WHIZARD¹

Wolfgang Kilian,² Thorsten Ohl,³ Jürgen Reuter⁴

Version 2.2.0 α -3, Oct 15 2013

with contributions from: Fabian Bach, Felix Braam, David Gordo
Gomez, Sebastian Schmidt, Marco Sekulla, Christian Speckner,
Daniel Wiesler

¹The original meaning of the acronym is *W, Higgs, Z, And Respective Decays*. The current program is much more than that, however.

Abstract

WHIZARD is an application of the VAMP algorithm: Adaptive multi-channel integration and event generation. The bare VAMP library is augmented by modules for Lorentz algebra, particles, phase space, etc., such that physical processes with arbitrary complex final states [well, in principle. . .] can be integrated and *unweighted* events be generated.

Chapter 1

Changes

For a comprehensive list of changes confer the ChangeLog file or the subversion log.

Chapter 2

Tools

This part contains modules needed for auxiliary purposes:

limits Compile-time (integer) constants: fixed array sizes, input field lengths, and such. Any module that uses such constants has to access them via **limits**.

mpi90 Parallel execution (currently disabled!). This module contains dummy replacements for the message passing interface subroutines.

clock Store and handle dates and times

diagnostics Error and diagnostic message handling. Any messages and errors issued by WHIZARD functions are handled by the subroutines in this module, if possible.

files Files and auxiliary routines that do not belong anywhere else.

permutations Handle permutations of integers.

unix_args Parse the command-line arguments and options. This part is system-dependent, and we provide a replacement if the functions are not available.

2.1 Preliminaries

The WHIZARD file header:

```
<File header>≡
! WHIZARD <Version> <Date>
!
! Copyright (C) 1999-2013 by
!   Wolfgang Kilian <kilian@physik.uni-siegen.de>
!   Thorsten Ohl <ohl@physik.uni-wuerzburg.de>
!   Juergen Reuter <juergen.reuter@desy.de>
!
!   with contributions by
!   Christian Speckner <cnspeckn@googlemail.com>
!   and Felix Braam, Sebastian Schmidt, Daniel Wiesler
!
! WHIZARD is free software; you can redistribute it and/or modify it
```

```

! under the terms of the GNU General Public License as published by
! the Free Software Foundation; either version 2, or (at your option)
! any later version.
!
! WHIZARD is distributed in the hope that it will be useful, but
! WITHOUT ANY WARRANTY; without even the implied warranty of
! MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the
! GNU General Public License for more details.
!
! You should have received a copy of the GNU General Public License
! along with this program; if not, write to the Free Software
! Foundation, Inc., 675 Mass Ave, Cambridge, MA 02139, USA.
!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
! This file has been stripped of most comments. For documentation, refer
! to the source 'whizard.nw'

```

We are strict with our names:

```

<Standard module head>≡
    implicit none
    private

```

This is the way to invoke the kinds module (not contained in this source)

```

<Use kinds>≡
    use kinds, only: default !NODEP!

```

And we make heavy use of variable-length strings

```

<Use strings>≡
    use iso_varying_string, string_t => varying_string !NODEP!

```

Some parameters (buffer sizes etc.) are hardcoded. They are collected in this module:

```

<limits.f90>≡
    <File header>

    module limits

    use iso_fortran_env, only: iostat_end, iostat_eor !NODEP!
    <Use kinds>

    <Standard module head>

    <Limits: public parameters>

    end module limits

```

The version string is used for checking files. Note that the string length MUST NOT be changed, because reading binary files relies on it.

```

<Limits: public parameters>≡
    integer, parameter, public :: VERSION_STRLEN = 255
    character(len=VERSION_STRLEN), parameter, public :: &
        & VERSION_STRING = "WHIZARD version <Version> (<Date>)"

```

2.2 Parallelization

This section has been removed, it was never used even in WHIZARD1. Parallelization should be reimplemented from scratch.

2.3 File utilities

This module provides miscellaneous tools associated with strings and files:

- Finding a free unit
- Selecting an output unit (stdout if undefined)
- Upper and lower case for strings
- Formatting a number for T_EX output.

```
<file_utils.f90>≡  
<File header>  
  
module file_utils  
  
    use iso_fortran_env, only: stdout => output_unit !NODEP!  
<Use kinds>  
<Use strings>  
    use limits, only: MIN_UNIT, MAX_UNIT !NODEP!  
    use, intrinsic :: iso_c_binding !NODEP!  
  
<Standard module head>  
  
<File utils: public>  
  
<File utils: interfaces>  
  
contains  
  
<File utils: procedures>  
  
end module file_utils
```

2.3.1 Finding an I/O unit

Fortran 95 (even Fortran 2003) has no notion of implicit I/O units. Therefore, we have to find a free unit by trial and error.

```
<Limits: public parameters>+≡  
    integer, parameter, public :: MIN_UNIT = 11, MAX_UNIT = 99  
<File utils: public>≡  
    public :: free_unit
```

```

<File utils: procedures>≡
function free_unit () result (unit)
  integer :: unit
  logical :: exists, is_open
  integer :: i, status
  do i = MIN_UNIT, MAX_UNIT
    inquire (unit=i, exist=exists, opened=is_open, iostat=status)
    if (status == 0) then
      if (exists .and. .not. is_open) then
        unit = i; return
      end if
    end if
  end do
  unit = -1
end function free_unit

```

```

<Use file utils>≡
use file_utils !NODEP!

```

Return the given unit, if present, otherwise the default STDOUT unit.

```

<File utils: public>+≡
public :: output_unit

<File utils: procedures>+≡
function output_unit (unit) result (u)
  integer, intent(in), optional :: unit
  integer :: u
  if (present (unit)) then
    u = unit
  else
    u = stdout
  end if
end function output_unit

```

2.3.2 Deleting a file

Fortran does not contain a command for deleting a file. Here, we provide a subroutine that deletes a file if it exists. We do not handle the subtleties, so we assume that it is writable if it exists.

```

<File utils: public>+≡
public :: delete_file

<File utils: procedures>+≡
subroutine delete_file (name)
  character(*), intent(in) :: name
  logical :: exist
  integer :: u
  inquire (file = name, exist = exist)
  if (exist) then
    u = free_unit ()
    open (unit = u, file = name)
    close (u, status = "delete")
  end if
end subroutine delete_file

```

```
end subroutine delete_file
```

2.3.3 String auxiliary functions

These are, unfortunately, not part of Fortran.

(File utils: public)+≡

```
public :: upper_case
public :: lower_case
```

(File utils: interfaces)≡

```
interface upper_case
  module procedure upper_case_char, upper_case_string
end interface
interface lower_case
  module procedure lower_case_char, lower_case_string
end interface
```

(File utils: procedures)+≡

```
function upper_case_char (string) result (new_string)
  character(*), intent(in) :: string
  character(len(string)) :: new_string
  integer :: pos, code
  integer, parameter :: offset = ichar('A')-ichar('a')
  do pos = 1, len (string)
    code = ichar (string(pos:pos))
    select case (code)
      case (ichar('a'):ichar('z'))
        new_string(pos:pos) = char (code + offset)
      case default
        new_string(pos:pos) = string(pos:pos)
    end select
  end do
end function upper_case_char

function lower_case_char (string) result (new_string)
  character(*), intent(in) :: string
  character(len(string)) :: new_string
  integer :: pos, code
  integer, parameter :: offset = ichar('a')-ichar('A')
  do pos = 1, len (string)
    code = ichar (string(pos:pos))
    select case (code)
      case (ichar('A'):ichar('Z'))
        new_string(pos:pos) = char (code + offset)
      case default
        new_string(pos:pos) = string(pos:pos)
    end select
  end do
end function lower_case_char

function upper_case_string (string) result (new_string)
  type(string_t), intent(in) :: string
  type(string_t) :: new_string
```

```

    new_string = upper_case_char (char (string))
end function upper_case_string

function lower_case_string (string) result (new_string)
    type(string_t), intent(in) :: string
    type(string_t) :: new_string
    new_string = lower_case_char (char (string))
end function lower_case_string

```

Quote underscore characters for use in T_EX output.

```

<File utils: public>+≡
    public :: quote_underscore

<File utils: procedures>+≡
    function quote_underscore (string) result (quoted)
        type(string_t) :: quoted
        type(string_t), intent(in) :: string
        type(string_t) :: part
        type(string_t) :: buffer
        buffer = string
        quoted = ""
        do
            call split (part, buffer, "_")
            quoted = quoted // part
            if (buffer == "") exit
            quoted = quoted // "\"
        end do
    end function quote_underscore

```

Convert a FORTRAN string into a zero terminated C string.

```

<File utils: public>+≡
    public :: string_f2c

<File utils: interfaces>+≡
    interface string_f2c
        module procedure string_f2c_char, string_f2c_var_str
    end interface string_f2c

<File utils: procedures>+≡
    pure function string_f2c_char (i) result (o)
        character(*), intent(in) :: i
        character(kind=c_char, len=len (i) + 1) :: o
        o = i // c_null_char
    end function string_f2c_char

    pure function string_f2c_var_str (i) result (o)
        type(string_t), intent(in) :: i
        character(kind=c_char, len=len (i) + 1) :: o
        o = char (i) // c_null_char
    end function string_f2c_var_str

```

2.3.4 Formatting numbers

Format a number with n significant digits for use in T_EX documents.

(File utils: public)+≡

```
public :: tex_format
```

(File utils: procedures)+≡

```
function tex_format (rval, n_digits) result (string)
  type(string_t) :: string
  real(default), intent(in) :: rval
  integer, intent(in) :: n_digits
  integer :: e, n, w, d
  real(default) :: absval
  real(default) :: mantissa
  character :: sign
  character(20) :: format
  character(80) :: cstr
  n = min (abs (n_digits), 16)
  if (rval == 0) then
    string = "0"
  else
    absval = abs (rval)
    e = log10 (absval)
    if (rval < 0) then
      sign = "-"
    else
      sign = ""
    end if
    select case (e)
    case (:-3)
      d = max (n - 1, 0)
      w = max (d + 2, 2)
      write (format, "('(F',IO,'.',IO,'A,IO,A)')") w, d
      mantissa = absval * 10._default ** (1 - e)
      write (cstr, fmt=format) mantissa, "\times 10^{", e - 1, "}"
    case (-2:0)
      d = max (n - e, 1 - e)
      w = max (d + e + 2, d + 2)
      write (format, "('(F',IO,'.',IO,')')") w, d
      write (cstr, fmt=format) absval
    case (1:2)
      d = max (n - e - 1, -e, 0)
      w = max (d + e + 2, d + 2, e + 2)
      write (format, "('(F',IO,'.',IO,')')") w, d
      write (cstr, fmt=format) absval
    case default
      d = max (n - 1, 0)
      w = max (d + 2, 2)
      write (format, "('(F',IO,'.',IO,'A,IO,A)')") w, d
      mantissa = absval * 10._default ** (- e)
      write (cstr, fmt=format) mantissa, "\times 10^{", e, "}"
    end select
    string = sign // trim (cstr)
  end if
end function tex_format
```

Write a number for use in Metapost code:

```

<File utils: public>+=
  public :: mp_format
<File utils: procedures>+=
  function mp_format (rval) result (string)
    type(string_t) :: string
    real(default), intent(in) :: rval
    character(16) :: tmp
    write (tmp, "(G16.8)")  rval
    string = lower_case (trim (adjustl (trim (tmp))))
  end function mp_format

```

2.4 Unit tests

Here, we provide functionality for automated unit tests. Each test is required to produce output which is compared against a reference file. If the two are identical, we signal success. Otherwise, we signal failure and write the output to a file.

```

<unit_tests.f90>=
  module unit_tests

    <Use strings>
    <Use file utils>

    <Standard module head>

    <Tests: public>

    <Tests: parameters>

    <Tests: types>

    <Tests: interfaces>

    contains

    <Tests: procedures>

  end module unit_tests

```

2.4.1 Parameters

Building blocks of file names:

```

<Tests: parameters>=
  character(*), parameter :: ref_prefix = "ref-output/"
  character(*), parameter :: ref = ".ref"

  character(*), parameter :: err_prefix = "err-output/"

```

```
character(*), parameter :: err = ".out"
```

2.4.2 Type for storing test results

We store the results of the individual unit tests in a linked list. Here is the entry:

```
<Tests: public>≡
    public :: test_results_t

<Tests: types>≡
    type :: test_result_t
        logical :: success = .false.
        type(string_t) :: name
        type(string_t) :: description
        type(test_result_t), pointer :: next => null ()
    end type test_result_t

    type :: test_results_t
        private
        type(test_result_t), pointer :: first => null ()
        type(test_result_t), pointer :: last => null ()
        integer :: n_success = 0
        integer :: n_failure = 0
        contains
        <Tests: test results: TBP>
    end type test_results_t
```

Add a test result.

```
<Tests: test results: TBP>≡
    procedure, private :: add => test_results_add

<Tests: procedures>≡
    subroutine test_results_add (list, name, description, success)
        class(test_results_t), intent(inout) :: list
        character(len=*), intent(in) :: name
        character(len=*), intent(in) :: description
        logical, intent(in) :: success
        type(test_result_t), pointer :: result
        allocate (result)
        result%success = success
        result%name = name
        result%description = description
        if (associated (list%first)) then
            list%last%next => result
        else
            list%first => result
        end if
        list%last => result
        if (success) then
            list%n_success = list%n_success + 1
        else
            list%n_failure = list%n_failure + 1
        end if
    end subroutine
```

```
end subroutine test_results_add
```

Display the current state.

<Tests: test results: TBP>+≡

```
procedure, private :: write => test_results_write
```

<Tests: procedures>+≡

```
subroutine test_results_write (list, u)
  class(test_results_t), intent(in) :: list
  integer, intent(in) :: u
  type(test_result_t), pointer :: result
  write (u, "(A)")  "*** Test Summary ***"
  if (list%n_success > 0) then
    write (u, "(2x,A)") "Success:"
    result => list%first
    do while (associated (result))
      if (result%success) write (u, "(4x,A,': ',A)") &
        char (result%name), char (result%description)
      result => result%next
    end do
  end if
  if (list%n_failure > 0) then
    write (u, "(2x,A)") "Failure:"
    result => list%first
    do while (associated (result))
      if (.not. result%success) write (u, "(4x,A,': ',A)") &
        char (result%name), char (result%description)
      result => result%next
    end do
  end if
  write (u, "(A,I0)") "Total   = ", list%n_success + list%n_failure
  write (u, "(A,I0)") "Success = ", list%n_success
  write (u, "(A,I0)") "Failure = ", list%n_failure
  write (u, "(A)")  "*** End of test Summary ***"
end subroutine test_results_write
```

Return true if all tests were successful (or no test).

<Tests: test results: TBP>+≡

```
procedure, private :: report => test_results_report
```

<Tests: procedures>+≡

```
subroutine test_results_report (list, success)
  class(test_results_t), intent(in) :: list
  logical, intent(out) :: success
  success = list%n_failure == 0
end subroutine test_results_report
```

Delete the list.

<Tests: test results: TBP>+≡

```
procedure, private :: final => test_results_final
```

<Tests: procedures>+≡

```
subroutine test_results_final (list)
  class(test_results_t), intent(inout) :: list
```

```

type(test_result_t), pointer :: result
do while (associated (list%first))
    result => list%first
    list%first => result%next
    deallocate (result)
end do
list%last => null ()
list%n_success = 0
list%n_failure = 0
end subroutine test_results_final

```

2.4.3 Wrapup

This will write results, report status, and finalize. This is the only method which we need to access from outside.

```

<Tests: test results: TBP>+≡
    procedure :: wrapup => test_results_wrapup

<Tests: procedures>+≡
    subroutine test_results_wrapup (list, u, success)
        class(test_results_t), intent(inout) :: list
        integer, intent(in) :: u
        logical, intent(out), optional :: success
        call list%write (u)
        if (present (success)) call list%report (success)
        call list%final ()
    end subroutine test_results_wrapup

```

2.4.4 Tool for Unit Tests

This procedure takes a test routine as an argument. It runs the test, output directed to a temporary file. Then, it compares the file against a reference file.

The test routine must take the output unit as argument.

```

<Tests: interfaces>≡
    abstract interface
        subroutine unit_test (u)
            integer, intent(in) :: u
        end subroutine unit_test
    end interface

```

The test routine can print to screen and, optionally, to a logging unit.

```

<Tests: public>+≡
    public :: test

<Tests: procedures>+≡
    subroutine test (test_proc, name, description, u_log, results)
        procedure(unit_test) :: test_proc
        character(*), intent(in) :: name
        character(*), intent(in) :: description
        integer, intent(in) :: u_log
        type(test_results_t), intent(inout) :: results
    end subroutine test

```

```

integer :: u_test, u_ref, u_err
logical :: exist
character(256) :: buffer1, buffer2
integer :: iostat1, iostat2
logical :: success
write (*, "(A)", advance="no") "Running test: " // name
write (u_log, "(A)") "Test: " // name
u_test = free_unit ()
open (u_test, status="scratch", action="readwrite")
call test_proc (u_test)
rewind (u_test)
inquire (file=ref_prefix//name//ref, exist=exist)
if (exist) then
    u_ref = free_unit ()
    open (u_ref, file=ref_prefix//name//ref, status="old", action="read")
    COMPARE_FILES: do
        read (u_test, "(A)", iostat=iostat1) buffer1
        read (u_ref, "(A)", iostat=iostat2) buffer2
        if (iostat1 /= iostat2) then
            success = .false.
            exit COMPARE_FILES
        else if (iostat1 < 0) then
            success = .true.
            exit COMPARE_FILES
        else if (buffer1 /= buffer2) then
            success = .false.
            exit COMPARE_FILES
        end if
    end do COMPARE_FILES
    close (u_ref)
else
    write (*, "(A)", advance="no") " ... no reference output available"
    write (u_log, "(A)") " No reference output available."
    success = .false.
end if
if (success) then
    write (*, "(A)") " ... success."
    write (u_log, "(A)") " Success."
else
    write (*, "(A)") " ... failure. See: " // err_prefix//name//err
    write (u_log, "(A)") " Failure."
    rewind (u_test)
    u_err = free_unit ()
    open (u_err, file=err_prefix//name//err, &
        action="write", status="replace")
    WRITE_OUTPUT: do
        read (u_test, "(A)", end=1) buffer1
        write (u_err, "(A)") trim (buffer1)
    end do WRITE_OUTPUT
1    close (u_err)
end if
close (u_test)
call results%add (name, description, success)
end subroutine test

```

2.5 Operating-system interface

For specific purposes, we need direct access to the OS (system calls). This is, of course, system dependent. The current version is valid for GNU/Linux; we expect to use a preprocessor for this module if different OSs are to be supported.

The current implementation lacks error handling.

```
<os_interface.f90>≡  
  <File header>  
  
  module os_interface  
  
    use iso_c_binding !NODEP!  
    <Use strings>  
    <Use file utils>  
    use system_dependencies !NODEP!  
    use limits, only: DLERROR_LEN, ENVVAR_LEN !NODEP!  
    use diagnostics !NODEP!  
  
    <Standard module head>  
  
    <OS interface: public>  
  
    <OS interface: types>  
  
    <OS interface: interfaces>  
  
    contains  
  
    <OS interface: procedures>  
  
  end module os_interface
```

2.5.1 Path variables

This is a transparent container for storing user-defined path variables.

```
<OS interface: public>≡  
  public :: paths_t  
  
<OS interface: types>≡  
  type :: paths_t  
    type(string_t) :: prefix  
    type(string_t) :: exec_prefix  
    type(string_t) :: bindir  
    type(string_t) :: libdir  
    type(string_t) :: includedir  
    type(string_t) :: datarootdir  
    type(string_t) :: localprefix  
    type(string_t) :: libtool  
    type(string_t) :: lhapdfdir  
  end type paths_t
```

```

<OS interface: public>+≡
    public :: paths_init

<OS interface: procedures>≡
    subroutine paths_init (paths)
        type(paths_t), intent(out) :: paths
        paths%prefix = ""
        paths%exec_prefix = ""
        paths%bindir = ""
        paths%libdir = ""
        paths%includedir = ""
        paths%datarootdir = ""
        paths%localprefix = ""
        paths%libtool = ""
        paths%lhapdfdir = ""
    end subroutine paths_init

```

2.5.2 System dependencies

We store all potentially system- and user/run-dependent data in a transparent container. This includes compiler/linker names and flags, file extensions, etc.

```

<OS interface: public>+≡
    public :: os_data_t

<OS interface: types>+≡
    type :: os_data_t
        logical :: use_libtool
        logical :: use_testfiles
        type(string_t) :: fc
        type(string_t) :: fcflags
        type(string_t) :: fcflags_pic
        type(string_t) :: fc_src_ext
        type(string_t) :: cc
        type(string_t) :: cflags
        type(string_t) :: cflags_pic
        type(string_t) :: obj_ext
        type(string_t) :: ld
        type(string_t) :: ldflags
        type(string_t) :: ldflags_so
        type(string_t) :: ldflags_static
        type(string_t) :: ldflags_hepmc
        type(string_t) :: shlib_ext
        type(string_t) :: makeflags
        type(string_t) :: prefix
        type(string_t) :: exec_prefix
        type(string_t) :: bindir
        type(string_t) :: libdir
        type(string_t) :: includedir
        type(string_t) :: datarootdir
        type(string_t) :: whizard_omega_binpath
        type(string_t) :: whizard_includes
        type(string_t) :: whizard_ldflags
        type(string_t) :: whizard_libtool

```

```

type(string_t) :: whizard_modelpath
type(string_t) :: whizard_models_libpath
type(string_t) :: whizard_susypath
type(string_t) :: whizard_gmlpath

Replace occurrences of GNU path variables (such as ``${prefix}``) by their values. Do this for all strings that could depend on them, and do the replacement in reverse order, since the path variables may be defined in terms of each other.

end subroutine os_data_write

```

2.5.3 Dynamic linking

We define a type that holds the filehandle for a dynamically linked library (shared object), together with functions to open and close the library, and to access functions in this library.

```

<OS interface: public>+≡
public :: dlaccess_t

<OS interface: types>+≡
type :: dlaccess_t
private
type(string_t) :: filename
type(c_ptr) :: handle = c_null_ptr
logical :: is_open = .false.
logical :: has_error = .false.
type(string_t) :: error
contains
<OS interface: dlaccess: TBP>
end type dlaccess_t

```

Output. This is called by the output routine for the process library.

```

<OS interface: dlaccess: TBP>≡
  procedure :: write => dlaccess_write
<OS interface: procedures>+≡
  subroutine dlaccess_write (object, unit)
    class(dlaccess_t), intent(in) :: object
    integer, intent(in) :: unit
    write (unit, "(1x,A)") "DL access info:"
    !!! This is OS dependent (could be wrapped with a logical though)
    !!! write (unit, "(3x,A,A,A)") "filename = ', char (object%filename), ""
    write (unit, "(3x,A,L1)") "is open = ", object%is_open
    if (object%has_error) then
      write (unit, "(3x,A,A,A)") "error = ', char (object%error), ""
    else
      write (unit, "(3x,A)") "error = [none]"
    end if
  end subroutine dlaccess_write

```

The interface to the library functions:

```

<OS interface: interfaces>≡
  interface
    function dlopen (filename, flag) result (handle) bind(C)
      import
      character(c_char), dimension(*) :: filename
      integer(c_int), value :: flag
      type(c_ptr) :: handle
    end function dlopen
  end interface

  interface
    function dlclose (handle) result (status) bind(C)
      import
      type(c_ptr), value :: handle
      integer(c_int) :: status
    end function dlclose
  end interface

  interface
    function dlerror () result (str) bind(C)
      import
      type(c_ptr) :: str
    end function dlerror
  end interface

  interface
    function dlsym (handle, symbol) result (fptr) bind(C)
      import
      type(c_ptr), value :: handle
      character(c_char), dimension(*) :: symbol
      type(c_funptr) :: fptr
    end function dlsym

```

```
end interface
```

This reads an error string and transforms it into a `string_t` object, if an error has occurred. If not, set the error flag to false and return an empty string.

```
<Limits: public parameters>+≡
    integer, parameter, public :: DLERROR_LEN = 160

<OS interface: procedures>+≡
    subroutine read_dlerror (has_error, error)
        logical, intent(out) :: has_error
        type(string_t), intent(out) :: error
        type(c_ptr) :: err_cptr
        character(len=DLERROR_LEN, kind=c_char), pointer :: err_fptr
        integer :: str_end
        err_cptr = dlerror ()
        if (c_associated (err_cptr)) then
            call c_f_pointer (err_cptr, err_fptr)
            has_error = .true.
            str_end = scan (err_fptr, c_null_char)
            if (str_end > 0) then
                error = err_fptr(1:str_end-1)
            else
                error = err_fptr
            end if
        else
            has_error = .false.
            error = ""
        end if
    end subroutine read_dlerror
```

This is the Fortran API. Init/final open and close the file, i.e., load and unload the library.

Note that a library can be opened more than once, and that for an ultimate close as many `dlclose` calls as `dlopen` calls are necessary. However, we assume that it is opened and closed only once.

```
<OS interface: public>+≡
    public :: dlaccess_init
    public :: dlaccess_final

<OS interface: dlaccess: TBP>+≡
    procedure :: init => dlaccess_init
    procedure :: final => dlaccess_final

<OS interface: procedures>+≡
    subroutine dlaccess_init (dlaccess, prefix, libname, os_data)
        class(dlaccess_t), intent(out) :: dlaccess
        type(string_t), intent(in) :: prefix, libname
        type(os_data_t), intent(in), optional :: os_data
        type(string_t) :: filename
        logical :: exist
        dlaccess%filename = libname
        filename = prefix // "/" // libname
        inquire (file=char(filename), exist=exist)
        if (.not. exist) then
```

```

        filename = prefix // "/.libs/" // libname
        inquire (file=char(filename), exist=exist)
        if (.not. exist) then
            dlaccess%has_error = .true.
            dlaccess%error = "Library '" // filename // "' not found"
            return
        end if
    end if
    dlaccess%handle = dlopen (char (filename) // c_null_char, ior ( &
        RTLD_LAZY, RTLD_LOCAL))
    dlaccess%is_open = c_associated (dlaccess%handle)
    call read_dlerror (dlaccess%has_error, dlaccess%error)
end subroutine dlaccess_init

subroutine dlaccess_final (dlaccess)
    class(dlaccess_t), intent(inout) :: dlaccess
    integer(c_int) :: status
    if (dlaccess%is_open) then
        status = dlclose (dlaccess%handle)
        dlaccess%is_open = .false.
        call read_dlerror (dlaccess%has_error, dlaccess%error)
    end if
end subroutine dlaccess_final

```

Return true if an error has occurred.

```

<OS interface: public>+≡
    public :: dlaccess_has_error

<OS interface: procedures>+≡
    function dlaccess_has_error (dlaccess) result (flag)
        logical :: flag
        type(dlaccess_t), intent(in) :: dlaccess
        flag = dlaccess%has_error
    end function dlaccess_has_error

```

Return the error string currently stored in the dlaccess object.

```

<OS interface: public>+≡
    public :: dlaccess_get_error

<OS interface: procedures>+≡
    function dlaccess_get_error (dlaccess) result (error)
        type(string_t) :: error
        type(dlaccess_t), intent(in) :: dlaccess
        error = dlaccess%error
    end function dlaccess_get_error

```

The symbol handler returns the C address of the function with the given string name. (It is a good idea to use `bind(C)` for all functions accessed by this, such that the name string is well-defined.) Call `c_f_procpointer` to cast this into a Fortran procedure pointer with an appropriate interface.

```

<OS interface: public>+≡
    public :: dlaccess_get_c_funptr

```

```

<OS interface: procedures>+≡
function dlaccess_get_c_funptr (dlaccess, fname) result (fptr)
  type(c_funptr) :: fptr
  type(dlaccess_t), intent(inout) :: dlaccess
  type(string_t), intent(in) :: fname
  fptr = dlsym (dlaccess%handle, char (fname) // c_null_char)
  call read_dlerror (dlaccess%has_error, dlaccess%error)
end function dlaccess_get_c_funptr

```

2.5.4 Predicates

Return true if the library is loaded. In particular, this is false if loading was unsuccessful.

```

<OS interface: public>+≡
  public :: dlaccess_is_open

<OS interface: procedures>+≡
function dlaccess_is_open (dlaccess) result (flag)
  logical :: flag
  type(dlaccess_t), intent(in) :: dlaccess
  flag = dlaccess%is_open
end function dlaccess_is_open

```

2.5.5 Shell access

This is the standard system call for executing a shell command, such as invoking a compiler.

In F2008 there will be the equivalent built-in command `execute_command_line`.

```

<OS interface: public>+≡
  public :: os_system_call

<OS interface: procedures>+≡
subroutine os_system_call (command_string, status, verbose)
  type(string_t), intent(in) :: command_string
  integer, intent(out), optional :: status
  logical, intent(in), optional :: verbose
  logical :: verb
  integer :: stat
  verb = .false.; if (present (verbose)) verb = verbose
  if (verb) &
    call msg_message ("command: " // char (command_string))
  stat = system (char (command_string) // c_null_char)
  if (present (status)) then
    status = stat
  else if (stat /= 0) then
    if (.not. verb) &
      call msg_message ("command: " // char (command_string))
    write (msg_buffer, "(A,I0)") "Return code = ", stat
    call msg_message ()
    call msg_fatal ("System command returned with nonzero status code")
  end if

```

```

end subroutine os_system_call

<OS interface: interfaces>+≡
interface
  function system (command) result (status) bind(C)
    import
    integer(c_int) :: status
    character(c_char), dimension(*) :: command
  end function system
end interface

```

2.5.6 Querying for a directory

This queries for the existence of a directory. There is no standard way to achieve this in FORTRAN, and if we were to call into `libc`, we would need access to C macros for evaluating the result, so we resort to calling `test` as a system call.

```

<OS interface: public>+≡
public :: os_dir_exist

<OS interface: procedures>+≡
function os_dir_exist (name) result (res)
  type(string_t), intent(in) :: name
  logical :: res
  integer :: status
  call os_system_call ('test -d "' // name // '"', status=status)
  res = status == 0
end function os_dir_exist

```

2.5.7 Fortran compiler and linker

Compile a single module for use in a shared library, but without linking.

```

<OS interface: public>+≡
public :: os_compile_shared

<OS interface: procedures>+≡
subroutine os_compile_shared (src, os_data, status)
  type(string_t), intent(in) :: src
  type(os_data_t), intent(in) :: os_data
  integer, intent(out), optional :: status
  type(string_t) :: command_string
  if (os_data%use_libtool) then
    command_string = &
      os_data%whizard_libtool // " --mode=compile " // &
      os_data%fc // " " // &
      "-c " // &
      os_data%whizard_includes // " " // &
      os_data%fcflags // " " // &
      "' " // src // os_data%fc_src_ext // "' "
  else
    command_string = &
      os_data%fc // " " // &
      "-c " // &

```

```

        os_data%fcflags_pic // " " // &
        os_data%whizard_includes // " " // &
        os_data%fcflags // " " // &
        "" // src // os_data%fc_src_ext // ""
    end if
    call os_system_call (command_string, status)
end subroutine os_compile_shared

```

Link an array of object files to build a shared object library. In the libtool case, we have to specify a `-rpath`, otherwise only a static library can be built. However, since the library is never installed, this `rpath` is irrelevant.

```

<OS interface: public>+=
    public :: os_link_shared

<OS interface: procedures>+=
    subroutine os_link_shared (objlist, lib, os_data, status)
        type(string_t), intent(in) :: objlist, lib
        type(os_data_t), intent(in) :: os_data
        integer, intent(out), optional :: status
        type(string_t) :: command_string
        if (os_data%use_libtool) then
            command_string = &
                os_data%whizard_libtool // " --mode=link " // &
                os_data%fc // " " // &
                "-module " // &
                "-rpath /usr/local/lib" // " " // &
                os_data%fcflags // " " // &
                os_data%whizard_ldflags // " " // &

2.5.8 Controlling OpenMP

OpenMP is handled automatically by the library for the most part. Here is a convenience routine for setting the number of threads, with some diagnostics.

```

<OS interface: public>+≡
  public :: openmp_set_num_threads_verbose

<OS interface: procedures>+≡
  subroutine openmp_set_num_threads_verbose (num_threads)
    integer, intent(in) :: num_threads
    integer :: n_threads
    n_threads = num_threads
    if (openmp_is_active ()) then
      if (num_threads == 1) then
        write (msg_buffer, "(A,I0,A)") "OpenMP: Using ", num_threads, &

```

```

        " thread"
        call msg_message
        n_threads = num_threads
    else if (num_threads > 1) then
        write (msg_buffer, "(A,I0,A)") "OpenMP: Using ", num_threads, &
            " threads"
        call msg_message
        n_threads = num_threads
    else
        write (msg_buffer, "(A,I0,A)") "OpenMP: " &
            // "Illegal value of openmp_num_threads (", num_threads, &
            ") ignored"
        call msg_error
        n_threads = openmp_get_default_max_threads ()
        write (msg_buffer, "(A,I0,A)") "OpenMP: Using ", &
            n_threads, " threads"
        call msg_message
    end if
    if (n_threads > openmp_get_default_max_threads ()) then
        write (msg_buffer, "(A,I0)") "OpenMP: " &
            // "Number of threads is greater than library default of ", &
            openmp_get_default_max_threads ()
        call msg_warning
    end if
    call openmp_set_num_threads (n_threads)
    else if (num_threads /= 1) then
        write (msg_buffer, "(A,I0,A)") "openmp_num_threads set to ", &
            num_threads, ", but OpenMP is not active: ignored"
        call msg_warning
    end if
end subroutine openmp_set_num_threads_verbose

```

2.5.9 Test

```

<OS interface: public>+≡

print *, "  result =", so_test(i)
if (so_test(i) / i .ne. 2) then
    call msg_fatal ("Compiling and linking ISO C functions failed.")

```

```

else
  print *, "* Successful."
end if
print *, "* Cleanup"
call dlaccess_final (dlaccess)
end subroutine os_interface_test1

```

2.6 CPU timing

This is a simplified module which replaces `clock.f90` below. The time is now stored in a simple derived type which just holds a floating-point number.

<cputime.f90>≡
<File header>

```
module cputime
```

<Use kinds>

<Use file utils>

<Use strings>

```
use diagnostics !NODEP!
```

<Standard module head>

<CPU time: public>

<CPU time: types>

<CPU time: interfaces>

```
contains
```

<CPU time: procedures>

```
end module cputime
```

The CPU time is a floating-point number with an arbitrary reference time. It is single precision (default real, not `real(default)`). It is measured in seconds.

<CPU time: public>≡

```
public :: time_t
```

<CPU time: types>≡

```
type :: time_t
```

```
private
```

```
logical :: known = .false.
```

```
real :: value = 0
```

```
end type time_t
```

<CPU time: public>+≡

```
public :: time_write
```

<CPU time: procedures>≡

```
subroutine time_write (time, unit)
```

```
type(time_t), intent(in) :: time
```

```

integer, intent(in), optional :: unit
integer :: u
u = output_unit (unit)
write (u, "(A)", advance="no") "Time in seconds = "
if (time%known) then
    write (u, *) time%value
else
    write (u, *) "[unknown]"
end if
end subroutine time_write

```

Set the current time

```

<CPU time: public>+≡
public :: time_current

<CPU time: procedures>+≡
function time_current () result (time)
    type(time_t) :: time
    integer :: msecs
    call system_clock (msecs)
    time%value = real (msecs) / 1000.
    time%known = time%value > 0
end function time_current

```

Assign to a real(default value. If the time is undefined, return zero.

```

<CPU time: public>+≡
public :: assignment(=)

<CPU time: interfaces>≡
interface assignment(=)
    module procedure real_assign_time
end interface

<CPU time: procedures>+≡
pure subroutine real_assign_time (r, time)
    real(default), intent(out) :: r
    type(time_t), intent(in) :: time
    if (time%known) then
        r = time%value
    else
        r = 0
    end if
end subroutine real_assign_time

```

Only time differences have a real meaning. If any input value is undefined, the result is undefined.

```

<CPU time: public>+≡
public :: operator(-)

<CPU time: interfaces>+≡
interface operator(-)
    module procedure subtract_times
end interface

```

```

<CPU time: procedures>+≡
pure function subtract_times (t_end, t_begin) result (time)
  type(time_t) :: time
  type(time_t), intent(in) :: t_end, t_begin
  if (t_end%known .and. t_begin%known) then
    time%known = .true.
    time%value = t_end%value - t_begin%value
  end if
end function subtract_times

```

We define functions for converting the time into ss / mm:ss / hh:mm:ss / dd:mm:hh:ss.

```

<CPU time: public>+≡
public :: time_retrieve
public :: time2string_s
public :: time2string_ms
public :: time2string_hms
public :: time2string_dhms
public :: time2string

<CPU time: interfaces>+≡

function time2string_dhms (time) result (str)
    integer, intent(in) :: time
    type(string_t) :: str
    integer :: day, hour, min, sec
    call time_retrieve (time, day, hour, min, sec)
    str = int2string (day) // "d:" // int2string (hour) // "h:" // &
        int2string (min) // "m:" // int2string (sec) // "s"
end function time2string_dhms

function time2string (time) result (str)
    integer, intent(in) :: time
    type(string_t) :: str
    integer :: day, hour, min, sec
    call time_retrieve (time, day, hour, min, sec)
    if (day /= 0) then
        str = time2string_dhms (time)
    else if (hour /= 0) then
        str = time2string_hms (time)
    else if (min /= 0) then
        str = time2string_ms (time)
    else
        str = time2string_s (time)
    end if
end function time2string

```

2.7 Accessing the system clock

This module is currently disabled, we are using the module above instead.

Fortran 90 provides a standard interface for the system clock. Here, we define a record for storing the information, and higher-level functions for accessing it.

```

<clock.f90>≡
  <File header>

  module clock

    <Use kinds>
    <Use file utils>

    <Standard module head>

    <Clock: public>

    <Clock: types>

    <Clock: interfaces>

    contains

    <Clock: procedures>

  end module clock

```

The format for storing the current date. We want to be able to store time differences, therefore everything is converted to the time difference between now and Jan 01 2000, 0:00. The timezone is ignored.

```

<Clock: public>≡
  public :: time_t

<Clock: types>≡
  type :: time_t
    integer :: day = 0
    integer :: hour = 0
    integer :: minute = 0
    integer :: second = 0
    integer :: millisecond = 0
  end type time_t

```

Write the time in readable form

```

<Clock: public>+≡
  public :: time_write

<Clock: interfaces>≡
  interface time_write
    module procedure time_write_unit
    module procedure time_write_string
  end interface

```

The maximal time that can be written is 999 days. No way to write negative times.

```

<Clock: procedures>≡
  subroutine time_write_unit (t, unit, advance, days, seconds, milliseconds)
    type(time_t), intent(in) :: t
    integer, intent(in) :: unit
    character(len=*), intent(in), optional :: advance

```

```

logical, intent(in), optional :: days, seconds, milliseconds
logical :: dd, ss, ms
character(len=3) :: adv
if (present (advance)) then
    adv = advance
else
    adv = "yes"
end if
dd = .false.; if (present (days)) dd = days
ss = .true.; if (present (seconds)) ss = seconds
ms = .false.; if (present (milliseconds)) ms = milliseconds
if (dd) then
    write (unit, "(I3,A,1x,I2.2,A,1x,I2.2,A)", advance="no") &
        t%day, "d", t%hour, "h", t%minute, "m"
else
    write (unit, "(I5,A,1x,I2.2,A)", advance="no") &
        t%day * 24 + t%hour, "h", t%minute, "m"
end if
if (ss) then
    write (unit, "(1x,I2.2)", advance="no") t%second
    if (ms) then
        write (unit, "(A,I3.3,A)", advance=trim(adv)) ".", t%millisecond, "s"
    else
        write (unit, "(A)", advance=trim(adv)) "s"
    end if
end if
end subroutine time_write_unit

```

Write the time to a string. This uses a scratch file for simplicity. Non-advancing output is not possible.

```

<Clock: procedures>+≡
subroutine time_write_string (t, string, days, seconds, milliseconds)
    type(time_t), intent(in) :: t
    character(*), intent(out) :: string
    logical, intent(in), optional :: days, seconds, milliseconds
    integer :: unit
    unit = free_unit ()
    open (unit, status="scratch", action="readwrite")
    call time_write_unit (t, unit, &
        days=days, seconds=seconds, milliseconds=milliseconds)
    rewind (unit)
    read (unit, "(A)") string
    close (unit)
end subroutine time_write_string

```

Set the current time to number of days, minutes, seconds, milliseconds elapsed since Jan 1 2000. Works for dates after Jan 1 2001 until Dec 31 2099.

```

<Clock: public>+≡
public :: time_current

<Clock: procedures>+≡
function time_current () result (t)
    type(time_t) :: t

```

```

integer, dimension(8) :: values

end function time_greater_equal

```

2.8 Hashtables

Hash tables, like lists, are not part of Fortran and must be defined on a per-case basis. In this section we define a module that contains a hash function.

Furthermore, for reference there is a complete framework of hashtable type definitions and access functions. This code is to be replicated where hash tables are used, mutatis mutandis.

```

<hashes.f90>≡
  <File header>

  module hashes

    use kinds, only: i8, i32 !NODEP!
    use bytes

    <Standard module head>

    <Hashes: public>

    contains

    <Hashes: procedures>

  end module hashes

```

2.8.1 The hash function

This is the one-at-a-time hash function by Bob Jenkins (from Wikipedia), re-implemented in Fortran. The function works on an array of bytes (8-bit integers), as could be produced by, e.g., the **transfer** function, and returns a single 32-bit integer. For determining the position in a hashtable, one can pick the lower bits of the result as appropriate to the hashtable size (which should be a power of 2). Note that we are working on signed integers, so the interpretation of values differs from the C version. This should not matter in practice, however.

```

<Hashes: public>≡
  public :: hash

<Hashes: procedures>≡
  function hash (key) result (hashval)
    integer(i32) :: hashval
    integer(i8), dimension(:), intent(in) :: key
    type(word32_t) :: w
    integer :: i
    w = 0_i32
    do i = 1, size (key)
      w = w + key(i)
    end do
  end function hash

```

```

        w = w + ishft (w, 10)
        w = ieor (w, ishft (w, -6))
    end do
    w = w + ishft (w, 3)
    w = ieor (w, ishft (w, -11))
    w = w + ishft (w, 15)
    hashval = w
end function hash

```

2.8.2 The hash table

We define a generic hashtable type (that depends on the `hash_data_t` type) together with associated methods.

This is a template:

```

<Hashtables: types>≡
    type :: hash_data_t
        integer :: i
    end type hash_data_t

```

Associated methods:

```

<Hashtables: procedures>≡
    subroutine hash_data_final (data)
        type(hash_data_t), intent(inout) :: data
    end subroutine hash_data_final

    subroutine hash_data_write (data, unit)
        type(hash_data_t), intent(in) :: data
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit); if (u < 0) return
        write (u, *) data%i
    end subroutine hash_data_write

```

Each hash entry stores the unmasked hash value, the key, and points to actual data if present. Note that this could be an allocatable scalar in principle, but making it a pointer avoids deep copy when expanding the hashtable.

```

<Hashtables: types>+≡
    type :: hash_entry_t
        integer(i32) :: hashval = 0
        integer(i8), dimension(:), allocatable :: key
        type(hash_data_t), pointer :: data => null ()
    end type hash_entry_t

```

The hashtable object holds the actual table, the number of filled entries and the number of entries after which the size should be doubled. The mask is equal to the table size minus one and thus coincides with the upper bound of the table index, which starts at zero.

```

<Hashtables: types>+≡
    type :: hashtable_t
        integer :: n_entries = 0

```

```

    real :: fill_ratio = 0
    integer :: n_entries_max = 0
    integer(i32) :: mask = 0
    type(hash_entry_t), dimension(:), allocatable :: entry
end type hashtable_t

```

Initializer: The size has to be a power of two, the fill ratio is a real (machine-default!) number between 0 and 1.

```

<Hashtables: procedures> +=
subroutine hashtable_init (hashtable, size, fill_ratio)
    type(hashtable_t), intent(out) :: hashtable
    integer, intent(in) :: size
    real, intent(in) :: fill_ratio
    hashtable%fill_ratio = fill_ratio
    hashtable%n_entries_max = size * fill_ratio
    hashtable%mask = size - 1
    allocate (hashtable%entry (0:hashtable%mask))
end subroutine hashtable_init

```

Finalizer: This calls a `hash_data_final` subroutine which must exist.

```

<Hashtables: procedures> +=
subroutine hashtable_final (hashtable)
    type(hashtable_t), intent(inout) :: hashtable
    integer :: i
    do i = 0, hashtable%mask
        if (associated (hashtable%entry(i)%data)) then
            call hash_data_final (hashtable%entry(i)%data)
            deallocate (hashtable%entry(i)%data)
        end if
    end do
    deallocate (hashtable%entry)
end subroutine hashtable_final

```

Output. Here, we refer to a `hash_data_write` subroutine.

```

<Hashtables: procedures> +=
subroutine hashtable_write (hashtable, unit)
    type(hashtable_t), intent(in) :: hashtable
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit); if (u < 0) return
    do i = 0, hashtable%mask
        if (associated (hashtable%entry(i)%data)) then
            write (u, *) i, "(hash =", hashtable%entry(i)%hashval, ")", &
                hashtable%entry(i)%key
            call hash_data_write (hashtable%entry(i)%data, unit)
        end if
    end do
end subroutine hashtable_write

```

2.8.3 Hashtable insertion

Insert a single entry with the hash value as trial place. If the table is filled, first expand it.

```
(Hashtables: procedures)+≡
subroutine hashtable_insert (hashtable, key, data)
  type(hashtable_t), intent(inout) :: hashtable
  integer(i8), dimension(:), intent(in) :: key
  type(hash_data_t), intent(in), target :: data
  integer(i32) :: h
  if (hashtable%n_entries >= hashtable%n_entries_max) &
    call hashtable_expand (hashtable)
  h = hash (key)
  call hashtable_insert_rec (hashtable, h, h, key, data)
end subroutine hashtable_insert
```

We need this auxiliary routine for doubling the size of the hashtable. We rely on the fact that default assignment copies the data pointer, not the data themselves. The temporary array must not be finalized; it is deallocated automatically together with its allocatable components.

```
(Hashtables: procedures)+≡
subroutine hashtable_expand (hashtable)
  type(hashtable_t), intent(inout) :: hashtable
  type(hash_entry_t), dimension(:), allocatable :: table_tmp
  integer :: i, s
  allocate (table_tmp (0:hashtable%mask))
  table_tmp = hashtable%entry
  deallocate (hashtable%entry)
  s = 2 * size (table_tmp)
  hashtable%n_entries = 0
  hashtable%n_entries_max = s * hashtable%fill_ratio
  hashtable%mask = s - 1
  allocate (hashtable%entry (0:hashtable%mask))
  do i = 0, ubound (table_tmp, 1)
    if (associated (table_tmp(i)%data)) then
      call hashtable_insert_rec (hashtable, table_tmp(i)%hashval, &
        table_tmp(i)%hashval, table_tmp(i)%key, table_tmp(i)%data)
    end if
  end do
end subroutine hashtable_expand
```

Insert a single entry at a trial place *h*, reduced to the table size. Collision resolution is done simply by choosing the next element, recursively until the place is empty. For bookkeeping, we preserve the original hash value. For a good hash function, there should be no clustering.

Note that if the new key exactly matches an existing key, nothing is done.

```
(Hashtables: procedures)+≡
recursive subroutine hashtable_insert_rec (hashtable, h, hashval, key, data)
  type(hashtable_t), intent(inout) :: hashtable
  integer(i32), intent(in) :: h, hashval
  integer(i8), dimension(:), intent(in) :: key
  type(hash_data_t), intent(in), target :: data
```

```

integer(i32) :: i
i = iand (h, hashtable%mask)
if (associated (hashtable%entry(i)%data)) then
    if (size (hashtable%entry(i)%key) /= size (key)) then
        call hashtable_insert_rec (hashtable, h + 1, hashval, key, data)
    else if (any (hashtable%entry(i)%key /= key)) then
        call hashtable_insert_rec (hashtable, h + 1, hashval, key, data)
    end if
else
    hashtable%entry(i)%hashval = hashval
    allocate (hashtable%entry(i)%key (size (key)))
    hashtable%entry(i)%key = key
    hashtable%entry(i)%data => data
    hashtable%n_entries = hashtable%n_entries + 1
end if
end subroutine hashtable_insert_rec

```

2.8.4 Hashtable lookup

The lookup function has to parallel the insert function. If the place is filled, check if the key matches. Yes: return the pointer; no: increment the hash value and check again.

```

<Hashtables: procedures>+=
function hashtable_lookup (hashtable, key) result (ptr)
    type(hash_data_t), pointer :: ptr
    type(hashtable_t), intent(in) :: hashtable
    integer(i8), dimension(:), intent(in) :: key
    ptr => hashtable_lookup_rec (hashtable, hash (key), key)
end function hashtable_lookup

<Hashtables: procedures>+=
recursive function hashtable_lookup_rec (hashtable, h, key) result (ptr)
    type(hash_data_t), pointer :: ptr
    type(hashtable_t), intent(in) :: hashtable
    integer(i32), intent(in) :: h
    integer(i8), dimension(:), intent(in) :: key
    integer(i32) :: i
    i = iand (h, hashtable%mask)
    if (associated (hashtable%entry(i)%data)) then
        if (size (hashtable%entry(i)%key) == size (key)) then
            if (all (hashtable%entry(i)%key == key)) then
                ptr => hashtable%entry(i)%data
            else
                ptr => hashtable_lookup_rec (hashtable, h + 1, key)
            end if
        else
            ptr => hashtable_lookup_rec (hashtable, h + 1, key)
        end if
    else
        ptr => null ()
    end if
end function hashtable_lookup_rec

```

```

<Hashtables: public>≡
    public :: hashtable_test

<Hashtables: procedures>+≡
    subroutine hashtable_test ()
        type(hash_data_t), pointer :: data
        type(hashtable_t) :: hashtable
        integer(i8) :: i
        call hashtable_init (hashtable, 16, 0.25)
        do i = 1, 10
            allocate (data)
            data%i = i*i
            call hashtable_insert (hashtable, (/i, i+i/), data)
        end do
        call hashtable_insert (hashtable, (/2_i8, 4_i8/), data)
        call hashtable_write (hashtable)
        data => hashtable_lookup (hashtable, (/5_i8, 10_i8/))
        if (associated (data)) then
            print *, "lookup:", data%i
        else
            print *, "lookup: --"
        end if
        data => hashtable_lookup (hashtable, (/6_i8, 12_i8/))
        if (associated (data)) then
            print *, "lookup:", data%i
        else
            print *, "lookup: --"
        end if
        data => hashtable_lookup (hashtable, (/4_i8, 9_i8/))
        if (associated (data)) then
            print *, "lookup:", data%i
        else
            print *, "lookup: --"
        end if
        call hashtable_final (hashtable)
    end subroutine hashtable_test

```

2.9 Message and signal handling

We are not so ambitious as to do proper exception handling in WHIZARD, but at least it may be useful to have a common interface for diagnostics: Results, messages, warnings, and such. As module variables we keep a buffer where the current message may be written to and a level indicator which tells which messages should be written on screen and which ones should be skipped. Alternatively, a string may be directly supplied to the message routine: this overrides the buffer, avoiding the necessity of formatted I/O in trivial cases.

```

<diagnostics.f90>≡
    <File header>

    module diagnostics

```

```

    use iso_c_binding !NODEP!
    use system_dependencies !NODEP!
    <Use kinds>
    <Use strings>
    use limits, only: BUFFER_SIZE, MAX_ERRORS !NODEP!
    use file_utils !NODEP!
    use iso_fortran_env, only: &
        stdout => output_unit, stdin => input_unit !NODEP!

    <Standard module head>

    <Diagnostics: public>

    <Diagnostics: parameters>

    <Diagnostics: types>

    <Diagnostics: variables>

    <Diagnostics: interfaces>

    contains

    <Diagnostics: procedures>

    end module diagnostics
Diagnostics levels:
    <Diagnostics: parameters>≡
        integer, parameter :: &
            & TERMINATE=-2, BUG=-1, &
            & FATAL=1, ERROR=2, WARNING=3, MESSAGE=4, RESULT=5, DEBUG=6
    <Diagnostics: variables>≡
        integer, save :: msg_level = RESULT
Mask fatal errors so that are treated as normal errors. Useful for interactive
mode.
    <Diagnostics: public>≡
        public :: mask_fatal_errors
    <Diagnostics: variables>+≡
        logical, save :: mask_fatal_errors = .false.
How to handle bugs and unmasked fatal errors. Either execute a normal stop
statement, or call the C exit() function, or try to cause a program crash by
dereferencing a null pointer.
    <Diagnostics: parameters>+≡
        integer, parameter :: TERM_STOP = 0, TERM_EXIT = 1, TERM_CRASH = 2
    <Diagnostics: variables>+≡
        integer, save :: handle_fatal_errors = TERM_EXIT
Keep track of errors. This might be used for exception handling, later. The
counter is incremented only for screen messages, to avoid double counting.
    <Diagnostics: public>+≡
        public :: msg_count

```

```

<Diagnostics: variables>+≡
    integer, dimension(TERMINATE:DEBUG), save :: msg_count = 0

```

Keep a list of all errors and warnings. Since we do not know the number of entries beforehand, we use a linked list.

```

<Diagnostics: types>≡
    type :: string_list
        character(len=BUFFER_SIZE) :: string
        type(string_list), pointer :: next
    end type string_list
    type :: string_list_pointer
        type(string_list), pointer :: first, last
    end type string_list_pointer

<Diagnostics: variables>+≡
    type(string_list_pointer), dimension(TERMINATE:WARNING), save :: &
        & msg_list = string_list_pointer (null(), null())

```

Add the current message buffer contents to the internal list.

```

<Diagnostics: procedures>≡
    subroutine msg_add (level)
        integer, intent(in) :: level
        type(string_list), pointer :: message
        select case (level)
        case (TERMINATE:WARNING)
            allocate (message)
            message%string = msg_buffer
            nullify (message%next)
            if (.not.associated (msg_list(level)%first)) &
                & msg_list(level)%first => message
            if (associated (msg_list(level)%last)) &
                & msg_list(level)%last%next => message
            msg_list(level)%last => message
            msg_count(level) = msg_count(level) + 1
        end select
    end subroutine msg_add

```

Initialization:

```

<Diagnostics: public>+≡
    public :: msg_list_clear

<Diagnostics: procedures>+≡
    subroutine msg_list_clear
        integer :: level
        type(string_list), pointer :: message
        do level = TERMINATE, WARNING
            do while (associated (msg_list(level)%first))
                message => msg_list(level)%first
                msg_list(level)%first => message%next
                deallocate (message)
            end do
            nullify (msg_list(level)%last)
        end do
        msg_count = 0
    end subroutine msg_list_clear

```

Display the summary of errors and warnings (no need to count fatals...)

```

<Diagnostics: public>+≡
    public :: msg_summary

<Diagnostics: procedures>+≡
    subroutine msg_summary (unit)
        integer, intent(in), optional :: unit
        call expect_summary (unit)
1    format (A,1x,I2,1x,A,I2,1x,A)
        if (msg_count(ERROR) > 0 .and. msg_count(WARNING) > 0) then
            write (msg_buffer, 1) "There were", &
                & msg_count(ERROR), "error(s) and ", &
                & msg_count(WARNING), "warning(s)."
            call msg_message (unit=unit)
        else if (msg_count(ERROR) > 0) then
            write (msg_buffer, 1) "There were", &
                & msg_count(ERROR), "error(s) and no warnings."
            call msg_message (unit=unit)
        else if (msg_count(WARNING) > 0) then
            write (msg_buffer, 1) "There were no errors and ", &
                & msg_count(WARNING), "warning(s)."
            call msg_message (unit=unit)
        end if
    end subroutine msg_summary

```

Print the list of all messages of a given level.

```

<Diagnostics: public>+≡
    public :: msg_listing

<Diagnostics: procedures>+≡
    subroutine msg_listing (level, unit, prefix)
        integer, intent(in) :: level
        integer, intent(in), optional :: unit
        character(len=*), intent(in), optional :: prefix
        type(string_list), pointer :: message
        integer :: u
        u = output_unit (unit); if (u < 0) return
        if (present (unit)) u = unit
        message => msg_list(level)%first
        do while (associated (message))
            if (present (prefix)) then
                write (u, "(A)") prefix // trim (message%string)
            else
                write (u, "(A)") trim (message%string)
            end if
            message => message%next
        end do
        flush (u)
    end subroutine msg_listing

```

There is a hard limit on the line length which we should export. This buffer size is used both by the message handler and by the lexer below.

```

<Limits: public parameters>+≡
    integer, parameter, public :: BUFFER_SIZE = 1000

```

The message buffer:

```

<Diagnostics: public>+≡
    public :: msg_buffer

<Diagnostics: variables>+≡
    character(len=BUFFER_SIZE), save :: msg_buffer = " "

```

After a message is issued, the buffer should be cleared:

```

<Diagnostics: procedures>+≡
    subroutine buffer_clear
        msg_buffer = " "
    end subroutine buffer_clear

```

The generic handler for messages. If the unit is omitted (or = 6), the message is written to standard output if the precedence is sufficiently high (as determined by the value of `msg_level`). If the string is omitted, the buffer is used. In any case, the buffer is cleared after printing. In accordance with FORTRAN custom, the first column in the output is left blank. For messages and warnings, an additional exclamation mark and a blank is prepended. Furthermore, each message is appended to the internal message list (without prepending anything).

```

<Diagnostics: procedures>+≡
    subroutine message_print (level, string, str_arr, unit, logfile)
        integer, intent(in) :: level
        character(len=*), intent(in), optional :: string

```

The specific handlers. In the case of fatal errors, bugs (failed assertions) and normal termination execution is stopped. For non-fatal errors a message is printed to standard output if no unit is given. Only if the number of `MAX_ERRORS` errors is reached, we abort the program. There are no further actions in the other cases, but this may change.

```

2.9.3 Signal handling

Killing the program by external signals may leave the files written by it in an undefined state. This can be avoided by catching signals and deferring program termination. Instead of masking only critical sections, we choose to mask signals globally (done in the main program) and terminate the program at predefined checkpoints only. Checkpoints are after each command, within the sampling function (so the program can be terminated after each event), and after each iteration in the phase-space generation algorithm.

Signal handling is done via a C interface to the `sigaction` system call. When a signal is raised that has been masked by the handler, the corresponding variable is set to the value of the signal. The variables are visible from the C signal handler.

