), allocatable :: ", &
            char (feature), "_tmp"
        write (unit, "(9A)") " integer :: i, j"
        write (unit, "(9A)") " select case (pid)"
        do i = 1, driver%n_processes
            write (unit, "(2x,A,IO,A)") "case (", i, ")"
            call driver%record(i)%write_int_sub_call (unit, feature)
        end do
        write (unit, "(9A)") " end select"
        write (unit, "(9A)") "end subroutine ", char (prefix), &
            "set_", char (feature), "_ptr"
    end subroutine write_set_int_sub
```

The actual call depends on the type of matrix element.

```
<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_int_sub_call => prclib_driver_record_write_int_sub_call
```

```

<Prclib interfaces: procedures>+≡
subroutine prclib_driver_record_write_int_sub_call (record, unit, feature)
  class(prclib_driver_record_t), intent(in) :: record
  integer, intent(in) :: unit
  type(string_t), intent(in) :: feature
  call record%writer%write_int_sub_call (unit, record%id, feature)
end subroutine prclib_driver_record_write_int_sub_call

```

The interface goes into the writer base type:

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure(write_feature_code), deferred :: write_int_sub_call

```

In the Fortran module case, we need an extra copy in the (academical) situation where default integer and `c_int` differ. Otherwise, we just associate a Fortran array with the C pointer and let the matrix-element subroutine fill the array.

```

<Prclib interfaces: prc writer f module: TBP>+≡
  procedure :: write_int_sub_call => prc_writer_f_module_write_int_sub_call

<Prclib interfaces: procedures>+≡
subroutine prc_writer_f_module_write_int_sub_call (writer, unit, id, feature)
  class(prc_writer_f_module_t), intent(in) :: writer
  integer, intent(in) :: unit
  type(string_t), intent(in) :: id, feature
  write (unit, "(5x,9A)") "allocate (", char (feature), "_tmp ", &
    "(shape(1), shape(2)))"
  write (unit, "(5x,9A)") "call ", &
    char (writer%get_c_procname (id, feature)), &
    " (", char (feature), "_tmp)"
  write (unit, "(5x,9A)") "forall (i=1:shape(1), j=1:shape(2)) "
  write (unit, "(8x,9A)") char (feature), "(i + shape(1)*(j-1)) = ", &
    char (feature), "_tmp", "(i,j)"
  write (unit, "(5x,9A)") "end forall"
end subroutine prc_writer_f_module_write_int_sub_call

```

In the C library case, we just transfer the C pointer to the library function.

```

<Prclib interfaces: prc writer c lib: TBP>+≡
  procedure :: write_int_sub_call => prc_writer_c_lib_write_int_sub_call

<Prclib interfaces: procedures>+≡
subroutine prc_writer_c_lib_write_int_sub_call (writer, unit, id, feature)
  class(prc_writer_c_lib_t), intent(in) :: writer
  integer, intent(in) :: unit
  type(string_t), intent(in) :: id, feature
  write (unit, "(5x,9A)") "call ", &
    char (writer%get_c_procname (id, feature)), " (", char (feature), ")"
end subroutine prc_writer_c_lib_write_int_sub_call

```

Color state table

The color-state specification needs a table of integers (one array per color flow) and a corresponding array of color-ghost flags.

```

<Prclib interfaces: public>+≡
  public :: prc_set_col_state

```

```

<Prclib interfaces: interfaces>+≡
  abstract interface
    subroutine prc_set_col_state (pid, col_state, ghost_flag, shape) bind(C)
      import
        integer(c_int), intent(in) :: pid
        integer(c_int), dimension(*), intent(out) :: col_state
        logical(c_bool), dimension(*), intent(out) :: ghost_flag
        integer(c_int), dimension(3), intent(in) :: shape
      end subroutine prc_set_col_state
  end interface

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: write_set_col_state_sub

<Prclib interfaces: procedures>+≡
  subroutine write_set_col_state_sub (driver, unit, prefix)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    integer :: i
    type(string_t) :: feature
    feature = "col_state"
    write (unit, "(A)") ""
    write (unit, "(9A)") "! Set tables: col_state, ghost_flag"
    write (unit, "(9A)") "subroutine ", char (prefix), &
      "set_col_state_ptr (pid, col_state, ghost_flag, shape) bind(C)"
    write (unit, "(9A)") " use iso_c_binding"
    call driver%write_interfaces (unit, feature)
    write (unit, "(9A)") " integer(c_int), intent(in) :: pid"
    write (unit, "(9A)") &
      " integer(c_int), dimension(*), intent(out) :: col_state"
    write (unit, "(9A)") &
      " logical(c_bool), dimension(*), intent(out) :: ghost_flag"
    write (unit, "(9A)") &
      " integer(c_int), dimension(3), intent(in) :: shape"
    write (unit, "(9A)") &
      " integer, dimension(:,:), allocatable :: col_state_tmp"
    write (unit, "(9A)") &
      " logical, dimension(:,:), allocatable :: ghost_flag_tmp"
    write (unit, "(9A)") " integer :: i, j, k"
    write (unit, "(A)") " select case (pid)"
    do i = 1, driver%n_processes
      write (unit, "(A,I0,A)") " case (" , i, ")"
      call driver%record(i)%write_col_state_call (unit)
    end do
    write (unit, "(A)") " end select"
    write (unit, "(9A)") "end subroutine ", char (prefix), &
      "set_col_state_ptr"
  end subroutine write_set_col_state_sub

```

The actual call depends on the type of matrix element.

```

<Prclib interfaces: prclib driver record: TBP>+≡
  procedure :: write_col_state_call => prclib_driver_record_write_col_state_call

```

```

<Prclib interfaces: procedures>+≡
subroutine prclib_driver_record_write_col_state_call (record, unit)
  class(prclib_driver_record_t), intent(in) :: record
  integer, intent(in) :: unit
  call record%writer%write_col_state_call (unit, record%id)
end subroutine prclib_driver_record_write_col_state_call

```

The interface goes into the writer base type:

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure(write_code), deferred :: write_col_state_call

```

In the Fortran module case, we need an extra copy in the (academical) situation where default integer and `c_int` differ. Otherwise, we just associate a Fortran array with the C pointer and let the matrix-element subroutine fill the array.

```

<Prclib interfaces: prc writer f module: TBP>+≡
  procedure :: write_col_state_call => prc_writer_f_module_write_col_state_call

<Prclib interfaces: procedures>+≡
subroutine prc_writer_f_module_write_col_state_call (writer, unit, id)
  class(prc_writer_f_module_t), intent(in) :: writer
  integer, intent(in) :: unit
  type(string_t), intent(in) :: id
  write (unit, "(9A)") "  allocate (col_state_tmp ", &
    "(shape(1), shape(2), shape(3)))"
  write (unit, "(5x,9A)") "allocate (ghost_flag_tmp ", &
    "(shape(2), shape(3)))"
  write (unit, "(5x,9A)") "call ", &
    char (writer%get_c_procname (id, var_str ("col_state"))), &
    " (col_state_tmp, ghost_flag_tmp)"
  write (unit, "(5x,9A)") "forall (i = 1:shape(2), j = 1:shape(3))"
  write (unit, "(8x,9A)") "forall (k = 1:shape(1))"
  write (unit, "(11x,9A)") &
    "col_state(k + shape(1) * (i + shape(2)*(j-1) - 1)) ", &
    "= col_state_tmp(k,i,j)"
  write (unit, "(8x,9A)") "end forall"
  write (unit, "(8x,9A)") &
    "ghost_flag(i + shape(2)*(j-1)) = ghost_flag_tmp(i,j)"
  write (unit, "(5x,9A)") "end forall"
end subroutine prc_writer_f_module_write_col_state_call

```

In the C library case, we just transfer the C pointer to the library function.

```

<Prclib interfaces: prc writer c lib: TBP>+≡
  procedure :: write_col_state_call => prc_writer_c_lib_write_col_state_call

<Prclib interfaces: procedures>+≡
subroutine prc_writer_c_lib_write_col_state_call (writer, unit, id)
  class(prc_writer_c_lib_t), intent(in) :: writer
  integer, intent(in) :: unit
  type(string_t), intent(in) :: id
  write (unit, "(5x,9A)") "call ", &
    char (writer%get_c_procname (id, var_str ("col_state"))), &
    " (col_state, ghost_flag)"
end subroutine prc_writer_c_lib_write_col_state_call

```

Color factors

For the color-factor information, we return two integer arrays and a complex array.

```

<Prclib interfaces: public>+≡
    public :: prc_set_color_factors

<Prclib interfaces: interfaces>+≡
    abstract interface
        subroutine prc_set_color_factors &
            (pid, cf_index1, cf_index2, color_factors, shape) bind(C)
        import
        integer(c_int), intent(in) :: pid
        integer(c_int), dimension(*), intent(out) :: cf_index1, cf_index2
        complex(c_default_complex), dimension(*), intent(out) :: color_factors
        integer(c_int), dimension(1), intent(in) :: shape
        end subroutine prc_set_color_factors
    end interface

```

This subroutine returns the color-flavor factor table.

```

<Prclib interfaces: prclib driver: TBP>+≡
    procedure :: write_set_color_factors_sub

<Prclib interfaces: procedures>+≡
    subroutine write_set_color_factors_sub (driver, unit, prefix)
        class(prclib_driver_t), intent(in) :: driver
        integer, intent(in) :: unit
        type(string_t), intent(in) :: prefix
        integer :: i
        type(string_t) :: feature
        feature = "color_factors"
        write (unit, "(A)") ""
        write (unit, "(A)") "! Set tables: color factors"
        write (unit, "(9A)") "subroutine ", char (prefix), &
            "set_color_factors_ptr (pid, cf_index1, cf_index2, color_factors, ", &
            "shape) bind(C)"
        write (unit, "(A)") " use iso_c_binding"
        write (unit, "(A)") " use kinds"
        write (unit, "(A)") " use omega_color"
        call driver%write_interfaces (unit, feature)
        write (unit, "(A)") " integer(c_int), intent(in) :: pid"
        write (unit, "(A)") " integer(c_int), dimension(1), intent(in) :: shape"
        write (unit, "(A)") " integer(c_int), dimension(*), intent(out) :: &
            &cf_index1, cf_index2"
        write (unit, "(A)") " complex(c_default_complex), dimension(*), &
            &intent(out) :: color_factors"
        write (unit, "(A)") " type(omega_color_factor), dimension(:), &
            &allocatable :: cf"
        write (unit, "(A)") " select case (pid)"
        do i = 1, driver%n_processes
            write (unit, "(2x,A,I0,A)") "case (", i, ")"
            call driver%record(i)%write_color_factors_call (unit)
        end do
        write (unit, "(A)") " end select"
        write (unit, "(A)") "end subroutine " // char (prefix) &

```

```

        // "set_color_factors_ptr"
    end subroutine write_set_color_factors_sub

```

The actual call depends on the type of matrix element.

```

<Prclib interfaces: prclib_driver_record: TBP>+≡
    procedure :: write_color_factors_call => prclib_driver_record_write_color_factors_call

<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_record_write_color_factors_call (record, unit)
        class(prclib_driver_record_t), intent(in) :: record
        integer, intent(in) :: unit
        call record%writer%write_color_factors_call (unit, record%id)
    end subroutine prclib_driver_record_write_color_factors_call

```

The interface goes into the writer base type:

```

<Prclib interfaces: prc_writer: TBP>+≡
    procedure(write_code), deferred :: write_color_factors_call

```

In the Fortran module case, the matrix-element procedure fills an array of `omega_color_factor` elements. We distribute this array among two integer arrays and one complex-valued array, for which we have the C pointers.

```

<Prclib interfaces: prc_writer_f_module: TBP>+≡
    procedure :: write_color_factors_call => prc_writer_f_module_write_color_factors_call

<Prclib interfaces: procedures>+≡
    subroutine prc_writer_f_module_write_color_factors_call (writer, unit, id)
        class(prc_writer_f_module_t), intent(in) :: writer
        integer, intent(in) :: unit
        type(string_t), intent(in) :: id
        write (unit, "(5x,A)") "allocate (cf (shape(1)))"
        write (unit, "(5x,9A)") "call ", &
            char (writer%get_c_procname (id, var_str ("color_factors"))), " (cf)"
        write (unit, "(5x,9A)") "cf_index1(1:shape(1)) = cf%i1"
        write (unit, "(5x,9A)") "cf_index2(1:shape(1)) = cf%i2"
        write (unit, "(5x,9A)") "color_factors(1:shape(1)) = cf%factor"
    end subroutine prc_writer_f_module_write_color_factors_call

```

In the C library case, we just transfer the C pointers to the library function. There are three arrays.

```

<Prclib interfaces: prc_writer_c_lib: TBP>+≡
    procedure :: write_color_factors_call => &
        prc_writer_c_lib_write_color_factors_call

<Prclib interfaces: procedures>+≡
    subroutine prc_writer_c_lib_write_color_factors_call (writer, unit, id)
        class(prc_writer_c_lib_t), intent(in) :: writer
        integer, intent(in) :: unit
        type(string_t), intent(in) :: id
        write (unit, "(5x,9A)") "call ", &
            char (writer%get_c_procname (id, var_str ("color_factors"))), &
            " (cf_index1, cf_index2, color_factors)"
    end subroutine prc_writer_c_lib_write_color_factors_call

```

14.1.10 Interfaces for C-library matrix element

If the matrix element code is not provided as a Fortran module but as a C or bind(C) Fortran library, we need explicit interfaces for the library functions. They are not identical to the Fortran module versions. They transfer pointers directly.

The implementation is part of the `prc_writer_c_lib` type, which serves as base type for all C-library writers. It writes specific interfaces depending on the feature.

We bind this as the method `write_standard_interface` instead of `write_interface`, because we have to override the latter. Otherwise we could not call the method because the writer type is abstract.

```
<Prclib interfaces: prc writer c lib: TBP>+=  
  procedure :: write_standard_interface => prc_writer_c_lib_write_interface  
  
<Prclib interfaces: procedures>+=  
  subroutine prc_writer_c_lib_write_interface (writer, unit, id, feature)  
    class(prc_writer_c_lib_t), intent(in) :: writer  
    integer, intent(in) :: unit  
    type(string_t), intent(in) :: id, feature  
    select case (char (feature))  
    case ("md5sum")  
      write (unit, "(2x,9A)") "interface"  
      write (unit, "(5x,9A)") "function ", &  
        char (writer%get_c_procname (id, var_str ("get_md5sum"))), &  
        " () result (cptr) bind(C)"  
      write (unit, "(7x,9A)") "import"  
      write (unit, "(7x,9A)") "implicit none"  
      write (unit, "(7x,9A)") "type(c_ptr) :: cptr"  
      write (unit, "(5x,9A)") "end function ", &  
        char (writer%get_c_procname (id, var_str ("get_md5sum")))  
      write (unit, "(2x,9A)") "end interface"  
    case ("openmp_supported")  
      write (unit, "(2x,9A)") "interface"  
      write (unit, "(5x,9A)") "function ", &  
        char (writer%get_c_procname (id, feature)), &  
        " () result (status) bind(C)"  
      write (unit, "(7x,9A)") "import"  
      write (unit, "(7x,9A)") "implicit none"  
      write (unit, "(7x,9A)") "logical(c_bool) :: status"  
      write (unit, "(5x,9A)") "end function ", &  
        char (writer%get_c_procname (id, feature))  
      write (unit, "(2x,9A)") "end interface"  
    case ("n_in", "n_out", "n_flv", "n_hel", "n_col", "n_cin", "n_cf")  
      write (unit, "(2x,9A)") "interface"

  write (unit, "(7x,9A)") "complex(c_default_complex), dimension(*), &
    &intent(out) :: color_factors"
  write (unit, "(5x,9A)") "end subroutine ", &
    char (writer%get_c_procname (id, feature))
  write (unit, "(2x,9A)") "end interface"
end select
end subroutine prc_writer_c_lib_write_interface

```

14.1.11 Retrieving the tables

In the previous section we had the writer routines for procedures that return tables, actually C pointers to tables. Here, we write convenience routines that unpack them and move the contents to suitable Fortran arrays.

The flavor and helicity tables are two-dimensional integer arrays. We use intermediate storage for correctly transforming C to Fortran data types.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: set_flv_state => prclib_driver_set_flv_state
  procedure :: set_hel_state => prclib_driver_set_hel_state

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_set_flv_state (driver, i, flv_state)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    integer, dimension(:,:), allocatable, intent(out) :: flv_state
    integer :: n_tot, n_flv
    integer(c_int) :: pid
    integer(c_int), dimension(:,:), allocatable :: c_flv_state
    pid = i
    n_tot = driver%get_n_in (pid) + driver%get_n_out (pid)
    n_flv = driver%get_n_flv (pid)
    allocate (flv_state (n_tot, n_flv))
    allocate (c_flv_state (n_tot, n_flv))
    call driver%set_flv_state_ptr &
      (pid, c_flv_state, int ([n_tot, n_flv], kind=c_int))
    flv_state = c_flv_state
  end subroutine prclib_driver_set_flv_state

  subroutine prclib_driver_set_hel_state (driver, i, hel_state)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    integer, dimension(:,:), allocatable, intent(out) :: hel_state
    integer :: n_tot, n_hel
    integer(c_int) :: pid
    integer(c_int), dimension(:,:), allocatable, target :: c_hel_state
    pid = i
    n_tot = driver%get_n_in (pid) + driver%get_n_out (pid)
    n_hel = driver%get_n_hel (pid)
    allocate (hel_state (n_tot, n_hel))
    allocate (c_hel_state (n_tot, n_hel))
    call driver%set_hel_state_ptr &
      (pid, c_hel_state, int ([n_tot, n_hel], kind=c_int))
    hel_state = c_hel_state
  end subroutine prclib_driver_set_hel_state

```

The color-flow table is three-dimensional, otherwise similar. We simultaneously set the ghost-flag table, which consists of logical entries.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: set_col_state => prclib_driver_set_col_state

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_set_col_state (driver, i, col_state, ghost_flag)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    integer, dimension(:,:,:), allocatable, intent(out) :: col_state
    logical, dimension(:,:), allocatable, intent(out) :: ghost_flag
    integer :: n_cin, n_tot, n_col
    integer(c_int) :: pid
    integer(c_int), dimension(:,:,:), allocatable :: c_col_state
    logical(c_bool), dimension(:,:), allocatable :: c_ghost_flag
    pid = i

```

```

n_cin = driver%get_n_cin (pid)
n_tot = driver%get_n_in (pid) + driver%get_n_out (pid)
n_col = driver%get_n_col (pid)
allocate (col_state (n_cin, n_tot, n_col))
allocate (c_col_state (n_cin, n_tot, n_col))
allocate (ghost_flag (n_tot, n_col))
allocate (c_ghost_flag (n_tot, n_col))
call driver%set_col_state_ptr (pid, &
    c_col_state, c_ghost_flag, int ([n_cin, n_tot, n_col], kind=c_int))
col_state = c_col_state
ghost_flag = c_ghost_flag
end subroutine prclib_driver_set_col_state

```

The color-factor table is a sparse matrix: a two-column array of indices and one array which contains the corresponding factors.

(Prclib interfaces: prclib driver: TBP)+≡

```

procedure :: set_color_factors => prclib_driver_set_color_factors

```

(Prclib interfaces: procedures)+≡

```

subroutine prclib_driver_set_color_factors (driver, i, color_factors, cf_index)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    complex(default), dimension(:), allocatable, intent(out) :: color_factors
    integer, dimension(:,:), allocatable, intent(out) :: cf_index
    integer :: n_cf
    integer(c_int) :: pid
    complex(c_default_complex), dimension(:), allocatable, target :: c_color_factors
    integer(c_int), dimension(:), allocatable, target :: c_cf_index1
    integer(c_int), dimension(:), allocatable, target :: c_cf_index2
    pid = i
    n_cf = driver%get_n_cf (pid)
    allocate (color_factors (n_cf))
    allocate (c_color_factors (n_cf))
    allocate (c_cf_index1 (n_cf))
    allocate (c_cf_index2 (n_cf))
    call driver%set_color_factors_ptr (pid, &
        c_cf_index1, c_cf_index2, &
        c_color_factors, int ([n_cf], kind=c_int))
    color_factors = c_color_factors
    allocate (cf_index (2, n_cf))
    cf_index(1,:) = c_cf_index1
    cf_index(2,:) = c_cf_index2
end subroutine prclib_driver_set_color_factors

```

14.1.12 Returning a procedure pointer

The functions that directly access the matrix element, event by event, are assigned to a process-specific driver object as procedure pointers. For the `dlopen` interface, we use C function pointers. This subroutine returns such a pointer:

(Prclib interfaces: public)+≡

```

public :: prc_get_fptr

```

```

<Prclib interfaces: interfaces>+≡
  abstract interface
    subroutine prc_get_fptr (pid, fid, fptr) bind(C)
      import
        integer(c_int), intent(in) :: pid
        integer(c_int), intent(in) :: fid
        type(c_funptr), intent(out) :: fptr
    end subroutine prc_get_fptr
  end interface

```

This procedure writes the source code for the procedure pointer returning subroutine.

All C functions that are provided by the matrix element code of a specific process are handled here. The selection consists of a double layered **select case** construct.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: write_get_fptr_sub

<Prclib interfaces: procedures>+≡
  subroutine write_get_fptr_sub (driver, unit, prefix)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    integer :: i, j
    write (unit, "(A)") ""
    write (unit, "(A)") "! Return C pointer to a procedure:"
    write (unit, "(A)") "! pid = process index; fid = function index"
    write (unit, "(4A)") "subroutine ", char (prefix), "get_fptr ", &
      "(pid, fid, fptr) bind(C)"
    write (unit, "(A)") " use iso_c_binding"
    write (unit, "(A)") " use kinds"
    write (unit, "(A)") " implicit none"
    write (unit, "(A)") " integer(c_int), intent(in) :: pid"
    write (unit, "(A)") " integer(c_int), intent(in) :: fid"
    write (unit, "(A)") " type(c_funptr), intent(out) :: fptr"
    do i = 1, driver%n_processes
      call driver%record(i)%write_interfaces (unit)
    end do
    write (unit, "(A)") " select case (pid)"
    do i = 1, driver%n_processes
      write (unit, "(2x,A,IO,A)") "case (", i, ")"
      write (unit, "(5x,A)") "select case (fid)"
      associate (record => driver%record(i))
        do j = 1, size (record%feature)
          write (unit, "(5x,A,IO,9A)") "case (", j, "); ", &
            "fptr = c_funloc (", &
            char (record%get_c_procname (record%feature(j))), &
            ")"
        end do
      end associate
      write (unit, "(5x,A)") "end select"
    end do
    write (unit, "(A)") " end select"
    write (unit, "(3A)") "end subroutine ", char (prefix), "get_fptr"
  end subroutine write_get_fptr_sub

```

```
end subroutine write_get_fptr_sub
```

The procedures for which we want to return a pointer (the 'features' of the matrix element code) are actually Fortran module procedures. If we want to have a C signature, we must write wrapper functions for all of them. The procedures, their signatures, and the appropriate writer routines are specific for the process type.

To keep this generic, we do not provide the writer routines here, but just the interface for a writer routine. The actual routines are stored in the process record.

The `prefix` indicates the library, the `id` indicates the process, and `procname` is the bare name of the procedure to be written.

```
<Prclib interfaces: public>+≡
public :: write_driver_code

<Prclib interfaces: interfaces>+≡
abstract interface
  subroutine write_driver_code (unit, prefix, id, procname)
    import
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    type(string_t), intent(in) :: id
    type(string_t), intent(in) :: procname
  end subroutine write_driver_code
end interface
```

14.1.13 Hooks

Interface for additional library unload / reload hooks (currently unused!)

```
<Prclib interfaces: public>+≡
public :: prclib_unload_hook
public :: prclib_reload_hook

<Prclib interfaces: interfaces>+≡
abstract interface
  subroutine prclib_unload_hook (libname)
    import
    type(string_t), intent(in) :: libname
  end subroutine prclib_unload_hook

  subroutine prclib_reload_hook (libname)
    import
    type(string_t), intent(in) :: libname
  end subroutine prclib_reload_hook
end interface
```

14.1.14 Make source, compile, link

Since we should have written a Makefile, these tasks amount to simple `make` calls. Note that the Makefile targets depend on each other, so calling `link` executes also the `source` and `compile` steps, when necessary.

The first routine writes source-code files for the individual processes. First it calls the writer routines directly for each process, then it calls `make source`. The `make` command may either post-process the files, or it may do the complete work, e.g., calling an external program that generates the files.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: make_source => prclib_driver_make_source

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_make_source (driver, os_data)
    class(prclib_driver_t), intent(in) :: driver
    type(os_data_t), intent(in) :: os_data
    integer :: i
    do i = 1, driver%n_processes
      call driver%record(i)%write_source_code ()
    end do
    call os_system_call ("make source " // os_data%makeflags &
      // " -f " // driver%basename // ".makefile")
  end subroutine prclib_driver_make_source

```

Compile matrix element source code and the driver source code.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: make_compile => prclib_driver_make_compile

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_make_compile (driver, os_data)
    class(prclib_driver_t), intent(in) :: driver
    type(os_data_t), intent(in) :: os_data
    call os_system_call ("make compile " // os_data%makeflags &
      // " -f " // driver%basename // ".makefile")
  end subroutine prclib_driver_make_compile

```

Combine all matrix-element code together with the driver in a process library on disk.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: make_link => prclib_driver_make_link

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_make_link (driver, os_data)
    class(prclib_driver_t), intent(in) :: driver
    type(os_data_t), intent(in) :: os_data
    call os_system_call ("make link " // os_data%makeflags &
      // " -f " // driver%basename // ".makefile")
  end subroutine prclib_driver_make_link

```

14.1.15 Clean up generated files

The task of cleaning any generated files should also be deferred to Makefile targets. Apart from removing everything, removing specific files may be useful for partial rebuilds. (Note that removing the makefile itself can only be done once, for obvious reasons.)

If there is no makefile, do nothing.

```

<Prclib interfaces: prclib driver: TBP>+≡

```

```

procedure :: clean_library => prclib_driver_clean_library
procedure :: clean_objects => prclib_driver_clean_objects
procedure :: clean_source => prclib_driver_clean_source
procedure :: clean_driver => prclib_driver_clean_driver
procedure :: clean_makefile => prclib_driver_clean_makefile

14.1.19 Test

This is the master for calling self-test procedures.

```

<Prclib interfaces: public>+≡
    public :: prclib_interfaces_test

```

```

<Prclib interfaces: tests>≡
  subroutine prclib_interfaces_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Prclib interfaces: execute tests>
  end subroutine prclib_interfaces_test

```

Empty process list

Test 1: Create a driver object and display its contents. One of the feature lists references a writer procedure; this is just a dummy that does nothing useful.

```

<Prclib interfaces: execute tests>≡
  call test (prclib_interfaces_1, "prclib_interfaces_1", &
    "create driver object", &
    u, results)

<Prclib interfaces: tests>+≡
  subroutine prclib_interfaces_1 (u)
    integer, intent(in) :: u
    type(prclib_driver_t) :: driver
    character(32), parameter :: md5sum = "prclib_interfaces_1_md5sum"
    class(prc_writer_t), pointer :: test_writer_1

    write (u, "(A)")  "* Test output: prclib_interfaces_1"
    write (u, "(A)")  "* Purpose: display the driver object contents"
    write (u, *)
    write (u, "(A)")  "* Create a prclib driver object"
    write (u, "(A)")

    call driver%init (var_str ("prclib"), 3)
    call driver%set_md5sum (md5sum)

    allocate (test_writer_1_t :: test_writer_1)

    call driver%set_record (1, var_str ("test1"), var_str ("test_model"), &

This version of test-code writer actually writes an interface and wrapper code.

The wrapped function is a no-parameter function with integer result.

The stored MD5 sum may be modified.

We will reuse this later, therefore public.

14.2 Abstract process core configuration

In this module, we define abstract data types that handle the method-specific part of defining a process (including all of its options) and accessing an external matrix element.

There are no unit tests, these are deferred to the `process_libraries` module below.

```

<prc_core_def.f90>=
<File header>

module prc_core_def

  <Use strings>
  <Use file utils>
  use diagnostics !NODEP!

  use process_constants
  use prclib_interfaces

  <Standard module head>

  <Prc core def: public>

  <Prc core def: types>

  <Prc core def: interfaces>

  contains

  <Prc core def: procedures>

end module prc_core_def

```

14.2.1 Process core definition type

For storing configuration data that depend on the specific process variant, we introduce a polymorphic type. At this point, we just declare an abstract base type. This allows us to defer the implementation to later modules.

There should be no components that need explicit finalization, otherwise we would have to call a finalizer from the `process_component_def_t` wrapper.

```
<Prc core def: public>≡
    public :: prc_core_def_t

<Prc core def: types>≡
    type, abstract :: prc_core_def_t
        class(prc_writer_t), allocatable :: writer
        contains
        <Prc core def: process core def: TBP>
    end type prc_core_def_t
```

Interfaces for the deferred methods.

This returns a string. No passed argument; the string is constant and depends just on the type.

```
<Prc core def: process core def: TBP>≡
    procedure (prc_core_def_get_string), nopass, deferred :: type_string

<Prc core def: interfaces>≡
    abstract interface
        function prc_core_def_get_string () result (string)
            import
            type(string_t) :: string
        end function prc_core_def_get_string
    end interface
```

The `write` method should display the content completely.

```
<Prc core def: process core def: TBP>+≡
    procedure (prc_core_def_write), deferred :: write

<Prc core def: interfaces>+≡
    abstract interface
        subroutine prc_core_def_write (object, unit)
            import
            class(prc_core_def_t), intent(in) :: object
            integer, intent(in) :: unit
        end subroutine prc_core_def_write
    end interface
```

The `read` method should fill the content completely.

```
<Prc core def: process core def: TBP>+≡
    procedure (prc_core_def_read), deferred :: read

<Prc core def: interfaces>+≡
    abstract interface
        subroutine prc_core_def_read (object, unit)
            import
            class(prc_core_def_t), intent(out) :: object
            integer, intent(in) :: unit
        end subroutine prc_core_def_read
    end interface
```

```

        end subroutine prc_core_def_read
    end interface

```

This communicates a MD5 checksum to the writer inside the `core_def` object, if there is any. Usually, this checksum is not yet known at the time when the writer is initialized.

```

<Prc core def: process core def: TBP>+≡
    procedure :: set_md5sum => prc_core_def_set_md5sum

<Prc core def: procedures>≡
    subroutine prc_core_def_set_md5sum (core_def, md5sum)
        class(prc_core_def_t), intent(inout) :: core_def
        character(32) :: md5sum
        if (allocated (core_def%writer)) core_def%writer%md5sum = md5sum
    end subroutine prc_core_def_set_md5sum

```

Allocate an appropriate driver object which corresponds to the chosen process core definition.

For internal matrix element (i.e., those which do not need external code), the driver should have access to all matrix element information from the beginning. In short, it is the matrix-element code.

For external matrix elements, the driver will get access to the external matrix element code.

```

<Prc core def: process core def: TBP>+≡
    procedure(prc_core_def_allocate_driver), deferred :: allocate_driver

<Prc core def: interfaces>+≡
    interface
        subroutine prc_core_def_allocate_driver (object, driver, basename)
            import
            class(prc_core_def_t), intent(in) :: object
            class(prc_core_driver_t), intent(out), allocatable :: driver
            type(string_t), intent(in) :: basename
        end subroutine prc_core_def_allocate_driver
    end interface

```

This flag tells whether the particular variant needs external code. We implement a default function which returns false. The flag depends only on the type, therefore we implement it as `nopass`.

```

<Prc core def: process core def: TBP>+≡
    procedure, nopass :: needs_code => prc_core_def_needs_code

<Prc core def: procedures>+≡
    function prc_core_def_needs_code () result (flag)
        logical :: flag
        flag = .false.
    end function prc_core_def_needs_code

```

This subroutine allocates an array which holds the name of all features that this process core implements. This feature applies to matrix element code that is not coded as a Fortran module but communicates via independent library functions, which follow the C calling conventions. The addresses of those functions are

returned as C function pointers, which can be converted into Fortran procedure pointers. The conversion is done in code specific for the process variant; here we just retrieve the C function pointer.

The array returned here serves the purpose of writing specific driver code. The driver interfaces only those C functions which are supported for the given process core.

If the process core does not require external code, this array is meaningless.

```

<Prc core def: process core def: TBP>+≡
  procedure(prc_core_def_get_features), nopass, deferred &
    :: get_features

<Prc core def: interfaces>+≡
  abstract interface
    subroutine prc_core_def_get_features (features)
      import
      type(string_t), dimension(:), allocatable, intent(out) :: features
    end subroutine prc_core_def_get_features
  end interface

```

Assign pointers to the process-specific procedures to the driver, if the process is external.

```

<Prc core def: process core def: TBP>+≡
  procedure(prc_core_def_connect), deferred :: connect

<Prc core def: interfaces>+≡
  abstract interface
    subroutine prc_core_def_connect (def, lib_driver, i, proc_driver)
      import
      class(prc_core_def_t), intent(in) :: def
      type(prclib_driver_t), intent(in) :: lib_driver
      integer, intent(in) :: i
      class(prc_core_driver_t), intent(inout) :: proc_driver
    end subroutine prc_core_def_connect
  end interface

```

14.2.2 Process core template

We must be able to automatically allocate a process core definition object with the appropriate type, given only the type name.

To this end, we introduce a `prc_template_t` type which is simply a wrapper for an empty `prc_core_def_t` object. Choosing one of the templates from an array, we can allocate the target object.

```

<Prc core def: public>+≡
  public :: prc_template_t

<Prc core def: types>+≡
  type :: prc_template_t
    class(prc_core_def_t), allocatable :: core_def
  end type prc_template_t

```

The allocation routine. We use the `source` option of the `allocate` statement. The `mold` option would probably more appropriate, but is a F2008 feature.

```

<Prc core def: public>+≡
    public :: allocate_core_def

<Prc core def: procedures>+≡
    subroutine allocate_core_def (template, name, core_def)
        type(prc_template_t), dimension(:), intent(in) :: template
        type(string_t), intent(in) :: name
        class(prc_core_def_t), allocatable :: core_def
        integer :: i
        do i = 1, size (template)
            if (template(i)%core_def%type_string () == name) then
                allocate (core_def, source = template(i)%core_def)
                return
            end if
        end do
    end subroutine allocate_core_def

```

14.2.3 Process driver

For each process component, we implement a driver object which holds the calls to the matrix element and various auxiliary routines as procedure pointers. Any actual calculation will use this object to communicate with the process.

Depending on the type of process (as described by a corresponding `prc_core_def` object), the procedure pointers may refer to external or internal code, and there may be additional procedures for certain types. The base type defined here is abstract.

```

<Prc core def: public>+≡
    public :: prc_core_driver_t

<Prc core def: types>+≡
    type, abstract :: prc_core_driver_t
    contains
        <Prc core def: process driver: TBP>
    end type prc_core_driver_t

```

This returns the process type. No reference to contents.

```

<Prc core def: process driver: TBP>≡
    procedure(prc_core_driver_type_name), nopass, deferred :: type_name

<Prc core def: interfaces>+≡
    abstract interface
        function prc_core_driver_type_name () result (type)
            import
            type(string_t) :: type
        end function prc_core_driver_type_name
    end interface

```

14.2.4 Process driver for intrinsic process

This is an abstract extension for the driver type. It has one additional method, namely a subroutine that fills the record of constant process data. For an external process, this task is performed by the external library driver instead.

```

<Prc core def: public>+≡
    public :: process_driver_internal_t

<Prc core def: types>+≡
    type, extends (prc_core_driver_t), abstract :: process_driver_internal_t
    contains
    <Prc core def: process driver internal: TBP>
    end type process_driver_internal_t

<Prc core def: process driver internal: TBP>≡
    procedure(process_driver_fill_constants), deferred :: fill_constants

<Prc core def: interfaces>+≡
    abstract interface
        subroutine process_driver_fill_constants (driver, data)
            import
            class(process_driver_internal_t), intent(in) :: driver
            type(process_constants_t), intent(out) :: data
        end subroutine process_driver_fill_constants
    end interface

```

14.3 Particle Specifiers

In this module we introduce a type for specifying a particle or particle alternative. In addition to the particle specifiers (strings separated by colons), the type contains an optional flag **polarized** and a string **decay**. If the **polarized** flag is set, particle polarization information should be kept when generating events for this process. If the **decay** string is set, it is the ID of a decay process which should be applied to this particle when generating events.

In input/output form, the **polarized** flag is indicated by an asterisk (*) in brackets, and the **decay** is indicated by its ID in brackets.

The **read** and **write** procedures in this module are not type-bound but generic procedures which handle scalar and array arguments.

```

<particle_specifiers.f90>≡
    <File header>

    module particle_specifiers

    <Use strings>
    <Use file utils>
        use diagnostics !NODEP!
        use unit_tests

    <Standard module head>

    <Particle specifiers: public>

```

```

    <Particle specifiers: types>

    <Particle specifiers: interfaces>

contains

    <Particle specifiers: procedures>

    <Particle specifiers: tests>

end module particle_specifiers

```

14.3.1 The type

The particle is unstable if the `decay` array is allocated. The `polarized` flag and decays may not be set simultaneously.

```

<Particle specifiers: public>≡
    public :: prt_spec_t

<Particle specifiers: types>≡
    type :: prt_spec_t
        private
        type(string_t) :: name
        logical :: polarized = .false.
        type(string_t), dimension(:), allocatable :: decay
    contains
        <Particle specifiers: prt spec: TBP>
    end type prt_spec_t

```

Output.

```

```

14.4 Process library access

Processes (the code and data that are necessary for evaluating matrix elements of a particular process or process component) are organized in process libraries. In full form, process libraries contain generated and dynamically compiled and linked code, so they are actual libraries on the OS level. Alternatively, there may be simple processes that can be generated without referring to external libraries, and external libraries that are just linked in.

This module interfaces the OS to create, build, and use process libraries.

We work with two related data structures. There is the list of process configurations that stores the user input and data derived from it. A given process configuration list is scanned for creating a process library, which consists of both data and code. The creation step involves calling external programs and incorporating external code.

For the subsequent integration and event generation steps, we read the process library. We also support partial (re)creation of the process library. To this end, we should be able to reconstruct the configuration data records from the process library.

```

⟨process_libraries.f90⟩≡

```

14.4.1 Auxiliary stuff

Here is a small subroutine that strips the left-hand side and the equals sign off an equation.

```

<Process libraries: procedures>≡
    subroutine strip_prefix (buffer)
        character(*), intent(inout) :: buffer
        type(string_t) :: string, prefix
        string = buffer
        call split (string, prefix, "=")
        buffer = string
    end subroutine strip_prefix

```

14.4.2 Process definition objects

We collect process configuration data in a derived type, `process_def_t`. A process can be a collection of several components which are treated as a single entity for the purpose of observables and event generation. Multiple process components may initially be defined by the user. The system may add additional components, e.g., subtraction terms. The common data type is

`process_component_def_t`. Within each component, there are several universal data items, and a part which depend on the particular process variant. The latter is covered by an abstract type `prc_core_def_t` and its extensions.

Wrapper for components

We define a wrapper type for the configuration of individual components.

The string `basename` is used for building file, module, and function names for the current process component. Initially, it will be built from the corresponding process basename by appending an alphanumeric suffix.

The logical `initial` tells whether this is a user-defined (true) or system-generated (false) configuration.

The numbers `n_in`, `n_out`, and `n_tot` denote the incoming, outgoing and total number of particles (partons) participating in the process component, respectively. These are the nominal particles, as input by the user (recombination may change the particle content, for the output events).

The string arrays `prt_in` and `prt_out` hold the particle specifications as provided by the user. For a system-generated process component, they remain deallocated.

The `method` string is used to determine the type of process matrix element and how it is obtained.

The `description` string collects the information about particle content and method in a single human-readable string.

The pointer object `core_def` is allocated according to the actual process variant, which depends on the method. The subobject holds any additional configuration data that is relevant for the process component.

We assume that no finalizer is needed.

```

(Process libraries: public)≡
    public :: process_component_def_t

end subroutine process_component_def_read

```

Compute the MD5 sum of a process component. We reset the stored MD5 sum to the empty string (so a previous value is not included in the calculation), the write a temporary file and calculate the MD5 sum of that file.

This implies that all data that are displayed by the `write` method become part of the MD5 sum calculation.

The `model` is not part of the object, but must be included in the MD5 sum.

Otherwise, modifying the model and nothing else would not trigger remaking the process-component source. Note that the model parameters may change later and therefore are not incorporated.

After the MD5 sum of the component has been computed, we communicate it to the `writer` subobject of the specific `core_def` component. Although these types are abstract, the MD5-related features are valid for the abstract types.

```

(Process libraries: process component def: TBP)+≡
  procedure :: compute_md5sum => process_component_def_compute_md5sum

    character(32) :: md5sum
    md5sum = component%md5sum
  end function process_component_def_get_md5sum

```

Process definition

The process component definitions are collected in a common process definition object.

The `id` is the ID string that the user has provided for identifying this process. It must be a string that is allowed as part of a Fortran variable name, since it may be used for generating code.

The number `n_in` is 1 or 2 for a decay or scattering process, respectively. This must be identical to `n_in` for all components.

The initial and extra component definitions (see above) are allocated as the `initial` and `extra` arrays, respectively. The latter are determined from the former.

The `md5sum` is used to verify the integrity of the configuration.

```

(Process libraries: public)+≡
  public :: process_def_t

```

```

<Process libraries: types>+≡
  type :: process_def_t
    private
      type(string_t) :: id
      type(model_t), pointer :: model => null ()
      type(string_t) :: model_name
      integer :: n_in = 0
      integer :: n_initial = 0
      integer :: n_extra = 0
      type(process_component_def_t), dimension(:), allocatable :: initial
      type(process_component_def_t), dimension(:), allocatable :: extra
      character(32) :: md5sum = ""
    contains
      <Process libraries: process def: TBP>
    end type process_def_t

```

Write the process definition including components:

```

<Process libraries: process def: TBP>≡
  procedure :: write => process_def_write

Initialize an entry (initialize the process definition inside). We allocate the 'initial' set of components. Extra components remain unallocated.

The model should be present as a pointer. This allows us to retrieve the model's MD5 sum. However, for various tests it is sufficient to have the name.

We create the basenames for the process components by appending a suffix which we increment for each component.

```

end subroutine process_def_init
```

Initialize an initial component. The particle content must be specified. The process core block is not (yet) allocated.

We assume that the particle arrays match the `n_in` and `n_out` values in size. The model is referred to by name; it is identified as an existing model later. The index `i` must refer to an existing element of the component array.

Data specific for the process core of a component are imported as the `core_def` argument. We should allocate an object of class `prc_core_def_t` with the appropriate specific type, fill it, and transfer it to the process component definition here. The allocation is moved, so the original allocated object is returned empty.

    integer, intent(in) :: i_component
    logical :: flag
    flag = def%initial(i_component)%needs_code ()
  end function process_def_needs_code

```

Process definition list

A list of process definitions is the starting point for creating a process library. The list is built when reading the user input. When reading an existing process library, the list is used for cross-checking and updating the configuration.

We need a type for the list entry. The simplest way is to extend the process definition type, so all methods apply to the process definition directly.

```

<Process libraries: public>+≡
  public :: process_def_entry_t

<Process libraries: types>+≡
  type, extends (process_def_t) :: process_def_entry_t
    private
    type(process_def_entry_t), pointer :: next => null ()
  end type process_def_entry_t

```

This is the type for the list itself.

```

<Process libraries: types>+≡
  type :: process_def_list_t
    private
    type(process_def_entry_t), pointer :: first => null ()
    type(process_def_entry_t), pointer :: last => null ()
  contains
    <Process libraries: process def list: TBP>
  end type process_def_list_t

```

The deallocates the list iteratively. We assume that the list entries do not need finalization themselves.

```

<Process libraries: process def list: TBP>≡
  procedure :: final => process_def_list_final

```

```

<Process libraries: procedures>+≡
subroutine process_def_list_final (list)
  class(process_def_list_t), intent(inout) :: list
  type(process_def_entry_t), pointer :: current
  nullify (list%last)
  do while (associated (list%first))
    current => list%first
    list%first => current%next
    deallocate (current)
  end do
end subroutine process_def_list_final

```

Write the complete list.

```

<Process libraries: process def list: TBP>+≡
  procedure :: write => process_def_list_write

<Process libraries: procedures>+≡
subroutine process_def_list_write (object, unit)
  class(process_def_list_t), intent(in) :: object
  integer, intent(in), optional :: unit
  type(process_def_entry_t), pointer :: entry
  integer :: i, u
  u = output_unit (unit)
  if (associated (object%first)) then
    i = 1
    entry => object%first
    do while (associated (entry))
      write (u, "(1x,A,IO,A)") "Process #", i, ":"
      call entry%write (u)
      i = i + 1
      entry => entry%next
      if (associated (entry)) write (u, *)
    end do
  else
    write (u, "(1x,A)") "Process definition list: [empty]"
  end if
end subroutine process_def_list_write

```

Read the complete list. We need an array of templates for the component sub-objects of abstract `prc_core_t` type, to allocate them with the correct specific type.

NOTE: Error handling is missing. Reading will just be aborted on error, or an I/O error occurs.

```

<Process libraries: process def list: TBP>+≡
  procedure :: read => process_def_list_read

<Process libraries: procedures>+≡
subroutine process_def_list_read (object, unit, core_def_templates)
  class(process_def_list_t), intent(out) :: object
  integer, intent(in) :: unit
  type(prc_template_t), dimension(:), intent(in) :: core_def_templates
  type(process_def_entry_t), pointer :: entry
  character(80) :: buffer, ref

```

```

integer :: i
read (unit, "(A)")  buffer
write (ref, "(1x,A)") "Process definition list: [empty]"
if (buffer == ref) return      ! OK: empty library
backspace (unit)
READ_ENTRIES: do i = 1, huge (0)
  if (i > 1) read (unit, *, end=1)
  read (unit, "(A)")  buffer

  write (ref, "(1x,A,I0,A)") "Process #", i, ":"
  if (buffer /= ref) return      ! Wrong process header: done.
  allocate (entry)
  call entry%read (unit, core_def_templates)
  call object%append (entry)
end do READ_ENTRIES
1  continue                      ! EOF: done
end subroutine process_def_list_read

```

Append an entry to the list. The entry should be allocated as a pointer, and the pointer allocation is transferred. The original pointer is returned null.

```

<Process libraries: process def list: TBP>+≡
  procedure :: append => process_def_list_append

end subroutine process_def_list_get_component_description_list

```

14.4.3 Process library

The process library object is the interface between the process definition data, as provided by the user, generated or linked process code on file, and the process run data that reference the process code.

Process library entry

For each process component that is part of the library, there is a separate library entry (`process_library_entry_t`). The library entry connects a process definition with the specific code (if any) in the compiled driver library.

The `status` indicates how far the process has been processed by the system (definition, code generation, compilation, linking). A process with status `STAT_LOADED` is accessible for computing matrix elements.

The `def` pointer identifies the corresponding process definition. The process component within that definition is identified by the `i_component` index.

The `i_external` index refers to the compiled library driver. If it is zero, there is no associated matrix-element code.

The `driver` component holds the pointers to the matrix-element specific functions, in particular the matrix element function itself.

```
<Process libraries: types>+≡
type :: process_library_entry_t
  private
  integer :: status = STAT_UNKNOWN
  type(process_def_t), pointer :: def => null ()
  integer :: i_component = 0
  integer :: i_external = 0
  class(prc_core_driver_t), allocatable :: driver
contains
  <Process libraries: process library entry: TBP>
end type process_library_entry_t
```

Here are the available status codes. An entry starts with `UNKNOWN` status. Once the association with a valid process definition is established, the status becomes `CONFIGURED`. If matrix element source code is to be generated by the system or provided from elsewhere, `CODE_GENERATED` indicates that this is done. The `COMPILED` status is next, it also applies to processes which are accessed as pre-compiled binaries. Finally, the library is linked and process pointers are set; this is marked as `LOADED`.

For a process library, the initial status is `OPEN`, since process definitions may be added. After configuration, the process content is fixed and the status becomes `CONFIGURED`. The further states are as above, always referring to the lowest status among the process entries.

```
<Process libraries: parameters>≡
integer, parameter :: STAT_UNKNOWN = 0
integer, parameter :: STAT_OPEN = 1
integer, parameter :: STAT_CONFIGURED = 2
integer, parameter :: STAT_SOURCE = 3
integer, parameter :: STAT_COMPILED = 4
integer, parameter :: STAT_LINKED = 5
integer, parameter :: STAT_ACTIVE = 6
```

These are the associated code letters, for output:

```

(Process libraries: parameters)+≡
  character, dimension(0:6), parameter :: STATUS_LETTER = &
    ["?", "o", "f", "s", "c", "l", "a"]

```

This produces a condensed account of the library entry. The status is indicated by a letter in brackets, then the ID and component index of the associated process definition, finally the library index, if available.

```

(Process libraries: process library entry: TBP)≡
  procedure :: to_string => process_library_entry_to_string

(Process libraries: procedures)+≡
  function process_library_entry_to_string (object) result (string)
    type(string_t) :: string
    class(process_library_entry_t), intent(in) :: object
    character(32) :: buffer
    string = "[" // STATUS_LETTER(object%status) // "]"
    select case (object%status)
    case (STAT_UNKNOWN)
    case default
      if (associated (object%def)) then
        write (buffer, "(IO)") object%i_component
        string = string // " " // object%def%id // "." // trim (buffer)
      end if
      if (object%i_external /= 0) then
        write (buffer, "(IO)") object%i_external
        string = string // " = ext:" // trim (buffer)
      else
        string = string // " = int"
      end if
      if (allocated (object%driver)) then
        string = string // " (" // object%driver%type_name () // ")"
      end if
    end select
  end function process_library_entry_to_string

```

Initialize with data. Used for the unit tests.

```

(Process libraries: process library entry: TBP)+≡
  procedure :: init => process_library_entry_init

(Process libraries: procedures)+≡
  subroutine process_library_entry_init (object, &
    status, def, i_component, i_external)
    class(process_library_entry_t), intent(out) :: object
    integer, intent(in) :: status
    type(process_def_t), target, intent(in) :: def
    integer, intent(in) :: i_component
    integer, intent(in) :: i_external
    object%status = status
    object%def => def
    object%i_component = i_component
    object%i_external = i_external
  end subroutine process_library_entry_init

```

Assign pointers for all process-specific features. We have to combine the method from the `core_def` specification, the assigned pointers within the library driver, the index within that driver, and the process driver which should receive the links.