The signal `SIGINT` is for keyboard interrupt (ctrl-C), `SIGTERM` is for system interrupt, e.g., at shutdown. The `SIGXCPU` and `SIGXFSZ` signals may be issued by batch systems.

```

<Diagnostics: public>+≡
  public :: wo_sigint
  public :: wo_sigterm
  public :: wo_sigxcpu
  public :: wo_sigxfsz

<Diagnostics: variables>+≡
  integer(c_int), bind(C), volatile :: wo_sigint = 0
  integer(c_int), bind(C), volatile :: wo_sigterm = 0
  integer(c_int), bind(C), volatile :: wo_sigxcpu = 0
  integer(c_int), bind(C), volatile :: wo_sigxfsz = 0

```

Here are the interfaces to the C functions. The routine `mask_term_signals` forces termination signals to be delayed. `release_term_signals` restores normal behavior. However, the program can be terminated anytime by calling `terminate_now_if_signal` which inspects the signals and terminates the program if requested..

```

<Diagnostics: public>+≡
  public :: mask_term_signals

<Diagnostics: procedures>+≡
  subroutine mask_term_signals ()

```

2.11 C wrapper for printf

The `printf` family of functions is implemented in C with an undefined number of arguments. This is not supported by the `bind(C)` interface. We therefore write wrappers for the versions of `sprintf` that we will actually use.

```

<sprintf_interface.c>≡
/*
  <File header>
*/
#include <stdio.h>

```

```

int sprintf_none(char* str, const char* format) {
    return sprintf(str, format);
}

int sprintf_int(char* str, const char* format, int val) {
    return sprintf(str, format, val);
}

int sprintf_double(char* str, const char* format, double val) {
    return sprintf(str, format, val);
}

int sprintf_str(char* str, const char* format, const char* val) {
    return sprintf(str, format, val);
}

```

(sprintf interfaces)≡

```

interface
    function sprintf_none (str, fmt) result (stat) bind(C)
        use iso_c_binding !NODEP!
        integer(c_int) :: stat
        character(c_char), dimension(*), intent(inout) :: str
        character(c_char), dimension(*), intent(in) :: fmt
    end function sprintf_none
end interface

interface
    function sprintf_int (str, fmt, val) result (stat) bind(C)
        use iso_c_binding !NODEP!
        integer(c_int) :: stat
        character(c_char), dimension(*), intent(inout) :: str
        character(c_char), dimension(*), intent(in) :: fmt
        integer(c_int), value :: val
    end function sprintf_int
end interface

interface
    function sprintf_double (str, fmt, val) result (stat) bind(C)
        use iso_c_binding !NODEP!
        integer(c_int) :: stat
        character(c_char), dimension(*), intent(inout) :: str
        character(c_char), dimension(*), intent(in) :: fmt
        real(c_double), value :: val
    end function sprintf_double
end interface

interface
    function sprintf_str(str, fmt, val) result (stat) bind(C)
        use iso_c_binding !NODEP!
        integer(c_int) :: stat
        character(c_char), dimension(*), intent(inout) :: str
        character(c_char), dimension(*), intent(in) :: fmt
        character(c_char), dimension(*), intent(in) :: val
    end function sprintf_str
end interface

```

```

    end function sprintf_str
end interface

```

2.12 Interface for formatted I/O

For access to formatted printing (possibly input), we interface the C `printf` family of functions. There are two important issues here:

1. `printf` takes an arbitrary number of arguments, relying on the C stack. This is not interoperable. We interface it with C wrappers that output a single integer, real or string and restrict the allowed formats accordingly.
2. Restricting format strings is essential also for preventing format string attacks. Allowing arbitrary format string would create a real security hole in a Fortran program.
3. The string returned by `sprintf` must be allocated to the right size.

```

2.12.1 Parsing a C format string

The C format string contains characters and format conversion specifications. The latter are initiated by a % sign. If the next letter is also a %, a percent sign is printed and no conversion is done. Otherwise, a conversion is done and applied to the next argument in the argument list. First comes an optional flag (#, 0, -, ,

+, or space), an optional field width (decimal digits starting not with zero), an optional precision (period, then another decimal digit string), a length modifier (irrelevant for us, therefore not supported), and a conversion specifier: **d** or **i** for integer; **e**, **f**, **g** (also upper case) for double-precision real, **s** for a string.

We explicitly exclude all other conversion specifiers, and we check the specifiers against the actual arguments.

A type for passing arguments

This is a polymorphic type that can hold integer, real (double), and string arguments.

```
(Formats: parameters)≡
  integer, parameter :: ARGTYPE_NONE = 0
  integer, parameter :: ARGTYPE_LOG = 1
  integer, parameter :: ARGTYPE_INT = 2
  integer, parameter :: ARGTYPE_REAL = 3
  integer, parameter :: ARGTYPE_STR = 4
```

The integer and real entries are actually scalars, but we avoid relying on the allocatable-scalar feature and make them one-entry arrays. The character entry is a real array which is a copy of the string.

Logical values are mapped to strings (true or false), so this type parameter value is mostly unused.

```
(Formats: public)≡
  public :: sprintf_arg_t
```

```
(Formats: types)≡
  type :: sprintf_arg_t
  private
    integer :: type = ARGTYPE_NONE
    integer(c_int), dimension(:), allocatable :: ival
    real(c_double), dimension(:), allocatable :: rval
    character(c_char), dimension(:), allocatable :: sval
  end type sprintf_arg_t
```

```
(Formats: public)+≡
  public :: sprintf_arg_init
```

```
(Formats: interfaces)≡
  interface sprintf_arg_init
    module procedure sprintf_arg_init_log
    module procedure sprintf_arg_init_int
    module procedure sprintf_arg_init_real
    module procedure sprintf_arg_init_str
  end interface
```

```
(Formats: procedures)≡
  subroutine sprintf_arg_init_log (arg, lval)
    type(sprintf_arg_t), intent(out) :: arg
    logical, intent(in) :: lval
    arg%type = ARGTYPE_STR
    if (lval) then
      allocate (arg%sval (5))
```

```

        arg%sval = (/ 't', 'r', 'u', 'e', c_null_char /)
    else
        allocate (arg%sval (6))
        arg%sval = (/ 'f', 'a', 'l', 's', 'e', c_null_char /)
    end if
end subroutine sprintf_arg_init_log

subroutine sprintf_arg_init_int (arg, ival)
    type(sprintf_arg_t), intent(out) :: arg
    integer, intent(in) :: ival
    arg%type = ARGTYPE_INT
    allocate (arg%ival (1))
    arg%ival = ival
end subroutine sprintf_arg_init_int

subroutine sprintf_arg_init_real (arg, rval)
    type(sprintf_arg_t), intent(out) :: arg
    real(default), intent(in) :: rval
    arg%type = ARGTYPE_REAL
    allocate (arg%rval (1))
    arg%rval = rval
end subroutine sprintf_arg_init_real

subroutine sprintf_arg_init_str (arg, sval)
    type(sprintf_arg_t), intent(out) :: arg
    type(string_t), intent(in) :: sval
    integer :: i
    arg%type = ARGTYPE_STR
    allocate (arg%sval (len (sval) + 1))
    do i = 1, len (sval)
        arg%sval(i) = extract (sval, i, i)
    end do
    arg%sval(len (sval) + 1) = c_null_char
end subroutine sprintf_arg_init_str

<Formats: procedures>+≡
subroutine sprintf_arg_write (arg, unit)
    type(sprintf_arg_t), intent(in) :: arg
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    select case (arg%type)
    case (ARGTYPE_NONE)
        write (u, *) "[none]"
    case (ARGTYPE_INT)
        write (u, "(1x,A,1x)", advance = "no") "[int]"
        write (u, *) arg%ival
    case (ARGTYPE_REAL)
        write (u, "(1x,A,1x)", advance = "no") "[real]"
        write (u, *) arg%rval
    case (ARGTYPE_STR)
        write (u, "(1x,A,1x,A)", advance = "no") "[string]", ""
        write (u, *) arg%rval, ""
    end select
end subroutine

```

```
end subroutine sprintf_arg_write
```

Return an upper bound for the length of the printed version; in case of strings the result is exact.

(Formats: procedures)+≡

```
elemental function sprintf_arg_get_length (arg) result (length)
  integer :: length
  type(sprintf_arg_t), intent(in) :: arg
  select case (arg%type)
  case (ARGTYPE_INT)
    length = log10 (real (huge (arg%ival(1)))) + 2
  case (ARGTYPE_REAL)
    length = log10 (real (radix (arg%rval(1))) ** digits (arg%rval(1))) + 8
  case (ARGTYPE_STR)
    length = size (arg%sval)
  case default
    length = 0
  end select
end function sprintf_arg_get_length
```

(Formats: procedures)+≡

```
subroutine sprintf_arg_apply_printf (arg, fmt, result, actual_length)
  type(sprintf_arg_t), intent(in) :: arg
  character(c_char), dimension(:), intent(in) :: fmt
  character(c_char), dimension(:), intent(inout) :: result
  integer, intent(out) :: actual_length
  integer(c_int) :: ival
  real(c_double) :: rval
  select case (arg%type)
  case (ARGTYPE_NONE)
    actual_length = sprintf_none (result, fmt)
  case (ARGTYPE_INT)
    ival = arg%ival(1)
    actual_length = sprintf_int (result, fmt, ival)
  case (ARGTYPE_REAL)
    rval = arg%rval(1)
    actual_length = sprintf_double (result, fmt, rval)
  case (ARGTYPE_STR)
    actual_length = sprintf_str (result, fmt, arg%sval)
  case default
    call msg_bug ("sprintf_arg_apply_printf called with illegal type")
  end select
  if (actual_length < 0) then
    write (msg_buffer, *) "Format: '", fmt, "'"
    call msg_message ()
    write (msg_buffer, *) "Output: '", result, "'"
    call msg_message ()
    call msg_error ("I/O error in sprintf call")
    actual_length = 0
  end if
end subroutine sprintf_arg_apply_printf
```

Container type for the output

There is a procedure which chops the format string into pieces that contain at most one conversion specifier. Pairing this with a `sprintf_arg` object, we get the actual input to the `sprintf` interface. The type below holds this input and can allocate the output string.

(Formats: types)+≡

```
type :: sprintf_interface_t
  private
  character(c_char), dimension(:), allocatable :: input_fmt
  type(sprintf_arg_t) :: arg
  character(c_char), dimension(:), allocatable :: output_str
  integer :: output_str_len = 0
end type sprintf_interface_t
```

(Formats: procedures)+≡

```
subroutine sprintf_interface_init (intf, fmt, arg)
  type(sprintf_interface_t), intent(out) :: intf
  type(string_t), intent(in) :: fmt
  type(sprintf_arg_t), intent(in) :: arg
  integer :: fmt_len, i
  fmt_len = len (fmt)
  allocate (intf%input_fmt (fmt_len + 1))
  do i = 1, fmt_len
    intf%input_fmt(i) = extract (fmt, i, i)
  end do
  intf%input_fmt(fmt_len+1) = c_null_char
  intf%arg = arg
  allocate (intf%output_str (len (fmt) + sprintf_arg_get_length (arg) + 1))
end subroutine sprintf_interface_init
```

(Formats: procedures)+≡

```
subroutine sprintf_interface_write (intf, unit)
  type(sprintf_interface_t), intent(in) :: intf
  integer, intent(in), optional :: unit
  integer :: u
  u = output_unit (unit)
  write (u, *) "Format string = ", "'", intf%input_fmt, "'"
  write (u, "(1x,A,1x)", advance = "no") "Argument = "
  call sprintf_arg_write (intf%arg, unit)
  if (intf%output_str_len > 0) then
    write (u, *) "Result string = ", &
      "'", intf%output_str (1:intf%output_str_len), "'"
  end if
end subroutine sprintf_interface_write
```

Return the output string:

(Formats: procedures)+≡

```
function sprintf_interface_get_result (intf) result (string)
  type(string_t) :: string
  type(sprintf_interface_t), intent(in) :: intf
  character(kind = c_char, len = max (intf%output_str_len, 0)) :: buffer
```

```

integer :: i
if (intf%output_str_len > 0) then
  do i = 1, intf%output_str_len
    buffer(i:i) = intf%output_str(i)
  end do
  string = buffer(1:intf%output_str_len)
else
  string = ""
end if
end function sprintf_interface_get_result

```

(Formats: procedures)+≡

```

subroutine sprintf_interface_apply_sprintf (intf)
  type(sprintf_interface_t), intent(inout) :: intf
  call sprintf_arg_apply_sprintf &
    (intf%arg, intf%input_fmt, intf%output_str, intf%output_str_len)
end subroutine sprintf_interface_apply_sprintf

```

Import the interfaces defined in the previous section:

(Formats: interfaces)+≡
(sprintf interfaces)

Scan the format string

Chop it into pieces that contain one conversion specifier each. The zero-th piece contains the part before the first specifier. Check the specifiers and allow only the subset that we support. Also check for an exact match between conversion specifiers and input arguments. The result is an allocated array of `sprintf_interface` object; each one contains a piece of the format string and the corresponding argument.

(Formats: procedures)+≡

```

```

2.13 Bytes and such

In a few instances we will need the notion of a byte (8-bit) and a word (32 bit), even a 64-bit word. A block of 512 bit is also needed (for MD5).

We rely on integers up to 64 bit being supported by the processor. The main difference to standard integers is the interpretation as unsigned integers.

```

  end module bytes

```

2.13.1 8-bit words: bytes

This is essentially a wrapper around 8-bit integers. The wrapper emphasises their special interpretation as a sequence of bits. However, we interpret bytes as unsigned integers.

```

<Bytes: public>≡
  public :: byte_t

```

```

<Bytes: types>≡
    type :: byte_t
        private
            integer(i8) :: i
        end type byte_t

<Bytes: public>+≡
    public :: byte_zero

<Bytes: parameters>≡
    type(byte_t), parameter :: byte_zero = byte_t (0_i8)

```

Set a byte from 8-bit integer:

```

<Bytes: public>+≡
    public :: assignment(=)

<Bytes: interfaces>≡
    interface assignment(=)
        module procedure set_byte_from_i8
    end interface

<Bytes: procedures>≡
    subroutine set_byte_from_i8 (b, i)
        type(byte_t), intent(out) :: b
        integer(i8), intent(in) :: i
        b%i = i
    end subroutine set_byte_from_i8

```

Write a byte in one of two formats: either as a hexadecimal number (two digits, default) or as a decimal number (one to three digits). The decimal version is nontrivial because bytes are unsigned integers. Optionally append a newline.

```

<Bytes: public>+≡
    public :: byte_write

<Bytes: interfaces>+≡
    interface byte_write
        module procedure byte_write_unit, byte_write_string
    end interface

<Bytes: procedures>+≡
    subroutine byte_write_unit (b, unit, decimal, newline)
        type(byte_t), intent(in), optional :: b
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: decimal, newline
        logical :: dc, nl
        type(word32_t) :: w
        integer :: u
        u = output_unit (unit); if (u < 0) return
        dc = .false.; if (present (decimal)) dc = decimal
        nl = .false.; if (present (newline)) nl = newline
        if (dc) then
            w = b
            write (u, '(I3)', advance='no') w%i
        else
            write (u, '(z2.2)', advance='no') b%i
        end if
    end subroutine byte_write_unit

```

```

    end if
    if (nl) write (u, *)
end subroutine byte_write_unit

```

The string version is hex-only

```

<Bytes: procedures>+≡
subroutine byte_write_string (b, s)
  type(byte_t), intent(in) :: b
  character(len=2), intent(inout) :: s
  write (s, '(z2.2)') b%i
end subroutine byte_write_string

```

2.13.2 32-bit words

This is not exactly a 32-bit integer. A word is to be filled with bytes, and it may be partially filled. The filling is done lowest-byte first, highest-byte last. We count the bits, so fill should be either 0, 8, 16, 24, or 32. In printing words, we correspondingly distinguish between printing zeros and printing blanks.

```

<Bytes: public>+≡
public :: word32_t

<Bytes: types>+≡
type :: word32_t
  private
  integer(i32) :: i
  integer :: fill = 0
end type word32_t

```

Assignment: the word is filled by inserting a 32-bit integer

```

<Bytes: interfaces>+≡
interface assignment(=)
  module procedure word32_set_from_i32
  module procedure word32_set_from_byte
end interface

<Bytes: procedures>+≡
subroutine word32_set_from_i32 (w, i)
  type(word32_t), intent(out) :: w
  integer(i32), intent(in) :: i
  w%i = i
  w%fill = 32
end subroutine word32_set_from_i32

```

Reverse assignment to a 32-bit integer. We do not check the fill status.

```

<Bytes: interfaces>+≡
interface assignment(=)
  module procedure i32_from_word32
end interface

```

```

<Bytes: procedures>+≡
  subroutine i32_from_word32 (i, w)
    integer(i32), intent(out) :: i
    type(word32_t), intent(in) :: w
    i = w%i
  end subroutine i32_from_word32

```

Filling with a 8-bit integer is slightly tricky, because in this interpretation integers are unsigned.

```

<Bytes: procedures>+≡
  subroutine word32_set_from_byte (w, b)
    type(word32_t), intent(out) :: w
    type(byte_t), intent(in) :: b
    if (b%i >= 0_i8) then
      w%i = b%i
    else
      w%i = 2_i32*(huge(0_i8)+1_i32) + b%i
    end if
    w%fill = 32
  end subroutine word32_set_from_byte

```

Check the fill status

```

<Bytes: public>+≡
  public :: word32_empty, word32_filled, word32_fill

<Bytes: procedures>+≡
  function word32_empty (w)
    type(word32_t), intent(in) :: w
    logical :: word32_empty
    word32_empty = (w%fill == 0)
  end function word32_empty

  function word32_filled (w)
    type(word32_t), intent(in) :: w
    logical :: word32_filled
    word32_filled = (w%fill == 32)
  end function word32_filled

  function word32_fill (w)
    type(word32_t), intent(in) :: w
    integer :: word32_fill
    word32_fill = w%fill
  end function word32_fill

```

Partial assignment: append a byte to a partially filled word. (Note: no assignment if the word is filled, so check this before if necessary.)

```

<Bytes: public>+≡
  public :: word32_append_byte

<Bytes: procedures>+≡
  subroutine word32_append_byte (w, b)
    type(word32_t), intent(inout) :: w
    type(byte_t), intent(in) :: b

```

```

type(word32_t) :: w1
if (.not. word32_filled (w)) then
    w1 = b
    call mvbits (w1%i, 0, 8, w%i, w%fill)
    w%fill = w%fill + 8
end if
end subroutine word32_append_byte

```

Extract a byte from a word. The argument *i* is the position, which may be 0, 1, 2, or 3.

For the final assignment, we set the highest bit separately. Otherwise, we might trigger an overflow condition for a compiler with strict checking turned on.

```

<Bytes: public>+≡
    public :: byte_from_word32

<Bytes: procedures>+≡
    function byte_from_word32 (w, i) result (b)
        type(word32_t), intent(in) :: w
        integer, intent(in) :: i
        type(byte_t) :: b
        integer(i32) :: j
        j = 0
        if (i >= 0 .and. i*8 < w%fill) then
            call mvbits (w%i, i*8, 8, j, 0)
        end if
        b%i = int (ibclr (j, 7), kind=i8)
        if (btest (j, 7)) b%i = ibset (b%i, 7)
    end function byte_from_word32

```

Write a word to file or STDOUT. We understand words as unsigned integers, therefore we cannot use the built-in routine unchanged. However, we can make use of the existence of 64-bit integers and their output routine.

In hexadecimal format, the default version prints eight hex characters, highest-first. The **bytes** version prints four bytes (two-hex characters), lowest first, with spaces in-between. The decimal bytes version is analogous. In the **bytes** version, missing bytes are printed as whitespace.

```

<Bytes: public>+≡
    public :: word32_write

<Bytes: interfaces>+≡
    interface word32_write
        module procedure word32_write_unit
    end interface

<Bytes: procedures>+≡
    subroutine word32_write_unit (w, unit, bytes, decimal, newline)
        type(word32_t), intent(in) :: w
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: bytes, decimal, newline
        logical :: dc, by, nl
        type(word64_t) :: ww
        integer :: i, u

```

```

u = output_unit (unit); if (u < 0) return
by = .false.; if (present (bytes)) by = bytes
dc = .false.; if (present (decimal)) dc = decimal
nl = .false.; if (present (newline)) nl = newline
if (by) then
  do i = 0, 3
    if (i>0) write (u, '(1x)', advance='no')
    if (8*i < w%fill) then
      call byte_write (byte_from_word32 (w, i), unit, decimal=decimal)
    else if (dc) then
      write (u, '(3x)', advance='no')
    else
      write (u, '(2x)', advance='no')
    end if
  end do
else if (dc) then
  ww = w
  write (u, '(I10)', advance='no') ww%i
else
  select case (w%fill)
  case ( 0)
  case ( 8); write (6, '(1x,z8.2)', advance='no') ibits (w%i, 0, 8)
  case (16); write (6, '(1x,z8.4)', advance='no') ibits (w%i, 0,16)
  case (24); write (6, '(1x,z8.6)', advance='no') ibits (w%i, 0,24)
  case (32); write (6, '(1x,z8.8)', advance='no') ibits (w%i, 0,32)
  end select
end if
if (nl) write (u, *)
end subroutine word32_write_unit

```

2.13.3 Operations on 32-bit words

Define the usual logical operations, as well as addition (mod 2^{32}). We assume that all operands are completely filled.

(Bytes: public)+≡

public :: not, ior, ieor, iand, ishft, ishftc

(Bytes: interfaces)+≡

```

interface not
  module procedure word_not
end interface
interface ior
  module procedure word_or
end interface
interface ieor
  module procedure word_eor
end interface
interface iand
  module procedure word_and
end interface
interface ishft
  module procedure word_shft
end interface

```

```

interface ishftc
  module procedure word_shftc
end interface

<Bytes: procedures>+≡
function word_not (w1) result (w2)
  type(word32_t), intent(in) :: w1
  type(word32_t) :: w2
  w2 = not (w1%i)
end function word_not

function word_or (w1, w2) result (w3)
  type(word32_t), intent(in) :: w1, w2
  type(word32_t) :: w3
  w3 = ior (w1%i, w2%i)
end function word_or

  end if
end function word_add_i32

```

2.13.4 64-bit words

These objects consist of two 32-bit words. They thus can hold integer numbers larger than 2^{32} (to be exact, 2^{31} since FORTRAN integers are signed). The order is low-word, high-word.

```

<Bytes: public>+≡
public :: word64_t

<Bytes: types>+≡
type :: word64_t
  private
  integer(i64) :: i
end type word64_t

```

Set a 64 bit word:

```

<Bytes: interfaces>+≡
    interface assignment(=)
        module procedure word64_set_from_i64
        module procedure word64_set_from_word32
    end interface

<Bytes: procedures>+≡
    subroutine word64_set_from_i64 (ww, i)
        type(word64_t), intent(out) :: ww
        integer(i64), intent(in) :: i
        ww%i = i
    end subroutine word64_set_from_i64

```

Filling with a 32-bit word:

```

<Bytes: procedures>+≡
    subroutine word64_set_from_word32 (ww, w)
        type(word64_t), intent(out) :: ww
        type(word32_t), intent(in) :: w
        if (w%i >= 0_i32) then
            ww%i = w%i
        else
            ww%i = 2_i64*(huge(0_i32)+1_i64) + w%i
        end if
    end subroutine word64_set_from_word32

```

Extract a byte from a word. The argument *i* is the position, which may be between 0 and 7.

For the final assignment, we set the highest bit separately. Otherwise, we might trigger an overflow condition for a compiler with strict checking turned on.

```

<Bytes: public>+≡
    public :: byte_from_word64, word32_from_word64

<Bytes: procedures>+≡
    function byte_from_word64 (ww, i) result (b)
        type(word64_t), intent(in) :: ww
        integer, intent(in) :: i
        type(byte_t) :: b
        integer(i64) :: j
        j = 0
        if (i >= 0 .and. i*8 < 64) then
            call mvbits (ww%i, i*8, 8, j, 0)
        end if
        b%i = int (ibclr (j, 7), kind=i8)
        if (btest (j, 7)) b%i = ibset (b%i, 7)
    end function byte_from_word64

```

Extract a 32-bit word from a 64-bit word. The position is either 0 or 1.

```

<Bytes: procedures>+≡
    function word32_from_word64 (ww, i) result (w)
        type(word64_t), intent(in) :: ww

```

```

integer, intent(in) :: i
type(word32_t) :: w
integer(i64) :: j
j = 0
select case (i)
case (0); call mvbits (ww%i, 0, 32, j, 0)
case (1); call mvbits (ww%i, 32, 32, j, 0)
end select
w = int (ibclr (j, 31), kind=i32)
if (btest (j, 31)) w = ibset (w%i, 31)
end function word32_from_word64

```

Print a 64-bit word. Decimal version works up to 2^{63} . The `words` version uses the 'word32' printout, separated by two spaces. The low-word is printed first. The `bytes` version also uses the 'word32' printout. This implies that the lowest byte is first. The default version prints a hexadecimal number without spaces, highest byte first.

(Bytes: public)+≡

```
public :: word64_write
```

(Bytes: interfaces)+≡

```

interface word64_write
  module procedure word64_write_unit
end interface

```

(Bytes: procedures)+≡

```

subroutine word64_write_unit (ww, unit, words, bytes, decimal, newline)
  type(word64_t), intent(in) :: ww
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: words, bytes, decimal, newline
  logical :: wo, by, dc, nl
  integer :: u
  u = output_unit (unit); if (u < 0) return
  wo = .false.; if (present (words)) wo = words
  by = .false.; if (present (bytes)) by = bytes
  dc = .false.; if (present (decimal)) dc = decimal
  nl = .false.; if (present (newline)) nl = newline
  if (wo .or. by) then
    call word32_write_unit (word32_from_word64 (ww, 0), unit, by, dc)
    write (u, '(2x)', advance='no')
    call word32_write_unit (word32_from_word64 (ww, 1), unit, by, dc)
  else if (dc) then
    write (u, '(I19)', advance='no') ww%i
  else
    write (u, '(Z16)', advance='no') ww%i
  end if
  if (nl) write (u, *)
end subroutine word64_write_unit

```

2.14 MD5 Checksums

It is a bit of an overkill, but implementing MD5 checksums allows us to check input/file integrity on the basis of a well-known standard. The building blocks have been introduced in the `bytes` module.

```
<md5.f90>≡  
  <File header>  
  
  module md5  
  
    use kinds, only: i8, i32, i64 !NODEP!  
    <Use file utils>  
    use diagnostics !NODEP!  
    use bytes  
    use limits, only: LF, EOR, EOF !NODEP!  
  
    <Standard module head>  
  
    <MD5: public>  
  
    <MD5: types>  
  
    <MD5: variables>  
  
    <MD5: interfaces>  
  
    contains  
  
    <MD5: procedures>  
  
  end module md5
```

2.14.1 Blocks

A block is a sequence of 16 words (64 bytes or 512 bits). We anticipate that blocks will be linked, so include a pointer to the next block. There is a fill status (word counter), as there is one for each word. The fill status is equal to the number of bytes that are in, so it may be between 0 and 64.

```
<MD5: types>≡  
  type :: block_t  
    private  
    type(word32_t), dimension(0:15) :: w  
    type(block_t), pointer :: next => null ()  
    integer :: fill = 0  
  end type block_t
```

Check if a block is completely filled or empty:

```
<MD5: procedures>≡  
  function block_is_empty (b)  
    type(block_t), intent(in) :: b  
    logical :: block_is_empty  
    block_is_empty = (b%fill == 0 .and. word32_empty (b%w(0)))
```

```

end function block_is_empty

function block_is_filled (b)
    type(block_t), intent(in) :: b
    logical :: block_is_filled
    block_is_filled = (b%fill == 64)
end function block_is_filled

```

Append a single byte to a block. Works only if the block is not yet filled.

(MD5: procedures)+≡

```

subroutine block_append_byte (bl, by)
    type(block_t), intent(inout) :: bl
    type(byte_t), intent(in) :: by
    if (.not. block_is_filled (bl)) then
        call word32_append_byte (bl%w(bl%fill/4), by)
        bl%fill = bl%fill + 1
    end if
end subroutine block_append_byte

```

The printing routine allows for printing as sequences of words or bytes, decimal or hex.

(MD5: interfaces)≡

```

interface block_write
    module procedure block_write_unit
end interface

```

(MD5: procedures)+≡

```

subroutine block_write_unit (b, unit, bytes, decimal)
    type(block_t), intent(in) :: b
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: bytes, decimal
    logical :: by, dc
    integer :: i, u
    u = output_unit (unit); if (u < 0) return
    by = .false.; if (present (bytes)) by = bytes
    dc = .false.; if (present (decimal)) dc = decimal
    do i = 0, b%fill/4 - 1
        call newline_or_blank (u, i, by, dc)
        call word32_write (b%w(i), unit, bytes, decimal)
    end do
    if (.not. block_is_filled (b)) then
        i = b%fill/4
        if (.not. word32_empty (b%w(i))) then
            call newline_or_blank (u, i, by, dc)
            call word32_write (b%w(i), unit, bytes, decimal)
        end if
    end if
    write (u, *)
contains
    subroutine newline_or_blank (u, i, bytes, decimal)
        integer, intent(in) :: u, i
        logical, intent(in) :: bytes, decimal
        if (decimal) then

```

```

        select case (i)
        case (0)
        case (2,4,6,8,10,12,14); write (u, *)
        case default
            write (u, '(2x)', advance='no')
        end select
    else if (bytes) then
        select case (i)
        case (0)
        case (4,8,12); write (u, *)
        case default
            write (u, '(2x)', advance='no')
        end select
    else
        if (i == 8) write (u, *)
    end if
end subroutine newline_or_blank
end subroutine block_write_unit

```

2.14.2 Messages

A message (within this module) is a linked list of blocks.

(MD5: types)+≡

```

type :: message_t
private
type(block_t), pointer :: first => null ()
type(block_t), pointer :: last => null ()
integer :: n_blocks = 0
end type message_t

```

Clear the message list

(MD5: procedures)+≡

```

subroutine message_clear (m)
type(message_t), intent(inout) :: m
type(block_t), pointer :: b
nullify (m%last)
do
    b => m%first
    if (.not.(associated (b))) exit
    m%first => b%next
    deallocate (b)
end do
m%n_blocks = 0
end subroutine message_clear

```

Append an empty block to the message list

(MD5: procedures)+≡

```

subroutine message_append_new_block (m)
type(message_t), intent(inout) :: m
if (associated (m%last)) then
    allocate (m%last%next)

```

```

        m%last => m%last%next
        m%n_blocks = m%n_blocks + 1
    else
        allocate (m%first)
        m%last => m%first
        m%n_blocks = 1
    end if
end subroutine message_append_new_block

```

Initialize: clear and allocate the first (empty) block.

```

<MD5: procedures>+≡
subroutine message_init (m)
    type(message_t), intent(inout) :: m
    call message_clear (m)
    call message_append_new_block (m)
end subroutine message_init

```

Append a single byte to a message. If necessary, allocate a new block. If the message is empty, initialize it.

```

<MD5: procedures>+≡
subroutine message_append_byte (m, b)
    type(message_t), intent(inout) :: m
    type(byte_t), intent(in) :: b
    if (.not. associated (m%last)) then
        call message_init (m)
    else if (block_is_filled (m%last)) then
        call message_append_new_block (m)
    end if
    call block_append_byte (m%last, b)
end subroutine message_append_byte

```

Append zero bytes until the current block is filled up to the required position. If we are already beyond that, append a new block and fill that one.

```

<MD5: procedures>+≡
subroutine message_pad_zero (m, i)
    type(message_t), intent(inout) :: m
    integer, intent(in) :: i
    type(block_t), pointer :: b
    integer :: j
    if (associated (m%last)) then
        b => m%last
        if (b%fill > i) then
            do j = b%fill + 1, 64 + i
                call message_append_byte (m, byte_zero)
            end do
        else
            do j = b%fill + 1, i
                call message_append_byte (m, byte_zero)
            end do
        end if
    end if
end subroutine message_pad_zero

```

This returns the number of bits within a message. We need a 64-bit word for the result since it may be more than 2^{31} . This is also required by the MD5 standard.

(MD5: procedures)+≡

```
function message_bits (m) result (length)
  type(message_t), intent(in) :: m
  type(word64_t) :: length
  type(block_t), pointer :: b
  integer(i64) :: n_blocks_filled, n_bytes_extra
  if (m%n_blocks > 0) then
    b => m%last
    if (block_is_filled (b)) then
      n_blocks_filled = m%n_blocks
      n_bytes_extra = 0
    else
      n_blocks_filled = m%n_blocks - 1
      n_bytes_extra = b%fill
    end if
    length = n_blocks_filled * 512 + n_bytes_extra * 8
  else
    length = 0_i64
  end if
end function message_bits
```

2.14.3 Message I/O

Append the contents of a string to a message. We first cast the character string into a 8-bit integer array and then append this byte by byte.

(MD5: procedures)+≡

```
subroutine message_append_string (m, s)
  type(message_t), intent(inout) :: m
  character(len=*), intent(in) :: s
  integer(i64) :: i, n_bytes
  integer(i8), dimension(:), allocatable :: buffer
  integer(i8), dimension(1) :: mold
  type(byte_t) :: b
  n_bytes = size (transfer (s, mold))
  allocate (buffer (n_bytes))
  buffer = transfer (s, mold)
  do i = 1, size (buffer)
    b = buffer(i)
    call message_append_byte (m, b)
  end do
  deallocate (buffer)
end subroutine message_append_string
```

Append the contents of a 32-bit integer to a message. We first cast the 32-bit integer into a 8-bit integer array and then append this byte by byte.

(MD5: procedures)+≡

```
subroutine message_append_i32 (m, x)
```

```

type(message_t), intent(inout) :: m
integer(i32), intent(in) :: x
integer(i8), dimension(4) :: buffer
type(byte_t) :: b
integer :: i
buffer = transfer (x, buffer, size(buffer))
do i = 1, size (buffer)
    b = buffer(i)
    call message_append_byte (m, b)
end do
end subroutine message_append_i32

```

Append one line from file to a message. Include the newline character.

(MD5: procedures)+≡

```

!  subroutine message_append_from_unit (m, u, iostat)
!      type(message_t), intent(inout) :: m
!      integer, intent(in) :: u
!      integer, intent(out) :: iostat
!      character(len=BUFFER_SIZE) :: buffer
!      read (u, *, iostat=iostat) buffer
!      call message_append_string (m, trim (buffer))
!      call message_append_string (m, LF)
!  end subroutine message_append_from_unit

```

Fill a message from file. (Each line counts as a string.)

(MD5: procedures)+≡

```

!  subroutine message_read_from_file (m, f)
!      type(message_t), intent(inout) :: m
!      character(len=*), intent(in) :: f
!      integer :: u, iostat
!      u = free_unit ()
!      open (file=f, unit=u, action='read')
!      do
!          call message_append_from_unit (m, u, iostat=iostat)
!          if (iostat < 0) exit
!      end do
!      close (u)
!  end subroutine message_read_from_file

```

Write a message. After each block, insert an empty line.

(MD5: interfaces)+≡

```

interface message_write
    module procedure message_write_unit
end interface

```

(MD5: procedures)+≡

```

subroutine message_write_unit (m, unit, bytes, decimal)
    type(message_t), intent(in) :: m
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: bytes, decimal
    type(block_t), pointer :: b
    integer :: u
    u = output_unit (unit); if (u < 0) return

```

```

b => m%first
if (associated (b)) then
  do
    call block_write_unit (b, unit, bytes, decimal)
    b => b%next
    if (.not. associated (b)) exit
    write (u, *)
  end do
end if
end subroutine message_write_unit

```

2.14.4 Auxiliary functions

These four functions on three words are defined in the MD5 standard:

```

⟨MD5: procedures⟩+≡
function ff (x, y, z)
  type(word32_t), intent(in) :: x, y, z
  type(word32_t) :: ff
  ff = ior (iand (x, y), iand (not (x), z))
end function ff

function fg (x, y, z)
  type(word32_t), intent(in) :: x, y, z
  type(word32_t) :: fg
  fg = ior (iand (x, z), iand (y, not (z)))
end function fg

function fh (x, y, z)
  type(word32_t), intent(in) :: x, y, z
  type(word32_t) :: fh
  fh = ieor (ieor (x, y), z)
end function fh

function fi (x, y, z)
  type(word32_t), intent(in) :: x, y, z
  type(word32_t) :: fi
  fi = ieor (y, ior (x, not (z)))
end function fi

```

2.14.5 Auxiliary stuff

This defines and initializes the table of transformation constants:

```

⟨MD5: variables⟩≡
  type(word32_t), dimension(64), save :: t
  logical, save :: table_initialized = .false.

⟨MD5: procedures⟩+≡
  subroutine table_init
    type(word64_t) :: ww
    integer :: i
    if (.not.table_initialized) then

```

```

do i = 1, 64
  ww = int (4294967296d0 * abs (sin (i * 1d0)), kind=i64)
  t(i) = word32_from_word64 (ww, 0)
end do
table_initialized = .true.
end if
end subroutine table_init

```

This encodes the message digest (4 words) into a 32-character string.

(MD5: procedures)+≡

```

function digest_string (aa) result (s)
  type(word32_t), dimension (0:3), intent(in) :: aa
  character(len=32) :: s
  integer :: i, j
  do i = 0, 3
    do j = 0, 3
      call byte_write (byte_from_word32 (aa(i), j), s(i*8+j*2+1:i*8+j*2+2))
    end do
  end do
end function digest_string

```

2.14.6 MD5 algorithm

Pad the message with a byte x80 and then pad zeros up to a full block minus two words; in these words, insert the message length (before padding) as a 64-bit word, low-word first.

(MD5: procedures)+≡

```

subroutine message_pad (m)
  type(message_t), intent(inout) :: m
  type(word64_t) :: length
  integer(i8), parameter :: ipad = -128 ! z'80'
  type(byte_t) :: b
  integer :: i
  length = message_bits (m)
  b = ipad
  call message_append_byte (m, b)
  call message_pad_zero (m, 56)
  do i = 0, 7
    call message_append_byte (m, byte_from_word64 (length, i))
  end do
end subroutine message_pad

```

Apply a series of transformations onto a state *a,b,c,d*, where the transform function uses each word of the message together with the predefined words. Finally, encode the state as a 32-character string.

(MD5: procedures)+≡

```

subroutine message_digest (m, s)
  type(message_t), intent(in) :: m
  character(len=32), intent(out) :: s
  integer(i32), parameter :: ia = 1732584193 ! z'67452301'
  integer(i32), parameter :: ib = -271733879 ! z'efcdab89'

```

```

integer(i32), parameter :: ic = -1732584194 ! z'98badcfe'
integer(i32), parameter :: id = 271733878 ! z'10325476'
type(word32_t) :: a, b, c, d
type(word32_t) :: aa, bb, cc, dd
type(word32_t), dimension(0:15) :: x
type(block_t), pointer :: bl
call table_init
a = ia; b = ib; c = ic; d = id
bl => m%first
do
  if (.not.associated (bl)) exit
  x = bl%w

contains
<MD5: Internal subroutine transform>
end subroutine message_digest

```

And this is the actual transformation that depends on one of the previous functions, four words, and three integers. The implicit arguments are **x**, the word from the message to digest, and **t**, the entry in the predefined table.

```

<MD5: Internal subroutine transform>≡
subroutine transform (f, a, b, c, d, k, s, i)
interface
function f (x, y, z)
import word32_t
type(word32_t), intent(in) :: x, y, z
type(word32_t) :: f
end function f
end interface
type(word32_t), intent(inout) :: a
type(word32_t), intent(in) :: b, c, d
integer, intent(in) :: k, s, i
a = b + ishftc (a + f(b, c, d) + x(k) + t(i), s)
end subroutine transform

```

2.14.7 User interface

```
<MD5: public>≡  
public :: md5sum
```

```
<MD5: interfaces>+≡  
interface md5sum  
  module procedure md5sum_from_string  
  module procedure md5sum_from_unit  
end interface
```

This function computes the MD5 sum of the input string and returns it as a 32-character string

```
<MD5: procedures>+≡  
function md5sum_from_string (s) result (digest)  
  character(len=*), intent(in) :: s  
  character(len=32) :: digest  
  type(message_t) :: m  
  call message_append_string (m, s)  
  call message_pad (m)  
  call message_digest (m, digest)  
  call message_clear (m)  
end function md5sum_from_string
```

This funct. reads from unit u (an unformatted sequence of integers) and computes the MD5 sum.

```
<MD5: procedures>+≡  
function md5sum_from_unit (u) result (digest)  
  integer, intent(in) :: u  
  character(len=32) :: digest  
  type(message_t) :: m  
  character :: char  
  integer :: iostat  
  READ_CHARS: do

  end do READ_CHARS  
  call message_pad (m)  
  call message_digest (m, digest)  
  call message_clear (m)  
end function md5sum_from_unit
```

This funct checks the implementation by computing the checksum of certain strings and comparing them with the known values. If some inconsistency is

```

    <Permutations: types>

    <Permutations: interfaces>

contains

    <Permutations: procedures>

end module permutations

```

2.15.1 Permutations

A permutation is an array of integers. Each integer between one and `size` should occur exactly once.

```

<Permutations: public>≡
    public :: permutation_t

<Permutations: types>≡
    type :: permutation_t
    private
        integer, dimension(:), allocatable :: p
    end type permutation_t

```

Initialize with the identity permutation.

```

<Permutations: public>+≡
    public :: permutation_init
    public :: permutation_final

<Permutations: procedures>≡
    elemental subroutine permutation_init (p, size)
        type(permutation_t), intent(inout) :: p
        integer, intent(in) :: size
        integer :: i
        allocate (p%p (size))
        forall (i = 1:size)
            p%p(i) = i
        end forall
    end subroutine permutation_init

    elemental subroutine permutation_final (p)
        type(permutation_t), intent(inout) :: p
        deallocate (p%p)
    end subroutine permutation_final

```

I/O:

```

<Permutations: public>+≡
    public :: permutation_write

<Permutations: procedures>+≡
    subroutine permutation_write (p, u)
        type(permutation_t), intent (in) :: p
        integer, intent(in) :: u
        integer :: i

```

```

do i = 1, size (p%p)
  if (size (p%p) < 10) then
    write (u,"(1x,I1)", advance="no") p%p(i)
  else
    write (u,"(1x,I3)", advance="no") p%p(i)
  end if
end do
write (u, *)
end subroutine permutation_write

```

Administration:

```

⟨Permutations: public⟩+=
  public :: permutation_size

⟨Permutations: procedures⟩+=
  elemental function permutation_size (perm) result (s)
    type(permutation_t), intent(in) :: perm
    integer :: s
    s = size (perm%p)
  end function permutation_size

```

Extract an entry in a permutation.

```

⟨Permutations: public⟩+=
  public :: permute

⟨Permutations: procedures⟩+=
  elemental function permute (i, p) result (j)
    integer, intent(in) :: i
    type(permutation_t), intent(in) :: p
    integer :: j
    if (i > 0 .and. i <= size (p%p)) then
      j = p%p(i)
    else
      j = 0
    end if
  end function permute

```

Check whether a permutation is valid: Each integer in the range occurs exactly once.

```

⟨Permutations: public⟩+=
  public :: permutation_ok

⟨Permutations: procedures⟩+=
  elemental function permutation_ok (perm) result (ok)
    type(permutation_t), intent(in) :: perm
    logical :: ok
    integer :: i
    logical, dimension(:), allocatable :: set
    ok = .true.
    allocate (set (size (perm%p)))
    set = .false.
    do i = 1, size (perm%p)
      ok = (perm%p(i) > 0 .and. perm%p(i) <= size (perm%p))
    end do
  end function permutation_ok

```

```

        if (.not.ok) return
        set(perm%p(i)) = .true.
    end do
    ok = all (set)
end function permutation_ok

```

Find the permutation that transforms the second array into the first one. We assume that this is possible and unique and all bounds are set correctly.

This cannot be elemental.

```

<Permutations: public>+≡
    public :: permutation_find

<Permutations: procedures>+≡
    subroutine permutation_find (perm, a1, a2)
        type(permutation_t), intent(inout) :: perm
        integer, dimension(:), intent(in) :: a1, a2
        integer :: i, j
        if (allocated (perm%p)) deallocate (perm%p)
        allocate (perm%p (size (a1)))
        do i = 1, size (a1)
            do j = 1, size (a2)
                if (a1(i) == a2(j)) then
                    perm%p(i) = j
                    exit
                end if
            end do
            perm%p(i) = 0
        end do
    end subroutine permutation_find

```

Find all permutations that transform an array of integers into itself. The resulting permutation list is allocated with the correct length and filled.

The first step is to count the number of different entries in `code`. Next, we scan `code` again and assign a mask to each different entry, true for all identical entries. Finally, we recursively permute the identity for each possible mask.

The permutation is done as follows: A list of all permutations of the initial one with respect to the current mask is generated, then the permutations are generated in turn for each permutation in this list with the next mask. The result is always stored back into the main list, starting from the end of the current list.

```

<Permutations: public>+≡
    public :: permutation_array_make

<Permutations: procedures>+≡
    subroutine permutation_array_make (pa, code)
        type(permutation_t), dimension(:), allocatable, intent(out) :: pa
        integer, dimension(:), intent(in) :: code
        logical, dimension(size(code)) :: mask
        logical, dimension(:,:), allocatable :: imask
        integer, dimension(:), allocatable :: n_i
        type(permutation_t) :: p_init
        type(permutation_t), dimension(:), allocatable :: p_tmp
        integer :: psize, i, j, k, n_different, n, nn_k

```

```

psize = size (code)
mask = .true.
n_different = 0
do i=1, psize
  if (mask(i)) then
    n_different = n_different + 1
    mask = mask .and. (code /= code(i))
  end if
end do
allocate (imask(psize, n_different), n_i(n_different))
mask = .true.
k = 0
do i=1, psize
  if (mask(i)) then
    k = k + 1
    imask(:,k) = (code == code(i))
    n_i(k) = factorial (count(imask(:,k)))
    mask = mask .and. (code /= code(i))
  end if
end do
n = product (n_i)
allocate (pa (n))
call permutation_init (p_init, psize)
pa(1) = p_init
nn_k = 1
do k = 1, n_different
  allocate (p_tmp (n_i(k)))
  do i = nn_k, 1, -1
    call permutation_array_with_mask (p_tmp, imask(:,k), pa(i))
    do j = n_i(k), 1, -1
      pa((i-1)*n_i(k) + j) = p_tmp(j)
    end do
  end do
  deallocate (p_tmp)
  nn_k = nn_k * n_i(k)
end do
call permutation_final (p_init)
deallocate (imask, n_i)
end subroutine permutation_array_make

```

Make a list of permutations of the elements marked true in the `mask` array. The final permutation list must be allocated with the correct length ($n!$). The third argument is the initial permutation to start with, which must have the same length as the `mask` array (this is not checked).

(Permutations: procedures) +=

```

subroutine permutation_array_with_mask (pa, mask, p_init)
  type(permutation_t), dimension(:), intent(inout) :: pa
  logical, dimension(:), intent(in) :: mask
  type(permutation_t), intent(in) :: p_init
  integer :: plen
  integer :: i, ii, j, fac_i, k, x
  integer, dimension(:), allocatable :: index
  plen = size (pa)

```

```

allocate (index(count(mask)))
ii = 0
do i = 1, size (mask)
  if (mask(i)) then
    ii = ii + 1
    index(ii) = i
  end if
end do
pa = p_init
ii = 0
fac_i = 1
do i = 1, size (mask)
  if (mask(i)) then
    ii = ii + 1
    fac_i = fac_i * ii
    x = permute (i, p_init)
    do j = 1, plen
      k = ii - mod (((j-1)*fac_i)/plen, ii)
      call insert (pa(j), x, k, ii, index)
    end do
  end if
end do
deallocate (index)
contains
subroutine insert (p, x, k, n, index)
  type(permutation_t), intent(inout) :: p
  integer, intent(in) :: x, k, n
  integer, dimension(:), intent(in) :: index
  integer :: i
  do i = n, k+1, -1
    p%p(index(i)) = p%p(index(i-1))
  end do
  p%p(index(k)) = x
end subroutine insert
end subroutine permutation_array_with_mask

```

The factorial function is needed for pre-determining the number of permutations that will be generated:

```

(Permutations: procedures) +=
function factorial (n) result (f)
  integer, intent(in) :: n
  integer :: f
  integer :: i
  f = 1
  do i=2, abs(n)
    f = f*i
  end do
end function factorial

```

2.15.2 Operations on binary codes

Binary codes are needed for phase-space trees. Since the permutation function uses permutations, and no other special type is involved, we put the functions here.

This is needed for phase space trees: permute bits in a tree binary code. If no permutation is given, leave as is. (We may want to access the permutation directly here if this is efficiency-critical.)

```

<Permutations: public>+=
    public :: tc_permute

<Permutations: procedures>+=
    function tc_permute (k, perm, mask_in) result (pk)
        integer(TC), intent(in) :: k, mask_in
        type(permutation_t), intent(in) :: perm
        integer(TC) :: pk
        integer :: i
        pk = iand (k, mask_in)
        do i = 1, size (perm%p)
!           if (btest(k,i-1)) pk = ibset (pk, permute (perm,i) - 1)
            if (btest(k,i-1)) pk = ibset (pk, perm%p(i)-1)
        end do
    end function tc_permute

```

This routine returns the number of set bits in the tree code value k. Hence, it is the number of externals connected to the current line. If *mask* is present, the complement of the tree code is also considered, and the smaller number is returned. This gives the true distance from the external states, taking into account the initial particles. The complement number is increased by one, since for a scattering diagram the vertex with the sum of all final-state codes is still one point apart from the initial particles.

```

<Permutations: public>+=
    public :: tc_decay_level

<Permutations: interfaces>=
    interface tc_decay_level
        module procedure decay_level_simple
        module procedure decay_level_complement
    end interface

<Permutations: procedures>+=
    function decay_level_complement (k, mask) result (l)
        integer(TC), intent(in) :: k, mask
        integer :: l
        l = min (decay_level_simple (k), &
            & decay_level_simple (ieor (k, mask)) + 1)
    end function decay_level_complement

    function decay_level_simple (k) result(l)
        integer(TC), intent(in) :: k
        integer :: l
        integer :: i
        l = 0
        do i=0, bit_size(k)-1

```

```

        if (btest(k,i)) l = l+1
    end do
end function decay_level_simple

```

2.16 Sorting

This small module provides functions for sorting integer or real arrays.

<sorting.f90>≡
<File header>

```
module sorting
```

<Use kinds>
 use diagnostics !NODEP!

<Standard module head>

<Sorting: public>

<Sorting: interfaces>

```
contains
```

<Sorting: procedures>

```
end module sorting
```

2.16.1 Implementation

The **sort** function returns, for a given integer or real array, the array sorted by increasing value. The current implementation is *mergesort*, which has $O(n \ln n)$ behavior in all cases, and is stable for elements of equal value.

<Sorting: public>≡

```
public :: sort
```

<Sorting: interfaces>≡

```
interface sort
    module procedure sort_int
    module procedure sort_real
end interface
```

The body is identical, just the interface differs.

<Sorting: procedures>≡

```
function sort_int (val_in) result (val)
    integer, dimension(:), intent(in) :: val_in
    integer, dimension(size(val_in)) :: val
<Sorting: sort>
end function sort_int
```

```
function sort_real (val_in) result (val)
```

```

    real(default), dimension(:), intent(in) :: val_in
    real(default), dimension(size(val_in)) :: val
    <Sorting: sort>
end function sort_real

```

```

<Sorting: sort>≡
    val = val_in( order (val_in) )

```

The `order` function returns, for a given integer or real array, the array of indices of the elements sorted by increasing value.

```

<Sorting: public>+≡
    public :: order

<Sorting: interfaces>+≡
    interface order
        module procedure order_int
        module procedure order_real
    end interface

```

```

<Sorting: procedures>+≡
    function order_int (val) result (idx)
        integer, dimension(:), intent(in) :: val
        integer, dimension(size(val)) :: idx
    <Sorting: order>
end function order_int

    function order_real (val) result (idx)
        real(default), dimension(:), intent(in) :: val
        integer, dimension(size(val)) :: idx
    <Sorting: order>
end function order_real

```

We start by individual elements, merge them to pairs, merge those to four-element subarrays, and so on. The last subarray can extend only up to the original array bound, of course, and the second of the subarrays to merge should contain at least one element.

```

<Sorting: order>≡
    integer :: n, i, s, b1, b2, e1, e2
    n = size (idx)
    forall (i = 1:n)
        idx(i) = i
    end forall
    s = 1
    do while (s < n)
        do b1 = 1, n-s, 2*s
            b2 = b1 + s
            e1 = b2 - 1
            e2 = min (e1 + s, n)
            call merge (idx(b1:e2), idx(b1:e1), idx(b2:e2), val)
        end do
        s = 2 * s
    end do

```

The merging step does the actual sorting. We take two sorted array sections and merge them to a sorted result array. We are working on the indices, and comparing is done by taking the associated `val` which is real or integer.

```

<Sorting: interfaces>+≡
  interface merge
    module procedure merge_int
    module procedure merge_real
  end interface

<Sorting: procedures>+≡
  subroutine merge_int (res, src1, src2, val)
    integer, dimension(:), intent(out) :: res
    integer, dimension(:), intent(in) :: src1, src2
    integer, dimension(:), intent(in) :: val
    integer, dimension(size(res)) :: tmp
  <Sorting: merge>
  end subroutine merge_int

  subroutine merge_real (res, src1, src2, val)
    integer, dimension(:), intent(out) :: res
    integer, dimension(:), intent(in) :: src1, src2
    real(default), dimension(:), intent(in) :: val
    integer, dimension(size(res)) :: tmp
  <Sorting: merge>
  end subroutine merge_real

<Sorting: merge>≡
  integer :: i1, i2, i
  i1 = 1
  i2 = 1
  do i = 1, size (tmp)
    if (val(src1(i1)) <= val(src2(i2))) then
      tmp(i) = src1(i1); i1 = i1 + 1
      if (i1 > size (src1)) then
        tmp(i+1:) = src2(i2:)
        exit
      end if
    else
      tmp(i) = src2(i2); i2 = i2 + 1
      if (i2 > size (src2)) then
        tmp(i+1:) = src1(i1:)
        exit
      end if
    end if
  end do
  res = tmp

```

2.16.2 Concatenating arrays

Not precisely a sorting function, but useful: Concatenate two arrays.

```

<Sorting: public>+≡
  public :: concat

```

```

<Sorting: interfaces>+≡
interface concat
  module procedure concat_int
  module procedure concat_real
end interface

<Sorting: procedures>+≡
function concat_int (val1, val2) result (val12)
  integer, dimension(:), intent(in) :: val1, val2
  integer, dimension(size(val1)+size(val2)) :: val12
<Sorting: concat>
end function concat_int

function concat_real (val1, val2) result (val12)
  real(default), dimension(:), intent(in) :: val1, val2
  integer, dimension(size(val1)+size(val2)) :: val12
<Sorting: concat>
end function concat_real

<Sorting: concat>≡
val12(:size(val1)) = val1
val12(size(val1)+1:) = val2

```

2.16.3 Test

```

<Sorting: public>+≡
public :: sorting_test

<Sorting: procedures>+≡
subroutine sorting_test ()
  integer, parameter :: NMAX = 10
  real(default), dimension(NMAX) :: rval
  integer, dimension(NMAX) :: ival
  real, dimension(NMAX) :: harvest
  integer :: i, j
  print *, "Sorting real values:"
  do i = 1, NMAX
    print *
    call random_number (harvest(:i))
    rval(:i) = harvest(:i)
    print "(10(1x,F7.4))", rval(:i)
    rval(:i) = sort (rval(:i))
    print "(10(1x,F7.4))", rval(:i)
    do j = i, 2, -1
      if (rval(j)-rval(j-1) < 0) &
        call msg_fatal ("Sorting failure")
    end do
  end do
  print *
  print *, "Sorting integer values:"
  do i = 1, NMAX
    print *
    call random_number (harvest(:i))

```

```

      ival(:i) = harvest(:i) * NMAX * 2
      print "(10(1x,I2))", ival(:i)
      ival(:i) = sort (ival(:i))
      print "(10(1x,I2))", ival(:i)
      do j = i, 2, -1
        if (ival(j)-ival(j-1) < 0) &
          call msg_fatal ("Sorting failure")
        end do
      end do
end subroutine sorting_test

```

Chapter 3

Text handling

WHIZARD has to handle complex structures in input (and output) data. Doing this in a generic and transparent way requires a generic lexer and parser. The necessary modules are implemented here:

ifiles Implementation of line-oriented internal files in a more flexible way (linked lists of variable-length strings) than the Fortran builtin features.

lexers Read text and transform it into a token stream.

syntax_rules Define the rules for interpreting tokens, to be used by the parser.

parser Categorize tokens (keyword, string, number etc.) and use a set of syntax rules to transform the input into a parse tree.

3.1 Internal files

The internal files introduced here (`ifile`) are a replacement for the built-in internal files, which are fixed-size arrays of fixed-length character strings. The `ifile` type is a doubly-linked list of variable-length character strings with line numbers.

```
<ifiles.f90>≡  
  <File header>  
  
  module ifiles  
  
    <Use strings>  
    <Use file utils>  
    use limits, only: EOF !NODEP!  
  
    <Standard module head>  
  
    <Ifiles: public>  
  
    <Ifiles: types>  
  
    <Ifiles: interfaces>  
  
    contains  
  
    <Ifiles: subroutines>  
  
  end module ifiles
```

3.1.1 iostat codes

```
<Limits: public parameters>+≡  
  integer, parameter, public :: EOF = iostat_end, EOR = iostat_eor
```

3.1.2 The line type

The line entry type is for internal use, it is the list entry to be collected in an `ifile` object.

```
<Ifiles: types>≡  
  type :: line_entry_t  
    private  
    type(line_entry_t), pointer :: previous => null ()  
    type(line_entry_t), pointer :: next => null ()  
    type(string_t) :: string  
    integer :: index  
  end type line_entry_t
```

Create a new list entry, given a varying string as input. The line number and pointers are not set, these make sense only within an `ifile`.

```
<Ifiles: subroutines>≡  
  subroutine line_entry_create (line, string)
```

```

    type(line_entry_t), pointer :: line
    type(string_t), intent(in) :: string
    allocate (line)
    line%string = string
end subroutine line_entry_create

```

Destroy a single list entry: Since the pointer components should not be deallocated explicitly, just deallocate the object itself.

```

<Ifiles: subroutines>+≡
    subroutine line_entry_destroy (line)
        type(line_entry_t), pointer :: line
        deallocate (line)
    end subroutine line_entry_destroy

```

3.1.3 The ifile type

The internal file is a linked list of line entries.

```

<Ifiles: public>≡
    public :: ifile_t

<Ifiles: types>+≡
    type :: ifile_t
    private
        type(line_entry_t), pointer :: first => null ()
        type(line_entry_t), pointer :: last => null ()
        integer :: n_lines = 0
    end type ifile_t

```

We need no explicit initializer, but a routine which recursively deallocates the contents may be appropriate. After this, existing line pointers may become undefined, so they should be nullified before the file is destroyed.

```

<Ifiles: public>+≡
    public :: ifile_clear

<Ifiles: subroutines>+≡
    subroutine ifile_clear (ifile)
        type(ifile_t), intent(inout) :: ifile
        type(line_entry_t), pointer :: current
        do while (associated (ifile%first))
            current => ifile%first
            ifile%first => current%next
            call line_entry_destroy (current)
        end do
        nullify (ifile%last)
        ifile%n_lines = 0
    end subroutine ifile_clear

```

The finalizer is just an alias for the above.

```

<Ifiles: public>+≡
    public :: ifile_final

```

```

<Ifiles: interfaces>≡
  interface ifile_final
    module procedure ifile_clear
  end interface

```

3.1.4 I/O on ifiles

Fill an ifile from an ordinary external file, i.e., I/O unit. If the ifile is not empty, the old contents will be destroyed. We can read a fixed-length character string, an ISO varying string, an ordinary internal file (character-string array), or from an external unit. In the latter case, lines are appended until EOF is reached. Finally, there is a variant which reads from another ifile, effectively copying it.

```

<Ifiles: public>+≡
  public :: ifile_read

<Ifiles: interfaces>+≡
  interface ifile_read
    module procedure ifile_read_from_string
    module procedure ifile_read_from_char
    module procedure ifile_read_from_unit
    module procedure ifile_read_from_char_array
    module procedure ifile_read_from_ifile
  end interface

<Ifiles: subroutines>+≡
  subroutine ifile_read_from_string (ifile, string)
    type(ifile_t), intent(inout) :: ifile
    type(string_t), intent(in) :: string
    call ifile_clear (ifile)
    call ifile_append (ifile, string)
  end subroutine ifile_read_from_string

  subroutine ifile_read_from_char (ifile, char)
    type(ifile_t), intent(inout) :: ifile
    character(*), intent(in) :: char
    call ifile_clear (ifile)
    call ifile_append (ifile, char)
  end subroutine ifile_read_from_char

  subroutine ifile_read_from_char_array (ifile, char)
    type(ifile_t), intent(inout) :: ifile
    character(*), dimension(:), intent(in) :: char
    call ifile_clear (ifile)
    call ifile_append (ifile, char)
  end subroutine ifile_read_from_char_array

  subroutine ifile_read_from_unit (ifile, unit, iostat)
    type(ifile_t), intent(inout) :: ifile
    integer, intent(in) :: unit
    integer, intent(out), optional :: iostat
    call ifile_clear (ifile)
    call ifile_append (ifile, unit, iostat)
  end subroutine ifile_read_from_unit

```

```

subroutine ifile_read_from_ifile (ifile, ifile_in)
  type(ifile_t), intent(inout) :: ifile
  type(ifile_t), intent(in) :: ifile_in
  call ifile_clear (ifile)
  call ifile_append (ifile, ifile_in)
end subroutine ifile_read_from_ifile

```

Append to an ifile. The same as reading, but without resetting the ifile. In addition, there is a routine for appending a whole ifile.

(Ifiles: public)+≡

```

public :: ifile_append

```

(Ifiles: interfaces)+≡

```

interface ifile_append
  module procedure ifile_append_from_string
  module procedure ifile_append_from_char
  module procedure ifile_append_from_unit
  module procedure ifile_append_from_char_array
  module procedure ifile_append_from_ifile
end interface

```

(Ifiles: subroutines)+≡

```

subroutine ifile_append_from_string (ifile, string)
  type(ifile_t), intent(inout) :: ifile
  type(string_t), intent(in) :: string
  type(line_entry_t), pointer :: current
  call line_entry_create (current, string)
  current%index = ifile%n_lines + 1
  if (associated (ifile%last)) then
    current%previous => ifile%last
    ifile%last%next => current
  else
    ifile%first => current
  end if
  ifile%last => current
  ifile%n_lines = current%index
end subroutine ifile_append_from_string

subroutine ifile_append_from_char (ifile, char)
  type(ifile_t), intent(inout) :: ifile
  character(*), intent(in) :: char
  call ifile_append_from_string (ifile, var_str (trim (char)))
end subroutine ifile_append_from_char

subroutine ifile_append_from_char_array (ifile, char)
  type(ifile_t), intent(inout) :: ifile
  character(*), dimension(:), intent(in) :: char
  integer :: i
  do i = 1, size (char)
    call ifile_append_from_string (ifile, var_str (trim (char(i))))
  end do
end subroutine ifile_append_from_char_array

subroutine ifile_append_from_unit (ifile, unit, iostat)
  type(ifile_t), intent(inout) :: ifile

```

```

integer, intent(in) :: unit
integer, intent(out), optional :: iostat
type(string_t) :: buffer
integer :: ios
ios = 0
READ_LOOP: do
    call get (unit, buffer, iostat = ios)
    if (ios == EOF .or. ios > 0) exit READ_LOOP
    call ifile_append_from_string (ifile, buffer)
end do READ_LOOP
if (present (iostat)) then
    iostat = ios
else if (ios > 0) then
    call get (unit, buffer) ! trigger error again
end if
end subroutine ifile_append_from_unit

subroutine ifile_append_from_ifile (ifile, ifile_in)
type(ifile_t), intent(inout) :: ifile
type(ifile_t), intent(in) :: ifile_in
type(line_entry_t), pointer :: current
current => ifile_in%first
do while (associated (current))
    call ifile_append_from_string (ifile, current%string)
    current => current%next
end do
end subroutine ifile_append_from_ifile

```

Write the ifile contents to an external unit

```

<Ifiles: public>+≡
public :: ifile_write

<Ifiles: subroutines>+≡
subroutine ifile_write (ifile, unit, iostat)
type(ifile_t), intent(in) :: ifile
integer, intent(in), optional :: unit
integer, intent(out), optional :: iostat
integer :: u
type(line_entry_t), pointer :: current
u = output_unit (unit); if (u < 0) return
current => ifile%first
do while (associated (current))
    call put_line (u, current%string, iostat)
    current => current%next
end do
end subroutine ifile_write

```

Convert the ifile to an array of strings, which is allocated by this function:

```

<Ifiles: public>+≡
public :: ifile_to_string_array

<Ifiles: subroutines>+≡
subroutine ifile_to_string_array (ifile, string)
type(ifile_t), intent(in) :: ifile

```

```

type(string_t), dimension(:), intent(inout), allocatable :: string
type(line_entry_t), pointer :: current
integer :: i
allocate (string (ifile_get_length (ifile)))
current => ifile%first
do i = 1, ifile_get_length (ifile)
    string(i) = current%string
    current => current%next
end do
end subroutine ifile_to_string_array

```

3.1.5 Ifile tools

```

<Ifiles: public>+≡
public :: ifile_get_length

<Ifiles: subroutines>+≡
function ifile_get_length (ifile) result (length)
    integer :: length
    type(ifile_t), intent(in) :: ifile
    length = ifile%n_lines
end function ifile_get_length

```

3.1.6 Line pointers

Instead of the implicit pointer used in ordinary file access, we define explicit pointers, so there can be more than one at a time.

```

<Ifiles: public>+≡
public :: line_p

<Ifiles: types>+≡
type :: line_p
private
type(line_entry_t), pointer :: p => null ()
end type line_p

```

Assign a file pointer to the first or last line in an ifile:

```

<Ifiles: public>+≡
public :: line_init

<Ifiles: subroutines>+≡
subroutine line_init (line, ifile, back)
    type(line_p), intent(inout) :: line
    type(ifile_t), intent(in) :: ifile
    logical, intent(in), optional :: back
    if (present (back)) then
        if (back) then
            line%p => ifile%last
        else
            line%p => ifile%first
        end if
    else

```

```

        line%p => ifile%first
    end if
end subroutine line_init

```

Remove the pointer association:

```

<Ifiles: public>+≡
    public :: line_final
<Ifiles: subroutines>+≡
    subroutine line_final (line)
        type(line_p), intent(inout) :: line
        nullify (line%p)
    end subroutine line_final

```

Go one step forward

```

<Ifiles: public>+≡
    public :: line_advance
<Ifiles: subroutines>+≡
    subroutine line_advance (line)
        type(line_p), intent(inout) :: line
        if (associated (line%p)) line%p => line%p%next
    end subroutine line_advance

```

Go one step backward

```

<Ifiles: public>+≡
    public :: line_backspace
<Ifiles: subroutines>+≡
    subroutine line_backspace (line)
        type(line_p), intent(inout) :: line
        if (associated (line%p)) line%p => line%p%previous
    end subroutine line_backspace

```

Check whether we are accessing a valid line

```

<Ifiles: public>+≡
    public :: line_is_associated
<Ifiles: subroutines>+≡
    function line_is_associated (line) result (ok)
        logical :: ok
        type(line_p), intent(in) :: line
        ok = associated (line%p)
    end function line_is_associated

```

3.1.7 Access lines via pointers

We do not need the ifile as an argument to these functions, because the `line` type will point to an existing ifile.

```

<Ifiles: public>+≡
    public :: line_get_string

```

```

<Ifiles: subroutines>+=
function line_get_string (line) result (string)
  type(string_t) :: string
  type(line_p), intent(in) :: line
  if (associated (line%p)) then
    string = line%p%string
  else
    string = ""
  end if
end function line_get_string

```

Variant where the line pointer is advanced after reading.

```

<Ifiles: public>+=
public :: line_get_string_advance
<Ifiles: subroutines>+=
function line_get_string_advance (line) result (string)
  type(string_t) :: string
  type(line_p), intent(inout) :: line
  if (associated (line%p)) then
    string = line%p%string
    call line_advance (line)
  else
    string = ""
  end if
end function line_get_string_advance

```

```

<Ifiles: public>+=
public :: line_get_index
<Ifiles: subroutines>+=
function line_get_index (line) result (index)
  integer :: index
  type(line_p), intent(in) :: line
  if (associated (line%p)) then
    index = line%p%index
  else
    index = 0
  end if
end function line_get_index

```

```

<Ifiles: public>+=
public :: line_get_length
<Ifiles: subroutines>+=
function line_get_length (line) result (length)
  integer :: length
  type(line_p), intent(in) :: line
  if (associated (line%p)) then
    length = len (line%p%string)
  else
    length = 0
  end if
end function line_get_length

```

3.2 Lexer

The lexer purpose is to read from a line-separated character input stream (usually a file) and properly chop the stream into lexemes (tokens). [The parser will transform lexemes into meaningful tokens, to be stored in a parse tree, therefore we do not use the term 'token' here.] The input is read line-by-line, but interpreted free-form, except for quotes and the comment syntax. (Fortran 2003 would allow us to use a stream type for reading.)

In an object-oriented approach, we can dynamically create and destroy lexers, including the lexer setup.

The main lexer function is to return a lexeme according to the basic lexer rules (quotes, comments, whitespace, special classes). There is also a routine to write back a lexeme to the input stream (but only once).

For the rules, we separate the possible characters into classes. Whitespace usually consists of blank, tab, and line-feed, where any number of consecutive whitespace is equivalent to one. Quoted strings are enclosed by a pair of quote characters, possibly multiline. Comments are similar to quotes, but interpreted as whitespace. Numbers are identified (not distinguishing real and integer) but not interpreted. Other character classes make up identifiers.

```
<lexers.f90>≡  
  <File header>  
  
  module lexers  
  
    <Use strings>  
    <Use file utils>  
    use limits, only: EOF, EOR !NODEP!  
    use limits, only: LF !NODEP!  
    use limits, only: WHITESPACE_CHARS, LCLETTERS, UCLETTERS, DIGITS !NODEP!  
    use diagnostics !NODEP!  
    use ifiles, only: ifile_t  
    use ifiles, only: line_p, line_is_associated, line_init, line_final  
    use ifiles, only: line_get_string_advance  
  
    <Standard module head>  
  
    <Lexer: public>  
  
    <Lexer: parameters>  
  
    <Lexer: types>  
  
    <Lexer: interfaces>  
  
  contains  
  
    <Lexer: procedures>  
  
  end module lexers
```

3.2.1 Input streams

For flexible input, we define a generic stream type that refers to either an external file, an external unit which is already open, a string, an `ifile` object (internal file, i.e., string list), or a line pointer to an `ifile` object. The stream type actually follows the idea of a formatted external file, which is line-oriented. Thus, the stream reader always returns a whole record (input line).

Note that only in the string version, the stream contents are stored inside the stream object. In the `ifile` version, the stream contains only the line pointer, while in the external-file case, the line pointer is implicitly created by the runtime library.

```
<Lexer: public>≡
    public :: stream_t

<Lexer: types>≡
    type :: stream_t
        type(string_t), pointer :: filename => null ()
        integer, pointer :: unit => null ()
        type(string_t), pointer :: string => null ()
        type(ifile_t), pointer :: ifile => null ()
        type(line_p), pointer :: line => null ()
        integer :: record = 0
        logical :: eof = .false.
    end type stream_t
```

The initializers refer to the specific version. The stream should be undefined before calling this.

```
<Lexer: public>+≡
    public :: stream_init

<Lexer: interfaces>≡
    interface stream_init
        module procedure stream_init_filename
        module procedure stream_init_unit
        module procedure stream_init_string
        module procedure stream_init_ifile
        module procedure stream_init_line
    end interface

<Lexer: procedures>≡
    subroutine stream_init_filename (stream, filename)
        type(stream_t), intent(out) :: stream
        character(*), intent(in) :: filename
        integer :: unit
        unit = free_unit ()
        open (unit=unit, file=filename, status="old", action="read")
        call stream_init_unit (stream, unit)
        allocate (stream%filename)
        stream%filename = filename
    end subroutine stream_init_filename

    subroutine stream_init_unit (stream, unit)
        type(stream_t), intent(out) :: stream
        integer, intent(in) :: unit
```

```

        allocate (stream%unit)
        stream%unit = unit
        stream%eof = .false.
    end subroutine stream_init_unit

subroutine stream_init_string (stream, string)
    type(stream_t), intent(out) :: stream
    type(string_t), intent(in) :: string
    allocate (stream%string)
    stream%string = string
end subroutine stream_init_string

subroutine stream_init_ifile (stream, ifile)
    type(stream_t), intent(out) :: stream
    type(ifile_t), intent(in) :: ifile
    type(line_p) :: line
    call line_init (line, ifile)
    call stream_init_line (stream, line)
    allocate (stream%ifile)
    stream%ifile = ifile
end subroutine stream_init_ifile

subroutine stream_init_line (stream, line)
    type(stream_t), intent(out) :: stream
    type(line_p), intent(in) :: line
    allocate (stream%line)
    stream%line = line
end subroutine stream_init_line

```

The finalizer restores the initial state. If an external file was opened, it is closed.

```

<Lexer: public>+≡
    public :: stream_final

<Lexer: procedures>+≡
    subroutine stream_final (stream)
        type(stream_t), intent(inout) :: stream
        if (associated (stream%filename)) then
            close (stream%unit)
            deallocate (stream%unit)
            deallocate (stream%filename)
        else if (associated (stream%unit)) then
            deallocate (stream%unit)
        else if (associated (stream%string)) then
            deallocate (stream%string)
        else if (associated (stream%ifile)) then
            call line_final (stream%line)
            deallocate (stream%line)
            deallocate (stream%ifile)
        else if (associated (stream%line)) then
            call line_final (stream%line)
            deallocate (stream%line)
        end if
    end subroutine stream_final

```

This returns the next record from the input stream. Depending on the stream type, the stream pointers are modified: Reading from external unit, the external file is advanced (implicitly). Reading from string, the string is replaced by an empty string. Reading from ifile, the line pointer is advanced. Note that the `iostat` argument is mandatory.

<Lexer: public>+≡

`public :: stream_get_record`

<Lexer: procedures>+≡

```
subroutine stream_get_record (stream, string, iostat)
  type(stream_t), intent(inout) :: stream
  type(string_t), intent(out) :: string
  integer, intent(out) :: iostat
  if (associated (stream%unit)) then
    if (stream%eof) then
      iostat = EOF
    else
      call get (stream%unit, string, iostat=iostat)
      if (iostat == EOR) then
        iostat = 0
        stream%record = stream%record + 1
      end if
      if (iostat == EOF) then
        iostat = 0
        stream%eof = .true.
        if (len (string) /= 0) stream%record = stream%record + 1
      end if
    end if
  else if (associated (stream%string)) then
    if (len (stream%string) /= 0) then
      string = stream%string
      stream%string = ""
      iostat = 0
      stream%record = stream%record + 1
    else
      string = ""
      iostat = EOF
    end if
  else if (associated (stream%line)) then
    if (line_is_associated (stream%line)) then
      string = line_get_string_advance (stream%line)
      iostat = 0
      stream%record = stream%record + 1
    else
      string = ""
      iostat = EOF
    end if
  else
    call msg_bug (" Attempt to read from uninitialized input stream")
  end if
end subroutine stream_get_record
```

Return the current stream source as a message string.

<Lexer: public>+≡

```

public :: stream_get_source_info_string
<Lexer: procedures>+≡
function stream_get_source_info_string (stream) result (string)
  type(string_t) :: string
  type(stream_t), intent(in) :: stream
  character(20) :: buffer
  if (associated (stream%filename)) then
    string = "File '" // stream%filename // "' (unit = "
    write (buffer, "(I0)") stream%unit
    string = string // trim (buffer) // ")"
  else if (associated (stream%unit)) then
    write (buffer, "(I0)") stream%unit
    string = "Unit " // trim (buffer)
  else if (associated (stream%string)) then
    string = "Input string"
  else if (associated (stream%ifile) .or. associated (stream%line)) then
    string = "Internal file"
  else
    string = ""
  end if
end function stream_get_source_info_string

```

Return the index of the record just read as a message string.

```

<Lexer: public>+≡
public :: stream_get_record_info_string
<Lexer: procedures>+≡
function stream_get_record_info_string (stream) result (string)
  type(string_t) :: string
  type(stream_t), intent(in) :: stream
  character(20) :: buffer
  string = stream_get_source_info_string (stream)
  if (string /= "") string = string // ", "
  write (buffer, "(I0)") stream%record
  string = string // "line " // trim (buffer)
end function stream_get_record_info_string

```

3.2.2 Keyword list

The lexer should be capable of identifying a token as a known keyword. To this end, we store a list of keywords:

```

<Lexer: public>+≡
public :: keyword_list_t
<Lexer: types>+≡
type :: keyword_entry_t
  private
  type(string_t) :: string
  type(keyword_entry_t), pointer :: next => null ()
end type keyword_entry_t

type :: keyword_list_t

```

```

private
type(keyword_entry_t), pointer :: first => null ()
type(keyword_entry_t), pointer :: last => null ()
end type keyword_list_t

```

Add a new string to the keyword list, unless it is already there:

```

<Lexer: public>+≡
public :: keyword_list_add

<Lexer: procedures>+≡
subroutine keyword_list_add (keylist, string)
type(keyword_list_t), intent(inout) :: keylist
type(string_t), intent(in) :: string
type(keyword_entry_t), pointer :: k_entry_new
if (.not. keyword_list_contains (keylist, string)) then
allocate (k_entry_new)
k_entry_new%string = string
if (associated (keylist%first)) then
keylist%last%next => k_entry_new
else
keylist%first => k_entry_new
end if
keylist%last => k_entry_new
end if
end subroutine keyword_list_add

```

Return true if a string is a keyword.

```

<Lexer: public>+≡
public :: keyword_list_contains

<Lexer: procedures>+≡
function keyword_list_contains (keylist, string) result (found)
type(keyword_list_t), intent(in) :: keylist
type(string_t), intent(in) :: string
logical :: found
found = .false.
call check_rec (keylist%first)
contains
recursive subroutine check_rec (k_entry)
type(keyword_entry_t), pointer :: k_entry
if (associated (k_entry)) then
if (k_entry%string /= string) then
call check_rec (k_entry%next)
else
found = .true.
end if
end if
end subroutine check_rec
end function keyword_list_contains

```

Write the keyword list

```

<Lexer: public>+≡
public :: keyword_list_write

```

```

<Lexer: interfaces>+=
  interface keyword_list_write
    module procedure keyword_list_write_unit
  end interface

<Lexer: procedures>+=
  subroutine keyword_list_write_unit (keylist, unit)
    type(keyword_list_t), intent(in) :: keylist
    integer, intent(in) :: unit
    write (unit, "(A)") "Keyword list:"
    if (associated (keylist%first)) then
      call keyword_write_rec (keylist%first)
      write (unit, *)
    else
      write (unit, "(1x,A)") "[empty]"
    end if
  contains
    recursive subroutine keyword_write_rec (k_entry)
      type(keyword_entry_t), intent(in), pointer :: k_entry
      if (associated (k_entry)) then
        write (unit, "(1x,A)", advance="no") char (k_entry%string)
        call keyword_write_rec (k_entry%next)
      end if
    end subroutine keyword_write_rec
  end subroutine keyword_list_write_unit

```

Clear the keyword list

```

<Lexer: public>+=
  public :: keyword_list_final

<Lexer: procedures>+=
  subroutine keyword_list_final (keylist)
    type(keyword_list_t), intent(inout) :: keylist
    call keyword_destroy_rec (keylist%first)
    nullify (keylist%last)
  contains
    recursive subroutine keyword_destroy_rec (k_entry)
      type(keyword_entry_t), pointer :: k_entry
      if (associated (k_entry)) then
        call keyword_destroy_rec (k_entry%next)
        deallocate (k_entry)
      end if
    end subroutine keyword_destroy_rec
  end subroutine keyword_list_final

```

3.2.3 Lexeme templates

This type is handled like a rudimentary regular expression. It determines the lexer behavior when matching a string. The actual objects made from this type and the corresponding matching routines are listed below.

```

<Lexer: types>+=
  type :: template_t

```

```

private
integer :: type
character(256) :: charset1, charset2
integer :: len1, len2
end type template_t

```

These are the types that valid lexemes can have:

```

<Lexer: public>+≡
public :: T_KEYWORD, T_IDENTIFIER, T_QUOTED, T_NUMERIC

<Lexer: parameters>≡
integer, parameter :: T_KEYWORD = 1
integer, parameter :: T_IDENTIFIER = 2, T_QUOTED = 3, T_NUMERIC = 4

```

These are special types:

```

<Lexer: parameters>+≡
integer, parameter :: EMPTY = 0, WHITESPACE = 10
integer, parameter :: NO_MATCH = 11, IO_ERROR = 12, OVERFLOW = 13
integer, parameter :: UNMATCHED_QUOTE = 14

```

In addition, we have EOF which is a negative integer, normally -1 . Printout for debugging:

```

<Lexer: procedures>+≡
subroutine lexeme_type_write (type, unit)
integer, intent(in) :: type
integer, intent(in) :: unit
select case (type)
case (EMPTY);      write(unit,"(A)",advance="no") " EMPTY      "
case (WHITESPACE); write(unit,"(A)",advance="no") " WHITESPACE "
case (T_IDENTIFIER);write(unit,"(A)",advance="no") " IDENTIFIER "
case (T_QUOTED);   write(unit,"(A)",advance="no") " QUOTED      "
case (T_NUMERIC);  write(unit,"(A)",advance="no") " NUMERIC      "
case (IO_ERROR);   write(unit,"(A)",advance="no") " IO_ERROR    "
case (OVERFLOW);   write(unit,"(A)",advance="no") " OVERFLOW    "
case (UNMATCHED_QUOTE); write(unit,"(A)",advance="no") " UNMATCHEDQ "
case (NO_MATCH);   write(unit,"(A)",advance="no") " NO_MATCH    "
case (EOF);        write(unit,"(A)",advance="no") " EOF          "
case default;      write(unit,"(A)",advance="no") " [illegal]   "
end select
end subroutine lexeme_type_write

subroutine template_write (tt, unit)
type(template_t), intent(in) :: tt
integer, intent(in) :: unit
call lexeme_type_write (tt%type, unit)
write (unit, "(A)", advance="no") " '" // tt%charset1(1:tt%len1) // "' "
write (unit, "(A)", advance="no") " '" // tt%charset2(1:tt%len2) // "' "
end subroutine template_write

```

The matching functions all return the number of matched characters in the provided string. If this number is zero, the match has failed.

The `template` functions are declared `pure` because they appear in `forall` loops below.

A template for whitespace:

```

<Lexer: procedures>+≡
pure function template_whitespace (chars) result (tt)
  character(*), intent(in) :: chars
  type(template_t) :: tt
  tt = template_t (WHITESPACE, chars, "", len (chars), 0)
end function template_whitespace

```

Just match the string against the character set.

```

<Lexer: procedures>+≡
subroutine match_whitespace (tt, s, n)
  type(template_t), intent(in) :: tt
  character(*), intent(in) :: s
  integer, intent(out) :: n
  n = verify (s, tt%charset1(1:tt%len1)) - 1
  if (n < 0) n = len (s)
end subroutine match_whitespace

```

A template for normal identifiers. To match, a lexeme should have a first character in class `chars1` and an arbitrary number of further characters in class `chars2`. If the latter is empty, we are looking for a single-character lexeme.

```

<Lexer: procedures>+≡
pure function template_identifier (chars1, chars2) result (tt)
  character(*), intent(in) :: chars1, chars2
  type(template_t) :: tt
  tt = template_t (T_IDENTIFIER, chars1, chars2, len(chars1), len(chars2))
end function template_identifier

```

Here, the first letter must match, the others may or may not.

```

<Lexer: procedures>+≡
subroutine match_identifier (tt, s, n)
  type(template_t), intent(in) :: tt
  character(*), intent(in) :: s
  integer, intent(out) :: n
  if (verify (s(1:1), tt%charset1(1:tt%len1)) == 0) then
    n = verify (s(2:), tt%charset2(1:tt%len2))
    if (n == 0) n = len (s)
  else
    n = 0
  end if
end subroutine match_identifier

```

A template for quoted strings. The same template applies for comments. The first character set indicates the left quote (could be a sequence of several characters), the second one the matching right quote.

```

<Lexer: procedures>+≡
pure function template_quoted (chars1, chars2) result (tt)
  character(*), intent(in) :: chars1, chars2
  type(template_t) :: tt
  tt = template_t (T_QUOTED, chars1, chars2, len (chars1), len (chars2))
end function template_quoted

```

Here, the beginning of the string must exactly match the first character set, then we look for the second one. If found, return. If there is a first quote but no second one, return a negative number, indicating this error condition.

```

<Lexer: procedures>+≡
subroutine match_quoted (tt, s, n, range)
  type(template_t), intent(in) :: tt
  character(*), intent(in) :: s
  integer, intent(out) :: n
  integer, dimension(2), intent(out) :: range
  character(tt%len1) :: ch1
  character(tt%len2) :: ch2
  integer :: i
  ch1 = tt%charset1
  if (s(1:tt%len1) == ch1) then
    ch2 = tt%charset2
    do i = tt%len1 + 1, len (s) - tt%len2 + 1
      if (s(i:i+tt%len2-1) == ch2) then
        n = i + tt%len2 - 1
        range(1) = tt%len1 + 1
        range(2) = i - 1
        return
      end if
    end do
    n = -1
    range = 0
  else
    n = 0
    range = 0
  end if
end subroutine match_quoted

```

A template for real numbers. The first character set is the set of allowed exponent letters. In accordance with the other functions we return the lexeme as a string but do not read it.

```

<Lexer: procedures>+≡
pure function template_numeric (chars) result (tt)
  character(*), intent(in) :: chars
  type(template_t) :: tt
  tt = template_t (T_NUMERIC, chars, "", len (chars), 0)
end function template_numeric

```

A numeric lexeme may be real or integer. We purposely do not allow for a preceding sign. If the number is followed by an exponent, this is included, otherwise the rest is ignored.

There is a possible pitfall with this behavior: while the string `1e3` will be interpreted as a single number, the analogous string `1a3` will be split into the number `1` and an identifier `a3`. There is no easy way around such an ambiguity. We should make sure that the syntax does not contain identifiers like `a3` or `e3`.

```

<Lexer: procedures>+≡
subroutine match_numeric (tt, s, n)
  type(template_t), intent(in) :: tt
  character(*), intent(in) :: s

```

```

integer, intent(out) :: n
integer :: i, n0
character(10), parameter :: digits = "0123456789"
character(2), parameter :: signs = "-+"
n = verify (s, digits) - 1
if (n < 0) then

        range(2) = len_trim (s)
    case (T_QUOTED)
        call match_quoted (tt, s, n, range)
    case (T_NUMERIC)

```

```

        call match_numeric (tt, s, n)
        range(1) = 1
        range(2) = len_trim (s)
    case default
        call msg_bug ("Invalid lexeme template encountered")
    end select
end subroutine match_template

```

Match against an array of templates. Return the index of the first template that matches together with the number of characters matched and the range of the relevant substring. If all fails, these numbers are zero.

<Lexer: procedures>+≡

```

subroutine match (tt, s, n, range, ii)
    type(template_t), dimension(:), intent(in) :: tt
    character(*), intent(in) :: s
    integer, intent(out) :: n
    integer, dimension(2), intent(out) :: range
    integer, intent(out) :: ii
    integer :: i
    do i = 1, size (tt)
        call match_template (tt(i), s, n, range)
        if (n /= 0) then
            ii = i
            return
        end if
    end do
    n = 0
    ii = 0
end subroutine match

```

3.2.4 The lexer setup

This object contains information about character classes. As said above, one class consists of quoting chars (matching left and right), another one of comment chars (similar), a class of whitespace, and several classes of characters that make up identifiers. When creating the lexer setup, the character classes are transformed into lexeme templates which are to be matched in a certain predefined order against the input stream.

BLANK should always be taken as whitespace, some things may depend on this. TAB is also fixed by convention, but may in principle be modified. Newline (DOS!) and linefeed are also defined as whitespace.

<Limits: public parameters>+≡

```

character, parameter, public :: BLANK = ' ', TAB = achar(9)
character, parameter, public :: CR = achar(13), LF = achar(10)
character, parameter, public :: BACKSLASH = achar(92)
character(*), parameter, public :: WHITESPACE_CHARS = BLANK// TAB // CR // LF
character(*), parameter, public :: LCLETTERS = "abcdefghijklmnopqrstuvwxyz"
character(*), parameter, public :: UCLETTERS = "ABCDEFGHIJKLMNOPQRSTUVWXYZ"
character(*), parameter, public :: DIGITS = "0123456789"

```

The lexer setup, containing the list of lexeme templates. No defaults yet. The type with index zero will be assigned to the NO_MATCH lexeme.

The keyword list is not stored, just a pointer to it. We anticipate that the keyword list is part of the syntax table, and the lexer needs not alter it. Furthermore, the lexer is typically finished before the syntax table is.

```

<Lexer: parameters>+=
    integer, parameter :: CASE_KEEP = 0, CASE_UP = 1, CASE_DOWN = 2

<Lexer: types>+=
    type :: lexer_setup_t
    private
    type(template_t), dimension(:), allocatable :: tt
    integer, dimension(:), allocatable :: type
    integer :: keyword_case = CASE_KEEP
    type(keyword_list_t), pointer :: keyword_list => null ()
end type lexer_setup_t

```

Fill the lexer setup object. Some things are hardcoded here (whitespace, alphanumeric identifiers), some are free: comment chars (but these must be single, and comments must be terminated by line-feed), quote chars and matches (must be single), characters to be read as one-character lexeme, special classes (characters of one class that should be glued together as identifiers).

```

<Lexer: procedures>+=
    subroutine lexer_setup_init (setup, &
        comment_chars, quote_chars, quote_match, &
        single_chars, special_class, &
        keyword_list, upper_case_keywords)
    type(lexer_setup_t), intent(inout) :: setup
    character(*), intent(in) :: comment_chars
    character(*), intent(in) :: quote_chars, quote_match

            call template_write (setup%tt(i), unit)
        end do
    end if
end subroutine lexer_setup_write

```

```

        write (unit, '(A)', advance = "no") " -> "
        call lexeme_type_write (setup%type(i), unit)
        write (unit, *)
    end do
else
    write (unit, *) "[empty]"
end if
if (associated (setup%keyword_list)) then
    call keyword_list_write (setup%keyword_list, unit)
end if
end subroutine lexer_setup_write

```

3.2.5 The lexeme type

An object of this type is returned by the lexer. Apart from the lexeme string, it gives information about the relevant substring (first and last character index) and the lexeme type. Interpreting the string is up to the parser.

```

<Lexer: public>+≡
    public :: lexeme_t

<Lexer: types>+≡
    type :: lexeme_t
    private
        integer :: type = EMPTY
        type(string_t) :: s
        integer :: b = 0, e = 0
    end type lexeme_t

```

Debugging aid:

```

<Lexer: public>+≡
    public :: lexeme_write

<Lexer: procedures>+≡
    subroutine lexeme_write (t, unit)
        type(lexeme_t), intent(in) :: t
        integer, intent(in) :: unit
        integer :: u
        u = output_unit (unit); if (u < 0) return
        select case (t%type)
        case (T_KEYWORD)
            write (u, *) "KEYWORD:  ' " // char (t%s) // "' "
        case (T_IDENTIFIER)
            write (u, *) "IDENTIFIER: ' " // char (t%s) // "' "
        case (T_QUOTED)
            write (u, *) "QUOTED:    ' " // char (t%s) // "' "
        case (T_NUMERIC)
            write (u, *) "NUMERIC:   ' " // char (t%s) // "' "
        case (UNMATCHED_QUOTE)
            write (u, *) "Unmatched quote: "// char (t%s)
        case (OVERFLOW); write (u, *) "Overflow: "// char (t%s)
        case (EMPTY);   write (u, *) "Empty lexeme"
        case (NO_MATCH); write (u, *) "No match"
        case (IO_ERROR); write (u, *) "IO error"
    end subroutine

```

```

        case (EOF);      write (u, *) "EOF"
        case default
            write (u, *) "Error"
        end select
    end subroutine lexeme_write

```

Store string and type in a lexeme. The range determines the beginning and end of the relevant part of the string. Check for a keyword.

<Lexer: procedures>+≡

```

subroutine lexeme_set (t, keyword_list, s, range, type, keyword_case)
    type.lexeme_t, intent(out) :: t
    type(keyword_list_t), pointer :: keyword_list
    type(string_t), intent(in) :: s
    type(string_t) :: keyword
    integer, dimension(2), intent(in) :: range
    integer, intent(in) :: type
    integer, intent(in), optional :: keyword_case
    t%type = type
    if (present (keyword_case)) then
        select case (keyword_case)
            case (CASE_KEEP);    keyword = s
            case (CASE_UP);      keyword = upper_case (s)
            case (CASE_DOWN);    keyword = lower_case (s)
        end select
    else
        keyword = s
    end if
    if (type == T_IDENTIFIER) then
        if (associated (keyword_list)) then
            if (keyword_list_contains (keyword_list, keyword)) &
                t%type = T_KEYWORD
            end if
        end if
        select case (t%type)
            case (T_KEYWORD);    t%s = keyword
            case default;        t%s = s
        end select
        t%b = range(1)
        t%e = range(2)
    end subroutine lexeme_set

subroutine lexeme_clear (t)
    type.lexeme_t, intent(out) :: t
    t%type = EMPTY
    t%s = ""
end subroutine lexeme_clear

```

Retrieve the lexeme string, the relevant part of it, and the type. The last function returns true if there is a break condition reached (error or EOF).

<Lexer: public>+≡

```

public :: lexeme_get_string
public :: lexeme_get_contents
public :: lexeme_get_delimiters

```

```

public :: lexeme_get_type
<Lexer: procedures>+≡
function lexeme_get_string (t) result (s)
  type(string_t) :: s

  type(string_t), dimension(2) :: del
  type(lexeme_t), intent(in) :: t
  del(1) = extract (t%s, finish = t%b-1)
  del(2) = extract (t%s, start = t%e+1)
end function lexeme_get_delimiters

function lexeme_get_type (t) result (type)
  integer :: type
  type(lexeme_t), intent(in) :: t
  type = t%type
end function lexeme_get_type

```

Check for a generic break condition (error/eof) and for eof in particular.

```

<Lexer: public>+≡
public :: lexeme_is_break
public :: lexeme_is_eof

<Lexer: procedures>+≡
function lexeme_is_break (t) result (break)
  logical :: break
  type(lexeme_t), intent(in) :: t
  select case (t%type)
    case (EOF, IO_ERROR, OVERFLOW, NO_MATCH)
      break = .true.
    case default
      break = .false.
  end select
end function lexeme_is_break

function lexeme_is_eof (t) result (ok)
  logical :: ok
  type(lexeme_t), intent(in) :: t
  ok = t%type == EOF
end function lexeme_is_eof

```

3.2.6 The lexer object

We store the current lexeme and the current line. The line buffer is set each time a new line is read from file. The working buffer has one character more, to hold any trailing blank. Pointers to line and column are for debugging, they will be used to make up readable error messages for the parser.

<Lexer: public>+≡

public :: lexer_t

<Lexer: types>+≡

type :: lexer_t

private

type(lexer_setup_t) :: setup

type(stream_t), pointer :: stream => null ()

type(lexeme_t) :: lexeme

type(string_t) :: previous_line2

type(string_t) :: previous_line1

type(string_t) :: current_line

integer :: lines_read = 0

integer :: current_column = 0

integer :: previous_column = 0

type(string_t) :: buffer

type(lexer_t), pointer :: parent => null ()

end type lexer_t

Create-setup wrapper

<Lexer: public>+≡

public :: lexer_init

logical, intent(in), optional :: upper_case_keywords

type(lexer_t), target, intent(in), optional :: parent

call lexer_setup_init (lexer%setup, &

comment_chars = comment_chars, &

quote_chars = quote_chars, &

quote_match = quote_match, &

single_chars = single_chars, &

special_class = special_class, &

keyword_list = keyword_list, &

upper_case_keywords = upper_case_keywords)

if (present (parent)) lexer%parent => parent

call lexer_clear (lexer)

end subroutine lexer_init

Clear the lexer state, but not the setup. This should be done when the lexing starts, but it is not known whether the lexer was used before.

```

<Lexer: public>+≡
    public :: lexer_clear

<Lexer: procedures>+≡
    subroutine lexer_clear (lexer)
        type(lexer_t), intent(inout) :: lexer
        call lexeme_clear (lexer%lexeme)
        lexer%previous_line2 = ""
        lexer%previous_line1 = ""
        lexer%current_line = ""
        lexer%lines_read = 0
        lexer%current_column = 0
        lexer%previous_column = 0
        lexer%buffer = ""
    end subroutine lexer_clear

```

Reset lexer state and delete setup

```

<Lexer: public>+≡
    public :: lexer_final

<Lexer: procedures>+≡
    subroutine lexer_final (lexer)
        type(lexer_t), intent(inout) :: lexer
        call lexer_clear (lexer)
        call lexer_setup_final (lexer%setup)
    end subroutine lexer_final

```

3.2.7 The lexer routine

For lexing we need to associate an input stream to the lexer.

```

<Lexer: public>+≡
    public :: lexer_assign_stream

<Lexer: procedures>+≡
    subroutine lexer_assign_stream (lexer, stream)
        type(lexer_t), intent(inout) :: lexer
        type(stream_t), intent(in), target :: stream
        lexer%stream => stream
    end subroutine lexer_assign_stream

```

The lexer. The lexer function takes the lexer and returns the currently stored lexeme. If there is none, it is read from buffer, matching against the lexeme templates in the lexer setup. Empty lexemes, i.e., comments and whitespace, are discarded and the buffer is read again until we have found a nonempty lexeme (which may also be EOF or an error condition).

The initial state of the lexer contains an empty lexeme, so reading from buffer is forced. The empty state is restored after returning the lexeme. A nonempty lexeme is present in the lexer only if `lex_back` has been executed before.

The workspace is the `lexer%buffer`, treated as a sort of input stream. We chop off lexemes from the beginning, adjusting the buffer to the left. Whenever the buffer is empty, or we are matching against an open quote which has not terminated, we read a new line and append it to the right. This may result in special conditions, which for simplicity are also returned as lexemes: I/O error, buffer overflow, end of file. If the latter happens during reading a quoted string, we return an unmatched-quote lexeme. Obviously, the special-condition lexemes have to be caught by the parser.

Note that reading further lines is only necessary when reading a quoted string. Otherwise, the line-feed that ends each line is interpreted as whitespace which terminates a preceding lexeme, so there are no other valid multiline lexemes.

To enable meaningful error messages, we also keep track of the line number of the last line read, and the beginning and the end of the current lexeme with respect to this line.

The lexer is implemented as a function that returns the next lexeme (i.e., token). It uses the `lexer` setup and modifies the buffers and pointers stored within the lexer, a side effect. The lexer reads from an input stream object, which also is modified by this reading, e.g., a line pointer is advanced.

```

(Lexer: public)+≡
    public :: lex

(Lexer: procedures)+≡

    lexer%current_column = lexer%current_column + pos
end do GET_LEXEME
lexeme = lexer%lexeme
call lexeme_clear (lexer%lexeme)
end subroutine lex

```

Read a line and append it to the input buffer. If the input buffer overflows, return `iostat=2`. Otherwise, `iostat=1` indicates an I/O error, and `iostat=-1` the EOF.

The input stream may either be an external unit or a `ifile` object. In the latter case, a line is read and the line pointer is advanced.

Note that inserting LF between input lines is the Unix convention. Since we are doing this explicitly when gluing lines together, we can pattern-match against LF without having to worry about the system.

```

<Lexer: procedures>+≡
subroutine lexer_read_line (lexer, iostat)
    type(lexer_t), intent(inout) :: lexer
    integer, intent(out) :: iostat
    type(string_t) :: current_line
    current_line = lexer%current_line
    call stream_get_record (lexer%stream, lexer%current_line, iostat)
    if (iostat == 0) then
        lexer%lines_read = lexer%lines_read + 1
        lexer%previous_line2 = lexer%previous_line1
        lexer%previous_line1 = current_line
        lexer%buffer = lexer%buffer // lexer%current_line // LF
        lexer%previous_column = 0
        lexer%current_column = 0
    end if
end subroutine lexer_read_line

```

Once in a while we have read one lexeme to many, which can be pushed back into the input stream. Do not do this more than once.

```

<Lexer: public>+≡
public :: lexer_put_back

<Lexer: procedures>+≡
subroutine lexer_put_back (lexer, lexeme)
    type(lexer_t), intent(inout) :: lexer
    type(lexeme_t), intent(in) :: lexeme
    if (lexeme_get_type (lexer%lexeme) == EMPTY) then

```

```

        lexer%lexeme = lexeme
    else
        call msg_bug (" Lexer: lex_back fails; probably called twice")
    end if
end subroutine lexer_put_back

```

3.2.8 Diagnostics

For debugging: print just the setup

```

<Lexer: public>+≡
    public :: lexer_write_setup

<Lexer: procedures>+≡
    subroutine lexer_write_setup (lexer, unit)
        type(lexer_t), intent(in) :: lexer
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit); if (u < 0) return
        call lexer_setup_write (lexer%setup, u)
    end subroutine lexer_write_setup

```

This is useful for error printing: show the current line with index and a pointer to the current column within the line.

```

<Lexer: public>+≡
    public :: lexer_show_location

<Lexer: procedures>+≡
    subroutine lexer_show_location (lexer)
        type(lexer_t), intent(in) :: lexer
        type(string_t) :: loc_str
        if (associated (lexer%parent)) then
            call lexer_show_source (lexer%parent)
            call msg_message ("[includes]")
        else
            call msg_message ()
        end if
        if (associated (lexer%stream)) then
            call msg_message &
                (char (stream_get_record_info_string (lexer%stream)) // ":")
        end if
        if (lexer%lines_read >= 4) call msg_result ("[...]")
        if (lexer%lines_read >= 3) call msg_result (char (lexer%previous_line2))
        if (lexer%lines_read >= 2) call msg_result (char (lexer%previous_line1))
        if (lexer%lines_read >= 1) then
            call msg_result (char (lexer%current_line))
            loc_str = repeat (" ", lexer%previous_column)
            loc_str = loc_str // "^"
            if (lexer%current_column > lexer%previous_column) then
                loc_str = loc_str &
                    // repeat ("-", max (lexer%current_column &
                        - lexer%previous_column - 1, 0)) &
                    // "^"
            end if
        end if
    end subroutine lexer_show_location

```

```

        call msg_result (char (loc_str))
    end if
end subroutine lexer_show_location

```

This just prints the current stream source.

<Lexer: procedures>+≡

```

recursive subroutine lexer_show_source (lexer)
    type(lexer_t), intent(in) :: lexer
    type(string_t) :: loc_str
    if (associated (lexer%parent)) then
        call lexer_show_source (lexer%parent)
        call msg_message ("[includes]")
    else
        call msg_message ()
    end if
    if (associated (lexer%stream)) then
        call msg_message &
            (char (stream_get_source_info_string (lexer%stream)) // ":")
    end if
end subroutine lexer_show_source

```

Test the lexer by lexing and printing all lexemes from unit u, one per line, using preset conventions

<Lexer: public>+≡

```

public :: lexer_test

```

<Lexer: procedures>+≡

```

subroutine lexer_test (lexer, unit)
    type(lexer_t), intent(inout) :: lexer
    integer, intent(in) :: unit
    type(stream_t), target :: stream
    type(string_t) :: string
    type(lexeme_t) :: lexeme
    string = "abcdefghij"
    call lexer_init (lexer, &
        comment_chars = "", &
        quote_chars = "<'\"", &
        quote_match = ">'\"", &
        single_chars = "?*+=,()", &
        special_class = ("/ "." /), &
        keyword_list = null ())
    call stream_init (stream, string)
    call lexer_assign_stream (lexer, stream)
    do
        call lex (lexeme, lexer)
        call lexeme_write (lexeme, unit)
        if (lexeme_is_break (lexeme)) exit
    end do
    call stream_final (stream)
    call lexer_final (lexer)
end subroutine lexer_test

```

3.3 Syntax rules

This module provides tools to handle syntax rules in an abstract way.

```
<syntax_rules.f90>≡  
<File header>  
  
module syntax_rules  
  
  <Use strings>  
  <Use file utils>  
  use limits, only: UNQUOTED !NODEP!  
  use diagnostics !NODEP!  
  use ifiles, only: line_p, line_init, line_get_string_advance, line_final  
  use ifiles, only: ifile_t, ifile_get_length  
  use lexers  
  
  <Standard module head>  
  
  <Syntax: public>  
  
  <Syntax: parameters>  
  
  <Syntax: types>  
  
  <Syntax: interfaces>  
  
contains  
  
  <Syntax: subroutines>  
  
end module syntax_rules
```

3.3.1 Syntax rules

Syntax rules are used by the parser. They determine how to translate the stream of lexemes as returned by the lexer into the parse tree node. A rule may be terminal, i.e., replace a matching lexeme into a terminal node. The node will contain the lexeme interpreted as a recognized token:

- a keyword: unquoted fixed character string;
- a real number, to be determined at runtime;
- an integer, to be determined at runtime;
- a boolean value, to be determined at runtime;
- a quoted token (e.g., string), to be determined at runtime;
- an identifier (unquoted string that is not a recognized keyword), to be determined at runtime.

It may be nonterminal, i.e., contain a sequence of child rules. These are matched consecutively (and recursively) against the input stream; the resulting node will be a branch node.

- the file, i.e., the input stream as a whole;
- a sequence of syntax elements, where the last syntax element may be optional, or optional repetitive;

Sequences carry a flag that tells whether the last child is optional or may be repeated an arbitrary number of times, corresponding to the regexp modifiers `?`, `*`, and `+`.

We also need an alternative rule; this will be replaced by the node generated by one of its children that matches; thus, it does not create a node of its own.

- an alternative of syntax elements.

We also define special types of sequences as convenience macros:

- a list: a sequence where the elements are separated by a separator keyword (e.g., commas), the separators are thrown away when parsing the list;
- a group: a sequence of three tokens, where the first and third ones are left and right delimiters, the delimiters are thrown away;
- an argument list: a delimited list, containing both delimiters and separators.

It would be great to have a polymorphic type for this purpose, but until Fortran 2003 is out we have to emulate this.

Here are the syntax element codes:

```

<Syntax: public>≡
  public :: S_UNKNOWN
  public :: S_LOGICAL, S_INTEGER, S_REAL, S_COMPLEX, S_QUOTED
  public :: S_IDENTIFIER, S_KEYWORD
  public :: S_SEQUENCE, S_LIST, S_GROUP, S_ARGS
  public :: S_ALTERNATIVE
  public :: S_IGNORE

<Syntax: parameters>≡
  integer, parameter :: &
    S_UNKNOWN = 0, &
    S_LOGICAL = 1, S_INTEGER = 2, S_REAL = 3, S_COMPLEX = 4, &
    S_QUOTED = 5, S_IDENTIFIER = 6, S_KEYWORD = 7, &
    S_SEQUENCE = 8, S_LIST = 9, S_GROUP = 10, S_ARGS = 11, &
    S_ALTERNATIVE = 12, &
    S_IGNORE = 99

```

We need arrays of rule pointers, therefore this construct.

```

<Syntax: types>≡
  type :: rule_p
  private
    type(syntax_rule_t), pointer :: p => null ()
  end type rule_p

```

Return the association status of the rule pointer:

```

<Syntax: subroutines>≡
  elemental function rule_is_associated (rp) result (ok)
    logical :: ok
    type (rule_p), intent(in) :: rp
    ok = associated (rp%p)
  end function rule_is_associated

```

The rule type is one of the types listed above, represented by an integer code. The keyword, for a non-keyword rule, is an identifier used for the printed syntax table. The array of children is needed for nonterminal rules. In that case, there is a modifier for the last element (blank, "?", "*", or "+"), mirrored in the flags **opt** and **rep**. Then, we have the character constants used as separators and delimiters for this rule. Finally, the **used** flag can be set to indicate that this rule is the child of another rule.

```

<Syntax: types>+≡
  public :: syntax_rule_t

<Syntax: types>+≡
  type :: syntax_rule_t
    private
    integer :: type = S_UNKNOWN
    logical :: used = .false.
    type(string_t) :: keyword
    type(string_t) :: separator
    type(string_t), dimension(2) :: delimiter
    type(rule_p), dimension(:), allocatable :: child
    character(1) :: modifier = ""
    logical :: opt = .false., rep = .false.
  end type syntax_rule_t

```

Initializer: Set type and key for a rule, but do not (yet) allocate anything.

Finalizer: not needed (no pointer components).

```

<Syntax: subroutines>+≡
  subroutine syntax_rule_init (rule, key, type)
    type(syntax_rule_t), intent(inout) :: rule
    type(string_t), intent(in) :: key
    integer, intent(in) :: type
    rule%keyword = key
    rule%type = type
    select case (rule%type)
      case (S_GROUP)
        call syntax_rule_set_delimiter (rule)
      case (S_LIST)
        call syntax_rule_set_separator (rule)
      case (S_ARGS)
        call syntax_rule_set_delimiter (rule)
        call syntax_rule_set_separator (rule)
    end select
  end subroutine syntax_rule_init

```

3.3.2 I/O

These characters will not be enclosed in quotes when writing syntax rules:

```
<Limits: public parameters>+≡
    character(*), parameter, public :: &
        UNQUOTED = "(),|_//LCLETTERS//UCLETTERS//DIGITS
```

Write an account of the rule. Setting `short` true will suppress the node type. Setting `key_only` true will suppress the definition. Setting `advance` false will suppress the trailing newline.

```
<Syntax: public>+≡
    public :: syntax_rule_write

<Syntax: subroutines>+≡
    subroutine syntax_rule_write (rule, unit, short, key_only, advance)
        type(syntax_rule_t), intent(in) :: rule
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: short, key_only, advance
        logical :: typ, def, adv
        integer :: u
        u = output_unit (unit); if (u < 0) return
        typ = .true.; if (present (short)) typ = .not. short
        def = .true.; if (present (key_only)) def = .not. key_only
        adv = .true.; if (present (advance)) adv = advance
        select case (rule%type)
            case (S_UNKNOWN); call write_atom ("???", typ)
            case (S_IGNORE); call write_atom ("IGNORE", typ)
            case (S_LOGICAL); call write_atom ("LOGICAL", typ)
            case (S_INTEGER); call write_atom ("INTEGER", typ)

    type(string_t), dimension(2), intent(in), optional :: del
    type(string_t), intent(in), optional :: sep
    integer :: i
    if (typ) call write_type (type)
    call write_key
    if (def) then
        write (u, "(1x, '=')", advance="no")
        if (present (del)) call write_maybe_quoted (char (del(1)))
        do i = 1, n
            if (i > 1 .and. present (sep)) &
                call write_maybe_quoted (char (sep))
            write (u, "(1x,A)", advance="no") &
                char (wkey (syntax_rule_get_sub_ptr(rule, i)))
            if (i == n) write (u, "(A)", advance="no") trim (rule%modifier)
        end do
    end if
end subroutine write_sequence

```

```

        end do
        if (present (del)) call write_maybe_quoted (char (del(2)))
    end if
end subroutine write_sequence
end subroutine syntax_rule_write

```

In the printed representation, the keyword strings are enclosed as `<...>`, unless they are bare keywords. Bare keywords are enclosed as `'..'` if they contain a character which is not a letter, digit, or underscore. If they contain a single-quote character, they are enclosed as `".."`. (A keyword must not contain both single- and double-quotes.)

```

<Syntax: subroutines>+≡
function wkey (rule) result (string)
    type(string_t) :: string
    type(syntax_rule_t), intent(in) :: rule
    select case (rule%type)
    case (S_KEYWORD)
        if (verify (rule%keyword, UNQUOTED) == 0) then
            string = rule%keyword
        else if (scan (rule%keyword, "'") == 0) then
            string = "'" // rule%keyword // "'"
        else
            string = '""' // rule%keyword // '""'
        end if
    case default
        string = "<" // rule%keyword // ">"
    end select
end function wkey

```

3.3.3 Completing syntax rules

Set the separator and delimiter entries, using defaults:

```

<Syntax: subroutines>+≡
subroutine syntax_rule_set_separator (rule, separator)
    type(syntax_rule_t), intent(inout) :: rule
    type(string_t), intent(in), optional :: separator
    if (present (separator)) then
        rule%separator = separator
    else
        rule%separator = ","
    end if
end subroutine syntax_rule_set_separator

subroutine syntax_rule_set_delimiter (rule, delimiter)
    type(syntax_rule_t), intent(inout) :: rule
    type(string_t), dimension(2), intent(in), optional :: delimiter
    if (present (delimiter)) then
        rule%delimiter = delimiter
    else
        rule%delimiter = (/ "(", ")" /)
    end if
end subroutine syntax_rule_set_delimiter

```

```
end subroutine syntax_rule_set_delimiter
```

Set the modifier entry and corresponding flags:

(Syntax: subroutines)+≡

```
function is_modifier (string) result (ok)
  logical :: ok
  type(string_t), intent(in) :: string
  select case (char (string))
    case (" ", "?", "*", "+"); ok = .true.
    case default; ok = .false.
  end select
end function is_modifier

subroutine syntax_rule_set_modifier (rule, modifier)
  type(syntax_rule_t), intent(inout) :: rule
  type(string_t), intent(in) :: modifier
  rule%modifier = char (modifier)
  select case (rule%modifier)
    case (" ")
    case ("?"); rule%opt = .true.
    case ("*"); rule%opt = .true.; rule%rep = .true.
    case ("+"); rule%rep = .true.
    case default
      call msg_bug (" Syntax: sequence modifier '" // rule%modifier &
        // "' is not one of '+' '*' '?'")
  end select
end subroutine syntax_rule_set_modifier
```

Check a finalized rule for completeness

(Syntax: subroutines)+≡

```
subroutine syntax_rule_check (rule)
  type(syntax_rule_t), intent(in) :: rule
  if (rule%keyword == "") call msg_bug ("Rule key not set")
  select case (rule%type)
    case (S_UNKNOWN); call bug (" Undefined rule")
    case (S_IGNORE, S_LOGICAL, S_INTEGER, S_REAL, S_COMPLEX, &
      S_IDENTIFIER, S_KEYWORD)
    case (S_QUOTED)
      if (any (rule%delimiter == "")) call bug (" Missing quote character(s)")
    case (S_SEQUENCE)
    case (S_GROUP)
      if (any (rule%delimiter == "")) call bug (" Missing delimiter(s)")
    case (S_LIST)
      if (rule%separator == "") call bug (" Missing separator")
    case (S_ARGS)
      if (any (rule%delimiter == "")) call bug (" Missing delimiter(s)")
      if (rule%separator == "") call bug (" Missing separator")
    case (S_ALTERNATIVE)
    case default
      call bug (" Undefined syntax code")
  end select
  select case (rule%type)
    case (S_SEQUENCE, S_GROUP, S_LIST, S_ARGS, S_ALTERNATIVE)
```

```

        if (allocated (rule%child)) then
            if (.not.all (rule_is_associated (rule%child))) &
                call bug (" Child rules not all associated")
        else
            call bug (" Parent rule without children")
        end if
    case default
        if (allocated (rule%child)) call bug (" Non-parent rule with children")
    end select
contains
    subroutine bug (string)
        character(*), intent(in) :: string
        call msg_bug (" Syntax table: Rule " // char (rule%keyword) // ": " &
            // string)
    end subroutine bug
end subroutine syntax_rule_check

```

3.3.4 Accessing rules

This is the API for syntax rules:

```

<Syntax: public>+≡
    public :: syntax_rule_get_type

<Syntax: subroutines>+≡
    function syntax_rule_get_type (rule) result (type)
        integer :: type
        type(syntax_rule_t), intent(in) :: rule
        type = rule%type
    end function syntax_rule_get_type

<Syntax: public>+≡
    public :: syntax_rule_get_key

<Syntax: subroutines>+≡
    function syntax_rule_get_key (rule) result (key)
        type(string_t) :: key
        type(syntax_rule_t), intent(in) :: rule
        key = rule%keyword
    end function syntax_rule_get_key

<Syntax: public>+≡
    public :: syntax_rule_get_separator
    public :: syntax_rule_get_delimiter

<Syntax: subroutines>+≡
    function syntax_rule_get_separator (rule) result (separator)
        type(string_t) :: separator
        type(syntax_rule_t), intent(in) :: rule
        separator = rule%separator
    end function syntax_rule_get_separator

    function syntax_rule_get_delimiter (rule) result (delimiter)
        type(string_t), dimension(2) :: delimiter

```

```

    type(syntax_rule_t), intent(in) :: rule
    delimiter = rule%delimiter
end function syntax_rule_get_delimiter

```

Accessing child rules. If we use `syntax_rule_get_n_sub` for determining loop bounds, we do not need a check in the second routine.

```

<Syntax: public>+≡
    public :: syntax_rule_get_n_sub
    public :: syntax_rule_get_sub_ptr

<Syntax: subroutines>+≡
    function syntax_rule_get_n_sub (rule) result (n)
        integer :: n
        type(syntax_rule_t), intent(in) :: rule
        if (allocated (rule%child)) then
            n = size (rule%child)
        else
            n = 0
        end if
    end function syntax_rule_get_n_sub

    function syntax_rule_get_sub_ptr (rule, i) result (sub)
        type(syntax_rule_t), pointer :: sub
        type(syntax_rule_t), intent(in), target :: rule
        integer, intent(in) :: i
        sub => rule%child(i)%p
    end function syntax_rule_get_sub_ptr

    subroutine syntax_rule_set_sub (rule, i, sub)
        type(syntax_rule_t), intent(inout) :: rule
        integer, intent(in) :: i
        type(syntax_rule_t), intent(in), target :: sub
        rule%child(i)%p => sub
    end subroutine syntax_rule_set_sub

```

Return the modifier flags:

```

<Syntax: public>+≡
    public :: syntax_rule_last_optional
    public :: syntax_rule_last_repetitive

<Syntax: subroutines>+≡
    function syntax_rule_last_optional (rule) result (opt)
        logical :: opt
        type(syntax_rule_t), intent(in) :: rule
        opt = rule%opt
    end function syntax_rule_last_optional
    function syntax_rule_last_repetitive (rule) result (rep)
        logical :: rep
        type(syntax_rule_t), intent(in) :: rule
        rep = rule%rep
    end function syntax_rule_last_repetitive

```

Return true if the rule is atomic, i.e., logical, real, keyword etc.

```
<Syntax: public>+≡
    public :: syntax_rule_is_atomic

<Syntax: subroutines>+≡
    function syntax_rule_is_atomic (rule) result (atomic)
        logical :: atomic
        type(syntax_rule_t), intent(in) :: rule
        select case (rule%type)
            case (S_LOGICAL, S_INTEGER, S_REAL, S_COMPLEX, S_IDENTIFIER, &
                 S_KEYWORD, S_QUOTED)
                atomic = .true.
            case default
                atomic = .false.
        end select
    end function syntax_rule_is_atomic
```

3.3.5 Syntax tables

A syntax table contains the tree of syntax rules and, for direct parser access, the list of valid keywords.

Types

The syntax contains an array of rules and a list of keywords. The array is actually used as a tree, where the top rule is the first array element, and the other rules are recursively pointed to by this first rule. (No rule should be used twice or be unused.) The keyword list is derived from the rule tree.

Objects of this type need the target attribute if they are associated with a lexer. The keyword list will be pointed to by this lexer.

```
<Syntax: public>+≡
    public :: syntax_t

<Syntax: types>+≡
    type :: syntax_t
        private
        type(syntax_rule_t), dimension(:), allocatable :: rule
        type(keyword_list_t) :: keyword_list
    end type syntax_t
```

Constructor/destructor

Initialize and finalize syntax tables

```
<Syntax: public>+≡
    public :: syntax_init
    public :: syntax_final
```

There are two ways to create a syntax: hard-coded from rules or dynamically from file.

```

<Syntax: interfaces>≡
interface syntax_init
  module procedure syntax_init_from_ifile
end interface

```

The syntax definition is read from an ifile object which contains the syntax definitions in textual form, one rule per line. This interface allows for determining the number of rules beforehand.

To parse the rule definitions, we make up a temporary lexer. Obviously, we cannot use a generic parser yet, so we have to hardcode the parsing process.

```

<Syntax: subroutines>+≡
subroutine syntax_init_from_ifile (syntax, ifile)
  type(syntax_t), intent(out), target :: syntax
  type(ifile_t), intent(in) :: ifile
  type(lexer_t) :: lexer
  type(line_p) :: line
  type(string_t) :: string
  integer :: n_token
  integer :: i
  call lexer_init (lexer, &
    comment_chars = "", &
    quote_chars = "<'\"", &
    quote_match = ">'\"", &
    single_chars = "?*+|=,()", &
    special_class = (/ "." /), &
    keyword_list = null ())
  allocate (syntax%rule (ifile_get_length (ifile)))
  call line_init (line, ifile)
  do i = 1, size (syntax%rule)
    string = line_get_string_advance (line)
    call set_rule_type_and_key (syntax%rule(i), string, lexer)
  end do
  call line_init (line, ifile)
  do i = 1, size (syntax%rule)
    string = line_get_string_advance (line)
    select case (syntax%rule(i)%type)
    case (S_QUOTED, S_SEQUENCE, S_GROUP, S_LIST, S_ARGS, S_ALTERNATIVE)
      n_token = get_n_token (string, lexer)
      call set_rule_contents &
        (syntax%rule(i), syntax, n_token, string, lexer)
    end select
  end do
  call line_final (line)
  call lexer_final (lexer)
  call syntax_make_keyword_list (syntax)
  if (.not. all (syntax%rule%used)) then
    do i = 1, size (syntax%rule)
      if (.not. syntax%rule(i)%used) then
        call syntax_rule_write (syntax%rule(i), 6)
      end if
    end do
  end if
end do

```

```

        call msg_bug (" Syntax table: unused rules")
    end if
end subroutine syntax_init_from_ifile

```

For a given rule defined in the input, the first task is to determine its type and key. With these, we can initialize the rule in the table, postponing the association of children.