```

<Process libraries: process library entry: TBP>+≡
    procedure :: connect => process_library_entry_connect

<Process libraries: procedures>+≡
    subroutine process_library_entry_connect (entry, lib_driver, i)
        class(process_library_entry_t), intent(inout) :: entry
        type(prclib_driver_t), intent(in) :: lib_driver
        integer, intent(in) :: i
        call entry%def%initial(entry%i_component)%connect &
            (lib_driver, i, entry%driver)
    end subroutine process_library_entry_connect

```

The process library object

The `process_library_t` type is an extension of the `process_def_list_t` type. Thus, it automatically contains the process definition list.

The `basename` identifies the library generically.

The `external` flag is true if any process within the library needs external code, so the library must correspond to an actual code library (statically or dynamically linked).

The `entry` array contains all process components that can be handled by this library. Each entry refers to the process (component) definition and to the associated external matrix element code, if there is any.

The `driver` object is needed only if `external` is true. This object handles all interactions with external matrix-element code.

The `md5sum` summarizes the complete `process_def_list_t` base object. It can be used to check if the library configuration has changed.

```

<Process libraries: public>+≡
    public :: process_library_t

<Process libraries: types>+≡
    type, extends (process_def_list_t) :: process_library_t
        private
        type(string_t) :: basename
        integer :: n_entries = 0
        logical :: external = .false.
        integer :: status = STAT_UNKNOWN
        logical :: driver_exists = .false.
        logical :: makefile_exists = .false.
        type(process_library_entry_t), dimension(:), allocatable :: entry
        type(prclib_driver_t) :: driver
        character(32) :: md5sum = ""
    contains
        <Process libraries: process library: TBP>
    end type process_library_t

```

For the output, we write first the metadata and the DL access record, then the library entries in short form, and finally the process definition list which is the base object.

```

(Process libraries: process library: TBP)≡
  procedure :: write => process_library_write

(Process libraries: procedures)+≡
  subroutine process_library_write (object, unit)
    class(process_library_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: i, u
    u = output_unit (unit)
    write (u, "(1x,A,A)") "Process library: ", char (object%basename)
    write (u, "(3x,A,L1)") "external      = ", object%external
    write (u, "(3x,A,L1)") "makefile exists = ", object%makefile_exists
    write (u, "(3x,A,L1)") "driver exists  = ", object%driver_exists
    write (u, "(3x,A,A1)") "code status   = ", &
      STATUS_LETTER (object%status)
    !   write (u, "(3x,A,A,A)") "MD5 sum       = '", object%md5sum, "'"
    write (u, *)
    if (allocated (object%entry)) then
      write (u, "(1x,A)", advance="no") "Process library entries:"
      write (u, "(1x,I0)") object%n_entries
      do i = 1, size (object%entry)
        write (u, "(1x,A,I0,A,A)") "Entry #", i, ": ", &
          char (object%entry(i)%to_string ())
      end do
      write (u, *)
    end if
    if (object%external) then
      call object%driver%write (u)
      write (u, *)
    end if
    call object%process_def_list_t%write (u)
  end subroutine process_library_write

```

The initializer defines just the basename. We may now add process definitions to the library.

```

(Process libraries: process library: TBP)+≡
  procedure :: init => process_library_init

(Process libraries: procedures)+≡
  subroutine process_library_init (lib, basename)
    class(process_library_t), intent(out) :: lib
    type(string_t), intent(in) :: basename
    lib%basename = basename
    lib%status = STAT_OPEN
    call msg_message ("Process library '" // char (basename) &
      // "' : initialized")
  end subroutine process_library_init

```

The `configure` procedure scans the allocated entries in the process definition list. The configuration proceeds in three passes.

In the first pass, we scan the process definition list and count the number of process components and the number of components which need external code. This is used to allocate the **entry** array.

In the second pass, we initialize the **entry** elements which connect process definitions, process driver objects, and external code.

In the third pass, we initialize the library driver object, allocating an entry for each external matrix element.

NOTE: Currently we handle only **initial** process components; **extra** components are ignored.

```

(Process libraries: process library: TBP)+≡
  procedure :: configure => process_library_configure

(Process libraries: procedures)+≡

            // "': writing driver")
        unit = free_unit ()
        open (unit, file = char (lib%driver%basename // ".f90"), &
            status="replace", action="write")
        call lib%driver%generate_driver_code (unit)
        close (unit)
    end if
    lib%driver_exists = .true.
end if
end subroutine process_library_write_driver

```

Update the compilation status of an external library.

Strictly speaking, this is not necessary for a one-time run, since the individual library methods will update the status themselves. However, it allows us to identify compilation steps that we can skip because the file exists or is already loaded, for the whole library or for particular entries.

Independently, the building process is controlled by a makefile. Thus, previous files are reused if they are not modified by the current compilation.

1. If it is not already loaded, attempt to load the library. If successful, check the overall MD5 sum. If it matches, just keep it loaded and mark as ACTIVE. If not, check the MD5 sum for all linked process components. Where it matches, mark the entry as COMPILED. Then, unload the library and mark as CONFIGURED.

Thus, we can identify compiled files for all matrix elements which are accessible via the previous compiled library, even if it is no longer up to date.

2. If the library is now in CONFIGURED state, look for valid source files. Each entry that is just in CONFIGURED state will advance to SOURCE if the MD5 sum matches. Finally, advance the whole library to SOURCE if all entries are at least in this condition.

(Process libraries: process library: TBP)+≡

```

            lib%status = STAT_SOURCE
        end if
    end if
end select

```

```

        end if
    end subroutine process_library_update_status

```

This procedure triggers code generation for all processes where this is possible.

We generate code only for external processes of status `STAT_CONFIGURED`, which then advance to `STAT_SOURCE`. If, for a particular process, the status is already advanced, we do not remove previous files, so `make` will consider them as up to date if they exist. Otherwise, we remove those files to force a fresh `make`.

Finally, if any source code has been generated, we need a driver file.

```

<Process libraries: process library: TBP>+≡
    procedure :: make_source => process_library_make_source

<Process libraries: procedures>+≡
    subroutine process_library_make_source (lib, os_data)

    call lib%load_entries ()
  end if
  lib%entry%status = STAT_ACTIVE
  lib%status = STAT_ACTIVE
end select
end subroutine process_library_load

```

This is the actual loading part for the process methods.

```

<Process libraries: process library: TBP>+≡
  procedure :: load_entries => process_library_load_entries

<Process libraries: procedures>+≡
  subroutine process_library_load_entries (lib)
    class(process_library_t), intent(inout) :: lib
    integer :: i
    do i = 1, size (lib%entry)
      associate (entry => lib%entry(i))
        if (entry%i_external /= 0) then
          call entry%connect (lib%driver, entry%i_external)
        end if
      end associate
    end do
  end subroutine process_library_load_entries

```

Unload the library, if possible. This reverts the status to “linked”.

```

<Process libraries: process library: TBP>+≡
  procedure :: unload => process_library_unload

<Process libraries: procedures>+≡
  subroutine process_library_unload (lib)
    class(process_library_t), intent(inout) :: lib
    select case (lib%status)
    case (STAT_ACTIVE)
      if (lib%external) then
        call msg_message ("Process library '" // char (lib%basename) &
          // "': unloading")
        call lib%driver%unload ()
      end if
      lib%entry%status = STAT_LINKED
      lib%status = STAT_LINKED
    end select
  end subroutine process_library_unload

```

Unload, clean all generated files and revert the library status. If distclean is set, also remove the makefile and the driver source.

```

<Process libraries: process library: TBP>+≡
  procedure :: clean => process_library_clean

```

```

<Process libraries: procedures>+≡
subroutine process_library_clean (lib, os_data, distclean)
  class(process_library_t), intent(inout) :: lib
  type(os_data_t), intent(in) :: os_data
  logical, intent(in) :: distclean
  call lib%unload ()
  if (lib%external) then
    call msg_message ("Process library '" // char (lib%basename) &
      // "': removing old files")
    if (distclean) then
      call lib%driver%distclean (os_data)
    else
      call lib%driver%clean (os_data)
    end if
  end if
  where (lib%entry%i_external /= 0)
    lib%entry%status = STAT_CONFIGURED
  elsewhere
    lib%entry%status = STAT_LINKED
  end where
  if (lib%external) then
    lib%status = STAT_CONFIGURED
  else
    lib%status = STAT_LINKED
  end if
end subroutine process_library_clean

```

Unload and revert the library status to INITIAL. This allows for appending new processes. No files are deleted.

```

<Process libraries: process library: TBP>+≡
procedure :: open => process_library_open

<Process libraries: procedures>+≡
subroutine process_library_open (lib)
  class(process_library_t), intent(inout) :: lib
  select case (lib%status)
  case (STAT_OPEN)
  case default
    call lib%unload ()
    lib%entry%status = STAT_OPEN
    lib%status = STAT_OPEN
    call msg_message ("Process library '" // char (lib%basename) &
      // "': open")
  end select
end subroutine process_library_open

```

14.4.4 Use the library

Return the base name of the library

```

<Process libraries: process library: TBP>+≡
procedure :: get_name => process_library_get_name

```

```

<Process libraries: procedures>+≡
function process_library_get_name (lib) result (name)
  class(process_library_t), intent(in) :: lib
  type(string_t) :: name
  name = lib%basename
end function process_library_get_name

```

Once activated, we view the process library object as an interface for accessing the matrix elements.

```

<Process libraries: process library: TBP>+≡
  procedure :: is_active => process_library_is_active

<Process libraries: procedures>+≡
function process_library_is_active (lib) result (flag)
  logical :: flag
  class(process_library_t), intent(in) :: lib
  flag = lib%status == STAT_ACTIVE
end function process_library_is_active

```

Retrieve constants using the process library driver. We assume that the process code has been loaded, if external.

```

<Process libraries: process library entry: TBP>+≡
  procedure :: fill_constants => process_library_entry_fill_constants

<Process libraries: procedures>+≡
subroutine process_library_entry_fill_constants (entry, driver, data)
  class(process_library_entry_t), intent(in) :: entry

            associate (entry => lib%entry(i))
                if (entry%def%id == id .and. entry%i_component == i_component) then
                    call entry%fill_constants (lib%driver, data)
                    allocate (proc_driver, source=entry%driver)
                    return
                end if
            end associate
        end do
        ! If we arrive here: Process not found
    end subroutine process_library_connect_process

```

14.4.5 Test

This is the master for calling self-test procedures.

```

<Process libraries: public>+≡
    public :: process_libraries_test

<Process libraries: tests>≡
    subroutine process_libraries_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Process libraries: execute tests>
    end subroutine process_libraries_test

```

Empty process list

Test 1: Write an empty process list.

```

<Process libraries: execute tests>≡
    call test (process_libraries_1, "process_libraries_1", &
        "empty process list", &
        u, results)

```

```

<Process libraries: tests>+≡
subroutine process_libraries_1 (u)
  integer, intent(in) :: u
  type(process_def_list_t) :: process_def_list

  write (u, "(A)")  "* Test output: process_libraries_1"
  write (u, "(A)")  "* Purpose: Display an empty process definition list"
  write (u, "(A)")

  call process_def_list%write (u)

  write (u, "(A)")
  write (u, "(A)")  "* Test output end: process_libraries_1"
end subroutine process_libraries_1

```

Process definition list

Test 2: Process definition list with processes and components. Construct the list, write to file, read it in again, and display. Finalize and delete the list after use.

We define a trivial 'test' type for the process variant. The test type contains just one (meaningless) data item, which is an integer.

```

<Process libraries: test declarations>≡
type, extends (prc_core_def_t) :: prcdef_2_t
  integer :: data = 0
  logical :: file = .false.
contains
  <Process libraries: prcdef 2: TBP>
end type prcdef_2_t

```

The process variant is named 'test'.

```

<Process libraries: prcdef 2: TBP>≡
  procedure, nopass :: type_string => prcdef_2_type_string

<Process libraries: tests>+≡
function prcdef_2_type_string () result (string)
  type(string_t) :: string
  string = "test"
end function prcdef_2_type_string

```

Write the contents (the integer value).

```

<Process libraries: prcdef 2: TBP>+≡
  procedure :: write => prcdef_2_write

<Process libraries: tests>+≡
subroutine prcdef_2_write (object, unit)
  class(prcdef_2_t), intent(in) :: object
  integer, intent(in) :: unit
  write (unit, "(3x,A,I0)") "Test data          = ", object%data
end subroutine prcdef_2_write

```

Recover the integer value.

```
<Process libraries: prcdef 2: TBP>+≡  
  procedure :: read => prcdef_2_read  
  
<Process libraries: tests>+≡  
  subroutine prcdef_2_read (object, unit)  
    class(prcdef_2_t), intent(out) :: object  
    integer, intent(in) :: unit  
    character(80) :: buffer  
    read (unit, "(A)") buffer  
    call strip_prefix (buffer)  
    read (buffer, *) object%data  
  end subroutine prcdef_2_read
```

No external procedures.

```
<Process libraries: prcdef 2: TBP>+≡  
  procedure, nopass :: get_features => prcdef_2_get_features  
  
<Process libraries: tests>+≡  
  subroutine prcdef_2_get_features (features)  
    type(string_t), dimension(:), allocatable, intent(out) :: features  
    allocate (features (0))  
  end subroutine prcdef_2_get_features
```

No code generated.

```
<Process libraries: prcdef 2: TBP>+≡  
  procedure :: generate_code => prcdef_2_generate_code  
  
<Process libraries: tests>+≡  
  subroutine prcdef_2_generate_code (object, &  
    basename, model_name, prt_in, prt_out)  
    class(prcdef_2_t), intent(in) :: object  
    type(string_t), intent(in) :: basename  
    type(string_t), intent(in) :: model_name  
    type(string_t), dimension(:), intent(in) :: prt_in  
    type(string_t), dimension(:), intent(in) :: prt_out  
  end subroutine prcdef_2_generate_code
```

Allocate the driver with the appropriate type.

```
<Process libraries: prcdef 2: TBP>+≡  
  procedure :: allocate_driver => prcdef_2_allocate_driver  
  
<Process libraries: tests>+≡  
  subroutine prcdef_2_allocate_driver (object, driver, basename)  
    class(prcdef_2_t), intent(in) :: object  
    class(prc_core_driver_t), intent(out), allocatable :: driver  
    type(string_t), intent(in) :: basename  
    allocate (prctest_2_t :: driver)  
  end subroutine prcdef_2_allocate_driver
```

Nothing to connect.

```
<Process libraries: prcdef 2: TBP>+≡  
  procedure :: connect => prcdef_2_connect
```

```

<Process libraries: tests>+≡
  subroutine prcdef_2_connect (def, lib_driver, i, proc_driver)
    class(prcdef_2_t), intent(in) :: def
    type(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i
    class(prc_core_driver_t), intent(inout) :: proc_driver
  end subroutine prcdef_2_connect

```

The associated driver type.

```

<Process libraries: types>+≡
  type, extends (process_driver_internal_t) :: prctest_2_t
  contains
    <Process libraries: prctest 2: TBP>
  end type prctest_2_t

```

Return the type name.

```

<Process libraries: prctest 2: TBP>≡
  procedure, nopass :: type_name => prctest_2_type_name

<Process libraries: procedures>+≡
  function prctest_2_type_name () result (type)
    type(string_t) :: type
    type = "test"
  end function prctest_2_type_name

```

This should fill constant process data. We do not check those here, however, therefore nothing done.

```

<Process libraries: prctest 2: TBP>+≡
  procedure :: fill_constants => prctest_2_fill_constants

<Process libraries: procedures>+≡
  subroutine prctest_2_fill_constants (driver, data)
    class(prctest_2_t), intent(in) :: driver
    type(process_constants_t), intent(out) :: data
  end subroutine prctest_2_fill_constants

```

Here is the actual test.

For reading, we need a list of templates, i.e., an array containing allocated objects for all available process variants. This is the purpose of `process_core_templates`. Here, we have only a single template for the 'test' variant.

```

<Process libraries: execute tests>+≡
  call test (process_libraries_2, "process_libraries_2", &
    "process definition list", &
    u, results)

<Process libraries: tests>+≡
  subroutine process_libraries_2 (u)
    integer, intent(in) :: u
    type(prc_template_t), dimension(:), allocatable :: process_core_templates

Build workflow for test matrix element

Test 5: We write source code for a dummy process.

We define another trivial type for the process variant. The test type contains just no variable data, but produces code on file.

```
<Process libraries: test declarations>+≡
  type, extends (prc_core_def_t) :: prcdef_5_t
  contains
    <Process libraries: prcdef 5: TBP>
  end type prcdef_5_t
```

The process variant is named `test_file`.

```
<Process libraries: prcdef 5: TBP>≡
  procedure, nopass :: type_string => prcdef_5_type_string

<Process libraries: tests>+≡
  function prcdef_5_type_string () result (string)
    type(string_t) :: string
    string = "test_file"
  end function prcdef_5_type_string
```

We reuse the writer `test_writer_4` from the previous module.

```
<Process libraries: prcdef 5: TBP>+≡
  procedure :: init => prcdef_5_init

<Process libraries: tests>+≡
  subroutine prcdef_5_init (object)
    class(prcdef_5_t), intent(out) :: object
    allocate (test_writer_4_t :: object%writer)
  end subroutine prcdef_5_init
```

Nothing to write.

```
<Process libraries: prcdef 5: TBP>+≡
  procedure :: write => prcdef_5_write

<Process libraries: tests>+≡
  subroutine prcdef_5_write (object, unit)
    class(prcdef_5_t), intent(in) :: object
    integer, intent(in) :: unit
  end subroutine prcdef_5_write
```

Nothing to read.

```
<Process libraries: prcdef 5: TBP>+≡
  procedure :: read => prcdef_5_read

<Process libraries: tests>+≡
  subroutine prcdef_5_read (object, unit)
    class(prcdef_5_t), intent(out) :: object
    integer, intent(in) :: unit
  end subroutine prcdef_5_read
```

Allocate the driver with the appropriate type.

```
<Process libraries: prcdef 5: TBP>+≡
  procedure :: allocate_driver => prcdef_5_allocate_driver
```

```

<Process libraries: tests>+≡
  subroutine prcdef_5_allocate_driver (object, driver, basename)
    class(prcdef_5_t), intent(in) :: object
    class(prc_core_driver_t), intent(out), allocatable :: driver
    type(string_t), intent(in) :: basename
    allocate (prctest_5_t :: driver)
  end subroutine prcdef_5_allocate_driver

```

This time we need code:

```

<Process libraries: prcdef 5: TBP>+≡
  procedure, nopass :: needs_code => prcdef_5_needs_code

<Process libraries: tests>+≡
  function prcdef_5_needs_code () result (flag)
    logical :: flag
    flag = .true.
  end function prcdef_5_needs_code

```

For the test case, we implement a single feature proc1.

```

<Process libraries: prcdef 5: TBP>+≡
  procedure, nopass :: get_features => prcdef_5_get_features

<Process libraries: tests>+≡
  subroutine prcdef_5_get_features (features)
    type(string_t), dimension(:), allocatable, intent(out) :: features
    allocate (features (1))
    features = [ var_str ("proc1") ]
  end subroutine prcdef_5_get_features

```

Nothing to connect.

```

<Process libraries: prcdef 5: TBP>+≡
  procedure :: connect => prcdef_5_connect

<Process libraries: tests>+≡
  subroutine prcdef_5_connect (def, lib_driver, i, proc_driver)
    class(prcdef_5_t), intent(in) :: def
    type(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i
    class(prc_core_driver_t), intent(inout) :: proc_driver
  end subroutine prcdef_5_connect

```

The driver type.

```

<Process libraries: types>+≡
  type, extends (prc_core_driver_t) :: prctest_5_t
    contains
    <Process libraries: prctest 5: TBP>
  end type prctest_5_t

```

Return the type name.

```

<Process libraries: prctest 5: TBP>≡

14.5 Process Library Stacks

For storing and handling multiple libraries, we define process library stacks. These are ordinary stacks where new entries are pushed onto the top.

```

<prclib_stacks.f90>≡
  <File header>

  module prclib_stacks

    <Use strings>
    <Use file utils>
    use unit_tests
    use os_interface
    use models

    use process_libraries

    <Standard module head>

    <Prclib stacks: public>

    <Prclib stacks: types>

    contains

    <Prclib stacks: procedures>

    <Prclib stacks: tests>

    end module prclib_stacks

```

14.5.1 The stack entry type

A stack entry is a process library object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, process libraries should be prepared as process entry objects.

```

<Prclib stacks: public>≡
  public :: prclib_entry_t

```

```

<Prclib stacks: types>≡
  type, extends (process_library_t) :: prclib_entry_t
    type(prclib_entry_t), pointer :: next => null ()
  end type prclib_entry_t

```

14.5.2 The prclib stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

```

<Prclib stacks: public>+≡
  public :: prclib_stack_t

<Prclib stacks: types>+≡
  type :: prclib_stack_t
    integer :: n = 0
    type(prclib_entry_t), pointer :: first => null ()
  contains
    <Prclib stacks: prclib stack: TBP>
  end type prclib_stack_t

```

Finalizer. Iteratively deallocate the stack entries. The resulting empty stack can be immediately recycled, if necessary.

```

<Prclib stacks: prclib stack: TBP>≡
  procedure :: final => prclib_stack_final

<Prclib stacks: procedures>≡
  subroutine prclib_stack_final (object)
    class(prclib_stack_t), intent(inout) :: object
    type(prclib_entry_t), pointer :: lib
    do while (associated (object%first))
      lib => object%first
      object%first => lib%next
      call lib%final ()
      deallocate (lib)
    end do
    object%n = 0
  end subroutine prclib_stack_final

```

Output. The entries on the stack will be ordered LIFO, i.e., backwards.

```

<Prclib stacks: prclib stack: TBP>+≡
  procedure :: write => prclib_stack_write

<Prclib stacks: procedures>+≡
  subroutine prclib_stack_write (object, unit)
    class(prclib_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    type(prclib_entry_t), pointer :: lib
    integer :: u
    u = output_unit (unit)
    call write_separator_double (u)
    select case (object%n)
    case (0)

```

```

        write (u, "(1x,A)") "Process library stack: [empty]"
    case default
        write (u, "(1x,A)") "Process library stack:"
        lib => object%first
        do while (associated (lib))
            call write_separator (u)
            call lib%write (u)
            lib => lib%next
        end do
    end select
    call write_separator_double (u)
end subroutine prclib_stack_write

```

14.5.3 Operating on Stacks

We take a library entry pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the library entry is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

<Prclib stacks: prclib stack: TBP>+≡
    procedure :: push => prclib_stack_push

<Prclib stacks: procedures>+≡
    subroutine prclib_stack_push (stack, lib)
        class(prclib_stack_t), intent(inout) :: stack
        type(prclib_entry_t), intent(inout), pointer :: lib
        lib%next => stack%first
        stack%first => lib
        lib => null ()
        stack%n = stack%n + 1
    end subroutine prclib_stack_push

```

14.5.4 Accessing Contents

Return a pointer to the topmost stack element. The result type is just the bare `process_library_t`. There is no `target` attribute required since the stack elements are allocated via pointers.

```

<Prclib stacks: prclib stack: TBP>+≡
    procedure :: get_first_ptr => prclib_stack_get_first_ptr

<Prclib stacks: procedures>+≡
    function prclib_stack_get_first_ptr (stack) result (ptr)
        class(prclib_stack_t), intent(in) :: stack
        type(process_library_t), pointer :: ptr
        ptr => stack%first%process_library_t
    end function prclib_stack_get_first_ptr

```

Return a complete list of the libraries (names) in the stack. The list is in the order in which the elements got pushed onto the stack, so the ‘first’ entry is listed last.

```

<Prclib stacks: prclib stack: TBP>+≡
    procedure :: get_names => prclib_stack_get_names

```

```

<Prclib stacks: procedures>+≡
subroutine prclib_stack_get_names (stack, libname)
  class(prclib_stack_t), intent(in) :: stack
  type(string_t), dimension(:), allocatable, intent(out) :: libname
  type(prclib_entry_t), pointer :: lib
  integer :: i
  allocate (libname (stack%n))
  i = stack%n
  lib => stack%first
  do while (associated (lib))
    libname(i) = lib%get_name ()
    i = i - 1
    lib => lib%next
  end do
end subroutine prclib_stack_get_names

```

Return a pointer to the library with given name.

```

<Prclib stacks: prclib_stack: TBP>+≡
  procedure :: get_library_ptr => prclib_stack_get_library_ptr

<Prclib stacks: procedures>+≡
function prclib_stack_get_library_ptr (stack, libname) result (ptr)
  class(prclib_stack_t), intent(in) :: stack
  type(string_t), intent(in) :: libname
  type(process_library_t), pointer :: ptr
  type(prclib_entry_t), pointer :: current
  current => stack%first
  do while (associated (current))
    if (current%get_name () == libname) then
      ptr => current%process_library_t
      return
    end if
    current => current%next
  end do
  ptr => null ()
end function prclib_stack_get_library_ptr

```

14.5.5 Auxiliary stuff

Write a separator line.

```

<Prclib stacks: procedures>+≡
subroutine write_separator (u)
  integer, intent(in) :: u
  write (u, "(A)") repeat ("-", 72)
end subroutine write_separator

subroutine write_separator_double (u)
  integer, intent(in) :: u
  write (u, "(A)") repeat ("=", 72)
end subroutine write_separator_double

```

14.5.6 Unit tests

```
<Prclib stacks: public>+≡
    public :: prclib_stacks_test

<Prclib stacks: tests>≡
    subroutine prclib_stacks_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Prclib stacks: execute tests>
    end subroutine prclib_stacks_test
```

Write an empty process library stack

The most trivial test is to write an uninitialized process library stack.

```
<Prclib stacks: execute tests>≡
    call test (prclib_stacks_1, "prclib_stacks_1", &
        "write an empty process library stack", &
        u, results)

<Prclib stacks: tests>+≡
    subroutine prclib_stacks_1 (u)
        integer, intent(in) :: u
        type(prclib_stack_t) :: stack

        write (u, "(A)")  "* Test output: prclib_stacks_1"
        write (u, "(A)")  "* Purpose: display an empty process library stack"
        write (u, "(A)")

        call stack%write (u)

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: prclib_stacks_1"

    end subroutine prclib_stacks_1
```

Fill a process library stack

Fill a process library stack with two (identical) processes.

```
<Prclib stacks: execute tests>+≡
    call test (prclib_stacks_2, "prclib_stacks_2", &
        "fill a process library stack", &
        u, results)

<Prclib stacks: tests>+≡
    subroutine prclib_stacks_2 (u)
        integer, intent(in) :: u
        type(prclib_stack_t) :: stack
        type(prclib_entry_t), pointer :: lib

        write (u, "(A)")  "* Test output: prclib_stacks_2"
        write (u, "(A)")  "* Purpose: fill a process library stack"
        write (u, "(A)")
```

```

write (u, "(A)")  "* Initialize two (empty) libraries &
                  &and push them on the stack"
write (u, "(A)")

allocate (lib)
call lib%init (var_str ("lib1"))
call stack%push (lib)

allocate (lib)
call lib%init (var_str ("lib2"))
call stack%push (lib)

call stack%write (u)

write (u, "(A)")
write (u, "(A)")  "* Cleanup"

call stack%final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: prclib_stacks_2"

end subroutine prclib_stacks_2

```

14.6 Trivial matrix element for tests

For the purpose of testing the workflow, we implement here a matrix element with the simplest possible structure.

This matrix element generator can only generate a single process: a quartic interaction of a massless, neutral and colorless scalar \mathbf{s} with unit coupling results in a trivial $2 \rightarrow 2$ scattering process. The matrix element is implemented internally, so we do not need the machinery of external process libraries.

```

<prc_test.f90>≡
  <File header>

  module prc_test

    use iso_c_binding !NODEP!
    use kinds !NODEP!
    <Use strings>
    use unit_tests
    use os_interface

    use process_constants
    use prclib_interfaces
    use prc_core_def
    use particle_specifiers
    use process_libraries

    <Standard module head>

```

```

    <Test ME: public>

    <Test ME: types>

    contains

    <Test ME: procedures>

    <Test ME: tests>

end module prc_test

```

14.6.1 Process definition

For the process definition we implement an extension of the `prc_core_def_t` abstract type.

```

<Test ME: public>≡
    public :: prc_test_def_t

<Test ME: types>≡
    type, extends (prc_core_def_t) :: prc_test_def_t
        type(string_t) :: model_name
        type(string_t), dimension(:), allocatable :: prt_in
        type(string_t), dimension(:), allocatable :: prt_out
    contains
        <Test ME: test me def: TBP>
    end type prc_test_def_t

<Test ME: test me def: TBP>≡
    procedure, nopass :: type_string => prc_test_def_type_string

<Test ME: procedures>≡
    function prc_test_def_type_string () result (string)
        type(string_t) :: string
        string = "test_me"
    end function prc_test_def_type_string

```

There is no 'feature' here since there is no external code.

```

<Test ME: test me def: TBP>+≡
    procedure, nopass :: get_features => prc_test_def_get_features

<Test ME: procedures>+≡
    subroutine prc_test_def_get_features (features)
        type(string_t), dimension(:), allocatable, intent(out) :: features
        allocate (features (0))
    end subroutine prc_test_def_get_features

```

Initialization: set some data (not really useful).

```

<Test ME: test me def: TBP>+≡
    procedure :: init => prc_test_def_init

```

```

<Test ME: procedures>+≡
  subroutine prc_test_def_init (object, model_name, prt_in, prt_out)
    class(prc_test_def_t), intent(out) :: object
    type(string_t), intent(in) :: model_name
    type(string_t), dimension(:), intent(in) :: prt_in
    type(string_t), dimension(:), intent(in) :: prt_out
    object%model_name = model_name
    allocate (object%prt_in (size (prt_in)))
    object%prt_in = prt_in
    allocate (object%prt_out (size (prt_out)))
    object%prt_out = prt_out
  end subroutine prc_test_def_init

```

Write/read process- and method-specific data. (No-op)

```

<Test ME: test me def: TBP>+≡
  procedure :: write => prc_test_def_write

<Test ME: procedures>+≡
  subroutine prc_test_def_write (object, unit)
    class(prc_test_def_t), intent(in) :: object
    integer, intent(in) :: unit
  end subroutine prc_test_def_write

```

```

<Test ME: test me def: TBP>+≡
  procedure :: read => prc_test_def_read

<Test ME: procedures>+≡
  subroutine prc_test_def_read (object, unit)
    class(prc_test_def_t), intent(out) :: object
    integer, intent(in) :: unit
  end subroutine prc_test_def_read

```

Allocate the driver for test ME matrix elements. We get the actual component ID (basename), and we can transfer all process-specific data from the process definition.

```

<Test ME: test me def: TBP>+≡
  procedure :: allocate_driver => prc_test_def_allocate_driver

<Test ME: procedures>+≡
  subroutine prc_test_def_allocate_driver (object, driver, basename)
    class(prc_test_def_t), intent(in) :: object
    class(prc_core_driver_t), intent(out), allocatable :: driver
    type(string_t), intent(in) :: basename
    allocate (prc_test_t :: driver)
    select type (driver)
    type is (prc_test_t)
      driver%id = basename
      driver%model_name = object%model_name
    end select
  end subroutine prc_test_def_allocate_driver

```

Nothing to connect. This subroutine will not be called.

```

<Test ME: test me def: TBP>+≡
  procedure :: connect => prc_test_def_connect

```

```

<Test ME: procedures>+≡
  subroutine prc_test_def_connect (def, lib_driver, i, proc_driver)
    class(prc_test_def_t), intent(in) :: def
    type(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i
    class(prc_core_driver_t), intent(inout) :: proc_driver
  end subroutine prc_test_def_connect

```

14.6.2 Driver

```

<Test ME: public>+≡
  public :: prc_test_t

<Test ME: types>+≡
  type, extends (process_driver_internal_t) :: prc_test_t
    type(string_t) :: id
    type(string_t) :: model_name
  contains
    <Test ME: test me driver: TBP>
  end type prc_test_t

```

In contrast to generic matrix-element implementations, we can hard-wire the amplitude method as a type-bound procedure.

```

<Test ME: test me driver: TBP>≡
  procedure, nopass :: get_amplitude => prc_test_get_amplitude

<Test ME: procedures>+≡
  function prc_test_get_amplitude (p) result (amp)
    complex(default) :: amp
    real(default), dimension(:,,:), intent(in) :: p
    amp = 1
  end function prc_test_get_amplitude

```

The reported type is the same as for the `prc_test_def_t` type.

```

<Test ME: test me driver: TBP>+≡
  procedure, nopass :: type_name => prc_test_type_name

<Test ME: procedures>+≡
  function prc_test_type_name () result (string)
    type(string_t) :: string
    string = "test_me"
  end function prc_test_type_name

```

Fill process constants.

```

<Test ME: test me driver: TBP>+≡
  procedure :: fill_constants => prc_test_fill_constants

<Test ME: procedures>+≡
  subroutine prc_test_fill_constants (driver, data)
    class(prc_test_t), intent(in) :: driver
    type(process_constants_t), intent(out) :: data
    data%id = driver%id
  end subroutine prc_test_fill_constants

```

```

end subroutine prc_test_fill_constants

```

14.6.3 Shortcut

Since this module is there for testing purposes, we set up a subroutine that does all the work at once: create a library with a single process, configure and load, and set up the driver.

```

<Test ME: public>+≡
public :: prc_test_create_library

<Test ME: procedures>+≡
subroutine prc_test_create_library (procname, lib)
  type(string_t), intent(in) :: procname
  type(process_library_t), intent(out) :: lib
  type(string_t) :: model_name
  type(string_t), dimension(:), allocatable :: prt_in, prt_out
  class(prc_core_def_t), allocatable :: def
  type(process_def_entry_t), pointer :: entry
  type(os_data_t) :: os_data
  call lib%init (procname)
  model_name = "Test"
  allocate (prt_in (2), prt_out (2))
  prt_in = [var_str ("s"), var_str ("s")]
  prt_out = [var_str ("s"), var_str ("s")]
  allocate (prc_test_def_t :: def)
  select type (def)
  type is (prc_test_def_t)
    call def%init (model_name, prt_in, prt_out)
  end select
  allocate (entry)
  call entry%init (procname, model_name = model_name, &
    n_in = 2, n_components = 1)
  call entry%import_component (1, n_out = size (prt_out), &

```

```

        prt_in = new_prt_spec (prt_in), &
        prt_out = new_prt_spec (prt_out), &
        method = var_str ("test_me"), &
        variant = def)
    call lib%append (entry)
    call lib%configure ()
    call lib%load (os_data)
end subroutine prc_test_create_library

```

14.6.4 Test

This is the master for calling self-test procedures.

```

<Test ME: public>+≡
    public :: prc_test_test

<Test ME: tests>≡
    subroutine prc_test_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Test ME: execute tests>
end subroutine prc_test_test

```

Generate and load the process

The process is $ss \rightarrow ss$, where s is a trivial scalar particle, for vanishing mass and unit coupling. We initialize the process, build the library, and compute the particular matrix element for momenta of unit energy and right-angle scattering. (The scattering is independent of angle.) The matrix element is equal to unity.

```

<Test ME: execute tests>≡
    call test (prc_test_1, "prc_test_1", &
        "build and load trivial process", &
        u, results)

<Test ME: tests>+≡

        write (u, "(A)")  "* Test output end: prc_test_2"

    end subroutine prc_test_2
```

Chapter 15

Integration and Event Generation

This is the central part of the WHIZARD package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

integration_results This module handles results from integrating processes. It records passes and iterations, calculates statistical averages, and provides the user output of integration results.

prc_core Here, we define the abstract `prc_core_t` type which handles all specific features of kinematics matrix-element evaluation that depend on a particular class of processes.

parton_states A `parton_state_t` object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

processes Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: `prc_core` for matrix-element evaluation, `prc_core_def` for the associated configuration and driver, `sf_base` for beams and structure-functions, `phs_base` for phase space, and `mci_base` for integration and event generation.

decays (not re-activated yet) Organize elementary processes in decay chains for on-shell particles.

showers (not re-activated yet) Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

events (not re-implemented yet) Combine all pieces to generate full events.

15.1 Integration results

We record integration results and errors in a dedicated type. This allows us to do further statistics such as weighted average, chi-squared, grouping by integration passes, etc.

Note WHIZARD 2.2.0: This code is taken from the previous **processes** module essentially unchanged and converted into a separate module. It lacks an overhaul and, in particular, self-tests.

```
<integration_results.f90>≡
  module integration_results

    use limits, only: GML_MIN_RANGE_RATIO !NODEP!
    <Use kinds>
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use md5
    use cputime
    use os_interface
    use mci_base

    <Standard module head>

    <Integration results: public>

    <Integration results: parameters>

    <Integration results: types>

    <Integration results: interfaces>

    contains

    <Integration results: procedures>

  end module integration_results
```

15.1.1 Integration results entry

This object collects the results of an integration pass and makes them available to the outside.

The results object has to distinguish the process type:

We store the process type, the index of the integration pass and the absolute iteration index, the number of iterations contained in this result (for averages), and the integral (cross section or partial width), error estimate, efficiency and time estimate.

For intermediate results, we set a flag if this result is an improvement w.r.t. previous ones.

The process type indicates decay or scattering. Dummy entries (skipped iterations) have a process type of PRC_UNKNOWN.

<Integration results: types>≡

```

type :: integration_entry_t
  private
  integer :: process_type = PRC_UNKNOWN
  integer :: pass = 0
  integer :: it = 0
  integer :: n_it = 0
  integer :: n_calls = 0
  logical :: improved = .false.
  real(default) :: integral = 0
  real(default) :: error = 0
  real(default) :: efficiency = 0
  real(default) :: chi2 = 0
  real(default), dimension(:), allocatable :: grove_weight
  type(time_t) :: time_start
  type(time_t) :: time_end
end type integration_entry_t

```

The possible values of the type indicator:

<Integration results: parameters>≡

```

integer, parameter, public :: PRC_UNKNOWN = 0
integer, parameter, public :: PRC_DECAY = 1
integer, parameter, public :: PRC_SCATTERING = 2

```

Initialize with all relevant data

<Integration results: procedures>≡

```

subroutine integration_entry_init (entry, &
  process_type, pass, it, n_it, n_calls, improved, &
  integral, error, efficiency, chi2, grove_weight, &
  time_start, time_end)
  type(integration_entry_t), intent(out) :: entry

    n_groves = size (entry%grove_weight)
  else
    n_groves = 0
  end if
end function integration_entry_get_n_groves

```

Output. This writes the header line for the result account below:

```

<Integration results: procedures>+≡
  subroutine write_header (process_type, unit, logfile)

```

```

integer, intent(in) :: process_type
integer, intent(in), optional :: unit
logical, intent(in), optional :: logfile
character(5) :: phys_unit
integer :: u
u = output_unit (unit); if (u < 0) return
select case (process_type)
case (PRC_DECAY);      phys_unit = "[GeV]"
case (PRC_SCATTERING); phys_unit = "[fb] "
case default
    phys_unit = ""
end select
write (msg_buffer, "(A)") &
    "It      Calls Integral" // phys_unit // &
    " Error" // phys_unit // &
    " Err[%]  Acc Eff[%]  Chi2 N[It] |"
call msg_message (unit=u, logfile=logfile)
end subroutine write_header

```

This writes a separator for result display:

(Integration results: procedures)+≡

```

subroutine write_hline (unit)
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit); if (u < 0) return
    write (u, "(A)")  "|" // (repeat("-", 77)) // "|"
    flush (u)
end subroutine write_hline

subroutine write_dline (unit)
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit); if (u < 0) return
    write (u, "(A)")  "|" // (repeat("=", 77)) // "|"
    flush (u)
end subroutine write_dline

```

This writes the standard result account into one screen line. The verbose version uses multiple lines and prints the unabridged values. Dummy entries are not written.

(Integration results: procedures)+≡

```

subroutine integration_entry_write (entry, unit, verbose)
    type(integration_entry_t), intent(in) :: entry

```

Compute the average for all entries in the specified integration pass. The integrals are weighted w.r.t. their individual errors, and we compute average, error of the average, and χ^2 value. All errors are assumed Gaussian, of course. The efficiency returned is the one of the last entry in the integration pass. For the time estimate, we simply take the minimum of all which should correspond to the best efficiency.

If any error vanishes, averaging by this algorithm would fail. In this case,

we simply average the entries and use the deviations from this average (if any) to estimate the error.

15.1.2 Combined integration results

We collect a list of results which grows during the execution of the program. This is implemented as an array which grows if necessary; so we can easily compute averages.

We implement this as an extension of the `mci_results_t` which is defined in `mci_base` as an abstract type. We thus decouple the implementation of the integrator from the implementation of the results display, but nevertheless can record intermediate results during integration. This implies that the present extension implements a `record` method.

```
<Integration results: public>≡
  public :: integration_results_t

<Integration results: types>+≡
  type, extends (mci_results_t) :: integration_results_t
    private
      integer :: process_type = PRC_UNKNOWN
      integer :: current_pass = 0
      integer :: n_pass = 0
      integer :: n_it = 0
      logical :: screen = .false.
      integer :: unit = 0
      type(integration_entry_t), dimension(:), allocatable :: entry
      type(integration_entry_t), dimension(:), allocatable :: average
    contains
      <Integration results: integration results: TBP>
    end type integration_results_t
```

The array is extended in chunks of 10 entries.

```
<Integration results: parameters>+≡
  integer, parameter :: RESULTS_CHUNK_SIZE = 10
```

The standard does not require to explicitly initialize the integers; however, some gfortran version has a bug here and misses the default initialization in the type definition.

```
<Integration results: integration results: TBP>≡
  procedure :: init => integration_results_init

<Integration results: procedures>+≡
  subroutine integration_results_init (results, process_type)
    class(integration_results_t), intent(out) :: results
    integer, intent(in) :: process_type
    results%process_type = process_type
    results%n_pass = 0
    results%n_it = 0
    allocate (results%entry (RESULTS_CHUNK_SIZE))
    allocate (results%average (RESULTS_CHUNK_SIZE))
  end subroutine integration_results_init
```

Output (ASCII format). The `verbose` format is used for writing the header in grid files.

(Integration results: integration results: TBP)+≡

end if
flush (u)
end subroutine integration_results_write

```

During integration, we do not want to print all results at once, but each intermediate result as soon as we get it. Thus, the previous procedure is chopped in pieces. First piece: store the output unit and a flag whether we want to print to standard output as well. Then write the header if the results are still empty, i.e., before integration has started. The second piece writes a single result to the saved output channels. We call this from the `record` method, which can be called from the integrator directly. The third piece writes the average result, once a pass has been completed. The fourth piece writes a footer (if any), assuming that this is the final result.

15.2 Abstract process core

In this module we provide abstract data types for process classes. Each process class represents a set of processes which are handled by a common “method”, e.g., by the O’MEGA matrix-element generator. The process class is also able to select a particular implementation for the phase-space and integration modules.

For a complete implementation of a process class, we have to provide extensions of the following abstract types:

prc_core_def_t process and matrix-element configuration

prc_writer_t (optional) writing external matrix-element code

prc_driver_t accessing the matrix element (internal or external)

prc_core_t evaluating kinematics and matrix element. The process core also selects phase-space and integrator implementations as appropriate for the process class and configuration.

In the actual process-handling data structures, each process component contains an instance of such a process class as its core. This allows us to keep the **processes** module below, which supervises matrix-element evaluation, integration, and event generation, free of any reference to concrete implementations (for the process class, phase space, and integrator).

There are no unit tests, these are deferred to the **processes** module.

```
<prc_core.f90>≡  
  <File header>  
  module prc_core  
  
    <Use kinds>  
    <Use strings>  
    <Use file utils>  
    use diagnostics !NODEP!  
    use lorentz !NODEP!  
    use interactions  
  
    use sf_base  
    use process_constants  
    use mci_base  
  
    use prc_core_def  
    use process_libraries  
  
    <Standard module head>  
  
    <Prc core: public>  
  
    <Prc core: types>

    contains  
  
    <Prc core: procedures>  
  
  end module prc_core
```

15.2.1 The process core

The process core is of abstract data type. Different types of matrix element will be represented by different implementations.

```
<Prc core: public>≡  
  public :: prc_core_t  
  
<Prc core: types>≡  
  type, abstract :: prc_core_t
```

```

class(prc_core_def_t), pointer :: def => null ()
logical :: data_known = .false.
type(process_constants_t) :: data
class(prc_core_driver_t), allocatable :: driver
contains
  <Prc core: process core: TBP>
end type prc_core_t

```

In any case there must be an output routine.

```

<Prc core: process core: TBP>≡
  procedure(prc_core_write), deferred :: write

<Prc core: interfaces>≡
  abstract interface
    subroutine prc_core_write (object, unit)
      import
      class(prc_core_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine prc_core_write
  end interface

```

For initialization, we assign a pointer to the process entry in the relevant library. This allows us to access all process functions via the implementation of `prc_core_t`.

We declare the object as `intent(inout)`, since just after allocation it may be useful to store some extra data in the object, which we can then use in the actual initialization. This applies to extensions of `prc_core` which override the `init` method.

```

<Prc core: process core: TBP>+≡
  procedure :: init => prc_core_init
  procedure :: base_init => prc_core_init

<Prc core: procedures>≡
  subroutine prc_core_init (object, def, lib, id, i_component)
    class(prc_core_t), intent(inout) :: object
    class(prc_core_def_t), intent(in), target :: def
    type(process_library_t), intent(in), target :: lib
    type(string_t), intent(in) :: id
    integer, intent(in) :: i_component
    object%def => def
    call lib%connect_process (id, i_component, object%data, object%driver)
    object%data_known = .true.
  end subroutine prc_core_init

```

Return true if a MC dataset should be attached to this process component. False if it shares the dataset with another component.

```

<Prc core: process core: TBP>+≡
  procedure(prc_core_get_flag), deferred :: needs_mcset

<Prc core: interfaces>+≡
  abstract interface
    function prc_core_get_flag (object) result (flag)
      import

```

```

        class(prc_core_t), intent(in) :: object
        logical :: flag
    end function prc_core_get_flag
end interface

```

Return an integer number

```

<Prc core: interfaces>+≡
    abstract interface
        function prc_core_get_integer (object) result (i)
            import
            class(prc_core_t), intent(in) :: object
            integer :: i
        end function prc_core_get_integer
    end interface

```

Return the number of distinct terms requested by this process component.

```

<Prc core: process core: TBP>+≡
    procedure(prc_core_get_integer), deferred :: get_n_terms

```

Tell whether a particular combination of flavor/helicity/color state is allowed for the matrix element.

```

<Prc core: process core: TBP>+≡
    procedure(prc_core_is_allowed), deferred :: is_allowed
<Prc core: interfaces>+≡
    abstract interface
        function prc_core_is_allowed (object, i_term, f, h, c) result (flag)
            import
            class(prc_core_t), intent(in) :: object
            integer, intent(in) :: i_term, f, h, c
            logical :: flag
        end function prc_core_is_allowed
    end interface

```

Set the constant process data for a specific term. By default, these are the constants stored inside the object, ignoring the term index. Type extensions may override this and provide term-specific data.

```

<Prc core: process core: TBP>+≡
    procedure :: get_constants => prc_core_get_constants
<Prc core: procedures>+≡
    subroutine prc_core_get_constants (object, data, i_term)
        class(prc_core_t), intent(in) :: object
        type(process_constants_t), intent(out) :: data
        integer, intent(in) :: i_term
        data = object%data
    end subroutine prc_core_get_constants

```

The strong coupling is not among the process constants. The default implementation is to return a negative number, which indicates that α_s is not available. This may be overridden by an implementation that provides an (event-specific) value. The value can be stored in the `tmp` workspace.

```

<Prc core: process core: TBP>+≡

```

```

    procedure :: get_alpha_s => prc_core_get_alpha_s
  <Prc core: procedures>+≡
    function prc_core_get_alpha_s (object, tmp) result (alpha)
      class(prc_core_t), intent(in) :: object
      class(workspace_t), intent(in), allocatable :: tmp
      real(default) :: alpha
      alpha = -1
    end function prc_core_get_alpha_s

```

Allocate the workspace associated to a process component. The default is that there is no workspace, so we do nothing. A type extension may override this and allocate a workspace object of appropriate type, which can be used in further calculations.

In any case, the `intent(out)` attribute deletes any previously allocated workspace.

```

  <Prc core: process core: TBP>+≡
    procedure :: allocate_workspace => prc_core_ignore_workspace
  <Prc core: procedures>+≡
    subroutine prc_core_ignore_workspace (object, tmp)
      class(prc_core_t), intent(in) :: object
      class(workspace_t), intent(inout), allocatable :: tmp
    end subroutine prc_core_ignore_workspace

```

Initialize the structure-function instance that corresponds to a process component. In ordinary cases, this amounts to a straightforward copy of the given template, but the process core may also choose to modify the setup, and it may access its own workspace.

The `sf_chain_instance` is the object that we want to prepare. The `sf_chain` argument is a template for its structure. For the initialization, we also need the number of channels `n_channel`.

Note: crash with nagfor 5.3.1 if `sf_chain_instance` is declared `intent(out)`, as would be more appropriate.

```

  <Prc core: process core: TBP>+≡
    procedure :: init_sf_chain => prc_core_init_sf_chain
  <Prc core: procedures>+≡
    subroutine prc_core_init_sf_chain &
      (object, sf_chain_instance, sf_chain, n_channel, tmp)
      class(prc_core_t), intent(in) :: object
      type(sf_chain_instance_t), intent(inout), target :: sf_chain_instance
      type(sf_chain_t), intent(in), target :: sf_chain
      integer, intent(in) :: n_channel
      class(workspace_t), intent(inout), allocatable :: tmp
      call sf_chain_instance%init (sf_chain, n_channel)
    end subroutine prc_core_init_sf_chain

```

Compute the momenta in the hard interaction, taking the seed kinematics as input. The `i_term` index tells us which term we want to compute. (The standard method is to just transfer the momenta to the hard interaction.)

```

  <Prc core: process core: TBP>+≡

```

```

    procedure(prc_core_compute_hard_kinematics), deferred :: &
        compute_hard_kinematics
<Prc core: interfaces>+=
    abstract interface
        subroutine prc_core_compute_hard_kinematics &
            (object, p_seed, i_term, int_hard, tmp)
            import
            class(prc_core_t), intent(in) :: object
            type(vector4_t), dimension(:), intent(in) :: p_seed
            integer, intent(in) :: i_term
            type(interaction_t), intent(inout) :: int_hard
            class(workspace_t), intent(inout), allocatable :: tmp
        end subroutine prc_core_compute_hard_kinematics
    end interface

```

Compute the momenta in the effective interaction, taking the hard kinematics as input. (This is called only if parton recombination is to be applied for the process variant.)