```

<Syntax: subroutines>+=
subroutine set_rule_type_and_key (rule, string, lexer)

end subroutine broken_rule
end subroutine set_rule_contents

```

This routine completes the syntax table object. We assume that the rule array is set up. We associate the top rule with the first entry in the rule array and build up the keyword list.

The keyword list includes delimiters and separators. Filling it can only be done after all rules are set. We scan the rule tree. For each keyword that we find, we try to add it to the keyword list; the pointer to the last element is carried along with the recursive scanning. Before appending a keyword, we check whether it is already in the list.

(Syntax: subroutines)+≡

```

subroutine syntax_make_keyword_list (syntax)
  type(syntax_t), intent(inout), target :: syntax
  type(syntax_rule_t), pointer :: rule
  rule => syntax%rule(1)
  call rule_scan_rec (rule, syntax%keyword_list)
contains
  recursive subroutine rule_scan_rec (rule, keyword_list)
    type(syntax_rule_t), pointer :: rule
    type(keyword_list_t), intent(inout) :: keyword_list
    integer :: i
    if (rule%used) return
    rule%used = .true.

```

```

select case (rule%type)
case (S_UNKNOWN)
  call msg_bug (" Syntax: rule tree contains undefined rule")

  call keyword_list_final (syntax%keyword_list)
end subroutine syntax_final

```

3.3.6 Accessing the syntax table

Return a pointer to the top rule

```

<Syntax: public>+≡
public :: syntax_get_top_rule_ptr

<Syntax: subroutines>+≡
function syntax_get_top_rule_ptr (syntax) result (rule)
  type(syntax_rule_t), pointer :: rule
  type(syntax_t), intent(in), target :: syntax
  if (allocated (syntax%rule)) then
    rule => syntax%rule(1)
  else

```

```

        rule => null ()
    end if
end function syntax_get_top_rule_ptr

```

Assign the pointer to the rule associated with a given key (assumes that the rule array is allocated)

```

<Syntax: public>+≡
    public :: syntax_get_rule_ptr

<Syntax: subroutines>+≡
    function syntax_get_rule_ptr (syntax, key) result (rule)
        type(syntax_rule_t), pointer :: rule
        type(syntax_t), intent(in), target :: syntax
        type(string_t), intent(in) :: key
        integer :: i
        do i = 1, size (syntax%rule)
            if (syntax%rule(i)%keyword == key) then
                rule => syntax%rule(i)
                return
            end if
        end do
        call msg_bug (" Syntax table: Rule " // char (key) // " not found")
    end function syntax_get_rule_ptr

```

Return a pointer to the keyword list

```

<Syntax: public>+≡
    public :: syntax_get_keyword_list_ptr

<Syntax: subroutines>+≡
    function syntax_get_keyword_list_ptr (syntax) result (keyword_list)
        type(keyword_list_t), pointer :: keyword_list
        type(syntax_t), intent(in), target :: syntax
        keyword_list => syntax%keyword_list
    end function syntax_get_keyword_list_ptr

```

3.3.7 I/O

Write a readable representation of the syntax table

```

<Syntax: public>+≡
    public :: syntax_write

<Syntax: subroutines>+≡
    subroutine syntax_write (syntax, unit)
        type(syntax_t), intent(in) :: syntax
        integer, intent(in), optional :: unit
        integer :: u
        integer :: i
        u = output_unit (unit); if (u < 0) return
        write (u, "(A)") "Syntax table:"
        if (allocated (syntax%rule)) then
            do i = 1, size (syntax%rule)
                call syntax_rule_write (syntax%rule(i), u)
            end do
        end if
    end subroutine syntax_write

```

```
        end do
    else
        write (u, "(1x,A)") "[not allocated]"
    end if
    call keyword_list_write (syntax%keyword_list, u)
end subroutine syntax_write
```

3.4 The parser

On a small scale, the parser interprets the string tokens returned by the lexer; they are interpreted as numbers, keywords and such and stored as a typed object. On a large scale, a text is read, parsed, and a syntax rule set is applied such that the tokens are stored as a parse tree. Syntax errors are spotted in this process, so the resulting parse tree is syntactically correct by definition.

```
<parser.f90>≡  
  <File header>  
  
  module parser  
  
    <Use kinds>  
    <Use strings>  
    use limits, only: DIGITS !NODEP!  
    <Use file utils>  
    use diagnostics !NODEP!  
    use md5  
    use lexers  
    use syntax_rules  
  
    <Standard module head>  
  
    <Parser: public>  
  
    <Parser: types>  
  
    <Parser: interfaces>  
  
    contains  
  
    <Parser: procedures>  
  
  end module parser
```

3.4.1 The token type

Tokens are elements of the parsed input that carry a value: logical, integer, real, quoted string, (unquoted) identifier, or known keyword. Note that non-keyword tokens also have an abstract key attached to them.

This is an obvious candidate for polymorphism.

```
<Parser: types>≡  
  type :: token_t  
    private  
    integer :: type = S_UNKNOWN  
    logical, pointer :: lval => null ()  
    integer, pointer :: ival => null ()  
    real(default), pointer :: rval => null ()  
    complex(default), pointer :: cval => null ()  
    type(string_t), pointer :: sval => null ()  
    type(string_t), pointer :: kval => null ()  
    type(string_t), dimension(:), pointer :: quote => null ()
```

```
end type token_t
```

Create a token from the lexeme returned by the lexer: Allocate storage and try to interpret the lexeme according to the type that is requested by the parser. For a keyword token, match the lexeme against the requested key. If successful, set the token type, value, and key. Otherwise, set the type to S_UNKNOWN.

(Parser: procedures)≡

```
subroutine token_init (token, lexeme, requested_type, key)
  type(token_t), intent(out) :: token
  type(lexeme_t), intent(in) :: lexeme
  integer, intent(in) :: requested_type

        end if
    end subroutine token_assign

```

3.4.2 Retrieve token contents

These functions all do a trivial sanity check that should avoid crashes.

```

(Parser: procedures)+≡
    function token_get_logical (token) result (lval)
        logical :: lval
        type(token_t), intent(in) :: token
        if (associated (token%lval)) then
            lval = token%lval
        else
            call token_mismatch (token, "logical")
        end if
    end function token_get_logical

    function token_get_integer (token) result (ival)
        integer :: ival
        type(token_t), intent(in) :: token

```

```

    if (associated (token%ival)) then
        ival = token%ival
    else
        call token_mismatch (token, "integer")
    end if
end function token_get_integer

function token_get_real (token) result (rval)
    real(default) :: rval
    type(token_t), intent(in) :: token
    if (associated (token%rval)) then
        rval = token%rval
    else
        call token_mismatch (token, "real")
    end if
end function token_get_real

function token_get_cmplx (token) result (cval)
    complex(default) :: cval
    type(token_t), intent(in) :: token
    if (associated (token%cval)) then
        cval = token%cval
    else
        call token_mismatch (token, "complex")
    end if
end function token_get_cmplx

function token_get_string (token) result (sval)
    type(string_t) :: sval
    type(token_t), intent(in) :: token
    if (associated (token%sval)) then
        sval = token%sval
    else
        call token_mismatch (token, "string")
    end if
end function token_get_string

function token_get_key (token) result (kval)
    type(string_t) :: kval
    type(token_t), intent(in) :: token
    if (associated (token%kval)) then
        kval = token%kval
    else
        call token_mismatch (token, "keyword")
    end if
end function token_get_key

function token_get_quote (token) result (quote)
    type(string_t), dimension(2) :: quote
    type(token_t), intent(in) :: token
    if (associated (token%quote)) then
        quote = token%quote
    else
        call token_mismatch (token, "quote")
    end if
end function token_get_quote

```

```

        end if
    end function token_get_quote

```

```

<Parser: procedures>+≡
    subroutine token_mismatch (token, type)
        type(token_t), intent(in) :: token
        character(*), intent(in) :: type
        write (6, "(A)", advance="no") "Token: "
        call token_write (token)
        call msg_bug (" Token type mismatch; value required as " // type)
    end subroutine token_mismatch

```

3.4.3 The parse tree: nodes

The parser will generate a parse tree from the input stream. Each node in this parse tree points to the syntax rule that was applied. (Since syntax rules are stored in a pointer-type array within the syntax table, they qualify as targets.) A leaf node contains a token. A branch node has subnodes. The subnodes are stored as a list, so each node also has a `next` pointer.

```

<Parser: public>≡
    public :: parse_node_t

<Parser: types>+≡
    type :: parse_node_t
    private
        type(syntax_rule_t), pointer :: rule => null ()
        type(token_t) :: token
        integer :: n_sub = 0
        type(parse_node_t), pointer :: sub_first => null ()
        type(parse_node_t), pointer :: sub_last => null ()
        type(parse_node_t), pointer :: next => null ()
    contains
        <Parser: parse node: TBP>
    end type parse_node_t

```

Container for parse node pointers, useful for creating pointer arrays:

```

<Parser: public>+≡
    public :: parse_node_p

<Parser: types>+≡
    type :: parse_node_p
        type(parse_node_t), pointer :: ptr => null ()
    end type parse_node_p

```

Output. The first version writes a node together with its sub-node tree, organized by indentation.

```

<Parser: parse node: TBP>≡
    procedure :: write => parse_node_write_rec

<Parser: public>+≡
    public :: parse_node_write_rec

```

```

(Parser: procedures)+≡
recursive subroutine parse_node_write_rec (node, unit, short, depth)
  class(parse_node_t), intent(in), target :: node
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: short
  integer, intent(in), optional :: depth
  integer :: u, d
  type(parse_node_t), pointer :: current
  u = output_unit (unit); if (u < 0) return
  d = 0; if (present (depth)) d = depth
  call parse_node_write (node, u, short=short)
  current => node%sub_first
  do while (associated (current))
    write (u, "(A)", advance = "no") repeat ("| ", d)
    call parse_node_write_rec (current, unit, short, d+1)
    current => current%next
  end do
end subroutine parse_node_write_rec

```

This does the actual output for a single node, without recursion.

```

(Parser: public)+≡
public :: parse_node_write

(Parser: procedures)+≡
subroutine parse_node_write (node, unit, short)
  class(parse_node_t), intent(in) :: node
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: short
  integer :: u
  type(parse_node_t), pointer :: current
  u = output_unit (unit); if (u < 0) return
  write (u, "(' + ')", advance = "no")
  if (associated (node%rule)) then
    call syntax_rule_write (node%rule, u, &
      short=short, key_only=.true., advance=.false.)
    if (token_is_valid (node%token)) then
      write (u, "(' = ')", advance="no")
      call token_write (node%token, u)
    else if (associated (node%sub_first)) then
      write (u, "(' = ')", advance="no")
      current => node%sub_first
      do while (associated (current))
        call syntax_rule_write (current%rule, u, &
          short=.true., key_only=.true., advance=.false.)
        current => current%next
      end do
      write (u, *)
    else
      write (u, *)
    end if
  else
    write (u, *) "[empty]"
  end if
end subroutine parse_node_write

```

Finalize the token and recursively finalize and deallocate all sub-nodes.

```

(Parser: public)+≡
    public :: parse_node_final

(Parser: procedures)+≡
    recursive subroutine parse_node_final (node, recursive)
        type(parse_node_t), intent(inout) :: node
        type(parse_node_t), pointer :: current
        logical, intent(in), optional :: recursive
        logical :: rec
        rec = .true.; if (present (recursive)) rec = recursive
        call token_final (node%token)
        if (rec) then
            do while (associated (node%sub_first))
                current => node%sub_first
                node%sub_first => node%sub_first%next
                call parse_node_final (current)
                deallocate (current)
            end do
        end if
    end subroutine parse_node_final

```

3.4.4 Filling nodes

The constructors allocate and initialize the node. There are two possible initializers (in a later version, should correspond to different type extensions).

First, leaf (terminal) nodes. The token constructor does the actual work, looking at the requested type and key for the given rule and matching against the lexeme contents. If it fails, the token will keep the type `S_UNKNOWN` and remain empty. Otherwise, we have a valid node which contains the new token.

If the lexeme argument is absent, the token is left empty.

```

(Parser: procedures)+≡
    subroutine parse_node_create_leaf (node, rule, lexeme)
        type(parse_node_t), pointer :: node
        type(syntax_rule_t), intent(in), target :: rule
        type(lexeme_t), intent(in) :: lexeme
        allocate (node)
        node%rule => rule
        call token_init (node%token, lexeme, &
            syntax_rule_get_type (rule), syntax_rule_get_key (rule))
        if (.not. token_is_valid (node%token)) deallocate (node)
    end subroutine parse_node_create_leaf

```

Second, branch nodes. We first assign the rule:

```

(Parser: public)+≡
    public :: parse_node_create_branch

(Parser: procedures)+≡
    subroutine parse_node_create_branch (node, rule)
        type(parse_node_t), pointer :: node

```

```

        type(syntax_rule_t), intent(in), target :: rule
        allocate (node)
        node%rule => rule
    end subroutine parse_node_create_branch

```

Append a sub-node. The sub-node must exist and be a valid target, otherwise nothing is done.

```

<Parser: public>+≡
    public :: parse_node_append_sub

<Parser: procedures>+≡
    subroutine parse_node_append_sub (node, sub)
        type(parse_node_t), intent(inout) :: node
        type(parse_node_t), pointer :: sub
        if (associated (sub)) then
            if (associated (node%sub_last)) then
                node%sub_last%next => sub
            else
                node%sub_first => sub
            end if
            node%sub_last => sub
        end if
    end subroutine parse_node_append_sub

```

For easy access, once the list is complete we count the number of sub-nodes. If there are no subnodes, the whole node is deleted.

```

<Parser: procedures>+≡
    subroutine parse_node_freeze_branch (node)
        type(parse_node_t), pointer :: node
        type(parse_node_t), pointer :: current
        node%n_sub = 0
        current => node%sub_first
        do while (associated (current))
            node%n_sub = node%n_sub + 1
            current => current%next
        end do
        if (node%n_sub == 0) deallocate (node)
    end subroutine parse_node_freeze_branch

```

Replace the last subnode by a new target. Use with care, this invites to memory mismanagement.

```

<Parser: public>+≡
    public :: parse_node_replace_last_sub

<Parser: procedures>+≡
    subroutine parse_node_replace_last_sub (node, pn_target)
        type(parse_node_t), intent(inout), target :: node
        type(parse_node_t), intent(in), target :: pn_target
        type(parse_node_t), pointer :: current
        integer :: i
        select case (node%n_sub)
        case (1)
            node%sub_first => pn_target

```

```

case (2:)
  current => node%sub_first
  do i = 1, node%n_sub - 2
    current => current%next
  end do
  current%next => pn_target
case default
  call parse_node_write (node)
  call msg_bug ("replace_last_sub' called for non-branch parse node")
end select
node%sub_last => pn_target
end subroutine parse_node_replace_last_sub

```

3.4.5 Accessing nodes

Return the node contents. Check if pointers are associated. No check when accessing a sub-node; assume that `parse_node_n_sub` is always used for the upper bound.

The token extractor returns a pointer.

(Parser: public)+≡

```

public :: parse_node_get_rule_ptr
public :: parse_node_get_n_sub
public :: parse_node_get_sub_ptr
public :: parse_node_get_next_ptr
public :: parse_node_get_last_sub_ptr

```

(Parser: procedures)+≡

```

function parse_node_get_rule_ptr (node) result (rule)
  type(syntax_rule_t), pointer :: rule
  type(parse_node_t), intent(in), target :: node
  if (associated (node%rule)) then
    rule => node%rule
  else
    rule => null ()
    call parse_node_undefined (node, "rule")
  end if
end function parse_node_get_rule_ptr

```

```

function parse_node_get_n_sub (node) result (n)
  integer :: n
  type(parse_node_t), intent(in) :: node
  n = node%n_sub
end function parse_node_get_n_sub

```

```

function parse_node_get_sub_ptr (node, n, tag, required) result (sub)
  type(parse_node_t), pointer :: sub
  type(parse_node_t), intent(in), target :: node
  integer, intent(in), optional :: n
  character(*), intent(in), optional :: tag
  logical, intent(in), optional :: required
  integer :: i
  sub => node%sub_first
  if (present (n)) then

```

```

        do i = 2, n
            if (associated (sub)) then
                sub => sub%next
            else
                return
            end if
        end do
    end if
    call parse_node_check (sub, tag, required)
end function parse_node_get_sub_ptr

function parse_node_get_next_ptr (sub, n, tag, required) result (next)
    type(parse_node_t), pointer :: next
    type(parse_node_t), intent(in), target :: sub
    integer, intent(in), optional :: n
    character(*), intent(in), optional :: tag
    logical, intent(in), optional :: required
    integer :: i
    next => sub%next
    if (present (n)) then
        do i = 2, n
            if (associated (next)) then
                next => next%next
            else
                exit
            end if
        end do
    end if
    call parse_node_check (next, tag, required)
end function parse_node_get_next_ptr

function parse_node_get_last_sub_ptr (node, tag, required) result (sub)
    type(parse_node_t), pointer :: sub
    type(parse_node_t), intent(in), target :: node
    character(*), intent(in), optional :: tag
    logical, intent(in), optional :: required
    sub => node%sub_last
    call parse_node_check (sub, tag, required)
end function parse_node_get_last_sub_ptr

<Parser: procedures>+≡
    subroutine parse_node_undefined (node, obj)
        type(parse_node_t), intent(in) :: node
        character(*), intent(in) :: obj
        call parse_node_write (node, 6)
        call msg_bug (" Parse-tree node: " // obj // " requested, but undefined")
    end subroutine parse_node_undefined

Check if a parse node has a particular tag, and if it is associated:

<Parser: public>+≡
    public :: parse_node_check

<Parser: procedures>+≡
    subroutine parse_node_check (node, tag, required)

```

```

type(parse_node_t), pointer :: node
character(*), intent(in), optional :: tag
logical, intent(in), optional :: required
if (associated (node)) then
    if (present (tag)) then
        if (parse_node_get_rule_key (node) /= tag) &
            call parse_node_mismatch (tag, node)
        end if
    else
        if (present (required)) then
            if (required) &
                call msg_bug (" Missing node, expected <" // tag // ">")
            end if
        end if
    end if
end if
end subroutine parse_node_check

```

This is called by a parse-tree scanner if the expected and the actual nodes do not match

```

(Parser: public)+≡
    public :: parse_node_mismatch

(Parser: procedures)+≡
    subroutine parse_node_mismatch (string, parse_node)
        character(*), intent(in) :: string
        type(parse_node_t), intent(in) :: parse_node
        call parse_node_write (parse_node)
        call msg_bug (" Syntax mismatch, expected <" // string // ">.")
    end subroutine parse_node_mismatch

```

The following functions are wrappers for extracting the token contents.

```

(Parser: public)+≡
    public :: parse_node_get_logical
    public :: parse_node_get_integer
    public :: parse_node_get_real
    public :: parse_node_get_cmplx
    public :: parse_node_get_string
    public :: parse_node_get_key
    public :: parse_node_get_rule_key

(Parser: procedures)+≡
    function parse_node_get_logical (node) result (lval)
        logical :: lval
        type(parse_node_t), intent(in), target :: node
        lval = token_get_logical (parse_node_get_token_ptr (node))
    end function parse_node_get_logical

    function parse_node_get_integer (node) result (ival)
        integer :: ival
        type(parse_node_t), intent(in), target :: node
        ival = token_get_integer (parse_node_get_token_ptr (node))
    end function parse_node_get_integer

    function parse_node_get_real (node) result (rval)
        real(default) :: rval

```

```

    type(parse_node_t), intent(in), target :: node
    rval = token_get_real (parse_node_get_token_ptr (node))
end function parse_node_get_real

function parse_node_get_cmplx (node) result (cval)
    complex(default) :: cval
    type(parse_node_t), intent(in), target :: node
    cval = token_get_cmplx (parse_node_get_token_ptr (node))
end function parse_node_get_cmplx

function parse_node_get_string (node) result (sval)
    type(string_t) :: sval
    type(parse_node_t), intent(in), target :: node
    sval = token_get_string (parse_node_get_token_ptr (node))
end function parse_node_get_string

    close (u)

```

```
end function parse_node_get_md5sum
```

3.4.6 The parse tree

The parse tree is a tree of nodes, where leaf nodes hold a valid token, while branch nodes point to a list of sub-nodes.

```
<Parser: public>+≡
    public :: parse_tree_t

<Parser: types>+≡
    type :: parse_tree_t
    private
        type(parse_node_t), pointer :: root_node => null ()
    end type parse_tree_t
```

The parser. Its arguments are the parse tree (which should be empty initially), the lexer (which should be already set up), the syntax table (which should be valid), and the input stream. The input stream is completely parsed, using the lexer setup and the syntax rules as given, and the parse tree is built accordingly.

If `check_eof` is absent or true, the parser will complain about trailing garbage. Otherwise, it will ignore it.

By default, the input stream is matched against the top rule in the specified syntax. If `key` is given, it is matched against the rule with the specified key instead.

Failure at the top level means that no rule could match at all; in this case the error message will show the top rule.

```
<Parser: public>+≡
    public :: parse_tree_init

<Parser: procedures>+≡
    subroutine parse_tree_init &
        (parse_tree, syntax, lexer, key, check_eof)

        ok = .true.
    case default
        ok = .false.
    end select
    node => null ()
end subroutine parse_ignore

```

If the match fails and we cannot step back:

```

(Parser: internal subroutines of parse_tree_init)+≡

```

```

subroutine parse_error (rule, lexeme)
  type(syntax_rule_t), intent(in) :: rule
  type(lexeme_t), intent(in) :: lexeme
  character(80) :: buffer
  integer :: u, iostat
  call lexer_show_location (lexer)
  u = free_unit ()
  open (u, status = "scratch")
  write (u, "(A)", advance="no") "Expected syntax:"
  call syntax_rule_write (rule, u)
  write (u, "(A)", advance="no") "Found token:"
  call lexeme_write (lexeme, u)
  rewind (u)
  do
    read (u, "(A)", iostat=iostat) buffer
    if (iostat /= 0) exit
    call msg_message (trim (buffer))
  end do
  call msg_fatal (" Syntax error " &
    // "(at or before the location indicated above)")
end subroutine parse_error

```

The finalizer recursively deallocates all nodes and their contents. For each node, `parse_node_final` is called on the sub-nodes, which in turn deallocates the token or sub-node array contained within each of them. At the end, only the top node remains to be deallocated.

```

(Parser: public)+≡
  public :: parse_tree_final

(Parser: procedures)+≡
  subroutine parse_tree_final (parse_tree)
    type(parse_tree_t), intent(inout) :: parse_tree
    if (associated (parse_tree%root_node)) then
      call parse_node_final (parse_tree%root_node)
      deallocate (parse_tree%root_node)
    end if
  end subroutine parse_tree_final

```

Print the parse tree. Print one token per line, indented according to the depth of the node.

The `verbose` version includes type identifiers for the nodes.

```

(Parser: public)+≡
  public :: parse_tree_write

(Parser: procedures)+≡
  subroutine parse_tree_write (parse_tree, unit, verbose)
    type(parse_tree_t), intent(in) :: parse_tree
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose
    integer :: u
    logical :: short
    u = output_unit (unit); if (u < 0) return
    short = .true.; if (present (verbose)) short = .not. verbose
    write (u, "(A)") "Parse tree:"

```

```

    if (associated (parse_tree%root_node)) then
        call parse_node_write_rec (parse_tree%root_node, unit, short, 1)
    else
        write (u, *) "[empty]"
    end if
end subroutine parse_tree_write

```

This is a generic error that can be issued if the parse tree does not meet the expectations of the parser. This most certainly indicates a bug.

```

<Parser: public>+≡
    public :: parse_tree_bug

<Parser: procedures>+≡
    subroutine parse_tree_bug (node, keys)
        type(parse_node_t), intent(in) :: node
        character(*), intent(in) :: keys
        call parse_node_write (node)
        call msg_bug (" Inconsistency in parse tree: expected " // keys)
    end subroutine parse_tree_bug

```

3.4.7 Access the parser

For scanning the parse tree we give access to the top node, as a node pointer. Of course, there should be no write access.

```

<Parser: public>+≡
    public :: parse_tree_get_root_ptr

<Parser: procedures>+≡
    function parse_tree_get_root_ptr (parse_tree) result (node)
        type(parse_node_t), pointer :: node
        type(parse_tree_t), intent(in), target :: parse_tree
        node => parse_tree%root_node
    end function parse_tree_get_root_ptr

```

3.4.8 Tools

This operation traverses the parse tree and simplifies any occurrences of a set of syntax rules. If such a parse node has only one sub-node, it is replaced by that subnode. (This makes sense only of the rules to eliminate have no meaningful token.)

```

<Parser: public>+≡
    public :: parse_tree_reduce

<Parser: procedures>+≡

Chapter 4

Physics library

This part consists of two modules:

constants Physical and mathematical parameters that never change. The file has been moved to the **src/misc** subdirectory of the **WHIZARD** project.

c_particles A simple data type for particles which is C compatible.

lorentz Define three-vectors, four-vectors and Lorentz transformations and common operations for them.

sm_physics Here, running functions are stored for special kinematical setup like running coupling constants, Catani-Seymour dipoles, or Sudakov factors.

4.1 C-compatible Particle Type

For easy communication with C code, we introduce a simple C-compatible type for particles. It has the contents of the `prt_t` type defined in the `subevents` module below (except the source information).

The `c_prt` type is transparent, and its contents should be regarded as part of the interface.

```

<c_particles.f90>≡
  <File header>

  module c_particles

    use iso_c_binding !NODEP!
    <Use file utils>

    <Standard module head>

    <C Particles: public>

    <C Particles: types>

    contains

    <C Particles: procedures>
  end module c_particles

<C Particles: public>≡
  public :: c_prt_t

<C Particles: types>≡
  type, bind(C) :: c_prt_t
    integer(c_int) :: type = 0
    integer(c_int) :: pdg = 0
    integer(c_int) :: polarized = 0
    integer(c_int) :: h = 0
    real(c_double) :: pe = 0
    real(c_double) :: px = 0
    real(c_double) :: py = 0
    real(c_double) :: pz = 0
    real(c_double) :: p2 = 0
  end type c_prt_t

```

This is for debugging only, there is no C binding. It is a simplified version of `prt_write`.

```

<C Particles: public>+≡
  public :: c_prt_write

<C Particles: procedures>≡
  subroutine c_prt_write (prt, unit)
    type(c_prt_t), intent(in) :: prt
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit); if (u < 0) return
    write (u, "(1x,A)", advance="no") "prt("

```

```

write (u, "(I0,':')", advance="no") prt%type
if (prt%polarized /= 0) then
  write (u, "(I0,'/',I0,'|')", advance="no") prt%pdg, prt%h
else
  write (u, "(I0,'|')", advance="no") prt%pdg
end if
write (u, "(ES14.7,';',ES14.7,';',ES14.7,';',ES14.7)", advance="no") &
  prt%pe, prt%px, prt%py, prt%pz
write (u, "('|',ES19.12)", advance="no") prt%p2
write (u, "(A)" " ")
end subroutine c_prt_write

```

4.2 Lorentz algebra

Define Lorentz vectors, three-vectors, boosts, and some functions to manipulate them.

To make maximum use of this, all functions, if possible, are declared elemental (or pure, if this is not possible).

```
<lorentz.f90>≡  
  <File header>  
  
  module lorentz  
  
    <Use kinds>  
    use constants, only: pi, twopi, degree !NODEP!  
    <Use file utils>  
    use diagnostics !NODEP!  
    use c_particles  
  
    <Standard module head>  
  
    <Lorentz: public>  
  
    <Lorentz: public operators>  
  
    <Lorentz: public functions>  
  
    <Lorentz: types>  
  
    <Lorentz: parameters>  
  
    <Lorentz: interfaces>  
  
    contains  
  
    <Lorentz: procedures>  
  end module lorentz
```

4.2.1 Three-vectors

First of all, let us introduce three-vectors in a trivial way. The functions and overloaded elementary operations clearly are too much overhead, but we like to keep the interface for three-vectors and four-vectors exactly parallel. By the way, we might attach a label to a vector by extending the type definition later.

```
<Lorentz: public>≡  
  public :: vector3_t  
  
<Lorentz: types>≡  
  type :: vector3_t  
    private  
    real(default), dimension(3) :: p  
  end type vector3_t
```

Output a vector

```

(Lorentz: public)+≡
    public :: vector3_write

(Lorentz: procedures)≡
    subroutine vector3_write (p, unit)
        type(vector3_t), intent(in) :: p
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit); if (u < 0) return
        write(u, 1) 'P = ', p%p
    1    format (1x,A,3(1x,ES19.12))
    end subroutine vector3_write

```

This is a three-vector with zero components

```

(Lorentz: public)+≡
    public :: vector3_null

(Lorentz: parameters)≡
    type(vector3_t), parameter :: vector3_null = &
        vector3_t ((/ 0._default, 0._default, 0._default /))

```

Canonical three-vector:

```

(Lorentz: public)+≡
    public :: vector3_canonical

(Lorentz: procedures)+≡
    elemental function vector3_canonical (k) result (p)
        type(vector3_t) :: p
        integer, intent(in) :: k
        p = vector3_null
        p%p(k) = 1
    end function vector3_canonical

```

A moving particle (k -axis, or arbitrary axis). Note that the function for the generic momentum cannot be elemental.

```

(Lorentz: public)+≡
    public :: vector3_moving

(Lorentz: interfaces)≡
    interface vector3_moving
        module procedure vector3_moving_canonical
        module procedure vector3_moving_generic
    end interface

(Lorentz: procedures)+≡
    elemental function vector3_moving_canonical (p, k) result(q)
        type(vector3_t) :: q
        real(default), intent(in) :: p
        integer, intent(in) :: k
        q = vector3_null
        q%p(k) = p
    end function vector3_moving_canonical
    pure function vector3_moving_generic (p) result(q)

```

```

    real(default), dimension(3), intent(in) :: p
    type(vector3_t) :: q
    q%p = p
end function vector3_moving_generic

```

Equality and inequality

```

<Lorentz: public operators>≡
    public :: operator(==), operator(/=)

<Lorentz: interfaces>+≡
    interface operator(==)
        module procedure vector3_eq
    end interface
    interface operator(/=)
        module procedure vector3_neq
    end interface

<Lorentz: procedures>+≡
    elemental function vector3_eq (p, q) result (r)
        logical :: r
        type(vector3_t), intent(in) :: p,q
        r = all (p%p == q%p)
    end function vector3_eq
    elemental function vector3_neq (p, q) result (r)
        logical :: r
        type(vector3_t), intent(in) :: p,q
        r = any (p%p /= q%p)
    end function vector3_neq

```

Define addition and subtraction

```

<Lorentz: public operators>+≡
    public :: operator(+), operator(-)

<Lorentz: interfaces>+≡
    interface operator(+)
        module procedure add_vector3
    end interface
    interface operator(-)
        module procedure sub_vector3
    end interface

<Lorentz: procedures>+≡
    elemental function add_vector3 (p, q) result (r)
        type(vector3_t) :: r
        type(vector3_t), intent(in) :: p,q
        r%p = p%p + q%p
    end function add_vector3
    elemental function sub_vector3 (p, q) result (r)
        type(vector3_t) :: r
        type(vector3_t), intent(in) :: p,q
        r%p = p%p - q%p
    end function sub_vector3

```

The multiplication sign is overloaded with scalar multiplication; similarly division:

```

(Lorentz: public operators)+≡
    public :: operator(*), operator(/)

(Lorentz: interfaces)+≡
    interface operator(*)
        module procedure prod_integer_vector3, prod_vector3_integer
        module procedure prod_real_vector3, prod_vector3_real
    end interface
    interface operator(/)
        module procedure div_vector3_real, div_vector3_integer
    end interface

(Lorentz: procedures)+≡
    elemental function prod_real_vector3 (s, p) result (q)
        type(vector3_t) :: q
        real(default), intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = s * p%p
    end function prod_real_vector3
    elemental function prod_vector3_real (p, s) result (q)
        type(vector3_t) :: q
        real(default), intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = s * p%p
    end function prod_vector3_real
    elemental function div_vector3_real (p, s) result (q)
        type(vector3_t) :: q
        real(default), intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = p%p/s
    end function div_vector3_real
    elemental function prod_integer_vector3 (s, p) result (q)
        type(vector3_t) :: q
        integer, intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = s * p%p
    end function prod_integer_vector3
    elemental function prod_vector3_integer (p, s) result (q)
        type(vector3_t) :: q
        integer, intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = s * p%p
    end function prod_vector3_integer
    elemental function div_vector3_integer (p, s) result (q)
        type(vector3_t) :: q
        integer, intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = p%p/s
    end function div_vector3_integer

```

The multiplication sign can also indicate scalar products:

```

(Lorentz: interfaces)+≡

```

```

interface operator(*)
  module procedure prod_vector3
end interface

<Lorentz: procedures>+≡
  elemental function prod_vector3 (p, q) result (s)
    real(default) :: s
    type(vector3_t), intent(in) :: p,q
    s = dot_product (p%p, q%p)
  end function prod_vector3

<Lorentz: public functions>≡
  public :: cross_product

<Lorentz: interfaces>+≡
  interface cross_product
    module procedure vector3_cross_product
  end interface

<Lorentz: procedures>+≡
  elemental function vector3_cross_product (p, q) result (r)
    type(vector3_t) :: r
    type(vector3_t), intent(in) :: p,q
    integer :: i
    do i=1,3
      r%p(i) = dot_product (p%p, matmul(epsilon_three(i,:,:), q%p))
    end do
  end function vector3_cross_product

```

Exponentiation is defined only for integer powers. Odd powers mean take the square root; so `p**1` is the length of `p`.

```

<Lorentz: public operators>+≡
  public :: operator(**)

<Lorentz: interfaces>+≡
  interface operator(**)
    module procedure power_vector3
  end interface

<Lorentz: procedures>+≡
  elemental function power_vector3 (p, e) result (s)
    real(default) :: s
    type(vector3_t), intent(in) :: p
    integer, intent(in) :: e
    s = dot_product (p%p, p%p)
    if (e/=2) then
      if (mod(e,2)==0) then
        s = s**(e/2)
      else
        s = sqrt(s)**e
      end if
    end if
  end function power_vector3

```

Finally, we need a negation.

```

<Lorentz: interfaces>+≡
  interface operator(-)
    module procedure negate_vector3
  end interface

<Lorentz: procedures>+≡
  elemental function negate_vector3 (p) result (q)
    type(vector3_t) :: q
    type(vector3_t), intent(in) :: p
    integer :: i
    do i = 1, 3
      if (p%p(i) == -p%p(i)) then
        q%p(i) = 0
      else
        q%p(i) = -p%p(i)
      end if
    end do
  end function negate_vector3

```

The sum function can be useful:

```

<Lorentz: public functions>+≡
  public :: sum

<Lorentz: interfaces>+≡
  interface sum
    module procedure sum_vector3
  end interface

```

There used to be a mask here, but the Intel compiler crashes with it

```

<Lorentz: procedures>+≡
  pure function sum_vector3 (p) result (q)
    type(vector3_t) :: q
    type(vector3_t), dimension(:), intent(in) :: p
    integer :: i
    do i=1, 3
      q%p(i) = sum (p%p(i))
    end do
  end function sum_vector3
!  pure function sum_vector3_mask (p, mask) result (q)
!    type(vector3_t) :: q
!    type(vector3_t), dimension(:), intent(in) :: p
!    logical, dimension(:), intent(in) :: mask
!    integer :: i
!    do i=1, 3
!      q%p(i) = sum (p%p(i), mask=mask)
!    end do
!  end function sum_vector3_mask

```

Any component:

```

<Lorentz: public>+≡
  public :: vector3_get_component

```

```

<Lorentz: procedures>+≡
  elemental function vector3_get_component (p, k) result (c)
    type(vector3_t), intent(in) :: p
    integer, intent(in) :: k
    real(default) :: c
    c = p%p(k)
  end function vector3_get_component

```

Extract all components. This is not elemental.

```

<Lorentz: public>+≡
  public :: vector3_get_components

<Lorentz: procedures>+≡
  pure function vector3_get_components (p) result (a)
    type(vector3_t), intent(in) :: p
    real(default), dimension(3) :: a
    a = p%p
  end function vector3_get_components

```

This function returns the direction of a three-vector, i.e., a normalized three-vector. If the vector is null, we return a null vector.

```

<Lorentz: public functions>+≡
  public :: direction

<Lorentz: interfaces>+≡
  interface direction
    module procedure vector3_get_direction
  end interface

<Lorentz: procedures>+≡
  elemental function vector3_get_direction (p) result (q)
    type(vector3_t) :: q
    type(vector3_t), intent(in) :: p
    real(default) :: pp
    pp = p**1
    if (pp /= 0) then
      q%p = p%p / pp
    else
      q%p = 0
    end if
  end function vector3_get_direction

```

4.2.2 Four-vectors

In four-vectors the zero-component needs special treatment, therefore we do not use the standard operations. Sure, we pay for the extra layer of abstraction by losing efficiency; so we have to assume that the time-critical applications do not involve four-vector operations.

```

<Lorentz: public>+≡
  public :: vector4_t

```

```

<Lorentz: types>+≡
  type :: vector4_t
  private
    real(default), dimension(0:3) :: p = &
      (/ 0._default, 0._default, 0._default, 0._default /)
  end type vector4_t

```

Output a vector

```

<Lorentz: public>+≡
  public :: vector4_write

<Lorentz: procedures>+≡
  subroutine vector4_write (p, unit, show_mass)
    type(vector4_t), intent(in) :: p
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: show_mass
    integer :: u
    u = output_unit (unit); if (u < 0) return
    write(u, 1) 'E = ', p%p(0)
    write(u, 1) 'P = ', p%p(1:)
    if (present (show_mass)) then
      if (show_mass) &
        write (u, 1) 'M = ', p**1
    end if
1   format (1x,A,3(1x,ES19.12))
  end subroutine vector4_write

```

Binary I/O

```

<Lorentz: public>+≡
  public :: vector4_write_raw
  public :: vector4_read_raw

<Lorentz: procedures>+≡
  subroutine vector4_write_raw (p, u)
    type(vector4_t), intent(in) :: p
    integer, intent(in) :: u
    write (u) p%p
  end subroutine vector4_write_raw

  subroutine vector4_read_raw (p, u, iostat)
    type(vector4_t), intent(out) :: p
    integer, intent(in) :: u
    integer, intent(out), optional :: iostat
    read (u, iostat=iostat) p%p
  end subroutine vector4_read_raw

```

This is a four-vector with zero components

```

<Lorentz: public>+≡
  public :: vector4_null

<Lorentz: parameters>+≡
  type(vector4_t), parameter :: vector4_null = &
    vector4_t (/ 0._default, 0._default, 0._default, 0._default /)

```

Canonical four-vector:

```

(Lorentz: public)+≡
    public :: vector4_canonical

(Lorentz: procedures)+≡
    elemental function vector4_canonical (k) result (p)
        type(vector4_t) :: p
        integer, intent(in) :: k
        p = vector4_null
        p%p(k) = 1
    end function vector4_canonical

```

A particle at rest:

```

(Lorentz: public)+≡
    public :: vector4_at_rest

(Lorentz: procedures)+≡
    elemental function vector4_at_rest (m) result (p)
        type(vector4_t) :: p
        real(default), intent(in) :: m
        p = vector4_t (/ m, 0._default, 0._default, 0._default /)
    end function vector4_at_rest

```

A moving particle (k -axis, or arbitrary axis)

```

(Lorentz: public)+≡
    public :: vector4_moving

(Lorentz: interfaces)+≡
    interface vector4_moving
        module procedure vector4_moving_canonical
        module procedure vector4_moving_generic
    end interface

(Lorentz: procedures)+≡
    elemental function vector4_moving_canonical (E, p, k) result (q)
        type(vector4_t) :: q
        real(default), intent(in) :: E, p
        integer, intent(in) :: k
        q = vector4_at_rest(E)
        q%p(k) = p
    end function vector4_moving_canonical
    elemental function vector4_moving_generic (E, p) result (q)
        type(vector4_t) :: q
        real(default), intent(in) :: E
        type(vector3_t), intent(in) :: p
        q%p(0) = E
        q%p(1:) = p%p
    end function vector4_moving_generic

```

Equality and inequality

```

(Lorentz: interfaces)+≡
    interface operator(==)
        module procedure vector4_eq
    end interface

```

```

interface operator(/=)
  module procedure vector4_neq
end interface

<Lorentz: procedures>+≡
elemental function vector4_eq (p, q) result (r)
  logical :: r
  type(vector4_t), intent(in) :: p,q
  r = all (p%p == q%p)
end function vector4_eq
elemental function vector4_neq (p, q) result (r)
  logical :: r
  type(vector4_t), intent(in) :: p,q
  r = any (p%p /= q%p)
end function vector4_neq

```

Addition and subtraction:

```

<Lorentz: interfaces>+≡
interface operator(+)
  module procedure add_vector4
end interface
interface operator(-)
  module procedure sub_vector4
end interface

<Lorentz: procedures>+≡
elemental function add_vector4 (p,q) result (r)
  type(vector4_t) :: r
  type(vector4_t), intent(in) :: p,q
  r%p = p%p + q%p
end function add_vector4
elemental function sub_vector4 (p,q) result (r)
  type(vector4_t) :: r
  type(vector4_t), intent(in) :: p,q
  r%p = p%p - q%p
end function sub_vector4

```

We also need scalar multiplication and division:

```

<Lorentz: interfaces>+≡
interface operator(*)
  module procedure prod_real_vector4, prod_vector4_real
  module procedure prod_integer_vector4, prod_vector4_integer
end interface
interface operator(/)
  module procedure div_vector4_real
  module procedure div_vector4_integer
end interface

<Lorentz: procedures>+≡
elemental function prod_real_vector4 (s, p) result (q)
  type(vector4_t) :: q
  real(default), intent(in) :: s
  type(vector4_t), intent(in) :: p
  q%p = s * p%p

```

```

end function prod_real_vector4
elemental function prod_vector4_real (p, s) result (q)
  type(vector4_t) :: q
  real(default), intent(in) :: s
  type(vector4_t), intent(in) :: p
  q%p = s * p%p
end function prod_vector4_real
elemental function div_vector4_real (p, s) result (q)
  type(vector4_t) :: q
  real(default), intent(in) :: s
  type(vector4_t), intent(in) :: p
  q%p = p%p/s
end function div_vector4_real
elemental function prod_integer_vector4 (s, p) result (q)
  type(vector4_t) :: q
  integer, intent(in) :: s
  type(vector4_t), intent(in) :: p
  q%p = s * p%p
end function prod_integer_vector4
elemental function prod_vector4_integer (p, s) result (q)
  type(vector4_t) :: q
  integer, intent(in) :: s
  type(vector4_t), intent(in) :: p
  q%p = s * p%p
end function prod_vector4_integer
elemental function div_vector4_integer (p, s) result (q)
  type(vector4_t) :: q
  integer, intent(in) :: s
  type(vector4_t), intent(in) :: p
  q%p = p%p/s
end function div_vector4_integer

```

Scalar products and squares in the Minkowski sense:

```

<Lorentz: interfaces>+≡
  interface operator(*)
    module procedure prod_vector4
  end interface
  interface operator(**)
    module procedure power_vector4
  end interface

<Lorentz: procedures>+≡
  elemental function prod_vector4 (p, q) result (s)
    real(default) :: s
    type(vector4_t), intent(in) :: p,q
    s = p%p(0)*q%p(0) - dot_product(p%p(1:), q%p(1:))
  end function prod_vector4

```

The power operation for four-vectors is signed, i.e., p^{**1} is positive for timelike and negative for spacelike vectors. Note that $(p^{**1})^{**2}$ is not necessarily equal to p^{**2} .

```

<Lorentz: procedures>+≡
  elemental function power_vector4 (p, e) result (s)

```

```

real(default) :: s
type(vector4_t), intent(in) :: p
integer, intent(in) :: e
s = p*p
if (e/=2) then
  if (mod(e,2)==0) then
    s = s**(e/2)
  elseif (s>=0) then
    s = sqrt(s)**e
  else
    s = -(sqrt(abs(s))**e)
  end if
end if
end function power_vector4

```

Finally, we introduce a negation

```

<Lorentz: interfaces>+≡
  interface operator(-)
    module procedure negate_vector4
  end interface

<Lorentz: procedures>+≡
  elemental function negate_vector4 (p) result (q)
    type(vector4_t) :: q
    type(vector4_t), intent(in) :: p
    integer :: i
    do i = 0, 3
      if (p%p(i) == -p%p(i)) then
        q%p(i) = 0
      else
        q%p(i) = -p%p(i)
      end if
    end do
  end function negate_vector4

```

The sum function can be useful:

```

<Lorentz: interfaces>+≡
  interface sum
    module procedure sum_vector4
  end interface

```

There used to be a mask here, but the Intel compiler crashes with it

```

<Lorentz: procedures>+≡
  pure function sum_vector4 (p) result (q)
    type(vector4_t) :: q
    type(vector4_t), dimension(:), intent(in) :: p
    integer :: i
    do i=0, 3
      q%p(i) = sum (p%p(i))
    end do
  end function sum_vector4
!   pure function sum_vector4_mask (p, mask) result (q)
!     type(vector4_t) :: q
!     type(vector4_t), dimension(:), intent(in) :: p

```

```

!      logical, dimension(:), intent(in) :: mask
!      integer :: i
!      do i=0, 3
!          q%p(i) = sum (p%p(i), mask=mask)
!      end do
!      end function sum_vector4_mask

```

4.2.3 Conversions

Manually set a component of the four-vector:

```

<Lorentz: public>+≡
    public :: vector4_set_component

<Lorentz: procedures>+≡
    subroutine vector4_set_component (p, k, c)
        type(vector4_t), intent(inout) :: p
        integer, intent(in) :: k
        real(default), intent(in) :: c
        p%p(k) = c
    end subroutine vector4_set_component

```

Any component:

```

<Lorentz: public>+≡
    public :: vector4_get_component

<Lorentz: procedures>+≡
    elemental function vector4_get_component (p, k) result (c)
        real(default) :: c
        type(vector4_t), intent(in) :: p
        integer, intent(in) :: k
        c = p%p(k)
    end function vector4_get_component

```

Extract all components. This is not elemental.

```

<Lorentz: public>+≡
    public :: vector4_get_components

<Lorentz: procedures>+≡
    pure function vector4_get_components (p) result (a)
        real(default), dimension(0:3) :: a
        type(vector4_t), intent(in) :: p
        a = p%p
    end function vector4_get_components

```

This function returns the space part of a four-vector, such that we can apply three-vector operations on it:

```

<Lorentz: public functions>+≡
    public :: space_part

<Lorentz: interfaces>+≡
    interface space_part
        module procedure vector4_get_space_part
    end interface

```

```

(Lorentz: procedures)+≡
  elemental function vector4_get_space_part (p) result (q)
    type(vector3_t) :: q
    type(vector4_t), intent(in) :: p
    q%p = p%p(1:)
  end function vector4_get_space_part

```

This function returns the direction of a four-vector, i.e., a normalized three-vector. If the four-vector has zero space part, we return a null vector.

```

(Lorentz: interfaces)+≡
  interface direction
    module procedure vector4_get_direction
  end interface

(Lorentz: procedures)+≡
  elemental function vector4_get_direction (p) result (q)
    type(vector3_t) :: q
    type(vector4_t), intent(in) :: p
    real(default) :: qq
    q%p = p%p(1:)
    qq = q**1
    if (qq /= 0) then
      q%p = q%p / qq
    else
      q%p = 0
    end if
  end function vector4_get_direction

```

This function returns the four-vector as an ordinary array. A second version for an array of four-vectors.

```

(Lorentz: public functions)+≡
  public :: array_from_vector4

(Lorentz: interfaces)+≡
  interface array_from_vector4
    module procedure array_from_vector4_1
    module procedure array_from_vector4_2
  end interface

(Lorentz: procedures)+≡
  pure function array_from_vector4_1 (p) result (a)
    type(vector4_t), intent(in) :: p
    real(default), dimension(0:3) :: a
    a = p%p
  end function array_from_vector4_1

  pure function array_from_vector4_2 (p) result (a)
    type(vector4_t), dimension(:), intent(in) :: p
    real(default), dimension(0:3, size(p)) :: a
    integer :: i
    forall (i=1:size(p))
      a(0:3,i) = p(i)%p
    end forall
  end function array_from_vector4_2

```

Transform the momentum of a `c_prt` object into a four-vector:

```

(Lorentz: public)+≡
    public :: vector4_from_c_prt

(Lorentz: procedures)+≡
    elemental function vector4_from_c_prt (c_prt) result (p)
        type(vector4_t) :: p
        type(c_prt_t), intent(in) :: c_prt
        p%p(0) = c_prt%pe
        p%p(1) = c_prt%px
        p%p(2) = c_prt%py
        p%p(3) = c_prt%pz
    end function vector4_from_c_prt

```

Initialize a `c_prt_t` object with the components of a four-vector as its kinematical entries. Compute the invariant mass, or use the optional mass-squared value instead.

```

(Lorentz: public)+≡
    public :: vector4_to_c_prt

(Lorentz: procedures)+≡
    elemental function vector4_to_c_prt (p, p2) result (c_prt)
        type(c_prt_t) :: c_prt
        type(vector4_t), intent(in) :: p
        real(default), intent(in), optional :: p2
        c_prt%pe = p%p(0)
        c_prt%px = p%p(1)
        c_prt%py = p%p(2)
        c_prt%pz = p%p(3)
        if (present (p2)) then
            c_prt%p2 = p2
        else
            c_prt%p2 = p ** 2
        end if
    end function vector4_to_c_prt

```

4.2.4 Angles

Return the angles in a canonical system. The angle ϕ is defined between $0 \leq \phi < 2\pi$. In degenerate cases, return zero.

```

(Lorentz: public functions)+≡
    public :: azimuthal_angle

(Lorentz: interfaces)+≡
    interface azimuthal_angle
        module procedure vector3_azimuthal_angle
        module procedure vector4_azimuthal_angle
    end interface

(Lorentz: procedures)+≡
    elemental function vector3_azimuthal_angle (p) result (phi)
        real(default) :: phi
        type(vector3_t), intent(in) :: p

```

```

    if (any(p%p(1:2)/=0)) then
        phi = atan2(p%p(2), p%p(1))
        if (phi < 0) phi = phi + twopi
    else
        phi = 0
    end if
end function vector3_azimuthal_angle
elemental function vector4_azimuthal_angle (p) result (phi)
    real(default) :: phi
    type(vector4_t), intent(in) :: p
    phi = vector3_azimuthal_angle (space_part (p))
end function vector4_azimuthal_angle

```

Azimuthal angle in degrees

```

<Lorentz: public functions>+≡
    public :: azimuthal_angle_deg

<Lorentz: interfaces>+≡
    interface azimuthal_angle_deg
        module procedure vector3_azimuthal_angle_deg
        module procedure vector4_azimuthal_angle_deg
    end interface

<Lorentz: procedures>+≡
    elemental function vector3_azimuthal_angle_deg (p) result (phi)
        real(default) :: phi
        type(vector3_t), intent(in) :: p
        phi = vector3_azimuthal_angle (p) / degree
    end function vector3_azimuthal_angle_deg
    elemental function vector4_azimuthal_angle_deg (p) result (phi)
        real(default) :: phi
        type(vector4_t), intent(in) :: p
        phi = vector4_azimuthal_angle (p) / degree
    end function vector4_azimuthal_angle_deg

```

The azimuthal distance of two vectors. This is the difference of the azimuthal angles, but cannot be larger than π : The result is between $-\pi < \Delta\phi \leq \pi$.

```

<Lorentz: public functions>+≡
    public :: azimuthal_distance

<Lorentz: interfaces>+≡
    interface azimuthal_distance
        module procedure vector3_azimuthal_distance
        module procedure vector4_azimuthal_distance
    end interface

<Lorentz: procedures>+≡
    elemental function vector3_azimuthal_distance (p, q) result (dphi)
        real(default) :: dphi
        type(vector3_t), intent(in) :: p,q
        dphi = vector3_azimuthal_angle (q) - vector3_azimuthal_angle (p)
        if (dphi <= -pi) then
            dphi = dphi + twopi
        else if (dphi > pi) then
            dphi = dphi - twopi
        end if
    end function vector3_azimuthal_distance

```

```

    end if
end function vector3_azimuthal_distance
elemental function vector4_azimuthal_distance (p, q) result (dphi)

    IL%L(1:,1:) = transpose(L%L(1:,1:))
  end function lorentz_transformation_inverse

```

4.2.8 Invariants

These are used below. The first array index is varying fastest in FORTRAN; therefore the extra minus in the odd-rank tensor epsilon.

```

<Lorentz: parameters>+≡
  integer, dimension(3,3), parameter :: delta_three = &
    & reshape( source = (/ 1,0,0, 0,1,0, 0,0,1 /), &
    & shape = (/3,3/) )
  integer, dimension(3,3,3), parameter :: epsilon_three = &
    & reshape( source = (/ 0, 0,0, 0,0,-1, 0,1,0,&

```

```

&                0, 0,1,  0,0, 0,  -1,0,0,&
&                0,-1,0,  1,0, 0,   0,0,0 /),&
&                shape = (/3,3,3/) )

```

This could be of some use:

```

<Lorentz: public>+≡
  public :: identity

<Lorentz: parameters>+≡
  type(lorentz_transformation_t), parameter :: &
    & identity = &
    & lorentz_transformation_t ( &
    & reshape( source = (/ 1._default, 0._default, 0._default, 0._default, &
    &                0._default, 1._default, 0._default, 0._default, &
    &                0._default, 0._default, 1._default, 0._default, &
    &                0._default, 0._default, 0._default, 1._default /),&
    &                shape = (/ 4,4 /) ) )

<Lorentz: public>+≡
  public :: space_reflection

<Lorentz: parameters>+≡
  type(lorentz_transformation_t), parameter :: &
    & space_reflection = &
    & lorentz_transformation_t ( &
    & reshape( source = (/ 1._default, 0._default, 0._default, 0._default, &
    &                0._default,-1._default, 0._default, 0._default, &
    &                0._default, 0._default,-1._default, 0._default, &
    &                0._default, 0._default, 0._default,-1._default /),&
    &                shape = (/ 4,4 /) ) )

```

4.2.9 Boosts

We build Lorentz transformations from boosts and rotations. In both cases we can supply a three-vector which defines the axis and (hyperbolic) angle. For a boost, this is the vector $\vec{\beta} = \vec{p}/E$, such that a particle at rest with mass m is boosted to a particle with three-vector \vec{p} . Here, we have

$$\beta = \tanh \chi = p/E, \quad \gamma = \cosh \chi = E/m, \quad \beta\gamma = \sinh \chi = p/m \quad (4.1)$$

```

<Lorentz: public functions>+≡
  public :: boost

<Lorentz: interfaces>+≡
  interface boost
    module procedure boost_from_rest_frame
    module procedure boost_from_rest_frame_vector3
    module procedure boost_generic
    module procedure boost_canonical
  end interface

```

In the first form, the argument is some four-momentum, the space part of which determines a direction, and the associated mass (which is not checked against the four-momentum). The boost vector $\gamma\vec{\beta}$ is then given by \vec{p}/m . This boosts from the rest frame of a particle to the current frame. To be explicit, if \vec{p} is the momentum of a particle and m its mass, $L(\vec{p}/m)$ is the transformation that

turns $(m; \vec{0})$ into $(E; \vec{p})$. Conversely, the inverse transformation boosts a vector *into* the rest frame of a particle, in particular $(E; \vec{p})$ into $(m; \vec{0})$.

(Lorentz: procedures) +=

```

elemental function boost_from_rest_frame (p, m) result (L)
  type(lorentz_transformation_t) :: L
  type(vector4_t), intent(in) :: p
  real(default), intent(in) :: m
  L = boost_from_rest_frame_vector3 (space_part (p), m)
end function boost_from_rest_frame
elemental function boost_from_rest_frame_vector3 (p, m) result (L)
  type(lorentz_transformation_t) :: L
  type(vector3_t), intent(in) :: p
  real(default), intent(in) :: m
  type(vector3_t) :: beta_gamma
  real(default) :: bg2, g, c
  integer :: i, j
  if (m /= 0) then
    beta_gamma = p / m
    bg2 = beta_gamma**2
  else
    bg2 = 0
  end if
  if (bg2 /= 0) then
    g = sqrt(1 + bg2); c = (g-1)/bg2
    L%L(0,0) = g
    L%L(0,1:) = beta_gamma%p
    L%L(1:,0) = L%L(0,1:)
    do i=1,3
      do j=1,3
        L%L(i,j) = delta_three(i,j) + c*beta_gamma%p(i)*beta_gamma%p(j)
      end do
    end do
  else
    L = identity
  end if
end function boost_from_rest_frame_vector3

```

A canonical boost is a boost along one of the coordinate axes, which we may supply as an integer argument. Here, $\gamma\beta$ is scalar.

(Lorentz: procedures) +=

```

elemental function boost_canonical (beta_gamma, k) result (L)
  type(lorentz_transformation_t) :: L
  real(default), intent(in) :: beta_gamma
  integer, intent(in) :: k
  real(default) :: g
  g = sqrt(1 + beta_gamma**2)
  L = identity
  L%L(0,0) = g
  L%L(0,k) = beta_gamma
  L%L(k,0) = L%L(0,k)
  L%L(k,k) = L%L(0,0)
end function boost_canonical

```

Instead of a canonical axis, we can supply an arbitrary axis which need not be normalized. If it is zero, return the unit matrix.

```

(Lorentz: procedures)+≡
  elemental function boost_generic (beta_gamma, axis) result (L)
    type(lorentz_transformation_t) :: L
    real(default), intent(in) :: beta_gamma
    type(vector3_t), intent(in) :: axis
    if (any(axis%p/=0)) then
      L = boost_from_rest_frame_vector3 (beta_gamma * axis, axis**1)
    else
      L = identity
    end if
  end function boost_generic

```

4.2.10 Rotations

For a rotation, the vector defines the rotation axis, and its length the rotation angle.

```

(Lorentz: public functions)+≡
  public :: rotation

(Lorentz: interfaces)+≡
  interface rotation
    module procedure rotation_generic
    module procedure rotation_canonical
    module procedure rotation_generic_cs
    module procedure rotation_canonical_cs
  end interface

```

If $\cos \phi$ and $\sin \phi$ is already known, we do not have to calculate them. Of course, the user has to ensure that $\cos^2 \phi + \sin^2 \phi = 1$, and that the given axis **n** is normalized to one. In the second form, the length of **axis** is the rotation angle.

```

(Lorentz: procedures)+≡
  elemental function rotation_generic_cs (cp, sp, axis) result (R)
    type(lorentz_transformation_t) :: R
    real(default), intent(in) :: cp, sp

    end if
end function rotation_to_2nd_canonical

```

4.2.11 Composite Lorentz transformations

This function returns the transformation that, given a pair of vectors $p_{1,2}$, (a) boosts from the rest frame of the c.m. system (with invariant mass m) into the lab frame where p_i are defined, and (b) turns the given axis (or the canonical vectors $\pm e_k$) in the rest frame into the directions of $p_{1,2}$ in the lab frame. Note that the energy components are not used; for a consistent result one should have $(p_1 + p_2)^2 = m^2$.

```

(Lorentz: public functions)+≡
    public :: transformation

(Lorentz: interfaces)+≡
    interface transformation
        module procedure transformation_rec_generic
        module procedure transformation_rec_canonical
    end interface

```

```

(Lorentz: procedures)+≡
  elemental function transformation_rec_generic (axis, p1, p2, m) result (L)

    type(vector4_t) :: np
    type(vector4_t), intent(in) :: p
    type(lorentz_transformation_t), intent(in) :: L
    np%p = matmul (p%p, L%L)
  end function prod_vector4_LT

```

4.2.13 Special Lorentz transformations

These routines have their application in the generation and extraction of angles in the phase-space sampling routine. Since this part of the program is

time-critical, we calculate the composition of transformations directly instead of multiplying rotations and boosts.

This Lorentz transformation is the composition of a rotation by ϕ around the 3 axis, a rotation by θ around the 2 axis, and a boost along the 3 axis:

$$L = B_3(\beta\gamma) R_2(\theta) R_3(\phi) \quad (4.2)$$

Instead of the angles we provide sine and cosine.

```

(Lorentz: public functions)+≡
  public :: LT_compose_r3_r2_b3

(Lorentz: procedures)+≡
  elemental function LT_compose_r3_r2_b3 &
    (cp, sp, ct, st, beta_gamma) result (L)

    end if
end function LT_compose_r2_r3_b3

```

This function returns the previous Lorentz transformation applied to an arbitrary four-momentum and extracts the space part of the result:

$$\vec{n} = [B_3(\beta\gamma) R_2(\theta) R_3(\phi) p]_{\text{space part}} \quad (4.4)$$

The second variant applies if there is no rotation

```

4.2.14 Special functions

The standard phase space function:

```
<Lorentz: public functions>+≡
    public :: lambda

<Lorentz: procedures>+≡
    elemental function lambda (m1sq, m2sq, m3sq)
        real(default) :: lambda
        real(default), intent(in) :: m1sq, m2sq, m3sq
        lambda = (m1sq - m2sq - m3sq)**2 - 4*m2sq*m3sq
    end function lambda
```

Return a pair of head-to-head colliding momenta, given the collider energy, particle masses, and optionally the momentum of the c.m. system.

```
<Lorentz: public functions>+≡
    public :: colliding_momenta

<Lorentz: procedures>+≡
    function colliding_momenta (sqrts, m, p_cm) result (p)
        type(vector4_t), dimension(2) :: p
        real(default), intent(in) :: squrts
        real(default), dimension(2), intent(in), optional :: m
        real(default), intent(in), optional :: p_cm
        real(default), dimension(2) :: dmsq
        real(default) :: ch, sh
        real(default), dimension(2) :: E0, p0
        integer, dimension(2), parameter :: sgn = (/1, -1/)
        if (sqrts == 0) then
            call msg_fatal (" Colliding beams: squrts is zero (please set squrts)")
            p = vector4_null; return
        else if (sqrts <= 0) then
            call msg_fatal (" Colliding beams: squrts is negative")
            p = vector4_null; return
        end if
        if (present (m)) then
            dmsq = sgn * (m(1)**2-m(2)**2)
            E0 = (sqrts + dmsq/sqrts) / 2
            if (any (E0 < m)) then
                call msg_fatal &
                    (" Colliding beams: beam energy is less than particle mass")
                p = vector4_null; return
            end if
            p0 = sgn * sqrt (E0**2 - m**2)
        else
            E0 = squrts / 2
            p0 = sgn * E0
        end if
        if (present (p_cm)) then
            sh = p_cm / squrts
            ch = sqrt (1 + sh**2)
            p = vector4_moving (E0 * ch + p0 * sh, E0 * sh + p0 * ch, 3)
        else
            p = vector4_moving (E0, p0, 3)
        end if
```

```
end function colliding_momenta
```

This subroutine is for the purpose of numerical checks and comparisons. The idea is to set a number to zero if it is numerically equivalent with zero. The equivalence is established by comparing with a **tolerance** argument. We implement this for vectors and transformations.

```
<Lorentz: public functions>+≡
  public :: pacify

<Lorentz: interfaces>+≡
  interface pacify
    module procedure pacify_real_default
    module procedure pacify_vector3
    module procedure pacify_vector4
    module procedure pacify_LT
  end interface pacify

    where (abs (LT%L) < tolerance) LT%L = 0
  end subroutine pacify_LT
```

4.3 Special Physics functions

Here, we declare functions that are specific for the Standard Model, including QCD: fixed and running α_s , Catani-Seymour dipole terms, loop functions, etc.

To make maximum use of this, all functions, if possible, are declared elemental (or pure, if this is not possible).

```

<sm_physics.f90>≡
  <File header>

  module sm_physics

    <Use kinds>
    use constants !NODEP!
    <Use file utils>
    use limits, only: MZ_REF, ALPHA_QCD_MZ_REF, LAMBDA_QCD_REF !NODEP!
    use diagnostics !NODEP!
    use lorentz !NODEP!

    <Standard module head>

    <SM physics: public>

    <SM physics: parameters>

    contains

    <SM physics: procedures>

  end module sm_physics

```

4.3.1 Running α_s

First we set a reference value for $\alpha_s(M_Z) = 0.1178$.

```

<Limits: public parameters>+≡
  real(default), public, parameter :: MZ_REF = 91.188_default
  real(default), public, parameter :: ALPHA_QCD_MZ_REF = 0.1178_default
  real(default), public, parameter :: LAMBDA_QCD_REF = 200.e-3_default

```

Then we define the coefficients of the beta function of QCD (as a reference cf. the Particle Data Group), where n_f is the number of active flavors in two different schemes:

$$\beta_0 = 11 - \frac{2}{3}n_f \quad (4.5)$$

$$\beta_1 = 51 - \frac{19}{3}n_f \quad (4.6)$$

$$\beta_2 = 2857 - \frac{5033}{9}n_f + \frac{325}{27}n_f^2 \quad (4.7)$$

$$b_0 = \frac{1}{12\pi} (11C_A - 2n_f) \quad (4.8)$$

$$b_1 = \frac{1}{24\pi^2} (17C_A^2 - 5C_An_f - 3C_Fn_f) \quad (4.9)$$

$$b_2 = \frac{1}{(4\pi)^3} \left(\frac{2857}{54} C_A^3 - \frac{1415}{54} C_A^2 n_f - \frac{205}{18} C_A C_F n_f + C_F^2 n_f + \frac{79}{54} C_A n_f^2 + \frac{11}{9} C_F n_f^2 \right) \quad (4.10)$$

$\langle SM \text{ physics: public} \rangle \equiv$

```
public :: beta0, beta1, beta2, coeff_b0, coeff_b1, coeff_b2
```

$\langle SM \text{ physics: procedures} \rangle \equiv$

```
pure function beta0 (nf)
  real(default), intent(in) :: nf
  real(default) :: beta0
  beta0 = 11.0_default - two/three * nf
end function beta0

pure function beta1 (nf)
  real(default), intent(in) :: nf
  real(default) :: beta1
  beta1 = 51.0_default - 19.0_default/three * nf
end function beta1

pure function beta2 (nf)
  real(default), intent(in) :: nf
  real(default) :: beta2
  beta2 = 2857.0_default - 5033.0_default / 9.0_default * &
    nf + 325.0_default/27.0_default * nf**2
end function beta2

pure function coeff_b0 (nf)
  real(default), intent(in) :: nf
  real(default) :: coeff_b0
  coeff_b0 = (11.0_default * CA - two * nf) / (12.0_default * pi)
end function coeff_b0

pure function coeff_b1 (nf)
  real(default), intent(in) :: nf
  real(default) :: coeff_b1
  coeff_b1 = (17.0_default * CA**2 - five * CA * nf - three * CF * nf) / &
    (24.0_default * pi**2)
end function coeff_b1

pure function coeff_b2 (nf)
  real(default), intent(in) :: nf
  real(default) :: coeff_b2
  coeff_b2 = (2857.0_default/54.0_default * CA**3 - &
    1415.0_default/54.0_default * &
    CA**2 * nf - 205.0_default/18.0_default * CA*CF*nf &
    + 79.0_default/54.0_default * CA*nf**2 + &
    11.0_default/9.0_default * CF * nf**2) / (four*pi)**3
end function coeff_b2
```

There should be two versions of running α_s , one which takes the scale and Λ_{QCD} as input, and one which takes the scale and e.g. $\alpha_s(m_Z)$ as input. Here, we take the one which takes the QCD scale and scale as inputs from the PDG book.

```

<SM physics: public>+≡

end select
end function running_as_lam

```

4.3.2 Catani-Seymour Parameters

These are fundamental constants of the Catani-Seymour dipole formalism. Since the corresponding parameters for the gluon case depend on the number of flavors which is treated as an argument, there we do have functions and not parameters.

$$\gamma_q = \gamma_{\bar{q}} = \frac{3}{2}C_F \quad \gamma_g = \frac{11}{6}C_A - \frac{2}{3}T_R N_f \quad (4.11)$$

$$K_q = K_{\bar{q}} = \left(\frac{7}{2} - \frac{\pi^2}{6} \right) C_F \quad K_g = \left(\frac{67}{18} - \frac{\pi^2}{6} \right) C_A - \frac{10}{9}T_R N_f \quad (4.12)$$

$\langle SM \text{ physics: parameters} \rangle \equiv$

```

real(kind=default), parameter, public :: gamma_q = three/two * CF, &
    k_q = (7.0_default/two - pi**2/6.0_default) * CF

```

$\langle SM \text{ physics: public} \rangle + \equiv$

```

public :: gamma_g, k_g

```

```

<SM physics: procedures>+≡
  elemental function gamma_g (nf) result (gg)
    real(kind=default), intent(in) :: nf
    real(kind=default) :: gg
    gg = 11.0_default/6.0_default * CA - two/three * TR * nf
  end function gamma_g

  elemental function k_g (nf) result (kg)
    real(kind=default), intent(in) :: nf
    real(kind=default) :: kg
    kg = (67.0_default/18.0_default - pi**2/6.0_default) * CA - &
          10.0_default/9.0_default * TR * nf
  end function k_g

```

4.3.3 Mathematical Functions

The dilogarithm. This simplified version is bound to double precision, and restricted to argument values less or equal to unity, so we do not need complex algebra. The wrapper converts it to default precision (which is, of course, a no-op if double=default).

The routine calculates the dilogarithm through mapping on the area where there is a quickly convergent series (adapted from an F77 routine by Hans Kuijf, 1988): Map x such that x is not in the neighbourhood of 1. Note that $|z| = -\ln(1-x)$ is always smaller than 1.10, but $\frac{1 \cdot 10^{19}}{19!} \text{Bernoulli}_{19} = 2.7 \times 10^{-15}$.

```

<SM physics: public>+≡

4.3.6 Functions for Catani-Seymour dipoles

For the automated Catani-Seymour dipole subtraction, we need the following functions.

```

<SM physics: public>+≡
  public :: ff_dipole

```

```

<SM physics: procedures>+≡
  pure subroutine ff_dipole (v_ijk,y_ijk,p_ij,pp_k,p_i,p_j,p_k)
    type(vector4_t), intent(in) :: p_i, p_j, p_k
    type(vector4_t), intent(out) :: p_ij, pp_k
    real(kind=default), intent(out) :: y_ijk
    real(kind=default) :: z_i
    real(kind=default), intent(out) :: v_ijk
    z_i = (p_i*p_k) / ((p_k*p_j) + (p_k*p_i))
    y_ijk = (p_i*p_j) / ((p_i*p_j) + (p_i*p_k) + (p_j*p_k))
    p_ij = p_i + p_j - y_ijk/(1.0_default - y_ijk) * p_k
    pp_k = (1.0/(1.0_default - y_ijk)) * p_k
    !!! We don't multiply by alpha_s right here:
    v_ijk = 8.0_default * PI * CF * &
      (2.0 / (1.0 - z_i*(1.0 - y_ijk)) - (1.0 + z_i))
  end subroutine ff_dipole

```

```

<SM physics: public>+≡
  public :: fi_dipole

```

```

<SM physics: procedures>+≡
  pure subroutine fi_dipole (v_ija,x_ija,p_ij,pp_a,p_i,p_j,p_a)
    type(vector4_t), intent(in) :: p_i, p_j, p_a
    type(vector4_t), intent(out) :: p_ij, pp_a
    real(kind=default), intent(out) :: x_ija
    real(kind=default) :: z_i
    real(kind=default), intent(out) :: v_ija
    z_i = (p_i*p_a) / ((p_a*p_j) + (p_a*p_i))
    x_ija = ((p_i*p_a) + (p_j*p_a) - (p_i*p_j)) &

```

```

      / ((p_i*p_a) + (p_j*p_a))
p_ij = p_i + p_j - (1.0_default - x_ija) * p_a
pp_a = x_ija * p_a
!!! We don't not multiply by alpha_s right here:
v_ija = 8.0_default * PI * CF * &
      (2.0 / (1.0 - z_i + (1.0 - x_ija)) - (1.0 + z_i)) / x_ija
end subroutine fi_dipole

```

```

<SM physics: public>+≡
public :: if_dipole

<SM physics: procedures>+≡
pure subroutine if_dipole (v_kja,u_j,p_aj,pp_k,p_k,p_j,p_a)
  type(vector4_t), intent(in) :: p_k, p_j, p_a
  type(vector4_t), intent(out) :: p_aj, pp_k
  real(kind=default), intent(out) :: u_j
  real(kind=default) :: x_kja
  real(kind=default), intent(out) :: v_kja
  u_j = (p_a*p_j) / ((p_a*p_j) + (p_a*p_k))
  x_kja = ((p_a*p_k) + (p_a*p_j) - (p_j*p_k)) &
    / ((p_a*p_j) + (p_a*p_k))
  p_aj = x_kja * p_a
  pp_k = p_k + p_j - (1.0_default - x_kja) * p_a
  v_kja = 8.0_default * PI * CF * &
    (2.0 / (1.0 - x_kja + u_j) - (1.0 + x_kja)) / x_kja
end subroutine if_dipole

```

This function depends on a variable number of final state particles whose kinematics all get changed by the initial-initial dipole insertion.

```

<SM physics: public>+≡
public :: ii_dipole

<SM physics: procedures>+≡
pure subroutine ii_dipole (v_jab,v_j,p_in,p_out,flag_1or2)

v_jab = 8.0_default * PI * CF * &
  (2.0 / (1.0 - x_jab) - (1.0 + x_jab)) / x_jab
end subroutine ii_dipole

```

4.3.7 Distributions for integrated dipoles and such

The Dirac delta distribution, modified for Monte-Carlo sampling:

```

<SM physics: public>+≡
  public :: delta

<SM physics: procedures>+≡
  elemental function delta (x,eps) result (z)
    real(kind=default), intent(in) :: x, eps
    real(kind=default) :: z
    if (x > 1.0_default - eps) then
      z = 1.0_default/eps
    else
      z = 0
    end if
  end function delta

```

The $+$ -distribution, $P_+(x) = \left(\frac{1}{1-x}\right)_+$, for the regularization of soft-collinear singularities. The constant part for the Monte-Carlo sampling is the integral over the splitting function divided by the weight for the WHIZARD numerical integration over the interval.

```

<SM physics: public>+≡
  public :: plus_distr

<SM physics: procedures>+≡
  elemental function plus_distr (x,eps) result (plusd)
    real(kind=default), intent(in) :: x, eps
    real(kind=default) :: plusd
    if (x > (1.0_default - eps)) then
      plusd = log(eps)/eps
    else
      plusd = one/(one-x)
    end if
  end function plus_distr

```

```

end if
end function plus_distr

```

The splitting function in $D = 4$ dimensions, regularized as $+$ -distributions if necessary:

$$P^{qq}(x) = P^{\bar{q}q}(x) = C_F \cdot \left(\frac{1+x^2}{1-x} \right)_+ \quad (4.13)$$

$$P^{qg}(x) = P^{\bar{q}g}(x) = C_F \cdot \frac{1+(1-x)^2}{x} \quad (4.14)$$

$$P^{gq}(x) = P^{g\bar{q}}(x) = T_R \cdot [x^2 + (1-x)^2] \quad (4.15)$$

$$P^{gg}(x) = 2C_A \left[\left(\frac{1}{1-x} \right)_+ + \frac{1-x}{x} - 1 + x(1-x) \right] + \delta(1-x) \left(\frac{11}{6}C_A - \frac{2}{3}N_f T_R \right) \quad (4.16)$$

Since the number of flavors summed over in the gluon splitting function might depend on the physics case under consideration it is implemented as an input variable.

```

⟨SM physics: public⟩+≡
  public :: pqq

⟨SM physics: procedures⟩+≡
  elemental function pqq (x,eps) result (pqqx)
    real(kind=default), intent(in) :: x, eps
    real(kind=default) :: pqqx
    if (x > (1.0_default - eps)) then
      pqqx = (eps-one)/two + two*log(eps)/eps - three*(eps-one)/eps/two
    else
      pqqx = (one + x**2)/(one-x)
    end if
    pqqx = CF * pqqx
  end function pqq

⟨SM physics: public⟩+≡
  public :: pgq

⟨SM physics: procedures⟩+≡
  elemental function pgq (x) result (pgqx)
    real(kind=default), intent(in) :: x
    real(kind=default) :: pgqx
    pgqx = TR * (x**2 + (one - x)**2)
  end function pgq

⟨SM physics: public⟩+≡
  public :: pqg

⟨SM physics: procedures⟩+≡
  elemental function pqg (x) result (pqgx)
    real(kind=default), intent(in) :: x
    real(kind=default) :: pqgx
    pqgx = CF * (one + (one - x)**2) / x
  end function pqg

```

```

⟨SM physics: public⟩+≡
  public :: pgg
⟨SM physics: procedures⟩+≡
  elemental function pgg (x, nf, eps) result (pggx)
    real(kind=default), intent(in) :: x, nf, eps
    real(kind=default) :: pggx
    pggx = two * CA * ( plus_distr (x, eps) + (one-x)/x - one + &
                        x*(one-x)) + delta (x, eps) * gamma_g(nf)
  end function pgg

```

For the qq and gg cases, there exist “regularized” versions of the splitting functions:

$$P_{\text{reg}}^{qq}(x) = -C_F \cdot (1 + x) \quad (4.17)$$

$$P_{\text{reg}}^{gg}(x) = 2C_A \left[\frac{1-x}{x} - 1 + x(1-x) \right] \quad (4.18)$$

$$(4.19)$$

```

⟨SM physics: public⟩+≡
  public :: pqq_reg
⟨SM physics: procedures⟩+≡
  elemental function pqq_reg (x) result (pqqregx)
    real(kind=default), intent(in) :: x
    real(kind=default) :: pqqregx
    pqqregx = - CF * (one + x)
  end function pqq_reg

```

```

⟨SM physics: public⟩+≡
  public :: pgg_reg
⟨SM physics: procedures⟩+≡
  elemental function pgg_reg (x) result (pggregx)
    real(kind=default), intent(in) :: x
    real(kind=default) :: pgregx
    pgregx = two * CA * ((one - x)/x - one + x*(one - x))
  end function pgg_reg

```

Here, we collect the expressions needed for integrated Catani-Seymour dipoles, and the so-called flavor kernels. We always distinguish between the “ordinary” Catani-Seymour version, and the one including a phase-space slicing parameter, α .

The standard flavor kernels \bar{K}^{ab} are:

$$\bar{K}^{qg}(x) = \bar{K}^{\bar{q}g}(x) = P^{qg}(x) \log((1-x)/x) + CF \times x \quad (4.20)$$

$$\bar{K}^{gq}(x) = \bar{K}^{g\bar{q}}(x) = P^{gq}(x) \log((1-x)/x) + TR \times 2x(1-x) \quad (4.21)$$

$$\bar{K}^{qq} = C_F \left[\left(\frac{2}{1-x} \log \frac{1-x}{x} \right)_+ - (1+x) \log((1-x)/x) + (1-x) \right] - (5 - \pi^2) \cdot C_F \cdot \delta(1-x) \quad (4.22)$$

$$\bar{K}^{gg} = 2C_A \left[\left(\frac{1}{1-x} \log \frac{1-x}{x} \right)_+ + \left(\frac{1-x}{x} - 1 + x(1-x) \right) \log((1-x)/x) \right] - \delta(1-x) \left[(f \right. \quad (4.23)$$

```

⟨SM physics: public⟩+≡
  public :: kbarqg

⟨SM physics: procedures⟩+≡
  function kbarqg (x) result (kbarqgx)
    real(kind=default), intent(in) :: x
    real(kind=default) :: kbarqgx
    kbarqgx = pqg(x) * log((one-x)/x) + CF * x
  end function kbarqg

  real(kind=default), intent(in) :: x, eps, alpha
  real(kind=default) :: ktildeqqx
  ktildeqqx = pqq_reg(x) * log((one-x)/alpha) + CF*( &
    - log2_plus_distr_al(x,alpha,eps) - Pi**2/three * delta(x,eps) &
    + (one+x**2)/(one-x) * log(min(one,(alpha/(one-x)))) &
    + two/(one-x) * log((one+alpha-x)/alpha))
  if (x > (one-alpha)) then
    ktildeqqx = ktildeqqx - CF*two/(one-x)*log(two-x)
  end if
end function ktildeqq_al

```

This is a logarithmic $+$ -distribution, $\left(\frac{\log((1-x)/x)}{1-x}\right)_+$. For the sampling, we need the integral over this function over the incomplete sampling interval $[0, 1 - \epsilon]$, which is $\log^2(x) + 2Li_2(x) - \frac{\pi^2}{3}$. As this function is negative definite for $\epsilon > 0.1816$, we take a hard upper limit for that sampling parameter, irrespective of the fact what the user chooses.

```

⟨SM physics: public⟩+≡
public :: log_plus_distr

⟨SM physics: procedures⟩+≡
function log_plus_distr (x,eps) result (lpd)
  real(kind=default), intent(in) :: x, eps

    else
      lpd_al = two*log(one/(one-x))/(one-x)
    end if
  end function log2_plus_distr_al

```

4.4 QCD Coupling

We provide various distinct implementations of the QCD coupling. In this module, we define an abstract data type and three implementations: fixed, running with $\alpha_s(M_Z)$ as input, and running with Λ_{QCD} as input. We use the functions defined above in the module `sm_physics` but provide a common interface. Later modules may define additional implementations.

```

⟨sm_qcd.f90⟩≡
  ⟨File header⟩

  module sm_qcd

    ⟨Use kinds⟩
    ⟨Use file utils⟩

```

```

    use limits, only: MZ_REF, ALPHA_QCD_MZ_REF, LAMBDA_QCD_REF !NODEP!
    use diagnostics !NODEP!
    use unit_tests

    use sm_physics !NODEP!

    <Standard module head>

    <SM qcd: public>

    <SM qcd: types>

    <SM qcd: interfaces>

    contains

    <SM qcd: procedures>

    <SM qcd: tests>

    end module sm_qcd

```

4.4.1 Coupling: Abstract Data Type

This is the abstract version of the QCD coupling implementation.

```

<SM qcd: public>≡
    public :: alpha_qcd_t

<SM qcd: types>≡
    type, abstract :: alpha_qcd_t
    contains
    <SM qcd: alpha qcd: TBP>
    end type alpha_qcd_t

```

There must be an output routine.

```

<SM qcd: alpha qcd: TBP>≡
    procedure (alpha_qcd_write), deferred :: write

<SM qcd: interfaces>≡
    abstract interface
        subroutine alpha_qcd_write (object, unit)
            import
            class(alpha_qcd_t), intent(in) :: object
            integer, intent(in), optional :: unit
        end subroutine alpha_qcd_write
    end interface

```

This method computes the running coupling, given a certain scale. All parameters (reference value, order of the approximation, etc.) must be set before calling this.

```

<SM qcd: alpha qcd: TBP>+≡
    procedure (alpha_qcd_get), deferred :: get

```

```

⟨SM qcd: interfaces⟩+≡
  abstract interface
    function alpha_qcd_get (alpha_qcd, scale) result (alpha)
      import
      class(alpha_qcd_t), intent(in) :: alpha_qcd
      real(default), intent(in) :: scale
      real(default) :: alpha
    end function alpha_qcd_get
  end interface

```

4.4.2 Fixed Coupling

In this version, the α_s value is fixed, the `scale` argument of the `get` method is ignored. There is only one parameter, the value. By default, this is the value at M_Z .

```

⟨SM qcd: public⟩+≡
  public :: alpha_qcd_fixed_t

⟨SM qcd: types⟩+≡
  type, extends (alpha_qcd_t) :: alpha_qcd_fixed_t
    real(default) :: val = ALPHA_QCD_MZ_REF
  contains
    ⟨SM qcd: alpha qcd fixed: TBP⟩
  end type alpha_qcd_fixed_t

```

Output.

```

⟨SM qcd: alpha qcd fixed: TBP⟩≡
  procedure :: write => alpha_qcd_fixed_write

⟨SM qcd: procedures⟩≡
  subroutine alpha_qcd_fixed_write (object, unit)
    class(alpha_qcd_fixed_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(3x,A)") "QCD parameters (fixed coupling):"
    write (u, "(5x,A,ES12.5)") "alpha = ", object%val
  end subroutine alpha_qcd_fixed_write

```

Calculation: the scale is ignored in this case.

```

⟨SM qcd: alpha qcd fixed: TBP⟩+≡
  procedure :: get => alpha_qcd_fixed_get

⟨SM qcd: procedures⟩+≡
  function alpha_qcd_fixed_get (alpha_qcd, scale) result (alpha)
    class(alpha_qcd_fixed_t), intent(in) :: alpha_qcd
    real(default), intent(in) :: scale
    real(default) :: alpha
    alpha = alpha_qcd%val
  end function alpha_qcd_fixed_get

```

4.4.3 Running Coupling

In this version, the α_s value runs relative to the value at a given reference scale. There are two parameters: the value of this scale (default: M_Z), the value of α_s at this scale, and the number of effective flavors. Furthermore, we have the order of the approximation.

```

⟨SM qcd: public⟩+≡
    public :: alpha_qcd_from_scale_t

⟨SM qcd: types⟩+≡
    type, extends (alpha_qcd_t) :: alpha_qcd_from_scale_t
        real(default) :: mu_ref = MZ_REF
        real(default) :: ref = ALPHA_QCD_MZ_REF
        integer :: order = 0
        integer :: nf = 5
    contains
        ⟨SM qcd: alpha qcd from scale: TBP⟩
    end type alpha_qcd_from_scale_t

```

Output.

```

⟨SM qcd: alpha qcd from scale: TBP⟩≡
    procedure :: write => alpha_qcd_from_scale_write

⟨SM qcd: procedures⟩+≡
    subroutine alpha_qcd_from_scale_write (object, unit)
        class(alpha_qcd_from_scale_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit)
        write (u, "(3x,A)") "QCD parameters (running coupling):"
        write (u, "(5x,A,ES12.5)") "Scale mu = ", object%mu_ref
        write (u, "(5x,A,ES12.5)") "alpha(mu) = ", object%ref
        write (u, "(5x,A,I0)") "LL order = ", object%order
        write (u, "(5x,A,I0)") "N(flv) = ", object%nf
    end subroutine alpha_qcd_from_scale_write

```

Calculation: here, we call the function for running α_s that was defined in `sm_physics` above. The function does not take into account thresholds, so the number of flavors should be the correct one for the chosen scale. Normally, this should be the Z boson mass.

```

⟨SM qcd: alpha qcd from scale: TBP⟩+≡
    procedure :: get => alpha_qcd_from_scale_get

⟨SM qcd: procedures⟩+≡
    function alpha_qcd_from_scale_get (alpha_qcd, scale) result (alpha)
        class(alpha_qcd_from_scale_t), intent(in) :: alpha_qcd
        real(default), intent(in) :: scale
        real(default) :: alpha
        alpha = running_as (scale, &
            alpha_qcd%ref, alpha_qcd%mu_ref, alpha_qcd%order, &
            real (alpha_qcd%nf, kind=default))
    end function alpha_qcd_from_scale_get

```

4.4.4 Running Coupling, determined by Λ_{QCD}

In this version, the input are the value Λ_{QCD} and the order of the approximation.

```
<SM qcd: public>+≡
  public :: alpha_qcd_from_lambda_t
<SM qcd: types>+≡
  type, extends (alpha_qcd_t) :: alpha_qcd_from_lambda_t
    real(default) :: lambda = LAMBDA_QCD_REF
    integer :: order = 0
    integer :: nf = 5
  contains
    <SM qcd: alpha qcd from lambda: TBP>
  end type alpha_qcd_from_lambda_t
```

Output.

```
<SM qcd: alpha qcd from lambda: TBP>≡
  procedure :: write => alpha_qcd_from_lambda_write
<SM qcd: procedures>+≡
  subroutine alpha_qcd_from_lambda_write (object, unit)
    class(alpha_qcd_from_lambda_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(3x,A)") "QCD parameters (Lambda_QCD as input):"
    write (u, "(5x,A,ES12.5)") "Lambda_QCD = ", object%lambda
    write (u, "(5x,A,I0)") "LL order = ", object%order
    write (u, "(5x,A,I0)") "N(flav) = ", object%nf
  end subroutine alpha_qcd_from_lambda_write
```

Calculation: here, we call the second function for running α_s that was defined in `sm_physics` above. The Λ value should be the one that is appropriate for the chosen number of effective flavors. Again, thresholds are not incorporated.

```
<SM qcd: alpha qcd from lambda: TBP>+≡
  procedure :: get => alpha_qcd_from_lambda_get
<SM qcd: procedures>+≡
  function alpha_qcd_from_lambda_get (alpha_qcd, scale) result (alpha)
    class(alpha_qcd_from_lambda_t), intent(in) :: alpha_qcd
    real(default), intent(in) :: scale
    real(default) :: alpha
    alpha = running_as_lam (real (alpha_qcd%nf, kind=default), scale, &
      alpha_qcd%lambda, alpha_qcd%order)
  end function alpha_qcd_from_lambda_get
```

4.4.5 Wrapper type

We could get along with a polymorphic QCD type, but a monomorphic wrapper type with a polymorphic component is easier to handle and probably safer (w.r.t. compiler bugs). However, we keep the object transparent, so we can set the type-specific parameters directly (by a `dispatch` routine).

```
<SM qcd: public>+≡
```

```

    public :: qcd_t
  <SM qcd: types>+≡
    type :: qcd_t
      class(alpha_qcd_t), allocatable :: alpha
      contains
        <SM qcd: qcd: TBP>
      end type qcd_t

```

Output. We first print the polymorphic `alpha` which contains a headline, then any extra components.

```

  <SM qcd: qcd: TBP>≡
    procedure :: write => qcd_write
  <SM qcd: procedures>+≡
    subroutine qcd_write (qcd, unit)
      class(qcd_t), intent(in) :: qcd
      integer, intent(in), optional :: unit
      integer :: u
      u = output_unit (unit)
      if (allocated (qcd%alpha)) then
        call qcd%alpha%write (u)
      else
        write (u, "(3x,A)") "QCD parameters (coupling undefined)"
      end if
    end subroutine qcd_write

```

4.4.6 Unit tests

```

  <SM qcd: public>+≡
    public :: sm_qcd_test
  <SM qcd: tests>≡
    subroutine sm_qcd_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
    <SM qcd: execute tests>
    end subroutine sm_qcd_test

```

QCD Coupling

We check two different implementations of the abstract QCD coupling.

```

  <SM qcd: execute tests>≡
    call test (sm_qcd_1, "sm_qcd_1", &
      "running alpha_s", &
      u, results)
  <SM qcd: tests>+≡
    subroutine sm_qcd_1 (u)
      integer, intent(in) :: u
      type(qcd_t) :: qcd

```

```

Chapter 5

Physics Analysis

This part contains the structures and tools that are necessary for defining parameters, particle sets, analysis objects such as histograms, and expressions that deal with them.

These are the modules:

analysis Observables, histograms, and plots.

pdg_arrays Useful for particle aliases (e.g., 'quark' for u, d, s etc.)

prt_lists Particle lists/arrays used for analyzing events.

variables Store values of various kind, used by expressions and accessed by the command interface.

expressions Expressions of values of all kinds. Includes the API for recording analysis data.

5.1 Analysis tools

This module defines structures useful for data analysis. These include observables, histograms, and plots.

Observables are quantities that are calculated and summed up event by event. At the end, one can compute the average and error.

Histograms have their bins in addition to the observable properties. Histograms are usually written out in tables and displayed graphically.

In plots, each record creates its own entry in a table. This can be used for scatter plots if called event by event, or for plotting dependencies on parameters if called once per integration run.

Graphs are container for histograms and plots, which carry their own graphics options.

The type layout is still somewhat obfuscated. This would become much simpler if type extension could be used.

```
<analysis.f90>≡  
  <File header>  
  
  module analysis  
  
    <Use kinds>  
    <Use strings>  
    use limits, only: HISTOGRAM_HEAD_FORMAT, HISTOGRAM_DATA_FORMAT !NODEP!  
    use limits, only: HISTOGRAM_INTG_FORMAT !NODEP!  
    <Use file utils>  
    use diagnostics !NODEP!  
    use os_interface  
    use ifiles  
  
    <Standard module head>  
  
    <Analysis: public>  
  
    <Analysis: parameters>  
  
    <Analysis: types>  
  
    <Analysis: interfaces>  
  
    <Analysis: variables>  
  
    contains  
  
    <Analysis: procedures>  
  
  end module analysis
```

5.1.1 Output formats

These formats share a common field width (alignment).

```
<Limits: public parameters>+≡  
  character(*), parameter, public :: HISTOGRAM_HEAD_FORMAT = "1x,A15,3x"
```

```

character(*), parameter, public :: HISTOGRAM_INTG_FORMAT = "3x,I9,3x"
character(*), parameter, public :: HISTOGRAM_DATA_FORMAT = "ES19.12"

```

5.1.2 Graph options

These parameters are used for displaying data. They apply to a whole graph, which may contain more than one plot element.

The GAMELAN code chunks are part of both `graph_options` and `drawing_options`. The `drawing_options` copy is used in histograms and plots, also as graph elements. The `graph_options` copy is used for `graph` objects as a whole. Both copies are usually identical.

```

<Analysis: public>≡

end if
if (present (graph_options)) then
    obs%graph_options = graph_options
else
    call graph_options_init (obs%graph_options)
end if
end subroutine observable_init

```

Reset all numeric entries.

<Analysis: procedures>+≡

```

subroutine observable_clear (obs)
    type(observable_t), intent(inout) :: obs
    obs%sum_values = 0
    obs%sum_squared_values = 0
    obs%sum_weights = 0
    obs%sum_squared_weights = 0
    obs%count = 0
end subroutine observable_clear

```

Record a a value. Always successful for observables.

<Analysis: interfaces>≡

```

interface observable_record_value
    module procedure observable_record_value_unweighted
    module procedure observable_record_value_weighted
end interface

```

<Analysis: procedures>+≡

```

subroutine observable_record_value_unweighted (obs, value, success)
    type(observable_t), intent(inout) :: obs
    real(default), intent(in) :: value
    logical, intent(out), optional :: success
    obs%sum_values = obs%sum_values + value
    obs%sum_squared_values = obs%sum_squared_values + value**2
    obs%sum_weights = obs%sum_weights + 1
    obs%sum_squared_weights = obs%sum_squared_weights + 1
    obs%count = obs%count + 1
    if (present (success)) success = .true.
end subroutine observable_record_value_unweighted

subroutine observable_record_value_weighted (obs, value, weight, success)
    type(observable_t), intent(inout) :: obs

```

```

real(default), intent(in) :: value, weight
logical, intent(out), optional :: success
obs%sum_values = obs%sum_values + value * weight
obs%sum_squared_values = obs%sum_squared_values + value**2 * weight
obs%sum_weights = obs%sum_weights + abs (weight)
obs%sum_squared_weights = obs%sum_squared_weights + weight**2
obs%count = obs%count + 1
if (present (success)) success = .true.
end subroutine observable_record_value_weighted

```

Here are the statistics formulas:

1. Unweighted case: Given a sample of n values x_i , the average is

$$\langle x \rangle = \frac{\sum x_i}{n} \quad (5.1)$$

and the error estimate

$$\Delta x = \sqrt{\frac{1}{n-1} \langle \sum (x_i - \langle x \rangle)^2 \rangle} \quad (5.2)$$

$$= \sqrt{\frac{1}{n-1} \left(\frac{\sum x_i^2}{n} - \frac{(\sum x_i)^2}{n^2} \right)} \quad (5.3)$$

2. Weighted case: Instead of weight 1, each event comes with weight w_i .

$$\langle x \rangle = \frac{\sum x_i w_i}{\sum w_i} \quad (5.4)$$

and

$$\Delta x = \sqrt{\frac{1}{n-1} \left(\frac{\sum x_i^2 w_i}{\sum w_i} - \frac{(\sum x_i w_i)^2}{(\sum w_i)^2} \right)} \quad (5.5)$$

For $w_i = 1$, this specializes to the previous formula.

<Analysis: procedures>+≡

h = h_in
if (present (drawing_options)) then
    h%drawing_options = drawing_options
end if
end subroutine histogram_init_histogram

```

Fill histograms

Clear the histogram contents, but do not modify the structure.

(Analysis: procedures)+≡

```

subroutine histogram_clear (h)
    type(histogram_t), intent(inout) :: h
    call observable_clear (h%obs)
    call observable_clear (h%obs_within_bounds)
    call bin_clear (h%underflow)
    if (allocated (h%bin)) call bin_clear (h%bin)
    call bin_clear (h%overflow)
end subroutine histogram_clear

```

Record a value. Successful if the value is within bounds, otherwise it is recorded as under-/overflow. Optionally, we may provide an excess weight that could be returned by the unweighting procedure.

(Analysis: procedures)+≡

```

subroutine histogram_record_value_unweighted (h, value, excess, success)
    type(histogram_t), intent(inout) :: h
    real(default), intent(in) :: value
    real(default), intent(in), optional :: excess

    // int2char (plot_get_n_entries (plot)))
end subroutine plot_get_header

```

5.1.8 Graphs

A graph is a container for several graph elements. Each graph element is either a plot or a histogram. There is an appropriate base type below (the `analysis_object_t`), but to avoid recursion, we define a separate base type here. Note that there is no actual recursion: a graph is an analysis object, but a graph cannot contain graphs.

(If we could use type extension, the implementation would be much more transparent.)

Graph elements

Graph elements cannot be filled by the `record` command directly. The contents are always copied from elementary histograms or plots.

```

<Analysis: types>+≡
type :: graph_element_t
  private
  integer :: type = AN_UNDEFINED
  type(histogram_t), pointer :: h => null ()
  type(plot_t), pointer :: p => null ()
end type graph_element_t

```

```

<Analysis: procedures>+≡
subroutine graph_element_final (el)
  type(graph_element_t), intent(inout) :: el
  select case (el%type)
  case (AN_HISTOGRAM)

```

```

        deallocate (el%h)
    case (AN_PLOT)
        call plot_final (el%p)
        deallocate (el%p)
    end select
    el%type = AN_UNDEFINED
end subroutine graph_element_final

```

Return the number of entries in the graph element:

<Analysis: procedures>+≡

```

function graph_element_get_n_entries (el) result (n)
    integer :: n
    type(graph_element_t), intent(in) :: el
    select case (el%type)
    case (AN_HISTOGRAM); n = histogram_get_n_entries (el%h)
    case (AN_PLOT);      n = plot_get_n_entries (el%p)
    case default;       n = 0
    end select
end function graph_element_get_n_entries

```

Return a pointer to the graph / drawing options.

<Analysis: procedures>+≡

```

function graph_element_get_graph_options_ptr (el) result (ptr)
    type(graph_options_t), pointer :: ptr
    type(graph_element_t), intent(in) :: el
    select case (el%type)
    case (AN_HISTOGRAM); ptr => histogram_get_graph_options_ptr (el%h)
    case (AN_PLOT);      ptr => plot_get_graph_options_ptr (el%p)
    case default;        ptr => null ()
    end select
end function graph_element_get_graph_options_ptr

function graph_element_get_drawing_options_ptr (el) result (ptr)
    type(drawing_options_t), pointer :: ptr
    type(graph_element_t), intent(in) :: el
    select case (el%type)
    case (AN_HISTOGRAM); ptr => histogram_get_drawing_options_ptr (el%h)
    case (AN_PLOT);      ptr => plot_get_drawing_options_ptr (el%p)
    case default;        ptr => null ()
    end select
end function graph_element_get_drawing_options_ptr

```

Output, simple wrapper for the plot/histogram writer.

<Analysis: procedures>+≡

```

subroutine graph_element_write (el, unit)
    type(graph_element_t), intent(in) :: el
    integer, intent(in), optional :: unit
    type(graph_options_t), pointer :: gro
    type(string_t) :: id
    integer :: u
    u = output_unit (unit); if (u < 0) return
    gro => graph_element_get_graph_options_ptr (el)

```

```

id = graph_options_get_id (gro)
write (u, "(A,A)" ' #', repeat ("-", 78)
select case (el%type)
case (AN_HISTOGRAM)
    write (u, "(A)", advance="no")  "# Histogram: "
    write (u, "(1x,A)") char (id)
    call histogram_write (el%h, unit)
case (AN_PLOT)
    write (u, "(A)", advance="no")  "# Plot: "
    write (u, "(1x,A)") char (id)
    call plot_write (el%p, unit)
end select
end subroutine graph_element_write

```

(Analysis: procedures)+≡

```

subroutine graph_element_write_gml_reader (el, filename, unit)
    type(graph_element_t), intent(in) :: el
    type(string_t), intent(in) :: filename
    integer, intent(in), optional :: unit
    select case (el%type)
    case (AN_HISTOGRAM); call histogram_write_gml_reader (el%h, filename, unit)
    case (AN_PLOT);      call plot_write_gml_reader (el%p, filename, unit)
    end select
end subroutine graph_element_write_gml_reader

```

The graph type

The actual graph type contains its own `graph_options`, which override the individual settings. The `drawing_options` are set in the graph elements. This distinction motivates the separation of the two types.

(Analysis: types)+≡

```

type :: graph_t
    private
    type(graph_element_t), dimension(:), allocatable :: el
    type(graph_options_t) :: graph_options
end type graph_t

```

Initializer/finalizer

The graph is created with a definite number of elements. The elements are filled one by one, optionally with modified drawing options.

(Analysis: procedures)+≡

```

subroutine graph_init (g, id, n_elements, graph_options)
    type(graph_t), intent(out) :: g
    type(string_t), intent(in) :: id
    integer, intent(in) :: n_elements
    type(graph_options_t), intent(in), optional :: graph_options
    allocate (g%el (n_elements))
    if (present (graph_options)) then
        g%graph_options = graph_options
    end if
end subroutine graph_init

```

```

else
    call graph_options_init (g%graph_options)
end if
call graph_options_set (g%graph_options, id = id)
end subroutine graph_init

```

<Analysis: procedures>+≡

```

subroutine graph_insert_histogram (g, i, h, drawing_options)
    type(graph_t), intent(inout), target :: g
    integer, intent(in) :: i
    type(histogram_t), intent(in) :: h
    type(drawing_options_t), intent(in), optional :: drawing_options
    type(graph_options_t), pointer :: gro
    type(drawing_options_t), pointer :: dro
    type(string_t) :: id
    g%el(i)%type = AN_HISTOGRAM
    allocate (g%el(i)%h)
    call histogram_init_histogram (g%el(i)%h, h, drawing_options)
    gro => histogram_get_graph_options_ptr (g%el(i)%h)
    dro => histogram_get_drawing_options_ptr (g%el(i)%h)
    id = graph_options_get_id (gro)
    call drawing_options_set (dro, dataset = "dat." // id)
end subroutine graph_insert_histogram

```

<Analysis: procedures>+≡

```

subroutine graph_insert_plot (g, i, p, drawing_options)
    type(graph_t), intent(inout) :: g
    integer, intent(in) :: i
    type(plot_t), intent(in) :: p
    type(drawing_options_t), intent(in), optional :: drawing_options
    type(graph_options_t), pointer :: gro
    type(drawing_options_t), pointer :: dro
    type(string_t) :: id
    g%el(i)%type = AN_PLOT
    allocate (g%el(i)%p)
    call plot_init_plot (g%el(i)%p, p, drawing_options)
    gro => plot_get_graph_options_ptr (g%el(i)%p)
    dro => plot_get_drawing_options_ptr (g%el(i)%p)
    id = graph_options_get_id (gro)
    call drawing_options_set (dro, dataset = "dat." // id)
end subroutine graph_insert_plot

```

Finalizer.

<Analysis: procedures>+≡

```

subroutine graph_final (g)
    type(graph_t), intent(inout) :: g
    integer :: i
    do i = 1, size (g%el)
        call graph_element_final (g%el(i))
    end do
    deallocate (g%el)
end subroutine graph_final

```

Access contents

The number of elements.

<Analysis: procedures>+≡

```
function graph_get_n_elements (graph) result (n)
  integer :: n
  type(graph_t), intent(in) :: graph
  n = size (graph%el)
end function graph_get_n_elements
```

Retrieve a pointer to the drawing options of an element, so they can be modified. (The `target` attribute is not actually needed because the components are pointers.)

<Analysis: procedures>+≡

```
function graph_get_drawing_options_ptr (g, i) result (ptr)
  type(drawing_options_t), pointer :: ptr
  type(graph_t), intent(in), target :: g
  integer, intent(in) :: i
  ptr => graph_element_get_drawing_options_ptr (g%el(i))
end function graph_get_drawing_options_ptr
```

Output

The default output format just writes histogram and plot data.

<Analysis: procedures>+≡

```
subroutine graph_write (graph, unit)
  type(graph_t), intent(in) :: graph
  integer, intent(in), optional :: unit
  integer :: i
  do i = 1, size (graph%el)
    call graph_element_write (graph%el(i), unit)
  end do
end subroutine graph_write
```

The GAMELAN driver is not a simple wrapper, but it writes the plot/histogram contents embedded the complete graph. First, data are read in, global background commands next, then individual elements, then global foreground commands.

<Analysis: procedures>+≡

```
subroutine graph_write_gml_driver (g, filename, unit)
  type(graph_t), intent(in) :: g
  type(string_t), intent(in) :: filename
  type(string_t) :: calc_cmd, bg_cmd, draw_cmd, err_cmd, symb_cmd, fg_cmd
  integer, intent(in), optional :: unit
  type(drawing_options_t), pointer :: dro

    call graph_options_get_header (graph%graph_options, header, comment)
    call ifile_append (header, &
        c // "number of graph elements: " &
        // int2char (graph_get_n_elements (graph)))
end subroutine graph_get_header

```

5.1.9 Analysis objects

This data structure holds all observables, histograms and such that are currently active. We have one global store; individual items are identified by their ID

strings.

(This should rather be coded by type extension.)

<Analysis: parameters>+≡

```
integer, parameter :: AN_UNDEFINED = 0
integer, parameter :: AN_OBSERVABLE = 1
integer, parameter :: AN_HISTOGRAM = 2
integer, parameter :: AN_PLOT = 3
integer, parameter :: AN_GRAPH = 4
```

<Analysis: public>+≡

```
public :: AN_UNDEFINED, AN_HISTOGRAM, AN_OBSERVABLE, AN_PLOT, AN_GRAPH
```

<Analysis: types>+≡

```
type :: analysis_object_t
private
type(string_t) :: id
integer :: type = AN_UNDEFINED
type(observable_t), pointer :: obs => null ()
type(histogram_t), pointer :: h => null ()
type(plot_t), pointer :: p => null ()
type(graph_t), pointer :: g => null ()
type(analysis_object_t), pointer :: next => null ()
end type analysis_object_t
```

Initializer/finalizer

Allocate with the correct type but do not fill initial values.

<Analysis: procedures>+≡

```
subroutine analysis_object_init (obj, id, type)
  type(analysis_object_t), intent(out) :: obj
  type(string_t), intent(in) :: id
  integer, intent(in) :: type
  obj%id = id
  obj%type = type
  select case (obj%type)
    case (AN_OBSERVABLE); allocate (obj%obs)
    case (AN_HISTOGRAM); allocate (obj%h)
    case (AN_PLOT); allocate (obj%p)
    case (AN_GRAPH); allocate (obj%g)
  end select
end subroutine analysis_object_init
```

<Analysis: procedures>+≡

```
subroutine analysis_object_final (obj)
  type(analysis_object_t), intent(inout) :: obj
  select case (obj%type)
    case (AN_OBSERVABLE)
      deallocate (obj%obs)
    case (AN_HISTOGRAM)
      deallocate (obj%h)
    case (AN_PLOT)
      call plot_final (obj%p)
```

```

        deallocate (obj%p)
    case (AN_GRAPH)
        call graph_final (obj%g)
        deallocate (obj%g)
    end select
    obj%type = AN_UNDEFINED
end subroutine analysis_object_final

```

Clear the analysis object, i.e., reset it to its initial state. Not applicable to graphs, which are always combinations of other existing objects.

(Analysis: procedures)+≡

```

subroutine analysis_object_clear (obj)
    type(analysis_object_t), intent(inout) :: obj
    select case (obj%type)
    case (AN_OBSERVABLE)
        call observable_clear (obj%obs)
    case (AN_HISTOGRAM)
        call histogram_clear (obj%h)
    case (AN_PLOT)
        call plot_clear (obj%p)
    end select
end subroutine analysis_object_clear

```

Fill with data

Record data. The effect depends on the type of analysis object.

(Analysis: procedures)+≡

```

subroutine analysis_object_record_data (obj, &
    x, y, yerr, xerr, weight, excess, success)
    type(analysis_object_t), intent(inout) :: obj
    real(default), intent(in) :: x
    real(default), intent(in), optional :: y, yerr, xerr, weight, excess
    logical, intent(out), optional :: success
    select case (obj%type)
    case (AN_OBSERVABLE)
        if (present (weight)) then
            call observable_record_value_weighted (obj%obs, x, weight, success)
        else
            call observable_record_value_unweighted (obj%obs, x, success)
        end if
    case (AN_HISTOGRAM)
        if (present (weight)) then
            call histogram_record_value_weighted (obj%h, x, weight, success)
        else
            call histogram_record_value_unweighted (obj%h, x, excess, success)
        end if
    case (AN_PLOT)
        if (present (y)) then
            call plot_record_value (obj%p, x, y, yerr, xerr, success)
        else
            if (present (success)) success = .false.
        end if
    end select
end subroutine analysis_object_record_data

```

```

        case default
            if (present (success)) success = .false.
        end select
    end subroutine analysis_object_record_data

```

Explicitly set the pointer to the next object in the list.

```

<Analysis: procedures>+≡
subroutine analysis_object_set_next_ptr (obj, next)
    type(analysis_object_t), intent(inout) :: obj
    type(analysis_object_t), pointer :: next
    obj%next => next
end subroutine analysis_object_set_next_ptr

```

Access contents

Return a pointer to the next object in the list.

```

<Analysis: procedures>+≡
function analysis_object_get_next_ptr (obj) result (next)
    type(analysis_object_t), pointer :: next
    type(analysis_object_t), intent(in) :: obj
    next => obj%next
end function analysis_object_get_next_ptr

```

Return data as appropriate for the object type.

```

<Analysis: procedures>+≡

  end select
end subroutine analysis_object_get_header

```

5.1.10 Analysis object iterator

Analysis objects are containers which have iterable data structures: histograms/bins and plots/points. If they are to be treated on a common basis, it is useful to have an iterator which hides the implementation details.

The iterator is used only for elementary analysis objects that contain plot data: histograms or plots. It is invalid for meta-objects (graphs) and non-graphical objects (observables).

```

<Analysis: public>+≡
  public :: analysis_iterator_t

<Analysis: types>+≡
  type :: analysis_iterator_t
  private
    integer :: type = AN_UNDEFINED
    type(analysis_object_t), pointer :: object => null ()
    integer :: index = 1
    type(point_t), pointer :: point => null ()
  end type

```

The initializer places the iterator at the beginning of the analysis object.

```

<Analysis: procedures>+≡
subroutine analysis_iterator_init (iterator, object)
  type(analysis_iterator_t), intent(out) :: iterator
  type(analysis_object_t), intent(in), target :: object
  iterator%object => object

```

```

    if (associated (iterator%object)) then
        iterator%type = iterator%object%type
        select case (iterator%type)
            case (AN_PLOT)
                iterator%point => iterator%object%p%first
            end select
        end if
    end if
end subroutine analysis_iterator_init

```

The iterator is valid as long as it points to an existing entry. An iterator for a data object without array data (observable) is always invalid.

```

<Analysis: public>+≡
    public :: analysis_iterator_is_valid

<Analysis: procedures>+≡
    function analysis_iterator_is_valid (iterator) result (valid)
        logical :: valid
        type(analysis_iterator_t), intent(in) :: iterator
        if (associated (iterator%object)) then
            select case (iterator%type)
                case (AN_HISTOGRAM)
                    valid = iterator%index <= histogram_get_n_bins (iterator%object%h)
                case (AN_PLOT)
                    valid = associated (iterator%point)
                case default
                    valid = .false.
            end select
        else
            valid = .false.
        end if
    end function analysis_iterator_is_valid

```

Advance the iterator.

```

<Analysis: public>+≡
    public :: analysis_iterator_advance

<Analysis: procedures>+≡
    subroutine analysis_iterator_advance (iterator)
        type(analysis_iterator_t), intent(inout) :: iterator
        if (associated (iterator%object)) then
            select case (iterator%type)
                case (AN_PLOT)
                    iterator%point => iterator%point%next
                end select
            iterator%index = iterator%index + 1
        end if
    end subroutine analysis_iterator_advance

```

Retrieve the object type:

```

<Analysis: public>+≡
    public :: analysis_iterator_get_type

```

```

<Analysis: procedures>+≡
function analysis_iterator_get_type (iterator) result (type)
  integer :: type
  type(analysis_iterator_t), intent(in) :: iterator
  type = iterator%type
end function analysis_iterator_get_type

```

Use the iterator to retrieve data. We implement a common routine which takes the data descriptors as optional arguments. Data which do not occur in the selected type trigger to an error condition.

The iterator must point to a valid entry.

```

<Analysis: public>+≡
public :: analysis_iterator_get_data

<Analysis: procedures>+≡
subroutine analysis_iterator_get_data (iterator, &
  x, y, yerr, xerr, width, excess, index, n_total)
  type(analysis_iterator_t), intent(in) :: iterator

    if (present (n_total)) &
      n_total = histogram_get_n_bins (iterator%object%h)
  case (AN_PLOT)
    if (present (x)) &
      x = point_get_x (iterator%point)
    if (present (y)) &
      y = point_get_y (iterator%point)
    if (present (yerr)) &
      yerr = point_get_yerr (iterator%point)
    if (present (xerr)) &
      xerr = point_get_xerr (iterator%point)
    if (present (width)) &
      call invalid ("plot", "width")
    if (present (excess)) &
      call invalid ("plot", "excess")
    if (present (index)) &
      index = iterator%index
    if (present (n_total)) &

```

```

        n_total = plot_get_n_entries (iterator%object%p)
    case default
        call msg_bug ("analysis_iterator_get_data: called " &
            // "for unsupported analysis object type")
    end select
contains
    subroutine invalid (typestr, objstr)
        character(*), intent(in) :: typestr, objstr
        call msg_bug ("analysis_iterator_get_data: attempt to get '" &
            // objstr // "' for type '" // typestr // "'")
    end subroutine invalid
end subroutine analysis_iterator_get_data

```

5.1.11 Analysis store

This data structure holds all observables, histograms and such that are currently active. We have one global store; individual items are identified by their ID strings and types.

<Analysis: variables>≡
 type(analysis_store_t), save :: analysis_store

<Analysis: types>+≡
 type :: analysis_store_t
 private
 type(analysis_object_t), pointer :: first => null ()
 type(analysis_object_t), pointer :: last => null ()
 end type analysis_store_t

Delete the analysis store

<Analysis: public>+≡
 public :: analysis_final

<Analysis: procedures>+≡
 subroutine analysis_final ()
 type(analysis_object_t), pointer :: current
 do while (associated (analysis_store%first))
 current => analysis_store%first
 analysis_store%first => current%next
 call analysis_object_final (current)
 end do
 analysis_store%last => null ()
 end subroutine analysis_final

Append a new analysis object

<Analysis: procedures>+≡
 subroutine analysis_store_append_object (id, type)
 type(string_t), intent(in) :: id
 integer, intent(in) :: type
 type(analysis_object_t), pointer :: obj
 allocate (obj)
 call analysis_object_init (obj, id, type)

```

    if (associated (analysis_store%last)) then
        analysis_store%last%next => obj
    else
        analysis_store%first => obj
    end if
    analysis_store%last => obj
end subroutine analysis_store_append_object

```

Return a pointer to the analysis object with given ID.

<Analysis: procedures>+≡

```

function analysis_store_get_object_ptr (id) result (obj)
    type(string_t), intent(in) :: id
    type(analysis_object_t), pointer :: obj
    obj => analysis_store%first
    do while (associated (obj))
        if (obj%id == id) return
        obj => obj%next
    end do
end function analysis_store_get_object_ptr

```

Initialize an analysis object: either reset it if present, or append a new entry.

<Analysis: procedures>+≡

```

subroutine analysis_store_init_object (id, type, obj)
    type(string_t), intent(in) :: id
    integer, intent(in) :: type
    type(analysis_object_t), pointer :: obj, next

    do while (associated (obj))
      call analysis_object_clear (obj)
      obj => obj%next
    end do
  end subroutine analysis_store_clear_all

```

There is one generic recording function whose behavior depends on the type of analysis object.

```

<Analysis: public>+≡
  public :: analysis_record_data

<Analysis: procedures>+≡
  subroutine analysis_record_data (id, x, y, yerr, xerr, &
    weight, excess, success, exist)
    type(string_t), intent(in) :: id
    real(default), intent(in) :: x
    real(default), intent(in), optional :: y, yerr, xerr, weight, excess
    logical, intent(out), optional :: success, exist
    type(analysis_object_t), pointer :: obj
    obj => analysis_store_get_object_ptr (id)
    if (associated (obj)) then
      call analysis_object_record_data (obj, x, y, yerr, xerr, &
        weight, excess, success)
      if (present (exist)) exist = .true.
    else
      if (present (success)) success = .false.
      if (present (exist)) exist = .false.
    end if
  end subroutine analysis_record_data

```

Build a graph

This routine sets up the array of graph elements by copying the graph elements given as input. The object must exist and already be initialized as a graph.

```
<Analysis: public>+≡
    public :: analysis_fill_graph

<Analysis: procedures>+≡
    subroutine analysis_fill_graph (id, i, id_in, drawing_options)
        type(string_t), intent(in) :: id
        integer, intent(in) :: i
        type(string_t), intent(in) :: id_in
        type(drawing_options_t), intent(in), optional :: drawing_options
        type(analysis_object_t), pointer :: obj

```

5.2 PDG arrays

For defining aliases, we introduce a special type which holds a set of (integer) PDG codes.

```
<pdg_arrays.f90>≡  
<File header>  
  
module pdg_arrays  
  
<Use file utils>  
  
<Standard module head>  
  
<PDG arrays: public>  
  
<PDG arrays: parameters>  
  
<PDG arrays: types>  
  
<PDG arrays: interfaces>  
  
contains  
  
<PDG arrays: procedures>  
  
end module pdg_arrays
```

5.2.1 Type definition

Using an allocatable array eliminates the need for initializer and/or finalizer.

```
<PDG arrays: public>≡  
public :: pdg_array_t  
  
<PDG arrays: types>≡  
type :: pdg_array_t  
private  
integer, dimension(:), allocatable :: pdg  
end type pdg_array_t
```

Output

```
<PDG arrays: public>+≡  
public :: pdg_array_write  
  
<PDG arrays: procedures>≡  
subroutine pdg_array_write (aval, unit)  
type(pdg_array_t), intent(in) :: aval  
integer, intent(in), optional :: unit  
integer :: u, i  
u = output_unit (unit); if (u < 0) return  
write (u, "(A)", advance="no") "PDG("  
if (allocated (aval%pdg)) then  
do i = 1, size (aval%pdg)  
if (i > 1) write (u, "(A)", advance="no") " , "
```

```

        write (u, "(I0)", advance="no")  aval%pdg(i)
    end do
end if
write (u, "(A)", advance="no")  ")"
end subroutine pdg_array_write

```

5.2.2 Parameters

We need an UNDEFINED value:

```

⟨PDG arrays: parameters⟩≡
    integer, parameter, public :: UNDEFINED = 0

```

5.2.3 Basic operations

Assignment. We define assignment from and to an integer array. Note that the integer array, if it is the l.h.s., must be declared allocatable by the caller.

```

⟨PDG arrays: public⟩+=
    public :: assignment(=)

⟨PDG arrays: interfaces⟩≡
    interface assignment(=)
        module procedure pdg_array_from_int_array
        module procedure pdg_array_from_int
        module procedure int_array_from_pdg_array
    end interface

⟨PDG arrays: procedures⟩+=
    subroutine pdg_array_from_int_array (aval, iarray)
        type(pdg_array_t), intent(out) :: aval
        integer, dimension(:), intent(in) :: iarray
        allocate (aval%pdg (size (iarray)))
        aval%pdg = iarray
    end subroutine pdg_array_from_int_array

    elemental subroutine pdg_array_from_int (aval, int)
        type(pdg_array_t), intent(out) :: aval
        integer, intent(in) :: int
        allocate (aval%pdg (1))
        aval%pdg = int
    end subroutine pdg_array_from_int

    subroutine int_array_from_pdg_array (iarray, aval)
        integer, dimension(:), allocatable, intent(out) :: iarray
        type(pdg_array_t), intent(in) :: aval
        if (allocated (aval%pdg)) then
            allocate (iarray (size (aval%pdg)))
            iarray = aval%pdg
        else
            allocate (iarray (0))
        end if
    end subroutine int_array_from_pdg_array

```

The only nontrivial operation: concatenate two PDG arrays

```

(PDG arrays: public)+≡
    public :: operator(//)

(PDG arrays: interfaces)+≡
    interface operator(//)
        module procedure concat_pdg_arrays
    end interface

(PDG arrays: procedures)+≡
    function concat_pdg_arrays (aval1, aval2) result (aval)
        type(pdg_array_t) :: aval
        type(pdg_array_t), intent(in) :: aval1, aval2
        integer :: n1, n2
        if (allocated (aval1%pdg) .and. allocated (aval2%pdg)) then
            n1 = size (aval1%pdg)
            n2 = size (aval2%pdg)
            allocate (aval%pdg (n1 + n2))
            aval%pdg(:n1) = aval1%pdg
            aval%pdg(n1+1:) = aval2%pdg
        else if (allocated (aval1%pdg)) then
            aval = aval1
        else if (allocated (aval2%pdg)) then
            aval = aval2
        end if
    end function concat_pdg_arrays

```

5.2.4 Matching

A PDG array matches a given PDG code if the code is present within the array. If either one is zero (UNDEFINED), the match also succeeds.

```

(PDG arrays: public)+≡
    public :: operator(.match.)

(PDG arrays: interfaces)+≡
    interface operator(.match.)
        module procedure pdg_array_match_integer
    end interface

(PDG arrays: procedures)+≡
    elemental function pdg_array_match_integer (aval, pdg) result (flag)
        logical :: flag
        type(pdg_array_t), intent(in) :: aval
        integer, intent(in) :: pdg
        if (allocated (aval%pdg)) then
            flag = pdg == UNDEFINED &
                .or. any (aval%pdg == UNDEFINED) &
                .or. any (aval%pdg == pdg)
        else
            flag = .false.
        end if
    end function pdg_array_match_integer

```

Equivalence. Two PDG arrays are equivalent if either both contain UNDEFINED or each element of array 1 is present in array 2, and vice versa.

```

(PDG arrays: public)+≡
    public :: operator(.eqv.)
    public :: operator(.neqv.)

(PDG arrays: interfaces)+≡
    interface operator(.eqv.)
        module procedure pdg_array_equivalent
    end interface
    interface operator(.neqv.)
        module procedure pdg_array_inequivalent
    end interface

(PDG arrays: procedures)+≡
    function pdg_array_equivalent (aval1, aval2) result (eq)
        logical :: eq
        type(pdg_array_t), intent(in) :: aval1, aval2
        logical, dimension(:), allocatable :: match1, match2
        integer :: i
        if (allocated (aval1%pdg) .and. allocated (aval2%pdg)) then
            eq = any (aval1%pdg == UNDEFINED) &
                .and. any (aval2%pdg == UNDEFINED)
            if (.not. eq) then
                allocate (match1 (size (aval1%pdg)))
                allocate (match2 (size (aval2%pdg)))
                match1 = .false.
                match2 = .false.
                do i = 1, size (aval1%pdg)
                    match2 = match2 .or. aval1%pdg(i) == aval2%pdg
                end do
                do i = 1, size (aval2%pdg)
                    match1 = match1 .or. aval2%pdg(i) == aval1%pdg
                end do
                eq = all (match1) .and. all (match2)
            end if
        else
            eq = .false.
        end if
    end function pdg_array_equivalent

    function pdg_array_inequivalent (aval1, aval2) result (neq)
        logical :: neq
        type(pdg_array_t), intent(in) :: aval1, aval2
        neq = .not. pdg_array_equivalent (aval1, aval2)
    end function pdg_array_inequivalent

```

5.3 subevents

The purpose of subevents is to store the relevant part of the physical event (either partonic or hadronic), and to hold particle selections and combinations which are constructed in cut or analysis expressions.

```
<subevents.f90>≡  
  <File header>  
  
  module subevents  
  
    use iso_c_binding !NODEP!  
    <Use kinds>  
    <Use file utils>  
    use c_particles !NODEP!  
    use lorentz !NODEP!  
    use sorting  
    use pdg_arrays  
  
    <Standard module head>  
  
    <Subevents: public>  
  
    <Subevents: parameters>  
  
    <Subevents: types>  
  
    <Subevents: interfaces>  
  
    contains  
  
    <Subevents: procedures>  
  
  end module subevents
```

5.3.1 Particles

For the purpose of this module, a particle has a type which can indicate a beam, incoming, outgoing, or composite particle, flavor and helicity codes (integer, undefined for composite), four-momentum and invariant mass squared. (Other particles types are used in extended event types, but also defined here.) Furthermore, each particle has an allocatable array of ancestors – particle indices which indicate the building blocks of a composite particle. For an incoming/outgoing particle, the array contains only the index of the particle itself.