```

<Prc core: process core: TBP>+=
    procedure(prc_core_compute_eff_kinematics), deferred :: &
        compute_eff_kinematics
<Prc core: interfaces>+=
    abstract interface
        subroutine prc_core_compute_eff_kinematics &
            (object, i_term, int_hard, int_eff, tmp)
            import
            class(prc_core_t), intent(in) :: object
            integer, intent(in) :: i_term
            type(interaction_t), intent(in) :: int_hard
            type(interaction_t), intent(inout) :: int_eff
            class(workspace_t), intent(inout), allocatable :: tmp
        end subroutine prc_core_compute_eff_kinematics
    end interface

```

Recover the missing pieces. We know the incoming momenta of the `p_seed` array and the outgoing momenta of the `int_eff` interaction. We have to recover the outgoing momenta of `p_seed` and the incoming momenta of `int_eff`.

(The trivial case is that these are identical.)

Furthermore, if `int_hard` and `int_eff` are not aliased, we have to set the momenta there. In the trivial case, `int_eff` is a pointer to `int_hard`, so `int_hard` should not be touched at all.

```

<Prc core: process core: TBP>+=
    procedure(prc_core_recover_kinematics), deferred :: &
        recover_kinematics
<Prc core: interfaces>+=
    abstract interface
        subroutine prc_core_recover_kinematics &
            (object, p_seed, int_hard, int_eff, tmp)
            import
            class(prc_core_t), intent(in) :: object
            type(vector4_t), dimension(:), intent(inout) :: p_seed

```

```

        type(interaction_t), intent(inout) :: int_hard
        type(interaction_t), intent(inout) :: int_eff
        class(workspace_t), intent(inout), allocatable :: tmp
    end subroutine prc_core_recover_kinematics
end interface

```

The process core must implement this function. Here, j is the index of the particular term we want to compute. The amplitude may depend on the factorization and renormalization scales.

The `tmp` (workspace) argument may be used if it is provided by the caller. Otherwise, the routine should compute the result directly.

```

<Prc core: process core: TBP>+≡
    procedure(prc_core_compute_amplitude), deferred :: compute_amplitude

<Prc core: interfaces>+≡
    abstract interface
        function prc_core_compute_amplitude &
            (object, j, p, f, h, c, fac_scale, ren_scale, tmp) result (amp)
            import
            class(prc_core_t), intent(in) :: object
            integer, intent(in) :: j
            type(vector4_t), dimension(:), intent(in) :: p
            integer, intent(in) :: f, h, c
            real(default), intent(in) :: fac_scale, ren_scale
            class(workspace_t), intent(inout), allocatable, optional :: tmp
            complex(default) :: amp
        end function prc_core_compute_amplitude
    end interface

```

15.2.2 Storage for intermediate results

The abstract `workspace_t` type allows process cores to set up temporary workspace. The object is an extra argument for each of the individual calculations between kinematics setup and matrix-element evaluation.

```

<Prc core: public>+≡
    public :: workspace_t

<Prc core: types>+≡
    type, abstract :: workspace_t
    contains
        procedure(workspace_write), deferred :: write
    end type workspace_t

```

For debugging, we should at least have an output routine.

```

<Prc core: interfaces>+≡
    abstract interface
        subroutine workspace_write (object, unit)
            import
            class(workspace_t), intent(in) :: object
            integer, intent(in), optional :: unit
        end subroutine workspace_write
    end interface

```

```
end interface
```

15.2.3 Helicity selection data

This is intended for use with O'MEGA, but may also be made available to other process methods. We set thresholds for counting the times a specific helicity amplitude is zero. When the threshold is reached, we skip this amplitude in subsequent calls.

For initializing the helicity counters, we need an object that holds the two parameters, the threshold (large real number) and the cutoff (integer).

A helicity value suppressed by more than `threshold` (a value which multiplies `epsilon`, to be compared with the average of the current amplitude, default is 10^{10}) is treated as zero. A matrix element is assumed to be zero and not called again if it has been zero `cutoff` times.

```
<Prc core: public>+≡
    public :: helicity_selection_t

<Prc core: types>+≡
    type :: helicity_selection_t
        logical :: active = .false.
        real(default) :: threshold = 0
        integer :: cutoff = 0
    contains
        <Prc core: helicity selection: TBP>
    end type helicity_selection_t
```

Output. If the selection is inactive, print nothing.

```
<Prc core: helicity selection: TBP>≡
    procedure :: write => helicity_selection_write

<Prc core: procedures>+≡
    subroutine helicity_selection_write (object, unit)
        class(helicity_selection_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit)
        if (object%active) then
            write (u, "(3x,A)") "Helicity selection data:"
            write (u, "(5x,A,ES17.10)") &
                "threshold =", object%threshold
            write (u, "(5x,A,I0)") &
                "cutoff    = ", object%cutoff
        end if
    end subroutine helicity_selection_write
```

15.3 Process observables

We define an abstract `subevt_expr_t` object as an extension of the `subevt_t` type. The object contains a local variable list, variable instances (as targets

for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the `subevt`.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression `selection` which determines whether the object passes user-defined cuts.

The intention is that we fill the `subevt_t` base object and compute the variables once we have evaluated a kinematical phase space point (or a complete event). We then evaluate the expressions and can use the results in further calculations.

The `process_expr_t` extension contains furthermore scale and weight expressions. The `event_expr_t` extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

```

<subevt_expr.f90>≡
  <File header>
  module subevt_expr

    <Use kinds>
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use unit_tests
    use os_interface

    use ifiles
    use lexers
    use parser

    use lorentz !NODEP!
    use subevents
    use variables
    use expressions
    use models
    use flavors
    use interactions
    use particles

    <Standard module head>

    <Subevt expr: public>

    <Subevt expr: types>

    <Subevt expr: interfaces>

    contains

    <Subevt expr: procedures>

    <Subevt expr: tests>

```

```
end module subevt_expr
```

15.3.1 Abstract base type

```
<Subevt expr: types>≡
  type, extends (subevt_t), abstract :: subevt_expr_t
    logical :: subevt_filled = .false.
    type(var_list_t) :: var_list
    real(default) :: sqrts_hat = 0
    integer :: n_in = 0
    integer :: n_out = 0
    integer :: n_tot = 0
    logical :: has_selection = .false.
    type(eval_tree_t) :: selection
  contains
    <Subevt expr: subevt expr: TBP>
  end type subevt_expr_t
```

Output: Base and extended version. We already have a `write` routine for the `subevt_t` parent type.

```
<Subevt expr: subevt expr: TBP>≡
  procedure :: base_write => subevt_expr_write

<Subevt expr: procedures>≡
  subroutine subevt_expr_write (object, unit)
    class(subevt_expr_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(1x,A)") "Local variables:"
    call write_separator (u)
    call var_list_write (object%var_list, u, follow_link=.false.)
    call write_separator (u)
    if (object%subevt_filled) then
      call object%subevt_t%write (u)
      if (object%has_selection) then
        call write_separator (u)
        write (u, "(1x,A)") "Selection expression:"
        call write_separator (u)
        call eval_tree_write (object%selection, u)
      end if
    else
      write (u, "(1x,A)") "subevt: [undefined]"
    end if
  end subroutine subevt_expr_write
```

Finalizer.

```
<Subevt expr: subevt expr: TBP>+≡
  procedure (subevt_expr_final), deferred :: final
  procedure :: base_final => subevt_expr_final
```

```

<Subvt expr: procedures>+≡
  subroutine subvt_expr_final (object)
    class(subvt_expr_t), intent(inout) :: object
    call var_list_final (object%var_list)
    if (object%has_selection) then
      call eval_tree_final (object%selection)
    end if
  end subroutine subvt_expr_final

```

15.3.2 Initialization

Initialization: define local variables and establish pointers.

The common variables are `sqrts` (the nominal beam energy, fixed), `sqrts_hat` (the actual energy), `n_in`, `n_out`, and `n_tot` for the `subvt`. With the exception of `sqrts`, all are implemented as pointers to subobjects.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure (subvt_expr_setup_vars), deferred :: setup_vars
  procedure :: base_setup_vars => subvt_expr_setup_vars

<Subvt expr: procedures>+≡
  subroutine subvt_expr_setup_vars (expr, sqrts)
    class(subvt_expr_t), intent(inout), target :: expr
    real(default), intent(in) :: sqrts
    call var_list_final (expr%var_list)
    call var_list_append_real (expr%var_list, &
      var_str ("sqrts"), sqrts, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_real_ptr (expr%var_list, &
      var_str ("sqrts_hat"), expr%sqrts_hat, &
      is_known = expr%subvt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_in"), expr%n_in, &
      is_known = expr%subvt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_out"), expr%n_out, &
      is_known = expr%subvt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_tot"), expr%n_tot, &
      is_known = expr%subvt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
  end subroutine subvt_expr_setup_vars

```

Link a variable list to the local one. This could be done event by event, but before evaluating expressions.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: link_var_list => subvt_expr_link_var_list

```

```

<Subvt expr: procedures>+≡
  subroutine subvt_expr_link_var_list (expr, var_list)
    class(subvt_expr_t), intent(inout) :: expr
    type(var_list_t), intent(in), target :: var_list
    call var_list_link (expr%var_list, var_list)
  end subroutine subvt_expr_link_var_list

```

Compile the selection expression. If the pointer is disassociated, there is no expression.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: setup_selection => subvt_expr_setup_selection

<Subvt expr: procedures>+≡
  subroutine subvt_expr_setup_selection (expr, pn_selection)
    class(subvt_expr_t), intent(inout), target :: expr
    type(parse_node_t), intent(in), pointer :: pn_selection
    if (associated (pn_selection)) then
      call eval_tree_init_lexpr (expr%selection, &
        pn_selection, expr%var_list, expr%subvt_t)
      expr%has_selection = .true.
    end if
  end subroutine subvt_expr_setup_selection

```

15.3.3 Evaluation

Reset to initial state, i.e., mark the subvt as invalid.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: reset => subvt_expr_reset

<Subvt expr: procedures>+≡
  subroutine subvt_expr_reset (expr)
    class(subvt_expr_t), intent(inout) :: expr
    expr%subvt_filled = .false.
  end subroutine subvt_expr_reset

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: base_evaluate => subvt_expr_evaluate

<Subvt expr: procedures>+≡
  subroutine subvt_expr_evaluate (expr, passed)
    class(subvt_expr_t), intent(inout) :: expr
    logical, intent(out) :: passed
    if (expr%has_selection) then
      call eval_tree_evaluate (expr%selection)
      if (eval_tree_result_is_known (expr%selection)) then
        passed = eval_tree_get_log (expr%selection)
      else
        passed = .false.  ! should be an error?
      end if
    else

```

```

        passed = .true.
    end if
end subroutine subevt_expr_evaluate

```

15.3.4 Implementation for partonic events

This implementation contains the expressions that we can evaluate for the partonic process during integration.

```

⟨Subevt expr: public⟩≡
    public :: parton_expr_t

⟨Subevt expr: types⟩+≡
    type, extends (subevt_expr_t) :: parton_expr_t
        integer, dimension(:), allocatable :: i_beam
        integer, dimension(:), allocatable :: i_in
        integer, dimension(:), allocatable :: i_out
        logical :: has_scale = .false.
        logical :: has_fac_scale = .false.

    end if
  end subroutine parton_expr_setup_weight

```

Filling the partonic state consists of two parts. The first routine prepares the subevt without assigning momenta. It takes the particles from an `interaction_t`. It needs the indices and flavors for the beam, incoming, and outgoing particles.

We can assume that the particle content of the subevt does not change. Therefore, we set the event variables `n_in`, `n_out`, `n_tot` already in this initialization step.

```

<Subevt expr: parton expr: TBP>+≡
  procedure :: setup_subevt => parton_expr_setup_subevt

```

<Subevt expr: procedures>+≡

```

subroutine parton_expr_setup_subevt (expr, int, &
    i_beam, i_in, i_out, f_beam, f_in, f_out)
    class(parton_expr_t), intent(inout) :: expr
    type(interaction_t), intent(in), target :: int
    integer, dimension(:), intent(in) :: i_beam, i_in, i_out
    type(flavor_t), dimension(:), intent(in) :: f_beam, f_in, f_out
    allocate (expr%i_beam (size (i_beam)))
    allocate (expr%i_in (size (i_in)))
    allocate (expr%i_out (size (i_out)))
    expr%i_beam = i_beam
    expr%i_in = i_in
    expr%i_out = i_out
    call interaction_to_subevt (int, &
        expr%i_beam, expr%i_in, expr%i_out, expr%subevt_t)
    call subevt_set_pdg_beam      (expr%subevt_t, flavor_get_pdg (f_beam))
    call subevt_set_pdg_incoming (expr%subevt_t, flavor_get_pdg (f_in))
    call subevt_set_pdg_outgoing (expr%subevt_t, flavor_get_pdg (f_out))

15.4 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states, depending on the the beam setup allows. The result is used for integration.

The `matrix` evaluator is the counterpart of `trace` which is kept exclusive in all observable quantum numbers. The `flows` evaluator is furthermore exclusive in colors, but neglecting all color interference. The `matrix` and `flows` evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. However, this causes memory corruption in gfortran 4.6.3. The extra `has_XXX` flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the `processes` module below.

```

    contains

    <Parton states: procedures>

  end module parton_states

```

15.4.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

<Parton states: types>≡

```

```

type, abstract :: parton_state_t
  logical :: has_trace = .false.
  logical :: has_matrix = .false.
  logical :: has_flows = .false.
  type(evaluator_t) :: trace
  type(evaluator_t) :: matrix
  type(evaluator_t) :: flows
contains
  ⟨Parton states: parton state: TBP⟩
end type parton_state_t

```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both implemented as a pointer. The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```

⟨Parton states: public⟩≡
  public :: isolated_state_t
⟨Parton states: types⟩+≡
  type, extends (parton_state_t) :: isolated_state_t
    logical :: sf_chain_is_allocated = .false.
    type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()
    logical :: int_is_allocated = .false.
    type(interaction_t), pointer :: int_eff => null ()
  contains
    ⟨Parton states: isolated state: TBP⟩
  end type isolated_state_t

```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

```

⟨Parton states: types⟩+≡
  public :: connected_state_t
⟨Parton states: types⟩+≡
  type, extends (parton_state_t) :: connected_state_t
    logical :: has_flows_sf = .false.
    type(evaluator_t) :: flows_sf
    type(parton_expr_t) :: expr
  contains
    ⟨Parton states: connected state: TBP⟩
  end type connected_state_t

```

Output: each evaluator is written only when it is active. The `sf_chain` is only written if it is explicitly allocated.

```

⟨Parton states: parton state: TBP⟩≡

```

```

15.4.2 Common Initialization

Initialize the isolated parton state. In this version, the effective structure-function chain `sf_chain_eff` and the effective interaction `int_eff` both are trivial pointers to the seed structure-function chain and to the hard interaction, respectively.

```

<Parton states: isolated state: TBP>≡
    procedure :: init => isolated_state_init_pointers

<Parton states: procedures>+≡
    subroutine isolated_state_init_pointers (state, sf_chain, int)
        class(isolated_state_t), intent(out) :: state
        type(sf_chain_instance_t), intent(in), target :: sf_chain
        type(interaction_t), intent(in), target :: int
    end subroutine

```

```

state%sf_chain_eff => sf_chain
state%int_eff => int
end subroutine isolated_state_init_pointers

```

15.4.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask_in`.

Note: The option for explicitly computing the color factor table (`use_hi_cf` false; `nc` defined) is disabled. We take the color factor table from the hard matrix element data.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_square_trace => isolated_state_setup_square_trace

(Parton states: procedures)+≡
  subroutine isolated_state_setup_square_trace (state, core, qn_mask_in, col)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), dimension(:), intent(in) :: qn_mask_in
    integer, dimension(:), intent(in) :: col
    !
    ! logical, intent(in), optional :: use_hi_color_factors
    ! integer, intent(in), optional :: nc
    ! logical :: use_hi_cf
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    ! if (present (use_hi_color_factors)) then
    !   use_hi_cf = use_hi_color_factors
    ! else
    !   use_hi_cf = .false.
    ! end if
    associate (data => core%data)
      allocate (qn_mask (data%n_in + data%n_out))
      qn_mask(:data%n_in) = &
        new_quantum_numbers_mask (.false., .true., .false.) &
        .or. qn_mask_in
      qn_mask(data%n_in+1:) = &
        new_quantum_numbers_mask (.true., .true., .true.)
    ! if (use_hi_cf) then
    !   call evaluator_init_square (state%trace, &
    !     state%int_eff, qn_mask, &
    !     data%cf_index, data%color_factors, col)
    ! else
    !   call evaluator_init_square (hi%eval_trace, hi%int, qn_mask, nc=nc)
    ! end if
    end associate
    state%has_trace = .true.
  end subroutine isolated_state_setup_square_trace

```

Setup the evaluator for the transition matrix, exclusive in helicities where this is requested. In particular, we keep initial-state polarization unless the mask

qn_mask_in says otherwise. For the final-state polarization, we look at the properties of the particle flavors individually.

(Parton states: isolated state: TBP)+≡

```
procedure :: setup_square_matrix => isolated_state_setup_square_matrix
```

(Parton states: procedures)+≡

```
subroutine isolated_state_setup_square_matrix &
  (state, core, model, qn_mask_in, col)

    state%has_flows_sf = .true.
    state%has_flows = .true.
  end subroutine connected_state_setup_connected_flows

```

15.4.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

```

(Parton states: connected state: TBP)+≡
  procedure :: setup_subevt => connected_state_setup_subevt

(Parton states: procedures)+≡
  subroutine connected_state_setup_subevt (state, sf_chain, f_beam, f_in, f_out)
    class(connected_state_t), intent(inout), target :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(flavor_t), dimension(:), intent(in) :: f_beam, f_in, f_out
    integer :: n_beam, n_in, n_out, n_vir, n_tot, i, j
    integer, dimension(:), allocatable :: i_beam, i_in, i_out
    integer :: sf_out_i
    type(interaction_t), pointer :: int, sf_int
    int => evaluator_get_int_ptr (state%trace)
    sf_int => sf_chain%get_out_int_ptr ()

    n_in = size (f_in)
    n_out = size (f_out)
    n_vir = interaction_get_n_vir (int)
    n_tot = interaction_get_n_tot (int)
    allocate (i_beam (n_beam), i_in (n_in), i_out (n_out))
    i_beam = [(i, i = 1, n_beam)]
    do j = 1, n_in
      sf_out_i = sf_chain%get_out_i (j)
      i_in(j) = interaction_find_link (int, sf_int, sf_out_i)
    end do
    i_out = [(i, i = n_vir + 1, n_tot)]
    call state%expr%setup_subevt (int, &
      i_beam, i_in, i_out, f_beam, f_in, f_out)
  end subroutine connected_state_setup_subevt

```

Initialize the variable list specific for this state/term. We insert event variables (`sqrts_hat`) and link the process variable list. The variable list acquires pointers to subobjects of `state`, which must therefore have a `target` attribute.

```

(Parton states: connected state: TBP)+≡
  procedure :: setup_var_list => connected_state_setup_var_list

(Parton states: procedures)+≡
  subroutine connected_state_setup_var_list (state, process_var_list, beam_data)
    class(connected_state_t), intent(inout), target :: state
    type(var_list_t), intent(in), target :: process_var_list
    type(beam_data_t), intent(in) :: beam_data
    call state%expr%setup_vars (beam_data_get_sqrts (beam_data))
    call state%expr%link_var_list (process_var_list)
  end subroutine connected_state_setup_var_list

```

Allocate the cut expression etc.

```

(Parton states: connected state: TBP)+≡
  procedure :: setup_expressions => connected_state_setup_expressions

```

```

<Parton states: procedures>+≡
  subroutine connected_state_setup_expressions (state, &
    pn_cuts, pn_scale, pn_fac_scale, pn_ren_scale, pn_weight)
    class(connected_state_t), intent(inout), target :: state
    type(parse_node_t), intent(in), pointer :: pn_cuts
    type(parse_node_t), intent(in), pointer :: pn_scale
    type(parse_node_t), intent(in), pointer :: pn_fac_scale
    type(parse_node_t), intent(in), pointer :: pn_ren_scale
    type(parse_node_t), intent(in), pointer :: pn_weight
    call state%expr%setup_selection (pn_cuts)
    call state%expr%setup_scales (pn_scale, pn_fac_scale, pn_ren_scale)
    call state%expr%setup_weight (pn_weight)
  end subroutine connected_state_setup_expressions

```

Reset the expression object: invalidate the subevt.

```

<Parton states: connected state: TBP>+≡
  procedure :: reset_expressions => connected_state_reset_expressions

<Parton states: procedures>+≡
  subroutine connected_state_reset_expressions (state)
    class(connected_state_t), intent(inout) :: state
    call state%expr%reset ()
  end subroutine connected_state_reset_expressions

```

15.4.6 Evaluation

Transfer momenta to the trace evaluator and fill the subevt with this effective kinematics, if applicable.

Note: we may want to apply a boost for the subevt.

```

<Parton states: parton state: TBP>+≡
  procedure :: receive_kinematics => parton_state_receive_kinematics

<Parton states: procedures>+≡
  subroutine parton_state_receive_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
    type(interaction_t), pointer :: int
    if (state%has_trace) then
      call evaluator_receive_momenta (state%trace)
      select type (state)
      class is (connected_state_t)
        int => evaluator_get_int_ptr (state%trace)
        call state%expr%fill_subevt (int)
      end select
    end if
  end subroutine parton_state_receive_kinematics

```

Recover kinematics: We assume that the trace evaluator is filled with momenta. Send those momenta back to the sources, then fill the variables and subevent as above.

The incoming momenta of the connected state are not connected to the isolated state but to the beam interaction. Therefore, the incoming momenta

within the isolated state do not become defined, yet. Instead, we reconstruct the beam (and ISR) momentum configuration.

```

(Parton states: parton state: TBP)+≡
  procedure :: send_kinematics => parton_state_send_kinematics
(Parton states: procedures)+≡
  subroutine parton_state_send_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
    type(interaction_t), pointer :: int
    real(default) :: s_hat
    if (state%has_trace) then
      call evaluator_send_momenta (state%trace)
      select type (state)
        class is (connected_state_t)
          int => evaluator_get_int_ptr (state%trace)
          call state%expr%fill_subevt (int)
        end select
      end if
    end subroutine parton_state_send_kinematics

```

Evaluate the expressions. The routine evaluates first the cut expression. If the event passes, it evaluates the other expressions. Where no expressions are defined, default values are inserted.

```

(Parton states: connected state: TBP)+≡
  procedure :: evaluate_expressions => connected_state_evaluate_expressions
(Parton states: procedures)+≡
  subroutine connected_state_evaluate_expressions (state, passed, &
    scale, fac_scale, ren_scale, weight)
    class(connected_state_t), intent(inout) :: state
    logical, intent(out) :: passed
    real(default), intent(out) :: scale, fac_scale, ren_scale, weight
    call state%expr%evaluate (passed, scale, fac_scale, ren_scale, weight)
  end subroutine connected_state_evaluate_expressions

```

Evaluate the structure-function chain, if it is allocated explicitly. The argument is the factorization scale.

If the chain is merely a pointer, the chain should already be evaluated at this point.

```

(Parton states: isolated state: TBP)+≡
  procedure :: evaluate_sf_chain => isolated_state_evaluate_sf_chain
(Parton states: procedures)+≡
  subroutine isolated_state_evaluate_sf_chain (state, fac_scale)
    class(isolated_state_t), intent(inout) :: state
    real(default), intent(in) :: fac_scale
    if (state%sf_chain_is_allocated) then
      call state%sf_chain_eff%evaluate (fac_scale)
    end if
  end subroutine isolated_state_evaluate_sf_chain

```

Evaluate the trace.

```

(Parton states: parton state: TBP)+≡
  procedure :: evaluate_trace => parton_state_evaluate_trace

```

```

(Parton states: procedures) +=
  subroutine parton_state_evaluate_trace (state)
    class(parton_state_t), intent(inout) :: state
    if (state%has_trace) then
      call evaluator_evaluate (state%trace)
    end if
  end subroutine parton_state_evaluate_trace

```

Evaluate the extra evaluators that we need for physical events.

```

(Parton states: parton state: TBP) +=
  procedure :: evaluate_event_data => parton_state_evaluate_event_data

(Parton states: procedures) +=
  subroutine parton_state_evaluate_event_data (state)
    class(parton_state_t), intent(inout) :: state
    select type (state)
    type is (connected_state_t)
      if (state%has_flows_sf) then
        call evaluator_receive_momenta (state%flows_sf)
        call evaluator_evaluate (state%flows_sf)
      end if
    end select
    if (state%has_matrix) then
      call evaluator_receive_momenta (state%matrix)
      call evaluator_evaluate (state%matrix)
    end if
    if (state%has_flows) then
      call evaluator_receive_momenta (state%flows)
      call evaluator_evaluate (state%flows)
    end if
  end subroutine parton_state_evaluate_event_data

```

15.4.7 Accessing the state

Three functions return a pointer to the event-relevant interactions.

```

(Parton states: parton state: TBP) +=
  procedure :: get_trace_int_ptr => parton_state_get_trace_int_ptr
  procedure :: get_matrix_int_ptr => parton_state_get_matrix_int_ptr
  procedure :: get_flows_int_ptr => parton_state_get_flows_int_ptr

(Parton states: procedures) +=
  function parton_state_get_trace_int_ptr (state) result (ptr)
    class(parton_state_t), intent(in), target :: state
    type(interaction_t), pointer :: ptr
    if (state%has_trace) then
      ptr => evaluator_get_int_ptr (state%trace)
    else
      ptr => null ()
    end if
  end function parton_state_get_trace_int_ptr

  function parton_state_get_matrix_int_ptr (state) result (ptr)
    class(parton_state_t), intent(in), target :: state

```

```

type(interaction_t), pointer :: ptr
if (state%has_matrix) then
    ptr => evaluator_get_int_ptr (state%matrix)
else
    ptr => null ()
end if
end function parton_state_get_matrix_int_ptr

function parton_state_get_flows_int_ptr (state) result (ptr)
class(parton_state_t), intent(in), target :: state
type(interaction_t), pointer :: ptr
if (state%has_flows) then
    ptr => evaluator_get_int_ptr (state%flows)
else
    ptr => null ()
end if
end function parton_state_get_flows_int_ptr

```

Return the indices of the beam particles and the outgoing particles within the trace (and thus, matrix and flows) evaluator, respectively.

```

(Parton states: connected state: TBP)+≡
    procedure :: get_beam_index => connected_state_get_beam_index
    procedure :: get_in_index => connected_state_get_in_index

(Parton states: procedures)+≡
    subroutine connected_state_get_beam_index (state, i_beam)
        class(connected_state_t), intent(in) :: state
        integer, dimension(:), intent(out) :: i_beam
        call state%expr%get_beam_index (i_beam)
    end subroutine connected_state_get_beam_index

    subroutine connected_state_get_in_index (state, i_in)
        class(connected_state_t), intent(in) :: state
        integer, dimension(:), intent(out) :: i_in
        call state%expr%get_in_index (i_in)
    end subroutine connected_state_get_in_index

```

15.4.8 Auxiliary stuff

Write a separator line.

```

(Parton states: procedures)+≡
    subroutine write_separator (u)
        integer, intent(in) :: u
        write (u, "(A)") repeat ("-", 72)
    end subroutine write_separator

    subroutine write_separator_double (u)
        integer, intent(in) :: u
        write (u, "(A)") repeat ("=", 72)
    end subroutine write_separator_double

```

15.5 Complete Elementary Processes

This module combines hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the **computed** state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the **observed** state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible subsequent decay processes on the parton level, which are full-fledged process objects themselves.

15.5.1 The Process Object

A process object is the workspace for creating process instances for event generation. After initialization, its contents are filled by integration passes which shape the integration grids and compute cross sections. Processes are set up initially from user-level configuration data. After calculating integrals and thus developing integration grid data, the program may use a process object or a copy of it for the purpose of generating events

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The **type** determines whether we are considering a decay or a scattering process.

The **meta** object describes the process and its environment. All contents become fixed when the object is initialized.

The **config** object holds physical and technical configuration data that have been obtained during process initialization, and which are common to all process components.

The individual process components are configured in the **component** objects. These objects contain more configuration parameters and workspace, as needed for the specific process variant.

The **term** objects describe parton configurations which are technically used as phase-space points. Each process component may split into several terms with distinct kinematics and particle content. Furthermore, each term may project on a different physical state, e.g., by particle recombination. The **term** object provides the framework for this projection, for applying cuts, weight, and thus completing the process calculation.

The **beam_config** object describes the incoming particles, either the decay mother or the scattering beams. It also contains the structure-function information.

The **mci_entry** objects configure a MC input parameter set and integrator, each. The number of parameters depends on the process component and on the beam and structure-function setup.

end do
process%config%n_terms = n_tot
end subroutine process_setup_terms

```

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam_data_t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by extending the code in the `beams` module.

```

(Processes: process: TBP)+≡
generic :: setup_beams => setup_beams_sqrts
procedure :: setup_beams_sqrts => process_setup_beams_sqrts

(Processes: procedures)+≡
subroutine process_setup_beams_sqrts (process, sqrts)
  class(process_t), intent(inout) :: process
  real(default), intent(in) :: sqrts
  integer, dimension(:, :), allocatable :: flv_state_in
  type(flavor_t), dimension(2) :: flv_in
  integer :: i
  allocate (flv_state_in (2, process%meta%n_components))
  do i = 1, process%meta%n_components
    flv_state_in (:,i) = process%component(i)%get_flv_state_in ()
  end do
  if (all (flv_state_in(1,:) == flv_state_in(1,1)) .and. &
      all (flv_state_in(2,:) == flv_state_in(2,1))) then
    call flavor_init (flv_in, flv_state_in(:,1), process%config%model)
    call process%beam_config%init_scattering (flv_in, sqrts)
  else
    call msg_fatal ("Setting up process '" &
                   // char (process%meta%id) // "' : inconsistent initial state")
  end if
end subroutine process_setup_beams_sqrts

```

Initialize from a complete beam setup.

```

(Processes: process: TBP)+≡

```

```

generic :: setup_beams => setup_beams_beam_data
procedure :: setup_beams_beam_data => process_setup_beams_beam_data
<Processes: procedures>+≡
  subroutine process_setup_beams_beam_data (process, beam_data)
    class(process_t), intent(inout) :: process
    type(beam_data_t), intent(in) :: beam_data
    call process%beam_config%init_beam_data (beam_data)
  end subroutine process_setup_beams_beam_data

```

Notify the user about beam setup.

```

<Processes: process: TBP>+≡
  procedure :: beams_startup_message => process_beams_startup_message
<Processes: procedures>+≡
  subroutine process_beams_startup_message (process, unit)
    class(process_t), intent(in) :: process
    integer, intent(in), optional :: unit
    call process%beam_config%startup_message (unit)
  end subroutine process_beams_startup_message

```

We complete the kinematics configuration after the beam setup, but before we configure the chain of structure functions. The reason is that we need the total energy `sqrts` for the kinematics, but the structure-function setup requires the number of channels, which depends on the kinematics configuration. For instance, the kinematics module may return the need for parameterizing an s-channel resonance.

```

<Processes: process: TBP>+≡
  procedure :: configure_phs => process_configure_phs
<Processes: procedures>+≡
  subroutine process_configure_phs (process, rebuild)
    class(process_t), intent(inout) :: process
    logical, intent(in), optional :: rebuild
    real(default) :: sqrts
    integer :: i
    sqrts = process%get_sqrts ()
    do i = 1, process%meta%n_components
      call process%component(i)%configure_phs &
        (sqrts, process%beam_config, rebuild)
    end do
  end subroutine process_configure_phs

```

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

```

<Processes: process: TBP>+≡

```

```

procedure :: init_sf_chain => process_init_sf_chain
generic :: set_sf_channel => set_sf_channel_single
procedure :: set_sf_channel_single => process_set_sf_channel
generic :: set_sf_channel => set_sf_channel_array
procedure :: set_sf_channel_array => process_set_sf_channel_array

<Processes: procedures>+≡
subroutine process_init_sf_chain (process, sf_config)
  class(process_t), intent(inout) :: process
  type(sf_config_t), dimension(:), intent(in) :: sf_config
  call process%beam_config%init_sf_chain (sf_config)
end subroutine process_init_sf_chain

subroutine process_set_sf_channel (process, c, sf_channel)
  class(process_t), intent(inout) :: process
  integer, intent(in) :: c

            call mci_entry%init (process%meta%type, &
              i_mci, i, component, process%beam_config)
          end associate
        end associate
      end if
    end do
  end subroutine process_setup_mci
```

Import a random-number generator state into a MCI entry component.

```
<Processes: process: TBP>+≡
  procedure :: import_rng => process_import_rng

<Processes: procedures>+≡
  subroutine process_import_rng (process, i_mci, rng)
    class(process_t), intent(inout) :: process
    integer, intent(in) :: i_mci
    class(rng_t), intent(inout), allocatable :: rng
    call process%mci_entry(i_mci)%mci%import_rng (rng)
  end subroutine process_import_rng
```

Set cuts. This is a parse node, namely the right-hand side of the cut assignment. When creating an instance, we compile this into an evaluation tree. The parse node may be null.

```
<Processes: process: TBP>+≡
  procedure :: set_cuts => process_set_cuts
```

```

<Processes: procedures>+≡
  subroutine process_set_cuts (process, pn_cuts)
    class(process_t), intent(inout) :: process
    type(parse_node_t), intent(in), pointer :: pn_cuts
    process%config%pn_cuts => pn_cuts
  end subroutine process_set_cuts

```

Analogously for the other expressions.

```

<Processes: process: TBP>+≡
  procedure :: set_scale => process_set_scale
  procedure :: set_fac_scale => process_set_fac_scale
  procedure :: set_ren_scale => process_set_ren_scale
  procedure :: set_weight => process_set_weight

    process%config%pn_ren_scale => pn_ren_scale
  end subroutine process_set_ren_scale

  subroutine process_set_weight (process, pn_weight)
    class(process_t), intent(inout) :: process
    type(parse_node_t), intent(in), pointer :: pn_weight
    process%config%pn_weight => pn_weight
  end subroutine process_set_weight

```

MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

```

<Processes: process: TBP>+≡
  procedure :: compute_md5sum => process_compute_md5sum

```

```

<Processes: procedures>+=
  subroutine process_compute_md5sum (process)
    class(process_t), intent(inout) :: process
    integer :: i
    call process%config%compute_md5sum ()
    do i = 1, process%config%n_components
      call process%component(i)%compute_md5sum ()
    end do
    call process%beam_config%compute_md5sum ()
    do i = 1, process%config%n_mci
      call process%mci_entry(i)%compute_md5sum &
        (process%config, process%component, process%beam_config)
    end do
  end subroutine process_compute_md5sum

```

Integration and event generation

Integrate the process, using a previously initialized process instance. We select one of the available MCI integrators by its index `i_mci` and thus integrate over (structure functions and) phase space for the associated (group of) process component(s).

The finalizer should be called after all integration passes have been completed. It will, for instance, write a summary of the integration results.

```

<Processes: process: TBP>+=
  procedure :: integrate => process_integrate
  procedure :: final_integration => process_final_integration

<Processes: procedures>+=
  subroutine process_integrate (process, instance, i_mci, n_it, n_calls, &
    adapt_grids, adapt_weights)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_it
    integer, intent(in) :: n_calls
    logical, intent(in), optional :: adapt_grids
    logical, intent(in), optional :: adapt_weights
    call process%mci_entry(i_mci)%integrate (instance, n_it, n_calls, &
      adapt_grids, adapt_weights)
  end subroutine process_integrate

  subroutine process_final_integration (process, i_mci)
    class(process_t), intent(inout) :: process
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%final_integration ()
  end subroutine process_final_integration

```

Initialize and finalize event generation for the specified MCI entry.

```

<Processes: process: TBP>+=
  procedure :: init_simulation => process_init_simulation
  procedure :: final_simulation => process_final_simulation

```

```

(Processes: procedures) +=
  subroutine process_init_simulation (process, instance, i_mci)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%init_simulation (instance)
  end subroutine process_init_simulation

  subroutine process_final_simulation (process, instance, i_mci)
    class(process_t), intent(in) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%final_simulation (instance)
  end subroutine process_final_simulation

```

Generate a weighted event. We select one of the available MCI integrators by its index *i_mci* and thus generate an event for the associated (group of) process component(s). The arguments exactly correspond to the initializer and finalizer above.

The resulting event is stored in the *process_instance* object, which also holds the workspace of the integrator.

Note: The *process* object is declared *intent(inout)* because it contains the random-number state, which changes for each event. Otherwise, all volatile data are inside the *instance* object.

```

(Processes: process: TBP) +=
  procedure :: generate_weighted_event => process_generate_weighted_event
  procedure :: generate_unweighted_event => process_generate_unweighted_event

(Processes: procedures) +=
  subroutine process_generate_weighted_event (process, instance, i_mci)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%generate_weighted_event (instance)
  end subroutine process_generate_weighted_event

  subroutine process_generate_unweighted_event (process, instance, i_mci)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%generate_unweighted_event (instance)
  end subroutine process_generate_unweighted_event

```

This replaces the event generation methods for the situation that the process instance object has been filled by other means (i.e., reading and/or recalculating its contents). We just have to fill in missing MCI data, especially the event weight.

```

(Processes: process: TBP) +=
  procedure :: recover_event => process_recover_event

(Processes: procedures) +=
  subroutine process_recover_event (process, instance, i_term)
    class(process_t), intent(inout) :: process

```

```

type(process_instance_t), intent(inout) :: instance
integer, intent(in) :: i_term
call process%mci_entry(instance%i_mci)%recover_event (instance, i_term)
end subroutine process_recover_event

```

Retrieve process data

Return the current integral and error obtained by the integrator *i_mci*.

```

(Processes: process: TBP)+≡
generic :: get_integral => get_integral_tot, get_integral_mci
generic :: get_error => get_error_tot, get_error_mci
procedure :: get_integral_tot => process_get_integral_tot
procedure :: get_integral_mci => process_get_integral_mci
procedure :: get_error_tot => process_get_error_tot
procedure :: get_error_mci => process_get_error_mci

(Processes: procedures)+≡
function process_get_integral_mci (process, i_mci) result (integral)

    class(process_t), intent(in) :: process
    integer, intent(in) :: i_mci
    character(32) :: md5sum
    md5sum = process%mci_entry(i_mci)%get_md5sum ()
  end function process_get_md5sum_mci

```

15.5.2 Metadata

This information describes the process and its environment. It is fixed upon initialization.

The **id** string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The **run_id** string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The **var_list** is a snapshot of the variable list, taken at the point where the process was initialized.

The **lib** pointer accesses the process library where the process definition and the process driver are located.

The **lib_index** is the index of entry in the process library that corresponds to the current process.

The **component_id** array identifies the individual process components.

The **component_description** is an array of human-readable strings that characterize the process components, for instance **a**, **b** => **c**, **d**.

```

15.5.3 Generic Configuration Data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the variable list.

The number **n_in** is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number **n_components** is the number of components that constitute the current process.

The number **n_terms** is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number **n_mci** is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also

the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The `model` pointer identifies the physics model and its parameters. This is a pointer to an external object.

The `qcd` object contains all QCD-related data that may influence the process.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the `effective_state` subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The `md5sum` is taken and used to verify the process configuration when re-reading data from file.

```

<Processes: process part types>+=
  type :: process_config_data_t
    private
      integer :: n_in = 0
      integer :: n_components = 0
      integer :: n_terms = 0
      integer :: n_mci = 0
      type(os_data_t) :: os_data

        end if
    else
        call write_separator (u)
        write (u, "(3x,A)") "Expressions (cut, scales, weight): [not shown]"
    end if
    if (config%md5sum /= "") then
        call write_separator (u)
        write (u, "(3x,A,A,A)") "MD5 sum (config) = '", config%md5sum, "'"
    end if
end subroutine process_config_data_write

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

Using the model name that the library gives us, we try to load the model here. Reading from the global model library, we are sure that we are looking at the model associated to the process, not the selected one at the user level. However, when the mode names are the same, the models will be identical.

Instead of storing a model pointer, we create an instance which contains the current values of model parameters. The captured values are now disconnected from user-level changes and will stay for the lifetime of the process object. Allocating the model via a pointer guarantees the **target** attribute.

```

<Processes: process config data: TBP>+=
  procedure :: init => process_config_data_init

<Processes: procedures>+=
  subroutine process_config_data_init (config, meta, os_data, model_list)
    class(process_config_data_t), intent(out) :: config
    type(process_metadata_t), intent(in) :: meta
    type(os_data_t), intent(in) :: os_data
    type(model_list_t), intent(inout) :: model_list
    type(string_t) :: filename
    type(model_t), pointer :: model
    config%n_in = meta%lib%get_n_in (meta%id)
    config%n_components = size (meta%component_id)
    config%os_data = os_data
    config%model_name = meta%lib%get_model_name (meta%id)
    if (config%model_name /= "") then
      filename = config%model_name // ".mdl"
      call model_list%read_model (config%model_name, &
        filename, config%os_data, model)
      allocate (config%model)
      call model_init_instance (config%model, model)
    end if
  end subroutine process_config_data_init

```

Since the captured model is a separate object allocated via a pointer, we need a finalizer.

```

<Processes: process config data: TBP>+=
  procedure :: final => process_config_data_final

<Processes: procedures>+=
  subroutine process_config_data_final (config)
    class(process_config_data_t), intent(inout) :: config
    if (associated (config%model)) then
      call model_final (config%model)
      deallocate (config%model)
    end if
  end subroutine process_config_data_final

```

Compute the MD5 sum of the configuration data. This encodes, in particular, the model and the expressions for cut, scales, weight, etc. It should not contain

the IDs and number of components, etc., since the MD5 sum should be useful for integrating individual components.

This is done only once. If the MD5 sum is nonempty, the calculation is skipped.

```

<Processes: process config data: TBP>+≡
  procedure :: compute_md5sum => process_config_data_compute_md5sum

<Processes: procedures>+≡

      call config%write (u, counters = .false., os_data = .false., &
        model = .true., expressions = .true.)
      rewind (u)
      config%md5sum = md5sum (u)
      close (u)
    end if
  end subroutine process_config_data_compute_md5sum

```

15.5.4 Beam configuration

The object `data` holds all details about the initial beam configuration. The allocatable array `sf` holds the structure-function configuration blocks. There are `n_strfun` entries in the structure-function chain (not counting the initial beam object). We maintain `n_channel` independent parameterizations of this chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is `n_sfpar`.

The flag `azimuthal_dependence` tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag `lab_is_cm_frame` is obvious.

```

<Processes: process part types>+≡
  type :: process_beam_config_t
  private
  type(beam_data_t) :: data
  integer :: n_strfun = 0
  integer :: n_channel = 1
  integer :: n_sfpar = 0
  type(sf_config_t), dimension(:), allocatable :: sf
  type(sf_channel_t), dimension(:), allocatable :: sf_channel
  logical :: azimuthal_dependence = .false.
  logical :: lab_is_cm_frame = .true.
  character(32) :: md5sum = ""
  contains
  <Processes: process beam config: TBP>
  end type process_beam_config_t

```

Here we write beam data only if they are actually used.

```

end subroutine process_beam_config_compute_md5sum

```

15.5.5 Multi-channel integration

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly the values that apply to the current pass. Previous values are archived in the `results` object.

The `results` object records results, broken down in passes and iterations.

```

<Processes: process part types>+≡
type :: process_mci_entry_t
  integer :: i_mci = 0
  integer, dimension(:), allocatable :: i_component
  integer :: process_type = PRC_UNKNOWN
  integer :: n_par = 0
  integer :: n_par_sf = 0
  integer :: n_par_phs = 0
  character(32) :: md5sum = ""
  integer :: pass = 0
  integer :: n_it = 0
  integer :: n_calls = 0

      call object%results%write (u)
    end if
  end subroutine process_mci_entry_write

```

Initialize. From the existing configuration, we obtain the number of channels and the number of parameters, separately for the structure-function chain and for the associated process component. We assume that the phase-space object has already been configured.

The allocation of the MCI integrator with the appropriate concrete type is the duty of the process core.

We assume that there is only one component associated with a MCI entry. This restriction should be relaxed.

```

<Processes: process mci entry: TBP>+≡
  procedure :: init => process_mci_entry_init

<Processes: procedures>+≡
  subroutine process_mci_entry_init &

    end if
end subroutine process_mci_entry_compute_md5sum

```

Integrate. The instance should be initialized.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

```

```

15.5.6 Process Components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components have different types. In short, `process_component_t` is a wrapper for the actual process variants.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

<Processes: process part types>+=
  type :: process_component_t
    private
      type(process_component_def_t), pointer :: config => null ()
      integer :: index = 0
      class(prc_core_t), allocatable :: core
      class(mci_t), allocatable :: mci_template
      integer, dimension(:), allocatable :: i_term
      integer :: i_mci = 0
      class(phs_config_t), allocatable :: phs_config
      character(32) :: md5sum_phs = ""
    contains
      <Processes: process component: TBP>
    end type process_component_t

```

Finalizer. The MCI template may (potentially) need a finalizer. The process configuration finalizer may include closing an open scratch file.

```

<Processes: process component: TBP>=
  procedure :: final => process_component_final

<Processes: procedures>+=
  subroutine process_component_final (object)
    class(process_component_t), intent(inout) :: object
    if (allocated (object%mci_template)) then
      call object%mci_template%final ()
    end if
    if (allocated (object%phs_config)) then
      call object%phs_config%final ()
    end if
  end subroutine process_component_final

```

The meaning of `verbose` depends on the process variant.

```

<Processes: process component: TBP>+=
  procedure :: write => process_component_write

<Processes: procedures>+=
  subroutine process_component_write (object, unit)
    class(process_component_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    if (allocated (object%core)) then
      write (u, "(1x,A,I0)") "Component #", object%index
      if (associated (object%config)) then

```

```

end function process_component_get_flv_state_in

```

15.5.7 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`. In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`. This is the total number of independent entries in the density matrix. For each combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

```

(Processes: process part types)+≡
type :: process_term_t
  integer :: i_term_global = 0
  integer :: i_component = 0
  integer :: i_term = 0

```

```

integer :: n_allowed = 0
type(process_constants_t) :: data
real(default) :: alpha_s = 0
integer, dimension(:), allocatable :: flv, hel, col
logical :: rearrange = .false.
type(interaction_t) :: int
type(interaction_t), pointer :: int_eff => null ()
contains
  <Processes: process term: TBP>
end type process_term_t

```

For the output, we skip the process constants and the tables of allowed quantum numbers. Those can also be read off from the interaction object.

```

<Processes: process term: TBP>≡
  procedure :: write => process_term_write

<Processes: procedures>+≡
  subroutine process_term_write (term, unit)
    class(process_term_t), intent(in) :: term
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit)
    write (u, "(1x,A,I0)") "Term #", term%i_term_global
    write (u, "(3x,A,I0)") "Process component index      = ", &
      term%i_component
    write (u, "(3x,A,I0)") "Term index w.r.t. component = ", &
      term%i_term
    write (u, "(3x,A,L1)") "Rearrange partons          = ", &
      term%rearrange
    call write_separator (u)
    write (u, "(1x,A)") "Hard interaction:"
    call write_separator (u)
    call interaction_write (term%int, u)
    if (term%rearrange) then
      call write_separator (u)
      write (u, "(1x,A)") "Rearranged hard interaction:"
      call write_separator (u)
      call interaction_write (term%int_eff, u)
    end if
  end subroutine process_term_write

```

Finalizer: the int and potentially int_eff components have a finalizer that we must call.

```

<Processes: process term: TBP>+≡
  procedure :: final => process_term_final

<Processes: procedures>+≡
  subroutine process_term_final (term)
    class(process_term_t), intent(inout) :: term
    call interaction_final (term%int)
    if (term%rearrange) then
      call interaction_final (term%int_eff)
      deallocate (term%int_eff)
    end if
  end subroutine process_term_final

```

```
end subroutine process_term_final
```

Initialize the term. We copy the process constants from the `core` object and set up the `int` hard interaction accordingly.

The `alpha_s` value is useful for writing external event records. This is the constant value which may be overridden by a event-specific running value. If the model does not contain the strong coupling, the value is zero.

Note: `intent(inout)` for `term` is a workaround for a NAG compiler bug.

```
(Processes: process term: TBP)+≡
  procedure :: init => process_term_init

(Processes: procedures)+≡
  subroutine process_term_init &
    (term, i_term_global, i_component, i_term, core, model)

    integer, intent(in) :: i_term_global
    integer, intent(in) :: i_component
    integer, intent(in) :: i_term
    class(prc_core_t), intent(in) :: core
    type(model_t), intent(in), target :: model
    type(var_list_t), pointer :: var_list
    term%i_term_global = i_term_global
    term%i_component = i_component
    term%i_term = i_term
    call core%get_constants (term%data, i_term)
    var_list => model_get_var_list_ptr (model)
    if (var_list_exists (var_list, var_str ("alphas"))) then
      term%alpha_s = var_list_get_rval (var_list, var_str ("alphas"))
    else
      term%alpha_s = -1
    end if
    call term%setup_interaction (core, model)
!   if (term%rearrange) then
!     call term%setup_effective_interaction (core, term%int, term%int_eff)
!   end if
  end subroutine process_term_init
```

We fetch the process constants which determine the quantum numbers and use those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

```

15.5.8 Default Iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

(Processes: process: TBP) +=
  procedure :: get_n_pass_default => process_get_n_pass_default
  procedure :: adapt_grids_default => process_adapt_grids_default
  procedure :: adapt_weights_default => process_adapt_weights_default

(Processes: procedures) +=
  function process_get_n_pass_default (process) result (n_pass)
    class(process_t), intent(in) :: process
    integer :: n_pass
    integer :: n_eff
    type(process_component_def_t), pointer :: config
    config => process%component(1)%config
    n_eff = config%get_n_tot () - 2
    select case (n_eff)
    case (1)
      n_pass = 1
    case default
      n_pass = 2
    end select
  end function process_get_n_pass_default

  function process_adapt_grids_default (process, pass) result (flag)
    class(process_t), intent(in) :: process
    integer, intent(in) :: pass
    logical :: flag
    integer :: n_eff
    type(process_component_def_t), pointer :: config
    config => process%component(1)%config
    n_eff = config%get_n_tot () - 2
    select case (n_eff)
    case (1)
      flag = .false.
    case default
      select case (pass)
      case (1); flag = .true.
      case (2); flag = .false.
      end select
    end select
  end function process_adapt_grids_default

  function process_adapt_weights_default (process, pass) result (flag)
    class(process_t), intent(in) :: process
    integer, intent(in) :: pass
    logical :: flag
    integer :: n_eff
    type(process_component_def_t), pointer :: config
    config => process%component(1)%config
    n_eff = config%get_n_tot () - 2
    select case (n_eff)
    case (1)
      flag = .false.