For incoming particles, the momentum is inverted before storing it in the particle object.

```
<Subevents: parameters>≡  
  integer, parameter, public :: PRT_UNDEFINED = 0  
  integer, parameter, public :: PRT_BEAM = -9  
  integer, parameter, public :: PRT_INCOMING = 1  
  integer, parameter, public :: PRT_OUTGOING = 2  
  integer, parameter, public :: PRT_COMPOSITE = 3  
  integer, parameter, public :: PRT_VIRTUAL = 4
```

```
integer, parameter, public :: PRT_RESONANT = 5
integer, parameter, public :: PRT_BEAM_REMNANT = 9
```

The type

We initialize only the type here and mark as unpolarized. The initializers below do the rest.

```
<Subevents: public>≡
  public :: prt_t

<Subevents: types>≡
  type :: prt_t
    private
    integer :: type = PRT_UNDEFINED
    integer :: pdg
    logical :: polarized = .false.
    integer :: h
    type(vector4_t) :: p
    real(default) :: p2
    integer, dimension(:), allocatable :: src
  end type prt_t
```

Initializers. Polarization is set separately. Finalizers are not needed.

```
<Subevents: procedures>≡
  subroutine prt_init_beam (prt, pdg, p, p2, src)
    type(prt_t), intent(out) :: prt
    integer, intent(in) :: pdg
    type(vector4_t), intent(in) :: p
    real(default), intent(in) :: p2
    integer, dimension(:), intent(in) :: src
    prt%type = PRT_BEAM
    call prt_set (prt, pdg, - p, p2, src)
  end subroutine prt_init_beam

  subroutine prt_init_incoming (prt, pdg, p, p2, src)
    type(prt_t), intent(out) :: prt
    integer, intent(in) :: pdg
    type(vector4_t), intent(in) :: p
    real(default), intent(in) :: p2
    integer, dimension(:), intent(in) :: src
    prt%type = PRT_INCOMING
    call prt_set (prt, pdg, - p, p2, src)
  end subroutine prt_init_incoming

  subroutine prt_init_outgoing (prt, pdg, p, p2, src)
    type(prt_t), intent(out) :: prt
    integer, intent(in) :: pdg
    type(vector4_t), intent(in) :: p
    real(default), intent(in) :: p2
    integer, dimension(:), intent(in) :: src
    prt%type = PRT_OUTGOING
    call prt_set (prt, pdg, p, p2, src)
```

```

end subroutine prt_init_outgoing

subroutine prt_init_composite (prt, p, src)
  type(prt_t), intent(out) :: prt

Setting data

Set the PDG, momentum and momentum squared, and ancestors. If allocation-assignment is available, this can be simplified.

```

<Subevents: procedures>+≡
    subroutine prt_set (prt, pdg, p, p2, src)
        type(prt_t), intent(inout) :: prt
        integer, intent(in) :: pdg
        type(vector4_t), intent(in) :: p
        real(default), intent(in) :: p2
        integer, dimension(:), intent(in) :: src
        prt%pdg = pdg
        prt%p = p
        prt%p2 = p2
        if (allocated (prt%src)) then
            if (size (src) /= size (prt%src)) then
                deallocate (prt%src)
                allocate (prt%src (size (src)))
            end if
        else
            allocate (prt%src (size (src)))
        end if
        prt%src = src
    end subroutine prt_set

```

Set the particle PDG code separately.

```

<Subevents: procedures>+≡
    elemental subroutine prt_set_pdg (prt, pdg)
        type(prt_t), intent(inout) :: prt

```

```

        integer, intent(in) :: pdg
        prt%pdg = pdg
    end subroutine prt_set_pdg

```

Set the momentum separately.

```

<Subevents: procedures>+≡
    elemental subroutine prt_set_p (prt, p)
        type(prt_t), intent(inout) :: prt
        type(vector4_t), intent(in) :: p
        prt%p = p
    end subroutine prt_set_p

```

Set the squared invariant mass separately.

```

<Subevents: procedures>+≡
    elemental subroutine prt_set_p2 (prt, p2)
        type(prt_t), intent(inout) :: prt
        real(default), intent(in) :: p2
        prt%p2 = p2
    end subroutine prt_set_p2

```

Set helicity (optional).

```

<Subevents: procedures>+≡
    subroutine prt_polarize (prt, h)
        type(prt_t), intent(inout) :: prt

      write (u, "(1x,I0)", advance="no") prt%src(i)
    end do
  end if
  write (u, "(A)" ) " "
end subroutine prt_write

```

Tools

Two particles match if their `src` arrays are the same.

```
<Subevents: interfaces>+≡
  interface operator(.match.)
    module procedure prt_match
  end interface

<Subevents: procedures>+≡
  elemental function prt_match (prt1, prt2) result (match)
    logical :: match
    type(prt_t), intent(in) :: prt1, prt2
    if (size (prt1%src) == size (prt2%src)) then
      match = all (prt1%src == prt2%src)
    else
      match = .false.
    end if
  end function prt_match
```

The combine operation makes a pseudoparticle whose momentum is the result of adding (the momenta of) the pair of input particles. We trace the particles from which a particle is built by storing a `src` array. Each particle entry in the `src` list contains a list of indices which indicates its building blocks. The indices refer to an original list of particles. Index lists are sorted, and they contain no element more than once.

We thus require that in a given pseudoparticle, each original particle occurs at most once.

The result is intent(inout), so it will not be initialized when the subroutine is entered.

```
<Subevents: procedures>+≡
  subroutine prt_combine (prt, prt_in1, prt_in2, ok)
    type(prt_t), intent(inout) :: prt
    type(prt_t), intent(in) :: prt_in1, prt_in2
    logical :: ok
    integer, dimension(:), allocatable :: src
    call combine_index_lists (src, prt_in1%src, prt_in2%src)
    ok = allocated (src)
    if (ok) call prt_init_composite (prt, prt_in1%p + prt_in2%p, src)
  end subroutine prt_combine
```

This variant does not produce the combined particle, it just checks whether the combination is valid (no common `src` entry).

```
<Subevents: public>+≡
  public :: are_disjoint

<Subevents: procedures>+≡
  function are_disjoint (prt_in1, prt_in2) result (flag)
    logical :: flag
    type(prt_t), intent(in) :: prt_in1, prt_in2
    flag = index_lists_are_disjoint (prt_in1%src, prt_in2%src)
  end function are_disjoint
```

`src` Lists with length > 1 are built by a `combine` operation which merges the lists in a sorted manner. If the result would have a duplicate entry, it is discarded, and the result is unallocated.

(Subevents: procedures)+≡

```
subroutine combine_index_lists (res, src1, src2)
  integer, dimension(:), intent(in) :: src1, src2
  integer, dimension(:), allocatable :: res
  integer :: i1, i2, i
  allocate (res (size (src1) + size (src2)))
  i1 = 1
  i2 = 1
  LOOP: do i = 1, size (res)
    if (src1(i1) < src2(i2)) then
      res(i) = src1(i1); i1 = i1 + 1
      if (i1 > size (src1)) then
        res(i+1:) = src2(i2:)
        exit LOOP
      end if
    else if (src1(i1) > src2(i2)) then
      res(i) = src2(i2); i2 = i2 + 1
      if (i2 > size (src2)) then
        res(i+1:) = src1(i1:)
        exit LOOP
      end if
    else
      deallocate (res)
      exit LOOP
    end if
  end do LOOP
end subroutine combine_index_lists
```

This function is similar, but it does not actually merge the list, it just checks whether they are disjoint (no common `src` entry).

(Subevents: procedures)+≡

```
function index_lists_are_disjoint (src1, src2) result (flag)
  logical :: flag
  integer, dimension(:), intent(in) :: src1, src2
  integer :: i1, i2, i
  flag = .true.
  i1 = 1
  i2 = 1
  LOOP: do i = 1, size (src1) + size (src2)
    if (src1(i1) < src2(i2)) then
      i1 = i1 + 1
      if (i1 > size (src1)) then
        exit LOOP
      end if
    else if (src1(i1) > src2(i2)) then
      i2 = i2 + 1
      if (i2 > size (src2)) then
        exit LOOP
      end if
    else
      exit LOOP
    end if
  end do LOOP
end function index_lists_are_disjoint
```

```

        flag = .false.
        exit LOOP
    end if
end do LOOP
end function index_lists_are_disjoint

```

5.3.2 C-compatible particle type

5.3.3 subevents

Particles are collected in subevents. This type is implemented as a dynamically allocated array, which need not be completely filled. The value `n_active` determines the number of meaningful entries.

Type definition

```

<Subevents: public>+≡
    public :: subevt_t

<Subevents: types>+≡
    type :: subevt_t
    private
        integer :: n_active = 0
        type(prt_t), dimension(:), allocatable :: prt
    contains
        <Subevents: subevt: TBP>
    end type subevt_t

```

Initialize, allocating with size zero (default) or given size. The number of contained particles is set equal to the size.

```

<Subevents: public>+≡
    public :: subevt_init

<Subevents: procedures>+≡
    subroutine subevt_init (subevt, n_active)
        type(subevt_t), intent(out) :: subevt
        integer, intent(in), optional :: n_active
        if (present (n_active)) subevt%n_active = n_active
        allocate (subevt%prt (subevt%n_active))
    end subroutine subevt_init

```

(Re-)allocate the subevent with some given size. If the size is greater than the previous one, do a real reallocation. Otherwise, just reset the recorded size. Contents are untouched, but become invalid.

```

<Subevents: public>+≡
    public :: subevt_reset

```

```

<Subevents: procedures>+≡
  subroutine subevt_reset (subevt, n_active)
    type(subevt_t), intent(inout) :: subevt
    integer, intent(in) :: n_active
    subevt%n_active = n_active
    if (subevt%n_active > size (subevt%prt)) then
      deallocate (subevt%prt)
      allocate (subevt%prt (subevt%n_active))
    end if
  end subroutine subevt_reset

```

Output. No prefix for the headline 'subevt', because this will usually be printed appending to a previous line.

```

<Subevents: public>+≡
  public :: subevt_write

<Subevents: subevt: TBP>≡
  procedure :: write => subevt_write

<Subevents: procedures>+≡
  subroutine subevt_write (object, unit, prefix)
    class(subevt_t), intent(in) :: object
    integer, intent(in), optional :: unit
    character(*), intent(in), optional :: prefix
    integer :: u, i
    u = output_unit (unit); if (u < 0) return
    write (u, "(1x,A)") "subevent:"
    do i = 1, object%n_active
      if (present (prefix)) write (u, "(A)", advance="no") prefix
      write (u, "(1x,I0)", advance="no") i
      call prt_write (object%prt(i), unit)
    end do
  end subroutine subevt_write

```

Defined assignment: transfer only meaningful entries. This is a deep copy (as would be default assignment).

```

<Subevents: interfaces>+≡
  interface assignment(=)
    module procedure subevt_assign
  end interface

<Subevents: procedures>+≡
  subroutine subevt_assign (subevt, subevt_in)
    type(subevt_t), intent(inout) :: subevt
    type(subevt_t), intent(in) :: subevt_in
    if (.not. allocated (subevt%prt)) then
      call subevt_init (subevt, subevt_in%n_active)
    else
      call subevt_reset (subevt, subevt_in%n_active)
    end if
    subevt%prt(:subevt%n_active) = subevt_in%prt(:subevt%n_active)
  end subroutine subevt_assign

```

Fill contents

Store incoming/outgoing particles which are completely defined.

```

Operations with subevents

The join operation joins two subevents. When appending the elements of the second list, we check for each particle whether it is already in the first list. If yes, it is discarded. The result list should be initialized already.

If a mask is present, it refers to the second subevent. Particles where the mask is not set are discarded.

<Subevents: public>+≡

```

public :: subevt_join

```

<Subevents: procedures>+≡

```

subroutine subevt_join (subevt, pl1, pl2, mask2)
  type(subevt_t), intent(inout) :: subevt
  type(subevt_t), intent(in) :: pl1, pl2
  logical, dimension(:), intent(in), optional :: mask2
  integer :: n1, n2, i, n
  n1 = pl1%n_active
  n2 = pl2%n_active
  call subevt_reset (subevt, n1 + n2)
  subevt%prt(:n1) = pl1%prt(:n1)
  n = n1
  if (present (mask2)) then
    do i = 1, pl2%n_active
      if (mask2(i)) then
        if (disjoint (i)) then
          n = n + 1
          subevt%prt(n) = pl2%prt(i)
        end if
      end if
    end do
  end if

```

```

        end if
    end do
else
    do i = 1, pl2%n_active
        if (disjoint (i)) then
            n = n + 1
            subevt%prt(n) = pl2%prt(i)
        end if
    end do
end if
subevt%n_active = n
contains
function disjoint (i) result (flag)
    integer, intent(in) :: i
    logical :: flag
    integer :: j
    do j = 1, pl1%n_active
        if (.not. are_disjoint (pl1%prt(j), pl2%prt(i))) then
            flag = .false.
            return
        end if
    end do
    flag = .true.
end function disjoint
end subroutine subevt_join

```

The combine operation makes a subevent whose entries are the result of adding (the momenta of) each pair of particles in the input lists. We trace the particles from which a particle is built by storing a `src` array. Each particle entry in the `src` list contains a list of indices which indicates its building blocks. The indices refer to an original list of particles. Index lists are sorted, and they contain no element more than once.

We thus require that in a given pseudoparticle, each original particle occurs at most once.

<Subevents: public>+≡

```
public :: subevt_combine
```

<Subevents: procedures>+≡

```

subroutine subevt_combine (subevt, pl1, pl2, mask12)
    type(subevt_t), intent(inout) :: subevt
    type(subevt_t), intent(in) :: pl1, pl2
    logical, dimension(:,,:), intent(in), optional :: mask12
    integer :: n1, n2, i1, i2, n, j
    logical :: ok
    n1 = pl1%n_active
    n2 = pl2%n_active
    call subevt_reset (subevt, n1 * n2)
    n = 1
    do i1 = 1, n1
        do i2 = 1, n2
            if (present (mask12)) then
                ok = mask12(i1,i2)
            else

```

```

        ok = .true.
    end if
    if (ok) call prt_combine &
        (subevt%prt(n), pl1%prt(i1), pl2%prt(i2), ok)
    if (ok) then
        CHECK_DOUBLES: do j = 1, n - 1
            if (subevt%prt(n) .match. subevt%prt(j)) then
                ok = .false.; exit CHECK_DOUBLES
            end if
        end do CHECK_DOUBLES
        if (ok) n = n + 1
    end if
end do
subevt%n_active = n - 1
end subroutine subevt_combine

```

The collect operation makes a single-entry subevent which results from combining (the momenta of) all particles in the input list. As above, the result does not contain an original particle more than once; this is checked for each particle when it is collected. Furthermore, each entry has a mask; where the mask is false, the entry is dropped.

(Thus, if the input particles are already composite, there is some chance that the result depends on the order of the input list and is not as expected. This situation should be avoided.)

```

<Subevents: public>+≡
    public :: subevt_collect

<Subevents: procedures>+≡
    subroutine subevt_collect (subevt, pl1, mask1)
        type(subevt_t), intent(inout) :: subevt

    j = 0
    do i = 1, n_active
        if (mask(i)) then
            j = j + 1
            subevt%prt(j) = subevt_in%prt(i)
        end if
    end do
end subroutine subevt_select_pdg_code

```

5.3.4 Eliminate numerical noise

This is useful for testing purposes: set entries to zero that are smaller in absolute values than a given tolerance parameter.

```

<Subevents: public>+≡
    public :: pacify

<Subevents: interfaces>+≡
    interface pacify
        module procedure pacify_prt
        module procedure pacify_subevt
    end interface pacify

<Subevents: procedures>+≡
    subroutine pacify_prt (prt)
        class(prt_t), intent(inout) :: prt
        real(default) :: e
        e = epsilon (1._default) * energy (prt%p)
        call pacify (prt%p, 10 * e)
        call pacify (prt%p2, 1e4 * e)
    end subroutine pacify_prt

    subroutine pacify_subevt (subevt)
        class(subevt_t), intent(inout) :: subevt
        integer :: i
        do i = 1, subevt%n_active
            call pacify (subevt%prt(i))
        end do
    end subroutine pacify_subevt

```

5.4 User Code Interface

Here we collect interface code that enables the user to inject his own code into the WHIZARD workflow. The code uses data types defined above, and is

referenced in the `expressions` module.

```
<user_code_interface.f90>≡  
  <File header>  
  
  module user_code_interface  
  
    use iso_c_binding !NODEP!  
    <Use kinds>  
    <Use strings>  
    use diagnostics !NODEP!  
    use c_particles !NODEP!  
    use os_interface  
  
    <Standard module head>  
  
    <User Code: public>  
  
    <User Code: variables>  
  
    <User Code: interfaces>  
  
    contains  
  
    <User Code: procedures>  
  
  end module user_code_interface
```

5.4.1 User Code Management

This data structure globally holds the filehandle of the user-code library:

```
<User Code: public>≡  
  public :: has_user_lib  
  
<User Code: variables>≡  
  type(dlaccess_t), save :: user_lib_handle  
  logical, save :: has_user_lib = .false.  
  type(string_t), save :: user
```

Compile, link and load user code files. Dlopen all user-provided libraries, included the one just compiled (if any).

By default, we are looking for a library `user.so`. If this is not present, try `user.f90` and compile it. This can be overridden.

In detail: First, compile all sources explicitly specified on the command line. Then collect all libraries specified on the command line, including `user.so` if it was generated. If there is still no code, check for an existing `user.f90` and compile this. Link everything into a `user.la` libtool library. When done, dlopen all libraries that we have so far.

```
<User Code: public>+≡  
  public :: user_code_init
```

```

{User Code: procedures}≡
subroutine user_code_init (user_src, user_lib, user_target, rebuild, os_data)
  type(string_t), dimension(:), intent(in) :: user_src, user_lib
  type(string_t), intent(in) :: user_target
  logical, intent(in) :: rebuild
  type(os_data_t), intent(in) :: os_data
  type(string_t) :: user_src_file, user_obj_files, user_lib_file
  logical :: exist
  type(c_funptr) :: fptr

                    // "' called without user library (missing -u flag?)")  
            end if  
        end if  
    end function user_code_find_proc
```

5.4.2 Libmanager interface

This is the interface to the libmanager library. The libmanager is generated when a static executable is built. The definitions are in Sec. 14.4.

```
<User Code: interfaces>=  
    <Libmanager: interfaces>  
  
<Libmanager: interfaces>=  
    interface  
        function libmanager_get_n_libs () result (n)  
            integer :: n  
        end function libmanager_get_n_libs  
    end interface
```

```

<Libmanager: interfaces>+≡
interface
  function libmanager_get_libname (i) result (name)
    use iso_varying_string, string_t => varying_string !NODEP!
    type(string_t) :: name
    integer, intent(in) :: i
  end function libmanager_get_libname
end interface

<Libmanager: interfaces>+≡
interface
  function libmanager_get_c_funptr (libname, fname) result (c_fptr)
    use iso_c_binding !NODEP!
    type(c_funptr) :: c_fptr
    character(*), intent(in) :: libname, fname
  end function libmanager_get_c_funptr
end interface

```

5.4.3 Interfaces for user-defined functions

The following functions represent user-defined real observables. There may be one or two particles as argument, the result is a real value.

```

<User Code: public>+≡
public :: user_obs_int_unary
public :: user_obs_int_binary
public :: user_obs_real_unary
public :: user_obs_real_binary

<User Code: interfaces>+≡
abstract interface
  function user_obs_int_unary (prt1) result (ival) bind(C)
    use iso_c_binding !NODEP!
    use c_particles !NODEP!
    type(c_prt_t), intent(in) :: prt1
    integer(c_int) :: ival
  end function user_obs_int_unary
end interface

abstract interface
  function user_obs_int_binary (prt1, prt2) result (ival) bind(C)
    use iso_c_binding !NODEP!
    use c_particles !NODEP!
    type(c_prt_t), intent(in) :: prt1, prt2
    integer(c_int) :: ival
  end function user_obs_int_binary
end interface

abstract interface
  function user_obs_real_unary (prt1) result (rval) bind(C)
    use iso_c_binding !NODEP!
    use c_particles !NODEP!
    type(c_prt_t), intent(in) :: prt1

```

```

        real(c_double) :: rval
    end function user_obs_real_unary
end interface

abstract interface
    function user_obs_real_binary (prt1, prt2) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        real(c_double) :: rval
    end function user_obs_real_binary
end interface

```

The following function takes an array of C-compatible particles and return a single value. The particle array represents a subevent. For C interoperability, we have to use an assumed-size array, hence the array size has to be transferred explicitly.

The cut function returns an `int`, which we should interpret as a logical value (`nonzero=true`).

```

<User Code: public>+≡
    public :: user_cut_fun

<User Code: interfaces>+≡
    abstract interface
        function user_cut_fun (prt, n_prt) result (iflag) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt
            integer(c_int), intent(in) :: n_prt
            integer(c_int) :: iflag
        end function user_cut_fun
    end interface

```

The event-shape function returns a real value.

```

<User Code: public>+≡
    public :: user_event_shape_fun

<User Code: interfaces>+≡
    abstract interface
        function user_event_shape_fun (prt, n_prt) result (rval) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt
            integer(c_int), intent(in) :: n_prt
            real(c_double) :: rval
        end function user_event_shape_fun
    end interface

```

5.4.4 Interfaces for user-defined interactions

The following procedure interfaces pertain to user-defined interactions, e.g., spectra or structure functions.

This subroutine retrieves the basic information for setting up the interaction and event generation. All parameters are `intent(inout)`, so we can provide default values. `n_in` and `n_out` are the number of incoming and outgoing particles, respectively. `n_states` is the total number of distinct states that should be generated (counting all states of the incoming particles). `n_col` is the maximal number of color entries a particle can have. `n_dim` is the number of input parameters, i.e., integration dimensions, that the structure function call requires for computing kinematics and matrix elements. `n_var` is the number of variables (e.g., momentum fractions) that the structure function call has to transfer from the kinematics to the dynamics evaluation.

```

<User Code: public>+≡
  public :: user_int_info

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_info (n_in, n_out, n_states, n_col, n_dim, n_var) &
      bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(inout) :: n_in, n_out, n_states, n_col
      integer(c_int), intent(inout) :: n_dim, n_var
    end subroutine user_int_info
  end interface

```

This subroutine retrieves the settings for the quantum number mask of a given particle index in the interaction. A nonzero value indicates that the corresponding quantum number is to be ignored. The lock index is the index of a particle that the current particle is related to. The relation applies if quantum numbers of one of the locked particles are summed over. (This is intended for helicity.)

```

<User Code: public>+≡
  public :: user_int_mask

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_mask (i_prt, m_flv, m_hel, m_col, i_lock) bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(in) :: i_prt
      integer(c_int), intent(inout) :: m_flv, m_hel, m_col, i_lock
    end subroutine user_int_mask
  end interface

```

This subroutine retrieves the quantum numbers for the particle index `i_prt` in state `i_state`. The `flv` value is a PDG code. The `hel` value is an integer helicity (twice the helicity for fermions). The `col` array is an array which has at most `n_col` entries (see above). All parameters are `intent(inout)` since default values exist. In particular, if a mask entry is set by the previous procedure, the corresponding quantum number is ignored anyway.

```

<User Code: public>+≡
  public :: user_int_state

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_state (i_state, i_prt, flv, hel, col) bind(C)

```

```

        use iso_c_binding !NODEP!
        integer(c_int), intent(in) :: i_state, i_prt
        integer(c_int), intent(inout) :: flv, hel
        integer(c_int), dimension(*), intent(inout) :: col
    end subroutine user_int_state
end interface

```

This subroutine takes an array of particle objects with array length `n_in` and an array of input parameters between 0 and 1 with array length `n_dim`. It returns an array of particle objects with array length `n_out`. In addition, it returns an array of internal variables (e.g., momentum fractions, Jacobian) with array length `n_var` that is used by the following subroutine for evaluating the dynamics, i.e., the matrix elements.

```

<User Code: public>+≡
    public :: user_int_kinematics

<User Code: interfaces>+≡
    abstract interface
        subroutine user_int_kinematics (prt_in, rval, prt_out, xval) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt_in
            real(c_double), dimension(*), intent(in) :: rval
            type(c_prt_t), dimension(*), intent(inout) :: prt_out
            real(c_double), dimension(*), intent(out) :: xval
        end subroutine user_int_kinematics
    end interface

```

This subroutine takes the array of variables (e.g., momentum fractions) with length `n_var` which has been generated by the previous subroutine and a real variable, the energy scale of the event. It returns an array of matrix-element values, one entry for each quantum state `n_states`. The ordering of matrix elements must correspond to the ordering of states.

```

<User Code: public>+≡
    public :: user_int_evaluate

<User Code: interfaces>+≡
    abstract interface
        subroutine user_int_evaluate (xval, scale, fval) bind(C)
            use iso_c_binding !NODEP!
            real(c_double), dimension(*), intent(in) :: xval
            real(c_double), intent(in) :: scale
            real(c_double), dimension(*), intent(out) :: fval
        end subroutine user_int_evaluate
    end interface

```

5.5 Variables

The user interface deals with variables that are handled similar to full-fledged programming languages. The system will add a lot of predefined variables

(model parameters, flags, etc.) that are accessible to the user by the same methods.

Variables can be of various type: logical (boolean/flag), integer, real (default precision), subevents (used in cut expressions), arrays of PDG codes (aliases for particles), strings. Furthermore, in cut expressions we have unary and binary observables, which are used like real parameters but behave like functions.

```

<variables.f90>≡
  <File header>

  module variables

    <Use kinds>
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use lorentz !NODEP!
    use pdg_arrays
    use subevents

    <Standard module head>

    <Variables: public>

    <Variables: parameters>

    <Variables: types>

    <Variables: interfaces>

    contains

    <Variables: procedures>

  end module variables

```

5.5.1 Variable list entries

Variable (and constant) values can be of one of the following types:

```

<Variables: parameters>≡
  integer, parameter, public :: V_NONE = 0, V_LOG = 1, V_INT = 2, V_REAL = 3
  integer, parameter, public :: V_CMLPX = 4, V_SEV = 5, V_PDG = 6, V_STR = 7
  integer, parameter, public :: V_OBS1_INT = 11, V_OBS2_INT = 12
  integer, parameter, public :: V_OBS1_REAL = 21, V_OBS2_REAL = 22
  integer, parameter, public :: V_UOBS1_INT = 31, V_UOBS2_INT = 32
  integer, parameter, public :: V_UOBS1_REAL = 41, V_UOBS2_REAL = 42

```

The type

This is an entry in the variable list. It can be of any type; in each case only one value is allocated. It may be physically allocated upon creation, in which case

`is_allocated` is true, or it may contain just a pointer to a value somewhere else, in which case `is_allocated` is false.

The flag `is_defined` is set when the variable is given a value, even the undefined value. (Therefore it is distinct from `is_known`.) This matters for variable declaration in the SINDARIN language. The variable is set up in the compilation step and initially marked as defined, but after compilation all variables are set undefined. Each variable becomes defined when it is explicitly set. The difference matters in loops.

`is_locked` means that it cannot be given a value using the interface routines `var_list_set_XXX` below. It can only be initialized, or change automatically due to a side effect.

`is_copy` means that this is a local copy of a global variable. The copy has a pointer to the original, which can be used to restore a previous value.

`is_intrinsic` means that this variable is defined by the program, not by the user. Intrinsic variables cannot be (re)declared, but their values can be reset unless they are locked. `is_user_var` means that the variable has been declared by the user. It could be a new variable, or a local copy of an intrinsic variable.

The flag `is_known` is a pointer which parallels the use of the value pointer. For pointer variables, it is set if the value should point to a known value. For ordinary variables, it should be true.

The value is implemented as a set of alternative type-specific pointers. This emulates polymorphism, and it allows for actual pointer variables. Observable-type variables have function pointers as values, so they behave like macros. The functions make use of the particle objects accessible via the pointers `p1` and `p2`.

Finally, the `next` pointer indicates that we are making lists of variables. A more efficient implementation might switch to hashes or similar; the current implementation has $O(N)$ lookup.

```

<Variables: public>≡
    public :: var_entry_t

<Variables: types>≡
    type :: var_entry_t
    private
    integer :: type = V_NONE
    type(string_t) :: name

5.5.3 Copies and pointer variables

Initialize an entry with a copy of an existing variable entry. The copy is physically allocated with the same type as the original.

(Variables: procedures)+≡

```

subroutine var_entry_init_copy (var, original, user)
type(var_entry_t), intent(out) :: var
type(var_entry_t), intent(in), target :: original
logical, intent(in), optional :: user
type(string_t) :: name

```

```

logical :: intrinsic
name = var_entry_get_name (original)
intrinsic = original%is_intrinsic
select case (original%type)
case (V_LOG)
    call var_entry_init_log (var, name, intrinsic=intrinsic, user=user)
case (V_INT)
    call var_entry_init_int (var, name, intrinsic=intrinsic, user=user)
case (V_REAL)
    call var_entry_init_real (var, name, intrinsic=intrinsic, user=user)
case (V_CMPLX)
    call var_entry_init_cmplx (var, name, intrinsic=intrinsic, user=user)
case (V_SEV)
    call var_entry_init_subevt (var, name, intrinsic=intrinsic, user=user)
case (V_PDG)
    call var_entry_init_pdg_array (var, name, intrinsic=intrinsic, user=user)
case (V_STR)
    call var_entry_init_string (var, name, intrinsic=intrinsic, user=user)
end select
var%is_copy = .true.
end subroutine var_entry_init_copy

```

Clear the pointer to the original.

```

<Variables: procedures> +=
subroutine var_entry_clear_original_pointer (var)
    type(var_entry_t), intent(inout) :: var
    var%original => null ()
end subroutine var_entry_clear_original_pointer

```

Set the pointer to the original. For a free parameter, the variable holds both the value and the pointer. For a derived parameter, we associate the pointer directly. Derived parameters thus need not be synchronized explicitly.

Update: this does not work. If locked parameters are accessed in expressions and the model is non-default, the pointers in the expression may be undefined at compile time. Reassigning the variables at runtime does not help, since the pointers in the expression are dereferenced before assignment. Hence, no special treatment for derived parameters.

```

<Variables: procedures> +=
subroutine var_entry_set_original_pointer (var, original)
    type(var_entry_t), intent(inout) :: var
    type(var_entry_t), intent(in), target :: original
    type(string_t) :: name
    type(var_entry_t), pointer :: next

        case (V_STR);  var%sval = var%original%sval
      end select
    end if
  end if
end subroutine var_entry_synchronize

```

Restore the previous value of the original, using the value stored in the variable. This is a side-effect operation.

(Variables: procedures)+≡

```

subroutine var_entry_restore (var)
  type(var_entry_t), intent(inout) :: var
  !!! ifort 11.1 rev5 chokes over the intent(in)
  !!! type(var_entry_t), intent(in) :: var
  if (associated (var%original)) then
    if (var%is_known) then
      select case (var%type)
        case (V_LOG);  var%original%lval = var%lval
        case (V_INT);  var%original%ival = var%ival
        case (V_REAL); var%original%rval = var%rval

```

```

        case (V_CMPLX); var%original%cval = var%cval
        case (V_SEV); var%original%pval = var%pval
        case (V_PDG); var%original%aval = var%aval
        case (V_STR); var%original%sval = var%sval
    end select
end if
end if
end subroutine var_entry_restore

```

5.5.4 Variable lists

The type

Variable lists can be linked together. No initializer needed. They are deleted separately.

```

<Variables: public>+≡
    public :: var_list_t

<Variables: types>+≡
    type :: var_list_t
        private
        type(var_entry_t), pointer :: first => null ()
        type(var_entry_t), pointer :: last => null ()
        type(var_list_t), pointer :: next => null ()
    end type var_list_t

```

Constructors

```

<Variables: public>+≡
    public :: var_list_link

<Variables: procedures>+≡

5.5.5 Tools

Return a pointer to the variable list linked to by the current one.

```

<Variables: public>+≡
    public :: var_list_get_next_ptr

<Variables: procedures>+≡
    function var_list_get_next_ptr (var_list) result (next_ptr)
    type(var_list_t), pointer :: next_ptr
    type(var_list_t), intent(in) :: var_list
    next_ptr => var_list%next
end function var_list_get_next_ptr

```

Return a pointer to the variable with the requested name. If no such name exists, return a null pointer. In that case, try the next list if present, unless follow_link is unset. If defined is set, ignore entries that exist but are undefined.

```

<Variables: public>+=

5.5.7 Observable initialization

Observables are formally treated as variables, which however are evaluated each time the observable is used. The arguments (pointers) to evaluate and the function are part of the variable-list entry.

The procedure pointer should be set by this subroutine. This, however, triggers a bug in nagfor 5.2(649). As a workaround, we return the variable pointer, so the pointer can be set directly.

(Variables: procedures)+≡

```

subroutine var_list_set_obs (var_list, name, type, var, prt1, prt2)
    type(var_list_t), intent(inout) :: var_list
    type(string_t), intent(in) :: name

```

```

integer, intent(in) :: type
type(var_entry_t), pointer :: var
type(prt_t), intent(in), target :: prt1
type(prt_t), intent(in), optional, target :: prt2
allocate (var)
call var_entry_init_obs (var, name, type, prt1, prt2)
call var_list_append (var_list, var)
end subroutine var_list_set_obs

```

Unary and binary observables are different. Most unary observables can be equally well evaluated for particle pairs. Binary observables cannot be evaluated for single particles.

```

Check if a variable name is defined as an observable:

```

<Variables: procedures>+≡
function string_is_observable_id (string) result (flag)
    logical :: flag
    type(string_t), intent(in) :: string
    select case (char (string))
    case ("PDG", "Hel", "M", "M2", "E", "Px", "Py", "Pz", "P", "Pl", "Pt", &
        "Theta", "Phi", "Rap", "Eta", "Theta_RF", "Dist", "kT")
        flag = .true.
    case default
        flag = .false.
    end select
end function string_is_observable_id

```

5.5.8 Observables

These are analogous to the unary and binary numeric functions listed above. An observable takes the `pval` component(s) of its one or two argument nodes and produces an integer or real value.

Integer-valued unary observables

The PDG code

```
<Variables: procedures>+≡
integer function obs_pdg1 (prt1) result (pdg)
  type(prt_t), intent(in) :: prt1
  pdg = prt_get_pdg (prt1)
end function obs_pdg1
```

The helicity. The return value is meaningful only if the particle is polarized, otherwise an invalid value is returned (-9).

```
<Variables: procedures>+≡
integer function obs_helicity1 (prt1) result (h)
  type(prt_t), intent(in) :: prt1
  if (prt_is_polarized (prt1)) then
    h = prt_get_helicity (prt1)
  else
    h = -9
  end if
end function obs_helicity1
```

Real-valued unary observables

The invariant mass squared, obtained from the separately stored value.

```
<Variables: procedures>+≡
real(default) function obs_mass_squared1 (prt1) result (p2)
  type(prt_t), intent(in) :: prt1
  p2 = prt_get_msq (prt1)
end function obs_mass_squared1
```

The signed invariant mass, which is the signed square root of the previous observable.

```
<Variables: procedures>+≡
real(default) function obs_signed_mass1 (prt1) result (m)
  type(prt_t), intent(in) :: prt1
  real(default) :: msq
  msq = prt_get_msq (prt1)
  m = sign (sqrt (abs (msq)), msq)
end function obs_signed_mass1
```

The particle energy

```
<Variables: procedures>+≡
real(default) function obs_energy1 (prt1) result (e)
  type(prt_t), intent(in) :: prt1
```

```

    e = energy (prt_get_momentum (prt1))
end function obs_energy1

```

Particle momentum (components)

< Variables: procedures >+≡

```

real(default) function obs_px1 (prt1) result (p)
    type(prt_t), intent(in) :: prt1
    p = vector4_get_component (prt_get_momentum (prt1), 1)
end function obs_px1

```

```

real(default) function obs_py1 (prt1) result (p)
    type(prt_t), intent(in) :: prt1
    p = vector4_get_component (prt_get_momentum (prt1), 2)
end function obs_py1

```

```

real(default) function obs_pz1 (prt1) result (p)
    type(prt_t), intent(in) :: prt1
    p = vector4_get_component (prt_get_momentum (prt1), 3)
end function obs_pz1

```

```

real(default) function obs_p1 (prt1) result (p)
    type(prt_t), intent(in) :: prt1
    p = space_part_norm (prt_get_momentum (prt1))
end function obs_p1

```

```

real(default) function obs_pl1 (prt1) result (p)
    type(prt_t), intent(in) :: prt1
    p = longitudinal_part (prt_get_momentum (prt1))
end function obs_pl1

```

```

real(default) function obs_pt1 (prt1) result (p)
    type(prt_t), intent(in) :: prt1
    p = transverse_part (prt_get_momentum (prt1))
end function obs_pt1

```

Polar and azimuthal angle (lab frame).

< Variables: procedures >+≡

```

real(default) function obs_theta1 (prt1) result (p)
    type(prt_t), intent(in) :: prt1
    p = polar_angle (prt_get_momentum (prt1))
end function obs_theta1

```

```

real(default) function obs_phi1 (prt1) result (p)
    type(prt_t), intent(in) :: prt1
    p = azimuthal_angle (prt_get_momentum (prt1))
end function obs_phi1

```

Rapidity and pseudorapidity

< Variables: procedures >+≡

```

real(default) function obs_rap1 (prt1) result (p)
    type(prt_t), intent(in) :: prt1
    p = rapidity (prt_get_momentum (prt1))

```

```

end function obs_rap1

real(default) function obs_eta1 (prt1) result (p)
  type(prt_t), intent(in) :: prt1
  p = pseudorapidity (prt_get_momentum (prt1))
end function obs_eta1

```

Meaningless: Polar angle in the rest frame of the 2nd argument.

```

<Variables: procedures>+≡
real(default) function obs_theta_rf1 (prt1) result (dist)
  type(prt_t), intent(in) :: prt1
  call msg_fatal (" 'Theta_RF' is undefined as unary observable")
  dist = 0
end function obs_theta_rf1

```

Meaningless: Distance on the η - ϕ cylinder.

```

<Variables: procedures>+≡
real(default) function obs_dist1 (prt1) result (dist)
  type(prt_t), intent(in) :: prt1
  call msg_fatal (" 'Dist' is undefined as unary observable")
  dist = 0
end function obs_dist1

```

Integer-valued binary observables

These observables are meaningless as binary functions.

```

<Variables: procedures>+≡
integer function obs_pdg2 (prt1, prt2) result (pdg)
  type(prt_t), intent(in) :: prt1, prt2
  call msg_fatal (" PDG_Code is undefined as binary observable")
  pdg = 0
end function obs_pdg2

integer function obs_helicity2 (prt1, prt2) result (h)
  type(prt_t), intent(in) :: prt1, prt2
  call msg_fatal (" Helicity is undefined as binary observable")
  h = 0
end function obs_helicity2

```

Real-valued binary observables

The invariant mass squared, obtained from the separately stored value.

```

<Variables: procedures>+≡
real(default) function obs_mass_squared2 (prt1, prt2) result (p2)
  type(prt_t), intent(in) :: prt1, prt2
  type(prt_t) :: prt
  call prt_init_combine (prt, prt1, prt2)
  p2 = prt_get_msq (prt)
end function obs_mass_squared2

```

The signed invariant mass, which is the signed square root of the previous observable.

```

<Variables: procedures>+=
  real(default) function obs_signed_mass2 (prt1, prt2) result (m)
    type(prt_t), intent(in) :: prt1, prt2
    type(prt_t) :: prt
    real(default) :: msq
    call prt_init_combine (prt, prt1, prt2)
    msq = prt_get_msq (prt)
    m = sign (sqrt (abs (msq)), msq)
  end function obs_signed_mass2

```

The particle energy

```

<Variables: procedures>+=
  real(default) function obs_energy2 (prt1, prt2) result (e)
    type(prt_t), intent(in) :: prt1, prt2
    type(prt_t) :: prt
    call prt_init_combine (prt, prt1, prt2)
    e = energy (prt_get_momentum (prt))
  end function obs_energy2

```

Particle momentum (components)

```

<Variables: procedures>+=
  real(default) function obs_px2 (prt1, prt2) result (p)

```

5.5.10 API for variable lists

Set a new value. If the variable holds a pointer, this pointer is followed, e.g., a model parameter is actually set. If `ignore` is set, do nothing if the variable does not exist. If `verbose` is set, echo the new value.

The specific versions:

```

<Variables: public>+≡

5.5.11 Linking model variables

The variable list of a model can be linked to the global variable list, so the model variables become available. However, the model may change during the execution of the command list, and this is not known at compile time. So, we make a copy of all variables that can be modified by the user; this will include all variables that are present in any of the models. At runtime, the linked list and the pointers to it can be exchanged, but the global variables will stay.

Append a single model variable to the local variable list. The pointer to the original is not set (yet). Check first if it already exists; in that case, do nothing.

```

<Variables: public>+≡
    public :: var_list_init_copy

<Variables: procedures>+≡
    subroutine var_list_init_copy (var_list, model_var, user)
        type(var_list_t), intent(inout), target :: var_list
        type(var_entry_t), intent(in), target :: model_var
        logical, intent(in), optional :: user
        type(var_entry_t), pointer :: var
        if (.not. var_list_exists &
            (var_list, model_var%name, follow_link = .false.)) then
            allocate (var)
            call var_entry_init_copy (var, model_var, user)
            call var_list_append (var_list, var)
        end if
    end subroutine var_list_init_copy

```

Append all model variables, or reuse (unset) them if they already exist. If `derived_only` is set, copy only derived parameters; these are real parameters

that are locked. How should we (should we at all?) generalize this to complex parameters?

```

<Variables: public>+≡
    public :: var_list_init_copies

<Variables: procedures>+≡
    subroutine var_list_init_copies (var_list, model_vars, derived_only)
        type(var_list_t), intent(inout), target :: var_list
        type(var_list_t), intent(in) :: model_vars
        logical, intent(in), optional :: derived_only
        type(var_entry_t), pointer :: model_var, var
        type(string_t) :: name
        logical :: copy_all, locked, derived
        integer :: type
        copy_all = .true.
        if (present (derived_only)) copy_all = .not. derived_only
        model_var => model_vars%first
        do while (associated (model_var))
            name = var_entry_get_name (model_var)
            type = var_entry_get_type (model_var)
            locked = var_entry_is_locked (model_var)
            derived = type == V_REAL .and. locked
            if (copy_all .or. derived) then
                var => var_list_get_var_ptr &
                    (var_list, name, type, follow_link = .false.)
                if (associated (var)) then
                    call var_entry_clear_value (var)
                else
                    allocate (var)
                    call var_entry_init_copy (var, model_var)
                    call var_list_append (var_list, var)
                end if
            end if
            model_var => model_var%next
        end do
    end subroutine var_list_init_copies

```

Clear all previously allocated pointers to some model:

```

<Variables: procedures>+≡
    subroutine var_list_clear_original_pointers (var_list)
        type(var_list_t), intent(inout) :: var_list
        type(var_entry_t), pointer :: var
        var => var_list%first
        do while (associated (var))
            call var_entry_clear_original_pointer (var)
            var => var%next
        end do
    end subroutine var_list_clear_original_pointers

```

Assign the pointer to the original for a single variable.

```

<Variables: public>+≡
    public :: var_list_set_original_pointer

```

```

{Variables: procedures}+=
subroutine var_list_set_original_pointer (var_list, name, model_vars)
  type(var_list_t), intent(inout) :: var_list
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in), target :: model_vars
  type(var_entry_t), pointer :: var, model_var
  integer :: type
  model_var => var_list_get_var_ptr (model_vars, name)
  if (associated (model_var)) then
    type = var_entry_get_type (model_var)
    var => var_list_get_var_ptr (var_list, name, type, follow_link=.false.)
    if (associated (var)) then
      call var_entry_set_original_pointer (var, model_var)
    end if
  end if
end subroutine var_list_set_original_pointer

```

Assign pointers to the originals for all variables in the model variable list.

```

{Variables: procedures}+=
subroutine var_list_set_original_pointers (var_list, model_vars)
  type(var_list_t), intent(inout) :: var_list
  type(var_list_t), intent(in), target :: model_vars
  type(var_entry_t), pointer :: var, model_var
  type(string_t) :: name
  integer :: type
  model_var => model_vars%first
  do while (associated (model_var))
    name = var_entry_get_name (model_var)
    type = var_entry_get_type (model_var)
    var => var_list_get_var_ptr (var_list, name, type, follow_link=.false.)
    if (associated (var)) then
      call var_entry_set_original_pointer (var, model_var)
    end if
    model_var => model_var%next
  end do
end subroutine var_list_set_original_pointers

```

Synchronize the local variable list with the model variable list (which is accessed by the pointers assigned in the previous subroutine).

If `reset_pointers` is unset, do not reset pointers but just update values where a variable is a copy. Resetting pointers is done only in the local variable list.

```

{Variables: public}+=
public :: var_list_synchronize

{Variables: procedures}+=
subroutine var_list_synchronize (var_list, model_vars, reset_pointers)
  type(var_list_t), intent(inout) :: var_list
  type(var_list_t), intent(in), target :: model_vars
  logical, intent(in), optional :: reset_pointers
  type(var_entry_t), pointer :: var
  if (present (reset_pointers)) then
    if (reset_pointers) then

```

```

        call var_list_clear_original_pointers (var_list)
        call var_list_set_original_pointers (var_list, model_vars)
    end if
end if
var => var_list%first
do while (associated (var))
    call var_entry_synchronize (var)
    var => var%next
end do
end subroutine var_list_synchronize

```

This is the inverse operation: synchronize the model variable list with the current variable list. This is necessary after discarding a local variable list.

```

<Variables: public>+≡
    public :: var_list_restore

<Variables: procedures>+≡
    recursive subroutine var_list_restore (var_list)
        type(var_list_t), intent(inout) :: var_list
        type(var_entry_t), pointer :: var
        var => var_list%first
        do while (associated (var))
            call var_entry_restore (var)
            var => var%next
        end do
    end subroutine var_list_restore

```

Mark all entries in the current variable list as undefined. This is done when a local variable list is discarded. If the local list is used again (by a loop), the entries will be re-initialized.

```

<Variables: public>+≡
    public :: var_list_undefine

<Variables: procedures>+≡
    recursive subroutine var_list_undefine (var_list, follow_link)
        type(var_list_t), intent(inout) :: var_list
        logical, intent(in), optional :: follow_link
        type(var_entry_t), pointer :: var
        logical :: rec
        rec = .true.; if (present (follow_link)) rec = follow_link
        var => var_list%first
        do while (associated (var))
            call var_entry_undefine (var)
            var => var%next
        end do
        if (rec .and. associated (var_list%next)) then
            call var_list_undefine (var_list%next, follow_link=follow_link)
        end if
    end subroutine var_list_undefine

```

Make a deep copy of a variable list. The copy does not contain any pointer variables. Clear the original pointer after use, since the original may be lost

when the copy is in use.

```

<Variables: public>+=
    public :: var_list_init_snapshot

<Variables: procedures>+=
    recursive subroutine var_list_init_snapshot (var_list, vars_in, follow_link)
        type(var_list_t), intent(out) :: var_list
        type(var_list_t), intent(in) :: vars_in
        logical, intent(in), optional :: follow_link
        type(var_entry_t), pointer :: var, var_in
        type(var_list_t), pointer :: var_list_next
        logical :: rec
        rec = .true.; if (present (follow_link)) rec = follow_link
        var_in => vars_in%first
        do while (associated (var_in))
            allocate (var)
            call var_entry_init_copy (var, var_in)
            call var_entry_set_original_pointer (var, var_in)
            call var_entry_synchronize (var)
            call var_entry_clear_original_pointer (var)
            call var_list_append (var_list, var)
            var_in => var_in%next
        end do
        if (rec .and. associated (vars_in%next)) then
            allocate (var_list_next)
            call var_list_init_snapshot (var_list_next, vars_in%next)
            call var_list_link (var_list, var_list_next)
        end if
    end subroutine var_list_init_snapshot

```

Check if a user variable can be set. The new flag is set if the user variable has an explicit declaration. If an error occurs, return V_NONE as variable type.

Also determine the actual type of generic numerical variables, which enter the procedure with type V_NONE.

```

<Variables: public>+=
    public :: var_list_check_user_var

    else
        flag = .false.
    end if
end function string_is_num_id

```

5.6 Expressions

In this module we define the structures needed to parse a user-defined expression, to compile it into an evaluation tree, and to evaluate it.

We have two flavors of expressions: one with particles and one without particles. The latter version is used for defining cut/selection criteria and for online analysis.

```
<expressions.f90>≡  
  <File header>  
  
  module expressions  
  
    use iso_c_binding !NODEP!  
    <Use kinds>  
    <Use strings>  
    use constants !NODEP!  
    <Use file utils>  
    use diagnostics !NODEP!  
    use lorentz !NODEP!  
    use md5  
    use formats  
    use sorting  
    use ifiles  
    use lexers  
    use syntax_rules  
    use parser  
    use analysis  
    use pdg_arrays  
    use subevents  
    use user_code_interface  
    use variables  
  
    <Standard module head>  
  
    <Expressions: public>

5.6.1 Tree nodes

The evaluation tree consists of branch nodes (unary and binary) and of leaf nodes, originating from a common root. The node object should be polymorphic. For the time being, polymorphism is emulated here. This means that we

have to maintain all possibilities that the node may hold, including associated procedures as pointers.

The following parameter values characterize the node. Unary and binary operators have sub-nodes. The other are leaf nodes. Possible leafs are literal constants or named-parameter references.

$\langle \text{Expressions: types} \rangle \equiv$

```
integer, parameter :: EN_UNKNOWN = 0, EN_UNARY = 1, EN_BINARY = 2
integer, parameter :: EN_CONSTANT = 3, EN_VARIABLE = 4
integer, parameter :: EN_CONDITIONAL = 5, EN_BLOCK = 6
integer, parameter :: EN_RECORD_CMD = 7
integer, parameter :: EN_OBS1_INT = 11, EN_OBS2_INT = 12
integer, parameter :: EN_OBS1_REAL = 21, EN_OBS2_REAL = 22
integer, parameter :: EN_UOBS1_INT = 31, EN_UOBS2_INT = 32
integer, parameter :: EN_UOBS1_REAL = 41, EN_UOBS2_REAL = 42
integer, parameter :: EN_PRT_FUN_UNARY = 101, EN_PRT_FUN_BINARY = 102
integer, parameter :: EN_EVAL_FUN_UNARY = 111, EN_EVAL_FUN_BINARY = 112
integer, parameter :: EN_LOG_FUN_UNARY = 121, EN_LOG_FUN_BINARY = 122
integer, parameter :: EN_INT_FUN_UNARY = 131, EN_INT_FUN_BINARY = 132
integer, parameter :: EN_REAL_FUN_UNARY = 141, EN_REAL_FUN_BINARY = 142
integer, parameter :: EN_FORMAT_STR = 161
```

end subroutine eval_node_init_obs

```

Initialize a block node which contains, in addition to the expression to be evaluated, a variable definition. The result type is not yet assigned, because we can compile the enclosed expression only after the var list is set up.

Note that the node always allocates a new variable list and appends it to the current one. Thus, if the variable redefines an existing one, it only shadows it but does not reset it. Any side-effects are therefore absent and need not be undone outside the block.

If the flag `new` is set, a variable is (re)declared. This must not be done for intrinsic variables. Vice versa, if the variable is not existent, the `new` flag is required.

(Expressions: procedures)+≡

```

subroutine eval_node_init_block (node, name, type, var_def, var_list)
    type(eval_node_t), intent(out), target :: node
    type(string_t), intent(in) :: name

end subroutine eval_node_init_block

```

Complete block initialization by assigning the expression to evaluate to `arg0`.

(Expressions: procedures)+≡

```

subroutine eval_node_set_expr (node, arg, result_type)
    type(eval_node_t), intent(inout) :: node
    type(eval_node_t), intent(in), target :: arg
    integer, intent(in), optional :: result_type
    if (present (result_type)) then
        node%result_type = result_type
    else
        node%result_type = arg%result_type
    end if
    call eval_node_allocate_value (node)
    node%arg0 => arg
end subroutine eval_node_set_expr

```

Initialize a conditional. There are three branches: the condition (evaluates to logical) and the two alternatives (evaluate both to the same arbitrary type).

(Expressions: procedures)+≡

```

subroutine eval_node_init_conditional (node, result_type, cond, arg1, arg2)
    type(eval_node_t), intent(out) :: node

```

```

integer, intent(in) :: result_type
type(eval_node_t), intent(in), target :: cond, arg1, arg2
node%type = EN_CONDITIONAL
node%tag = "cond"
node%result_type = result_type
call eval_node_allocate_value (node)
node%arg0 => cond
node%arg1 => arg1
node%arg2 => arg2
end subroutine eval_node_init_conditional

```

Initialize a recording command (which evaluates to a logical constant). The first branch is the ID of the analysis object to be filled, the optional branches 1 to 4 are the values to be recorded.

If the event-weight pointer is null, we record values with unit weight. Otherwise, we use the value pointed to as event weight.

There can be up to four arguments which represent x , y , Δy , Δx . Therefore, this is the only node type that may fill four sub-nodes.

(Expressions: procedures)+≡

```

subroutine eval_node_init_record_cmd &
  (node, event_weight, id, arg1, arg2, arg3, arg4)
type(eval_node_t), intent(out) :: node
real(default), pointer :: event_weight

```

Initialize a node for operations on subevents. The particle lists (one or two) are inserted as **arg1** and **arg2**. We allocated particle pointers as temporaries for iterating over particle lists. The procedure pointer which holds the function to evaluate for the subevents (e.g., combine, select) is also initialized.

(Expressions: procedures)+≡

```

subroutine eval_node_init_prt_fun_unary (node, arg1, name, proc)
type(eval_node_t), intent(out) :: node
type(eval_node_t), intent(in), target :: arg1

```

```

    type(string_t), intent(in) :: name

    allocate (node%ival)
    node%ival = n_args
  end subroutine eval_node_init_format_string

```

If particle functions depend upon a condition (or an expression is evaluated), the observables that can be evaluated for the given particles have to be thrown on the local variable stack. This is done here. Each observable is initialized with the particle pointers which have been allocated for the node.

The integer variable that is referred to by the Index pseudo-observable is always known when it is referred to.

```

<Expressions: procedures>+≡
  subroutine eval_node_set_observables (node, var_list)
    type(eval_node_t), intent(inout) :: node
    type(var_list_t), intent(in), target :: var_list
    logical, save, target :: known = .true.
    allocate (node%var_list)
    call var_list_link (node%var_list, var_list)
    allocate (node%index)
    call var_list_append_int_ptr &
      (node%var_list, var_str ("Index"), node%index, known, intrinsic=.true.)
    if (.not. associated (node%prt2)) then
      call var_list_set_observables_unary &

5.6.2 Operation types

For the operations associated to evaluation tree nodes, we define abstract interfaces for all cases.

Particles/subevents are transferred by-reference, to avoid unnecessary copying. Therefore, subroutines instead of functions. (Furthermore, the function version of `unary_prt` triggers an obscure bug in nagfor 5.2(649) [invalid C code].)