```

```

case default
  select case (pass)
    case (1); flag = .true.
    case (2); flag = .false.
  end select
end select
end function process_adapt_weights_default

```

The number of iterations and calls per iteration depends on the number of outgoing particles.

```

    ptr => process%config%model
  end function process_get_model_ptr
```

15.5.10 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```
<Processes: process: TBP>+≡
  procedure :: compute_amplitude => process_compute_amplitude
```

```

<Processes: procedures>+=
function process_compute_amplitude &
    (process, i, j, p, f, h, c, fac_scale, ren_scale) result (amp)

            end if
        end associate
    end if
end function process_compute_amplitude

```

15.5.11 Process instances

Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

sf_chain is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

phs is an instance of the phase space for the elementary process.

The array **f** contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either **sf_chain** or **phs** are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be

regarded as a proper component ('owned' by the object) or as a pointer.

```

<Processes: types>≡
  type :: kinematics_t
    integer :: n_in = 0
    integer :: n_channel = 0
    integer :: selected_channel = 0
    type(sf_chain_instance_t), pointer :: sf_chain => null ()
    class(phs_t), pointer :: phs => null ()
    real(default), dimension(:), pointer :: f => null ()
    real(default) :: phs_factor
    logical :: sf_chain_allocated = .false.
    logical :: phs_allocated = .false.
    logical :: f_allocated = .false.
  contains
    <Processes: kinematics: TBP>
  end type kinematics_t

```

Output. Show only those components which are marked as owned.

```

<Processes: kinematics: TBP>≡
  procedure :: write => kinematics_write

<Processes: procedures>+≡
  subroutine kinematics_write (object, unit)
    class(kinematics_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, c
    u = output_unit (unit)
    if (object%f_allocated) then
      write (u, "(1x,A)") "Flux * PHS volume:"
      write (u, "(2x,ES19.12)") object%phs_factor
      write (u, "(1x,A)") "Jacobian factors per channel:"
      do c = 1, size (object%f)
        write (u, "(3x,I0,':',1x,ES13.7)", advance="no") c, object%f(c)
        if (c == object%selected_channel) then
          write (u, "(1x,A)") "[selected]"
        else
          write (u, *)
        end if
      end do
    end if
    if (object%sf_chain_allocated) then
      call write_separator (u)
      call object%sf_chain%write (u)
    end if
    if (object%phs_allocated) then
      call write_separator (u)
      call object%phs%write (u)
    end if
  end subroutine kinematics_write

```

Finalizer. Delete only those components which are marked as owned.

```

<Processes: kinematics: TBP>+≡
  procedure :: final => kinematics_final

```

```

<Processes: procedures>+≡
  subroutine kinematics_final (object)
    class(kinematics_t), intent(inout) :: object
    if (object%sf_chain_allocated) then
      call object%sf_chain%final ()
      deallocate (object%sf_chain)
      object%sf_chain_allocated = .false.
    end if
    if (object%phs_allocated) then
      call object%phs%final ()
      deallocate (object%phs)
      object%phs_allocated = .false.
    end if
    if (object%f_allocated) then
      deallocate (object%f)
      object%f_allocated = .false.
    end if
  end subroutine kinematics_final

```

Allocate the structure-function chain instance, initialize it as a copy of the `sf_chain` template, and prepare it for evaluation.

The `sf_chain` remains a target because the (constant) beam momenta are taken from there.

```

<Processes: kinematics: TBP>+≡

else
  k%phs_factor = 0
  success = .false.
end if
end subroutine kinematics_compute

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

(Processes: kinematics: TBP)+≡

```

procedure :: get_incoming_momenta => kinematics_get_incoming_momenta

```

(Processes: procedures)+≡

```

subroutine kinematics_get_incoming_momenta (k, p)
  class(kinematics_t), intent(in) :: k
  type(vector4_t), dimension(:), intent(out) :: p
  type(interaction_t), pointer :: int
  integer :: i
  int => k%sf_chain%get_out_int_ptr ()
  do i = 1, k%n_in
    p(i) = interaction_get_momentum (int, k%sf_chain%get_out_i (i))
  end do
end subroutine kinematics_get_incoming_momenta

```

This inverts the remainder of the above `compute` method. We know the momenta and recover the rest, as far as needed. If we select a channel, we can complete the inversion and reconstruct the MC parameter set.

        call k%sf_chain%evaluate (fac_scale)
    end select
end subroutine kinematics_evaluate_sf_chain

```

Process component instance

The actual calculation of a sampling point is done from here.

The `config` pointer accesses the corresponding configuration in the `process` object.

The `active` flag indicates that we are currently computing this component, together with all other components that share the same MC parameter set. Inactive components are using a different MC parameter set and are not in use for this sampling point.

The `k_seed` subobject contains the kinematics (structure-function chain, phase space, etc.) that implements the ‘seed’ configuration of momenta. This version of the process kinematics is accessed by the MCI setup.

`p_seed` is the array of momenta that we compute from the MC input parameters, via the `k_seed` subobject. Depending on the process variant, these may or may not coincide with the momenta that enter the process terms associated to this component.

The `tmp` object can be used for storing intermediate results. Its precise type and contents depend on the process variant.

```

<Processes: types>+≡
    type :: component_instance_t
        type(process_component_t), pointer :: config => null ()
        logical :: active = .false.
        type(kinematics_t) :: k_seed
        type(vector4_t), dimension(:), allocatable :: p_seed
        logical :: sqme_known = .false.

        end do
      end associate
    end associate
  end subroutine component_instance_compute_hard_kinematics

```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

```

  end subroutine component_instance_evaluate_sqme

```

Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The `k_term` object is the instance of the kinematics setup (structure-function chain, phase space, etc.) that applies specifically to this term. In ordinary cases, it consists of straight pointers to the seed kinematics.

The `amp` array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The `int_hard` interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The `isolated` object holds the effective parton state for the elementary interaction. The amplitude entries are computed from `int_hard`.

The `connected` evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The `checked` flag is set once we have applied cuts on this term. The result of this is stored in the `passed` flag. Once the term has passed cuts, we calculate the various scale and weight expressions.

        call interaction_final (term%int_hard)
    end subroutine term_instance_final

```

For initialization, we make use of defined assignment for the `interaction_t` type. This creates a deep copy.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (`rearrange`) as effective structure-function chain and interaction, respectively.

Finally, we set up the `subevt` component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

  subroutine term_instance_reset (term)
    class(term_instance_t), intent(inout) :: term
    call term%connected%reset_expressions ()
    term%active = .false.
  end subroutine term_instance_reset

```

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain.

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

```

(Processes: term instance: TBP)+≡
  procedure :: compute_eff_kinematics => &
    term_instance_compute_eff_kinematics

(Processes: procedures)+≡
  subroutine term_instance_compute_eff_kinematics (term, component)
    class(term_instance_t), intent(inout) :: term
    type(component_instance_t), dimension(:), intent(inout) :: component
    integer :: i_component, i_term
    term%checked = .false.
    term%passed = .false.
    if (term%config%rearrange) then
      ! should evaluate k_term first if allocated separately, not impl. yet
      i_component = term%config%i_component
      i_term = term%config%i_term
      associate (core => component(i_component)%config%core)
        call core%compute_eff_kinematics &
          (i_term, term%int_hard, term%isolated%int_eff, &
            component(i_component)%tmp)
      end associate
    end if
    call term%isolated%receive_kinematics ()
    call term%connected%receive_kinematics ()
  end subroutine term_instance_compute_eff_kinematics

```

Inverse. Reconstruct the connected state from the momenta in the trace evaluator (which we assume to be set), then reconstruct the isolated state as far as possible. The second part finalizes the momentum configuration, using the incoming seed momenta

```

<Processes: term instance: TBP>+≡
  procedure :: recover_hard_kinematics => &
    term_instance_recover_hard_kinematics

<Processes: procedures>+≡
  subroutine term_instance_recover_hard_kinematics (term, component)
    class(term_instance_t), intent(inout) :: term
    type(component_instance_t), dimension(:), intent(inout) :: component
    integer :: i_component, i_term
    term%checked = .false.
    term%passed = .false.
    call term%connected%send_kinematics ()
    call term%isolated%send_kinematics ()
  end subroutine term_instance_recover_hard_kinematics

```

Check the term whether it passes cuts and, if successful, evaluate scales and weights. The factorization scale is also given to the term kinematics, enabling structure-function evaluation.

```

<Processes: term instance: TBP>+≡
  procedure :: evaluate_expressions => &
    term_instance_evaluate_expressions

<Processes: procedures>+≡
  subroutine term_instance_evaluate_expressions (term)
    class(term_instance_t), intent(inout) :: term
    call term%connected%evaluate_expressions (term%passed, &
      term%scale, term%fac_scale, term%ren_scale, term%weight)
    term%checked = .true.
  end subroutine term_instance_evaluate_expressions

```

Evaluate the trace: first evaluate the hard interaction, then the trace evaluator. We use the `evaluate_interaction` method of the process component which generated this term. The `subevt` and cut expressions are not yet filled.

The `component` argument is `intent(inout)` because the `compute_amplitude` method may modify the `tmp` workspace object.

```

<Processes: term instance: TBP>+≡
  procedure :: evaluate_interaction => term_instance_evaluate_interaction

<Processes: procedures>+≡
  subroutine term_instance_evaluate_interaction (term, component)
    class(term_instance_t), intent(inout) :: term
    type(component_instance_t), dimension(:), intent(inout) :: component
    integer :: i_component, i_term, i
    i_component = term%config%i_component
    i_term = term%config%i_term
    associate (core => component(i_component)%config%core)
      do i = 1, term%config%n_allowed
        term%amp(i) = core%compute_amplitude (i_term, &
          interaction_get_momenta (term%int_hard), &

```

```

        term%config%flv(i), term%config%hel(i), term%config%col(i), &
        term%fac_scale, term%ren_scale, &
        component(i_component)%tmp)
    end do
    call interaction_set_matrix_element (term%int_hard, term%amp)
end associate
end subroutine term_instance_evaluate_interaction

```

Evaluate the trace. First evaluate the structure-function chain (i.e., the density matrix of the incoming partons). Do this twice, in case the sf-chain instances within `k_term` and `isolated` differ. Next, evaluate the hard interaction, then compute the convolution with the initial state.

```

<Processes: term instance: TBP>+≡
    procedure :: evaluate_trace => term_instance_evaluate_trace

<Processes: procedures>+≡
    subroutine term_instance_evaluate_trace (term)
        class(term_instance_t), intent(inout) :: term
        call term%k_term%evaluate_sf_chain (term%fac_scale)
        call term%isolated%evaluate_sf_chain (term%fac_scale)
        call term%isolated%evaluate_trace ()
        call term%connected%evaluate_trace ()
    end subroutine term_instance_evaluate_trace

```

Evaluate the extra data that we need for processing the object as a physical event.

```

<Processes: term instance: TBP>+≡
    procedure :: evaluate_event_data => term_instance_evaluate_event_data

<Processes: procedures>+≡
    subroutine term_instance_evaluate_event_data (term)
        class(term_instance_t), intent(inout) :: term
        call term%isolated%evaluate_event_data ()
        call term%connected%evaluate_event_data ()
    end subroutine term_instance_evaluate_event_data

```

Return data that might be useful for external processing. The factorization scale:

```

<Processes: term instance: TBP>+≡
    procedure :: get_fac_scale => term_instance_get_fac_scale

<Processes: procedures>+≡
    function term_instance_get_fac_scale (term) result (fac_scale)
        class(term_instance_t), intent(in) :: term
        real(default) :: fac_scale
        fac_scale = term%fac_scale
    end function term_instance_get_fac_scale

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take

the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

<Processes: term instance: TBP>+≡
  procedure :: get_alpha_s => term_instance_get_alpha_s

<Processes: procedures>+≡
  function term_instance_get_alpha_s (term, component) result (alpha_s)
    class(term_instance_t), intent(in) :: term
    type(component_instance_t), dimension(:), intent(in) :: component
    real(default) :: alpha_s
    integer :: i_component
    i_component = term%config%i_component
    associate (core => component(i_component)%config%core)
      alpha_s = core%get_alpha_s (component(i_component)%tmp)
    end associate
    if (alpha_s < 0) alpha_s = term%config%alpha_s
  end function term_instance_get_alpha_s

```

MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

```

<Processes: types>+≡
  type :: mci_work_t
    type(process_mci_entry_t), pointer :: config => null ()
    real(default), dimension(:), allocatable :: x
    class(mci_instance_t), pointer :: mci => null ()
  contains
    <Processes: mci work: TBP>
  end type mci_work_t

```

First write configuration data, then the current values.

```

<Processes: mci work: TBP>≡
  procedure :: write => mci_work_write

<Processes: procedures>+≡
  subroutine mci_work_write (mci_work, unit)
    class(mci_work_t), intent(in) :: mci_work
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit)
    write (u, "(1x,A,I0,A)") "Active MCI instance #", &
      mci_work%config%i_mci, " ="
    write (u, "(2x)", advance="no")
    do i = 1, mci_work%config%n_par
      write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
      if (i == mci_work%config%n_par_sf) &
        write (u, "(1x,'|')", advance="no")
    end do
    write (u, *)

```

```

        if (associated (mci_work%mci)) then
            call mci_work%mci%write (u)
        end if
    end subroutine mci_work_write

```

The mci component may require finalization.

```

<Processes: mci work: TBP>+≡
    procedure :: final => mci_work_final

<Processes: procedures>+≡
    subroutine mci_work_final (mci_work)
        class(mci_work_t), intent(inout) :: mci_work
        if (associated (mci_work%mci)) then
            call mci_work%mci%final ()
            deallocate (mci_work%mci)
        end if
    end subroutine mci_work_final

```

Initialize with the maximum length that we will need. Contents are not initialized.

The integrator inside the mci_entry object is responsible for allocating and initializing its own instance, which is referred to by a pointer in the mci_work object.

```

<Processes: mci work: TBP>+≡
    procedure :: init => mci_work_init

  end function mci_work_get_x_process

```

The process instance

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `sqme` value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The `weight` value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the `sqme` value times Jacobian weights from the integration, or unity, respectively.

The `i_mci` index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The `sf_chain` subobject is a realization of the beam and structure-function configuration in the `process` object. It is not used for calculation directly but serves as the template for the sf-chain instances that are contained in the `component` objects.

The `component` subobjects determine the state of each component.

The `term` subobjects are workspace for evaluating kinematics, matrix elements, cuts etc.

The `mci_work` subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the `mci_work` array is selected by the `i_mci` index above.

```

<Processes: public>+≡
    public :: process_instance_t

<Processes: types>+≡
    type, extends (mci_sampler_t) :: process_instance_t
        type(process_t), pointer :: process => null ()
        integer :: evaluation_status = STAT_UNDEFINED
        real(default) :: sqme = 0
        real(default) :: weight = 0
        integer :: i_mci = 0
        integer :: selected_channel = 0
        type(sf_chain_t) :: sf_chain
        type(component_instance_t), dimension(:), allocatable :: component
        type(term_instance_t), dimension(:), allocatable :: term

    end subroutine process_instance_activate

```

Initialization connects the instance with a process. All initial information is transferred from the process object. The process object contains templates for the interaction subobjects (beam and term), but no evaluators. The initialization routine creates evaluators for the matrix element trace, other evaluators are left untouched.

The **instance** object must have the **target** attribute (also in any caller) since the initialization routine assigns various pointers to subobject of **instance**.

```

⟨Processes: process instance: TBP⟩+≡
    procedure :: init => process_instance_init

⟨Processes: procedures⟩+≡
    subroutine process_instance_init (instance, process)
        class(process_instance_t), intent(out), target :: instance

                call term%init (process%term(i), &
                    component%k_seed, &
                    process%beam_config, &
                    process%component(i_component)%core, &
                    process%meta%var_list)
                call term%setup_expressions (process%meta, process%config)
            end associate
        end associate
    end do
    instance%evaluation_status = STAT_INITIAL
end subroutine process_instance_init

```

Subroutine of the initialization above: initialize the beam and structure-function chain template. We establish pointers to the configuration data, so *beam_config* must have a *target* attribute.

The resulting chain is not used directly for calculation. It will acquire instances which are stored in the process-component instance objects.

(Processes: process instance: TBP)+≡

```

    procedure :: setup_sf_chain => process_instance_setup_sf_chain

```

(Processes: procedures)+≡

```

subroutine process_instance_setup_sf_chain (instance, config)
    class(process_instance_t), intent(inout) :: instance
    type(process_beam_config_t), intent(in), target :: config
    integer :: n_strfun
    n_strfun = config%n_strfun
    if (n_strfun /= 0) then
        call instance%sf_chain%init (config%data, config%sf)
    else
        call instance%sf_chain%init (config%data)
    end if
end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam

and structure-function chain.

```

<Processes: process instance: TBP>+=
  procedure :: setup_event_data => process_instance_setup_event_data

<Processes: procedures>+=
  subroutine process_instance_setup_event_data (instance)
    class(process_instance_t), intent(inout), target :: instance
    integer :: i, i_component
    do i = 1, size (instance%term)
      associate (term => instance%term(i))
        i_component = term%config%i_component
        associate (component => instance%process%component(i_component))
          call term%setup_event_data (component%core, &
            instance%process%config%model)
        end associate
      end associate
    end do
  end subroutine process_instance_setup_event_data

```

Choose a MC parameter set and the corresponding integrator.

The choice persists beyond calls of the `reset` method above. This method is automatically called here.

```

<Processes: process instance: TBP>+=
  procedure :: choose_mci => process_instance_choose_mci

<Processes: procedures>+=
  subroutine process_instance_choose_mci (instance, i_mci)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    integer :: i, j
    instance%i_mci = i_mci
    call instance%reset ()
  end subroutine process_instance_choose_mci

```

Explicitly set a MC parameter set. Works only if we are in initial state. We assume that the length of the parameter set is correct.

After setting the parameters, activate the components and terms that correspond to the chosen MC parameter set.

```

<Processes: process instance: TBP>+=
  procedure :: set_mcpair => process_instance_set_mcpair

<Processes: procedures>+=
  subroutine process_instance_set_mcpair (instance, x)
    class(process_instance_t), intent(inout) :: instance
    real(default), dimension(:), intent(in) :: x
    integer :: i, j
    if (instance%evaluation_status == STAT_INITIAL) then
      associate (mci_work => instance%mci_work(instance%i_mci))
        call mci_work%set (x)
      end associate
      call instance%activate ()
    else
      ! error?
    end if
  end subroutine process_instance_set_mcpair

```

```
end subroutine process_instance_set_mcpair
```

Explicitly choose MC integration channel. We assume here that the channel count is identical for all active components.

```
<Processes: process instance: TBP>+≡
  procedure :: select_channel => process_instance_select_channel

<Processes: procedures>+≡
  subroutine process_instance_select_channel (instance, channel)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    instance%selected_channel = channel
  end subroutine process_instance_select_channel
```

First step of process evaluation: set up seed kinematics. That is, for each active process component, compute a momentum array from the MC input parameters.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```
<Processes: process instance: TBP>+≡
  procedure :: compute_seed_kinematics => &
    process_instance_compute_seed_kinematics

<Processes: procedures>+≡
  subroutine process_instance_compute_seed_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: channel, skip_component, i
    logical :: success
    channel = instance%selected_channel
    if (channel == 0) then
      call msg_bug ("Compute seed kinematics: undefined integration channel")
    end if
    if (present (skip_term)) then
      skip_component = instance%term(skip_term)%config%i_component
    else
      skip_component = 0
    end if
    if (instance%evaluation_status >= STAT_ACTIVATED) then
      success = .true.
      do i = 1, size (instance%component)
        if (i == skip_component) cycle
        if (instance%component(i)%active) then
          call instance%component(i)%compute_seed_kinematics &
            (instance%mci_work(instance%i_mci), channel, success)
          if (.not. success) exit
        end if
      end do
      if (success) then
        instance%evaluation_status = STAT_SEED_KINEMATICS
      else
        instance%evaluation_status = STAT_FAILED_KINEMATICS
      end if
    end if
```

```

else
  ! error?
end if
end subroutine process_instance_compute_seed_kinematics

```

Inverse: recover missing parts of the kinematics from the momentum configuration, which we know for a single term and component. Given a channel, reconstruct the MC parameter set.

```

<Processes: process instance: TBP>+=
  procedure :: recover_mcpair => process_instance_recover_mcpair

<Processes: procedures>+=
  subroutine process_instance_recover_mcpair (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    integer :: channel
    integer :: i
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
      channel = instance%selected_channel
      if (channel == 0) then
        call msg_bug ("Recover MC parameters: undefined integration channel")
      end if
      i = instance%term(i_term)%config%i_component
      call instance%component(i)%recover_mcpair &
        (instance%mci_work(instance%i_mci), channel)
    else
      ! error?
    end if
  end subroutine process_instance_recover_mcpair

```

Second step of process evaluation: compute all momenta, for all active components, from the seed kinematics.

```

<Processes: process instance: TBP>+=
  procedure :: compute_hard_kinematics => &
    process_instance_compute_hard_kinematics

<Processes: procedures>+=
  subroutine process_instance_compute_hard_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: i
    if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
      do i = 1, size (instance%component)
        if (instance%component(i)%active) then
          call instance%component(i)% &
            compute_hard_kinematics (instance%term, skip_term)
        end if
      end do
      instance%evaluation_status = STAT_HARD_KINEMATICS
    else
      ! failed kinematics
    end if
  end subroutine process_instance_compute_hard_kinematics

```

Inverse: recover seed kinematics. We know the beam momentum configuration and the outgoing momenta of the effective interaction, for one specific term.

```

(Processes: process instance: TBP)+≡
  procedure :: recover_seed_kinematics => &
    process_instance_recover_seed_kinematics

(Processes: procedures)+≡
  subroutine process_instance_recover_seed_kinematics (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
      associate (i_component => instance%term(i_term)%config%i_component)
        call instance%component(i_component)% &

      end associate
    else
      ! error?
    end if
  end subroutine process_instance_recover_seed_kinematics

```

Third step of process evaluation: compute the effective momentum configurations, for all active terms, from the hard kinematics.

```

(Processes: process instance: TBP)+≡
  procedure :: compute_eff_kinematics => &
    process_instance_compute_eff_kinematics

(Processes: procedures)+≡
  subroutine process_instance_compute_eff_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: i
    if (instance%evaluation_status >= STAT_HARD_KINEMATICS) then
      do i = 1, size (instance%term)
        if (present (skip_term)) then
          if (i == skip_term) cycle
        end if
        if (instance%term(i)%active) then
          call instance%term(i)% &
            compute_eff_kinematics (instance%component)
        end if
      end do
      instance%evaluation_status = STAT_EFF_KINEMATICS
    else
      ! failed kinematics
    end if
  end subroutine process_instance_compute_eff_kinematics

```

Inverse: recover the hard kinematics from effective kinematics for one term, then compute effective kinematics for the other terms.

```

(Processes: process instance: TBP)+≡
  procedure :: recover_hard_kinematics => &
    process_instance_recover_hard_kinematics

```

```

<Processes: procedures>+≡
subroutine process_instance_recover_hard_kinematics (instance, i_term)
class(process_instance_t), intent(inout) :: instance
integer, intent(in) :: i_term
integer :: i
if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
call instance%term(i_term)%recover_hard_kinematics (instance%component)
do i = 1, size (instance%term)
if (i /= i_term) then
if (instance%term(i)%active) then
call instance%term(i)% &
compute_eff_kinematics (instance%component)
end if
end if
end do
instance%evaluation_status = STAT_EFF_KINEMATICS
else
! error?
end if
end subroutine process_instance_recover_hard_kinematics

```

Fourth step of process evaluation: check cuts for all terms. Where successful, compute any scales and weights. Otherwise, deactivate the term. If any of the terms has passed, set the state to STAT_PASSED_CUTS.

```

<Processes: process instance: TBP>+≡
procedure :: evaluate_expressions => &
process_instance_evaluate_expressions

<Processes: procedures>+≡
subroutine process_instance_evaluate_expressions (instance)
class(process_instance_t), intent(inout) :: instance
integer :: i
if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
do i = 1, size (instance%term)
if (instance%term(i)%active) then
call instance%term(i)%evaluate_expressions ()
end if
end do
if (any (instance%term%passed)) then
instance%evaluation_status = STAT_PASSED_CUTS
else
instance%evaluation_status = STAT_FAILED_CUTS
end if
else
! failed kinematics
end if
end subroutine process_instance_evaluate_expressions

```

Fifth step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

```

<Processes: process instance: TBP>+≡
procedure :: evaluate_trace => process_instance_evaluate_trace

```

```

(Processes: procedures) +=
  subroutine process_instance_evaluate_trace (instance)
    class(process_instance_t), intent(inout) :: instance
    integer :: i
    if (instance%evaluation_status >= STAT_PASSED_CUTS) then
      do i = 1, size (instance%term)
        if (instance%term(i)%passed) then
          call instance%term(i)%evaluate_interaction (instance%component)
          call instance%term(i)%evaluate_trace ()
        end if
      end do
      instance%sqme = 0
      do i = 1, size (instance%component)
        if (instance%component(i)%active) then
          call instance%component(i)%evaluate_sqme (instance%term)
          instance%sqme = instance%sqme + instance%component(i)%sqme
        end if
      end do
      instance%evaluation_status = STAT_EVALUATED_TRACE
    else
      ! failed kinematics, failed cuts
      instance%sqme = 0
    end if
  end subroutine process_instance_evaluate_trace

```

Final step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

If **weight** is provided, we already know the kinematical event weight (the MCI weight which depends on the kinematics sampling algorithm, but not on the matrix element), so we do not need to take it from the MCI record.

```

(Processes: process instance: TBP) +=
  procedure :: evaluate_event_data => process_instance_evaluate_event_data

(Processes: procedures) +=
  subroutine process_instance_evaluate_event_data (instance, weight)
    class(process_instance_t), intent(inout) :: instance
    real(default), intent(in), optional :: weight
    integer :: i
    if (instance%evaluation_status >= STAT_EVALUATED_TRACE) then
      do i = 1, size (instance%term)
        if (instance%term(i)%passed) then
          call instance%term(i)%evaluate_event_data ()
        end if
      end do
      if (present (weight)) then
        instance%weight = weight
      else
        instance%weight = &
          instance%mci_work(instance%i_mci)%mci%get_event_weight ()
      end if
      instance%evaluation_status = STAT_EVENT_COMPLETE
    else
      ! failed kinematics etc.
    end if
  end subroutine process_instance_evaluate_event_data

```

```

        instance%weight = 0
    end if
end subroutine process_instance_evaluate_event_data

```

For unweighted event generation, we should reset the reported event weight to unity (signed) or zero. The latter case is appropriate for an event which failed for whatever reason.

```

⟨Processes: process instance: TBP⟩+≡
    procedure :: normalize_weight => process_instance_normalize_weight

⟨Processes: procedures⟩+≡
    subroutine process_instance_normalize_weight (instance)
        class(process_instance_t), intent(inout) :: instance
        if (instance%weight /= 0) then
            instance%weight = sign (1._default, instance%weight)
        end if
    end subroutine process_instance_normalize_weight

```

This is a convenience routine that performs the computations of the steps 1 to 5 in a single step. The arguments are the input for `set_mcp`. After this, the evaluation status should be either `STAT_FAILED_KINEMATICS`, `STAT_FAILED_CUTS` or `STAT_EVALUATED_TRACE`.

Before calling this, we should call `choose_mci`.

```

⟨Processes: process instance: TBP⟩+≡
    procedure :: evaluate_sqme => process_instance_evaluate_sqme

⟨Processes: procedures⟩+≡
    subroutine process_instance_evaluate_sqme (instance, channel, x)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
        real(default), dimension(:), intent(in) :: x
        call instance%reset ()
        call instance%set_mcp (x)
        call instance%select_channel (channel)
        call instance%compute_seed_kinematics ()
        call instance%compute_hard_kinematics ()
        call instance%compute_eff_kinematics ()
        call instance%evaluate_expressions ()
        call instance%evaluate_trace ()
    end subroutine process_instance_evaluate_sqme

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

```

⟨Processes: process instance: TBP⟩+≡
    procedure :: recover => process_instance_recover

```

```

<Processes: procedures>+≡
  subroutine process_instance_recover (instance, channel, i_term, update_sqme)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    integer, intent(in) :: i_term
    logical, intent(in) :: update_sqme
    call instance%activate ()
    instance%evaluation_status = STAT_EFF_KINEMATICS
    call instance%recover_hard_kinematics (i_term)
    call instance%recover_seed_kinematics (i_term)
    call instance%select_channel (channel)
    call instance%recover_mcpair (i_term)
    call instance%compute_seed_kinematics (i_term)
    call instance%compute_hard_kinematics (i_term)
    call instance%compute_eff_kinematics (i_term)
    call instance%evaluate_expressions ()
    if (update_sqme) call instance%evaluate_trace ()
  end subroutine process_instance_recover

```

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the x array, and the f Jacobian array are exposed by the `sampler_t` object.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate => process_instance_evaluate

<Processes: procedures>+≡
  subroutine process_instance_evaluate (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call sampler%evaluate_sqme (c, x_in)
    call sampler%fetch (val, x, f)
  end subroutine process_instance_evaluate

```

The `rebuild` method should rebuild the kinematics section out of the `x_in` parameter set. The integrand value `val` should not be computed, but is provided as input.

```

<Processes: process instance: TBP>+≡
  procedure :: rebuild => process_instance_rebuild

<Processes: procedures>+≡
  subroutine process_instance_rebuild (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(in) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f

```

```

        call msg_bug ("process_instance_rebuild not implemented yet")
    end subroutine process_instance_rebuild

```

This is another method required by the `sampler_t` base type: fetch the data that are relevant for the MCI record.

```

<Processes: process instance: TBP>+≡
    procedure :: fetch => process_instance_fetch

<Processes: procedures>+≡
    subroutine process_instance_fetch (sampler, val, x, f)
        class(process_instance_t), intent(in) :: sampler
        real(default), intent(out) :: val
        real(default), dimension(:,:), intent(out) :: x
        real(default), dimension(:), intent(out) :: f
        integer :: i, cc
        integer :: n_channel
        val = 0
        FIND_COMPONENT: do i = 1, size (sampler%component)
            associate (component => sampler%component(i))
                if (component%active) then
                    associate (k => component%k_seed)
                        n_channel = k%n_channel
                        do cc = 1, n_channel
                            call k%get_mcpair (cc, x(:,cc))
                        end do
                        f = k%f
                        val = sampler%sqme * k%phs_factor
                    end associate
                end if
            end associate
        end do FIND_COMPONENT
    end subroutine process_instance_fetch

```

15.5.12 Accessing the process instance

Once the seed kinematics is complete, we can retrieve the MC input parameters for all channels, not just the seed channel.

Note: We choose the first active component. This makes sense only if the seed kinematics is identical for all active components.

```

<Processes: process instance: TBP>+≡
    procedure :: get_mcpair => process_instance_get_mcpair

<Processes: procedures>+≡
    subroutine process_instance_get_mcpair (instance, channel, x)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
        real(default), dimension(:), intent(out) :: x
        integer :: i
        if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
            do i = 1, size (instance%component)
                if (instance%component(i)%active) then

```

```

        call instance%component(i)%k_seed%get_mcpair (channel, x)
        return
    end if
end do
x = 0
! error?
else
    x = 0
    ! error?
end if
end subroutine process_instance_get_mcpair

```

Return true if the event is complete. In particular, the event must be kinematically valid, passed all cuts, and the event data have been computed.

```

<Processes: process instance: TBP>+≡
    procedure :: is_complete_event => process_instance_is_complete_event

<Processes: procedures>+≡
    function process_instance_is_complete_event (instance) result (flag)
        class(process_instance_t), intent(in) :: instance
        logical :: flag
        flag = instance%evaluation_status >= STAT_EVENT_COMPLETE
    end function process_instance_is_complete_event

```

Select a term for the process instance which is to provide the event record.

Note: this should be done using random numbers and applying probabilities for the various terms and components. The current implementation simply selects the first term for the first active component.

```

<Processes: process instance: TBP>+≡
    procedure :: select_i_term => process_instance_select_i_term

<Processes: procedures>+≡
    subroutine process_instance_select_i_term (instance, i_term)
        class(process_instance_t), intent(in) :: instance
        integer, intent(out) :: i_term
        integer :: i_mci, i_component
        i_mci = instance%i_mci
        i_component = instance%process%mci_entry(i_mci)%i_component(1)
        i_term = instance%process%component(i_component)%i_term(1)
    end subroutine process_instance_select_i_term

```

Return pointers to the matrix and flows interactions, given a term index.

```

<Processes: process instance: TBP>+≡
    procedure :: get_trace_int_ptr => process_instance_get_trace_int_ptr
    procedure :: get_matrix_int_ptr => process_instance_get_matrix_int_ptr
    procedure :: get_flows_int_ptr => process_instance_get_flows_int_ptr

<Processes: procedures>+≡
    function process_instance_get_trace_int_ptr (instance, i_term) result (ptr)
        class(process_instance_t), intent(in), target :: instance
        integer, intent(in) :: i_term
        type(interaction_t), pointer :: ptr
        ptr => instance%term(i_term)%connected%get_trace_int_ptr ()
    end function process_instance_get_trace_int_ptr

```

```

end function process_instance_get_trace_int_ptr

function process_instance_get_matrix_int_ptr (instance, i_term) result (ptr)
  class(process_instance_t), intent(in), target :: instance
  integer, intent(in) :: i_term
  type(interaction_t), pointer :: ptr
  ptr => instance%term(i_term)%connected%get_matrix_int_ptr ()
end function process_instance_get_matrix_int_ptr

function process_instance_get_flows_int_ptr (instance, i_term) result (ptr)
  class(process_instance_t), intent(in), target :: instance
  integer, intent(in) :: i_term
  type(interaction_t), pointer :: ptr
  ptr => instance%term(i_term)%connected%get_flows_int_ptr ()
end function process_instance_get_flows_int_ptr

```

Return the indices of the beam particles and incoming partons within the currently active state matrix, respectively.

```

⟨Processes: process instance: TBP⟩+≡
  procedure :: get_beam_index => process_instance_get_beam_index
  procedure :: get_in_index => process_instance_get_in_index

⟨Processes: procedures⟩+≡
  subroutine process_instance_get_beam_index (instance, i_term, i_beam)
    class(process_instance_t), intent(in) :: instance
    integer, intent(in) :: i_term
    integer, dimension(:), intent(out) :: i_beam
    call instance%term(i_term)%connected%get_beam_index (i_beam)
  end subroutine process_instance_get_beam_index

  subroutine process_instance_get_in_index (instance, i_term, i_in)
    class(process_instance_t), intent(in) :: instance
    integer, intent(in) :: i_term
    integer, dimension(:), intent(out) :: i_in
    call instance%term(i_term)%connected%get_in_index (i_in)
  end subroutine process_instance_get_in_index

```

Return squared matrix element and event weight.

```

⟨Processes: process instance: TBP⟩+≡
  procedure :: get_sqme => process_instance_get_sqme
  procedure :: get_weight => process_instance_get_weight

⟨Processes: procedures⟩+≡
  function process_instance_get_sqme (instance) result (sqme)
    class(process_instance_t), intent(in) :: instance
    real(default) :: sqme
    if (instance%evaluation_status >= STAT_EVALUATED_TRACE) then
      sqme = instance%sqme
    else
      sqme = 0    ! error?
    end if
  end function process_instance_get_sqme

  function process_instance_get_weight (instance) result (weight)

```

```

class(process_instance_t), intent(in) :: instance
real(default) :: weight
if (instance%evaluation_status >= STAT_EVENT_COMPLETE) then
    weight = instance%weight
else
    weight = 0    ! error?
end if
end function process_instance_get_weight

```

Return the currently selected MCI channel.

```

(Processes: process instance: TBP)+≡
    procedure :: get_channel => process_instance_get_channel

(Processes: procedures)+≡
    function process_instance_get_channel (instance) result (channel)
        class(process_instance_t), intent(in) :: instance
        integer :: channel
        channel = instance%selected_channel
    end function process_instance_get_channel

```

Return factorization scale and strong coupling. We have to select a term instance.

```

(Processes: process instance: TBP)+≡
    procedure :: get_fac_scale => process_instance_get_fac_scale
    procedure :: get_alpha_s => process_instance_get_alpha_s

(Processes: procedures)+≡
    function process_instance_get_fac_scale (instance, i_term) result (fac_scale)
        class(process_instance_t), intent(in) :: instance
        integer, intent(in) :: i_term
        real(default) :: fac_scale
        fac_scale = instance%term(i_term)%get_fac_scale ()
    end function process_instance_get_fac_scale

    function process_instance_get_alpha_s (instance, i_term) result (alpha_s)
        class(process_instance_t), intent(in) :: instance
        integer, intent(in) :: i_term
        real(default) :: alpha_s
        alpha_s = instance%term(i_term)%get_alpha_s (instance%component)
    end function process_instance_get_alpha_s

```

15.5.13 Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

```

<Processes: process instance: TBP>+≡
  procedure :: get_trace => process_instance_get_trace
  procedure :: set_trace => process_instance_set_trace

<Processes: procedures>+≡
  subroutine process_instance_get_trace (instance, pset, i_term)
    class(process_instance_t), intent(in), target :: instance
    type(particle_set_t), intent(out) :: pset
    integer, intent(in) :: i_term
    type(interaction_t), pointer :: int
    logical :: ok
    int => instance%get_trace_int_ptr (i_term)
    call particle_set_init (pset, ok, int, int, FM_IGNORE_HELICITY, &
      [0._default, 0._default], .false., .true.)
  end subroutine process_instance_get_trace

  subroutine process_instance_set_trace (instance, pset, i_term)
    class(process_instance_t), intent(inout), target :: instance
    type(particle_set_t), intent(in) :: pset
    integer, intent(in) :: i_term
    type(interaction_t), pointer :: int
    integer :: n_in
    int => instance%get_trace_int_ptr (i_term)
    n_in = instance%process%get_n_in ()
    call particle_set_fill_interaction (pset, int, n_in)
  end subroutine process_instance_set_trace

```

15.5.14 Auxiliary stuff

Write a separator line.

```

<Processes: procedures>+≡
  subroutine write_separator (u)
    integer, intent(in) :: u
    write (u, "(A)") repeat (" ", 72)
  end subroutine write_separator

  subroutine write_separator_double (u)
    integer, intent(in) :: u
    write (u, "(A)") repeat ("=", 72)
  end subroutine write_separator_double

```

15.5.15 Unit tests

```

<Processes: public>+≡
  public :: processes_test

<Processes: tests>≡
  subroutine processes_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Processes: execute tests>

```

```
end subroutine processes_test
```

Test process type

For the following tests, we define a simple implementation of the abstract `prc_core_t`, designed such as to complement the `prc_test_t` process definition type.

Note that it is not given that the actual process is defined as `prc_test_t` type. We enforce this by calling `prc_test_create_library`. The driver component in the process core will then become of type `prc_test_t`.

```
<Processes: public>+≡
  public :: test_t

<Processes: test types>≡
  type, extends (prc_core_t) :: test_t
    contains
      procedure :: write => test_write
      procedure :: needs_mcset => test_needs_mcset
      procedure :: get_n_terms => test_get_n_terms
      procedure :: is_allowed => test_is_allowed
      procedure :: compute_hard_kinematics => test_compute_hard_kinematics
      procedure :: compute_eff_kinematics => test_compute_eff_kinematics
      procedure :: recover_kinematics => test_recover_kinematics
      procedure :: compute_amplitude => test_compute_amplitude
    end type test_t

<Processes: tests>+≡
  subroutine test_write (object, unit)
    class(test_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(3x,A)") "test type implementing prc_test"
  end subroutine test_write
```

This process type always needs a MC parameter set and a single term. This only state is always allowed.

```
<Processes: tests>+≡
  function test_needs_mcset (object) result (flag)
    class(test_t), intent(in) :: object
    logical :: flag
    flag = .true.
  end function test_needs_mcset

  function test_get_n_terms (object) result (n)
    class(test_t), intent(in) :: object
    integer :: n
    n = 1
  end function test_get_n_terms

  function test_is_allowed (object, i_term, f, h, c) result (flag)
```

```

class(test_t), intent(in) :: object
integer, intent(in) :: i_term, f, h, c
logical :: flag
flag = .true.
end function test_is_allowed

```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

```

<Processes: tests>+≡
subroutine test_compute_hard_kinematics &
  (object, p_seed, i_term, int_hard, tmp)
class(test_t), intent(in) :: object
type(vector4_t), dimension(:), intent(in) :: p_seed
integer, intent(in) :: i_term
type(interaction_t), intent(inout) :: int_hard
class(workspace_t), intent(inout), allocatable :: tmp
call interaction_set_momenta (int_hard, p_seed)
end subroutine test_compute_hard_kinematics

```

This procedure is not called for `test_t`, just a placeholder.

```

<Processes: tests>+≡
subroutine test_compute_eff_kinematics &
  (object, i_term, int_hard, int_eff, tmp)
class(test_t), intent(in) :: object
integer, intent(in) :: i_term
type(interaction_t), intent(in) :: int_hard
type(interaction_t), intent(inout) :: int_eff
class(workspace_t), intent(inout), allocatable :: tmp
end subroutine test_compute_eff_kinematics

```

Transfer the incoming momenta of `p_seed` directly to the effective interaction, and vice versa for the outgoing momenta.

`int_hard` is left untouched since `int_eff` is an alias (via pointer) to it.

```

<Processes: tests>+≡
subroutine test_recover_kinematics &
  (object, p_seed, int_hard, int_eff, tmp)
class(test_t), intent(in) :: object
type(vector4_t), dimension(:), intent(inout) :: p_seed
type(interaction_t), intent(inout) :: int_hard
type(interaction_t), intent(inout) :: int_eff
class(workspace_t), intent(inout), allocatable :: tmp
integer :: n_in
n_in = interaction_get_n_in (int_eff)
call interaction_set_momenta (int_eff, p_seed(1:n_in), outgoing = .false.)
p_seed(n_in+1:) = interaction_get_momenta (int_eff, outgoing = .true.)
end subroutine test_recover_kinematics

```

Compute the amplitude. The driver ignores all quantum numbers and, in fact, returns a constant. Nevertheless, we properly transfer the momentum vectors.

```

<Processes: tests>+≡
function test_compute_amplitude &

```

```

        (object, j, p, f, h, c, fac_scale, ren_scale, tmp) result (amp)
class(test_t), intent(in) :: object
integer, intent(in) :: j
type(vector4_t), dimension(:), intent(in) :: p
integer, intent(in) :: f, h, c
real(default), intent(in) :: fac_scale, ren_scale
class(workspace_t), intent(inout), allocatable, optional :: tmp
complex(default) :: amp
real(default), dimension(:,:), allocatable :: parray
integer :: i
select type (driver => object%driver)
type is (prc_test_t)
    allocate (parray (0:3,4))
    forall (i = 1:4) parray(:,i) = vector4_get_components (p(i))
    amp = driver%get_amplitude (parray)
end select
end function test_compute_amplitude

```

Write an empty process object

The most trivial test is to write an uninitialized process object.

```

<Processes: execute tests>≡
    call test (processes_1, "processes_1", &
        "write an empty process object", &
        u, results)

<Processes: tests>+≡
    subroutine processes_1 (u)
        integer, intent(in) :: u
        type(process_t) :: process

        write (u, "(A)")  "* Test output: processes_1"
        write (u, "(A)")  "* Purpose: display an empty process object"
        write (u, "(A)")

        call process%write (u)

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: processes_1"

    end subroutine processes_1

```

Initialize a process object

Initialize a process and display it.

```

<Processes: execute tests>+≡
    call test (processes_2, "processes_2", &
        "initialize a simple process object", &
        u, results)

```

<Processes: tests>+≡

```
subroutine processes_2 (u)
  integer, intent(in) :: u
  type(process_library_t), target :: lib
  type(string_t) :: libname
  type(string_t) :: procname
  type(string_t) :: run_id
  type(os_data_t) :: os_data
  type(model_list_t) :: model_list
  type(process_t), allocatable :: process
  class(prc_core_t), allocatable :: core_template
  class(mci_t), allocatable :: mci_template
  class(phs_config_t), allocatable :: phs_config_template

  write (u, "(A)")  "* Test output: processes_2"
  write (u, "(A)")  "* Purpose: initialize a simple process object"
  write (u, "(A)")

  write (u, "(A)")  "* Build and load a test library with one process"
  write (u, "(A)")

  libname = "processes2"
  procname = libname
  run_id = "run2"
  call os_data_init (os_data)
  call prc_test_create_library (libname, lib)
  call syntax_model_file_init ()

  write (u, "(A)")  "* Initialize a process object"
  write (u, "(A)")

  allocate (process)
  call process%init (procname, run_id, lib, os_data, model_list)

  allocate (test_t :: core_template)
  allocate (phs_test_config_t :: phs_config_template)
  call process%init_component &
    (1, core_template, mci_template, phs_config_template)

  call process%setup_mci ()

  call process%write (u)

  write (u, "(A)")
  write (u, "(A)")  "* Cleanup"

  call process%final ()
  deallocate (process)

  call model_list%final ()
  call syntax_model_file_final ()

  write (u, "(A)")
  write (u, "(A)")  "* Test output end: processes_2"
```

```
end subroutine processes_2
```

Compute a trivial matrix element

Initialize a process, retrieve some information and compute a matrix element.

We use the same trivial process as for the previous test. All momentum and state dependence is trivial, so we just test basic functionality.

```
<Processes: execute tests>+≡
  call test (processes_3, "processes_3", &
    "retrieve a trivial matrix element", &
    u, results)

<Processes: tests>+≡
  subroutine processes_3 (u)

Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```

15.6 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

```

<process_stacks.f90>≡
  <File header>

  module process_stacks

    <Use strings>
    <Use file utils>
    use unit_tests
    use os_interface
    use models

    use process_libraries
    use prc_test
    use processes

    <Standard module head>

    <Process stacks: public>

    <Process stacks: types>

    contains

```

```

    <Process stacks: procedures>

```

```

    <Process stacks: tests>

```

```

end module process_stacks

```

15.6.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```

<Process stacks: public>≡
    public :: process_entry_t

<Process stacks: types>≡
    type, extends (process_t) :: process_entry_t
        type(process_entry_t), pointer :: next => null ()
    end type process_entry_t

```

15.6.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

```

<Process stacks: public>+≡
    public :: process_stack_t

<Process stacks: types>+≡
    type :: process_stack_t
        integer :: n = 0
        type(process_entry_t), pointer :: first => null ()
    contains
        <Process stacks: process stack: TBP>
    end type process_stack_t

```

Finalizer. Iteratively deallocate the stack entries. The resulting empty stack can be immediately recycled, if necessary.

```

<Process stacks: process stack: TBP>≡
    procedure :: final => process_stack_final

<Process stacks: procedures>≡
    subroutine process_stack_final (object)
        class(process_stack_t), intent(inout) :: object
        type(process_entry_t), pointer :: process
        do while (associated (object%first))
            process => object%first
            object%first => process%next
            call process%final ()
            deallocate (process)
        end do
        object%n = 0
    end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

(Process stacks: process stack: TBP)+≡
  procedure :: write => process_stack_write

(Process stacks: procedures)+≡
  subroutine process_stack_write (object, unit)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    type(process_entry_t), pointer :: process
    integer :: u
    u = output_unit (unit)
    call write_separator_double (u)
    select case (object%n)
    case (0)
      write (u, "(1x,A)") "Process stack: [empty]"
      call write_separator_double (u)
    case default
      write (u, "(1x,A)") "Process stack:"
      process => object%first
      do while (associated (process))
        call process%write (u)
        process => process%next
      end do
    end select
  end subroutine process_stack_write

```

15.6.3 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

(Process stacks: process stack: TBP)+≡
  procedure :: push => process_stack_push

(Process stacks: procedures)+≡
  subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    process%next => stack%first
    stack%first => process
    process => null ()
    stack%n = stack%n + 1
  end subroutine process_stack_push

```

15.6.4 Data Access

Return a pointer to a process with specific ID.

```

(Process stacks: process stack: TBP)+≡
  procedure :: get_process_ptr => process_stack_get_process_ptr

```

```

<Process stacks: procedures>+≡
function process_stack_get_process_ptr (stack, id) result (ptr)
  class(process_stack_t), intent(in) :: stack
  type(string_t), intent(in) :: id
  type(process_t), pointer :: ptr
  type(process_entry_t), pointer :: entry
  ptr => null ()
  entry => stack%first
  do while (associated (entry))
    if (entry%get_id () == id) then
      ptr => entry%process_t
      return
    end if
    entry => entry%next
  end do
end function process_stack_get_process_ptr

```

15.6.5 Auxiliary stuff

Write a separator line.

```

<Process stacks: procedures>+≡
subroutine write_separator (u)
  integer, intent(in) :: u
  write (u, "(A)") repeat ("-", 72)
end subroutine write_separator

subroutine write_separator_double (u)
  integer, intent(in) :: u
  write (u, "(A)") repeat ("=", 72)
end subroutine write_separator_double

```

15.6.6 Unit tests

```

<Process stacks: public>+≡
public :: process_stacks_test

<Process stacks: tests>≡
subroutine process_stacks_test (u, results)
  integer, intent(in) :: u
  type(test_results_t), intent(inout) :: results
  <Process stacks: execute tests>
end subroutine process_stacks_test

```

Write an empty process stack

The most trivial test is to write an uninitialized process stack.

```

<Process stacks: execute tests>≡
call test (process_stacks_1, "process_stacks_1", &
  "write an empty process stack", &
  u, results)

```

```

<Process stacks: tests>+≡
subroutine process_stacks_1 (u)
  integer, intent(in) :: u
  type(process_stack_t) :: stack

  write (u, "(A)")  "* Test output: process_stacks_1"
  write (u, "(A)")  "*   Purpose: display an empty process stack"
  write (u, "(A)")

  call stack%write (u)

  write (u, "(A)")
  write (u, "(A)")  "* Test output end: process_stacks_1"

end subroutine process_stacks_1

```

Fill a process stack

Fill a process stack with two (identical) processes.

```

<Process stacks: execute tests>+≡
call test (process_stacks_2, "process_stacks_2", &
  "fill a process stack", &
  u, results)

<Process stacks: tests>+≡
subroutine process_stacks_2 (u)
  integer, intent(in) :: u
  type(process_stack_t) :: stack
  type(process_library_t), target :: lib
  type(string_t) :: libname
  type(string_t) :: procname
  type(string_t) :: run_id
  type(os_data_t) :: os_data
  type(model_list_t) :: model_list
  type(process_entry_t), pointer :: process => null ()

  write (u, "(A)")  "* Test output: process_stacks_2"
  write (u, "(A)")  "*   Purpose: fill a process stack"
  write (u, "(A)")

  write (u, "(A)")  "* Build, initialize and store two test processes"
  write (u, "(A)")

  libname = "process_stacks2"
  procname = libname
  call os_data_init (os_data)

  call syntax_model_file_init ()

  allocate (process)
  run_id = "run1"
  call process%init (procname, run_id, lib, os_data, model_list)
  call stack%push (process)

```

```

allocate (process)
run_id = "run2"
call process%init (procname, run_id, lib, os_data, model_list)
call stack%push (process)

call stack%write (u)

write (u, "(A)")
write (u, "(A)")  "* Cleanup"

call stack%final ()

call model_list%final ()
call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: process_stacks_2"

end subroutine process_stacks_2

```

15.7 Complete Events

This module combines hard processes with decay chains, shower, and hadronization (not implemented yet) to complete events. It also manages the input and output of event records in various formats.

```

(events.f90)≡
  <File header>

  module events

    <Use kinds>
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use unit_tests
    use os_interface

    use parser

    use subevents
    use variables
    use expressions
    use models

    use state_matrices
    use particles
    use interactions
    use subvt_expr

```

```

    use processes

    <Standard module head>

    <Events: public>

    <Events: types>

    <Events: interfaces>

contains

    <Events: procedures>

    <Events: tests>

end module events

```

15.7.1 Event configuration

The parameters govern the transformation of an event to a particle set.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the `event_expr_t` objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

```

<Events: types>≡
    type :: event_config_t
        logical :: unweighted = .false.
        integer :: factorization_mode = FM_IGNORE_HELICITY
        logical :: keep_correlations = .false.
        type(parse_node_t), pointer :: pn_selection => null ()
        type(parse_node_t), pointer :: pn_reweight => null ()
        type(parse_node_t), pointer :: pn_analysis => null ()
    contains
        <Events: event config: TBP>
    end type event_config_t

```

Output.

```

<Events: event config: TBP>≡
    procedure :: write => event_config_write

<Events: procedures>≡
    subroutine event_config_write (object, unit, show_expressions)
        class(event_config_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: show_expressions
        integer :: u
        u = output_unit (unit)
        write (u, "(3x,A,L1)") "Unweighted          = ", object%unweighted

      call object%pn_analysis%write (u)
    end if
  end if
end if
end if
end subroutine event_config_write

```

15.7.2 The event type

Each event has a single elementary process as its core. This process may be dressed by a shower, a decay chain etc. For this core we implement pointers to a process instance.

The actual (dressed) event record is implemented as a **particle_set** object.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the **expr** subobject. In particular, evaluating the event-selection expression sets the **passed** flag.

```

<Events: public>≡
  public :: event_t

<Events: types>+≡
  type :: event_t
    type(event_config_t) :: config
    type(process_t), pointer :: process => null ()
    type(process_instance_t), pointer :: instance => null ()
    integer :: selected_i_mci = 0
    integer :: selected_i_term = 0
    integer :: selected_channel = 0
    logical :: is_complete = .false.
    logical :: particle_set_exists = .false.
    type(particle_set_t) :: particle_set
    logical :: sqme_is_known = .false.
    real(default) :: sqme = 0

```

```

    real(default) :: weight = 0
    type(event_expr_t) :: expr
    logical :: selection_evaluated = .false.
    logical :: passed = .false.
    real(default) :: reweight = 1
    logical :: analysis_flag = .false.
contains
  <Events: event: TBP>
end type event_t

```

Finalizer: needed for the particle set.

```

<Events: event: TBP>≡
  procedure :: final => event_final

<Events: procedures>+≡
  subroutine event_final (object)
    class(event_t), intent(inout) :: object
    call particle_set_final (object%particle_set)
  end subroutine event_final

```

Output.

```

<Events: event: TBP>+≡
  procedure :: write => event_write

<Events: procedures>+≡
  subroutine event_write (object, unit, verbose)
    class(event_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose
    logical :: verb
    integer :: u
    u = output_unit (unit)
    verb = .false.; if (present (verbose)) verb = verbose
    call write_separator_double (u)
    if (object%is_complete) then
      write (u, "(1x,A)") "Event"
    else
      write (u, "(1x,A)") "Event [incomplete]"

  end if
  if (object%expr%subevt_filled) then
    call object%expr%write (u)
    call write_separator_double (u)
  end if
else
  call write_separator_double (u)
  write (u, "(1x,A)") "Process instance: [undefined]"
  call write_separator_double (u)
end if
end subroutine event_write

```

15.7.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

```

<Events: event: TBP>+≡
  procedure :: basic_init => event_init

<Events: procedures>+≡
  subroutine event_init (event, var_list)
    class(event_t), intent(out) :: event
    type(var_list_t), intent(in) :: var_list
    event%config%unweighted = var_list_get_lval (var_list, &
      var_str ("?unweighted"))
  end subroutine event_init

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

```

```

<Events: procedures>+≡
  subroutine event_connect (event, process_instance)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    event%process => process_instance%process
    event%instance => process_instance
    call event%expr%setup_vars (event%process%get_sqrts ())
    call event%expr%link_var_list (event%process%get_var_list_ptr ())
  end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
  procedure :: set_selection => event_set_selection
  procedure :: set_reweight => event_set_reweight
  procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡
  subroutine event_set_selection (event, pn_selection)
    class(event_t), intent(inout) :: event
    type(parse_node_t), intent(in), pointer :: pn_selection
    event%config%pn_selection => pn_selection
  end subroutine event_set_selection

  subroutine event_set_reweight (event, pn_reweight)
    class(event_t), intent(inout) :: event
    type(parse_node_t), intent(in), pointer :: pn_reweight
    event%config%pn_reweight => pn_reweight
  end subroutine event_set_reweight

  subroutine event_set_analysis (event, pn_analysis)
    class(event_t), intent(inout) :: event
    type(parse_node_t), intent(in), pointer :: pn_analysis
    event%config%pn_analysis => pn_analysis
  end subroutine event_set_analysis

```

Create evaluation trees from the parse trees. The `target` attribute is required because the expressions contain pointers to event subobjects.

```

<Events: event: TBP>+≡
  procedure :: setup_expressions => event_setup_expressions

<Events: procedures>+≡
  subroutine event_setup_expressions (event)
    class(event_t), intent(inout), target :: event
    call event%expr%setup_selection (event%config%pn_selection)
    call event%expr%setup_analysis (event%config%pn_analysis)
    call event%expr%setup_reweight (event%config%pn_reweight)
  end subroutine event_setup_expressions

```

15.7.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to factorize the density matrix and either select a state or trace over unobserved quantum

numbers. There are several parameters in the event configuration that control this.

Note: we have to provide two random numbers. This may be replaced by a call to a random-number generator.

```

<Events: event: TBP>+≡
  procedure :: factorize_process => event_factorize_process

<Events: procedures>+≡
  subroutine event_factorize_process (event, r)
    class(event_t), intent(inout) :: event
    real(default), dimension(2), intent(in) :: r
    integer :: i_term
    type(interaction_t), pointer :: int_matrix, int_flows
    integer, dimension(:), allocatable :: beam_index
    integer, dimension(:), allocatable :: in_index
    integer :: n_in
    event%particle_set_exists = .false.
    if (event%instance%is_complete_event ()) then
      call event%instance%select_i_term (i_term)
      event%selected_i_term = i_term
      int_matrix => event%instance%get_matrix_int_ptr (i_term)
      int_flows => event%instance%get_flows_int_ptr (i_term)
      n_in = event%process%get_n_in ()
      call particle_set_init (event%particle_set, event%particle_set_exists, &
        int_matrix, int_flows, event%config%factorization_mode, r, &
        event%config%keep_correlations, keep_virtual=.true.)
      allocate (beam_index (n_in))
      call event%instance%get_beam_index (i_term, beam_index)
      call particle_set_reset_status (event%particle_set, &
        beam_index, PRT_BEAM)

    else
      ! error?
    end if
  end subroutine

```

```
end subroutine event_evaluate_expressions
```

15.7.5 Reset to empty state

Applying this, current event contents are marked as incomplete but are not deleted. In particular, the initialization is kept.

```
<Events: event: TBP>+≡
  procedure :: reset => event_reset

<Events: procedures>+≡
  subroutine event_reset (event)
    class(event_t), intent(inout) :: event
    event%selected_i_mci = 0
    event%selected_i_term = 0
    event%selected_channel = 0
    event%is_complete = .false.
    event%particle_set_exists = .false.
    event%sqme_is_known = .false.
    call event%expr%reset ()
    event%selection_evaluated = .false.
    event%passed = .false.
    event%analysis_flag = .false.
    if (associated (event%instance)) then
      call event%instance%reset (reset_mci = .true.)
    end if
  end subroutine event_reset
```

15.7.6 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

Note: We should apply decays, shower, hadronization before the transfer. This is not (re-)implemented yet.

The explicit random number argument `r` should be generated by a random-number generator. It is used for the factorization algorithm.

```
<Events: event: TBP>+≡
  procedure :: generate => event_generate

<Events: procedures>+≡
  subroutine event_generate (event, i_mci, r)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci
    real(default), dimension(2), intent(in) :: r
    call event%reset ()
    event%selected_i_mci = i_mci
    if (event%config%unweighted) then
      call event%process%generate_unweighted_event (event%instance, i_mci)
      call event%instance%evaluate_event_data ()
      call event%instance%normalize_weight ()
    else
```

```

        call event%process%generate_weighted_event (event%instance, i_mci)
        call event%instance%evaluate_event_data ()
    end if
    event%selected_channel = event%instance%get_channel ()
    call event%accept_sqme ()
    call event%factorize_process (r)
    call event%evaluate_expressions ()
end subroutine event_generate

```

Transfer the results of the process instance calculation to the event record header.

```

<Events: event: TBP>+≡
    procedure :: accept_sqme => event_accept_sqme

<Events: procedures>+≡
    subroutine event_accept_sqme (event)
        class(event_t), intent(inout) :: event
        if (associated (event%instance)) then
            if (event%instance%is_complete_event ()) then
                call event%set_sqme (event%instance%get_sqme (), &
                    event%instance%get_weight ())
            end if
        end if
    end subroutine event_accept_sqme

```

Copy squared matrix element and event weight into the event record.

```

<Events: event: TBP>+≡
    procedure :: set_sqme => event_set_sqme

<Events: procedures>+≡
    subroutine event_set_sqme (event, sqme, weight)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: sqme, weight
        event%sqme = sqme
        event%weight = weight
        event%sqme_is_known = .true.
        if (associated (event%instance)) then
            event%is_complete = event%instance%is_complete_event () &
                .and. event%sqme_is_known .and. event%particle_set_exists
        end if
    end subroutine event_set_sqme

```

15.7.7 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
    procedure :: select => event_select

<Events: procedures>+≡
    subroutine event_select (event, i_mci, i_term, channel)
        class(event_t), intent(inout) :: event
        integer, intent(in) :: i_mci, i_term, channel

```

```

    if (associated (event%instance)) then
        event%selected_i_mci = i_mci
        event%selected_i_term = i_term
        event%selected_channel = channel
    else
        call msg_bug ("Event: select term: process instance undefined")
    end if
end subroutine event_select

```

Copy a particle set into the event record.

```

<Events: event: TBP>+≡
    procedure :: set_particle_set => event_set_particle_set

<Events: procedures>+≡
    subroutine event_set_particle_set (event, pset)
        class(event_t), intent(inout) :: event
        type(particle_set_t), intent(in) :: pset
        event%particle_set = pset
        call event%accept_particle_set ()
    end subroutine event_set_particle_set

```

Mark the particle set as existing, assuming that it has just been filled somehow.

```

<Events: event: TBP>+≡
    procedure :: accept_particle_set => event_accept_particle_set

<Events: procedures>+≡
    subroutine event_accept_particle_set (event)
        class(event_t), intent(inout) :: event
        event%particle_set_exists = .true.
    end subroutine event_accept_particle_set

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The kinematical `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. Otherwise, this routine will attempt to fetch it from the MCI record in the process instance, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

<Events: event: TBP>+≡
    procedure :: recalculate => event_recalculate

```

```

<Events: procedures>+≡
subroutine event_recalculate (event, update_sqme)
  class(event_t), intent(inout) :: event
  logical, intent(in) :: update_sqme
  integer :: i_mci, i_term, channel
  if (event%particle_set_exists) then
    i_mci = event%selected_i_mci
    i_term = event%selected_i_term
    channel = event%selected_channel
    if (i_mci == 0 .or. i_term == 0 .or. channel == 0) then
      call msg_bug ("Event: recalculate: undefined selection parameters")
    end if
    call event%instance%choose_mci (i_mci)

Chapter 16

Matrix Element Implementations

In this chapter, we define concrete implementations for the workflow, from matrix-element code generation via matrix-element access to integration and event generation.

16.1 O’MEGA Interface

The standard method for process computation with WHIZARD is the O’MEGA matrix element generator.

This section implements the interface to the code generator (via the makefile) and the driver for the features provided by the O’MEGA matrix element.

```
<prc_omega.f90>≡  
  <File header>  
  
  module prc_omega  
  
    use iso_c_binding !NODEP!  
    use kinds !NODEP!  
    <Use file utils>  
    <Use strings>  
    use limits, only: TAB !NODEP!  
    use diagnostics !NODEP!  
    use unit_tests  
    use os_interface  
    use lorentz !NODEP!  
    use sm_qcd  
    use interactions  
    use variables  
    use models  
  
    use process_constants  
    use prclib_interfaces  
    use prc_core_def  
    use particle_specifiers  
    use process_libraries
```

```

    use prc_core

    <Standard module head>

    <Omega interface: public>

    <Omega interface: types>

    <Omega interface: interfaces>

    contains

    <Omega interface: procedures>

    <Omega interface: tests>

    end module prc_omega

```

16.1.1 Process definition

For the process definition we implement an extension of the `prc_core_def_t` abstract type.

```

<Omega interface: public>≡
    public :: omega_def_t

<Omega interface: types>≡
    type, extends (prc_core_def_t) :: omega_def_t
    contains
    <Omega interface: omega def: TBP>
    end type omega_def_t

<Omega interface: omega def: TBP>≡
    procedure, nopass :: type_string => omega_def_type_string

<Omega interface: procedures>≡
    function omega_def_type_string () result (string)
        type(string_t) :: string
        string = "omega"
    end function omega_def_type_string

```

Initialization: allocate the writer for the O'MEGA matrix element. Also set any data for this process that the writer needs.

```

<Omega interface: omega def: TBP>+≡
    procedure :: init => omega_def_init

<Omega interface: procedures>+≡
    subroutine omega_def_init (object, model_name, prt_in, prt_out, &
        restrictions, openmp_support, report_progress, extra_options)
        class(omega_def_t), intent(out) :: object
        type(string_t), intent(in) :: model_name
        type(string_t), dimension(:), intent(in) :: prt_in
        type(string_t), dimension(:), intent(in) :: prt_out
        type(string_t), intent(in), optional :: restrictions
        logical, intent(in), optional :: openmp_support
    end subroutine omega_def_init

```

```

logical, intent(in), optional :: report_progress
type(string_t), intent(in), optional :: extra_options
type(string_t) :: process_string
integer :: n_in
allocate (omega_writer_t :: object%writer)
select type (writer => object%writer)
type is (omega_writer_t)
    call writer%init (model_name, prt_in, prt_out, &
        restrictions, openmp_support, report_progress, extra_options)
end select
end subroutine omega_def_init

```

Write/read process- and method-specific data.

```

<Omega interface: omega def: TBP>+≡
    procedure :: write => omega_def_write

<Omega interface: procedures>+≡
    subroutine omega_def_write (object, unit)
        class(omega_def_t), intent(in) :: object
        integer, intent(in) :: unit
        select type (writer => object%writer)
        type is (omega_writer_t)
            call writer%write (unit)
        end select
    end subroutine omega_def_write

```

```

<Omega interface: omega def: TBP>+≡
    procedure :: read => omega_def_read

<Omega interface: procedures>+≡
    subroutine omega_def_read (object, unit)
        class(omega_def_t), intent(out) :: object
        integer, intent(in) :: unit
        call msg_bug ("O'Mega process definition: input not supported yet")
    end subroutine omega_def_read

```

Allocate the driver for O'MEGAmatrix elements.

```

<Omega interface: omega def: TBP>+≡
    procedure :: allocate_driver => omega_def_allocate_driver

<Omega interface: procedures>+≡
    subroutine omega_def_allocate_driver (object, driver, basename)
        class(omega_def_t), intent(in) :: object
        class(prc_core_driver_t), intent(out), allocatable :: driver
        type(string_t), intent(in) :: basename
        allocate (omega_driver_t :: driver)
    end subroutine omega_def_allocate_driver

```

We need code:

```

<Omega interface: omega def: TBP>+≡
    procedure, nopass :: needs_code => omega_def_needs_code

```

```

<Omega interface: procedures>+≡
  function omega_def_needs_code () result (flag)
    logical :: flag
    flag = .true.
  end function omega_def_needs_code

```

These are the features that an O'MEGA matrix element provides.

```

<Omega interface: omega def: TBP>+≡
  procedure, nopass :: get_features => omega_def_get_features

<Omega interface: procedures>+≡
  subroutine omega_def_get_features (features)
    type(string_t), dimension(:), allocatable, intent(out) :: features
    allocate (features (6))
    features = [ &
      var_str ("init"), &
      var_str ("update_alpha_s"), &
      var_str ("reset_helicity_selection"), &
      var_str ("is_allowed"), &
      var_str ("new_event"), &
      var_str ("get_amplitude")]
  end subroutine omega_def_get_features

```

The interface of the specific features.

```

<Omega interface: interfaces>≡
  abstract interface
    subroutine init_t (par) bind(C)
      import
      real(c_default_float), dimension(*), intent(in) :: par
    end subroutine init_t
  end interface

  abstract interface
    subroutine update_alpha_s_t (alpha_s) bind(C)
      import
      real(c_default_float), intent(in) :: alpha_s
    end subroutine update_alpha_s_t
  end interface

  abstract interface
    subroutine reset_helicity_selection_t (threshold, cutoff) bind(C)
      import
      real(c_default_float), intent(in) :: threshold
      integer(c_int), intent(in) :: cutoff
    end subroutine reset_helicity_selection_t
  end interface

  abstract interface
    subroutine is_allowed_t (flv, hel, col, flag) bind(C)
      import
      integer(c_int), intent(in) :: flv, hel, col
      logical(c_bool), intent(out) :: flag
    end subroutine is_allowed_t

```

```

end interface

abstract interface
  subroutine new_event_t (p) bind(C)
    import
    real(c_default_float), dimension(0:3,*), intent(in) :: p
  end subroutine new_event_t
end interface

abstract interface
  subroutine get_amplitude_t (flv, hel, col, amp) bind(C)
    import
    integer(c_int), intent(in) :: flv, hel, col
    complex(c_default_complex), intent(out):: amp
  end subroutine get_amplitude_t
end interface

```

Connect the O'MEGA features with the process driver.

```

<Omega interface: omega def: TBP>+≡
  procedure :: connect => omega_def_connect

<Omega interface: procedures>+≡
  subroutine omega_def_connect (def, lib_driver, i, proc_driver)
    class(omega_def_t), intent(in) :: def
    type(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i
    class(prc_core_driver_t), intent(inout) :: proc_driver
    integer(c_int) :: pid, fid
    type(c_funptr) :: fptr
    select type (proc_driver)
    type is (omega_driver_t)
      pid = i
      fid = 1
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%init)
      fid = 2
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%update_alpha_s)
      fid = 3
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%reset_helicity_selection)
      fid = 4
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%is_allowed)
      fid = 5
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%new_event)
      fid = 6
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%get_amplitude)
    end select
  end subroutine omega_def_connect

```

16.1.2 The O'MEGA writer

The O'MEGA writer is responsible for inserting the appropriate lines in the make-file that call O'MEGA, and for writing interfaces and wrappers.

```
<Omega interface: types>+≡
  type, extends (prc_writer_f_module_t) :: omega_writer_t
    type(string_t) :: model_name
    type(string_t) :: process_mode
    type(string_t) :: process_string
    type(string_t) :: restrictions
    logical :: openmp_support = .false.
    logical :: report_progress = .false.
    type(string_t) :: extra_options
  contains
    <Omega interface: omega writer: TBP>
  end type omega_writer_t
```

The reported type is the same as for the omega_def_t type.

```
<Omega interface: omega writer: TBP>≡
  procedure, nopass :: type_name => omega_writer_type_name

<Omega interface: procedures>+≡
  function omega_writer_type_name () result (string)
    type(string_t) :: string
    string = "omega"
  end function omega_writer_type_name
```

Output. This is called by omega_def_write.

```
<Omega interface: omega writer: TBP>+≡
  procedure :: write => omega_writer_write

<Omega interface: procedures>+≡
  subroutine omega_writer_write (object, unit)
    class(omega_writer_t), intent(in) :: object
    integer, intent(in) :: unit
    write (unit, "(5x,A,A)") "Mode string      = ", &
      ''' // char (object%process_mode) // '''
    write (unit, "(5x,A,A)") "Process string = ", &
      ''' // char (object%process_string) // '''
    write (unit, "(5x,A,A)") "Restrictions  = ", &
      ''' // char (object%restrictions) // '''
    write (unit, "(5x,A,L1)") "OpenMP support = ", object%openmp_support
    write (unit, "(5x,A,L1)") "Report progress = ", object%report_progress
    write (unit, "(5x,A,A)") "Extra options  = ", &
      ''' // char (object%extra_options) // '''
  end subroutine omega_writer_write
```

Initialize with process data.

```
<Omega interface: omega writer: TBP>+≡
  procedure :: init => omega_writer_init
```

<Omega interface: procedures>+≡

```

subroutine omega_writer_init (writer, model_name, prt_in, prt_out, &
    restrictions, openmp_support, report_progress, extra_options)
    class(omega_writer_t), intent(out) :: writer
    type(string_t), intent(in) :: model_name
    type(string_t), dimension(:), intent(in) :: prt_in
    type(string_t), dimension(:), intent(in) :: prt_out
    type(string_t), intent(in), optional :: restrictions
    logical, intent(in), optional :: openmp_support
    logical, intent(in), optional :: report_progress
    type(string_t), intent(in), optional :: extra_options
    integer :: i
    writer%model_name = model_name
    if (present (restrictions)) then
        writer%restrictions = restrictions
    else
        writer%restrictions = ""
    end if
    if (present (openmp_support)) writer%openmp_support = openmp_support
    if (present (report_progress)) writer%report_progress = report_progress
    if (present (extra_options)) then
        writer%extra_options = " " // extra_options
    else
        writer%extra_options = ""
    end if
    select case (size (prt_in))
    case (1); writer%process_mode = " -decay"
    case (2); writer%process_mode = " -scatter"
    end select
    associate (s => writer%process_string)
        s = " '"
        do i = 1, size (prt_in)
            if (i > 1) s = s // " "
            s = s // prt_in(i)
        end do
        s = s // " ->"
        do i = 1, size (prt_out)
            s = s // " " // prt_out(i)
        end do
        s = s // "' "
    end associate
end subroutine omega_writer_init

```

The makefile implements the actual O'MEGA call.

<Omega interface: omega writer: TBP>+≡

```

procedure :: write_makefile_code => omega_write_makefile_code

```

16.1.3 Driver

```

<Omega interface: types>+≡
type, extends (prc_core_driver_t) :: omega_driver_t
  procedure(init_t), nopass, pointer :: &
    init => null ()
  procedure(update_alpha_s_t), nopass, pointer :: &
    update_alpha_s => null ()
  procedure(reset_helicity_selection_t), nopass, pointer :: &
    reset_helicity_selection => null ()
  procedure(is_allowed_t), nopass, pointer :: &
    is_allowed => null ()
  procedure(new_event_t), nopass, pointer :: &
    new_event => null ()
  procedure(get_amplitude_t), nopass, pointer :: &
    get_amplitude => null ()
contains
  <Omega interface: omega driver: TBP>
end type omega_driver_t

```

The reported type is the same as for the `omega_def_t` type.

```

<Omega interface: omega driver: TBP>≡
  procedure, nopass :: type_name => omega_driver_type_name

<Omega interface: procedures>+≡
  function omega_driver_type_name () result (string)
    type(string_t) :: string
    string = "omega"
  end function omega_driver_type_name

```

16.1.4 High-level process definition

This procedure wraps the details filling a process-component definition entry as appropriate for an O'MEGA matrix element.

NOTE: For calling the `import_component` method, we must explicitly address the `process_def_t` parent object. The natural way to call the method of the extended type triggers a bug in gfortran 4.6. The string array arguments `prt_in` and `prt_out` become corrupted and cause a segfault.

```

<Omega interface: procedures>+≡
  subroutine omega_make_process_component (entry, component_index, &

```

```

        model_name, prt_in, prt_out, &
        restrictions, openmp_support, report_progress, extra_options)
class(process_def_entry_t), intent(inout) :: entry
integer, intent(in) :: component_index
type(string_t), intent(in) :: model_name
type(string_t), dimension(:), intent(in) :: prt_in
type(string_t), dimension(:), intent(in) :: prt_out
type(string_t), intent(in), optional :: restrictions
logical, intent(in), optional :: openmp_support
logical, intent(in), optional :: report_progress
type(string_t), intent(in), optional :: extra_options
class(prc_core_def_t), allocatable :: def
allocate (omega_def_t :: def)
select type (def)
type is (omega_def_t)
    call def%init (model_name, prt_in, prt_out, &
        restrictions, openmp_support, report_progress, extra_options)
end select
call entry%process_def_t%import_component (component_index, &
    n_out = size (prt_out), &
    prt_in = new_prt_spec (prt_in), &
    prt_out = new_prt_spec (prt_out), &
    method = var_str ("omega"), &
    variant = def)
end subroutine omega_make_process_component

```

16.1.5 The prc_omega_t wrapper

This is an instance of the generic `prc_core_t` object. It contains a pointer to the process definition (`omega_def_t`), a data component (`process_constants_t`), and the matrix-element driver (`omega_driver_t`).

```

<Omega interface: public>+≡
    public :: prc_omega_t

<Omega interface: types>+≡
    type, extends (prc_core_t) :: prc_omega_t
        real(default), dimension(:), allocatable :: par
        type(helicity_selection_t) :: helicity_selection
        type(qcd_t) :: qcd
    contains
        <Omega interface: prc omega: TBP>
    end type prc_omega_t

```

The workspace associated to a `prc_omega_t` object contains a single flag. The flag is used to suppress re-evaluating the matrix element for each quantum-number combination, after the first amplitude belonging to a given kinematics has been computed.

We can also store the value of a running coupling once it has been calculated for an event. The default value is negative, which indicates an undefined value in this context.

```

<Omega interface: types>+≡

```

```

type, extends (workspace_t) :: omega_state_t
  logical :: new_kinematics = .true.
  real(default) :: alpha_qcd = -1
contains
  procedure :: write => omega_state_write
end type omega_state_t

```

```

<Omega interface: procedures>+≡
  subroutine omega_state_write (object, unit)
    class(omega_state_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(3x,A,L1)") "0'Mega state: new kinematics = ", &
      object%new_kinematics
  end subroutine omega_state_write

```

Allocate the workspace with the above specific type.

```

<Omega interface: prc omega: TBP>≡
  procedure :: allocate_workspace => prc_omega_allocate_workspace

<Omega interface: procedures>+≡
  subroutine prc_omega_allocate_workspace (object, tmp)
    class(prc_omega_t), intent(in) :: object
    class(workspace_t), intent(inout), allocatable :: tmp
    allocate (omega_state_t :: tmp)
  end subroutine prc_omega_allocate_workspace

```

The following procedures are inherited from the base type as deferred, thus must be implemented. The corresponding unit tests are skipped here; the procedures are tested when called from the `processes` module.

Output: print just the ID of the associated matrix element. Then display any stored parameters and the helicity selection data. (The latter are printed only if active.)

```

<Omega interface: prc omega: TBP>+≡
  procedure :: write => prc_omega_write

<Omega interface: procedures>+≡
  subroutine prc_omega_write (object, unit)
    class(prc_omega_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit)
    write (u, "(3x,A)", advance="no") "0'Mega process core:"
    if (object%data_known) then
      write (u, "(1x,A)") char (object%data%id)
    else
      write (u, "(1x,A)") "[undefined]"
    end if
    if (allocated (object%par)) then
      write (u, "(3x,A)") "Parameter array:"
      do i = 1, size (object%par)
        write (u, "(5x,I0,1x,ES17.10)") i, object%par(i)
      end do
    end if
  end subroutine prc_omega_write

```

```

        end do
    end if
    call object%helicity_selection%write (u)
    call object%qcd%write (u)
end subroutine prc_omega_write

```

Temporarily store the parameter array inside the `prc_omega` object, so we can use it later during the actual initialization. Also store threshold and cutoff for helicity selection.

```

<Omega interface: prc omega: TBP>+=
    procedure :: set_parameters => prc_omega_set_parameters

<Omega interface: procedures>+=
    subroutine prc_omega_set_parameters &
        (prc_omega, model, helicity_selection, qcd)
        class(prc_omega_t), intent(inout) :: prc_omega
        type(model_t), intent(in), target, optional :: model
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        type(qcd_t), intent(in), optional :: qcd
        if (present (model)) then
            if (allocated (prc_omega%par)) deallocate (prc_omega%par)
            call model_parameters_to_c_array (model, prc_omega%par)
        end if
        if (present (helicity_selection)) then
            prc_omega%helicity_selection = helicity_selection
        end if
        if (present (qcd)) then
            prc_omega%qcd = qcd
        end if
    end subroutine prc_omega_set_parameters

```

To fully initialize the process core, we perform base initialization, then initialize the external matrix element code.

This procedure overrides the `init` method of the base type, which we nevertheless can access via its binding `base_init`. When done, we have an allocated driver. The driver will call the `init` procedure for the external matrix element, and thus transfer the parameter set to where it finally belongs.

If requested, we initialize the helicity selection counter.

```

<Omega interface: prc omega: TBP>+=
    procedure :: init => prc_omega_init

<Omega interface: procedures>+=
    subroutine prc_omega_init (object, def, lib, id, i_component)
        class(prc_omega_t), intent(inout) :: object
        class(prc_core_def_t), intent(in), target :: def
        type(process_library_t), intent(in), target :: lib
        type(string_t), intent(in) :: id
        integer, intent(in) :: i_component
        call object%base_init (def, lib, id, i_component)
        call object%activate_parameters ()
    end subroutine prc_omega_init

```

Activate the stored parameters by transferring them to the external matrix element. Also reset the helicity selection, if requested.

```

<Omega interface: prc omega: TBP>+≡
  procedure :: activate_parameters => prc_omega_activate_parameters

<Omega interface: procedures>+≡
  subroutine prc_omega_activate_parameters (object)

        end if
      end if
    end select
  end subroutine prc_omega_reset_helicity_selection

```

Compute the amplitude. For the tree-level process, we can ignore the scale settings. The term index `j` is also irrelevant.

We first call `new_event` for the given momenta (which we must unpack), then retrieve the amplitude value for the given quantum numbers.

If the `tmp` status flag is present, we can make sure that we call `new_event` only once for a given kinematics. After the first call, we unset the `new_kinematics` flag.

```

<Omega interface: prc omega: TBP>+=

```

```

    end function prc_omega_get_alpha_s
```

16.1.6 Test

This is the master for calling self-test procedures.

```
<Omega interface: public>+≡
  public :: prc_omega_test
<Omega interface: tests>+≡
  subroutine prc_omega_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Omega interface: execute tests>
  end subroutine prc_omega_test
```

Generate, compile and load a simple process matrix element

The process is $e^+e^- \rightarrow \mu^+\mu^-$ for vanishing masses and $e = 0.3$. We initialize the process, build the library, and compute a particular matrix element for momenta of unit energy and right-angle scattering. The matrix element, as it happens, is equal to e^2 . (Note that are no conversion factors applied, so this result is exact.)

For GNU `make`, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

Check prc_omega_t wrapper and options

The process is $e^-e^+ \rightarrow e^-e^+$ for vanishing masses and $e = 0.3$. We build the library using the high-level procedure `omega_make_process_component` and

the “black box” `prc_omega_t` object. Two variants with different settings for restrictions and OpenMP.

For GNU make, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

```

QCD coupling

The process is $u\bar{u} \rightarrow d\bar{d}$ for vanishing masses. We compute the amplitude for a fixed configuration once, then reset α_s , then compute again.

For GNU make, makeflags is set to -j1. This eliminates a potential clash with a -j<n> flag if this test is called from a parallel make.

Chapter 17

Event I/O

In this chapter we provide a generic handler for event I/O and the various implementations: raw, HepMC, Les Houches, etc.

17.1 Event Sample Data

We define a simple and transparent container for (meta)data that are associated with an event sample.

```
<eio_data.f90>≡  
<File header>  
  
module eio_data  
  
    use kinds !NODEP!  
<Use file utils>  
    use unit_tests  
  
<EIO data: public>  
  
<EIO data: types>  
  
contains  
  
<EIO data: procedures>  
  
<EIO data: tests>  
  
end module eio_data
```

17.1.1 Event Sample Data

These are data that apply to an event sample as a whole. They are given in an easily portable form (no fancy structure) and are used for initializing event formats.

There are two MD5 sums here. `md5sum_proc` depends only on the definition of the contributing processes. A sample with matching checksum can be

rescanned with modified model parameters, beam structure etc, to recalculate observables. `md5sum_config` includes all relevant data. Rescanning a sample with matching checksum will produce identical observables. (A third checksum might be added which depends on the event sample itself. This is not needed, so far.)

```

<EIO data: public>≡
    public :: event_sample_data_t

<EIO data: types>≡
    type :: event_sample_data_t
        character(32) :: md5sum_prc = ""
        character(32) :: md5sum_cfg = ""
        logical :: unweighted = .true.
        logical :: negative_weights = .false.
        integer :: n_beam = 0
        integer, dimension(2) :: pdg_beam = 0
        real(default), dimension(2) :: energy_beam = 0
        integer :: n_proc = 0
        integer, dimension(:), allocatable :: proc_num_id
        real(default), dimension(:), allocatable :: cross_section
        real(default), dimension(:), allocatable :: error
    contains
        <EIO data: event sample data: TBP>
    end type event_sample_data_t

```

Initialize: allocate for the number of processes

```

<EIO data: event sample data: TBP>≡
    procedure :: init => event_sample_data_init

<EIO data: procedures>≡
    subroutine event_sample_data_init (data, n_proc)
        class(event_sample_data_t), intent(out) :: data
        integer, intent(in) :: n_proc
        data%n_proc = n_proc
        allocate (data%proc_num_id (n_proc), source = 0)
        allocate (data%cross_section (n_proc), source = 0._default)
        allocate (data%error (n_proc), source = 0._default)
    end subroutine event_sample_data_init

```

Output.

```

```

17.2 Abstract I/O Handler

This module defines an abstract object for event I/O and the associated methods.

There are `output` and `input` methods which write or read a single event from/to the I/O stream, respectively. The I/O stream itself may be a file, a common block, or an externally linked structure, depending on the concrete implementation.

A `write` method prints the current content of the implementation-dependent event record in human-readable form.

The `init_in/init_out` and `final` prepare and finalize the I/O stream, respectively. There is also a `switch_inout` method which turns an input stream into an output stream where events can be appended.

$\langle \text{eio_base.f90} \rangle \equiv$
 $\langle \text{File header} \rangle$

```

module eio_base

  use kinds !NODEP!

```

```

<Use file utils>
<Use strings>
  use diagnostics !NODEP!
  use unit_tests

  use lorentz !NODEP!
  use models
  use particles
  use beams
  use processes
  use events
  use eio_data

<Standard module head>

<EIO base: public>

<EIO base: types>

<EIO base: interfaces>

<EIO base: test types>

contains

<EIO base: procedures>

<EIO base: tests>

end module eio_base

```

17.2.1 Process pointer

For handling multiple processes, we need an array of process pointers. This requires a wrapper:

```

<EIO base: public>≡
  public :: process_ptr_t

<EIO base: types>≡
  type :: process_ptr_t
    type(process_t), pointer :: ptr => null ()
  end type process_ptr_t

```

17.2.2 Type

```

<EIO base: public>+≡
  public :: eio_t

<EIO base: types>+≡
  type, abstract :: eio_t
    contains
      <EIO base: eio base: TBP>
    end type eio_t

```

Write to screen. If possible, this should display the contents of the current event, i.e., the last one that was written or read.

```

<EIO base: eio base: TBP>≡
    procedure (eio_write), deferred :: write
<EIO base: interfaces>≡
    abstract interface
        subroutine eio_write (object, unit)
            import
            class(eio_t), intent(in) :: object
            integer, intent(in), optional :: unit
        end subroutine eio_write
    end interface

```

Finalize. This should write/read footer data and close input/output channels.

```

<EIO base: eio base: TBP>+≡
    procedure (eio_final), deferred :: final
<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_final (object)
            import
            class(eio_t), intent(inout) :: object
        end subroutine eio_final
    end interface

```

Initialize for output. We provide process pointers. This should open an event file if appropriate and write header data. Some methods may require event sample data.

```

<EIO base: eio base: TBP>+≡
    procedure (eio_init_out), deferred :: init_out
<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_init_out (eio, sample, process_ptr, data, success)
            import
            class(eio_t), intent(inout) :: eio
            type(string_t), intent(in) :: sample
            type(process_ptr_t), dimension(:), intent(in) :: process_ptr
            type(event_sample_data_t), intent(in), optional :: data
            logical, intent(out), optional :: success
        end subroutine eio_init_out
    end interface

```

Initialize for input. We provide process names. This should open an event file if appropriate and read header data. The md5sum can be used to check the integrity of the configuration, it it provides a checksum to compare with.

```

<EIO base: eio base: TBP>+≡
    procedure (eio_init_in), deferred :: init_in

```

```

<EIO base: interfaces>+≡
  abstract interface
    subroutine eio_init_in (eio, sample, process_ptr, data, success)
      import
      class(eio_t), intent(inout) :: eio
      type(string_t), intent(in) :: sample
      type(process_ptr_t), dimension(:), intent(in) :: process_ptr
      type(event_sample_data_t), intent(in), optional :: data
      logical, intent(out), optional :: success
    end subroutine eio_init_in
  end interface

```

Re-initialize for output. This should change the status of any event file from input to output and position it for appending new events.

```

<EIO base: eio base: TBP>+≡
  procedure (eio_switch_inout), deferred :: switch_inout

<EIO base: interfaces>+≡
  abstract interface
    subroutine eio_switch_inout (eio, success)
      import
      class(eio_t), intent(inout) :: eio
      logical, intent(out), optional :: success
    end subroutine eio_switch_inout
  end interface

```

Output an event. All data can be taken from the `event` record. The index `i_prc` identifies the process among the processes that are contained in the current sample.

```

<EIO base: eio base: TBP>+≡
  procedure (eio_output), deferred :: output

<EIO base: interfaces>+≡
  abstract interface
    subroutine eio_output (eio, event, i_prc)
      import
      class(eio_t), intent(inout) :: eio
      type(event_t), intent(in), target :: event
      integer, intent(in) :: i_prc
    end subroutine eio_output
  end interface

```

Input an event. This should fill all event data that cannot be inferred from the associated process.

The input is broken down into two parts. First we read the `i_prc` index. So we know which process to expect in the subsequent event. If we have reached end of file, we also will know. Then, we read the event itself.

The parameter `iostat` is supposed to be set as the Fortran standard requires, negative for EOF and positive for error.

```

<EIO base: eio base: TBP>+≡
  procedure (eio_input_i_prc), deferred :: input_i_prc
  procedure (eio_input_event), deferred :: input_event

```

```

<EIO base: interfaces>+≡

      import
      class(eio_t), intent(inout) :: eio
      integer, intent(out) :: i_prc
      integer, intent(out) :: iostat
    end subroutine eio_input_i_prc
  end interface

  abstract interface
    subroutine eio_input_event (eio, event, iostat)
      import
      class(eio_t), intent(inout) :: eio
      type(event_t), intent(inout), target :: event
      integer, intent(out) :: iostat
    end subroutine eio_input_event
  end interface

```

17.2.3 Unit tests

```

<EIO base: public>+≡
  public :: eio_base_test

<EIO base: tests>≡
  subroutine eio_base_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <EIO base: execute tests>
  end subroutine eio_base_test

```

Test type for event I/O

The contents simulate the contents of an external file. We have the `sample` string as the file name, `sqrts` and the array of `process_ids` as metadata, and the array of momenta `event_p` as the list of events. The second index is the event index. The `event_i` component is the pointer to the current event, `event_n` is the total number of stored events.

```

<EIO base: test types>≡
  type, extends (eio_t) :: eio_test_t
    type(string_t) :: sample
    real(default) :: sqrts
    type(string_t) :: process_id
    integer :: event_n = 0
    integer :: event_i = 0
    integer :: i_prc = 0
    type(vector4_t), dimension(:,,:), allocatable :: event_p
  contains
  <EIO base: eio test: TBP>
  end type eio_test_t

```

Write to screen. Pretend that this is an actual event format.

```

<EIO base: eio test: TBP>≡
  procedure :: write => eio_test_write

<EIO base: procedures>≡
  subroutine eio_test_write (object, unit)
    class(eio_test_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit)
    write (u, "(1x,A)") "Test event stream"
    write (u, "(3x,A,A,A)") "Process ID = '", char (object%process_id), "' "
    write (u, "(3x,A,ES19.12)") "sqrts      = ", object%sqrts
    if (object%event_i /= 0) then
      write (u, "(1x,A,I0,A)") "Event #", object%event_i, ":"
      do i = 1, size (object%event_p, 1)
        call vector4_write (object%event_p(i, object%event_i), u)
      end do
    end if
  end subroutine eio_test_write

```

Finalizer. For the test case, we just reset the event count, but keep the stored “events”. For the real implementations, the events would be stored on an external medium, so we would delete the object contents.

```

<EIO base: eio test: TBP>+≡
  procedure :: final => eio_test_final

<EIO base: procedures>+≡
  subroutine eio_test_final (object)
    class(eio_test_t), intent(inout) :: object
    object%event_i = 0
  end subroutine eio_test_final

```

Initialization: We store the process IDs and the energy from the beam-data object. We also allocate the momenta (i.e., the simulated event record) for a fixed maximum size of 10 events, 2 momenta each. There is only a single process.

```

<EIO base: eio test: TBP>+≡
  procedure :: init_out => eio_test_init_out

<EIO base: procedures>+≡
  subroutine eio_test_init_out (eio, sample, process_ptr, data, success)

17.4 HEP Common Blocks

Long ago, to transfer data between programs one had to set up a common block and link both programs as libraries to the main executable. The HEP community standardizes several of those common blocks.

The modern way of data exchange uses data files with standard formats. However, the LHEF standard data format derives from a common block (actually, two).

WHIZARD used to support those common blocks, and LHEF was implemented via writing/reading blocks. We still keep this convention, but intend to eliminate common blocks (or any other static storage) from the workflow in the future. This will gain flexibility towards concurrent running of program images.

We encapsulate everything here in a module. The module holds the variables which are part of the common block.

Note: This code is taken essentially unchanged from WHIZARD 2.1 and does not (yet) provide unit tests.

```

<hep_common.f90>≡
<File header>

module hep_common

  use kinds !NODEP!
  <Use file utils>
  <Use strings>
  use diagnostics !NODEP!

  use lorentz !NODEP!
  use polarizations
  use particles
  use subevents
  use events

```

```

    <Standard module head>

    <HEP common: public>

    <HEP common: interfaces>

    <HEP common: parameters>

    <HEP common: variables>

    <HEP common: common blocks>

contains

    <HEP common: procedures>

end module hep_common

```

17.4.1 Event characteristics

The maximal number of particles in an event record.

```

<HEP common: parameters>≡
    integer, parameter :: MAXNUP = 500

```

The number of particles in this event.

```

<HEP common: variables>≡
    integer :: NUP

```

The process ID for this event.

```

<HEP common: variables>+≡
    integer :: IDPRUP

```

The weight of this event (± 1 for unweighted events).

```

<HEP common: variables>+≡
    double precision :: XWGTUP

```

The factorization scale that is used for PDF calculation (-1 if undefined).

```

<HEP common: variables>+≡
    double precision :: SCALUP

```

The QED and QCD couplings α used for this event (-1 if undefined).

```

<HEP common: variables>+≡
    double precision :: AQEDUP
    double precision :: AQCDUP

```

17.4.2 Particle characteristics

The PDG code:

```

<HEP common: variables>+≡
    integer, dimension(MAXNUP) :: IDUP

```

The status code. Incoming: -1 , outgoing: $+1$. Intermediate t-channel propagator: -2 (currently not used by WHIZARD). Intermediate resonance whose mass should be preserved: 2 . Intermediate resonance for documentation: 3 (currently not used). Beam particles: -9 .

<HEP common: variables>+≡
integer, dimension(MAXNUP) :: ISTUP

Index of first and last mother.

<HEP common: variables>+≡
integer, dimension(2,MAXNUP) :: MOTHUP

Color line index of the color and anticolor entry for the particle. The standard recommends using large numbers; we start from MAXNUP+1.

<HEP common: variables>+≡
integer, dimension(2,MAXNUP) :: ICOLUP

Momentum, energy, and invariant mass: (p_x, p_y, p_z, E, M) . For space-like particles, M is the negative square root of the absolute value of the invariant mass.

<HEP common: variables>+≡
double precision, dimension(5,MAXNUP) :: PUP

Invariant lifetime (distance) from production to decay in mm.

<HEP common: variables>+≡
double precision, dimension(MAXNUP) :: VTIMUP

Cosine of the angle between the spin-vector and a particle and the 3-momentum of its mother, given in the lab frame. If undefined/unpolarized: 9 .

<HEP common: variables>+≡
double precision, dimension(MAXNUP) :: SPINUP

17.4.3 The HEPRUP common block

This common block is filled once per run.

Run characteristics

The maximal number of different processes.

<HEP common: parameters>+≡
integer, parameter :: MAXPUP = 100

The beam PDG codes.

<HEP common: variables>+≡
integer, dimension(2) :: IDBMUP

The beam energies in GeV.

<HEP common: variables>+≡
double precision, dimension(2) :: EBMUP

The PDF group and set for the two beams. (Undefined: use -1 ; LHAPDF: use group = 0).

<HEP common: variables>+≡
integer, dimension(2) :: PDFGUP
integer, dimension(2) :: PDFSUP

The (re)weighting model. 1: events are weighted, the shower generator (SHG) selects processes according to the maximum weight (in pb) and unweights events. 2: events are weighted, the SHG selects processes according to their cross section (in pb) and unweights events. 3: events are unweighted and simply run through the SHG. 4: events are weighted, and the SHG keeps the weight. Negative numbers: negative weights are allowed (and are reweighted to ± 1 by the SHG, if allowed).

WHIZARD only supports modes 3 and 4, as the SHG is not given control over process selection. This is consistent with writing events to file, for offline showering.

```
<HEP common: variables>+≡
    integer :: IDWTUP
```

The number of different processes.

```
<HEP common: variables>+≡
    integer :: NPRUP
```

Process characteristics

Cross section and error in pb. (Cross section is needed only for IDWTUP = 2, so here both values are given for informational purposes only.)

```
<HEP common: variables>+≡
    double precision, dimension(MAXPUP) :: XSECUP
    double precision, dimension(MAXPUP) :: XERRUP
```

Maximum weight, i.e., the maximum value that XWGTUP can take. Also unused for the supported weighting models. It is ± 1 for unweighted events.

```
<HEP common: variables>+≡
    double precision, dimension(MAXPUP) :: XMAXUP
```

Internal ID of the selected process, matches IDPRUP below.

```
<HEP common: variables>+≡
    integer, dimension(MAXPUP) :: LPRUP
```

The common block

```
<HEP common: common blocks>≡
    common /HEPRUP/ &
        IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP, &
        XSECUP, XERRUP, XMAXUP, LPRUP
    save /HEPRUP/
```

Fill the run characteristics of the common block. The initialization sets the beam properties, number of processes, and weighting model.

```
<HEP common: public>≡
    public :: heprup_init

<HEP common: procedures>≡
    subroutine heprup_init &
        (beam_pdg, beam_energy, n_processes, unweighted, negative_weights)
        integer, dimension(2), intent(in) :: beam_pdg
        real(default), dimension(2), intent(in) :: beam_energy
        integer, intent(in) :: n_processes
```

```

logical, intent(in) :: unweighted
logical, intent(in) :: negative_weights
IDBMUP = beam_pdg
EBMUP = beam_energy
PDFGUP = -1
PDFSUP = -1
if (unweighted) then
    IDWTUP = 3
else
    IDWTUP = 4
end if
if (negative_weights) IDWTUP = - IDWTUP
NPRUP = n_processes
end subroutine heprup_init

```

Specify PDF set info. Since we support only LHAPDF, the group entry is zero.

```

<HEP common: public>+≡
    public :: heprup_set_lhapdf_id

<HEP common: procedures>+≡
    subroutine heprup_set_lhapdf_id (i_beam, pdf_id)
        integer, intent(in) :: i_beam, pdf_id
        PDFGUP(i_beam) = 0
        PDFSUP(i_beam) = pdf_id
    end subroutine heprup_set_lhapdf_id

```

Fill the characteristics for a particular process. Only the process ID is mandatory. Note that WHIZARD computes cross sections in fb, so we have to rescale to pb. The maximum weight is meaningless for unweighted events.

```

<HEP common: public>+≡
    public :: heprup_set_process_parameters

<HEP common: procedures>+≡
    subroutine heprup_set_process_parameters &
        (i, process_id, cross_section, error, max_weight)

        do i = 1, NPRUP
            write (u, "(1x,A,I0)") "Subprocess #", i
            write (u, "(3x,A6,' = ',F12.5,1x,12x,8x,A)") "XSECUP", XSECUP(i), &
                "Cross section in pb"
            write (u, "(3x,A6,' = ',F12.5,1x,12x,8x,A)") "XERRUP", XERRUP(i), &
                "Cross section error in pb"
            write (u, "(3x,A6,' = ',F12.5,1x,12x,8x,A)") "XMAXUP", XMAXUP(i), &
                "Maximum event weight (cf. IDWTUP)"
            write (u, "(3x,A6,' = ',I9,3x,1x,12x,8x,A)") "LPRUP ", LPRUP(i), &
                "Subprocess ID"
        end do
    end subroutine heprup_write_verbose

```

17.4.5 Run parameter output (other formats)

This routine writes the initialization block according to the LHEF standard. It uses the current contents of the HEPRUP block.

```

<HEP common: public>+≡
    public :: heprup_write_lhef

```

```

<HEP common: procedures>+≡
subroutine heprup_write_lhef (unit)
  integer, intent(in), optional :: unit
  integer :: u, i
  u = output_unit (unit); if (u < 0) return
  write (u, '(A)') "<init>"
  write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
    IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
  do i = 1, NPRUP
    write (u, "(3(1x,ES17.10),1x,I0)") &
      XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
  end do
  write (u, '(A)') "</init>"
end subroutine heprup_write_lhef

```

This routine is a complete dummy at the moment. It uses the current contents of the HEPRUP block. At the end, it should depend on certain input flags for the different ASCII event formats.

```

<HEP common: public>+≡
public :: heprup_write_ascii

<HEP common: procedures>+≡
subroutine heprup_write_ascii (unit)
  integer, intent(in), optional :: unit
  integer :: u, i
  u = output_unit (unit); if (u < 0) return
  write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
    IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
  do i = 1, NPRUP
    write (u, "(3(1x,ES17.10),1x,I0)") &
      XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
  end do
end subroutine heprup_write_ascii

```

17.4.6 The HEPEUP common block

```

<HEP common: common blocks>+≡
common /HEPEUP/ &
  NUP, IDPRUP, XWGTUP, SCALUP, AQEDUP, AQCDUP, &
  IDUP, ISTUP, MOTHUP, ICOLUP, PUP, VTIMUP, SPINUP
save /HEPEUP/

```

Fill the event characteristics of the common block. The initialization sets only the number of particles and initializes the rest with default values. The other routine sets the optional parameters.

```

<HEP common: public>+≡
public :: hepeup_init
public :: hepeup_set_event_parameters

<HEP common: procedures>+≡
subroutine hepeup_init (n_tot)
  integer, intent(in) :: n_tot

```

```

NUP = n_tot
IDPRUP = 0
XWGTUP = 1
SCALUP = -1
AQEDUP = -1
AQCDUP = -1
end subroutine hepeup_init

subroutine hepeup_set_event_parameters &
  (proc_id, weight, scale, alpha_qed, alpha_qcd)
  integer, intent(in), optional :: proc_id
  real(default), intent(in), optional :: weight, scale, alpha_qed, alpha_qcd
  if (present (proc_id)) IDPRUP = proc_id
  if (present (weight)) XWGTUP = weight
  if (present (scale)) SCALUP = scale
  if (present (alpha_qed)) AQEDUP = alpha_qed
  if (present (alpha_qcd)) AQCDUP = alpha_qcd
end subroutine hepeup_set_event_parameters

```

Below we need the particle status codes which are actually defined in the `subevents` module.