(Expressions: interfaces)≡

```

abstract interface

5.6.3 Specific operators

Our expression syntax contains all Fortran functions that make sense. These functions have to be provided in a form that they can be used in procedures pointers, and have the abstract interfaces above. For some intrinsic functions, we could use specific versions provided by Fortran directly. However, this has two drawbacks: (i) We should work with the values instead of the eval-nodes as argument, which complicates the interface; (ii) more importantly, the **default**

real type need not be equivalent to double precision. This would, at least, introduce system dependencies. Finally, for operators there are no specific versions.

Therefore, we write wrappers for all possible functions, at the expense of some overhead.

Binary numerical functions

```

(Expressions: procedures) +=
  integer function add_ii (en1, en2) result (y)

end subroutine user_event_shape_a

```

Binary particle-list functions

This joins two subevents, stored in the evaluation nodes **en1** and **en2**. If **en0** is also present, it amounts to a logical test returning true or false for every pair of particles. A particle of the second list gets a mask entry only if it passes the test for all particles of the first list.

(Expressions: procedures)+≡

```
subroutine join_pp (subevt, en1, en2, en0)
  type(subevt_t), intent(inout) :: subevt
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0
  logical, dimension(:), allocatable :: mask2
  integer :: i, j, n1, n2
  n1 = subevt_get_length (en1%pval)
  n2 = subevt_get_length (en2%pval)
  allocate (mask2 (n2))
  mask2 = .true.
  if (present (en0)) then
    do i = 1, n1
      en0%index = i
      en0%prt1 = subevt_get_prt (en1%pval, i)
      do j = 1, n2
        en0%prt2 = subevt_get_prt (en2%pval, j)
        call eval_node_evaluate (en0)
        mask2(j) = mask2(j) .and. en0%lval
      end do
    end do
  end if
  call subevt_join (subevt, en1%pval, en2%pval, mask2)
end subroutine join_pp
```

Combine two subevents, i.e., make a list of composite particles built from all possible particle pairs from the two lists. If **en0** is present, create a mask which is true only for those pairs that pass the test.

(Expressions: procedures)+≡

```
subroutine combine_pp (subevt, en1, en2, en0)
  type(subevt_t), intent(inout) :: subevt
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0
  logical, dimension(:,:), allocatable :: mask12
  integer :: i, j, n1, n2
  n1 = subevt_get_length (en1%pval)
  n2 = subevt_get_length (en2%pval)
  if (present (en0)) then
    allocate (mask12 (n1, n2))
    do i = 1, n1
      en0%index = i
      en0%prt1 = subevt_get_prt (en1%pval, i)
      do j = 1, n2
        en0%prt2 = subevt_get_prt (en2%pval, j)
        call eval_node_evaluate (en0)
        mask12(i,j) = en0%lval
      end do
    end do
  end if
end subroutine combine_pp
```

```

        end do
        call subevt_combine (subevt, en1%pval, en2%pval, mask12)
    else
        call subevt_combine (subevt, en1%pval, en2%pval)
    end if
end subroutine combine_pp

```

Combine all particles of the first argument. If `en0` is present, create a mask which is true only for those particles that pass the test w.r.t. all particles in the second argument. If `en0` is absent, the second argument is ignored.

(Expressions: procedures)+≡

```

subroutine collect_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:), allocatable :: mask1
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    allocate (mask1 (n1))
    mask1 = .true.
    if (present (en0)) then

end function no_pp

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

(Expressions: procedures) +≡

```

```

Real, complex and integer values are numeric literals with an optional unit attached. In case of an integer, the unit actually makes it a real value in disguise. The signed version of real values is not possible in generic expressions; it is a special case for numeric constants in model files (see below). We do not introduce signed versions of complex values.

```

Compile a variable, with or without a specified type. Take the list of variables, look for the name and make a node with a pointer to the value. If no type is provided, the variable is numeric, and the stored value determines whether it is real or integer.

We explicitly demand that the variable is defined, so we do not accidentally point to variables that are declared only later in the script but have come into existence in a previous compilation pass.

Variables may actually be anonymous, these are expressions in disguise. In that case, the expression replaces the variable name in the parse tree, and we allocate an ordinary expression node in the eval tree.

Variables of type V_PDG (pdg-code array) are not treated here. They are handled by eval_node_compile_cvariable.

Retrieve the result of an integration. If the requested process has been integrated, the results are available as special variables. (The variables cannot be accessed in the usual way since they contain brackets in their names.)

Since this compilation step may occur before the processes have been loaded, we have to initialize the required variables before they are used.

This user observable behaves like a variable. We link the node to the generic user-observable entry in the variable list. The syntax element has an argument which provides the name of the user variable, this is stored as an eval-node alongside with the variable. When the variable value is used, the user-supplied external function is called and provides the (real) result value.

Variable definition

A block expression contains a variable definition (first argument) and an expression where the definition can be used (second argument). The **result_type** decides which type of expression is expected for the second argument. For numeric variables, if there is a mismatch between real and integer type, insert an extra node for type conversion.

Conditionals

A conditional has the structure `if lexpr then expr else expr`. So we first evaluate the logical expression, then depending on the result the first or second expression. Note that the second expression is mandatory.

The `result_type`, if present, defines the requested type of the `then` and `else` clauses. Default is numeric (int/real). If there is a mismatch between real and integer result types, insert conversion nodes.

(Expressions: procedures)+≡

```

Comparisons

Up to the loop, this is easy. There is always at least one comparison. This is evaluated, and the result is the logical node **en**. If it is constant, we keep its second sub-node as **en2**. (Thus, at the very end **en2** has to be deleted if **en** is (still) constant.)

If there is another comparison, we first check if the first comparison was constant. In that case, there are two possibilities: (i) it was true. Then, its right-hand side is compared with the new right-hand side, and the result replaces the previous one which is deleted. (ii) it was false. In this case, the result of the whole comparison is false, and we can exit the loop without evaluating anything else.

Now assume that the first comparison results in a valid branch, its second sub-node kept as **en2**. We first need a copy of this, which becomes the new left-hand side. If **en2** is constant, we make an identical constant node **en1**. Otherwise, we make **en1** an appropriate pointer node. Next, the first branch is saved as **en0** and we evaluate the comparison between **en1** and the a right-hand side. If this turns out to be constant, there are again two possibilities: (i) true, then we revert to the previous result. (ii) false, then the wh

```

```

end if
end subroutine eval_node_compile_compared_expr

```

This takes two extra arguments: **en1**, the left-hand-side of the comparison, is already allocated and evaluated. **en2** (the right-hand side) and **en** (the result) are allocated by the routine. **pn** is the parse node which contains the operator and the right-hand side as subnodes.

If the result of the comparison is constant, **en1** is deleted but **en2** is kept, because it may be used in a subsequent comparison. **en** then becomes a constant. If the result is variable, **en** becomes a branch node which refers to **en1** and **en2**.

  print *, "done pterm"
end if
end subroutine eval_node_compile_pterm

```

A particle-list value is a PDG-code array, a particle identifier, a variable, a (grouped) pexpr, a block pexpr, a conditional, or a particle-list function.

The `cexpr` node is responsible for transforming a constant PDG-code array into a subevent. It takes the code array as its first argument, the event subevent as its second argument, and the requested particle type (incoming/outgoing) as its zero-th argument. The result is the list of particles in the event that match the code array.

(Expressions: procedures)+≡

```

Particle functions

This combines the treatment of 'join', 'combine', 'collect', 'select', and 'extract' which all have the same syntax. The one or two argument nodes are allocated. If there is a condition, the condition node is also allocated as a logical expression, for which the variable list is augmented by the appropriate (unary/binary) observables.

(Expressions: procedures)+≡

```

5.6.5 Auxiliary functions for the compiler

Issue an error that the current node could not be compiled because of type mismatch:

```

(Expressions: procedures) +=
subroutine eval_type_error (pn, string, t)
    type(parse_node_t), intent(in) :: pn
    character(*), intent(in) :: string
    integer, intent(in) :: t
    type(string_t) :: type
    select case (t)
    case (V_NONE); type = "(none)"
    case (V_LOG); type = "'logical'"
    case (V_INT); type = "'integer'"
    case (V_REAL); type = "'real'"
    case (V_CMPLX); type = "'complex'"
    case default; type = "(unknown)"
    end select

```

```

call parse_node_write (pn)
call msg_fatal (" The " // string // &
               " operation is not defined for the given argument type " // &
               char (type))
end subroutine eval_type_error

```

If two numerics are combined, the result is integer if both arguments are integer, if one is integer and the other real or both are real, than its argument is real, otherwise complex.

(Expressions: procedures)+≡

```

function numeric_result_type (t1, t2) result (t)
integer, intent(in) :: t1, t2
integer :: t
if (t1 == V_INT .and. t2 == V_INT) then
    t = V_INT
else if (t1 == V_INT .and. t2 == V_REAL) then
    t = V_REAL
else if (t1 == V_REAL .and. t2 == V_INT) then
    t = V_REAL
else if (t1 == V_REAL .and. t2 == V_REAL) then
    t = V_REAL
else
    t = V_CMPLX
end if
end function numeric_result_type

```

5.6.6 Evaluation

Evaluation is done recursively. For leaf nodes nothing is to be done.

Evaluating particle-list functions: First, we evaluate the particle lists. If a condition is present, we assign the particle pointers of the condition node to the allocated particle entries in the parent node, keeping in mind that the observables in the variable stack used for the evaluation of the condition also contain pointers to these entries. Then, the assigned procedure is evaluated, which sets the subevent in the parent node. If required, the procedure evaluates the condition node once for each (pair of) particles to determine the result.

(Expressions: procedures)+≡

```

recursive subroutine eval_node_evaluate (en)

5.6.7 Evaluation syntax

We have two different flavors of the syntax: with and without particles.

```

<Expressions: variables>+≡
    type(syntax_t), target, save :: syntax_expr
    type(syntax_t), target, save :: syntax_pexpr

```

These are for testing only and may be removed:

```

<Expressions: public>≡
    public :: syntax_expr_init
    public :: syntax_pexpr_init

```

```

<Expressions: procedures>+≡
  subroutine syntax_expr_init ()
    type(ifile_t) :: ifile
    call define_expr_syntax (ifile, particles=.false., analysis=.false.)
    call syntax_init (syntax_expr, ifile)
    call ifile_final (ifile)
  end subroutine syntax_expr_init

  subroutine syntax_pexpr_init ()
    type(ifile_t) :: ifile
    call define_expr_syntax (ifile, particles=.true., analysis=.false.)
    call syntax_init (syntax_pexpr, ifile)
    call ifile_final (ifile)
  end subroutine syntax_pexpr_init

<Expressions: public>+≡
  public :: syntax_expr_final
  public :: syntax_pexpr_final

<Expressions: procedures>+≡
  subroutine syntax_expr_final ()
    call syntax_final (syntax_expr)
  end subroutine syntax_expr_final

  subroutine syntax_pexpr_final ()
    call syntax_final (syntax_pexpr)
  end subroutine syntax_pexpr_final

<Expressions: public>+≡
  public :: syntax_pexpr_write

<Expressions: procedures>+≡
  subroutine syntax_pexpr_write (unit)
    integer, intent(in), optional :: unit
    call syntax_write (syntax_pexpr, unit)
  end subroutine syntax_pexpr_write

<Expressions: public>+≡
  public :: define_expr_syntax

Numeric expressions.

<Expressions: procedures>+≡
  subroutine define_expr_syntax (ifile, particles, analysis)
    type(ifile_t), intent(inout) :: ifile
    logical, intent(in) :: particles, analysis

Chapter 6

Physics Models

A model object represents a physics model. It contains a table of particle data, a list of parameters, and a vertex table. The list of parameters is a variable list which includes the real parameters (which are pointers to the particle data table) and PDG array variables for the particles themselves. The vertex list is used for phase-space generation, not for calculating the matrix element.

Model definitions are read from model files. Therefore, this module contains a parser for model files. The parameter definitions (derived parameters) are Sindarin expressions.

The models, as read from file, are stored in a model library which is a simple list of model definitions. For setting up a process object we should make a copy (an instance) of a model, which gets the current parameter values from the global variable list.

6.1 Model module

```
<models.f90>≡  
  <File header>  
  
  module models  
  
    use iso_c_binding !NODEP!  
    <Use kinds>  
    use kinds, only: i8, i32 !NODEP!  
    use kinds, only: c_default_float !NODEP!  
    <Use strings>  
    use limits, only: VERTEX_TABLE_SCALE_FACTOR !NODEP!  
    <Use file utils>  
    use unit_tests  
    use md5  
    use os_interface  
    use hashes, only: hash  
    use diagnostics !NODEP!  
    use ifiles  
    use syntax_rules  
    use lexers  
    use parser
```

```

    use pdg_arrays
    use variables
    use expressions

    <Standard module head>

    <Models: public>

    <Models: parameters>

    <Models: types>

    <Models: interfaces>

    <Models: variables>

contains

    <Models: procedures>

    <Models: tests>

end module models

```

6.1.1 Physics Parameters

A parameter has a name, a value. Derived parameters also have a definition in terms of other parameters, which is stored as an `eval_tree`. External parameters are set by an external program.

The `pn` component is a pointer to the parameter definition inside the model parse tree. It allows us to recreate the `eval_tree` when making copies (instances) of the parameter object.

```

<Models: parameters>≡
    integer, parameter :: PAR_NONE = 0
    integer, parameter :: PAR_INDEPENDENT = 1, PAR_DERIVED = 2
    integer, parameter :: PAR_EXTERNAL = 3

<Models: public>≡
    public :: parameter_t

<Models: types>≡
    type :: parameter_t
    private
    integer :: type = PAR_NONE
    type(string_t) :: name
    real(default) :: value = 0
    type(parse_node_t), pointer :: pn => null ()
    type(eval_tree_t) :: eval_tree
end type parameter_t

```

Initialization depends on parameter type. Independent parameters are initialized by a constant value or a constant numerical expression (which may contain

a unit). Derived parameters are initialized by an arbitrary numerical expression, which makes use of the current variable list. The expression is evaluated by the function `parameter_reset`.

<Models: procedures>+≡

```

subroutine parameter_init_independent_value (par, name, value)
  type(parameter_t), intent(out) :: par
  type(string_t), intent(in) :: name
  real(default), intent(in) :: value
  par%type = PAR_INDEPENDENT
  par%name = name
  par%value = value
end subroutine parameter_init_independent_value

subroutine parameter_init_independent (par, name, pn)
  type(parameter_t), intent(out) :: par
  type(string_t), intent(in) :: name
  type(parse_node_t), intent(in), target :: pn
  par%type = PAR_INDEPENDENT
  par%name = name
  par%pn => pn
  call eval_tree_init_numeric_value (par%eval_tree, pn)
  par%value = eval_tree_get_real (par%eval_tree)
end subroutine parameter_init_independent

subroutine parameter_init_derived (par, name, pn, var_list)
  type(parameter_t), intent(out) :: par
  type(string_t), intent(in) :: name
  type(parse_node_t), intent(in), target :: pn
  type(var_list_t), intent(in), target :: var_list
  par%type = PAR_DERIVED
  par%name = name
  par%pn => pn
  call eval_tree_init_expr (par%eval_tree, pn, var_list=var_list)
  call parameter_reset_derived (par)
end subroutine parameter_init_derived

subroutine parameter_init_external (par, name)
  type(parameter_t), intent(out) :: par
  type(string_t), intent(in) :: name
  par%type = PAR_EXTERNAL
  par%name = name
end subroutine parameter_init_external

```

The finalizer is needed for the evaluation tree in the definition.

<Models: procedures>+≡

```

subroutine parameter_final (par)
  type(parameter_t), intent(inout) :: par
  call eval_tree_final (par%eval_tree)
end subroutine parameter_final

```

All derived parameters should be recalculated if some independent parameters have changed:

<Models: procedures>+≡

```

subroutine parameter_reset_derived (par)
  type(parameter_t), intent(inout) :: par
  select case (par%type)
  case (PAR_DERIVED)
    call eval_tree_evaluate (par%eval_tree)
    par%value = eval_tree_get_real (par%eval_tree)
  end select
end subroutine parameter_reset_derived

```

Direct access to the parameter value:

(Models: procedures)+≡

```

function parameter_get_value_ptr (par) result (val)
  real(default), pointer :: val
  type(parameter_t), intent(in), target :: par
  val => par%value
end function parameter_get_value_ptr

```

Output. [We should have a formula format for the eval tree, suitable for input and output!]

(Models: procedures)+≡

```

subroutine parameter_write (par, unit, write_defs)
  type(parameter_t), intent(in) :: par
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: write_defs
  integer :: u
  u = output_unit (unit); if (u < 0) return
  select case (par%type)
  case (PAR_INDEPENDENT)
    write (u, "(3x,A)", advance="no") "parameter"
  case (PAR_DERIVED)
    write (u, "(3x,A)", advance="no") "derived"
  case (PAR_EXTERNAL)
    write (u, "(3x,A)", advance="no") "external"
  end select
  write (u, "(1x,A,1x,A)", advance="no") char (par%name), "= "
  write (u, "(ES19.12)", advance="no") par%value
  select case (par%type)
  case (PAR_DERIVED)
    if (present (write_defs)) then
      if (write_defs) then
        call eval_tree_write (par%eval_tree, unit)
      end if
    end if
  case default
    write (u, *)
  end select
end subroutine parameter_write

```

6.1.2 Particle codes

Let us define a few particle codes independent of the model.

SM fermions:

```
(Models: types)+≡  
integer, parameter, public :: ELECTRON = 11
```

Gauge bosons:

```
(Models: types)+≡  
integer, parameter, public :: GLUON = 21  
integer, parameter, public :: PHOTON = 22  
integer, parameter, public :: Z_BOSON = 23  
integer, parameter, public :: W_BOSON = 24
```

Hadrons:

```
(Models: types)+≡  
integer, parameter, public :: PROTON = 2212  
  
(Models: types)+≡  
integer, parameter, public :: PION = 111  
integer, parameter, public :: PIPLUS = 211  
integer, parameter, public :: PIMINUS = - PIPLUS
```

Hadron remnants (internal)

```
(Models: types)+≡  
integer, parameter, public :: HADRON_REMNANT = 90  
integer, parameter, public :: HADRON_REMNANT_SINGLET = 91  
integer, parameter, public :: HADRON_REMNANT_TRIPLET = 92  
integer, parameter, public :: HADRON_REMNANT_OCTET = 93
```

Generic particles for internal use in event analysis:

```
(Models: types)+≡  
integer, parameter, public :: PRT_ANY = 81  
integer, parameter, public :: PRT_VISIBLE = 82  
integer, parameter, public :: PRT_CHARGED = 83  
integer, parameter, public :: PRT_COLORED = 84
```

Further particle codes for internal use:

```
(Models: types)+≡  
integer, parameter, public :: INVALID = 97  
integer, parameter, public :: KEYSTONE = 98  
integer, parameter, public :: COMPOSITE = 99
```

6.1.3 Spin codes

Somewhat redundant, but for better readability we define named constants for spin types. If the mass is nonzero, this is equal to the number of degrees of freedom.

```
(Models: types)+≡  
integer, parameter, public :: UNKNOWN=0  
integer, parameter, public :: SCALAR=1, SPINOR=2, VECTOR=3, &  
VECTORSPINOR=4, TENSOR=5
```

Isospin types and charge types are counted in an analogous way, where charge type 1 is charge 0, 2 is charge 1/3, and so on. Zero always means unknown. Note that charge and isospin types have an explicit sign.

Color types are defined as the dimension of the representation.

6.1.4 Particle data

The particle-data type holds all information that pertains to a particular particle within a particular model. Information such as spin type, particle code etc. is stored within the object itself, while mass and width are associated to parameters, otherwise assumed zero.

```

<Models: public>+≡
    public :: particle_data_t

<Models: types>+≡
    type :: particle_data_t
        private
            type(string_t) :: longname
            integer :: pdg = UNDEFINED
            logical :: is_visible = .true.
            logical :: is_parton = .false.
            logical :: is_gauge = .false.
            logical :: is_left_handed = .false.
            logical :: is_right_handed = .false.
            logical :: has_antiparticle = .false.
            logical :: p_is_stable = .true.
            logical :: p_decays_isotropically = .false.
            logical :: p_decays_diagonal = .false.
            logical :: a_is_stable = .true.
            logical :: a_decays_isotropically = .false.
            logical :: a_decays_diagonal = .false.
            logical :: p_polarized = .false.
            logical :: a_polarized = .false.
            type(string_t), dimension(:), allocatable :: name, anti
            type(string_t) :: tex_name, tex_anti
            integer :: spin_type = UNDEFINED
            integer :: isospin_type = 1
            integer :: charge_type = 1
            integer :: color_type = 1
            real(default), pointer :: mass_val => null ()
            type(parameter_t), pointer :: mass_src => null ()
            real(default), pointer :: width_val => null ()
            type(parameter_t), pointer :: width_src => null ()
            integer :: multiplicity = 1
        end type particle_data_t

```

Initialize particle data with PDG long name and PDG code. TeX names should be initialized to avoid issues with accessing unallocated string contents.

```

<Models: public>+≡
    public :: particle_data_init

<Models: procedures>+≡
    subroutine particle_data_init (prt, longname, pdg)

```

```

    type(particle_data_t), intent(out) :: prt
    type(string_t), intent(in) :: longname
    integer, intent(in) :: pdg
    prt%longname = longname
    prt%pdg = pdg
    prt%tex_name = ""
    prt%tex_anti = ""
end subroutine particle_data_init

```

Copy quantum numbers from another particle

<Models: procedures>+≡

```

subroutine particle_data_copy (prt, prt_src)
    type(particle_data_t), intent(inout) :: prt

```

6.1.5 Vertex data

The vertex object contains an array of particle-data pointers, for which we need a separate type. (We could use the flavor type defined in another module.)

The program does not (yet?) make use of vertex definitions, so they are not stored here.

```

<Models: types>+≡
  type :: particle_p
    type(particle_data_t), pointer :: p => null ()
  end type particle_p

<Models: types>+≡
  type :: vertex_t
    logical :: trilinear
    integer, dimension(:), allocatable :: pdg
    type(particle_p), dimension(:), allocatable :: prt
  end type vertex_t

```

Initialize using PDG codes. The model is used for finding particle data pointers associated with the pdg codes.

```

<Models: procedures>+≡
  subroutine vertex_init (vtx, pdg, model)
    type(vertex_t), intent(out) :: vtx
    integer, dimension(:), intent(in) :: pdg
    type(model_t), intent(in), target, optional :: model
    integer :: i
    allocate (vtx%pdg (size (pdg)))
    allocate (vtx%prt (size (pdg)))
    vtx%trilinear = size (pdg) == 3
    vtx%pdg = pdg
    if (present (model)) then
      do i = 1, size (pdg)
        vtx%prt(i)%p => model_get_particle_ptr (model, pdg(i))
      end do
    end if
  end subroutine vertex_init

<Models: procedures>+≡
  subroutine vertex_write (vtx, unit)
    type(vertex_t), intent(in) :: vtx
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit); if (u < 0) return
    write (u, "(3x,A)", advance="no") "vertex"
    do i = 1, size (vtx%prt)
      if (associated (vtx%prt(i)%p)) then
        write (u, "(1x,A)", advance="no") &
          ''' // char (particle_data_get_name &
            (vtx%prt(i)%p, vtx%pdg(i) < 0)) &
          // '''
      else

      end if
    end do
  end subroutine vertex_write

```

```

        end if
    end do
    write (u, *)
end subroutine vertex_write

```

6.1.6 Vertex lookup table

The vertex lookup table is a hash table: given two particle codes, we check which codes are allowed for the third one.

The size of the hash table should be large enough that collisions are rare. We first select a size based on the number of vertices (multiplied by six because all permutations count), with some margin, and then choose the smallest integer power of two larger than this.

```

<Limits: public parameters>+≡
    integer, parameter, public :: VERTEX_TABLE_SCALE_FACTOR = 60

<Models: procedures>+≡
    function vertex_table_size (n_vtx) result (n)
        integer(i32) :: n
        integer, intent(in) :: n_vtx
        integer :: i, s
        s = VERTEX_TABLE_SCALE_FACTOR * n_vtx
        n = 1
        do i = 1, 31
            n = ishft (n, 1)
            s = ishft (s,-1)
            if (s == 0) exit
        end do
    end function vertex_table_size

```

The specific hash function takes two particle codes (arbitrary integers) and returns a 32-bit integer. It makes use of the universal function `hash` which operates on a byte array.

```

<Models: procedures>+≡
    function hash2 (pdg1, pdg2)
        integer(i32) :: hash2
        integer, intent(in) :: pdg1, pdg2
        integer(i8), dimension(1) :: mold
        hash2 = hash (transfer ((/pdg1, pdg2/), mold))
    end function hash2

```

Each entry in the vertex table stores the two particle codes and an array of possibilities for the third code.

```

<Models: types>+≡
    type :: vertex_table_entry_t
        integer :: pdg1 = 0, pdg2 = 0
        integer :: n = 0
        integer, dimension(:), allocatable :: pdg3
    end type vertex_table_entry_t

```

The vertex table:

(Models: types)+≡

```

type :: vertex_table_t
  type(vertex_table_entry_t), dimension(:), allocatable :: entry
  integer :: n_collisions = 0
  integer(i32) :: mask
end type vertex_table_t

```

Initializing the vertex table: This is done in two passes. First, we scan all permutations for all vertices and count the number of entries in each bucket of the hashtable. Then, the buckets are allocated accordingly and filled.

Collision resolution is done by just incrementing the hash value until an empty bucket is found. The vertex table size is fixed, since we know from the beginning the number of entries.

(Models: procedures)+≡

```

6.1.7 Model data

A model object holds all information about parameters, particles, and vertices. For models that require an external program for parameter calculation, there is the pointer to a function that does this calculation, given the set of independent and derived parameters.

When reading a model, we create a parse tree. Parameter definitions are available via parse nodes. Since we may need those later when making model instances, we keep the whole parse tree in the model definition (but not in the instances).

```

<Models: public>+≡
  public :: model_t

<Models: types>+≡
  type :: model_t
  private
  type(string_t) :: name
  character(32) :: md5sum = ""
  type(parameter_t), dimension(:), allocatable :: par
  type(particle_data_t), dimension(:), allocatable :: prt
  type(vertex_t), dimension(:), allocatable :: vtx
  type(vertex_table_t) :: vt
  type(var_list_t) :: var_list
  type(string_t) :: dlname
  procedure(model_init_external_parameters), nopass, pointer :: &
    init_external_parameters => null ()
  type(dlaccess_t) :: dlaccess
  type(parse_tree_t) :: parse_tree
contains

```

```

    <Models: model: TBP>
end type model_t

```

This is the interface for a procedure that initializes the calculation of external parameters, given the array of all parameters.

```

<Models: interfaces>≡
abstract interface
    subroutine model_init_external_parameters (par) bind (C)
        import
        real(c_default_float), dimension(*), intent(inout) :: par
    end subroutine model_init_external_parameters
end interface

```

Initialization: Specify the number of parameters, particles, vertices and allocate memory. If an associated DL library is specified, load this library.

```

<Models: procedures>+≡
subroutine model_init &

            return
        end if
        call c_f_procpointer (c_fptr, model% init_external_parameters)
    end if
end if
end subroutine model_init

```

For a model instance, we do not attempt to load a DL library. This is the core of the full initializer above.

```

<Models: procedures>+≡
subroutine model_basic_init (model, name, n_par, n_prt, n_vtx)
    type(model_t), intent(out) :: model
    type(string_t), intent(in) :: name
    integer, intent(in) :: n_par, n_prt, n_vtx
    model%name = name
    allocate (model%par (n_par))
    allocate (model%prt (n_prt))
    allocate (model%vtx (n_vtx))
end subroutine model_basic_init

```

Finalization: The variable list contains allocated pointers, also the parse tree. We also close the DL access object, if any, that enables external parameter calculation.

```

<Models: public>+≡
    public :: model_final

<Models: procedures>+≡
subroutine model_final (model)
    type(model_t), intent(inout) :: model
    call var_list_final (model%var_list)
    if (model%dlname /= "") call dlaccess_final (model%dlaccess)
    call parse_tree_final (model%parse_tree)
end subroutine model_final

```

Output. By default, the output is in the form of an input file. If `verbose` is true, for each derived parameter the definition (eval tree) is displayed, and the vertex hash table is shown.

```

```

6.1.10 Model instances

A model instance is a copy of a model object. The parameters are true copies. The particle data and the variable list pointers should point to the copy, so modifying the parameters has only a local effect. Hence, we build them up explicitly. The vertex array is also rebuilt, it contains particle pointers. Finally, the vertex hash table can be copied directly since it contains no pointers.

The instance must carry the `target` attribute.

```

<Models: public>+≡
    public :: model_init_instance

<Models: procedures>+≡
    subroutine model_init_instance (model, orig)

Chapter 7

Quantum Numbers

We introduce separate types and modules for particle quantum numbers and use them for defining independent particles and entangled states.

helicities Types and methods for spin density matrices.

colors Dealing with colored particles, using the color-flow representation.

flavors PDG codes and particle properties, depends on the model.

quantum_states Quantum numbers and density matrices for entangled particle systems.

7.1 Helicities

This module defines types and tools for dealing with helicity information.

```
<helicities.f90>≡  
  <File header>  
  
  module helicities  
  
    <Use file utils>  
  
    <Standard module head>  
  
    <Helicities: public>  
  
    <Helicities: types>  
  
    <Helicities: interfaces>  
  
    contains  
  
    <Helicities: procedures>  
  
  end module helicities
```

7.1.1 Helicity types

Helicities may be defined or undefined, corresponding to a polarized or unpolarized state. Each helicity is actually a pair of helicities, corresponding to an entry in the spin density matrix. Obviously, diagonal entries are distinguished. In addition, we have a ghost flag that would apply to FP ghosts in particular.

```
<Helicities: public>≡  
  public :: helicity_t  
  
<Helicities: types>≡  
  type :: helicity_t  
    private  
    logical :: defined = .false.  
    integer :: h1, h2  
    logical :: ghost = .false.  
  end type helicity_t
```

Initializers:

```
<Helicities: public>+≡  
  public :: helicity_init  
  
<Helicities: interfaces>≡  
  interface helicity_init  
    module procedure helicity_init0, helicity_init0g  
    module procedure helicity_init1, helicity_init1g  
    module procedure helicity_init2, helicity_init2g  
  end interface
```

```

<Helicities: procedures>+≡
  elemental subroutine helicity_init0 (hel)
    type(helicity_t), intent(out) :: hel
  end subroutine helicity_init0

  elemental subroutine helicity_init0g (hel, ghost)
    type(helicity_t), intent(out) :: hel
    logical, intent(in) :: ghost
    hel%ghost = ghost
  end subroutine helicity_init0g

  elemental subroutine helicity_init1 (hel, h)
    type(helicity_t), intent(out) :: hel
    integer, intent(in) :: h
    hel%defined = .true.
    hel%h1 = h
    hel%h2 = h
  end subroutine helicity_init1

  elemental subroutine helicity_init1g (hel, h, ghost)
    type(helicity_t), intent(out) :: hel
    integer, intent(in) :: h
    logical, intent(in) :: ghost
    call helicity_init1 (hel, h)
    hel%ghost = ghost
  end subroutine helicity_init1g

  elemental subroutine helicity_init2 (hel, h2, h1)
    type(helicity_t), intent(out) :: hel
    integer, intent(in) :: h1, h2
    hel%defined = .true.
    hel%h2 = h2
    hel%h1 = h1
  end subroutine helicity_init2

  elemental subroutine helicity_init2g (hel, h2, h1, ghost)
    type(helicity_t), intent(out) :: hel
    integer, intent(in) :: h1, h2
    logical, intent(in) :: ghost
    call helicity_init2 (hel, h2, h1)
    hel%ghost = ghost
  end subroutine helicity_init2g

```

Set the ghost property separately:

```

<Helicities: public>+≡
  public :: helicity_set_ghost

<Helicities: procedures>+≡
  elemental subroutine helicity_set_ghost (hel, ghost)
    type(helicity_t), intent(inout) :: hel
    logical, intent(in) :: ghost
    hel%ghost = ghost
  end subroutine helicity_set_ghost

```

Undefine:

```
<Helicities: public>+≡
    public :: helicity_undefine

<Helicities: procedures>+≡
    elemental subroutine helicity_undefine (hel)
        type(helicity_t), intent(inout) :: hel
        hel%defined = .false.
        hel%ghost = .false.
    end subroutine helicity_undefine
```

Diagonalize by removing the second entry (use with care!)

```
<Helicities: public>+≡
    public :: helicity_diagonalize

<Helicities: procedures>+≡
    elemental subroutine helicity_diagonalize (hel)
        type(helicity_t), intent(inout) :: hel
        hel%h2 = hel%h1
    end subroutine helicity_diagonalize
```

Output (no linebreak). No output if undefined.

```
<Helicities: public>+≡
    public :: helicity_write

<Helicities: procedures>+≡
    subroutine helicity_write (hel, unit)
        type(helicity_t), intent(in) :: hel
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit); if (u < 0) return
        if (hel%defined) then
            if (hel%ghost) then
                write (u, "(A)", advance="no") "h*"
            else
                write (u, "(A)", advance="no") "h("
            end if
            write (u, "(IO)", advance="no") hel%h1
            if (hel%h1 /= hel%h2) then
                write (u, "(A)", advance="no") "|"
                write (u, "(IO)", advance="no") hel%h2
            end if
            write (u, "(A)", advance="no") ")"
        else if (hel%ghost) then
            write (u, "(A)", advance="no") "h*"
        end if
    end subroutine helicity_write
```

Binary I/O. Write contents only if defined.

```
<Helicities: public>+≡
    public :: helicity_write_raw
    public :: helicity_read_raw
```

```

<Helicities: procedures>+≡
  subroutine helicity_write_raw (hel, u)
    type(helicity_t), intent(in) :: hel
    integer, intent(in) :: u
    write (u) hel%defined
    if (hel%defined) then
      write (u) hel%h1, hel%h2
      write (u) hel%ghost
    end if
  end subroutine helicity_write_raw

  subroutine helicity_read_raw (hel, u, iostat)
    type(helicity_t), intent(out) :: hel
    integer, intent(in) :: u
    integer, intent(out), optional :: iostat
    read (u, iostat=iostat) hel%defined
    if (hel%defined) then
      read (u, iostat=iostat) hel%h1, hel%h2
      read (u, iostat=iostat) hel%ghost
    end if
  end subroutine helicity_read_raw

```

7.1.2 Predicates

Check if the helicity is defined:

```

<Helicities: public>+≡
  public :: helicity_is_defined

<Helicities: procedures>+≡
  elemental function helicity_is_defined (hel) result (defined)
    logical :: defined
    type(helicity_t), intent(in) :: hel
    defined = hel%defined
  end function helicity_is_defined

```

Return true if the two helicities are equal or the particle is unpolarized:

```

<Helicities: public>+≡
  public :: helicity_is_diagonal

<Helicities: procedures>+≡
  elemental function helicity_is_diagonal (hel) result (diagonal)
    logical :: diagonal
    type(helicity_t), intent(in) :: hel
    if (hel%defined) then
      diagonal = hel%h1 == hel%h2
    else
      diagonal = .true.
    end if
  end function helicity_is_diagonal

```

Return the ghost flag

```

<Helicities: public>+≡
  public :: helicity_is_ghost

```

```

<Helicities: procedures>+≡
  elemental function helicity_is_ghost (hel) result (ghost)
    logical :: ghost
    type(helicity_t), intent(in) :: hel
    ghost = hel%ghost
  end function helicity_is_ghost

```

7.1.3 Accessing contents

This returns a two-element array and thus cannot be elemental. The result is unpredictable if the helicity is undefined.

```

<Helicities: public>+≡
  public :: helicity_get

<Helicities: procedures>+≡
  pure function helicity_get (hel) result (h)
    integer, dimension(2) :: h
    type(helicity_t), intent(in) :: hel
    h(1) = hel%h2
    h(2) = hel%h1
  end function helicity_get

```

7.1.4 Comparisons

When comparing helicities, if either one is undefined, they are considered to match. In other words, an unpolarized particle matches any polarization. In the `dmatch` variant, it matches only diagonal helicity.

The ghost flag is ignored when matching, but matters when testing for equality.

```

<Helicities: public>+≡
  public :: operator(.match.)
  public :: operator(.dmatch.)
  public :: operator(==)
  public :: operator(/=)

<Helicities: interfaces>+≡
  interface operator(.match.)
    module procedure helicity_match
  end interface
  interface operator(.dmatch.)
    module procedure helicity_match_diagonal
  end interface
  interface operator(==)
    module procedure helicity_eq
  end interface
  interface operator(/=)
    module procedure helicity_neq
  end interface

```

```

<Helicities: procedures>+=
  elemental function helicity_match (hel1, hel2) result (eq)
    logical :: eq
    type(helicity_t), intent(in) :: hel1, hel2
    if (hel1%defined .and. hel2%defined) then
      eq = (hel1%h1 == hel2%h1) .and. (hel1%h2 == hel2%h2)
    else
      eq = .true.
    end if
  end function helicity_match

  elemental function helicity_match_diagonal (hel1, hel2) result (eq)
    logical :: eq
    type(helicity_t), intent(in) :: hel1, hel2
    if (hel1%defined .and. hel2%defined) then
      eq = (hel1%h1 == hel2%h1) .and. (hel1%h2 == hel2%h2)
    else if (hel1%defined) then
      eq = hel1%h1 == hel1%h2
    else if (hel2%defined) then
      eq = hel2%h1 == hel2%h2
    else
      eq = .true.
    end if
  end function helicity_match_diagonal

<Helicities: procedures>+=
  elemental function helicity_eq (hel1, hel2) result (eq)
    logical :: eq
    type(helicity_t), intent(in) :: hel1, hel2
    if (hel1%defined .and. hel2%defined) then
      eq = (hel1%h1 == hel2%h1) .and. (hel1%h2 == hel2%h2) &
        .and. (hel1%ghost .eqv. hel2%ghost)
    else if (.not. hel1%defined .and. .not. hel2%defined) then
      eq = hel1%ghost .eqv. hel2%ghost
    else
      eq = .false.
    end if
  end function helicity_eq

<Helicities: procedures>+=
  elemental function helicity_neq (hel1, hel2) result (neq)
    logical :: neq
    type(helicity_t), intent(in) :: hel1, hel2
    if (hel1%defined .and. hel2%defined) then
      neq = (hel1%h1 /= hel2%h1) .or. (hel1%h2 /= hel2%h2) &
        .or. (hel1%ghost .neqv. hel2%ghost)
    else if (.not. hel1%defined .and. .not. hel2%defined) then
      neq = hel1%ghost .neqv. hel2%ghost
    else
      neq = .true.
    end if
  end function helicity_neq

```

7.1.5 Tools

Merge two helicity objects by taking the first entry from the first and the second entry from the second argument. Makes sense only if the input helicities were defined and diagonal. The handling of ghost flags is not well-defined; one should verify beforehand that they match.

```
<Helicities: public>+≡
    public :: operator(.merge.)

<Helicities: interfaces>+≡
    interface operator(.merge.)
        module procedure merge_helicities
    end interface

<Helicities: procedures>+≡
    elemental function merge_helicities (hel1, hel2) result (hel)
        type(helicity_t) :: hel
        type(helicity_t), intent(in) :: hel1, hel2
        if (helicity_is_defined (hel1) .and. helicity_is_defined (hel2)) then
            call helicity_init2g (hel, hel2%h1, hel1%h1, hel1%ghost)
        else if (helicity_is_defined (hel1)) then
            hel = hel1
        else if (helicity_is_defined (hel2)) then
            hel = hel2
        end if
    end function merge_helicities
```

7.2 Colors

This module defines a type and tools for dealing with color information.

Each particle can have zero or more (in practice, usually not more than two) color indices. Color indices are positive; flow direction can be determined from the particle nature.

While parton shower matrix elements are diagonal in color, some special applications (e.g., subtractions for NLO matrix elements) require non-diagonal color matrices.

```
<colors.f90>≡
  <File header>

  module colors

    <Use kinds>
    <Use file utils>
    use diagnostics !NODEP!

    <Standard module head>

    <Colors: public>

    <Colors: types>

    <Colors: interfaces>

    contains

    <Colors: procedures>

  end module colors
```

7.2.1 The color type

A particle may have an arbitrary number of color indices (in practice, from zero to two, but more are possible). This object acts as a container.

The fact that color comes as an array prohibits elemental procedures in some places. (May add interfaces and multi versions where necessary.)

The color may be undefined; this corresponds to unallocated arrays.

NOTE: Due to a compiler bug in nagfor 5.2, we do not use allocatable but fixed-size arrays with dimension 2. Only nonzero entries count. This may be more efficient anyway, but gives up some flexibility. However, the squaring algorithm currently works only for singlets, (anti)triplets and octets anyway, so two components are enough.

```
<Colors: public>≡
  public :: color_t

<Colors: types>≡
  type :: color_t
    private
    ! integer, dimension(:), allocatable :: c1, c2
    integer, dimension(2) :: c1 = 0, c2 = 0
```

```

        logical :: ghost = .false.
    end type color_t

```

Initializers:

```

<Colors: public>+≡
    public :: color_init

<Colors: interfaces>≡
    interface color_init
        module procedure color_init_undefined, color_init_undefined_ghost
        module procedure color_init_array, color_init_array_ghost
        module procedure color_init_arrays, color_init_arrays_ghost
    end interface

```

Undefined color: array remains unallocated

```

<Colors: procedures>≡
    pure subroutine color_init_undefined (col)
        type(color_t), intent(out) :: col
    end subroutine color_init_undefined

    pure subroutine color_init_undefined_ghost (col, ghost)
        type(color_t), intent(out) :: col
        logical, intent(in) :: ghost
        col%ghost = ghost
    end subroutine color_init_undefined_ghost

```

This defines color from an arbitrary length color array, suitable for any representation. We may have two color arrays (non-diagonal matrix elements). This cannot be elemental. The third version assigns an array of colors, using a two-dimensional array as input.

```

<Colors: procedures>+≡
    pure subroutine color_init_array (col, c1)
        type(color_t), intent(out) :: col
        integer, dimension(:), intent(in) :: c1
    !    allocate (col%c1 (size (c1)))
    !    allocate (col%c2 (size (c1)))
        col%c1 = pack (c1, c1 /= 0, col%c1)
        col%c2 = col%c1
    end subroutine color_init_array

    pure subroutine color_init_array_ghost (col, c1, ghost)
        type(color_t), intent(out) :: col
        integer, dimension(:), intent(in) :: c1
        logical, intent(in) :: ghost
        call color_init_array (col, c1)
        col%ghost = ghost
    end subroutine color_init_array_ghost

    pure subroutine color_init_arrays (col, c1, c2)
        type(color_t), intent(out) :: col
        integer, dimension(:), intent(in) :: c1, c2
        if (size (c1) == size (c2)) then

```

```

!      allocate (col%c1 (size (c1)))
!      allocate (col%c2 (size (c2)))
      col%c1 = pack (c1, c1 /= 0, col%c1)
      col%c2 = pack (c2, c2 /= 0, col%c2)
    else if (size (c1) /= 0) then
!      allocate (col%c1 (size (c1)))
!      allocate (col%c2 (size (c1)))
      col%c1 = pack (c1, c1 /= 0, col%c1)
      col%c2 = col%c1
    else if (size (c2) /= 0) then
!      allocate (col%c1 (size (c2)))
!      allocate (col%c2 (size (c2)))
      col%c1 = pack (c2, c2 /= 0, col%c2)
      col%c2 = col%c1
    end if
  end subroutine color_init_arrays

  pure subroutine color_init_arrays_ghost (col, c1, c2, ghost)
    type(color_t), intent(out) :: col
    integer, dimension(:), intent(in) :: c1, c2
    logical, intent(in) :: ghost
    call color_init_arrays (col, c1, c2)
    col%ghost = ghost
  end subroutine color_init_arrays_ghost

```

This version is restricted to singlets, triplets, antitriplets, and octets: The input contains the color and anticolor index, each of the may be zero.

<Colors: public>+≡

```
public :: color_init_col_acl
```

<Colors: procedures>+≡

```

elemental subroutine color_init_col_acl (col, col_in, acl_in)
  type(color_t), intent(out) :: col
  integer, intent(in) :: col_in, acl_in
  integer, dimension(0) :: null_array
  select case (col_in)
  case (0)
    select case (acl_in)
    case (0)
      call color_init_array (col, null_array)
    case default
      call color_init_array (col, (/ -acl_in /))
    end select
  case default
    select case (acl_in)
    case (0)
      call color_init_array (col, (/ col_in /))
    case default
      call color_init_array (col, (/ col_in, -acl_in /))
    end select
  end select
end subroutine color_init_col_acl

```

This version is used for the external interface. We convert a fixed-size array

of colors (for each particle) to the internal form by packing only the nonzero entries.

```

    end do SCAN1
    allocate (c_index (n))
    c_index = c_tmp(1:n)
end subroutine extract_color_line_indices

```

Given a color array, pairwise contract the color lines in all possible ways and

return the resulting array of arrays. The input color array must be diagonal, and each color should occur exactly twice, once as color and once as anticolor.

Gluon entries with equal color and anticolor are explicitly excluded.

This algorithm is generic, but for long arrays it is neither efficient, nor does it avoid duplicates. It is intended for small arrays, in particular for the state matrix of a structure-function pair.

```

end function compute_color_factor

```

We have a pair of color index arrays which corresponds to a squared matrix element. We want to determine the number of color loops in this square matrix element. So we first copy the colors (stored in a single color array with a pair of color lists in each entry) to a temporary where the color indices are shifted by some offset. We then recursively follow each loop, starting at the first color that has the offset, resetting the first color index to the loop index and each further index to zero as we go. We check that (a) each color index occurs twice within the left (right) color array, (b) the loops are closed, so we always come back to a line which has the loop index.

In order for the algorithm to work we have to conjugate the colors of initial state particles (one for decays, two for scatterings) into their corresponding anticolors of outgoing particles.

```

7.2.7 The Madgraph color model

This section describes the method for matrix element and color flow calculation within Madgraph.

For each Feynman diagram, the colorless amplitude for a specified helicity and momentum configuration (in- and out- combined) is computed:

$$A_d(p, h) \quad (7.1)$$

Inserting color, the squared matrix element for definite helicity and momentum is

$$M^2(p, h) = \sum_{dd'} A_d(p, h) C_{dd'} A_{d'}^*(p, h) \quad (7.2)$$

where $C_{dd'}$ describes the color interference of the two diagrams A_d and $A_{d'}$, which is independent of momentum and helicity and can be calculated for each Feynman diagram pair by reducing it to the corresponding color graph. Obviously, one could combine all diagrams with identical color structure, such that the index d runs only over different color graphs. For colorless diagrams all elements of $C_{dd'}$ are equal to unity.

The hermitian matrix $C_{dd'}$ is diagonalized once and for all, such that it can be written in the form

$$C_{dd'} = \sum_{\lambda} c_d^{\lambda} \lambda c_{d'}^{\lambda*}, \quad (7.3)$$

where the eigenvectors c_d are normalized,

$$\sum_d |c_d^{\lambda}|^2 = 1, \quad (7.4)$$

and the λ values are the corresponding eigenvalues. In the colorless case, this means $c_d = 1/\sqrt{N_d}$ for all diagrams (N_d = number of diagrams), and $\lambda = N_d$ is the only nonzero eigenvalue.

Consequently, the squared matrix element for definite helicity and momentum can also be written as

$$M^2(p, h) = \sum_{\lambda} A_{\lambda}(p, h) \lambda A_{\lambda}(p, h)^* \quad (7.5)$$

with

$$A_{\lambda}(p, h) = \sum_d c_d^{\lambda} A_d(p, h). \quad (7.6)$$

For generic spin density matrices, this is easily generalized to

$$M^2(p, h, h') = \sum_{\lambda} A_{\lambda}(p, h) \lambda A_{\lambda}(p, h')^* \quad (7.7)$$

To determine the color flow probabilities of a given momentum-helicity configuration, the color flow amplitudes are calculated as

$$a_f(p, h) = \sum_d \beta_d^f A_d(p, h), \quad (7.8)$$

where the coefficients β_d^f describe the amplitude for a given Feynman diagram (or color graph) d to correspond to a definite color flow f . They are computed from $C_{dd'}$ by transforming this matrix into the color flow basis and neglecting all off-diagonal elements. Again, these coefficients do not depend on momentum or helicity and can therefore be calculated in advance. This gives the color flow transition matrix

$$F^f(p, h, h') = a_f(p, h) a_f^*(p, h') \quad (7.9)$$

which is assumed diagonal in color flow space and is separate from the color-summed transition matrix M^2 . They are, however, equivalent (up to a factor) to leading order in $1/N_c$, and using the color flow transition matrix is appropriate for matching to hadronization.

Note that the color flow transition matrix is not normalized at this stage. To make use of it, we have to fold it with the in-state density matrix to get a pseudo density matrix

$$\hat{\rho}_{\text{out}}^f(p, h_{\text{out}}, h'_{\text{out}}) = \sum_{h_{\text{in}} h'_{\text{in}}} F^f(p, h, h') \rho_{\text{in}}(p, h_{\text{in}}, h'_{\text{in}}) \quad (7.10)$$

which gets a meaning only after contracted with projections on the outgoing helicity states k_{out} , given as linear combinations of helicity states with the unitary coefficient matrix $c(k_{\text{out}}, h_{\text{out}})$. Then the probability of finding color flow f when the helicity state k_{out} is measured is given by

$$P^f(p, k_{\text{out}}) = Q^f(p, k_{\text{out}}) / \sum_f Q^f(p, k_{\text{out}}) \quad (7.11)$$

where

$$Q^f(p, k_{\text{out}}) = \sum_{h_{\text{out}} h'_{\text{out}}} c(k_{\text{out}}, h_{\text{out}}) \hat{\rho}_{\text{out}}^f(p, h_{\text{out}}, h'_{\text{out}}) c^*(k_{\text{out}}, h'_{\text{out}}) \quad (7.12)$$

However, if we can assume that the out-state helicity basis is the canonical one, we can throw away the off diagonal elements in the color flow density matrix and normalize the ones on the diagonal to obtain

$$P^f(p, h_{\text{out}}) = \hat{\rho}_{\text{out}}^f(p, h_{\text{out}}, h_{\text{out}}) / \sum_f \hat{\rho}_{\text{out}}^f(p, h_{\text{out}}, h_{\text{out}}) \quad (7.13)$$

Finally, the color-summed out-state density matrix is computed by the scattering formula

$$\rho_{\text{out}}(p, h_{\text{out}}, h'_{\text{out}}) = \sum_{h_{\text{in}} h'_{\text{in}}} M^2(p, h, h') \rho_{\text{in}}(p, h_{\text{in}}, h'_{\text{in}}) \quad (7.14)$$

$$= \sum_{h_{\text{in}} h'_{\text{in}} \lambda} A_{\lambda}(p, h) \lambda A_{\lambda}(p, h')^* \rho_{\text{in}}(p, h_{\text{in}}, h'_{\text{in}}), \quad (7.15)$$

The trace of ρ_{out} is the squared matrix element, summed over all internal degrees of freedom. To get the squared matrix element for a definite helicity k_{out} and color flow f , one has to project the density matrix onto the given helicity state and multiply with $P^f(p, k_{\text{out}})$.

For diagonal helicities the out-state density reduces to

$$\rho_{\text{out}}(p, h_{\text{out}}) = \sum_{h_{\text{in}} \lambda} \lambda |A_{\lambda}(p, h)|^2 \rho_{\text{in}}(p, h_{\text{in}}). \quad (7.16)$$

Since no basis transformation is involved, we can use the normalized color flow probability $P^f(p, h_{\text{out}})$ and express the result as

$$\rho_{\text{out}}^f(p, h_{\text{out}}) = \rho_{\text{out}}(p, h_{\text{out}}) P^f(p, h_{\text{out}}) \quad (7.17)$$

$$= \sum_{h_{\text{in}} \lambda} \frac{|a^f(p, h)|^2}{\sum_f |a^f(p, h)|^2} \lambda |A_{\lambda}(p, h)|^2 \rho_{\text{in}}(p, h_{\text{in}}). \quad (7.18)$$

From these considerations, the following calculation strategy can be derived:

- Before the first event is generated, the color interference matrix $C_{dd'}$ is computed and diagonalized, so the eigenvectors c_d^{λ} , eigenvalues λ and color flow coefficients β_d^f are obtained. In practice, these calculations are done when the matrix element code is generated, and the results are hardcoded in the matrix element subroutine as **DATA** statements.
- For each event, one loops over helicities once and stores the matrices $A_{\lambda}(p, h)$ and $a^f(p, h)$. The allowed color flows, helicity combinations and eigenvalues are each labeled by integer indices, so one has to store complex matrices of dimension $N_{\lambda} \times N_h$ and $N_f \times N_h$, respectively.
- The further strategy depends on the requested information.
 1. If colorless diagonal helicity amplitudes are required, the eigenvalues $A_{\lambda}(p, h)$ are squared, summed with weight λ , and the result contracted with the in-state probability vector $\rho_{\text{in}}(p, h_{\text{in}})$. The result is a probability vector $\rho_{\text{out}}(p, h_{\text{out}})$.

2. For colored diagonal helicity amplitudes, the color coefficients $a^f(p, h)$ are also squared and used as weights to obtain the color-flow probability vector $\rho_{\text{out}}^f(p, h_{\text{out}})$.
3. For colorless non-diagonal helicity amplitudes, we contract the tensor product of $A_\lambda(p, h)$ with $A_\lambda(p, h')$, weighted with λ , with the correlated in-state density matrix, to obtain a correlated out-state density matrix.
4. In the general (colored, non-diagonal) case, we do the same as in the colorless case, but return the un-normalized color flow density matrix $\hat{\rho}_{\text{out}}^f(p, h_{\text{out}}, h'_{\text{out}})$ in addition. When the relevant helicity basis is known, the latter can be used by the caller program to determine flow probabilities. (In reality, we assume the canonical basis and reduce the correlated out-state density to its diagonal immediately.)

7.3 Flavors: Particle properties

This module contains a type for holding the flavor code, and all functions that depend on the model, i.e., that determine particle properties.

The PDG code is packed in a special **flavor** type. (This prohibits meaningless operations, and it allows for a different implementation, e.g., some non-PDG scheme internally, if appropriate at some point.) In addition, the flavor object holds a pointer to a **particle_data** object which is centrally stored (as part of a physics model). In this way, all particle data can be accessed using just the **flv** object without having to carry them around.

The pointer component imposes a technical restriction: Assignment of flavor objects cannot be used, directly or indirectly, in pure, and thus in elemental procedures.

```
<flavors.f90>≡  
<File header>  
  
module flavors  
  
  <Use kinds>  
  <Use strings>  
  <Use file utils>  
  use pdg_arrays  
  use colors, only: color_t, color_init  
  use models  
  
  <Standard module head>  
  
  <Flavors: public>  
  
  <Flavors: types>  
  
  <Flavors: interfaces>  
  
contains  
  
  <Flavors: procedures>  
  
end module flavors
```

7.3.1 The flavor type

The flavor type is an integer representing the PDG code, or undefined (zero). Negative codes represent antiparticles.

For full generality, and analogy with helicity and color, we allow for non-diagonal flavor indices in density matrices. This is probably academic; an obscure application is the definition of proper isospin states.

Further properties of the given flavor can be retrieved via the particle-data pointer, if it is associated.

```
<Flavors: public>≡  
  public :: flavor_t
```

```

<Flavors: types>≡
  type :: flavor_t
  private
  integer :: f = UNDEFINED
  type(particle_data_t), pointer :: prt => null ()
end type flavor_t

```

Initializer form. If the model is assigned, the procedure is impure, therefore we have to define a separate array version.

```

<Flavors: public>+≡
  public :: flavor_init

<Flavors: interfaces>≡
  interface flavor_init
    module procedure flavor_init0_empty
    module procedure flavor_init0
    module procedure flavor_init0_particle_data
    module procedure flavor_init0_model
    module procedure flavor_init0_name_model

end subroutine flavor_init0_name_model

subroutine flavor_init1_name_model (flv, name, model)
    type(flavor_t), dimension(:), intent(out) :: flv
    type(string_t), dimension(:), intent(in) :: name
    type(model_t), intent(in), target :: model
    integer :: i
    do i = 1, size (name)
        call flavor_init0_name_model (flv(i), name(i), model)
    end do
end subroutine flavor_init1_name_model

```

This version transforms a PDG array value into a flavor array. The flavor array must be allocatable.

```

<Flavors: procedures>+≡
subroutine flavor_init_aval_model (flv, aval, model)
    type(flavor_t), dimension(:), intent(out), allocatable :: flv
    type(pdg_array_t), intent(in) :: aval
    type(model_t), intent(in), target :: model
    integer, dimension(:), allocatable :: pdg
    pdg = aval
    allocate (flv (size (pdg)))
    call flavor_init (flv, pdg, model)
end subroutine flavor_init_aval_model

```

Undefine the flavor state:

```

<Flavors: public>+≡
public :: flavor_undefine

<Flavors: procedures>+≡
elemental subroutine flavor_undefine (flv)

```

```

    type(flavor_t), intent(inout) :: flv
    flv%f = UNDEFINED
    flv%prt => null ()
end subroutine flavor_undefine

```

Output: dense, no linebreak

<Flavors: public>+≡

```

public :: flavor_write

```

<Flavors: procedures>+≡

```

subroutine flavor_write (flv, unit)
    type(flavor_t), intent(in) :: flv
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit); if (u < 0) return
    if (associated (flv%prt)) then
        write (u, "(A)", advance="no") "f("
    else
        write (u, "(A)", advance="no") "p("
    end if
    write (u, "(I0)", advance="no") flv%f
    write (u, "(A)", advance="no") ")"
end subroutine flavor_write

```

Binary I/O. Currently, the model information is not written/read, so after reading the particle-data pointer is empty.

<Flavors: public>+≡

```

public :: flavor_write_raw
public :: flavor_read_raw

```

<Flavors: procedures>+≡

```

subroutine flavor_write_raw (flv, u)
    type(flavor_t), intent(in) :: flv
    integer, intent(in) :: u
    write (u) flv%f
end subroutine flavor_write_raw

subroutine flavor_read_raw (flv, u, iostat)
    type(flavor_t), intent(out) :: flv
    integer, intent(in) :: u
    integer, intent(out), optional :: iostat
    read (u, iostat=iostat) flv%f
end subroutine flavor_read_raw

```

Assignment

Default assignment of flavor objects is possible, but cannot be used in pure procedures, because a pointer assignment is involved.

Assign the particle pointer separately. This cannot be elemental, so we define a scalar and an array version explicitly. We refer to an array of flavors, not an array of models.

<Flavors: public>+≡

```

    public :: flavor_set_model
<Flavors: interfaces>+≡
    interface flavor_set_model
        module procedure flavor_set_model_single
        module procedure flavor_set_model_array
    end interface
<Flavors: procedures>+≡
    subroutine flavor_set_model_single (flv, model)
        type(flavor_t), intent(inout) :: flv
        type(model_t), intent(in), target :: model
        if (flv%f /= UNDEFINED) &
            flv%prt => model_get_particle_ptr (model, flv%f)
    end subroutine flavor_set_model_single

    subroutine flavor_set_model_array (flv, model)
        type(flavor_t), dimension(:), intent(inout) :: flv
        type(model_t), intent(in), target :: model
        integer :: i
        do i = 1, size (flv)
            if (flv(i)%f /= UNDEFINED) &
                flv(i)%prt => model_get_particle_ptr (model, flv(i)%f)
        end do
    end subroutine flavor_set_model_array

```

Predicates

Return the definition status

```

<Flavors: public>+≡
    public :: flavor_is_defined
<Flavors: procedures>+≡
    elemental function flavor_is_defined (flv) result (defined)
        logical :: defined
        type(flavor_t), intent(in) :: flv
        defined = flv%f /= UNDEFINED
    end function flavor_is_defined

```

Check for valid flavor (including undefined):

```

<Flavors: public>+≡
    public :: flavor_is_valid
<Flavors: procedures>+≡
    elemental function flavor_is_valid (flv) result (valid)
        logical :: valid
        type(flavor_t), intent(in) :: flv
        valid = flv%f /= INVALID
    end function flavor_is_valid

```

Return true if the particle-data pointer is associated. (Debugging aid)

```

<Flavors: public>+≡
    public :: flavor_is_associated

```

```

<Flavors: procedures>+≡
  elemental function flavor_is_associated (flv) result (flag)
    logical :: flag
    type(flavor_t), intent(in) :: flv
    flag = associated (flv%prt)
  end function flavor_is_associated

```

Accessing contents

With the exception of the PDG code, all particle properties are accessible only via the `prt` pointer. If this is unassigned, some access function will crash.

Return the flavor as an integer

```

<Flavors: public>+≡
  public :: flavor_get_pdg

<Flavors: procedures>+≡
  elemental function flavor_get_pdg (flv) result (f)
    integer :: f
    type(flavor_t), intent(in) :: flv
    f = flv%f
  end function flavor_get_pdg

```

Return the flavor of the antiparticle

```

<Flavors: public>+≡
  public :: flavor_get_pdg_anti

<Flavors: procedures>+≡
  elemental function flavor_get_pdg_anti (flv) result (f)
    integer :: f
    type(flavor_t), intent(in) :: flv
    if (associated (flv%prt)) then
      if (particle_data_has_antiparticle (flv%prt)) then
        f = -flv%f
      else
        f = flv%f
      end if
    else
      f = 0
    end if
  end function flavor_get_pdg_anti

```

Absolute value:

```

<Flavors: public>+≡
  public :: flavor_get_pdg_abs

<Flavors: procedures>+≡
  elemental function flavor_get_pdg_abs (flv) result (f)
    integer :: f
    type(flavor_t), intent(in) :: flv
    f = abs (flv%f)
  end function flavor_get_pdg_abs

```

    else if (flv1%f == UNDEFINED .and. flv2%f == UNDEFINED) then
        neq = .false.
    else
        neq = .true.
    end if
end function flavor_neq

```

Tools

Merge two flavor indices. This works only if both are equal or either one is undefined, because we have no off-diagonal flavor entries. Otherwise, generate an invalid flavor.