Set the entry for a specific particle. All parameters are set with the exception of lifetime and spin, where default values are stored.

```

<HEP common: public>+≡
  public :: hepeup_set_particle

<HEP common: procedures>+≡
  subroutine hepeup_set_particle (i, pdg, status, parent, col, p, m2)
    integer, intent(in) :: i
    integer, intent(in) :: pdg, status
    integer, dimension(:), intent(in) :: parent
    type(vector4_t), intent(in) :: p
    integer, dimension(2), intent(in) :: col
    real(default), intent(in) :: m2
    if (i > MAXNUP) then
      call msg_error (arr=(/ &
var_str ("Too many particles in HEPEUP common block. If this happened "), &
var_str ("during event output, your events will be invalid; please consider "), &
var_str ("switching to a modern event format like HEPMC. If you are not "), &
var_str ("using an old, HEPEUP based format and nevertheless get this error,"), &
var_str ("please notify the WHIZARD developers,") &
      /))
      return
    end if
    IDUP(i) = pdg
    select case (status)
    case (PRT_BEAM); ISTUP(i) = -9
    case (PRT_INCOMING); ISTUP(i) = -1
    case (PRT_BEAM_REMNANT); ISTUP(i) = 3
    case (PRT_OUTGOING); ISTUP(i) = 1
    case (PRT_RESONANT); ISTUP(i) = 2
    case (PRT_VIRTUAL); ISTUP(i) = 3
    case default; ISTUP(i) = 0
    end select

```

```

select case (size (parent))
case (0);      MOTHUP(:,i) = 0

VTIMUP(i) = 0
SPINUP(i) = 9
end subroutine hepeup_set_particle

```

Set the lifetime, actually $c\tau$ measured in mm, where τ is the invariant lifetime.

```

<HEP common: public>+≡
    public :: hepeup_set_particle_lifetime

<HEP common: procedures>+≡
    subroutine hepeup_set_particle_lifetime (i, lifetime)
        integer, intent(in) :: i
        real(default), intent(in) :: lifetime
        VTIMUP(i) = lifetime
    end subroutine hepeup_set_particle_lifetime

```

Set the particle spin entry. We need the cosine of the angle of the spin axis with respect to the three-momentum of the parent particle.

If the particle has a full polarization density matrix given, we need the particle momentum and polarization as well as the mother-particle momentum. The polarization is transformed into a spin vector (which is sensible only for spin-1/2 or massless particles), which then is transformed into the lab frame (by a rotation of the 3-axis to the particle momentum axis). Finally, we compute the scalar product of this vector with the mother-particle three-momentum.

This puts severe restrictions on the applicability of this definition, and Lorentz invariance is lost. Unfortunately, the Les Houches Accord requires this computation.

```

<HEP common: public>+≡
    public :: hepeup_set_particle_spin

    s3 = vector3_moving (polarization_get_axis (pol))
    p3 = space_part (p)
    s4 = rotation_to_2nd (3, p3) * vector4_moving (0._default, s3)
    SPINUP(i) = enclosed_angle_ct (s4, p_mother)
  end subroutine hepeup_set_particle_spin_pol

```

17.4.7 The HEPEVT common block

For the LEP Monte Carlos, a standard common block has been proposed in AKV89. We strongly recommend its use. (The description is an abbreviated transcription of AKV89, Vol. 3, pp. 327-330).

NMXHEP is the maximum number of entries:

```

<HEP common: variables>+≡
  integer, parameter :: NMXHEP = 4000

```

NEVHEP is normally the event number, but may take special values as follows:

0 the program does not keep track of event numbers. -1 a special initialization record. -2 a special final record.

```

<HEP common: variables>+≡
  integer :: NEVHEP

```

NHEP holds the number of entries for this event.

```

<HEP common: variables>+≡
  integer :: NHEP

```

The entry ISTHEP(N) gives the status code for the Nth entry, with the following semantics: 0 a null entry. 1 an existing entry, which has not decayed or fragmented. 2 a decayed or fragmented entry, which is retained for event history information. 3 documentation line. 4- 10 reserved for future standards. 11-200 at the disposal of each model builder. 201- at the disposal of users.

```

<HEP common: variables>+≡
  integer, dimension(NMXHEP) :: ISTHEP

```

The Particle Data Group has proposed standard particle codes, which are to be stored in IDHEP(N).

```

<HEP common: variables>+≡
  integer, dimension(NMXHEP) :: IDHEP

```

JMOHEP(1,N) points to the mother of the Nth entry, if any. It is set to zero for initial entries. JMOHEP(2,N) points to the second mother, if any.

```
<HEP common: variables>+≡
    integer, dimension(2, NMXHEP) :: JMOHEP
```

JDAHEP(1,N) and JDAHEP(2,N) point to the first and last daughter of the Nth entry, if any. These are zero for entries which have not yet decayed. The other daughters are stored in between these two.

```
<HEP common: variables>+≡
    integer, dimension(2, NMXHEP) :: JDAHEP
```

In PHEP we store the momentum of the particle, more specifically this means that PHEP(1,N), PHEP(2,N), and PHEP(3,N) contain the momentum in the x , y , and z direction (as defined by the machine people), measured in GeV/c. PHEP(4,N) contains the energy in GeV and PHEP(5,N) the mass in GeV/ c^2 . The latter may be negative for spacelike partons.

```
<HEP common: variables>+≡
    double precision, dimension(5, NMXHEP) :: PHEP
```

Finally VHEP is the place to store the position of the production vertex. VHEP(1,N), VHEP(2,N), and VHEP(3,N) contain the x , y , and z coordinate (as defined by the machine people), measured in mm. VHEP(4,N) contains the production time in mm/c.

```
<HEP common: variables>+≡
    double precision, dimension(4, NMXHEP) :: VHEP
```

As an amendment to the proposed standard common block HEPEVT, we also have a polarisation common block HEPSPN, as described in AKV89. SHEP(1,N), SHEP(2,N), and SHEP(3,N) give the x , y , and z component of the spinvector s of a fermion in the fermions restframe.

Furthermore, we add the polarization of the corresponding outgoing particles:

```
<HEP common: variables>+≡
    integer, dimension(NMXHEP) :: hepevt_pol
```

By convention, SHEP(4,N) is always 1. All this is taken from StdHep 4.06 manual and written using Fortran90 conventions.

```
<HEP common: common blocks>+≡
    common /HEPEVT/ &
        NEVHEP, NHEP, ISTHEP, IDHEP, &
        JMOHEP, JDAHEP, PHEP, VHEP
    save /HEPEVT/
```

Here we store HEPEVT parameters of the WHIZARD 1 realization which are not part of the HEPEVT common block.

```
<HEP common: variables>+≡
    integer :: hepevt_n_out, hepevt_n_remnants
```

```

<HEP common: variables>+≡
    double precision :: hepevt_weight, hepevt_function_value
    double precision :: hepevt_function_ratio

```

Filling HEPEVT: If the event count is not provided, set NEVHEP to zero. If the event count is -1 or -2, the record corresponds to initialization and finalization, and the event is irrelevant.

Note that the event count may be larger than 2^{31} (2 GEvents). In that case, cut off the upper bits since NEVHEP is probably limited to default integer.

```

<HEP common: public>+≡
    public :: hepevt_init
    public :: hepevt_set_event_parameters

<HEP common: procedures>+≡
    subroutine hepevt_init (n_tot, n_out)
        integer, intent(in) :: n_tot, n_out
        NHEP                = n_tot
        NEVHEP              = 0
        hepevt_n_out        = n_out

PUP(:,i), VTIMUP(i), SPINUP(i)
end do
write (u, '(A)') "</event>"
end subroutine hepeup_write_lhef

subroutine hepeup_write_ascii (unit)

```

```

integer, intent(in), optional :: unit
integer :: u, i
integer, dimension(MAXNUP) :: spin_up
spin_up = SPINUP
u = output_unit (unit); if (u < 0) return
write (u, "(2(1x,I0),4(1x,ES17.10))") &
    NUP, IDPRUP, XWGTUP, SCALUP, AQEDUP, AQCDUP
do i = 1, NUP
    write (u, "(6(1x,I0),7(1x,ES17.10))") &
        IDUP(i), ISTUP(i), MOTHUP(:,i), ICOLUP(:,i), &
            PUP(:,i), VTIMUP(i), SPINUP(i)
end do
end subroutine hepeup_write_ascii

```

This routine writes event output according to the HEPEVT standard. It uses the current contents of the HEPEVT block and some additional parameters according to the standard in WHIZARD 1. For the long ASCII format, the value of the sample function (i.e. the product of squared matrix element, structure functions and phase space factor is printed out). The option of reweighting matrix elements with respect to some reference cross section is not implemented in WHIZARD 2, therefore the second entry in the long ASCII format (the function ratio) is always one. The ATHENA format is an implementation of the HEPEVT format that is readable by the ATLAS ATHENA software framework. It is very similar to the WHIZARD 1 HEPEVT format, except that it contains an event counter, a particle counter inside the event, and has the HEPEVT ISTHEP status before the PDG code. The MOKKA format is a special ASCII format that contains the information to be parsed to the MOKKA LC fast simulation software.

```

17.4.10 Data Transfer: particle sets

The WHIZARD format for handling particle data in events is `particle_set_t`. We have to interface this to the common blocks.

We first create a new particle set that contains only the particles that are supported by the LHEF format. These are: beam, incoming, resonant, outgoing. We drop particles with unknown, virtual or beam-remnant status.

From this set we fill the common block. Event information such as process ID and weight is not transferred here; this has to be done by the caller. The spin information is set only if the particle has a unique mother, and if its polarization is fully defined.

```

<HEP common: public>+≡
  public :: hepeup_from_particle_set

<HEP common: procedures>+≡
  subroutine hepeup_from_particle_set (particle_set, keep_beams)
    type(particle_set_t), intent(in), target :: particle_set
    logical, intent(in), optional :: keep_beams
    type(particle_t), pointer :: prt

```

```

type(particle_set_t), target :: pset_hepevt
integer :: i, n_parents
integer, dimension(1) :: i_mother
call particle_set_to_hepevt_form (particle_set, pset_hepevt, keep_beams)
call hepeup_init (pset_hepevt%n_tot)
do i = 1, pset_hepevt%n_tot
  prt => pset_hepevt%prt(i)
  call hepeup_set_particle (i, &
    particle_get_pdg (prt), &
    particle_get_status (prt), &
    particle_get_parents (prt), &
    particle_get_color (prt), &
    particle_get_momentum (prt), &
    particle_get_p2 (prt))
  n_parents = particle_get_n_parents (prt)
  if (n_parents == 1) then
    i_mother = particle_get_parents (prt)
    select case (particle_get_polarization_status (prt))
    case (PRT_GENERIC_POLARIZATION)
      call hepeup_set_particle_spin (i, &
        particle_get_momentum (prt), &
        particle_get_polarization (prt), &
        particle_get_momentum (pset_hepevt%prt(i_mother(1))))
    end select
  end if
end do
call particle_set_final (pset_hepevt)
end subroutine hepeup_from_particle_set

```

The HEPEVT common block is quite similar, but does contain less information, e.g. no color flows (it was LEP time). The spin information is set only if the particle has a unique mother, and if its polarization is fully defined.

```

<HEP common: public>+≡
  public :: hepevt_from_particle_set

<HEP common: procedures>+≡
  subroutine hepevt_from_particle_set (particle_set, keep_beams)
    type(particle_set_t), intent(in), target :: particle_set

17.6 HepMC events

This section provides the interface to the HepMC C++ library for handling Monte-Carlo events.

Each C++ class of HepMC that we use is mirrored by a Fortran type, which contains as its only component the C pointer to the C++ object.

Each C++ method of HepMC that we use has a C wrapper function. This function takes a pointer to the host object as its first argument. Further arguments are either C pointers, or in the case of simple types (integer, real), interoperable C/Fortran objects.

The C wrapper functions have explicit interfaces in the Fortran module. They are called by Fortran wrapper procedures. These are treated as methods of the corresponding Fortran type.

```

<hepmc_interface.f90>≡
  <File header>

  module hepmc_interface

    use iso_c_binding !NODEP!
    <Use kinds>
    <Use strings>
    use constants !NODEP!
    use lorentz !NODEP!
    use models
    use flavors
    use colors
    use helicities
    use quantum_numbers
    use polarizations

    <Standard module head>

    <HepMC interface: public>

    <HepMC interface: types>

    <HepMC interface: interfaces>

    contains

    <HepMC interface: procedures>

  end module hepmc_interface

```

17.6.1 Interface check

This function can be called in order to verify that we are using the actual HepMC library, and not the dummy version.

```

<HepMC interface: interfaces>≡
  interface
    logical(c_bool) function hepmc_available () bind(C)
      import
    end function hepmc_available
  end interface

  <HepMC interface: public>≡
    public :: hepmc_is_available

```

```

<HepMC interface: procedures>≡
  function hepmc_is_available () result (flag)
    logical :: flag
    flag = hepmc_available ()
  end function hepmc_is_available

```

17.6.2 FourVector

The C version of four-vectors is often transferred by value, and the associated procedures are all inlined. The wrapper needs to transfer by reference, so we create FourVector objects on the heap which have to be deleted explicitly. The input is a `vector4_t` or `vector3_t` object from the `lorentz` module.

```

<HepMC interface: public>+≡
  public :: hepmc_four_vector_t

<HepMC interface: types>≡
  type :: hepmc_four_vector_t
  private
  type(c_ptr) :: obj
  end type hepmc_four_vector_t

```

In the C constructor, the zero-component (fourth argument) is optional; if missing, it is set to zero. The Fortran version has initializer form and takes either a three-vector or a four-vector. A further version extracts the four-vector from a HepMC particle object.

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_four_vector_xyz (x, y, z) bind(C)
      import
      real(c_double), value :: x, y, z
    end function new_four_vector_xyz
  end interface
  interface

    end subroutine hepmc_four_vector_to_vector4

```

17.6.3 Polarization

Polarization objects are temporarily used for assigning particle polarization. We add a flag `polarized`. If this is false, the polarization is not set and should not be transferred to `hepmc_particle` objects.

```

<HepMC interface: public>+≡
    public :: hepmc_polarization_t
<HepMC interface: types>+≡
    type :: hepmc_polarization_t
        private
        logical :: polarized = .false.
        type(c_ptr) :: obj
    end type hepmc_polarization_t

```

Constructor. The C wrapper takes polar and azimuthal angle as arguments. The Fortran version allows for either a complete polarization density matrix, or for a definite (diagonal) helicity.

HepMC does not allow to specify the degree of polarization, therefore we have to map it to either 0 or 1. We choose 0 for polarization less than 0.5 and 1 for polarization greater than 0.5. Even this simplification works only for spin-1/2 and for massless particles; massive vector bosons cannot be treated this way. In particular, zero helicity is always translated as unpolarized.

```

(HepMC interface: interfaces)+≡
  interface
    type(c_ptr) function new_polarization (theta, phi) bind(C)
      import
      real(c_double), value :: theta, phi

  n_out = gen_vertex_particles_out_size (v%obj)
end function hepmc_vertex_get_n_out

```

17.6.6 Vertex-particle-in iterator

This iterator iterates over all incoming particles in an vertex. We store a pointer to the vertex in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

```

<HepMC interface: public>+≡
  public :: hepmc_vertex_particle_in_iterator_t

<HepMC interface: types>+≡
  type :: hepmc_vertex_particle_in_iterator_t
  private
  type(c_ptr) :: obj
  type(c_ptr) :: v_obj
end type hepmc_vertex_particle_in_iterator_t

```

Constructor. The iterator is initialized at the first particle in the vertex.

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function &
      new_vertex_particles_in_const_iterator (v_obj) bind(C)
    import
    type(c_ptr), value :: v_obj
    end function new_vertex_particles_in_const_iterator
  end interface

<HepMC interface: public>+≡
  public :: hepmc_vertex_particle_in_iterator_init

<HepMC interface: procedures>+≡
  subroutine hepmc_vertex_particle_in_iterator_init (it, v)
    type(hepmc_vertex_particle_in_iterator_t), intent(out) :: it
    type(hepmc_vertex_t), intent(in) :: v
    it%obj = new_vertex_particles_in_const_iterator (v%obj)
    it%v_obj = v%obj
  end subroutine hepmc_vertex_particle_in_iterator_init

```

Destructor. Necessary because the iterator is allocated on the heap.

```

<HepMC interface: interfaces>+≡
  interface
    subroutine vertex_particles_in_const_iterator_delete (it_obj) bind(C)
    import
    type(c_ptr), value :: it_obj
    end subroutine vertex_particles_in_const_iterator_delete
  end interface

```

```

<HepMC interface: public>+≡
    public :: hepmc_vertex_particle_in_iterator_final
<HepMC interface: procedures>+≡
    subroutine hepmc_vertex_particle_in_iterator_final (it)
        type(hepmc_vertex_particle_in_iterator_t), intent(inout) :: it
        call vertex_particles_in_const_iterator_delete (it%obj)
    end subroutine hepmc_vertex_particle_in_iterator_final

```

Increment

```

<HepMC interface: interfaces>+≡
    interface
        subroutine vertex_particles_in_const_iterator_advance (it_obj) bind(C)
            import
            type(c_ptr), value :: it_obj
        end subroutine vertex_particles_in_const_iterator_advance
    end interface
<HepMC interface: public>+≡
    public :: hepmc_vertex_particle_in_iterator_advance
<HepMC interface: procedures>+≡
    subroutine hepmc_vertex_particle_in_iterator_advance (it)

```

```
end function hepmc_vertex_particle_out_iterator_get
```

17.6.8 GenEvent

The main object of HepMC is a GenEvent. The object is filled by GenVertex objects, which in turn contain GenParticle objects.

```
<HepMC interface: public>+≡
  public :: hepmc_event_t

<HepMC interface: types>+≡
  type :: hepmc_event_t
  private
  type(c_ptr) :: obj
end type hepmc_event_t
```

Constructor. Arguments are process ID (integer) and event ID (integer).

The Fortran version has initializer form.

```
<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_gen_event (proc_id, event_id) bind(C)
    import
    integer(c_int), value :: proc_id, event_id
    end function new_gen_event
  end interface

<HepMC interface: public>+≡
  public :: hepmc_event_init

<HepMC interface: procedures>+≡
  subroutine hepmc_event_init (evt, proc_id, event_id)
    type(hepmc_event_t), intent(out) :: evt
    integer, intent(in), optional :: proc_id, event_id

    end subroutine gen_event_set_cross_section
  end interface

```

```
end interface
```

17.6.9 Event-particle iterator

This iterator iterates over all particles in an event. We store a pointer to the event in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

```
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_t
<HepMC interface: types>+≡
  type :: hepmc_event_particle_iterator_t
  private
    type(c_ptr) :: obj
    type(c_ptr) :: evt_obj
  end type hepmc_event_particle_iterator_t
```

Constructor. The iterator is initialized at the first particle in the event.

```
<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_event_particle_const_iterator (evt_obj) bind(C)
    import
      type(c_ptr), value :: evt_obj
    end function new_event_particle_const_iterator
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_init
<HepMC interface: procedures>+≡
  subroutine hepmc_event_particle_iterator_init (it, evt)
    type(hepmc_event_particle_iterator_t), intent(out) :: it
    type(hepmc_event_t), intent(in) :: evt
    it%obj = new_event_particle_const_iterator (evt%obj)
    it%evt_obj = evt%obj
  end subroutine hepmc_event_particle_iterator_init
```

Destructor. Necessary because the iterator is allocated on the heap.

```
<HepMC interface: interfaces>+≡
  interface
    subroutine event_particle_const_iterator_delete (it_obj) bind(C)
    import
      type(c_ptr), value :: it_obj
    end subroutine event_particle_const_iterator_delete
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_final
<HepMC interface: procedures>+≡
  subroutine hepmc_event_particle_iterator_final (it)
    type(hepmc_event_particle_iterator_t), intent(inout) :: it
    call event_particle_const_iterator_delete (it%obj)
  end subroutine hepmc_event_particle_iterator_final
```

Increment

```
<HepMC interface: interfaces>+≡
  interface
    subroutine event_particle_const_iterator_advance (it_obj) bind(C)
      import
      type(c_ptr), value :: it_obj
    end subroutine event_particle_const_iterator_advance
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_advance
<HepMC interface: procedures>+≡
  subroutine hepmc_event_particle_iterator_advance (it)
    type(hepmc_event_particle_iterator_t), intent(inout) :: it
    call event_particle_const_iterator_advance (it%obj)
  end subroutine hepmc_event_particle_iterator_advance
```

Reset to the beginning

```
<HepMC interface: interfaces>+≡
  interface
    subroutine event_particle_const_iterator_reset (it_obj, evt_obj) bind(C)
      import
      type(c_ptr), value :: it_obj, evt_obj
    end subroutine event_particle_const_iterator_reset
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_reset
<HepMC interface: procedures>+≡
  subroutine hepmc_event_particle_iterator_reset (it)
    type(hepmc_event_particle_iterator_t), intent(inout) :: it
    call event_particle_const_iterator_reset (it%obj, it%evt_obj)
  end subroutine hepmc_event_particle_iterator_reset
```

Test: return true as long as we are not past the end.

```
<HepMC interface: interfaces>+≡
  interface
    function event_particle_const_iterator_is_valid &
      (it_obj, evt_obj) result (flag) bind(C)
      import
      logical(c_bool) :: flag
      type(c_ptr), value :: it_obj, evt_obj
    end function event_particle_const_iterator_is_valid
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_is_valid
<HepMC interface: procedures>+≡
  function hepmc_event_particle_iterator_is_valid (it) result (flag)
    logical :: flag
    type(hepmc_event_particle_iterator_t), intent(in) :: it
    flag = event_particle_const_iterator_is_valid (it%obj, it%evt_obj)
  end function hepmc_event_particle_iterator_is_valid
```

Return the particle pointed to by the iterator. (The particle object should not be finalized, since it contains merely a pointer to the particle which is owned by the vertex.)

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function event_particle_const_iterator_get (it_obj) bind(C)
    import
    type(c_ptr), value :: it_obj
    end function event_particle_const_iterator_get
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_get
<HepMC interface: procedures>+≡
  function hepmc_event_particle_iterator_get (it) result (prt)
    type(hepmc_particle_t) :: prt
    type(hepmc_event_particle_iterator_t), intent(in) :: it
    prt%obj = event_particle_const_iterator_get (it%obj)
  end function hepmc_event_particle_iterator_get

```

17.6.10 I/O streams

There is a specific I/O stream type for handling the output of GenEvent objects (i.e., Monte Carlo event samples) to file. Opening the file is done by the constructor, closing by the destructor.

```

<HepMC interface: public>+≡
  public :: hepmc_iostream_t
<HepMC interface: types>+≡
  type :: hepmc_iostream_t
  private
  type(c_ptr) :: obj
  end type hepmc_iostream_t

```

Constructor for an output stream associated to a file.

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_io_gen_event_out (filename) bind(C)
    import
    character(c_char), dimension(*), intent(in) :: filename
    end function new_io_gen_event_out
  end interface
<HepMC interface: public>+≡
  public :: hepmc_iostream_open_out
<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_open_out (iostream, filename)
    type(hepmc_iostream_t), intent(out) :: iostream
    type(string_t), intent(in) :: filename
    iostream%obj = new_io_gen_event_out (char (filename) // c_null_char)
  end subroutine hepmc_iostream_open_out

```

Constructor for an input stream associated to a file.

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_io_gen_event_in (filename) bind(C)
    import
      character(c_char), dimension(*), intent(in) :: filename
    end function new_io_gen_event_in
  end interface
<HepMC interface: public>+≡
  public :: hepmc_iostream_open_in
<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_open_in (iostream, filename)
    type(hepmc_iostream_t), intent(out) :: iostream
    type(string_t), intent(in) :: filename
    iostream%obj = new_io_gen_event_in (char (filename) // c_null_char)
  end subroutine hepmc_iostream_open_in

```

Destructor:

```

<HepMC interface: interfaces>+≡
  interface
    subroutine io_gen_event_delete (io_obj) bind(C)
    import
      type(c_ptr), value :: io_obj
    end subroutine io_gen_event_delete
  end interface
<HepMC interface: public>+≡
  public :: hepmc_iostream_close
<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_close (iostream)
    type(hepmc_iostream_t), intent(inout) :: iostream
    call io_gen_event_delete (iostream%obj)
  end subroutine hepmc_iostream_close

```

Write a single event to the I/O stream.

```

<HepMC interface: interfaces>+≡
  interface
    subroutine io_gen_event_write_event (io_obj, evt_obj) bind(C)
    import
      type(c_ptr), value :: io_obj, evt_obj
    end subroutine io_gen_event_write_event
  end interface
<HepMC interface: public>+≡
  public :: hepmc_iostream_write_event
<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_write_event (iostream, evt)
    type(hepmc_iostream_t), intent(inout) :: iostream
    type(hepmc_event_t), intent(in) :: evt
    call io_gen_event_write_event (iostream%obj, evt%obj)
  end subroutine hepmc_iostream_write_event

```

Read a single event from the I/O stream. Return true if successful.

```

<HepMC interface: interfaces>+=
  interface
    logical(c_bool) function io_gen_event_read_event (io_obj, evt_obj) bind(C)
    import
    type(c_ptr), value :: io_obj, evt_obj
    end function io_gen_event_read_event
  end interface
<HepMC interface: public>+=
  public :: hepmc_iostream_read_event
<HepMC interface: procedures>+=
  subroutine hepmc_iostream_read_event (iostream, evt, ok)
    type(hepmc_iostream_t), intent(inout) :: iostream
    type(hepmc_event_t), intent(in) :: evt
    logical, intent(out) :: ok
    ok = io_gen_event_read_event (iostream%obj, evt%obj)
  end subroutine hepmc_iostream_read_event

```

17.6.11 Test

This test example is an abridged version from the build-from-scratch example in the HepMC distribution. We create two vertices for $p \rightarrow q$ PDF splitting, then a vertex for a $qq \rightarrow W^- g$ hard-interaction process, and finally a vertex for $W^- \rightarrow qq$ decay. The setup is for LHC kinematics.

Extending the original example, we set color flow for the incoming quarks and polarization for the outgoing photon. For the latter, we have to define a particle-data object for the photon, so a flavor object can be correctly initialized.

```

<CCC HepMC interface: public>=
  public :: hepmc_test
<CCC HepMC interface: procedures>=
  subroutine hepmc_test
    type(hepmc_event_t) :: evt
    type(hepmc_vertex_t) :: v1, v2, v3, v4
    type(hepmc_particle_t) :: prt1, prt2, prt3, prt4, prt5, prt6, prt7, prt8
    type(hepmc_iostream_t) :: iostream
    type(flavor_t) :: flv
    type(color_t) :: col
    type(polarization_t) :: pol
    type(particle_data_t), target :: photon_data

  end subroutine eio_hepmc_input_event

```

17.7.4 Particle Set Transfer

The master output function fills a HepMC GenEvent object that is already initialized, but has no vertices in it.

We first set up the vertex lists and enter the vertices into the HepMC event. Then, we assign first all incoming particles and then all outgoing particles to their associated vertices. Particles which have neither parent nor children entries (this should not happen) are dropped.

Finally, we insert the beam particles. If there are none, use the incoming particles instead.

```

<EIO HepMC: procedures>+≡
  subroutine hepmc_event_from_particle_set (evt, particle_set)
    type(hepmc_event_t), intent(inout) :: evt
    type(particle_set_t), intent(in) :: particle_set
    type(hepmc_vertex_t), dimension(:), allocatable :: v
    type(hepmc_particle_t), dimension(:), allocatable :: hpvt
    type(hepmc_particle_t), dimension(2) :: hbeam
    logical, dimension(:), allocatable :: is_beam
    integer, dimension(:), allocatable :: v_from, v_to
    integer :: n_vertices, n_tot, i
    n_tot = particle_set%n_tot
    allocate (v_from (n_tot), v_to (n_tot))
    call particle_set_assign_vertices (particle_set, v_from, v_to, n_vertices)
    allocate (v (n_vertices))
    do i = 1, n_vertices

```

```

        call hepmc_vertex_init (v(i))
        call hepmc_event_add_vertex (evt, v(i))
    end do
    allocate (hprt (n_tot))
    do i = 1, n_tot
        if (v_to(i) /= 0 .or. v_from(i) /= 0) then
            call particle_to_hepmc (particle_set%prt(i), hprt(i))
        end if
    end do
    allocate (is_beam (n_tot))
    is_beam = particle_get_status (particle_set%prt(1:n_tot)) == PRT_BEAM
    if (.not. any (is_beam)) then
        is_beam = particle_get_status (particle_set%prt(1:n_tot)) == PRT_INCOMING
    end if
    if (count (is_beam) == 2) then
        hbeam = pack (hprt, is_beam)
        call hepmc_event_set_beam_particles (evt, hbeam(1), hbeam(2))
    end if
    do i = 1, n_tot
        if (v_to(i) /= 0) then
            call hepmc_vertex_add_particle_in (v(v_to(i)), hprt(i))
        end if
    end do
    do i = 1, n_tot
        if (v_from(i) /= 0) then
            call hepmc_vertex_add_particle_out (v(v_from(i)), hprt(i))
        end if
    end do
end subroutine hepmc_event_from_particle_set

```

Transform a particle into a `hepmc_particle` object, including color and polarization. The HepMC status is equivalent to the HEPEVT status, in particular: 0 = null entry, 1 = physical particle, 2 = decayed/fragmented SM hadron, tau or muon, 3 = other unphysical particle entry, 4 = incoming particles, 11 = intermediate resonance such as squarks. The use of 11 for intermediate resonances is as done by HERWIG, see <http://herwig.hepforge.org/trac/wiki/FaQs>.

(EIO HepMC: procedures)+≡

17.8 ASCII File Formats

Here, we implement several ASCII file formats. It is possible to switch between them using flags.

`<eio_ascii.f90>`≡
<File header>

```

module eio_ascii

  use kinds !NODEP!
  <Use file utils>
  <Use strings>
  use diagnostics !NODEP!
  use unit_tests

  use lorentz !NODEP!
  use models

```

```

    use particles
    use beams
    use processes
    use events
    use eio_data
    use eio_base
    use hep_common

    <Standard module head>

    <EIO ascii: public>

    <EIO ascii: types>

    contains

    <EIO ascii: procedures>

    <EIO ascii: tests>

    end module eio_ascii

```

17.8.1 Type

```

<EIO ascii: public>≡
    public :: eio_ascii_t

<EIO ascii: types>≡
    type, extends (eio_t) :: eio_ascii_t
        type(string_t) :: filename
        logical :: writing = .false.
        integer :: unit = 0
        logical :: keep_beams = .false.
    contains
        <EIO ascii: eio ascii: TBP>
    end type eio_ascii_t

```

17.9 Event Weight Output

This is an output-only format. For each event, we print the indices that identify process, process part (MCI group), and term. As numerical information we print the squared matrix element (trace) and the event weight.

18.0.3 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

<SLHA: parameters>≡

```
integer, parameter :: MODE_SKIP = 0, MODE_DATA = 1, MODE_INFO = 2
```

<SLHA: procedures>≡

```
subroutine slha_preprocess (stream, ifile)

    call ifile_append (ifile, "ALT sign = '+' | '-'")
    call ifile_append (ifile, "ALT number = integer | real")
    call ifile_append (ifile, "INT integer")
    call ifile_append (ifile, "KEY '-'")
    call ifile_append (ifile, "KEY '+'")
    call ifile_append (ifile, "SEQ block_info = INFO info_line '$'")
    call ifile_append (ifile, "KEY INFO")
    call ifile_append (ifile, "SEQ info_line = integer string_literal")
  end subroutine define_slha_syntax

```

```

call ifile_append (ifile, "QUO string_literal = '""'...'""')
call ifile_append (ifile, "SEQ decay_def = " &
// "DECAY decay_spec '$' decay_data*")
call ifile_append (ifile, "KEY DECAY")
call ifile_append (ifile, "SEQ decay_spec = pdg_code data_item")
call ifile_append (ifile, "ALT pdg_code = signed_integer | integer")
call ifile_append (ifile, "SEQ signed_integer = sign integer")
call ifile_append (ifile, "SEQ decay_data = DATA decay_line '$'")
call ifile_append (ifile, "SEQ decay_line = data_item integer pdg_code+")
end subroutine define_slha_syntax

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

```

18.0.5 Interpreter

Find blocks

From the parse tree, find the node that represents a particular block. If `required` is true, issue an error if not found. Since `block_name` is always invoked with capital letters, we have to capitalize `pn_block_name`.

```

⟨SLHA: procedures⟩+=
    function slha_get_block_ptr &
        (parse_tree, block_name, required) result (pn_block)
        type(parse_node_t), pointer :: pn_block
        type(parse_tree_t), intent(in) :: parse_tree
        type(string_t), intent(in) :: block_name
        logical, intent(in) :: required
        type(parse_node_t), pointer :: pn_root, pn_block_spec, pn_block_name
        pn_root => parse_tree_get_root_ptr (parse_tree)
        pn_block => parse_node_get_sub_ptr (pn_root)
        do while (associated (pn_block))
            select case (char (parse_node_get_rule_key (pn_block)))
            case ("block_def")
                pn_block_spec => parse_node_get_sub_ptr (pn_block, 2)

```

```

        pn_block_name => parse_node_get_sub_ptr (pn_block_spec)
        if (trim (adjustl (upper_case (parse_node_get_string &
            (pn_block_name)))) == block_name) then
            return
        end if
    end select
    pn_block => parse_node_get_next_ptr (pn_block)
end do
if (required) then

SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is not defined in the block, we use the previous value from the model variable list. For the basic parameters we have to do a small recalculation, since SLHA uses the G_F - α - m_Z scheme, while WHIZARD derives them from G_F , m_W , and m_Z .

```

18.0.7 Parser

Read a SLHA file from stream, including preprocessing, and make up a parse tree.

(SLHA: procedures)+≡

```

subroutine slha_parse_stream (stream, parse_tree)
    type(stream_t), intent(inout), target :: stream
    type(parse_tree_t), intent(out) :: parse_tree
    type(ifile_t) :: ifile
    type(lexer_t) :: lexer
    type(stream_t), target :: stream_tmp
    call slha_preprocess (stream, ifile)
    call stream_init (stream_tmp, ifile)
    call lexer_init_slha (lexer)
    call lexer_assign_stream (lexer, stream_tmp)
    call parse_tree_init (parse_tree, syntax_slha, lexer)
    call lexer_final (lexer)
    call stream_final (stream_tmp)
    call ifile_final (ifile)
end subroutine slha_parse_stream

```

Read a SLHA file chosen by name. Check first the current directory, then the directory where SUSY input files should be located.

(SLHA: procedures)+≡

```

subroutine slha_parse_file (file, os_data, parse_tree)
    type(string_t), intent(in) :: file
    type(os_data_t), intent(in) :: os_data
    type(parse_tree_t), intent(out) :: parse_tree
    logical :: exist
    type(string_t) :: filename

```

```

type(stream_t), target :: stream
call msg_message ("Reading SLHA input file '" // char (file) // "'")
filename = file
inquire (file=char(filename), exist=exist)
if (.not. exist) then
  filename = os_data%whizard_susypath // "/" // file
  inquire (file=char(filename), exist=exist)
  if (.not. exist) then
    call msg_fatal ("SLHA input file '" // char (file) // "' not found")
    return
  end if
end if
call stream_init (stream, char (filename))
call slha_parse_stream (stream, parse_tree)
call stream_final (stream)
end subroutine slha_parse_file

```

18.0.8 API

Read the SLHA file, parse it, and interpret the parse tree. The model parameters retrieved from the file will be inserted into the appropriate model, which is loaded and modified in the background. The pointer to this model is returned as the last argument.

```

<SLHA: public>+≡
  public :: slha_read_file

<SLHA: procedures>+≡
  subroutine slha_read_file (file, os_data, model, input, spectrum, decays)
    type(string_t), intent(in) :: file
    type(os_data_t), intent(in) :: os_data
    ! type(model_t), pointer, intent(out) :: model
    type(model_t), pointer, intent(inout) :: model
    logical, intent(in) :: input, spectrum, decays
    type(parse_tree_t) :: parse_tree
    call slha_parse_file (file, os_data, parse_tree)
    if (associated (parse_tree_get_root_ptr (parse_tree))) then
      call slha_interpret_parse_tree &
        (parse_tree, os_data, model, input, spectrum, decays)
      call parse_tree_final (parse_tree)
      call model_parameters_update (model)
    end if
  end subroutine slha_read_file

```

Write the SLHA contents, as far as possible, to external file.

```

<SLHA: public>+≡
  public :: slha_write_file

<SLHA: procedures>+≡
  subroutine slha_write_file (file, model, input, spectrum, decays)
    type(string_t), intent(in) :: file
    type(model_t), target, intent(in) :: model
    logical, intent(in) :: input, spectrum, decays

```

```

integer :: mssm_type
integer :: u
u = free_unit ()
call msg_message ("Writing SLHA output file '" // char (file) // "'")
open (unit=u, file=char(file), action="write", status="replace")
write (u, "(A)")  "# SUSY Les Houches Accord"
write (u, "(A)")  "# Output generated by " // trim (VERSION_STRING)
call slha_write_MODSEL (u, model, mssm_type)
if (input) then
    call slha_write_SMINPUTS (u, model)
    call slha_write_MINPAR (u, model, mssm_type)
end if
if (spectrum) then
    call msg_bug ("SLHA: spectrum output not supported yet")
end if
if (decays) then
    call msg_bug ("SLHA: decays output not supported yet")
end if
close (u)
end subroutine slha_write_file

```

18.0.9 Test

(SLHA: public)+≡

```
public :: slha_test
```

(SLHA: procedures)+≡

```

subroutine slha_test ()
    type(os_data_t), pointer :: os_data => null ()
    type(parse_tree_t), pointer :: parse_tree => null ()
    integer :: unit
    character(*), parameter :: file_test = "slha_test.out"
    character(*), parameter :: file_slha = "slha_test.dat"
    type(model_list_t) :: model_list
    type(model_t), pointer :: model => null ()
    allocate (os_data)
    allocate (parse_tree)
    call os_data_init (os_data)
    call model_list%read_model (var_str("MSSM"), var_str("MSSM.mdl"), os_data, model)
    call slha_parse_file (var_str ("spslap_decays.slha"), os_data, parse_tree)
    call msg_message ("Writing parse tree to '" // file_test // "'")
    unit = free_unit ()
    open (unit=unit, file=file_test, action="write", status="replace")
    call parse_tree_write (parse_tree, unit)
    call slha_interpret_parse_tree (parse_tree, os_data, model, &
        input=.true., spectrum=.true., decays=.true.)
    call parse_tree_final (parse_tree)
    call var_list_write (model_get_var_list_ptr (model), only_type=V_REAL)
    call msg_message ("Writing SLHA output to '" // file_slha // "'")
    call slha_write_file (var_str (file_slha), model, input=.true., &
        spectrum=.false., decays=.false.)
    call parse_tree_final (parse_tree)
    deallocate (parse_tree)

```

```
      deallocate (os_data)
end subroutine slha_test
```

Chapter 19

Integration and simulation

This layer of modules is just below the top-level API. We lay out specific data types for integration and simulation and implement the corresponding algorithms as methods acting on them. This helps to keep the command-level implementation concise and simple.

19.1 Iterations

This module defines a container for the list of iterations and calls, to be submitted to integration.

```
<iterations.f90>≡  
  <File header>  
  
  module iterations  
  
    <Use strings>  
    <Use file utils>  
    use limits, only: ITERATIONS_DEFAULT_LIST_SIZE !NODEP!  
    use diagnostics !NODEP!  
    use unit_tests  
    use processes  
  
    <Standard module head>  
  
    <Iterations: public>  
  
    <Iterations: types>  
  
    <Iterations: interfaces>  
  
    contains  
  
    <Iterations: procedures>  
  
    <Iterations: tests>  
  
  end module iterations
```

19.1.1 The iterations list

Each integration pass has a number of iterations and a number of calls per iteration. The last pass produces the end result; the previous passes are used for adaptation.

The flags `adapt_grid` and `adapt_weight` are used only if `custom_adaptation` is set. Otherwise, default settings are used that depend on the integration pass.

```
<Iterations: types>≡
  type :: iterations_spec_t
  private
    integer :: n_it = 0
    integer :: n_calls = 0
    logical :: custom_adaptation = .false.
    logical :: adapt_grids = .false.
    logical :: adapt_weights = .false.
  end type iterations_spec_t
```

We build up a list of iterations.

```
<Iterations: public>≡
  public :: iterations_list_t
```

```
<Iterations: types>+≡
  type :: iterations_list_t
  private
    integer :: n_pass = 0
    type(iterations_spec_t), dimension(:), allocatable :: pass
  contains
    <Iterations: iterations list: TBP>
  end type iterations_list_t
```

```
<Iterations: iterations list: TBP>≡
  procedure :: init => iterations_list_init
```

```
<Iterations: procedures>≡
  subroutine iterations_list_init (it_list, n_it, n_calls, adapt, adapt_code)
    class(iterations_list_t), intent(inout) :: it_list
    integer, dimension(:), intent(in) :: n_it, n_calls
    logical, dimension(:), intent(in), optional :: adapt
    type(string_t), dimension(:), intent(in), optional :: adapt_code
    it_list%n_pass = size (n_it)
    if (allocated (it_list%pass)) deallocate (it_list%pass)
    allocate (it_list%pass (it_list%n_pass))
    it_list%pass%n_it = n_it
    it_list%pass%n_calls = n_calls
    if (present (adapt)) then
      it_list%pass%custom_adaptation = adapt
      if (any (verify (adapt_code, "wg") /= 0)) then
        call msg_error ("iteration specification: " &
          // "adaptation code letters must be 'w' or 'g'")
      end if
      it_list%pass%adapt_grids = scan (adapt_code, "g") /= 0
      it_list%pass%adapt_weights = scan (adapt_code, "w") /= 0
    end if
  end subroutine iterations_list_init
```

Fill all zero entries by corresponding entries from a default iterations list:

```

<CCC Iterations: public>≡
    public :: iterations_list_complete

<CCC Iterations: procedures>≡
    subroutine iterations_list_complete (it_list, it_list_default)
        type(iterations_list_t), intent(inout) :: it_list
        type(iterations_list_t), intent(in) :: it_list_default
        if (it_list%n_pass >= 1) then
            if (it_list%pass(1)%n_it == 0) &
                it_list%pass(1)%n_it = it_list_default%pass(1)%n_it
            if (it_list%pass(1)%n_calls == 0) &
                it_list%pass(1)%n_calls = it_list_default%pass(1)%n_calls
        end if
        if (it_list%n_pass >= 2) then
            where (it_list%pass%n_it == 0) &
                it_list%pass%n_it = it_list_default%pass(2)%n_it
            where (it_list%pass%n_calls == 0) &
                it_list%pass%n_calls = it_list_default%pass(2)%n_calls
        end if
    end subroutine iterations_list_complete

<Iterations: iterations list: TBP>+≡
    procedure :: clear => iterations_list_clear

<Iterations: procedures>+≡
    subroutine iterations_list_clear (it_list)
        class(iterations_list_t), intent(inout) :: it_list
        it_list%n_pass = 0
        deallocate (it_list%pass)
    end subroutine iterations_list_clear

```

Write the list of iterations as a message.

```

<Iterations: iterations list: TBP>+≡
    procedure :: write => iterations_list_write

<Iterations: procedures>+≡
    subroutine iterations_list_write (it_list, unit)
        class(iterations_list_t), intent(in) :: it_list
        integer, intent(in), optional :: unit
        integer :: u
        type(string_t) :: buffer
        character(30) :: ibuf
        integer :: i
        u = output_unit (unit)
        buffer = "iterations = "
        if (it_list%n_pass > 0) then
            do i = 1, it_list%n_pass
                if (i > 1) buffer = buffer // ", "
                write (ibuf, "(I0,':',I0)") &
                    it_list%pass(i)%n_it, it_list%pass(i)%n_calls
                buffer = buffer // trim (ibuf)
                if (it_list%pass(i)%custom_adaptation) then

```

```

        buffer = buffer // ':'
        if (it_list%pass(i)%adapt_grids) buffer = buffer // "g"
        if (it_list%pass(i)%adapt_weights) buffer = buffer // "w"
        buffer = buffer // ','
    end if
end do
else
    buffer = buffer // "[undefined]"
end if
!    call msg_message (char (buffer), unit)
    write (u, "(A)") char (buffer)
end subroutine iterations_list_write

```

19.1.2 Tools

Transform the iterations list into arrays that indicate pass index and number of calls for each iteration.

<CCC Iterations: public>+≡

```

public :: iterations_list_get_pass_array
public :: iterations_list_get_n_calls_array

```

<CCC Iterations: procedures>+≡

```

function iterations_list_get_pass_array (it_list) result (pass)
    integer, dimension(:), allocatable :: pass
    type(iterations_list_t), intent(in) :: it_list
    integer :: it, i
    allocate (pass (sum (it_list%pass%n_it)))
    it = 0
    do i = 1, it_list%n_pass
        pass(it+1 : it+it_list%pass(i)%n_it) = i
        it = it + it_list%pass(i)%n_it
    end do
end function iterations_list_get_pass_array

function iterations_list_get_n_calls_array (it_list) result (n_calls)
    integer, dimension(:), allocatable :: n_calls
    type(iterations_list_t), intent(in) :: it_list
    integer :: it, i
    allocate (n_calls (sum (it_list%pass%n_it)))
    it = 0
    do i = 1, it_list%n_pass
        n_calls(it+1 : it+it_list%pass(i)%n_it) = it_list%pass(i)%n_calls
        it = it + it_list%pass(i)%n_it
    end do
end function iterations_list_get_n_calls_array

```

Return the total number of passes.

<Iterations: iterations list: TBP>+≡

```

procedure :: get_n_pass => iterations_list_get_n_pass

```

<Iterations: procedures>+≡

```

function iterations_list_get_n_pass (it_list) result (n_pass)
    class(iterations_list_t), intent(in) :: it_list

```

```

integer :: n_pass
n_pass = it_list%n_pass
end function iterations_list_get_n_pass

```

Return the number of calls for a specific pass.

<Iterations: iterations list: TBP>+≡

```

procedure :: get_n_calls => iterations_list_get_n_calls

```

<Iterations: procedures>+≡

```

function iterations_list_get_n_calls (it_list, pass) result (n_calls)
class(iterations_list_t), intent(in) :: it_list
integer :: n_calls
integer, intent(in) :: pass
if (pass <= it_list%n_pass) then
    n_calls = it_list%pass(pass)%n_calls
else
    n_calls = 0
end if
end function iterations_list_get_n_calls

```

Get the adaptation mode (automatic/custom) and, for custom adaptation, the flags for a specific pass.

<CCC Iterations: public>+≡

```

public :: iterations_list_has_custom_adaptation
public :: iterations_list_adapt_grids
public :: iterations_list_adapt_weights

```

<Iterations: iterations list: TBP>+≡

```

procedure :: adapt_grids => iterations_list_adapt_grids
procedure :: adapt_weights => iterations_list_adapt_weights

```

<Iterations: procedures>+≡

```

!!! JRR: WK please check. Still needed?
!   function iterations_list_has_custom_adaptation (it_list, pass) result (flag)
!       logical :: flag
!       type(iterations_list_t), intent(in) :: it_list
!       integer, intent(in) :: pass
!       if (pass <= it_list%n_pass) then
!           flag = it_list%pass(pass)%custom_adaptation
!       else
!           flag = .false.
!       end if
!   end function iterations_list_has_custom_adaptation

```

```

function iterations_list_adapt_grids (it_list, pass) result (flag)
logical :: flag
class(iterations_list_t), intent(in) :: it_list
integer, intent(in) :: pass
if (pass <= it_list%n_pass) then
    flag = it_list%pass(pass)%adapt_grids
else
    flag = .false.
end if
end function iterations_list_adapt_grids

```

```

function iterations_list_adapt_weights (it_list, pass) result (flag)
  logical :: flag
  class(iterations_list_t), intent(in) :: it_list
  integer, intent(in) :: pass
  if (pass <= it_list%n_pass) then
    flag = it_list%pass(pass)%adapt_weights
  else
    flag = .false.
  end if
end function iterations_list_adapt_weights

```

Return the total number of iterations / the iterations for a specific pass.

<Iterations: iterations list: TBP>+≡

```

  procedure :: get_n_it => iterations_list_get_n_it

```

<CCC Iterations: interfaces>≡

```

  interface iterations_list_get_n_it
    module procedure iterations_list_get_n_it_tot
    module procedure iterations_list_get_n_it_pass
  end interface

```

<Iterations: procedures>+≡

```

!   function iterations_list_get_n_it_tot (it_list) result (n_it)
!     integer :: n_it
!     type(iterations_list_t), intent(in) :: it_list
!     n_it = sum (it_list%pass%n_it)
!   end function iterations_list_get_n_it_tot

```

```

function iterations_list_get_n_it (it_list, pass) result (n_it)
  class(iterations_list_t), intent(in) :: it_list
  integer :: n_it
  integer, intent(in) :: pass
  if (pass <= it_list%n_pass) then
    n_it = it_list%pass(pass)%n_it
  else
    n_it = 0
  end if
end function iterations_list_get_n_it

```

This routine corrects for a number of calls that is too low.

<CCC Iterations: public>+≡

```

  public :: iterations_list_adjust_n_calls

```

<CCC Iterations: procedures>+≡

```

  subroutine iterations_list_adjust_n_calls (it_list, process, grid_parameters)
    type(iterations_list_t), intent(inout), target :: it_list
    type(process_t), intent(in) :: process
    type(grid_parameters_t), intent(in) :: grid_parameters
    type(iterations_spec_t), pointer :: it_spec
    integer :: n_calls, pass
    logical :: changed
    changed = .false.

```

```

do pass = 1, it_list%n_pass
  it_spec => it_list%pass(pass)
  n_calls = max (it_spec%n_calls, &
    process_get_n_channels (process) &
    * grid_parameters%min_calls_per_channel)
  if (n_calls /= it_spec%n_calls) then
    it_spec%n_calls = n_calls
    changed = .true.
  end if
end do
if (changed) then
  write (msg_buffer, "(A,I0)") "Process '" &
    // char (process_get_id (process)) // "' : " &
    // "resetting n_calls to ", n_calls
  call msg_warning ()
end if
end subroutine iterations_list_adjust_n_calls

```

Allocate the default iterations lists and fill with some sensible values. This is implemented as a pointer since it is not intended to be modified by the user; the local RT dataset will thus contain another pointer to the same list, not a copy.

```

<Limits: public parameters>+≡
  integer, parameter, public :: ITERATIONS_DEFAULT_LIST_SIZE = 7
<CCC Iterations: public>+≡
  public :: iterations_lists_init_default
<CCC Iterations: procedures>+≡

  end subroutine iterations_lists_init_default

```

19.1.3 Test

This is the master for calling self-test procedures.

```

<Iterations: public>+≡
  public :: iterations_test
<Iterations: tests>≡
  subroutine iterations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Iterations: execute tests>
  end subroutine iterations_test

```

Empty list

```
<Iterations: execute tests>≡
  call test (iterations_1, "iterations_1", &
    "empty iterations list", &
    u, results)

<Iterations: tests>+≡
  subroutine iterations_1 (u)
    integer, intent(in) :: u
    type(iterations_list_t) :: it_list

    write (u, "(A)")  "* Test output: iterations_1"
    write (u, "(A)")  "* Purpose: display empty iterations list"
    write (u, "(A)")

    call it_list%write (u)

    write (u, "(A)")
    write (u, "(A)")  "* Test output end: iterations_1"

  end subroutine iterations_1
```

Fill list

```
<Iterations: execute tests>+≡
  call test (iterations_2, "iterations_2", &
    "create iterations list", &
    u, results)

<Iterations: tests>+≡
  subroutine iterations_2 (u)
    integer, intent(in) :: u
    type(iterations_list_t) :: it_list

    write (u, "(A)")  "* Test output: iterations_2"
    write (u, "(A)")  "* Purpose: fill and display iterations list"
    write (u, "(A)")

    write (u, "(A)")  "* Minimal setup (2 passes)"
    write (u, "(A)")

    call it_list%init ([2, 4], [5000, 20000])

    call it_list%write (u)
    call it_list%clear ()

    write (u, "(A)")
    write (u, "(A)")  "* Setup with flags (3 passes)"
    write (u, "(A)")

    call it_list%init ([2, 4, 5], [5000, 20000, 400], &
      [.false., .true., .true.], &
      [var_str (""), var_str ("g"), var_str ("wg")])
```

```

call it_list%write (u)

write (u, "(A)")
write (u, "(A)")  "* Extract data"
write (u, "(A)")

write (u, "(A,I0)")  "n_pass = ", it_list%get_n_pass ()
write (u, "(A)")

write (u, "(A)")
write (u, "(A,I0)")  "n_it(3) = ", it_list%get_n_it (3)

write (u, "(A)")
write (u, "(A)")  "* Test output end: iterations_2"

end subroutine iterations_2

```

19.2 Beam polarization

Beam polarization is encapsulated in a designated type and only converted into a density matrix when the beams are actually initialized — the flavor information necessary for initialization is not available earlier.

```

⟨beam_polarizations.f90⟩≡
  ⟨File header⟩

  module beam_polarizations

    ⟨Use kinds⟩
    ⟨Use strings⟩
    ⟨Use file utils⟩
    use diagnostics !NODEP!
    use flavors
    use polarizations

    ⟨Standard module head⟩

    ⟨Beam polarizations: public⟩

    ⟨Beam polarizations: parameters⟩

    ⟨Beam polarizations: types⟩

    contains

    ⟨Beam polarizations: procedures⟩

  end module beam_polarizations

```

19.2.1 Parameters and type definition

```
<Beam polarizations: public>≡
  public :: BP_NONE, BP_CIRC, BP_TRANS, BP_LONG, BP_AXIS, BP_DIAG, BP_DENSITY
  public :: BP_TRIVIAL
  public :: beam_polarization_t

```

19.3 Beam structure

This module stores the beam structure definition as it is declared in the SIN-DARIN script. The structure definition is not analyzed, just recorded for later use.

```

⟨beam_structures.f90⟩≡
  ⟨File header⟩

  module beam_structures

    ⟨Use strings⟩
    ⟨Use file utils⟩
    use diagnostics !NODEP!
    use unit_tests
    use variables

    ⟨Standard module head⟩

    ⟨Beam structures: public⟩

```

```

    <Beam structures: types>

    <Beam structures: interfaces>

    contains

    <Beam structures: procedures>

    <Beam structures: tests>

    end module beam_structures

```

19.3.1 Beam structure elements

An entry in a beam-structure record consists of a string that denotes a type of structure function.

```

<Beam structures: types>≡
    type :: beam_structure_entry_t
        logical :: is_valid = .false.
        type(string_t) :: name
    contains
    <Beam structures: beam structure entry: TBP>
    end type beam_structure_entry_t

```

Output.

```

<Beam structures: beam structure entry: TBP>≡
    procedure :: to_string => beam_structure_entry_to_string

<Beam structures: procedures>≡
    function beam_structure_entry_to_string (object) result (string)
        class (beam_structure_entry_t), intent(in) :: object
        type(string_t) :: string
        if (object%is_valid) then
            string = object%name
        else
            string = "none"
        end if
    end function beam_structure_entry_to_string

```

A record in the beam-structure sequence denotes either a structure-function entry, a pair of such entries, or a pair spectrum.

```

<Beam structures: types>+≡
    type :: beam_structure_record_t
        type (beam_structure_entry_t), dimension(:), allocatable :: entry
    end type beam_structure_record_t

```

19.3.2 Beam structure type

The beam-structure object is a sequence of records.

```

<Beam structures: public>≡

```

```

    public :: beam_structure_t
<Beam structures: types>+≡
    type :: beam_structure_t
        type (beam_structure_record_t), dimension(:), allocatable :: record
        type (var_list_t) :: var_list
    contains
        <Beam structures: beam structure: TBP>
    end type beam_structure_t

```

Output. The actual information fits in a single line, therefore we can provide a `to_string` method.

```

<Beam structures: beam structure: TBP>≡
    procedure :: write => beam_structure_write
    procedure :: to_string => beam_structure_to_string
<Beam structures: procedures>+≡

                    end do
                end do
            else
                string = "[trivial]"
            end if
        else
            string = "[undefined]"
        end if
    end function beam_structure_to_string

```

Initializer: dimension the beam structure record. Each array element denotes the number of entries for a record within the beam-structure sequence. The number of entries is either one or two, while the number of records is unlimited.

```

<Beam structures: beam structure: TBP>+=
  procedure :: init => beam_structure_init

<Beam structures: procedures>+=
  subroutine beam_structure_init (beam_structure, dim_array, var_list)
    class(beam_structure_t), intent(out) :: beam_structure
    integer, dimension(:), intent(in) :: dim_array
    type(var_list_t), intent(in) :: var_list
    integer :: i
    allocate (beam_structure%record (size (dim_array)))
    do i = 1, size (dim_array)
      allocate (beam_structure%record(i)%entry (dim_array(i)))
    end do
    call var_list_init_snapshot (beam_structure%var_list, var_list)
  end subroutine beam_structure_init

```

Set an entry, specified by record number and entry number.

```

<Beam structures: beam structure: TBP>+=
  procedure :: set_entry => beam_structure_set_entry

<Beam structures: procedures>+=
  subroutine beam_structure_set_entry (beam_structure, i, j, name)
    class(beam_structure_t), intent(inout) :: beam_structure
    integer, intent(in) :: i, j
    type(string_t), intent(in) :: name
    associate (entry => beam_structure%record(i)%entry(j))
      entry%name = name
      entry%is_valid = .true.
    end associate
  end subroutine beam_structure_set_entry

```

Expand the beam-structure object. (i) For a pair spectrum, keep the entry. (ii) For a single-particle structure function written as a single entry, replace this by a record with two entries. (ii) For a record with two nontrivial entries, separate this into two records with one trivial entry each.

To achieve this, we need a function that tells us whether an entry is a spectrum or a structure function. It returns 0 for a trivial entry, 1 for a single-particle structure function, and 2 for a two-particle spectrum.

```

<Beam structures: interfaces>=
  abstract interface
    function strfun_mode_fun (name) result (n)
      import
      type(string_t), intent(in) :: name
      integer :: n
    end function strfun_mode_fun
  end interface

```

Algorithm: (1) Mark entries as invalid where necessary. (2) Count the number of entries that we will need. (3) Expand and copy entries to a new record array. (4) Replace the old array by the new one.

19.3.3 Get contents

Return the number of records.

```

(Beam structures: beam structure: TBP)+≡
    procedure :: get_n_record => beam_structure_get_n_record

(Beam structures: procedures)+≡
    function beam_structure_get_n_record (beam_structure) result (n)
        class(beam_structure_t), intent(in) :: beam_structure
        integer :: n
        if (allocated (beam_structure%record)) then
            n = size (beam_structure%record)
        else
            n = 0
        end if
    end function beam_structure_get_n_record

```

Return an array consisting of the beam indices affected by the valid entries within a record. After expansion, there should be exactly one valid entry per record.

```

(Beam structures: beam structure: TBP)+≡
    procedure :: get_i_entry => beam_structure_get_i_entry

```

```

<Beam structures: procedures>+≡
function beam_structure_get_i_entry (beam_structure, i) result (i_entry)
  class(beam_structure_t), intent(in) :: beam_structure
  integer, intent(in) :: i
  integer, dimension(:), allocatable :: i_entry
  integer :: j
  associate (record => beam_structure%record(i))
    select case (size (record%entry))
    case (1)
      if (record%entry(1)%is_valid) then
        allocate (i_entry (2), source = [1, 2])
      else
        allocate (i_entry (0))
      end if
    case (2)

      name = record%entry(1)%name
    else if (size (record%entry) == 2) then
      name = record%entry(2)%name
    end if
  end associate
end function beam_structure_get_name

```

19.3.4 Unit Tests

```

<Beam structures: public>+≡
public :: beam_structures_test

```

```

<Beam structures: tests>≡
  subroutine beam_structures_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Beam structures: execute tests>
  end subroutine beam_structures_test

```

Empty structure

```

<Beam structures: execute tests>≡
  call test (beam_structures_1, "beam_structures_1", &
    "empty beam structure record", &
    u, results)

<Beam structures: tests>+≡
  subroutine beam_structures_1 (u)
    integer, intent(in) :: u
    type(beam_structure_t) :: beam_structure

    write (u, "(A)")  "* Test output: beam_structures_1"
    write (u, "(A)")  "* Purpose: display empty beam structure record"
    write (u, "(A)")

    call beam_structure%write (u)

    write (u, "(A)")
    write (u, "(A)")  "* Test output end: beam_structures_1"

  end subroutine beam_structures_1

```

Nontrivial configurations

```

<Beam structures: execute tests>+≡
  call test (beam_structures_2, "beam_structures_2", &
    "beam structure records", &
    u, results)

<Beam structures: tests>+≡
  subroutine beam_structures_2 (u)
    integer, intent(in) :: u
    type(beam_structure_t) :: beam_structure
    integer, dimension(0) :: empty_array
    type(var_list_t) :: var_list

    write (u, "(A)")  "* Test output: beam_structures_2"
    write (u, "(A)")  "* Purpose: setup beam structure records"
    write (u, "(A)")

    call var_list_append_int (var_list, var_str ("foo"), 42)

    call beam_structure%init (empty_array, var_list)
    call beam_structure%write (u)

```

```

write (u, "(A)")
write (u, "(1x,A)" "Variables:")
call var_list_write (beam_structure%var_list, u)

write (u, "(A)")

call beam_structure%init ([1], var_list)
call beam_structure%set_entry (1, 1, var_str ("a"))
call beam_structure%write (u)

call beam_structure%set_entry (1, 2, var_str ("b"))
call beam_structure%set_entry (2, 1, var_str ("c"))
call beam_structure%write (u)

write (u, "(A)")
write (u, "(A)" " * Test output end: beam_structures_2"

end subroutine beam_structures_2

```

Expansion

Provide a function that tells, for the dummy structure function names used here, whether they are considered a two-particle spectrum or a single-particle structure function:

```

<Beam structures: tests>+≡
function test_strfun_mode (name) result (n)
  type(string_t), intent(in) :: name
  integer :: n
  select case (char (name))
    case ("a"); n = 2
    case ("b"); n = 1
    case default; n = 0
  end select
end function test_strfun_mode

<Beam structures: execute tests>+≡
call test (beam_structures_3, "beam_structures_3", &
  "beam structure expansion", &
  u, results)

```

```

(Beam structures: tests) +=
subroutine beam_structures_3 (u)
  integer, intent(in) :: u
  type(beam_structure_t) :: beam_structure
  type(var_list_t) :: var_list

  write (u, "(A)")  "* Test output: beam_structures_3"
  write (u, "(A)")  "* Purpose: expand beam structure records"
  write (u, "(A)")

  write (u, "(A)")  "* Pair spectrum (keep as-is)"
  write (u, "(A)")

  call beam_structure%init ([1], var_list)
  call beam_structure%set_entry (1, 1, var_str ("a"))
  call beam_structure%write (u)

  write (u, "(A)")

  call beam_structure%expand (test_strfun_mode)
  call beam_structure%write (u)

  write (u, "(A)")
  write (u, "(A)")  "* Structure function pair (expand)"
  write (u, "(A)")

  call beam_structure%init ([2], var_list)
  call beam_structure%set_entry (1, 1, var_str ("b"))
  call beam_structure%set_entry (1, 2, var_str ("b"))
  call beam_structure%write (u)

  write (u, "(A)")

  call beam_structure%expand (test_strfun_mode)
  call beam_structure%write (u)

  write (u, "(A)")
  write (u, "(A)")  "* Structure function (separate and expand)"
  write (u, "(A)")

  call beam_structure%init ([1], var_list)
  call beam_structure%set_entry (1, 1, var_str ("b"))
  call beam_structure%write (u)

  write (u, "(A)")

  call beam_structure%expand (test_strfun_mode)
  call beam_structure%write (u)

  write (u, "(A)")
  write (u, "(A)")  "* Combination"
  write (u, "(A)")

  call beam_structure%init ([1, 1], var_list)

```

```

call beam_structure%set_entry (1, 1, var_str ("a"))
call beam_structure%set_entry (2, 1, var_str ("b"))
call beam_structure%write (u)

write (u, "(A)")

call beam_structure%expand (test_strfun_mode)
call beam_structure%write (u)

write (u, "(A)")
write (u, "(A)")  "* Test output end: beam_structures_3"

end subroutine beam_structures_3

```

Public methods

Check the methods that can be called to get the beam-structure contents.

```

<Beam structures: execute tests>+≡
  call test (beam_structures_4, "beam_structures_4", &
    "beam structure contents", &
    u, results)

<Beam structures: tests>+≡
subroutine beam_structures_4 (u)
  integer, intent(in) :: u
  type(beam_structure_t) :: beam_structure
  type(var_list_t) :: var_list
  integer :: i

  write (u, "(A)")  "* Test output: beam_structures_4"
  write (u, "(A)")  "* Purpose: check the API"
  write (u, "(A)")

  write (u, "(A)")  "* Structure-function combination"
  write (u, "(A)")

  call beam_structure%init ([1, 2, 2], var_list)
  call beam_structure%set_entry (1, 1, var_str ("a"))
  call beam_structure%set_entry (2, 1, var_str ("b"))
  call beam_structure%set_entry (3, 2, var_str ("c"))
  call beam_structure%write (u)

  write (u, "(A)")
  write (u, "(1x,A,I0)")  "n_record = ", beam_structure%get_n_record ()

  do i = 1, 3
    write (u, "(A)")
    write (u, "(1x,A,I0,A,A)")  "name(", i, ") = ", &
      char (beam_structure%get_name (i))
    write (u, "(1x,A,I0,A,2(1x,I0))")  "i_entry(", i, ") =", &
      beam_structure%get_i_entry (i)
  end do

```

```

write (u, "(A)")
write (u, "(A)")  "* Test output end: beam_structures_4"

end subroutine beam_structures_4

```

19.4 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```

⟨user_files.f90⟩≡
  ⟨File header⟩

  module user_files

    ⟨Use strings⟩
    ⟨Use file utils⟩
    use diagnostics !NODEP!
    use ifiles
    use analysis

    ⟨Standard module head⟩

    ⟨User files: public⟩

    ⟨User files: types⟩

    ⟨User files: interfaces⟩

    contains

    ⟨User files: procedures⟩

  end module user_files

```

19.4.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```

⟨User files: types⟩≡
  type :: file_t
    private
    type(string_t) :: name
    integer :: unit = -1
    logical :: reading = .false.
    logical :: writing = .false.
    type(file_t), pointer :: prev => null ()
    type(file_t), pointer :: next => null ()
  end type file_t

```

The initializer opens the file.

```
<User files: procedures>+=
subroutine file_init (file, name, action, status, position)
  type(file_t), intent(out) :: file
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position
  file%unit = free_unit ()
  file%name = name
  open (unit = file%unit, file = char (file%name), &
        action = action, status = status, position = position)
  select case (action)
  case ("read")
    file%reading = .true.
  case ("write")
    file%writing = .true.
  case ("readwrite")
    file%reading = .true.
    file%writing = .true.
  end select
end subroutine file_init
```

The finalizer closes it.

```
<User files: procedures>+=
subroutine file_final (file)
  type(file_t), intent(inout) :: file
  close (unit = file%unit)
  file%unit = -1
end subroutine file_final
```

Check if a file is open with correct status.

```
<User files: procedures>+=
function file_is_open (file, action) result (flag)
  logical :: flag
  type(file_t), intent(in) :: file
  character(*), intent(in) :: action
  select case (action)
  case ("read")
    flag = file%reading
  case ("write")
    flag = file%writing
  case ("readwrite")
    flag = file%reading .and. file%writing
  case default
    call msg_bug ("Checking file '" // char (file%name) &
                  // "': illegal action specifier")
  end select
end function file_is_open
```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the `advancing` option.

```
<User files: procedures>+=
subroutine file_write_string (file, string, advancing)
```

```

type(file_t), intent(in) :: file
type(string_t), intent(in), optional :: string
logical, intent(in), optional :: advancing
if (file%writing) then
  if (present (string)) then
    if (present (advancing)) then
      if (advancing) then
        write (file%unit, "(A)") char (string)
      else
        write (file%unit, "(A)", advance="no") char (string)
      end if
    else
      write (file%unit, "(A)") char (string)
    end if
  else
    write (file%unit, *)
  end if
else
  call msg_error ("Writing to file: File '" // char (file%name) &
    // "' is not open for writing.")
end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
subroutine file_write_ifile (file, ifile)
  type(file_t), intent(in) :: file
  type(ifile_t), intent(in) :: ifile
  type(line_p) :: line
  call line_init (line, ifile)
  do while (line_is_associated (line))
    call file_write_string (file, line_get_string_advance (line))
  end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
subroutine file_write_analysis (file, tag)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: tag
  if (file%writing) then
    if (present (tag)) then
      call analysis_write (tag, unit = file%unit)
    else
      call analysis_write (unit = file%unit)
    end if
  else
    call msg_error ("Writing analysis to file: File '" // char (file%name) &
      // "' is not open for writing.")
  end if
end subroutine file_write_analysis

```

19.4.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```
<User files: public>≡
    public :: file_list_t

<User files: types>+≡
    type :: file_list_t
        type(file_t), pointer :: first => null ()
        type(file_t), pointer :: last => null ()
    end type file_list_t
```

There is no initialization routine, but a finalizer which deletes all:

```
<User files: public>+≡
    public :: file_list_final

<User files: procedures>+≡
    subroutine file_list_final (file_list)
        type(file_list_t), intent(inout) :: file_list
        type(file_t), pointer :: current
        do while (associated (file_list%first))
            current => file_list%first
            file_list%first => current%next
            call file_final (current)
            deallocate (current)
        end do
        file_list%last => null ()
    end subroutine file_list_final
```

Find an entry in the list. Return null pointer on failure.

```
<User files: procedures>+≡
    function file_list_get_file_ptr (file_list, name) result (current)
        type(file_t), pointer :: current
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        current => file_list%first
        do while (associated (current))
            if (current%name == name) return
            current => current%next
        end do
    end function file_list_get_file_ptr
```

Check if a file is open, public version:

```
<User files: public>+≡
    public :: file_list_is_open

<User files: procedures>+≡
    function file_list_is_open (file_list, name, action) result (flag)
        logical :: flag
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action
        type(file_t), pointer :: current
```

```

current => file_list_get_file_ptr (file_list, name)
if (associated (current)) then
    flag = file_is_open (current, action)
else
    flag = .false.
end if
end function file_list_is_open

```

Append a new file entry, i.e., open this file. Error if it is already open.

```

<User files: public>+≡
    public :: file_list_open

<User files: procedures>+≡
    subroutine file_list_open (file_list, name, action, status, position)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action, status, position
        type(file_t), pointer :: current
        if (.not. associated (file_list_get_file_ptr (file_list, name))) then
            allocate (current)
            call file_init (current, name, action, status, position)
            if (associated (file_list%last)) then
                file_list%last%next => current
                current%prev => file_list%last
            else
                file_list%first => current
            end if
            file_list%last => current
        else
            call msg_error ("Opening file: File '" // char (name) &
                // "' is already open.")
        end if
    end subroutine file_list_open

```

Delete a file entry, i.e., close this file. Error if it is not open.

```

<User files: public>+≡
    public :: file_list_close

<User files: procedures>+≡
    subroutine file_list_close (file_list, name)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            if (associated (current%prev)) then
                current%prev%next => current%next
            else
                file_list%first => current%next
            end if
            if (associated (current%next)) then
                current%next%prev => current%prev
            else
                file_list%last => current%prev
            end if
        end if
    end subroutine file_list_close

```

```

        end if
        call file_final (current)
        deallocate (current)
    else
        call msg_error ("Closing file: File '" // char (name) &
            // "' is not open.")
    end if
end subroutine file_list_close

```

Write a string to file. Error if it is not open.

```

<User files: public>+≡
    public :: file_list_write

<User files: interfaces>≡
    interface file_list_write
        module procedure file_list_write_string
        module procedure file_list_write_ifile
    end interface

<User files: procedures>+≡
    subroutine file_list_write_string (file_list, name, string, advancing)
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        type(string_t), intent(in), optional :: string
        logical, intent(in), optional :: advancing

19.5.1 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()
    type(parse_node_t), pointer :: fac_scale_expr => null ()
    type(parse_node_t), pointer :: ren_scale_expr => null ()
    type(parse_node_t), pointer :: weight_expr => null ()
    type(parse_node_t), pointer :: selection_lexpr => null ()
    type(parse_node_t), pointer :: reweight_expr => null ()
    type(parse_node_t), pointer :: analysis_lexpr => null ()
  contains
    <RT data: rt parse nodes: TBP>
  end type rt_parse_nodes_t

```

Output for the parse nodes.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: write => rt_parse_nodes_write

<RT data: procedures>≡
  subroutine rt_parse_nodes_write (object, unit)
    class(rt_parse_nodes_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    call wrt ("Cuts", object%cuts_lexpr)
    call write_separator (u)
  end subroutine

```

```

call wrt ("Scale", object%scale_expr)

19.5.5 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```
<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init
<RT data: procedures>+≡
  subroutine rt_data_local_init (local, global, env)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(in), target :: global
    integer, intent(in), optional :: env
    call var_list_link (local%var_list, global%var_list)
    if (associated (global%model)) then
      call var_list_init_copies (local%var_list, &
        model_get_var_list_ptr (global%model), &
        derived_only = .true.)
    end if
    call local%init_pointer_variables ()
    local%os_data = global%os_data
    !   if (present (env)) local%environment = env
  end subroutine rt_data_local_init
```

This copies global objects, for which local modifications should be kept.

```
<RT data: rt data: TBP>+≡
  procedure :: copy_globals => rt_data_copy_globals
<RT data: procedures>+≡
  subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
    local%model_list = global%model_list
    local%prclib_stack = global%prclib_stack
    local%process_stack = global%process_stack
  end subroutine rt_data_copy_globals
```

These variables point to objects which get local copies:

```
<RT data: rt data: TBP>+≡
  procedure :: init_pointer_variables => rt_data_init_pointer_variables
<RT data: procedures>+≡
  subroutine rt_data_init_pointer_variables (local)
    class(rt_data_t), intent(inout), target :: local
    logical, target, save :: known = .true.
    call var_list_append_string_ptr &
      (local%var_list, var_str (" $fc"), local%os_data%fc, known, &
        intrinsic=.true.)
    call var_list_append_string_ptr &
      (local%var_list, var_str (" $fcflags"), local%os_data%fcflags, known, &
        intrinsic=.true.)
  end subroutine rt_data_init_pointer_variables
```

This is done at execution time: Copy data, transfer pointers. `local` has intent(inout) because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+=
  procedure :: link => rt_data_link
<RT data: procedures>+=
  subroutine rt_data_link (local, global)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(in), target :: global
    local%lexer => global%lexer
    call global%copy_globals (local)
    local%os_data = global%os_data
    call var_list_link (local%var_list, global%var_list)
    if (associated (global%model)) then
      local%model => &
        local%model_list%get_model_ptr (model_get_name (global%model))
      call var_list_synchronize (local%var_list, &
        model_get_var_list_ptr (local%model), reset_pointers = .true.)
    end if
    if (associated (global%prclib)) then
      local%prclib => &
        local%prclib_stack%get_library_ptr (global%prclib%get_name ())
    end if
    local%it_list = global%it_list
    !   local%it_list_default => global%it_list_default
    local%beam_data = global%beam_data
    local%beam_structure = global%beam_structure
    !!! JRR: WK please check
    !!! is this still needed
    !   local%lhpdf_status = global%lhpdf_status
    !   local%sf_list_allocated = .false.
    !   local%sf_list => global%sf_list
    local%pn = global%pn
    if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
    if (allocated (global%sample_fmt)) then
      allocate (local%sample_fmt (size (global%sample_fmt)), &
        source = global%sample_fmt)
    end if
    !   local%out_files => global%out_files
    !   local%rng => global%rng
    !   local%beam_polarization => global%beam_polarization
    !   local%analysis_data_unit = global%analysis_data_unit
  end subroutine rt_data_link

```

Restore the previous state of data; in particular, the variable list. This applies only to model variables (which are copies); other variables are automatically restored when local variables are removed.

Model list, process library stack, and process stack are copied back. Thus, they behave like global objects: all changes in the local environment are kept in the global context. Note that these are shallow copies.

Some command (`read_slha`) reads in model variables as local entities. In this case, the original values of model variables should not be restored, but the global variable list should be synchronized. However, this matters only if the local model is identical to the global model; otherwise, restoring will apply to a different model.

```

<RT data: rt data: TBP>+≡
  procedure :: restore => rt_data_restore

<RT data: procedures>+≡
  subroutine rt_data_restore (global, local, keep_model_vars)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(inout) :: local
    logical, intent(in), optional :: keep_model_vars
    logical :: same_model, restore
    if (associated (global%model)) then
      same_model = &
        model_get_name (global%model) == model_get_name (local%model)
      if (present (keep_model_vars) .and. same_model) then
        restore = .not. keep_model_vars
      else
        if (.not. same_model) call msg_message ("Restoring model '" // &
          char (model_get_name (global%model)) // "'")
        restore = .true.
      end if
    end if
    if (restore) then
      call var_list_restore (global%var_list)
    else
      call var_list_synchronize &
        (global%var_list, model_get_var_list_ptr (global%model))
    end if
  end if
  call var_list_undefine (local%var_list, follow_link=.false.)
  call global%restore_globals (local)
end subroutine rt_data_restore

```

This restores global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡
  procedure :: restore_globals => rt_data_restore_globals

<RT data: procedures>+≡
  subroutine rt_data_restore_globals (global, local)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(in) :: local
    global%model_list = local%model_list
    global%prclib_stack = local%prclib_stack
    global%process_stack = local%process_stack
  end subroutine rt_data_restore_globals

```

19.5.6 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```
<RT data: rt data: TBP>+≡
  procedure :: final => rt_data_global_final

<RT data: procedures>+≡
  subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
    call global%model_list%final ()
    call var_list_final (global%var_list)
    !   if (global%sf_list_allocated) then
    !       call sf_list_final (global%sf_list)
    !       deallocate (global%sf_list)
    !       global%sf_list_allocated = .false.
    !   end if
    deallocate (global%it_list_default)
    call file_list_final (global%out_files)
    deallocate (global%out_files)
    deallocate (global%rng)
  end subroutine rt_data_global_final
```

19.5.7 Filling Contents

Read a model, filling the model list component and assigning this as the current model. Copy the model variables to the global var list.

```
<RT data: rt data: TBP>+≡
  procedure :: read_model => rt_data_read_model

<RT data: procedures>+≡
  subroutine rt_data_read_model (global, name, filename, synchronize)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name, filename
    type(var_list_t), pointer :: model_vars
    logical, intent(in), optional :: synchronize
    logical :: sync
    sync = .true.; if (present (synchronize)) sync = synchronize
    call global%model_list%read_model &
      (name, filename, global%os_data, global%model)
    if (associated (global%model)) then
      call var_list_set_string (global%var_list, var_str ("$model_name"), &
        name, is_known = .true.)
      model_vars => model_get_var_list_ptr (global%model)
      call var_list_init_copies (global%var_list, model_vars)
      if (sync) then
        call var_list_synchronize (global%var_list, model_vars, &
          reset_pointers = .true.)
      end if
    end if
  end subroutine
```

```
end subroutine rt_data_read_model
```

Select a model, assuming that it has already been read.

```
<RT data: rt data: TBP>+≡
  procedure :: select_model => rt_data_select_model

<RT data: procedures>+≡
  subroutine rt_data_select_model (global, name)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(var_list_t), pointer :: model_vars
    global%model => global%model_list%get_model_ptr (name)
    if (associated (global%model)) then
      call var_list_set_string (global%var_list, var_str ("$model_name"), &
        name, is_known = .true.)
      model_vars => model_get_var_list_ptr (global%model)
      call var_list_synchronize (global%var_list, model_vars, &
        reset_pointers = .true.)
    end if
  end subroutine rt_data_select_model
```

Add a library (available via a pointer of type `prclib_entry_t`) to the stack and update the pointer and variable list to the current library. The pointer association of `prclib_entry` will be discarded.

```
<RT data: rt data: TBP>+≡
  procedure :: add_prclib => rt_data_add_prclib

<RT data: procedures>+≡
  subroutine rt_data_add_prclib (global, prclib_entry)
    class(rt_data_t), intent(inout) :: global
    type(prclib_entry_t), intent(inout), pointer :: prclib_entry
    call global%prclib_stack%push (prclib_entry)
    call global%update_prclib (global%prclib_stack%get_first_ptr ())
  end subroutine rt_data_add_prclib
```

Given a pointer to a process library, make this the currently active library.

```
<RT data: rt data: TBP>+≡
  procedure :: update_prclib => rt_data_update_prclib

<RT data: procedures>+≡
  subroutine rt_data_update_prclib (global, lib)
    class(rt_data_t), intent(inout) :: global
    type(process_library_t), intent(in), target :: lib
    type(var_entry_t), pointer :: var
    global%prclib => lib
    var => var_list_get_var_ptr (global%var_list, &
      var_str ("library_name"), follow_link = .false.)
    if (associated (var)) then
      call var_entry_set_string (var, &
        global%prclib%get_name (), is_known=.true.)
    else
      call var_list_append_string (global%var_list, &
        var_str ("library_name"), global%prclib%get_name (), &
```

```

        intrinsic = .true.)
    end if
end subroutine rt_data_update_prclib

```

19.5.8 Get contents

The helicity selection data are distributed among several parameters. Here, we collect them in a single record.

```

<RT data: rt data: TBP>+≡
    procedure :: get_helicity_selection => rt_data_get_helicity_selection

<RT data: procedures>+≡
function rt_data_get_helicity_selection (rt_data) result (helicity_selection)
    class(rt_data_t), intent(in) :: rt_data
    type(helicity_selection_t) :: helicity_selection
    associate (var_list => rt_data%var_list)
        helicity_selection%active = var_list_get_lval (var_list, &
            var_str ("?helicity_selection_active"))
        if (helicity_selection%active) then
            helicity_selection%threshold = var_list_get_rval (var_list, &
                var_str ("helicity_selection_threshold"))
            helicity_selection%cutoff = var_list_get_ival (var_list, &
                var_str ("helicity_selection_cutoff"))
        end if
    end associate
end function rt_data_get_helicity_selection

```

19.5.9 Auxiliary stuff

Write a separator line.

```

<RT data: procedures>+≡
    subroutine write_separator (u)
        integer, intent(in) :: u
        write (u, "(A)") repeat ("-", 72)
    end subroutine write_separator

    subroutine write_separator_double (u)
        integer, intent(in) :: u
        write (u, "(A)") repeat ("=", 72)
    end subroutine write_separator_double

```

19.5.10 Test

This is the master for calling self-test procedures.

```

<RT data: public>+≡
    public :: rt_data_test

```

```

<RT data: tests>≡
  subroutine rt_data_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <RT data: execute tests>
  end subroutine rt_data_test

```

Initial content

Display the RT data in the state just after (global) initialization.

```

<RT data: execute tests>≡
  call test (rt_data_1, "rt_data_1", &
    "initialize", &
    u, results)

<RT data: tests>+≡
  subroutine rt_data_1 (u)

```

Save and restore

Set up a local runtime data block, change some contents, restore the global block.

For a model variable, the save-restore procedure is nontrivial. We first allocate a local copy of this variable and set a pointer to the original model variable. We set a new value, update the dependent variables and synchronize them with the local variable list, if modified. When restoring the old data, we recover the model variables from the stored values and delete the local instances.

```

<RT data: execute tests>+≡
    call test (rt_data_3, "rt_data_3", &
        "save/restore", &
        u, results)

19.6 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

This module provides no new types, just procedures.

```

<dispatch.f90>≡
  <File header>

  module dispatch

19.6.1 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable.

Note: `core_def` has `intent(inout)` because gfortran 4.7.1 crashes for `intent(out)`.

⟨Dispatch: public⟩≡

```
public :: dispatch_core_def
```

⟨Dispatch: procedures⟩≡

```

subroutine dispatch_core_def (core_def, prt_in, prt_out, global)
  class(prc_core_def_t), allocatable, intent(inout) :: core_def
  type(string_t), dimension(:), intent(in) :: prt_in

```

```

type(string_t), dimension(:), intent(in) :: prt_out
type(rt_data_t), intent(in) :: global
type(string_t) :: method
type(string_t) :: model_name
type(string_t) :: restrictions
logical :: openmp_support
logical :: report_progress
type(string_t) :: extra_options
associate (var_list => global%var_list)
  method = var_list_get_sval (var_list, var_str ("method"))
  model_name = var_list_get_sval (var_list, var_str ("model_name"))
  select case (char (method))
  case ("unit_test")
    allocate (prc_test_def_t :: core_def)
    select type (core_def)
    type is (prc_test_def_t)
      call core_def%init (model_name, prt_in, prt_out)
    end select
  case ("omega")
    restrictions = var_list_get_sval (var_list, &
      var_str ("restrictions"))
    openmp_support = var_list_get_lval (var_list, &
      var_str ("?omega_openmp"))
    report_progress = var_list_get_lval (var_list, &
      var_str ("?report_progress"))
    extra_options = var_list_get_sval (var_list, &
      var_str ("$omega_flags"))
    allocate (omega_def_t :: core_def)
    select type (core_def)
    type is (omega_def_t)
      call core_def%init (model_name, prt_in, prt_out, &
        restrictions, openmp_support, report_progress, extra_options)
    end select
  case default
    call msg_fatal ("Process configuration: method '" &
      // char (method) // "' not implemented")
  end select
end associate
end subroutine dispatch_core_def

```

19.6.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```

<Dispatch: public>+≡
  public :: dispatch_core

<Dispatch: procedures>+≡
  subroutine dispatch_core (core, core_def, model, helicity_selection, qcd)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_def_t), intent(in) :: core_def
    type(model_t), intent(in), target, optional :: model

```

```

type(helicity_selection_t), intent(in), optional :: helicity_selection
type(qcd_t), intent(in), optional :: qcd
select type (core_def)
type is (prc_test_def_t)
    allocate (test_t :: core)
type is (omega_def_t)
    allocate (prc_omega_t :: core)
    select type (core)
    type is (prc_omega_t)
        call core%set_parameters (model, helicity_selection, qcd)
    end select
class default
    call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

19.6.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

```

<Dispatch: public>+≡
public :: dispatch_core_update
public :: dispatch_core_restore

<Dispatch: procedures>+≡
subroutine dispatch_core_update (core, model, helicity_selection, qcd, &
    saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    type(model_t), intent(in), optional, target :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    class(prc_core_t), allocatable, intent(inout), optional :: saved_core
    if (present (saved_core)) then
        allocate (saved_core, source = core)
    end if
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
        call core%set_parameters (model, helicity_selection, qcd)
        call core%activate_parameters ()
    class default
        call msg_bug ("Process core update: unexpected process definition type")
    end select
end subroutine dispatch_core_update

subroutine dispatch_core_restore (core, saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_t), allocatable, intent(inout) :: saved_core
    call move_alloc (from = saved_core, to = core)

```

```

select type (core)
type is (test_t)
type is (prc_omega_t)
    call core%activate_parameters ()
class default
    call msg_bug ("Process core restore: unexpected process definition type")
end select
end subroutine dispatch_core_restore

```

19.6.4 Integrator allocation

Allocate an integrator according to the variable `$integration_method`.

```

<Dispatch: public>+≡
    public :: dispatch_mci

<Dispatch: procedures>+≡
    subroutine dispatch_mci (mci, global, process_id)
        class(mci_t), allocatable, intent(inout) :: mci
        type(rt_data_t), intent(in) :: global
        type(string_t), intent(in) :: process_id
        type(string_t) :: run_id
        type(string_t) :: integration_method

```

This is an auxiliary procedure, used by the beam-structure expansion: tell for a given structure function name, whether it corresponds to a pair spectrum ($n = 2$), a single-particle structure function ($n = 1$), or nothing ($n = 0$).

(Dispatch: procedures)+≡

```

function strfun_mode(name) result (n)
    type(string_t), intent(in) :: name
    integer :: n
    select case (char (name))
    case ("none")
        n = 0
    case ("sf_test_0", "sf_test_1")
        n = 1
    case ("pdf_builtin", "lhpdf", "isr", "epa", "ewa")
        n = 1
    case default
        call msg_bug ("Structure function '" // char (name) &
            // "' not supported yet")
    end select
end function

```

```
end function strfun_mode
```

Dispatch a whole structure-function chain, given beam data and beam structure data.

This could be done generically, but we should look at the specific combination of structure functions in order to select appropriate mappings.

The `beam_structure` argument gets copied because we want to expand it to canonical form (one valid structure-function entry per record) before proceeding further.

Note: Should add global mappings, as appropriate for a specific combination of structure functions.

19.6.9 QCD coupling

Allocate the `alpha` (running coupling) component of the `qcd` block with a concrete implementation, depending on the variable settings in the `global` record.

If a fixed α_s is requested, we do not allocate the `qcd%alpha` object. In this case, the matrix element code will just take the model parameter as-is, which implies fixed α_s . If the object is allocated, the α_s value is computed and updated for each matrix-element call.

```

19.7 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

```

<process_configurations.f90>≡
  <File header>

```

```

module process_configurations

```

```

  <Use strings>
  use diagnostics !NODEP!

```

```

    use unit_tests
    use variables
    use models
    use prc_core_def
    use particle_specifiers
    use process_libraries
    use prclib_stacks
    use prc_test
    use prc_omega
    use rt_data
    use dispatch

    <Standard module head>

    <Process configurations: public>

    <Process configurations: types>

contains

    <Process configurations: procedures>

    <Process configurations: tests>

end module process_configurations

```

19.7.1 Data Type

```

    <Process configurations: public>≡
        public :: process_configuration_t

    <Process configurations: types>≡
        type :: process_configuration_t
            type(process_def_entry_t), pointer :: entry => null ()
            type(string_t) :: id
        contains
            <Process configurations: process configuration: TBP>
        end type process_configuration_t

```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

```

    <Process configurations: process configuration: TBP>≡
        procedure :: init => process_configuration_init

    <Process configurations: procedures>≡
        subroutine process_configuration_init &
            (config, prc_name, n_in, n_components, global)
            class(process_configuration_t), intent(out) :: config
            type(string_t), intent(in) :: prc_name
            integer, intent(in) :: n_in
            integer, intent(in) :: n_components
            type(rt_data_t), intent(in) :: global
            type(model_t), pointer :: model
            model => global%model

```

```

    config%id = prc_name
    allocate (config%entry)
    call config%entry%init (prc_name, &
        model = model, n_in = n_in, n_components = n_components)
end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

```

(Process configurations: process configuration: TBP)+≡

            // "' : active process library undefined")
    end if
end subroutine process_configuration_record

```

19.7.2 Test

This is the master for calling self-test procedures.

```

<Process configurations: public>+≡
    public :: process_configurations_test

<Process configurations: tests>≡
    subroutine process_configurations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Process configurations: execute tests>
end subroutine process_configurations_test

```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one **prc_test** and one **omega** type) and appends this to the process library stack in the global data set.

The **mode** argument determines which processes to build.

The **procname** argument replaces the predefined **procname(s)**.

```

<Process configurations: public>+≡
    public :: prepare_test_library

<Process configurations: tests>+≡
    subroutine prepare_test_library (global, libname, mode, procname)
        type(rt_data_t), intent(inout), target :: global
        type(string_t), intent(in) :: libname
        integer, intent(in) :: mode
        type(string_t), intent(in), dimension(:), optional :: procname

        type(prclib_entry_t), pointer :: lib
        type(string_t) :: prc_name
        type(string_t), dimension(:), allocatable :: prt_in, prt_out
        integer :: n_components
        type(process_configuration_t) :: prc_config

        allocate (lib)

```

```

call lib%init (libname)
call global%add_prclib (lib)

if (btest (mode, 0)) then
    call global%read_model (var_str ("Test"), var_str ("Test.mdl"))
end if

if (btest (mode, 1)) then
    call global%read_model (var_str ("QED"), var_str ("QED.mdl"))
end if

if (btest (mode, 0)) then

    call global%select_model (var_str ("Test"))

    if (present (procname)) then
        prc_name = procname(1)
    else
        prc_name = "prc_config_a"
    end if
    n_components = 1
    allocate (prt_in (2), prt_out (2))
    prt_in = [var_str ("s"), var_str ("s")]
    prt_out = [var_str ("s"), var_str ("s")]

19.8 Compilation

This module manages compilation and loading of process libraries. It is needed as a separate module because integration depends on it.

```

<compilations.f90>≡
  <File header>

  module compilations

    <Use strings>
    use diagnostics !NODEP!

```

```

    use os_interface
    use unit_tests
    use variables
    use models
    use process_libraries
    use prclib_stacks
    use rt_data
    use process_configurations

    <Standard module head>

    <Compilations: public>

    <Compilations: types>

    <Compilations: interfaces>

    contains

    <Compilations: procedures>

    <Compilations: tests>

end module compilations

```

19.8.1 The data type

This data type serves as a container that collects all necessary data; the procedures compile and load operate on it internally.

```

<Compilations: types>≡
    type :: compilation_t
        type(string_t) :: libname
        type(process_library_t), pointer :: lib => null ()
        logical :: recompile_library = .false.
        logical :: make_executable = .false.
    contains
        <Compilations: compilation: TBP>
    end type compilation_t

Initialize:

<Compilations: compilation: TBP>≡
    procedure :: init => compilation_init

<Compilations: procedures>≡
    subroutine compilation_init (comp, libname, stack, var_list)
        class(compilation_t), intent(out) :: comp
        type(string_t), intent(in) :: libname
        type(prclib_stack_t), intent(inout) :: stack
        type(var_list_t), intent(in) :: var_list
        comp%libname = libname
        comp%lib => stack%get_library_ptr (comp%libname)
        if (.not. associated (comp%lib)) then
            call msg_fatal ("Process library '" // char (comp%libname) &

```

```

        // '' has not been declared.")
    end if
    comp%recompile_library = &
        var_list_get_lval (var_list, var_str ("?recompile_library"))
end subroutine compilation_init

```

Compile and load the current library. The `force` flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

```

<Compilations: compilation: TBP>+=
    procedure :: compile_and_load => compilation_compile_and_load

<Compilations: procedures>+=
    subroutine compilation_compile_and_load (comp, os_data, force)
        class(compilation_t), intent(inout) :: comp
        type(os_data_t), intent(in) :: os_data
        logical, intent(in) :: force
        if (associated (comp%lib)) then
            call msg_message ("Process library '" &
                // char (comp%libname) // "': compiling ...")

19.8.2 API for compilation and loading

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>≡
    public :: compile_library

<Compilations: procedures>+≡
    subroutine compile_library (libname, global)
        type(string_t), intent(in) :: libname
        type(rt_data_t), intent(inout), target :: global
        type(compilation_t) :: comp
        logical :: force
        force = var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
        call comp%init (libname, global%prclib_stack, global%var_list)
    end subroutine compile_library

```

```

        call comp%compile_and_load (global%os_data, force)
    end subroutine compile_library

```

Compile the processes. Do not load the library (libraries), but link them to a separate executable.

```

<XXX Compilations: public>≡
    public :: compile_executable

<XXX Compilations: interfaces>≡
    interface compile_executable
        module procedure compile_executable0
        module procedure compile_executable1
    end interface

<XXX Compilations: procedures>+≡
    subroutine compile_executable0 (libname, exec_name, global)
        type(string_t), intent(in) :: libname, exec_name

            (libname(lib), global, global_var_list, global_prc_lib)
    end do
end subroutine load_library1

```

19.8.3 Test

This is the master for calling self-test procedures.

```

<Compilations: public>+≡
    public :: compilations_test

<Compilations: tests>≡
    subroutine compilations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Compilations: execute tests>
end subroutine compilations_test

```

Intrinsic Matrix Element

Compile an intrinsic test matrix element (prc_test type).

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```

<Compilations: execute tests>≡
    call test (compilations_1, "compilations_1", &
        "intrinsic test processes", &
        u, results)

<Compilations: tests>+≡

19.9 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

```

19.9.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process. We need not export it.

```

<Integrations: types>≡
    type :: integration_t
    private
        type(string_t) :: process_id

19.9.5 Test

This is the master for calling self-test procedures.

```

<Integrations: public>+≡
public :: integrations_test

```

```

<Integrations: tests>≡
  subroutine integrations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Integrations: execute tests>
  end subroutine integrations_test

```

Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (19.1)$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (19.2)$$

f is the flux of the incoming particles with mass $m = 125 \text{ GeV}$ and energy $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (19.3)$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (19.4)$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (19.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function $f(x) = x$ for both beams. Together with the $1/x_1 x_2$ factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the m_s mass which we set to zero here.

19.10 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

`(event_streams.f90)`≡
⟨File header⟩

```
module event_streams
```

```

⟨Use kinds⟩
⟨Use strings⟩
⟨Use file utils⟩
  use diagnostics !NODEP!
  use unit_tests
  use models
  use processes
  use events
  use eio_data
  use eio_base
  use rt_data
  use dispatch

```

⟨Standard module head⟩

⟨Event streams: public⟩

⟨Event streams: parameters⟩

```

    <Event streams: types>

contains

    <Event streams: tests>

    <Event streams: procedures>

end module event_streams

```

19.10.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```

<Event streams: types>≡
    type :: event_stream_entry_t
        class(eio_t), allocatable :: eio
    end type event_stream_entry_t

```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```

<Event streams: public>≡
    public :: event_stream_array_t

<Event streams: types>+≡
    type :: event_stream_array_t
        type(event_stream_entry_t), dimension(:), allocatable :: entry
        integer :: i_in = 0
    contains
        <Event streams: event stream array: TBP>
    end type event_stream_array_t

```

Output.

```

<Event streams: event stream array: TBP>≡
    procedure :: write => event_stream_array_write

<Event streams: procedures>≡
    subroutine event_stream_array_write (object, unit)
        class(event_stream_array_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = output_unit (unit)
        write (u, "(1x,A)") "Event stream array:"
        if (allocated (object%entry)) then
            select case (size (object%entry))
            case (0)
                write (u, "(3x,A)") "[empty]"
            case default
                do i = 1, size (object%entry)
                    if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
                    call object%entry(i)%eio%write (u)
                end do
            end select
        else

```

```

        write (u, "(3x,A)") "[undefined]"
    end if
end subroutine event_stream_array_write

```

Finalize all streams.

```

(Event streams: event stream array: TBP)+≡
    procedure :: final => event_stream_array_final

(Event streams: procedures)+≡
    subroutine event_stream_array_final (es_array)
        class(event_stream_array_t), intent(inout) :: es_array
        integer :: i
        do i = 1, size (es_array%entry)
            call es_array%entry(i)%eio%final ()
        end do
    end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provides stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

```

```

```

    if (integral_prc /= 0) then
        mci_set%weight_mci = mci_set%integral / integral_prc
    end if
end subroutine mci_set_compute_weight

```

19.11.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

```

<Simulations: types>+≡
    type :: core_safe_t
        class(prc_core_t), allocatable :: core
    end type core_safe_t

```

19.11.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration is not yet done, do it.

```

<Simulations: procedures>+≡
    subroutine prepare_process (process, process_id, global)
        type(process_t), pointer, intent(out) :: process
        type(string_t), intent(in) :: process_id
        type(rt_data_t), intent(inout), target :: global
        process => global%process_stack%get_process_ptr (process_id)
        if (.not. associated (process)) then
            call msg_message ("Simulate: process '" &
                // char (process_id) // "' needs integration")
            call integrate_process (process_id, global)
            process => global%process_stack%get_process_ptr (process_id)
            if (associated (process)) then
                call msg_message ("Simulate: integration done")
            else
                call msg_fatal ("Simulate: process '" &
                    // char (process_id) // "' could not be integrated: aborting")
            end if
        end if
    end subroutine prepare_process

```

This variant prepares an alternate process object, without integration. The process object is local.

```

<Simulations: procedures>+≡

    end subroutine prepare_alt_process

```

```
end subroutine prepare_alt_process
```

19.11.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

```
<Simulations: types>+≡
type, extends (event_t) :: entry_t
  private
  type(string_t) :: process_id
  type(string_t) :: library
  type(string_t) :: run_id
  real(default) :: integral = 0
  real(default) :: error = 0
  real(default) :: weight_prc = 0
  type(counter_t) :: counter
  integer :: n_mci = 0
  type(mci_set_t), dimension(:), allocatable :: mci_set
  real(default), dimension(:), allocatable :: acc_weight_mci
  type(core_safe_t), dimension(:), allocatable :: core_safe
contains
  <Simulations: entry: TBP>
end type entry_t
```

Output. Write just the configuration, the event is written by a separate routine.

The `verbose` option is unused, it is required by the interface of the base-object method.

```
<Simulations: entry: TBP>≡
procedure :: write => entry_write

<Simulations: procedures>+≡
subroutine entry_write (object, unit, verbose)
  class(entry_t), intent(in) :: object
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: verbose
  integer :: u, i
  u = output_unit (unit)
  write (u, "(3x,A,A,A)") "Process   = ", char (object%process_id), ""
  write (u, "(3x,A,A,A)") "Library   = ", char (object%library), ""
  write (u, "(3x,A,A,A)") "Run       = ", char (object%run_id), ""
```

```

write (u, "(3x,A,ES19.12)") "Integral = ", object%integral
write (u, "(3x,A,ES19.12)") "Error = ", object%error
write (u, "(3x,A,F13.10)") "Weight = ", object%weight_prc
write (u, "(3x,A,I0)") "MCI sets = ", object%n_mci
call object%counter%write (u)
do i = 1, size (object%mci_set)
  write (u, "(A)")
  write (u, "(1x,A,I0,A)") "MCI set #", i, ":"
  call object%mci_set(i)%write (u)
end do
if (allocated (object%core_safe)) then
  do i = 1, size (object%core_safe)
    write (u, "(1x,A,I0,A)") "Saved process-component core #", i, ":"
    call object%core_safe(i)%core%write (u)
  end do
end if
end subroutine entry_write

```

Write the event and process instance to an (optional) output unit.

```

<Simulations: entry: TBP>+≡
  procedure :: write_event => entry_write_event
<Simulations: procedures>+≡
  subroutine entry_write_event (object, unit, verbose)
    class(entry_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose
    call object%event_t%write (unit, verbose)
  end subroutine entry_write_event

```

Finalizer. The `instance` pointer component of the `event_t` base type points to a target which we did explicitly allocate in the `entry_init` procedure. Therefore, we finalize and explicitly deallocate it here. Then we call the finalizer of the base type.

```

<Simulations: entry: TBP>+≡
  procedure :: final => entry_final
<Simulations: procedures>+≡
  subroutine entry_final (object)
    class(entry_t), intent(inout) :: object
    integer :: i
    if (associated (object%instance)) then
      do i = 1, object%n_mci
        call object%process%final_simulation (object%instance, i)
      end do
      call object%instance%final ()
      deallocate (object%instance)
    end if
    call object%event_t%final ()
  end subroutine entry_final

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the `process_instance` pointer. Assign data by looking at the process object and at the environment.

If the process object is not found initially, attempt an integration pass and try again.

When done, we assign the `instance` and `process` pointers of the base type by the `connect` method, so we can reference them later.

```

<Simulations: entry: TBP>+≡
  procedure :: init => entry_init

<Simulations: procedures>+≡

```

Compute the event matrix element and weight for all alternative environments,

given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

```

19.11.8 Event Stream I/O

Write an event to a generic `eio` event stream. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+=
  generic :: write_event => write_event_eio
  procedure :: write_event_eio => simulation_write_event_eio

<Simulations: procedures>+=
  subroutine simulation_write_event_eio (object, eio, i_prc)
    class(simulation_t), intent(in) :: object
    class(eio_t), intent(inout) :: eio
    integer, intent(in), optional :: i_prc
    integer :: current
    if (present (i_prc)) then
      current = i_prc
    else
      current = object%i_prc
    end if
    if (current > 0) then
      call eio%output (object%entry(current)%event_t, current)
    else
      call msg_fatal ("Simulation: write event: no process selected")
    end if
  end subroutine simulation_write_event_eio

```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```

<Simulations: simulation: TBP>+≡

        integer :: i_prc
        i_prc = simulation%i_prc
        call simulation%entry(i_prc)%recalculate (update_sqme)
        call simulation%entry(i_prc)%evaluate_expressions ()
    end subroutine simulation_recalculate

```

19.11.11 Auxiliary stuff

Write a separator line.

```

<Simulations: procedures>+≡
    subroutine write_separator (u)
        integer, intent(in) :: u
        write (u, "(A)") repeat (" ", 72)
    end subroutine write_separator

    subroutine write_separator_double (u)
        integer, intent(in) :: u
        write (u, "(A)") repeat ("=", 72)
    end subroutine write_separator_double

```

19.11.12 Extract contents

Return an array of pointers to the currently selected processes.

```

<Simulations: simulation: TBP>+≡
    procedure :: get_process_ptr => simulation_get_process_ptr

<Simulations: procedures>+≡
    function simulation_get_process_ptr (simulation) result (ptr)
        class(simulation_t), intent(in) :: simulation
        type(process_ptr_t), dimension(:), allocatable :: ptr
        integer :: i
        allocate (ptr (simulation%n_prc))
        do i = 1, size (ptr)

```

```

        ptr(i)%ptr => simulation%entry(i)%get_process_ptr ()
    end do
end function simulation_get_process_ptr

```

Return the MD5 sum that summarizes configuration and integration (but not the event file). Used for initializing the event streams.

```

<Simulations: simulation: TBP>+≡
    procedure :: get_md5sum_prc => simulation_get_md5sum_prc
    procedure :: get_md5sum_cfg => simulation_get_md5sum_cfg

<Simulations: procedures>+≡
    function simulation_get_md5sum_prc (simulation) result (md5sum)

20.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```

⟨Commands: types⟩≡
  type, abstract :: command_t
    type(parse_node_t), pointer :: pn => null ()
    class(command_t), pointer :: next => null ()
    type(parse_node_t), pointer :: pn_opt => null ()
    type(command_list_t), pointer :: options => null ()
    type(rt_data_t), pointer :: local => null ()
  contains
    ⟨Commands: command: TBP⟩
  end type command_t

```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```

⟨Commands: command: TBP⟩≡
  procedure :: final => command_final

⟨Commands: procedures⟩≡
  recursive subroutine command_final (cmd)
    class(command_t), intent(inout) :: cmd
    if (associated (cmd%options)) then
      call cmd%options%final ()
      deallocate (cmd%options)
      deallocate (cmd%local)
    else
      cmd%local => null ()
    end if
  end subroutine command_final

```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

```

⟨Commands: procedures⟩+≡
  subroutine dispatch_command (command, pn)
    class(command_t), intent(inout), pointer :: command
    type(parse_node_t), intent(in), target :: pn

!           call cmd_scan_compile (command%loop, pn, global)
case ("cmd_if")
    allocate (cmd_if_t :: command)
case ("cmd_include")
    allocate (cmd_include_t :: command)
!       case ("cmd_quit")
!           command%type = CMD_QUIT
!           call cmd_quit_compile (command%quit, pn, global)
case default
    print *, char (parse_node_get_rule_key (pn))
    call msg_bug ("Command not implemented")

```

```

end select
command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_write), deferred :: write
⟨Commands: interfaces⟩≡
  abstract interface
    subroutine command_write (cmd, unit, indent)
      import
      class(command_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
    end subroutine command_write
  end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_compile), deferred :: compile
⟨Commands: interfaces⟩+≡
  abstract interface
    subroutine command_compile (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_compile
  end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_execute), deferred :: execute
⟨Commands: interfaces⟩+≡
  abstract interface
    subroutine command_execute (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_execute
  end interface

```

Auxiliary for output:

```

⟨Commands: procedures⟩+≡
  subroutine write_indent (unit, indent)
    integer, intent(in) :: unit
    integer, intent(in), optional :: indent
    if (present (indent)) then
      write (unit, "(A)", advance="no") repeat (" ", indent)
    end if
  end subroutine

```

```
end subroutine write_indent
```

20.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```
<Commands: command: TBP>+≡
  procedure :: write_options => command_write_options

<Commands: procedures>+≡
  recursive subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options
```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```
<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
  recursive subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call command_list_compile (cmd%options, cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
    else
      cmd%local => global
    end if
  end subroutine command_compile_options
```

Execute options. First prepare the local environment, then execute the command list.

```
<Commands: command: TBP>+≡
  procedure :: execute_options => cmd_execute_options

<Commands: procedures>+≡
  recursive subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
```

```

        if (associated (cmd%options)) then
            call cmd%local%link (global)
            call cmd%options%execute (cmd%local)
        end if
    end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the global environment.

```

⟨Commands: command: TBP⟩+≡
    procedure :: reset_options => cmd_reset_options

⟨Commands: procedures⟩+≡
    subroutine cmd_reset_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call global%restore (cmd%local)
        end if
    end subroutine cmd_reset_options

```

20.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_model_t
        private
        type(string_t) :: name
    contains
        ⟨Commands: cmd model: TBP⟩
    end type cmd_model_t

```

Output

```

⟨Commands: cmd model: TBP⟩≡
    procedure :: write => cmd_model_write

⟨Commands: procedures⟩+≡
    subroutine cmd_model_write (cmd, unit, indent)
        class(cmd_model_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,1x,'"',A,'\"') "model =", char (cmd%name)
    end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed.

```

⟨Commands: cmd model: TBP⟩+≡
    procedure :: compile => cmd_model_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_model_compile (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_name
  type(string_t) :: filename
  pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
  cmd%name = parse_node_get_string (pn_name)
  filename = cmd%name // ".mdl"
  call global%read_model (cmd%name, filename)
end subroutine cmd_model_compile

```

Execute: Insert a pointer into the global data record and reassign the variable list.

```

⟨Commands: cmd model: TBP⟩+≡
  procedure :: execute => cmd_model_execute

⟨Commands: procedures⟩+≡
subroutine cmd_model_execute (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(model_t), pointer :: mdl
  type(var_list_t), pointer :: model_vars
  logical :: new_model
  new_model = .true.
  if (associated (global%model)) then
    new_model = model_get_name (global%model) /= cmd%name
  end if
  if (new_model) then
    if (global%model_list%model_exists (cmd%name)) then
      call msg_message ("Switching to model '" &
        // char (cmd%name) &
        // "' : reassigning model parameters")
      call global%select_model (cmd%name)
    else
      call msg_fatal ("Switching to model '" &
        // char (cmd%name) &
        // "' : unknown model name")
    end if
  end if
end subroutine cmd_model_execute

```

Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_library_t
  private
  type(string_t) :: name
contains

```

```

    <Commands: cmd library: TBP>
end type cmd_library_t

```

Output.

```

<Commands: cmd library: TBP>≡
    procedure :: write => cmd_library_write

<Commands: procedures>+≡
    subroutine cmd_library_write (cmd, unit, indent)
        class(cmd_library_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = output_unit (unit)
        call write_indent (u, indent)
        write (u, "(1x,A,1x,'"',A,'\"')") "library =", char (cmd%name)
    end subroutine cmd_library_write

```

Compile. Get the library name.

```

<Commands: cmd library: TBP>+≡
    procedure :: compile => cmd_library_compile

<Commands: procedures>+≡
    subroutine cmd_library_compile (cmd, global)
        class(cmd_library_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_name
        pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
        cmd%name = parse_node_get_string (pn_name)
    end subroutine cmd_library_compile

```

Execute: Initialize a new library and push it on the library stack (if it does not yet exist). Insert a pointer to the library into the global data record. Then, try to load the library unless the rebuild flag is set.

```

<Commands: cmd library: TBP>+≡
    procedure :: execute => cmd_library_execute

<Commands: procedures>+≡
    subroutine cmd_library_execute (cmd, global)
        class(cmd_library_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(prclib_entry_t), pointer :: lib_entry
        type(process_library_t), pointer :: lib
        logical :: rebuild_library, recompile_library
        lib => global%prclib_stack%get_library_ptr (cmd%name)
        !!! JRR: WK please check
        rebuild_library = &
            var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
        !!! recompile_library = &
            var_list_get_lval (global%var_list, var_str ("?recompile_library"))
        if (.not. (associated (lib))) then
            allocate (lib_entry)
            call lib_entry%init (cmd%name)
            lib => lib_entry%process_library_t
            call global%add_prclib (lib_entry)
        end if
    end subroutine cmd_library_execute

```

```

else
  call global%update_prclib (lib)
end if
if (associated (lib) .and. .not. rebuild_library) then
  call lib%update_status (global%os_data)
end if
end subroutine cmd_library_execute

```

Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

This also includes the choice of method for the corresponding process: **omega** for O'MEGA matrix elements, **test** for special processes generated by WHIZARD, **external** for using an external matrix element and **dipole** for generating dipole subtraction terms.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_process_t
  private
  type(string_t) :: id
  integer :: n_in = 0
  integer :: n_out = 0
  type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
  type(parse_node_p), dimension(:), allocatable :: pn_pdg_out
  contains
  ⟨Commands: cmd process: TBP⟩
end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming and outgoing particles.

```

⟨Commands: cmd process: TBP⟩≡
  procedure :: write => cmd_process_write

⟨Commands: procedures⟩+≡
  subroutine cmd_process_write (cmd, unit, indent)
    class(cmd_process_t), intent(in) :: cmd

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```
<CCC Commands: types>+≡
  type :: cmd_slha_t
    private
    type(string_t) :: file
    logical :: write = .false.
    type(command_list_t), pointer :: options => null ()
    type(rt_data_t) :: local
  end type cmd_slha_t
```

Finalizer.

```
<CCC Commands: procedures>+≡
  subroutine cmd_slha_final (slha)
    type(cmd_slha_t), intent(inout) :: slha
    if (associated (slha%options)) then

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

<CCC Commands: types>+≡
type :: cmd_expect_t
private
type(parse_node_t), pointer :: pn_lexpr => null ()
type(command_list_t), pointer :: options => null ()
type(rt_data_t) :: local
end type cmd_expect_t

```

Finalize.

```

<CCC Commands: procedures>+≡
subroutine cmd_expect_final (expect)
type(cmd_expect_t), intent(inout) :: expect
if (associated (expect%options)) then
    call command_list_final (expect%options)
    deallocate (expect%options)
end if
end subroutine cmd_expect_final

```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

```

<CCC Commands: procedures>+≡
subroutine cmd_expect_compile (expect, pn, global)
type(cmd_expect_t), pointer :: expect
type(parse_node_t), intent(in), target :: pn
type(rt_data_t), intent(in), target :: global
type(parse_node_t), pointer :: pn_arg, pn_opt
pn_arg => parse_node_get_sub_ptr (pn, 2)
pn_opt => parse_node_get_next_ptr (pn_arg)
allocate (expect)
call rt_data_local_init (expect%local, global)
if (associated (pn_opt)) then
    allocate (expect%options)

```

```

        call command_list_compile (expect%options, pn_opt, expect%local)
    end if
    expect%pn_lexpr => parse_node_get_sub_ptr (pn_arg)
    call rt_data_local_reset (expect%local)
end subroutine cmd_expect_compile

```

Execute. Evaluate both arguments, print them and their difference (if numerical), and whether they agree. Record the result.

```

<CCC Commands: procedures>+≡
subroutine cmd_expect_execute (expect, global)
    type(cmd_expect_t), intent(inout) :: expect
    type(rt_data_t), intent(inout), target :: global
    logical :: success, is_known
    integer :: u
    u = logfile_unit ()
    call rt_data_link (expect%local, global)
    if (associated (expect%options)) then
        call command_list_execute (expect%options, expect%local)
    end if

Command execution: Beam initialization. The output is a beam-data object, which is copied to the global data block.

Structure functions are configured in the option section. They are linked to the global data block, where they can be found by the integration command.

Note: polarization, beam structure, local options not implemented yet.

```

The individual register procedures. They unpack data from the local var list, allocate structure function data blocks and fill them. Depending on the structure function and on the beams on which it should apply, one or two such entries are added to the structure function list. For double structure functions, it is useful to add a pair-mapping.

For user structure functions, it is not evident whether they apply to single beams or to the beam pair, before the data set has been initialized. Therefore, we have to shortcut the scan over the two beams if we encounter a structure function that applies to the beam pair.

Beam polarization

We define an assortment of containers for the options of the different beam polarization constructors.

```

<CCC Commands: types>+≡
type :: bp_circ_data_t
  private
  type(parse_node_t), pointer :: pn_fraction => null ()
  real(default) :: fraction
end type bp_circ_data_t

type :: bp_trans_data_t
  private
  type(parse_node_t), pointer :: pn_fraction => null ()
  type(parse_node_t), pointer :: pn_phi => null ()
  real(default) :: fraction, phi
end type bp_trans_data_t

type :: bp_long_data_t
  private
  type(parse_node_t), pointer :: pn_fraction => null ()
  real(default) :: fraction
end type bp_long_data_t

type :: bp_axis_data_t
  private
  type(parse_node_t), pointer :: pn_fraction => null ()
  type(parse_node_t), pointer :: pn_theta => null ()
  type(parse_node_t), pointer :: pn_phi => null ()
  real(default) :: fraction, theta, phi
end type bp_axis_data_t

type :: bp_diag_data_t

```

```

    private
    type(parse_node_p), dimension(:), allocatable :: pn_hel
    type(parse_node_p), dimension(:), allocatable :: pn_fraction
    integer, dimension(:), allocatable :: hel
    real(default), dimension(:), allocatable :: fraction
end type bp_diag_data_t

type :: bp_density_data_t
    private
    type(parse_node_t), pointer :: pn_d => null ()
    type(parse_node_t), pointer :: pn_nd => null ()
    real(default) :: d
    complex(default) :: nd
end type bp_density_data_t

```

The actual scratch container for the command. A negative **n** means the structure is invalid, and a negative **type** tells the execution subprogram to disable beam polarization altogether.

<CCC Commands: types>+≡

```

type :: cmd_beam_polarization_t
    private
    integer :: n = -1
    integer, dimension(2) :: type = -1
    type(bp_circ_data_t), dimension(:), pointer :: circ_data => null ()
    type(bp_trans_data_t), dimension(:), pointer :: trans_data => null ()
    type(bp_long_data_t), dimension(:), pointer :: long_data => null ()
    type(bp_axis_data_t), dimension(:), pointer :: axis_data => null ()
    type(bp_diag_data_t), dimension(:), pointer :: diag_data => null ()
    type(bp_density_data_t), dimension(:), pointer :: &
        density_data => null ()
    type(command_list_t), pointer :: options => null ()
    type(rt_data_t) :: local
    type(beam_polarization_t), dimension(:), pointer :: &
        beam_polarization => null ()
end type cmd_beam_polarization_t

```

Finalize the container. We define a separate finalizer for each subcontainer.

Cuts

Define a cut expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the cut expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_cuts_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  ⟨Commands: cmd cuts: TBP⟩
end type cmd_cuts_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```

⟨Commands: cmd cuts: TBP⟩≡
  procedure :: write => cmd_cuts_write

⟨Commands: procedures⟩+≡
  subroutine cmd_cuts_write (cmd, unit, indent)
    class(cmd_cuts_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "cuts: [defined]"
  end subroutine cmd_cuts_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd cuts: TBP>+≡
  procedure :: compile => cmd_cuts_compile

<Commands: procedures>+≡
  subroutine cmd_cuts_compile (cmd, global)
    class(cmd_cuts_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_cuts_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd cuts: TBP>+≡
  procedure :: execute => cmd_cuts_execute

<Commands: procedures>+≡
  subroutine cmd_cuts_execute (cmd, global)
    class(cmd_cuts_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%cuts_lexpr => cmd%pn_lexpr
  end subroutine cmd_cuts_execute

```

General, Factorization and Renormalization Scales

Define a scale expression for either the renormalization or the factorization scale. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

<CCC Commands: types>+≡
  type :: cmd_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  end type cmd_scale_t

```

```

<CCC Commands: types>+≡
  type :: cmd_fac_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  end type cmd_fac_scale_t

```

```

<CCC Commands: types>+≡
  type :: cmd_ren_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  end type cmd_ren_scale_t

```

Compile. Simply store the parse (sub)tree.

```

<CCC Commands: procedures>+≡
  subroutine cmd_scale_compile (scale, pn)
    type(cmd_scale_t), pointer :: scale

```

```

    type(parse_node_t), intent(in), target :: pn
    allocate (scale)
    scale%pn_expr => parse_node_get_sub_ptr (pn, 3)
end subroutine cmd_scale_compile

```

<CCC Commands: procedures>+≡

```

subroutine cmd_fac_scale_compile (scale, pn)
    type(cmd_fac_scale_t), pointer :: scale
    type(parse_node_t), intent(in), target :: pn
    allocate (scale)
    scale%pn_expr => parse_node_get_sub_ptr (pn, 3)
end subroutine cmd_fac_scale_compile

```

<CCC Commands: procedures>+≡

```

subroutine cmd_ren_scale_compile (scale, pn)
    type(cmd_ren_scale_t), pointer :: scale
    type(parse_node_t), intent(in), target :: pn
    allocate (scale)
    scale%pn_expr => parse_node_get_sub_ptr (pn, 3)
end subroutine cmd_ren_scale_compile

```

Instead of evaluating the scale expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

<CCC Commands: procedures>+≡

```

subroutine cmd_scale_execute (scale, global)
    type(cmd_scale_t), intent(inout), target :: scale
    type(rt_data_t), intent(inout), target :: global
    global%pn_scale_expr => scale%pn_expr
end subroutine cmd_scale_execute

```

<CCC Commands: procedures>+≡

```

subroutine cmd_fac_scale_execute (scale, global)
    type(cmd_fac_scale_t), intent(inout), target :: scale
    type(rt_data_t), intent(inout), target :: global
    global%pn_fac_scale_expr => scale%pn_expr
end subroutine cmd_fac_scale_execute

```

<CCC Commands: procedures>+≡

```

subroutine cmd_ren_scale_execute (scale, global)
    type(cmd_ren_scale_t), intent(inout), target :: scale
    type(rt_data_t), intent(inout), target :: global
    global%pn_ren_scale_expr => scale%pn_expr
end subroutine cmd_ren_scale_execute

```

Weight

Define a weight expression. The weight is applied to a process to be integrated, event by event. We store the parse tree for the right-hand side instead of

compiling it. Compilation is deferred to the process environment where the expression is used.

```

<CCC Commands: types>+≡
  type :: cmd_weight_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  end type cmd_weight_t

```

Compile. Simply store the parse (sub)tree.

```

<CCC Commands: procedures>+≡
  subroutine cmd_weight_compile (weight, pn)
    type(cmd_weight_t), pointer :: weight
    type(parse_node_t), intent(in), target :: pn
    allocate (weight)
    weight%pn_expr => parse_node_get_sub_ptr (pn, 3)
  end subroutine cmd_weight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<CCC Commands: procedures>+≡
  subroutine cmd_weight_execute (weight, global)
    type(cmd_weight_t), intent(inout), target :: weight
    type(rt_data_t), intent(inout), target :: global
    global%pn_weight_expr => weight%pn_expr
  end subroutine cmd_weight_execute

```

Selection

Define a selection expression. This is to applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<CCC Commands: types>+≡
  type :: cmd_selection_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  end type cmd_selection_t

```

Compile. Simply store the parse (sub)tree.

```

<CCC Commands: procedures>+≡
  subroutine cmd_selection_compile (selection, pn)
    type(cmd_selection_t), pointer :: selection
    type(parse_node_t), intent(in), target :: pn
    allocate (selection)
    selection%pn_expr => parse_node_get_sub_ptr (pn, 3)
  end subroutine cmd_selection_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```
<CCC Commands: procedures>+≡
subroutine cmd_selection_execute (selection, global)
  type(cmd_selection_t), intent(inout), target :: selection
  type(rt_data_t), intent(inout), target :: global
  global%pn_selection_lexpr => selection%pn_expr
end subroutine cmd_selection_execute
```

Reweight

Define a reweight expression. This is to applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```
<CCC Commands: types>+≡
type :: cmd_reweight_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()
end type cmd_reweight_t
```

Compile. Simply store the parse (sub)tree.

```
<CCC Commands: procedures>+≡
subroutine cmd_reweight_compile (reweight, pn)
  type(cmd_reweight_t), pointer :: reweight
  type(parse_node_t), intent(in), target :: pn
  allocate (reweight)
  reweight%pn_expr => parse_node_get_sub_ptr (pn, 3)
end subroutine cmd_reweight_compile
```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```
<CCC Commands: procedures>+≡
subroutine cmd_reweight_execute (reweight, global)
  type(cmd_reweight_t), intent(inout), target :: reweight
  type(rt_data_t), intent(inout), target :: global
  global%pn_reweight_expr => reweight%pn_expr
end subroutine cmd_reweight_execute
```

Integration

Integrate several processes, consecutively with identical parameters.

```
<Commands: types>+≡
type, extends (command_t) :: cmd_integrate_t
  private
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id
contains
<Commands: cmd integrate: TBP>
```

```
end type cmd_integrate_t
```

Output: we know the process IDs.

<Commands: cmd integrate: TBP>≡

```
procedure :: write => cmd_integrate_write
```

<Commands: procedures>+≡

```
subroutine cmd_integrate_write (cmd, unit, indent)
  class(cmd_integrate_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u, i
  u = output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A)", advance="no") "integrate ("
  do i = 1, cmd%n_proc
    if (i > 1) write (u, "(A,1x)", advance="no") ", "
    write (u, "(A)", advance="no") char (cmd%process_id(i))
  end do
  write (u, "(A)") ")"
end subroutine cmd_integrate_write
```

Compile.

<Commands: cmd integrate: TBP>+≡

```
procedure :: compile => cmd_integrate_compile
```

<Commands: procedures>+≡

```
subroutine cmd_integrate_compile (cmd, global)
  class(cmd_integrate_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_proclist, pn_proc
  integer :: i
  pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
  call cmd%compile_options (global)
  cmd%n_proc = parse_node_get_n_sub (pn_proclist)
  allocate (cmd%process_id (cmd%n_proc))
  pn_proc => parse_node_get_sub_ptr (pn_proclist)
  do i = 1, cmd%n_proc
    cmd%process_id(i) = parse_node_get_string (pn_proc)
    ! call var_list_init_process_results (global%var_list, &
    ! cmd%process_id (i))
    pn_proc => parse_node_get_next_ptr (pn_proc)
  end do
end subroutine cmd_integrate_compile
```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

(Re-)Integrating a decay process may invalidate a previous decay configuration, therefore we update the decay store.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

<Commands: cmd integrate: TBP>+≡
  procedure :: execute => cmd_integrate_execute

<Commands: procedures>+≡
  subroutine cmd_integrate_execute (cmd, global)
    class(cmd_integrate_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    integer :: i
    do i = 1, cmd%n_proc

Plots

Declare a plot. No mandatory arguments, just options.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_plot_t
    private
    type(string_t) :: id
    !     logical :: use_id_expr = .false.
    !     type(parse_node_t), pointer :: pn_id => null ()
    contains
    <Commands: cmd plot: TBP>
end type cmd_plot_t

```

Output. Just print the ID.

```
<Commands: cmd plot: TBP>≡
  procedure :: write => cmd_plot_write

<Commands: procedures>+≡
  subroutine cmd_plot_write (cmd, unit, indent)
    class(cmd_plot_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "plot: ", char (cmd%id)
  end subroutine cmd_plot_write
```

Compile. Record the plot ID and initialize lower, upper bound and bin width.

```
<Commands: cmd plot: TBP>+≡
  procedure :: compile => cmd_plot_compile

<Commands: procedures>+≡
  subroutine cmd_plot_compile (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_tag

    call set_graph_options (graph_options, cmd%local%var_list)
    call drawing_options_init_plot (drawing_options)
    call set_drawing_options (drawing_options, cmd%local%var_list)

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_graph_t
    private
    type(string_t) :: id
    !      type(parse_node_t), pointer :: pn_id
    !      logical :: use_id_expr = .false.
    integer :: n_elements = 0
    !      type(cmd_plot_t), dimension(:), allocatable :: el
    type(string_t), dimension(:), allocatable :: element_id
  contains
    <Commands: cmd graph: TBP>
  end type cmd_graph_t

```

Finalizer for the eval trees.

```

<CCC Commands: procedures>+≡
  subroutine cmd_graph_final (graph)
    type(cmd_graph_t), intent(inout) :: graph
    integer :: i
    if (allocated (graph%el)) then
      do i = 1, size (graph%el)
        call cmd_plot_final (graph%el(i))
      end do
      deallocate (graph%el)
    end if
    if (associated (graph%options)) then
      call command_list_final (graph%options)
      deallocate (graph%options)
    end if
  end subroutine cmd_graph_final

```

```

        end if
    end subroutine cmd_graph_final

```

Output. Just print the ID.

```

⟨Commands: cmd graph: TBP⟩≡
    procedure :: write => cmd_graph_write

⟨Commands: procedures⟩+≡
    subroutine cmd_graph_write (cmd, unit, indent)
        class(cmd_graph_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u, i
        u = output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A,A,I0,A)") "graph: ", char (cmd%id), &
            " (" , cmd%n_elements, " entries)"
    end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

⟨Commands: cmd graph: TBP⟩+≡
    procedure :: compile => cmd_graph_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_graph_compile (cmd, global)
        class(cmd_graph_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global

        cmd%element_id(i) = parse_node_get_string (pn_tag)
        pn_app => parse_node_get_next_ptr (pn_app)
    end do

end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

<Commands: cmd graph: TBP>+≡
    procedure :: execute => cmd_graph_execute

<Commands: procedures>+≡
    subroutine cmd_graph_execute (cmd, global)
        class(cmd_graph_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global

!               drawing_options)
        end do
    end subroutine cmd_graph_execute

```

Analysis

Hold the analysis ID either as a string or as an expression:

```
<CCC Commands: types>+≡
  type :: analysis_id_t
  type(string_t) :: tag
  type(parse_node_t), pointer :: pn_sexpr => null ()
end type analysis_id_t
```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_analysis_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  <Commands: cmd analysis: TBP>
end type cmd_analysis_t
```

Output. Print just a message that analysis has been defined.

```
<Commands: cmd analysis: TBP>≡
  procedure :: write => cmd_analysis_write

<Commands: procedures>+≡
  subroutine cmd_analysis_write (cmd, unit, indent)
    class(cmd_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "analysis: [defined]"
  end subroutine cmd_analysis_write
```

Compile. Simply store the parse (sub)tree.

```
<Commands: cmd analysis: TBP>+≡
  procedure :: compile => cmd_analysis_compile

<Commands: procedures>+≡
  subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_analysis_compile
```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```
<Commands: cmd analysis: TBP>+≡
  procedure :: execute => cmd_analysis_execute
```

```

{Commands: procedures}+≡
subroutine cmd_analysis_execute (cmd, global)
  class(cmd_analysis_t), intent(inout) :: cmd

```

Clear analysis objects

The syntax is analogous to `compile_analysis`. Each argument clears a particular analysis object. No argument clears the whole analysis store. The objects are cleared, but not deleted.

```

{CCC Commands: types}+≡
type :: cmd_clear_t
  private
  integer :: n_args = 0
  type(string_t), dimension(:), allocatable :: id
  logical, dimension(:), allocatable :: use_id_expr
  type(parse_node_p), dimension(:), allocatable :: pn_id
end type cmd_clear_t

```

Finalizer for the eval trees.

```

{CCC Commands: procedures}+≡
subroutine cmd_clear_final (clear)
  type(cmd_clear_t), intent(inout) :: clear
  if (allocated (clear%pn_id)) deallocate (clear%pn_id)
end subroutine cmd_clear_final

```

Compile. Record the clear ID and initialize lower, upper bound and bin width.

```

end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

(Limits: public parameters)+≡
character(*), parameter, public :: &
    DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
    FORBIDDEN_ENDINGS1 = (/ "o", "a" /)
character(len=2), dimension(5), parameter, public :: &
    FORBIDDEN_ENDINGS2 = (/ "mp", "ps", "vg", "lo", "la" /)
character(len=3), dimension(13), parameter, public :: &
    FORBIDDEN_ENDINGS3 = (/ "aux", "dvi", "evx", "f03", "f90", "log", &
        "ltp", "mpx", "pdf", "phs", "sin", "tex", "vbg" /)

```

Execute. If the `data_filename` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. Otherwise, we use the parameters and macros for custom data processing.

```

  advance = var_list_get_lval (printf%local%var_list, &
    var_str ("out_advance"))
  if (len (file) == 0) then
    call msg_result (char (string))
  else
    call file_list_write (global%out_files, file, string, advance)
  end if
  call rt_data_restore (global, printf%local)
end subroutine cmd_printf_execute

```

Record data

The expression syntax already contains a `record` keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_record_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  <Commands: cmd record: TBP>
end type cmd_record_t

```

Finalizer for the eval trees.

```

<CCC Commands: procedures>+≡
subroutine cmd_record_final (record)
  type(cmd_record_t), intent(inout) :: record
end subroutine cmd_record_final

```

Output. With the compile hack below, there is nothing of interest to print here.

```

<Commands: cmd record: TBP>≡
procedure :: write => cmd_record_write

<Commands: procedures>+≡
subroutine cmd_record_write (cmd, unit, indent)
  class(cmd_record_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = output_unit (unit); if (u < 0) return
  call write_indent (u, indent)

```

```

        write (u, "(1x,A)") "record"
    end subroutine cmd_record_write

```

Compile. This is a hack which transforms the `record` command into a `record` expression, which we handle in the `expressions` module.

```

<Commands: cmd record: TBP>+≡
    procedure :: compile => cmd_record_compile

<Commands: procedures>+≡
    subroutine cmd_record_compile (cmd, global)
        class(cmd_record_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
        call parse_node_create_branch (pn_lexpr, &
            syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))
        call parse_node_create_branch (pn_lsinglet, &
            syntax_get_rule_ptr (syntax_cmd_list, var_str ("lsinglet")))
        call parse_node_append_sub (pn_lexpr, pn_lsinglet)
        call parse_node_create_branch (pn_lterm, &
            syntax_get_rule_ptr (syntax_cmd_list, var_str ("lterm")))
        call parse_node_append_sub (pn_lsinglet, pn_lterm)
        pn_record => parse_node_get_sub_ptr (cmd%pn)
        call parse_node_append_sub (pn_lterm, pn_record)
        cmd%pn_lexpr => pn_lexpr
    end subroutine cmd_record_compile

```

Command execution. Again, transfer this to the embedded expression and just forget the logical result.

```

<Commands: cmd record: TBP>+≡
    procedure :: execute => cmd_record_execute

<Commands: procedures>+≡
    subroutine cmd_record_execute (cmd, global)
        class(cmd_record_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        logical :: lval
        lval = eval_log (cmd%pn_lexpr, global%var_list)
    end subroutine cmd_record_execute

```

Decay properties

This record holds decay properties for a particle. To be used for `unstable` and `stable` declarations, which contain an array of that type.

```

<CCC Commands: types>+≡
    type :: decay_properties_t
        type(parse_node_t), pointer :: pn_pdg => null ()
        type(string_t) :: prt
        type(flavor_t) :: flv
        integer :: n_proc = 0
        type(string_t), dimension(:), allocatable :: process_id
        real(default), dimension(:), allocatable :: br
        logical :: invalid = .false.

```

```
end type decay_properties_t
```

The finalizer is generic:

```
<CCC Commands: procedures>+≡
subroutine decay_properties_final (decay)
  type(decay_properties_t), intent(inout) :: decay
end subroutine decay_properties_final
```

Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

```
<CCC Commands: types>+≡
type :: cmd_unstable_t
  private
  type(decay_properties_t), dimension(:), allocatable :: decay
  type(command_list_t), pointer :: options => null ()
  type(rt_data_t) :: local
end type cmd_unstable_t
```

Delete the eval tree.

```
<CCC Commands: procedures>+≡
subroutine cmd_unstable_final (unstable)
  type(cmd_unstable_t), intent(inout) :: unstable
  integer :: d
  if (allocated (unstable%decay)) then
    do d = 1, size (unstable%decay)
      call decay_properties_final (unstable%decay(d))
    end do
    deallocate (unstable%decay)
  end if
  if (associated (unstable%options)) then
    call command_list_final (unstable%options)
    deallocate (unstable%options)
  end if
end subroutine cmd_unstable_final
```

Compile. Initiate an eval tree for the decaying particle and determine the decay channel process IDs.

```
<CCC Commands: procedures>+≡
subroutine cmd_unstable_compile (unstable, pn, global)
  type(cmd_unstable_t), pointer :: unstable
  type(parse_node_t), intent(in), target :: pn
  type(rt_data_t), intent(in), target :: global
  type(parse_node_t), pointer :: pn_list, pn_decl
  type(parse_node_t), pointer :: pn_ptr, pn_arg, pn_proc, pn_opt

(Un)polarized particles

Toggle flavors to be (un)polarized and make WHIZARD carry along the polarization. As the code is nearly duplicate between both case, we use a single data type and set of subroutines information.

<CCC Commands: types>+≡

```
type :: cmd_un_polarized_t
  private
  type(parse_node_p), dimension(:), allocatable :: pn_pdg
  type(string_t), dimension(:), allocatable :: name
  type(command_list_t), pointer :: options => null ()
  type(rt_data_t) :: local
end type cmd_un_polarized_t
```

Compile. Initialize the data structure with the pdg expression trees.

<CCC Commands: procedures>+≡

```
subroutine cmd_un_polarized_compile (polarized, pn, global)
  type(cmd_un_polarized_t), pointer :: polarized
  type(parse_node_t), intent(in), target :: pn
  type(rt_data_t), intent(in), target :: global
  type(parse_node_t), pointer :: pn_list, pn_opt, pn_prt
  integer :: n
  allocate (polarized)
  pn_list => parse_node_get_sub_ptr (pn, 2)
  call rt_data_local_init (polarized%local, global)
  if (.not. associated (pn_list)) then
    allocate (polarized%pn_pdg (0))
    allocate (polarized%name (0))
    return
  end if
  pn_opt => parse_node_get_next_ptr (pn_list)
  if (associated (pn_opt)) then
    allocate (polarized%options)
    call command_list_compile (polarized%options, pn_opt, polarized%local)
  end if
  n = parse_node_get_n_sub (pn_list)
  allocate (polarized%pn_pdg(n), polarized%name(n))

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of `else if` constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```
(Commands: types)+≡
  type, extends (command_t) :: cmd_if_t
  private
    type(parse_node_t), pointer :: pn_if_lexpr => null ()
    type(command_list_t), pointer :: if_body => null ()
    type(cmd_if_t), dimension(:), pointer :: elsif_cmd => null ()
    type(command_list_t), pointer :: else_body => null ()
  contains
    (Commands: cmd if: TBP)
  end type cmd_if_t
```

Finalizer. There are no local options, therefore we can simply override the default finalizer.

```
(Commands: cmd if: TBP)≡
  procedure :: final => cmd_if_final

(Commands: procedures)+≡
  recursive subroutine cmd_if_final (cmd)
    class(cmd_if_t), intent(inout) :: cmd
    integer :: i
    if (associated (cmd%if_body)) then
      call command_list_final (cmd%if_body)
      deallocate (cmd%if_body)
    end if
    if (associated (cmd%elsif_cmd)) then
      do i = 1, size (cmd%elsif_cmd)
        call cmd_if_final (cmd%elsif_cmd(i))
      end do
      deallocate (cmd%elsif_cmd)
    end if
    if (associated (cmd%else_body)) then
      call command_list_final (cmd%else_body)
      deallocate (cmd%else_body)
    end if
  end subroutine cmd_if_final
```

Output. Recursively write the command lists.

```
(Commands: cmd if: TBP)+≡
  procedure :: write => cmd_if_write

(Commands: procedures)+≡
  subroutine cmd_if_write (cmd, unit, indent)

  allocate (cmd%command_list)
  call cmd%command_list%compile (parse_tree_get_root_ptr (cmd%parse_tree), &
    global)

```

```
end subroutine cmd_include_compile
```

Execute file contents in the global context.

```
<Commands: cmd include: TBP>+≡
  procedure :: execute => cmd_include_execute

<Commands: procedures>+≡
  subroutine cmd_include_execute (cmd, global)
    class(cmd_include_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%command_list)) then
      call msg_message &
        ("Including Sindarin from '" // char (cmd%file) // "'")
      call cmd%command_list%execute (global)
      call msg_message &
        ("End of included '" // char (cmd%file) // "'")
    end if
  end subroutine cmd_include_execute
```

Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```
<CCC Commands: types>+≡
  type :: cmd_quit_t
  private
  logical :: has_code = .false.
  type(parse_node_t), pointer :: pn_code_expr => null ()
end type cmd_quit_t
```

Finalizer.

```
<CCC Commands: procedures>+≡
  subroutine cmd_quit_final (quit)
    type(cmd_quit_t), intent(inout) :: quit
  end subroutine cmd_quit_final
```

Compile: allocate a quit object which serves as a placeholder.

```
<CCC Commands: procedures>+≡
  subroutine cmd_quit_compile (quit, pn, global)
    type(cmd_quit_t), pointer :: quit
    type(parse_node_t), intent(in), target :: pn
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_arg
    allocate (quit)
    pn_arg => parse_node_get_sub_ptr (pn, 2)
    if (associated (pn_arg)) then
      quit%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
      quit%has_code = .true.
    end if
  end subroutine cmd_quit_compile
```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```

<CCC Commands: procedures>+≡
subroutine cmd_quit_execute (quit, global)
  type(cmd_quit_t), intent(inout), target :: quit
  type(rt_data_t), intent(inout), target :: global
  logical :: is_known
  if (quit%has_code) then
    global%quit_code = eval_int (quit%pn_code_expr, global%var_list, &
      is_known=is_known)
    if (.not. is_known) then
      call msg_error ("Undefined return code of quit/exit command")
    end if
  end if
  global%quit = .true.
end subroutine cmd_quit_execute

```

20.2.3 The command list

The command list holds a list of commands and relevant global data.

```

<Commands: public>≡
public :: command_list_t

<Commands: types>+≡
type :: command_list_t
  ! not private anymore as required by the whizard-c-interface
  class(command_t), pointer :: first => null ()
  class(command_t), pointer :: last => null ()
contains
  <Commands: command list: TBP>
end type command_list_t

```

Output.

```

<Commands: command list: TBP>≡
procedure :: write => command_list_write

<Commands: procedures>+≡
recursive subroutine command_list_write (cmd_list, unit, indent)
  class(command_list_t), intent(in) :: cmd_list

    procedure :: append => command_list_append

<Commands: procedures>+≡
    subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
        if (associated (cmd_list%last)) then
            cmd_list%last%next => command
        else
            cmd_list%first => command
        end if
        cmd_list%last => command
        command => null ()
    end subroutine command_list_append

```

Finalize.

```

<Commands: command list: TBP>+≡
    procedure :: final => command_list_final

<Commands: procedures>+≡
    recursive subroutine command_list_final (cmd_list)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), pointer :: command
        do while (associated (cmd_list%first))
            command => cmd_list%first
            cmd_list%first => cmd_list%first%next
            call command%final ()
            deallocate (command)
        end do
        cmd_list%last => null ()
    end subroutine command_list_final

```

20.2.4 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```

<Commands: command list: TBP>+≡
    procedure :: compile => command_list_compile

<Commands: procedures>+≡
    recursive subroutine command_list_compile (cmd_list, pn, global)
        class(command_list_t), intent(inout), target :: cmd_list
        type(parse_node_t), intent(in), target :: pn
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_cmd
        class(command_t), pointer :: command
        integer :: i
        pn_cmd => parse_node_get_sub_ptr (pn)
        do i = 1, parse_node_get_n_sub (pn)
            call dispatch_command (command, pn_cmd)
        end do
    end subroutine command_list_compile

```

```

        call command%compile (global)
        call cmd_list%append (command)
        call terminate_now_if_signal ()
        pn_cmd => parse_node_get_next_ptr (pn_cmd)
    end do
end subroutine command_list_compile

```

20.2.5 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```

<Commands: command list: TBP>+≡
    procedure :: execute => command_list_execute

<Commands: procedures>+≡
    recursive subroutine command_list_execute (cmd_list, global)
        class(command_list_t), intent(in) :: cmd_list
        type(rt_data_t), intent(inout), target :: global
        class(command_t), pointer :: command
        command => cmd_list%first
        COMMAND_COND: do while (associated (command))
            call command%execute_options (global)
            call command%execute (global)
            call command%reset_options (global)
            call terminate_now_if_signal ()
            if (global%quit) exit COMMAND_COND
            command => command%next
        end do COMMAND_COND
    end subroutine command_list_execute

```

20.2.6 Command list syntax

```

20.3.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the **whizard** object. Most parameters are used for initializing the **global** state.

```

<WHIZARD: public>≡
    public :: whizard_options_t

<WHIZARD: types>≡
    type :: whizard_options_t
        type(string_t) :: preload_model
        type(string_t) :: preload_library
        logical :: rebuild_library = .false.
    ! logical :: rebuild_user
        logical :: rebuild_phs = .false.
        logical :: rebuild_grids = .false.
        logical :: rebuild_events = .false.
    end type whizard_options_t

```

20.3.2 The whizard object

An object of type **whizard_t** is the top-level wrapper for a **WHIZARD** instance. The object holds various default settings and the current state of the generator, the **global** object of type **rt_data_t**. This object contains, for instance, the list of variables and the process libraries.

Since components of the **global** subobject are frequently used as targets, the **whizard** object should also consistently carry the **target** attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the

syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+≡
    public :: whizard_t

<WHIZARD: types>+≡
    type :: whizard_t
        type(whizard_options_t) :: options
        type(rt_data_t) :: global
    contains
        <WHIZARD: whizard: TBP>
    end type whizard_t

```

20.3.3 Initialization and finalization

```

<WHIZARD: whizard: TBP>≡
    procedure :: init => whizard_init

<WHIZARD: procedures>≡
    subroutine whizard_init (whizard, options)
        class(whizard_t), intent(out), target :: whizard
        type(whizard_options_t), intent(in) :: options
        call init_syntax_tables ()
        whizard%options = options
        call whizard%global%global_init ()
        call whizard%init_rebuild_flags ()
        call whizard%preload_model ()
        call whizard%preload_library ()
    end subroutine whizard_init

<WHIZARD: whizard: TBP>+≡
    procedure :: final => whizard_final

<WHIZARD: procedures>+≡
    subroutine whizard_final (whizard)
        class(whizard_t), intent(inout), target :: whizard
        call whizard%global%final ()
        call final_syntax_tables ()
    end subroutine whizard_final

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: procedures>+≡
    subroutine whizard_init_rebuild_flags (whizard)
        class(whizard_t), intent(inout), target :: whizard
        associate (var_list => whizard%global%var_list, options => whizard%options)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_library"), options%rebuild_library, &
                    intrinsic=.true.)
            call var_list_append_log &

```

```

        (var_list, var_str ("?rebuild_phase_space"), options%rebuild_phs, &
        intrinsic=.true.)
    call var_list_append_log &
        (var_list, var_str ("?rebuild_grids"), options%rebuild_grids, &
        intrinsic=.true.)
    call var_list_append_log &
        (var_list, var_str ("?rebuild_events"), options%rebuild_events, &
        intrinsic=.true.)
end associate
end subroutine whizard_init_rebuild_flags

```

This procedure preloads a model, if a model name is given.

<WHIZARD: whizard: TBP>+≡

```

    procedure :: preload_model => whizard_preload_model

```

<WHIZARD: procedures>+≡

```

subroutine whizard_preload_model (whizard)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t) :: model_name, filename
    model_name = whizard%options%preload_model
    if (model_name /= "") then
        filename = model_name // ".mdl"
        call whizard%global%read_model (model_name, filename)
        if (associated (whizard%global%model)) then
            call msg_message ("Preloaded model: " &
                // char (model_name))
        else
            call msg_fatal ("Preloading model " // char (model_name) &
                // " failed")
        end if
    else
        call msg_message ("No model preloaded")
    end if
end subroutine whizard_preload_model

```

This procedure preloads a library, if a library name is given.

Note: This version just opens a new library with that name. It does not load (yet) an existing library on file, as previous WHIZARD versions would do.

<WHIZARD: whizard: TBP>+≡

```

    procedure :: preload_library => whizard_preload_library

```

<WHIZARD: procedures>+≡

```

subroutine whizard_preload_library (whizard)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t) :: library_name, filename
    type(prclib_entry_t), pointer :: lib_entry
    type(process_library_t), pointer :: lib
    library_name = whizard%options%preload_library
    if (library_name /= "") then
        allocate (lib_entry)
        call lib_entry%init (library_name)
        call whizard%global%add_prclib (lib_entry)
        call msg_message ("Preloaded library: " // char (library_name))
    else

```

```

        call msg_message ("No library preloaded")
    end if
end subroutine whizard_preload_library

```

20.3.4 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags.