We cannot use elemental procedures because of the pointer component.

```

<Flavors: public>+≡
    public :: operator(.merge.)

<Flavors: interfaces>+≡
    interface operator(.merge.)
        module procedure merge_flavors0
        module procedure merge_flavors1
    end interface

<Flavors: procedures>+≡
function merge_flavors0 (flv1, flv2) result (flv)
    type(flavor_t) :: flv
    type(flavor_t), intent(in) :: flv1, flv2
    if (flavor_is_defined (flv1) .and. flavor_is_defined (flv2)) then
        if (flv1 == flv2) then
            flv = flv1
        else
            flv%f = INVALID
        end if
    else if (flavor_is_defined (flv1)) then
        flv = flv1
    else if (flavor_is_defined (flv2)) then
        flv = flv2
    end if
end function merge_flavors0

function merge_flavors1 (flv1, flv2) result (flv)
    type(flavor_t), dimension(:), intent(in) :: flv1, flv2
    type(flavor_t), dimension(size(flv1)) :: flv
    integer :: i

```

```

do i = 1, size (flv1)
  flv(i) = flv1(i) .merge. flv2(i)
end do
end function merge_flavors1

```

Generate consecutive color indices for a given flavor. The indices are counted starting with the stored value of *c*, so new indices are created each time this (impure) function is called. The counter can be reset by the optional argument *c_seed* if desired. The optional flag *reverse* is used only for octets. If set, the color and anticolor entries of the octet particle are exchanged.

```

<Flavors: public>+≡
  public :: color_from_flavor

<Flavors: interfaces>+≡
  interface color_from_flavor
    module procedure color_from_flavor0
    module procedure color_from_flavor1
  end interface

<Flavors: procedures>+≡
  function color_from_flavor0 (flv, c_seed, reverse) result (col)
    type(color_t) :: col
    type(flavor_t), intent(in) :: flv
    integer, intent(in), optional :: c_seed
    logical, intent(in), optional :: reverse
    integer, save :: c = 1
    logical :: rev
    if (present (c_seed)) c = c_seed
    rev = .false.; if (present (reverse)) rev = reverse
    select case (flavor_get_color_type (flv))
    case (1)
    case (3)
      call color_init (col, (/ c /)); c = c + 1

  subroutine quantum_numbers_set_model_single (qn, model)
    type(quantum_numbers_t), intent(inout) :: qn
    type(model_t), intent(in), target :: model
    call flavor_set_model (qn%f, model)
  end subroutine quantum_numbers_set_model_single

  subroutine quantum_numbers_set_model_array (qn, model)
    type(quantum_numbers_t), dimension(:), intent(inout) :: qn
    type(model_t), intent(in), target :: model
    call flavor_set_model (qn%f, model)
  end subroutine quantum_numbers_set_model_array
```

This is a convenience function: return the color type for the flavor (array).

```
<Quantum numbers: public>+≡
  public :: quantum_numbers_get_color_type

<Quantum numbers: procedures>+≡
  elemental function quantum_numbers_get_color_type (qn) result (color_type)
    integer :: color_type
    type(quantum_numbers_t), intent(in) :: qn
    color_type = flavor_get_color_type (qn%f)
  end function quantum_numbers_get_color_type
```

7.4.4 Predicates

Check if the flavor index is valid (including UNDEFINED).

```
<Quantum numbers: public>+≡
  public :: quantum_numbers_are_valid

<Quantum numbers: procedures>+≡
  elemental function quantum_numbers_are_valid (qn) result (valid)
    logical :: valid
    type(quantum_numbers_t), intent(in) :: qn
    valid = flavor_is_valid (qn%f)
  end function quantum_numbers_are_valid
```

Check if the flavor part has its particle-data pointer associated (debugging aid).

```
<Quantum numbers: public>+≡
  public :: quantum_numbers_are_associated

<Quantum numbers: procedures>+≡
  elemental function quantum_numbers_are_associated (qn) result (flag)
    logical :: flag
    type(quantum_numbers_t), intent(in) :: qn
    flag = flavor_is_associated (qn%f)
  end function quantum_numbers_are_associated
```

Check if the helicity and color quantum numbers are diagonal. (Unpolarized/colorless also counts as diagonal.) Flavor is diagonal by definition.

```

<Quantum numbers: public>+≡
  public :: quantum_numbers_are_diagonal

<Quantum numbers: procedures>+≡
  elemental function quantum_numbers_are_diagonal (qn) result (diagonal)
    logical :: diagonal
    type(quantum_numbers_t), intent(in) :: qn
    diagonal = helicity_is_diagonal (qn%h) .and. color_is_diagonal (qn%c)
  end function quantum_numbers_are_diagonal

```

Check if the color and/or helicity part has the ghost property.

```

<Quantum numbers: public>+≡
  public :: quantum_numbers_is_color_ghost
  public :: quantum_numbers_is_helicity_ghost

<Quantum numbers: procedures>+≡
  elemental function quantum_numbers_is_color_ghost (qn) result (ghost)
    logical :: ghost
    type(quantum_numbers_t), intent(in) :: qn
    ghost = color_is_ghost (qn%c)
  end function quantum_numbers_is_color_ghost

  elemental function quantum_numbers_is_helicity_ghost (qn) result (ghost)
    logical :: ghost
    type(quantum_numbers_t), intent(in) :: qn
    ghost = helicity_is_ghost (qn%h)
  end function quantum_numbers_is_helicity_ghost

```

7.4.5 Comparisons

Matching and equality is derived from the individual quantum numbers. The variant `fhmatch` matches only flavor and helicity. The variant `dhmatch` matches only diagonal helicity, if the matching helicity is undefined.

```

<Quantum numbers: public>+≡
  public :: operator(.match.)
  public :: operator(.fmatch.)
  public :: operator(.fhmatch.)
  public :: operator(.dhmatch.)
  public :: operator(==)
  public :: operator(/=)

<Quantum numbers: interfaces>+≡
  interface operator(.match.)
    module procedure quantum_numbers_match
  end interface
  interface operator(.fmatch.)
    module procedure quantum_numbers_match_f
  end interface
  interface operator(.fhmatch.)
    module procedure quantum_numbers_match_fh
  end interface

```

```

interface operator(.dhmatch.)
  module procedure quantum_numbers_match_hel_diag
end interface
interface operator(==)
  module procedure quantum_numbers_eq
end interface
interface operator(/=)
  module procedure quantum_numbers_neq
end interface

(Quantum numbers: procedures) +=
  elemental function quantum_numbers_match (qn1, qn2) result (match)
    logical :: match

    type(quantum_numbers_t), intent(in) :: qn1, qn2
    neq = (qn1%f /= qn2%f) .or. &
      (qn1%c /= qn2%c) .or. &
      (qn1%h /= qn2%h)
  end function quantum_numbers_neq

```

Two sets of quantum numbers are compatible if the individual quantum numbers are compatible, depending on the mask. Flavor has to match, regardless of the flavor mask.

If the color flag is set, color is compatible if the ghost property is identical. If the color flag is unset, color has to be identical. I.e., if the flag is set, the color amplitudes can interfere. If it is not set, they must be identical, and there must be no ghost. The latter property is used for expanding physical color flows.

Helicity is compatible if the mask is unset, otherwise it has to match. This determines if two amplitudes can be multiplied (no mask) or traced (mask).

```

<Quantum numbers: public>+≡
    public :: quantum_numbers_are_compatible

<Quantum numbers: procedures>+≡
    elemental function quantum_numbers_are_compatible (qn1, qn2, mask) &
        result (flag)
        logical :: flag
        type(quantum_numbers_t), intent(in) :: qn1, qn2
        type(quantum_numbers_mask_t), intent(in) :: mask
        if (mask%h .or. mask%hd) then
            flag = (qn1%f .match. qn2%f) .and. (qn1%h .match. qn2%h)
        else
            flag = (qn1%f .match. qn2%f)
        end if
        if (mask%c) then
            flag = flag .and. (color_is_ghost (qn1%c) .eqv. color_is_ghost (qn2%c))
        else
            flag = flag .and. &
                .not. (color_is_ghost (qn1%c) .or. color_is_ghost (qn2%c)) .and. &
                (qn1%c == qn2%c)
        end if
    end function quantum_numbers_are_compatible

```

This is the analog for a single quantum-number set. We just check for color ghosts; they are excluded if the color mask is unset (color-flow expansion).

```

<Quantum numbers: public>+≡
    public :: quantum_numbers_are_physical

<Quantum numbers: procedures>+≡
    elemental function quantum_numbers_are_physical (qn, mask) result (flag)
        logical :: flag
        type(quantum_numbers_t), intent(in) :: qn
        type(quantum_numbers_mask_t), intent(in) :: mask
        if (mask%c) then
            flag = .true.
        else
            flag = .not. color_is_ghost (qn%c)
        end if
    end function quantum_numbers_are_physical

```

7.4.6 Operations

Inherited from the color component: reassign color indices in canonical order.

```
<Quantum numbers: public>+≡
    public :: quantum_numbers_canonicalize_color

<Quantum numbers: procedures>+≡
    subroutine quantum_numbers_canonicalize_color (qn)
        type(quantum_numbers_t), dimension(:), intent(inout) :: qn
        call color_canonicalize (qn%c)
    end subroutine quantum_numbers_canonicalize_color
```

Inherited from the color component: make a color map for two matching quantum-number arrays.

```
<Quantum numbers: public>+≡
    public :: quantum_numbers_set_color_map

<Quantum numbers: procedures>+≡
    subroutine quantum_numbers_set_color_map (map, qn1, qn2)
        integer, dimension(:,:), intent(out), allocatable :: map

    qn_out(:,i)%c = col(:,i)
    qn_out(:,i)%h = qn_in%h
end do
end subroutine quantum_number_array_make_color_contractions

```

Inherited from the color component: invert the color, switching particle/antiparticle.

```

<Quantum numbers: public>+≡
    public :: quantum_numbers_invert_color

<Quantum numbers: procedures>+≡
    elemental subroutine quantum_numbers_invert_color (qn)
        type(quantum_numbers_t), intent(inout) :: qn
        call color_invert (qn%c)
    end subroutine quantum_numbers_invert_color

```

Merge two quantum number sets: for each entry, if both are defined, combine them to an off-diagonal entry (meaningful only if the input was diagonal). If either entry is undefined, take the defined one.

For flavor, off-diagonal entries are invalid, so both flavors must be equal, otherwise an invalid flavor is inserted.

```

<Quantum numbers: public>+≡
    public :: operator(.merge.)

<Quantum numbers: interfaces>+≡
    interface operator(.merge.)
        module procedure merge_quantum_numbers0
        module procedure merge_quantum_numbers1
    end interface

<Quantum numbers: procedures>+≡
    function merge_quantum_numbers0 (qn1, qn2) result (qn3)
        type(quantum_numbers_t) :: qn3
        type(quantum_numbers_t), intent(in) :: qn1, qn2
        qn3%f = qn1%f .merge. qn2%f

        qn3%h = qn1%h .merge. qn2%h
    end function merge_quantum_numbers0

    function merge_quantum_numbers1 (qn1, qn2) result (qn3)
        type(quantum_numbers_t), dimension(:), intent(in) :: qn1, qn2
        type(quantum_numbers_t), dimension(size(qn1)) :: qn3
        qn3%f = qn1%f .merge. qn2%f
        qn3%c = qn1%c .merge. qn2%c
        qn3%h = qn1%h .merge. qn2%h
    end function merge_quantum_numbers1

```

7.4.7 The quantum number mask

The quantum numbers mask is true for quantum numbers that should be ignored or summed over. The three mandatory entries correspond to flavor, color, and helicity, respectively.

There is an additional entry `cg`: If false, the color-ghosts property should be kept even if color is ignored. This is relevant only if `c` is set, otherwise it is always false.

The flag `hd` tells that only diagonal entries in helicity should be kept. If `h` is set, `hd` is irrelevant and will be kept `.false.`

```

<Quantum numbers: public>+≡
    public :: quantum_numbers_mask_t

<Quantum numbers: types>+≡
    type :: quantum_numbers_mask_t
        private
        logical :: f = .false.
        logical :: c = .false.
        logical :: cg = .false.
        logical :: h = .false.
        logical :: hd = .false.
    end type quantum_numbers_mask_t

```

Define a quantum number mask: Constructor form

```

<Quantum numbers: public>+≡
    public :: new_quantum_numbers_mask

<Quantum numbers: procedures>+≡
    elemental function new_quantum_numbers_mask &
        (mask_f, mask_c, mask_h, mask_cg, mask_hd) result (mask)
        type(quantum_numbers_mask_t) :: mask
        logical, intent(in) :: mask_f, mask_c, mask_h
        logical, intent(in), optional :: mask_cg
        logical, intent(in), optional :: mask_hd

    end subroutine quantum_numbers_mask_write_array

```

7.4.8 Setting mask components

```

<Quantum numbers: public>+≡
    public :: quantum_numbers_mask_set_flavor

```

```

public :: quantum_numbers_mask_set_color
public :: quantum_numbers_mask_set_helicity

<Quantum numbers: procedures>+≡
elemental subroutine quantum_numbers_mask_set_flavor (mask, mask_f)
  type(quantum_numbers_mask_t), intent(inout) :: mask
  logical, intent(in) :: mask_f
  mask%f = mask_f
end subroutine quantum_numbers_mask_set_flavor

elemental subroutine quantum_numbers_mask_set_color (mask, mask_c, mask_cg)
  type(quantum_numbers_mask_t), intent(inout) :: mask
  logical, intent(in) :: mask_c
  logical, intent(in), optional :: mask_cg
  mask%c = mask_c
  if (present (mask_cg)) then
    if (mask%c) mask%cg = mask_cg
  else
    mask%cg = mask_c
  end if
end subroutine quantum_numbers_mask_set_color

elemental subroutine quantum_numbers_mask_set_helicity (mask, mask_h, mask_hd)
  type(quantum_numbers_mask_t), intent(inout) :: mask
  logical, intent(in) :: mask_h
  logical, intent(in), optional :: mask_hd
  mask%h = mask_h
  if (present (mask_hd)) then
    if (.not. mask%h) mask%hd = mask_hd
  end if
end subroutine quantum_numbers_mask_set_helicity

```

The following routines assign part of a mask, depending on the flags given.

```

<Quantum numbers: public>+≡
public :: quantum_numbers_mask_assign

<Quantum numbers: procedures>+≡
elemental subroutine quantum_numbers_mask_assign &
  (mask, mask_in, flavor, color, helicity)
  type(quantum_numbers_mask_t), intent(inout) :: mask
  type(quantum_numbers_mask_t), intent(in) :: mask_in
  logical, intent(in), optional :: flavor, color, helicity
  if (present (flavor)) then
    if (flavor) then
      mask%f = mask_in%f
    end if
  end if
  if (present (color)) then
    if (color) then
      mask%c = mask_in%c
      mask%cg = mask_in%cg
    end if
  end if
  if (present (helicity)) then
    if (helicity) then

```

```

        mask%h = mask_in%h
        mask%hd = mask_in%hd
    end if
end if
end subroutine quantum_numbers_mask_assign

```

7.4.9 Mask predicates

Return true if either one of the entries is set:

```

<Quantum numbers: public>+≡
    public :: any

<Quantum numbers: interfaces>+≡
    interface any
        module procedure quantum_numbers_mask_any
    end interface

<Quantum numbers: procedures>+≡
    function quantum_numbers_mask_any (mask) result (match)
        logical :: match
        type(quantum_numbers_mask_t), intent(in) :: mask
        match = mask%f .or. mask%c .or. mask%h .or. mask%hd
    end function quantum_numbers_mask_any

```

7.4.10 Operators

The OR operation is applied to all components.

```

<Quantum numbers: public>+≡
    public :: operator(.or.)

<Quantum numbers: interfaces>+≡
    interface operator(.or.)
        module procedure quantum_numbers_mask_or
    end interface

<Quantum numbers: procedures>+≡
    elemental function quantum_numbers_mask_or (mask1, mask2) result (mask)
        type(quantum_numbers_mask_t) :: mask
        type(quantum_numbers_mask_t), intent(in) :: mask1, mask2
        mask%f = mask1%f .or. mask2%f
        mask%c = mask1%c .or. mask2%c
        if (mask%c) mask%cg = mask1%cg .or. mask2%cg
        mask%h = mask1%h .or. mask2%h
        if (.not. mask%h) mask%hd = mask1%hd .or. mask2%hd
    end function quantum_numbers_mask_or

```

7.4.11 Mask comparisons

Return true if the two masks are equivalent / differ:

```

<Quantum numbers: public>+≡

```

```

public :: operator(.eqv.)
public :: operator(.neqv.)

<Quantum numbers: interfaces>+≡
interface operator(.eqv.)
  module procedure quantum_numbers_mask_eqv
end interface
interface operator(.neqv.)
  module procedure quantum_numbers_mask_neqv
end interface

<Quantum numbers: procedures>+≡
elemental function quantum_numbers_mask_eqv (mask1, mask2) result (eqv)
  logical :: eqv
  type(quantum_numbers_mask_t), intent(in) :: mask1, mask2
  eqv = (mask1%f .eqv. mask2%f) .and. &
        (mask1%c .eqv. mask2%c) .and. &
        (mask1%cg .eqv. mask2%cg) .and. &
        (mask1%h .eqv. mask2%h) .and. &
        (mask1%hd .eqv. mask2%hd)
end function quantum_numbers_mask_eqv

elemental function quantum_numbers_mask_neqv (mask1, mask2) result (neqv)
  logical :: neqv
  type(quantum_numbers_mask_t), intent(in) :: mask1, mask2
  neqv = (mask1%f .neqv. mask2%f) .or. &
        (mask1%c .neqv. mask2%c) .or. &
        (mask1%cg .neqv. mask2%cg) .or. &
        (mask1%h .neqv. mask2%h) .or. &
        (mask1%hd .neqv. mask2%hd)
end function quantum_numbers_mask_neqv

```

7.4.12 Apply a mask

Applying a mask to the quantum number object means undefining those entries where the mask is set. The others remain unaffected.

The `hd` mask has the special property that it “diagonalizes” helicity, i.e., the second helicity entry is dropped and the result is a diagonal helicity quantum number.

```

<Quantum numbers: public>+≡
public :: quantum_numbers_undefine
public :: quantum_numbers_undefined

<Quantum numbers: interfaces>+≡
interface quantum_numbers_undefined
  module procedure quantum_numbers_undefined0
  module procedure quantum_numbers_undefined1
  module procedure quantum_numbers_undefined11
end interface

<Quantum numbers: procedures>+≡
elemental subroutine quantum_numbers_undefine (qn, mask)
  type(quantum_numbers_t), intent(inout) :: qn

```

```

type(quantum_numbers_mask_t), intent(in) :: mask
if (mask%f) call flavor_undefine (qn%f)
if (mask%c) call color_undefine (qn%c, undefine_ghost=mask%cg)
if (mask%h) then
    call helicity_undefine (qn%h)
else if (mask%hd) then
    if (.not. helicity_is_diagonal (qn%h)) then
        call helicity_diagonalize (qn%h)
    end if
end if
end if
end subroutine quantum_numbers_undefine

function quantum_numbers_undefined0 (qn, mask) result (qn_new)
type(quantum_numbers_t), intent(in) :: qn
type(quantum_numbers_mask_t), intent(in) :: mask
type(quantum_numbers_t) :: qn_new
qn_new = qn
call quantum_numbers_undefine (qn_new, mask)
end function quantum_numbers_undefined0

function quantum_numbers_undefined1 (qn, mask) result (qn_new)
type(quantum_numbers_t), dimension(:), intent(in) :: qn
type(quantum_numbers_mask_t), intent(in) :: mask
type(quantum_numbers_t), dimension(size(qn)) :: qn_new
qn_new = qn
call quantum_numbers_undefine (qn_new, mask)
end function quantum_numbers_undefined1

function quantum_numbers_undefined11 (qn, mask) result (qn_new)
type(quantum_numbers_t), dimension(:), intent(in) :: qn
type(quantum_numbers_mask_t), dimension(:), intent(in) :: mask
type(quantum_numbers_t), dimension(size(qn)) :: qn_new
qn_new = qn
call quantum_numbers_undefine (qn_new, mask)
end function quantum_numbers_undefined11

```

Return true if the input quantum number set has entries that would be removed by the applied mask, e.g., if polarization is defined but `mask%h` is set:

```

<Quantum numbers: public>+≡
public :: quantum_numbers_are_redundant

<Quantum numbers: procedures>+≡
elemental function quantum_numbers_are_redundant (qn, mask) &
    result (redundant)
logical :: redundant
type(quantum_numbers_t), intent(in) :: qn
type(quantum_numbers_mask_t), intent(in) :: mask
redundant = .false.
if (mask%f) then
    redundant = flavor_is_defined (qn%f)
end if
if (mask%c) then
    redundant = color_is_defined (qn%c)
end if

```

```

    if (mask%h) then
        redundant = helicity_is_defined (qn%h)
    else if (mask%hd) then
        redundant = .not. helicity_is_diagonal (qn%h)
    end if
end function quantum_numbers_are_redundant

```

Return true if the helicity flag is set or the diagonal-helicity flag is set.

```

<Quantum numbers: public>+≡
    public :: quantum_numbers_mask_diagonal_helicity

<Quantum numbers: procedures>+≡
    elemental function quantum_numbers_mask_diagonal_helicity (mask) &
        result (flag)
        logical :: flag
        type(quantum_numbers_mask_t), intent(in) :: mask
        flag = mask%h .or. mask%hd
    end function quantum_numbers_mask_diagonal_helicity

```

7.5 State matrices

This module deals with the internal state of a particle system, i.e., with its density matrix in flavor, color, and helicity space.

```
<state_matrices.f90>≡  
  <File header>  
  
  module state_matrices  
  
    <Use kinds>

    use flavors  
    use colors  
    use helicities  
    use quantum_numbers  
  
    <Standard module head>  
  
    <State matrices: public>  
  
    <State matrices: parameters>  
  
    <State matrices: types>  
  
    <State matrices: interfaces>  
  
    contains  
  
    <State matrices: procedures>  
  
  end module state_matrices
```

7.5.1 Nodes of the quantum state trie

A quantum state object represents an unnormalized density matrix, i.e., an array of possibilities for flavor, color, and helicity indices with associated complex values. Physically, the trace of this matrix is the summed squared matrix element for an interaction, and the matrix elements divided by this value correspond to the flavor-color-helicity density matrix. (Flavor and color are diagonal.)

We store density matrices as tries, that is, as trees where each branching represents the possible quantum numbers of a particle. The first branching is the first particle in the system. A leaf (the node corresponding to the last particle) contains the value of the matrix element.

Each node contains a flavor, color, and helicity entry. Note that each of those entries may be actually undefined, so we can also represent, e.g., unpolarized particles.

The value is meaningful only for leaves, which have no child nodes. There is a pointer to the parent node which allows for following the trie downwards from a leaf, it is null for a root node. The child nodes are implemented as a list,

so there is a pointer to the first and last child, and each node also has a **next** pointer to the next sibling.

The root node does not correspond to a particle, only its children do. The quantum numbers of the root node are irrelevant and will not be set. However, we use a common type for the three classes (root, branch, leaf); they may easily be distinguished by the association status of parent and child.

Node type

The node is linked in all directions: the parent, the first and last in the list of children, and the previous and next sibling. This allows us for adding and removing nodes and whole branches anywhere in the trie. (Circular links are not allowed, however.). The node holds its associated set of quantum numbers. The integer index, which is set only for leaf nodes, is the index of the corresponding matrix element value within the state matrix.

Temporarily, matrix-element values may be stored within a leaf node. This is used during state-matrix factorization. When the state matrix is **frozen**, these values are transferred to the matrix-element array within the host state matrix.

```

(State matrices: types)≡
  type :: node_t
    private
    type(quantum_numbers_t) :: qn
    type(node_t), pointer :: parent => null ()
    type(node_t), pointer :: child_first => null ()
    type(node_t), pointer :: child_last => null ()
    type(node_t), pointer :: next => null ()
    type(node_t), pointer :: previous => null ()
    integer :: me_index = 0
    integer, dimension(:), allocatable :: me_count
    complex(default) :: me = 0
  end type node_t

```

Operations on nodes

Recursively deallocate all children of the current node. This includes any values associated with the children.

```

(State matrices: procedures)≡
  pure recursive subroutine node_delete_offspring (node)
    type(node_t), pointer :: node
    type(node_t), pointer :: child
    child => node%child_first
    do while (associated (child))
      node%child_first => node%child_first%next
      call node_delete_offspring (child)
      deallocate (child)
    end do
    node%child_last => null ()
  end subroutine node_delete_offspring

```

Remove a node including its offspring. Adjust the pointers of parent and siblings, if necessary.

```

<State matrices: procedures>+≡
  pure subroutine node_delete (node)
    type(node_t), pointer :: node
    call node_delete_offspring (node)
    if (associated (node%previous)) then
      node%previous%next => node%next
    else if (associated (node%parent)) then
      node%parent%child_first => node%next
    end if
    if (associated (node%next)) then
      node%next%previous => node%previous
    else if (associated (node%parent)) then
      node%parent%child_last => node%previous
    end if
    deallocate (node)
  end subroutine node_delete

```

Append a child node

```

<State matrices: procedures>+≡
  subroutine node_append_child (node, child)
    type(node_t), target, intent(inout) :: node
    type(node_t), pointer :: child
    allocate (child)
    if (associated (node%child_last)) then
      node%child_last%next => child
      child%previous => node%child_last
    else
      node%child_first => child
    end if
    node%child_last => child
    child%parent => node
  end subroutine node_append_child

```

I/O

Output of a single node, no recursion. We print the quantum numbers in square brackets, then the value (if any).

```

<State matrices: procedures>+≡
  subroutine node_write (node, me_array, verbose, unit)
    type(node_t), intent(in) :: node
    complex(default), dimension(:), intent(in), optional :: me_array
    logical, intent(in), optional :: verbose
    integer, intent(in), optional :: unit
    logical :: verb
    integer :: u
    verb = .false.; if (present (verbose)) verb = verbose
    u = output_unit (unit); if (u < 0) return
    call quantum_numbers_write (node%qn, u)
    if (node%me_index /= 0) then
      write (u, "(A,I0,A)", advance="no") " => ME(", node%me_index, ")"

```

```

        if (present (me_array)) then
            write (u, "(A)", advance="no") " = "
            write (u, "('(',ES19.12,',',',ES19.12,')')'", advance="no") &
                me_array(node%me_index)
        end if
    end if
write (u, *)
if (verb) then
    call ptr_write ("parent      ", node%parent)
    call ptr_write ("child_first", node%child_first)
    call ptr_write ("child_last ", node%child_last)
    call ptr_write ("next        ", node%next)
    call ptr_write ("previous   ", node%previous)
end if
contains
subroutine ptr_write (label, node)
    character(*), intent(in) :: label
    type(node_t), pointer :: node
    if (associated (node)) then
        write (u, "(10x,A,1x,'->',1x)", advance="no") label
        call quantum_numbers_write (node%qn, u)
        write (u, *)
    end if
end subroutine ptr_write
end subroutine node_write

```

Recursive output of a node:

```

<State matrices: procedures>+≡
recursive subroutine node_write_rec (node, me_array, verbose, indent, unit)
    type(node_t), intent(in), target :: node
    complex(default), dimension(:), intent(in), optional :: me_array
    logical, intent(in), optional :: verbose
    integer, intent(in), optional :: indent
    integer, intent(in), optional :: unit
    type(node_t), pointer :: current
    logical :: verb
    integer :: i, u
    verb = .false.; if (present (verbose)) verb = verbose
    i = 0; if (present (indent)) i = indent
    u = output_unit (unit); if (u < 0) return
    current => node%child_first
    do while (associated (current))
        write (u, "(A)", advance="no") repeat (" ", i)
        call node_write (current, me_array, verb, u)
        call node_write_rec (current, me_array, verb, i+2, u)
        current => current%next
    end do
end subroutine node_write_rec

```

Binary I/O. Matrix elements are written only for leaf nodes. this was actually a pointer is lost.

```

<State matrices: procedures>+≡
recursive subroutine node_write_raw_rec (node, u)

```

```

type(node_t), intent(in), target :: node
integer, intent(in) :: u
logical :: associated_child_first, associated_next
call quantum_numbers_write_raw (node%qn, u)
associated_child_first = associated (node%child_first)
write (u) associated_child_first
associated_next = associated (node%next)
write (u) associated_next
if (associated_child_first) then
    call node_write_raw_rec (node%child_first, u)
else
    write (u) node%me_index
end if
if (associated_next) then
    call node_write_raw_rec (node%next, u)
end if
end subroutine node_write_raw_rec

recursive subroutine node_read_raw_rec (node, u, parent, iostat)
type(node_t), intent(out), target :: node
integer, intent(in) :: u
type(node_t), intent(in), optional, target :: parent
integer, intent(out), optional :: iostat
logical :: associated_child_first, associated_next
type(node_t), pointer :: child
call quantum_numbers_read_raw (node%qn, u, iostat=iostat)
read (u, iostat=iostat) associated_child_first
read (u, iostat=iostat) associated_next
if (present (parent)) node%parent => parent
if (associated_child_first) then
    allocate (child)
    node%child_first => child
    node%child_last => null ()
    call node_read_raw_rec (child, u, node, iostat=iostat)
    do while (associated (child))
        child%previous => node%child_last
        node%child_last => child
        child => child%next
    end do
else
    read (u, iostat=iostat) node%me_index
end if
if (associated_next) then
    allocate (node%next)
    call node_read_raw_rec (node%next, u, parent, iostat=iostat)
end if
end subroutine node_read_raw_rec

```

7.5.2 State matrix

Definition

The quantum state object is a container that keeps and hides the root node. For direct accessibility of values, they are stored in a separate array. The leaf nodes of the quantum-number tree point to those values, once the state matrix is finalized.

The `norm` component is redefined if a common factor is extracted from all nodes.

```
<State matrices: public>≡
  public :: state_matrix_t

<State matrices: types>+≡
  type :: state_matrix_t
    private
      type(node_t), pointer :: root => null ()
      integer :: depth = 0
      integer :: n_matrix_elements = 0
      logical :: leaf_nodes_store_values = .false.
      integer :: n_counters = 0
      complex(default), dimension(:), allocatable :: me
      real(default) :: norm = 1
  end type state_matrix_t
```

This initializer allocates the root node but does not fill anything. We declare whether values are stored within the nodes during state-matrix construction, and how many counters should be maintained (default: none).

```
<State matrices: public>+≡
  public :: state_matrix_init

<State matrices: procedures>+≡
  elemental subroutine state_matrix_init (state, store_values, n_counters)
    type(state_matrix_t), intent(out) :: state
    logical, intent(in), optional :: store_values
    integer, intent(in), optional :: n_counters
    allocate (state%root)
    if (present (store_values)) &
      state%leaf_nodes_store_values = store_values
    if (present (n_counters)) state%n_counters = n_counters
  end subroutine state_matrix_init
```

This recursively deletes all children of the root node, restoring the initial state. The matrix element array is not finalized, since it does not contain physical entries, just pointers.

```
<State matrices: public>+≡
  public :: state_matrix_final

<State matrices: procedures>+≡
  elemental subroutine state_matrix_final (state)
    type(state_matrix_t), intent(inout) :: state
    if (allocated (state%me)) deallocate (state%me)
    if (associated (state%root)) call node_delete (state%root)
    state%depth = 0
```

```

state%n_matrix_elements = 0
end subroutine state_matrix_final

```

Output: Present the tree as a nested list with appropriate indentation.

```

<State matrices: public>+≡
public :: state_matrix_write

<State matrices: procedures>+≡
subroutine state_matrix_write (state, unit, write_value_list, verbose)
  type(state_matrix_t), intent(in) :: state
  logical, intent(in), optional :: write_value_list, verbose
  integer, intent(in), optional :: unit
  integer :: u
  integer :: i
  u = output_unit (unit); if (u < 0) return
  write (u, "(1x,A,ES19.12)") "State matrix: norm = ", state%norm
  if (associated (state%root)) then
    if (allocated (state%me)) then
      call node_write_rec (state%root, state%me, verbose, 1, u)
    else
      call node_write_rec (state%root, verbose=verbose, indent=1, unit=u)
    end if
  end if
  if (present (write_value_list)) then
    if (write_value_list .and. allocated (state%me)) then
      do i = 1, size (state%me)
        write (u, "(1x,I0,A)", advance="no") i, ":"
        write (u, "('(',ES19.12,',',',',ES19.12,')')") state%me(i)
      end do
    end if
  end if
end subroutine state_matrix_write

```

Binary I/O. The auxiliary matrix-element array is not written, but reconstructed after reading the tree.

```

<State matrices: public>+≡
public :: state_matrix_write_raw
public :: state_matrix_read_raw

<State matrices: procedures>+≡
subroutine state_matrix_write_raw (state, u)
  type(state_matrix_t), intent(in) :: state
  integer, intent(in) :: u
  logical :: associated_root
  associated_root = associated (state%root)
  write (u) associated_root
  if (associated_root) then
    write (u) state%depth
    write (u) state%norm
    call node_write_raw_rec (state%root, u)
  end if
end subroutine state_matrix_write_raw

subroutine state_matrix_read_raw (state, u, iostat)

```

```

type(state_matrix_t), intent(out) :: state
integer, intent(in) :: u
integer, intent(out), optional :: iostat
logical :: associated_root
read (u, iostat=iostat) associated_root
if (associated_root) then
    read (u, iostat=iostat) state%depth
    read (u, iostat=iostat) state%norm
    call state_matrix_init (state)
    call node_read_raw_rec (state%root, u, iostat=iostat)
    call state_matrix_freeze (state)
end if
end subroutine state_matrix_read_raw

```

Properties of the quantum state

A state is defined if its root is allocated:

```

<State matrices: public>+≡
    public :: state_matrix_is_defined

<State matrices: procedures>+≡
    elemental function state_matrix_is_defined (state) result (defined)
        logical :: defined
        type(state_matrix_t), intent(in) :: state
        defined = associated (state%root)
    end function state_matrix_is_defined

```

A state is empty if its depth is zero:

```

<State matrices: public>+≡
    public :: state_matrix_is_empty

<State matrices: procedures>+≡
    elemental function state_matrix_is_empty (state) result (flag)
        logical :: flag
        type(state_matrix_t), intent(in) :: state
        flag = state%depth == 0
    end function state_matrix_is_empty

```

Return the number of matrix-element values.

```

<State matrices: public>+≡
    public :: state_matrix_get_n_matrix_elements

<State matrices: procedures>+≡
    function state_matrix_get_n_matrix_elements (state) result (n)
        integer :: n
        type(state_matrix_t), intent(in) :: state
        n = state%n_matrix_elements
    end function state_matrix_get_n_matrix_elements

```

Return the number of leaves. This can be larger than the number of independent matrix elements.

```

<State matrices: public>+≡
    public :: state_matrix_get_n_leaves

```

```

<State matrices: procedures>+≡
function state_matrix_get_n_leaves (state) result (n)
  integer :: n
  type(state_matrix_t), intent(in) :: state
  type(state_iterator_t) :: it
  n = 0
  call state_iterator_init (it, state)
  do while (state_iterator_is_valid (it))
    n = n + 1
    call state_iterator_advance (it)
  end do
end function state_matrix_get_n_leaves

```

Return the depth:

```

<State matrices: public>+≡
public :: state_matrix_get_depth

<State matrices: procedures>+≡
function state_matrix_get_depth (state) result (depth)
  integer :: depth
  type(state_matrix_t), intent(in) :: state
  depth = state%depth
end function state_matrix_get_depth

```

Return the norm:

```

<State matrices: public>+≡
public :: state_matrix_get_norm

<State matrices: procedures>+≡
function state_matrix_get_norm (state) result (norm)
  real(default) :: norm
  type(state_matrix_t), intent(in) :: state
  norm = state%norm
end function state_matrix_get_norm

```

Retrieving contents

Return the quantum number array, using an index. We have to scan the state matrix since there is no shortcut.

```

<State matrices: public>+≡
public :: state_matrix_get_quantum_numbers

<State matrices: procedures>+≡
function state_matrix_get_quantum_numbers (state, i) result (qn)
  type(state_matrix_t), intent(in), target :: state
  integer, intent(in) :: i
  type(quantum_numbers_t), dimension(state%depth) :: qn
  type(state_iterator_t) :: it
  integer :: k
  k = 0
  call state_iterator_init (it, state)
  do while (state_iterator_is_valid (it))

```

```

        k = k + 1
        if (k == i) then
            qn = state_iterator_get_quantum_numbers (it)
            return
        end if
        call state_iterator_advance (it)
    end do
end function state_matrix_get_quantum_numbers

```

Return a single matrix element using its index. Works only if the shortcut array is allocated.

```

<State matrices: public>+≡
    public :: state_matrix_get_matrix_element

<State matrices: procedures>+≡
    function state_matrix_get_matrix_element (state, i) result (me)
        complex(default) :: me
        type(state_matrix_t), intent(in) :: state
        integer, intent(in) :: i
        if (associated (state%me)) then
            me = state%me(i)
        else
            me = 0
        end if
    end function state_matrix_get_matrix_element

```

Return the color index with maximum absolute value that is present within the state matrix.

```

<State matrices: public>+≡
    public :: state_matrix_get_max_color_value

<State matrices: procedures>+≡
    function state_matrix_get_max_color_value (state) result (cmax)
        integer :: cmax
        type(state_matrix_t), intent(in) :: state
        if (associated (state%root)) then
            cmax = node_get_max_color_value (state%root)
        else
            cmax = 0
        end if
    contains
        recursive function node_get_max_color_value (node) result (cmax)
            integer :: cmax
            type(node_t), intent(in), target :: node
            type(node_t), pointer :: current
            cmax = quantum_numbers_get_max_color_value (node%qn)
            current => node%child_first
            do while (associated (current))
                cmax = max (cmax, node_get_max_color_value (current))
                current => current%next
            end do
        end function node_get_max_color_value
    end function state_matrix_get_max_color_value

```

Building the quantum state

The procedure generates a branch associated to the input array of quantum numbers. If the branch exists already, it is used.

Optionally, we set the matrix-element index, a value (which may be added to the previous one), and increment one of the possible counters. We may also return the matrix element index of the current node.

```
<State matrices: public>+≡
  public :: state_matrix_add_state

<State matrices: procedures>+≡
  subroutine state_matrix_add_state &
    (state, qn, index, value, sum_values, counter_index, me_index)
    type(state_matrix_t), intent(inout) :: state
    type(quantum_numbers_t), dimension(:), intent(in) :: qn
    integer, intent(in), optional :: index
    complex(default), intent(in), optional :: value
    logical, intent(in), optional :: sum_values
    integer, intent(in), optional :: counter_index
    integer, intent(out), optional :: me_index
    logical :: set_index, get_index, add
    set_index = present (index)
    get_index = present (me_index)
    add = .false.; if (present (sum_values)) add = sum_values
    if (state%depth == 0) then
      state%depth = size (qn)
    else if (state%depth /= size (qn)) then
      call state_matrix_write (state)
      call msg_bug ("State matrix: depth mismatch")
    end if
    if (size (qn) > 0) call node_make_branch (state%root, qn)
  contains
    recursive subroutine node_make_branch (parent, qn)
      type(node_t), pointer :: parent
      type(quantum_numbers_t), dimension(:), intent(in) :: qn
      type(node_t), pointer :: child
      logical :: match
      match = .false.

            call node_make_branch (child, qn(2:))
        end select
    end subroutine node_make_branch
end subroutine state_matrix_add_state

```

Remove irrelevant flavor/color/helicity labels and the corresponding branchings. The masks indicate which particles are affected; the masks length should coincide with the depth of the trie (without the root node). Recursively scan the whole tree, starting from the leaf nodes and working up to the root node. If a mask entry is set for the current tree level, scan the children there. For each child within that level make a new empty branch where the masked quantum number is undefined. Then recursively combine all following children with matching quantum number into this new node and move on.

```

<State matrices: public>+≡
    public :: state_matrix_collapse

<State matrices: procedures>+≡
    subroutine state_matrix_collapse (state, mask)
        type(state_matrix_t), intent(inout) :: state
        type(quantum_numbers_mask_t), dimension(:), intent(in) :: mask
        type(state_matrix_t) :: red_state
        if (state_matrix_is_defined (state)) then
            call state_matrix_reduce (state, mask, red_state)
            call state_matrix_final (state)
            state = red_state
        end if
    end subroutine state_matrix_collapse

```

Transform the given state matrix into a reduced state matrix where some quantum numbers are removed, as indicated by the mask. The procedure creates a new state matrix, so the old one can be deleted after this if it is no longer used.

```

<State matrices: public>+≡

```

```

public :: state_matrix_reduce
<State matrices: procedures>+≡
subroutine state_matrix_reduce (state, mask, red_state)
  type(state_matrix_t), intent(in), target :: state
  type(quantum_numbers_mask_t), dimension(:), intent(in) :: mask
  type(state_matrix_t), intent(out) :: red_state
  type(state_iterator_t) :: it
  type(quantum_numbers_t), dimension(size(mask)) :: qn
  call state_matrix_init (red_state)
  call state_iterator_init (it, state)
  do while (state_iterator_is_valid (it))
    qn = state_iterator_get_quantum_numbers (it)
    call quantum_numbers_undefine (qn, mask)
    call state_matrix_add_state (red_state, qn)
    call state_iterator_advance (it)
  end do
end subroutine state_matrix_reduce

```

This subroutine sets up the matrix-element array. The leaf nodes acquire the index values that point to the appropriate matrix-element entry.

We recursively scan the trie. Once we arrive at a leaf node, the index is increased and associated to that node. Finally, we allocate the matrix-element array with the appropriate size.

If matrix element values are temporarily stored within the leaf nodes, we scan the state again and transfer them to the matrix-element array.

```

<State matrices: public>+≡
public :: state_matrix_freeze

<State matrices: interfaces>≡
interface state_matrix_freeze
  module procedure state_matrix_freeze1
  module procedure state_matrix_freeze2
end interface

<State matrices: procedures>+≡
subroutine state_matrix_freeze1 (state)
  type(state_matrix_t), intent(inout), target :: state
  type(state_iterator_t) :: it
  if (associated (state%root)) then
    if (allocated (state%me)) deallocate (state%me)
    allocate (state%me (state%n_matrix_elements))
    state%me = 0
  end if
  if (state%leaf_nodes_store_values) then
    call state_iterator_init (it, state)
    do while (state_iterator_is_valid (it))
      state%me(state_iterator_get_me_index (it)) &
        = state_iterator_get_matrix_element (it)
      call state_iterator_advance (it)
    end do
    state%leaf_nodes_store_values = .false.
  end if
end subroutine state_matrix_freeze1

```

```

subroutine state_matrix_freeze2 (state)
  type(state_matrix_t), dimension(:), intent(inout), target :: state
  integer :: i
  do i = 1, size (state)
    call state_matrix_freeze1 (state(i))
  end do
end subroutine state_matrix_freeze2

```

Direct access to the value array

Several methods for setting a value directly are summarized in this generic:

```

<State matrices: public>+≡
  public :: state_matrix_set_matrix_element

<State matrices: interfaces>+≡
  interface state_matrix_set_matrix_element
    module procedure state_matrix_set_matrix_element_qn
    module procedure state_matrix_set_matrix_element_all
    module procedure state_matrix_set_matrix_element_array
    module procedure state_matrix_set_matrix_element_single
    module procedure state_matrix_set_matrix_element_clone
  end interface

```

Set a value that corresponds to a quantum number array:

```

<State matrices: procedures>+≡
  subroutine state_matrix_set_matrix_element_qn (state, qn, value)
    type(state_matrix_t), intent(inout) :: state
    type(quantum_numbers_t), dimension(:), intent(in) :: qn
    complex(default), intent(in) :: value
    type(state_iterator_t) :: it
    if (.not. allocated (it%state%me)) then
      allocate (it%state%me (size(qn)))
    end if
    call state_iterator_init (it, state)
    do while (state_iterator_is_valid (it))
      if (all (qn == state_iterator_get_quantum_numbers (it))) then
        call state_iterator_set_matrix_element (it, value)
        return
      end if
      call state_iterator_advance (it)
    end do
  end subroutine state_matrix_set_matrix_element_qn

```

Set all matrix elements to a single value

```

<State matrices: procedures>+≡
  subroutine state_matrix_set_matrix_element_all (state, value)
    type(state_matrix_t), intent(inout) :: state
    complex(default), intent(in) :: value
    if (.not. allocated (state%me)) then
      allocate (state%me (state%n_matrix_elements))
    end if
    state%me = value
  end subroutine state_matrix_set_matrix_element_all

```

Set the matrix-element array directly.

```

<State matrices: procedures>+≡
  subroutine state_matrix_set_matrix_element_array (state, value)
    type(state_matrix_t), intent(inout) :: state
    complex(default), dimension(:), intent(in) :: value
    if (.not. allocated (state%me)) then
      allocate (state%me (size (value)))
    end if
    state%me = value
  end subroutine state_matrix_set_matrix_element_array

  pure subroutine state_matrix_set_matrix_element_single (state, i, value)
    type(state_matrix_t), intent(inout) :: state
    integer, intent(in) :: i
    complex(default), intent(in) :: value
    if (.not. allocated (state%me)) then
      allocate (state%me (state%n_matrix_elements))
    end if
    state%me(i) = value
  end subroutine state_matrix_set_matrix_element_single

```

Clone the matrix elements from another (matching) state matrix.

```

<State matrices: procedures>+≡
  subroutine state_matrix_set_matrix_element_clone (state, state1)
    type(state_matrix_t), intent(inout) :: state
    type(state_matrix_t), intent(in) :: state1
    if (.not. allocated (state%me)) return
    if (.not. allocated (state%me)) allocate (state%me (size (state1%me)))
    state%me = state1%me
  end subroutine state_matrix_set_matrix_element_clone

```

Add a value to a matrix element

```

<State matrices: public>+≡
  public :: state_matrix_add_to_matrix_element

<State matrices: procedures>+≡
  subroutine state_matrix_add_to_matrix_element (state, i, value)
    type(state_matrix_t), intent(inout) :: state
    integer, intent(in) :: i
    complex(default), intent(in) :: value
    state%me(i) = state%me(i) + value
  end subroutine state_matrix_add_to_matrix_element

```

7.5.3 State iterators

Accessing the quantum state from outside is best done using a specialized iterator, i.e., a pointer to a particular branch of the quantum state trie. Technically, the iterator contains a pointer to a leaf node, but via parent pointers it allows

to access the whole branch where the leaf is attached. For quick access, we also keep the branch depth (which is assumed to be universal for a quantum state).

```

<State matrices: public>+≡
    public :: state_iterator_t

<State matrices: types>+≡
    type :: state_iterator_t
    private
        integer :: depth = 0
        type(state_matrix_t), pointer :: state => null ()
        type(node_t), pointer :: node => null ()
    end type state_iterator_t

```

The initializer: Point at the first branch. Note that this cannot be pure, thus not be elemental, because the iterator can be used to manipulate data in the state matrix.

```

<State matrices: public>+≡
    public :: state_iterator_init

<State matrices: procedures>+≡
    subroutine state_iterator_init (it, state)
        type(state_iterator_t), intent(out) :: it
        type(state_matrix_t), intent(in), target :: state
        it%state => state
        it%depth = state%depth
        if (state_matrix_is_defined (state)) then
            it%node => state%root
            do while (associated (it%node%child_first))
                it%node => it%node%child_first
            end do
        else
            it%node => null ()
        end if
    end subroutine state_iterator_init

```

Go forward. Recursively programmed: if the next node does not exist, go back to the parent node and look at its successor (if present), etc.

There is a possible pitfall in the implementation: If the dummy pointer argument to the `find_next` routine is used directly, we still get the correct result for the iterator, but calling the recursion on `node%parent` means that we manipulate a parent pointer in the original state in addition to the iterator. Making a local copy of the pointer avoids this. Using pointer intent would be helpful, but we do not yet rely on this F2003 feature.

```

<State matrices: public>+≡
    public :: state_iterator_advance

<State matrices: procedures>+≡
    subroutine state_iterator_advance (it)
        type(state_iterator_t), intent(inout) :: it
        call find_next (it%node)
    contains
        recursive subroutine find_next (node_in)
            type(node_t), intent(in), target :: node_in

```

```

type(node_t), pointer :: node
node => node_in
if (associated (node%next)) then
    node => node%next
    do while (associated (node%child_first))
        node => node%child_first
    end do
    it%node => node
else if (associated (node%parent)) then
    call find_next (node%parent)
else
    it%node => null ()
end if
end subroutine find_next
end subroutine state_iterator_advance

```

If all has been scanned, the iterator is at an undefined state. Check for this:

```

<State matrices: public>+≡
public :: state_iterator_is_valid

<State matrices: procedures>+≡
function state_iterator_is_valid (it) result (defined)
    logical :: defined
    type(state_iterator_t), intent(in) :: it
    defined = associated (it%node)
end function state_iterator_is_valid

```

Return the matrix-element index that corresponds to the current node

```

<State matrices: public>+≡
public :: state_iterator_get_me_index

<State matrices: procedures>+≡
function state_iterator_get_me_index (it) result (n)
    integer :: n
    type(state_iterator_t), intent(in) :: it
    n = it%node%me_index
end function state_iterator_get_me_index

```

Return the number of times this quantum-number state has been added (noting that it is physically inserted only the first time). Note that for each state, there is an array of counters.

```

<State matrices: public>+≡
public :: state_iterator_get_me_count

<State matrices: procedures>+≡
function state_iterator_get_me_count (it) result (n)
    integer, dimension(:), allocatable :: n
    type(state_iterator_t), intent(in) :: it
    if (allocated (it%node%me_count)) then
        allocate (n (size (it%node%me_count)))
        n = it%node%me_count
    else
        allocate (n (0))
    end if
end function state_iterator_get_me_count

```

```

        end if
    end function state_iterator_get_me_count

```

Use the iterator to retrieve quantum-number information:

```

<State matrices: public>+≡
    public :: state_iterator_get_quantum_numbers
    public :: state_iterator_get_flavor
    public :: state_iterator_get_color
    public :: state_iterator_get_helicity

<State matrices: interfaces>+≡
    interface state_iterator_get_quantum_numbers
        module procedure state_iterator_get_qn_multi
        module procedure state_iterator_get_qn_slice
        module procedure state_iterator_get_qn_range
        module procedure state_iterator_get_qn_single
    end interface

    interface state_iterator_get_flavor
        module procedure state_iterator_get_flv_multi
        module procedure state_iterator_get_flv_slice
        module procedure state_iterator_get_flv_range
        module procedure state_iterator_get_flv_single
    end interface

    interface state_iterator_get_color
        module procedure state_iterator_get_col_multi
        module procedure state_iterator_get_col_slice
        module procedure state_iterator_get_col_range
        module procedure state_iterator_get_col_single
    end interface

    interface state_iterator_get_helicity
        module procedure state_iterator_get_hel_multi
        module procedure state_iterator_get_hel_slice
        module procedure state_iterator_get_hel_range
        module procedure state_iterator_get_hel_single
    end interface

```

These versions return the whole quantum number array

```

<State matrices: procedures>+≡
    function state_iterator_get_qn_multi (it) result (qn)
        type(state_iterator_t), intent(in) :: it
        type(quantum_numbers_t), dimension(it%depth) :: qn
        type(node_t), pointer :: node
        integer :: i
        node => it%node
        do i = it%depth, 1, -1
            qn(i) = node%qn
            node => node%parent
        end do
    end function state_iterator_get_qn_multi

```

```

function state_iterator_get_flv_multi (it) result (flv)

```

This procedure merges two state matrices of equal depth. For each quantum number (flavor, color, helicity), we take the entry from the first argument where defined, otherwise the second one. (If both are defined, we get an off-diagonal matrix.) The resulting trie combines the information of the input tries in all possible ways. Note that values are ignored, all values in the result are zero.

<State matrices: public>+≡

```

Multiply matrix elements from two state matrices. Choose the elements as given by the integer index arrays, multiply them and store the sum of products in the indicated matrix element. The suffixes mean: c=conjugate first factor; f=include weighting factor.

Note that the `dot_product` intrinsic function conjugates its first complex argument. This is intended for the c suffix case, but must be reverted for the plain-product case.

7.5.5 Factorization

In physical events, the state matrix is factorized into single-particle state matrices. This is essentially a measurement.

In a simulation, we select one particular branch of the state matrix with a probability that is determined by the matrix elements at the leaves. (This makes sense only if the state matrix represents a squared amplitude.) The selection is based on a (random) value x between 0 and one that is provided as the third argument.

For flavor and color, we select a unique value for each particle. For polarization, we have three options (modes). Option 1 is to drop helicity information altogether and sum over all diagonal helicities. Option 2 is to select a unique diagonal helicity in the same way as flavor and color. Option 3 is, for each particle, to trace over all remaining helicities in order to obtain an array of independent single-particle helicity matrices.

Only branches that match the given quantum-number array `qn_in`, if present, are considered. For this array, color is ignored.

If the optional `correlated_state` is provided, it is assigned the correlated density matrix for the selected flavor-color branch, so multi-particle spin correlations remain available even if they are dropped in the single-particle density matrices.

The algorithm is as follows: First, we determine the normalization by summing over all diagonal matrix elements. In a second scan, we select one of the diagonal matrix elements by a cumulative comparison with the normalized random number. In the corresponding quantum number array, we undefine the

helicity entries. Then, we scan the third time. For each branch that matches the selected quantum number array (i.e., definite flavor and color, arbitrary helicity), we determine its contribution to any of the single-particle state matrices. The matrix-element value is added if all other quantum numbers are diagonal, while the helicity of the chosen particle may be arbitrary; this helicity determines the branch in the single-particle state.

As a result, flavor and color quantum numbers are selected with the correct probability. Within this subset of states, each single-particle state matrix results from tracing over all other particles. Note that the single-particle state matrices are not normalized.

The flag `ok` is set to false if the matrix element sum is zero, so factorization is not possible. This can happen if an event did not pass cuts.

7.6 Interactions

This module defines the `interaction_t` type. It is an extension of the `state_matrix_t` type.

The state matrix is a representation of a multi-particle density matrix. It implements all possible flavor, color, and quantum-number assignments of the entries in a generic density matrix, and it can hold a complex matrix element for each entry. (Note that this matrix can hold non-diagonal entries in color and helicity space.) The `interaction_t` object associates this with a list of momenta, such that the whole object represents a multi-particle state.

The `interaction_t` holds information about which particles are incoming, virtual (i.e., kept for the records), or outgoing. Each particle can be associated to a source within another interaction. This allows us to automatically fill those interaction momenta which have been computed or defined elsewhere. It also contains internal parent-child relations and flags for (virtual) particles which are to be treated as resonances.

A quantum-number mask array summarizes, for each particle within the interaction, the treatment of flavor, color, or helicity (expose or ignore). A list of locks states which particles are bound to have an identical quantum-number mask. This is useful when the mask is changed at one place.

```

    <Interactions: interfaces>

contains

    <Interactions: procedures>

end module interactions

```

7.6.1 External interaction links

Each particle in an interaction can have a link to a corresponding particle in another interaction. This allows to fetch the momenta of incoming or virtual particles from the interaction where they are defined. The link object consists of a pointer to the interaction and an index.

```

<Interactions: types>≡
    type :: external_link_t
    private
        type(interaction_t), pointer :: int => null ()
        integer :: i
    end type external_link_t

```

Set an external link.

```

<Interactions: procedures>≡
    subroutine external_link_set (link, int, i)
        type(external_link_t), intent(out) :: link
        type(interaction_t), target, intent(in) :: int
        integer, intent(in) :: i
        if (i /= 0) then
            link%int => int
            link%i = i
        end if
    end subroutine external_link_set

```

Reassign an external link to a new interaction (which should be an image of the original target).

```

<Interactions: procedures>+≡
    subroutine external_link_reassign (link, int_src, int_target)
        type(external_link_t), intent(inout) :: link
        type(interaction_t), intent(in) :: int_src
        type(interaction_t), intent(in), target :: int_target
        if (associated (link%int)) then
            if (link%int%tag == int_src%tag) link%int => int_target

```

```

        end if
    end subroutine external_link_reassign

```

Return true if the link is set

```

<Interactions: procedures>+=
    function external_link_is_set (link) result (flag)
        logical :: flag
        type(external_link_t), intent(in) :: link
        flag = associated (link%int)
    end function external_link_is_set

```

Return the interaction pointer.

```

<Interactions: public>=
    public :: external_link_get_ptr

<Interactions: procedures>+=
    function external_link_get_ptr (link) result (int)
        type(interaction_t), pointer :: int
        type(external_link_t), intent(in) :: link
        int => link%int
    end function external_link_get_ptr

```

Return the index within that interaction

```

<Interactions: public>+=
    public :: external_link_get_index

<Interactions: procedures>+=
    function external_link_get_index (link) result (i)
        integer :: i
        type(external_link_t), intent(in) :: link
        i = link%i
    end function external_link_get_index

```

Return a pointer to the momentum of the corresponding particle. If there is no association, return a null pointer.

```

<Interactions: procedures>+=
    function external_link_get_momentum_ptr (link) result (p)
        type(vector4_t), pointer :: p
        type(external_link_t), intent(in) :: link
        if (associated (link%int)) then
            p => link%int%p(link%i)
        else
            p => null ()
        end if
    end function external_link_get_momentum_ptr

```

7.6.2 Internal relations

In addition to the external links, particles within the interaction have parent-child relations. Here, more than one link is possible, and we set up a list.

```

<Interactions: types>+=

```

```

type :: internal_link_t
  private
  integer :: i
  type(internal_link_t), pointer :: next => null ()
end type internal_link_t

type :: internal_link_list_t
  private
  integer :: length = 0
  type(internal_link_t), pointer :: first => null ()
  type(internal_link_t), pointer :: last => null ()
end type internal_link_list_t

```

Add an internal link.

```

<Interactions: procedures>+=
subroutine internal_link_list_append (link_list, i)
  type(internal_link_list_t), intent(inout) :: link_list
  integer, intent(in) :: i
  type(internal_link_t), pointer :: current
  allocate (current)
  current%i = i
  if (associated (link_list%first)) then
    link_list%last%next => current
  else
    link_list%first => current
  end if
  link_list%last => current
  link_list%length = link_list%length + 1
end subroutine internal_link_list_append

```

Finalize the list of internal links.

```

<Interactions: procedures>+=
subroutine internal_link_list_final (link_list)
  type(internal_link_list_t), intent(inout) :: link_list
  type(internal_link_t), pointer :: current
  do while (associated (link_list%first))
    current => link_list%first
    link_list%first => current%next
    deallocate (current)
  end do
  link_list%last => null ()
  link_list%length = 0
end subroutine internal_link_list_final

```

We need a deep copy of this list when we assign interaction objects.

```

<Interactions: interfaces>=
interface assignment(=)
  module procedure internal_link_list_assign
end interface

<Interactions: procedures>+=
subroutine internal_link_list_assign (link_list_out, link_list_in)

```

```

type(internal_link_list_t), intent(in) :: link_list_in
type(internal_link_list_t), intent(out) :: link_list_out
type(internal_link_t), pointer :: current, copy
current => link_list_in%first
do while (associated (current))
  allocate (copy)
  copy%i = current%i
  if (associated (link_list_out%first)) then
    link_list_out%last%next => copy
  else
    link_list_out%first => copy
  end if
  link_list_out%last => copy
  current => current%next
end do
end subroutine internal_link_list_assign

```

Return true if the link list is nonempty:

```

<Interactions: procedures>+≡
function internal_link_list_has_entries (link_list) result (flag)
  logical :: flag
  type(internal_link_list_t), intent(in) :: link_list
  flag = associated (link_list%first)
end function internal_link_list_has_entries

```

Return a pointer to the first entry:

```

<Interactions: procedures>+≡
function internal_link_list_get_first_ptr (link_list) result (link)
  type(internal_link_list_t), intent(in) :: link_list
  type(internal_link_t), pointer :: link
  link => link_list%first
end function internal_link_list_get_first_ptr

```

Advance this pointer.

```

<Interactions: procedures>+≡
subroutine internal_link_advance (link)
  type(internal_link_t), pointer :: link
  link => link%next
end subroutine internal_link_advance

```

Return the index.

```

<Interactions: procedures>+≡
function internal_link_get_index (link) result (i)
  integer :: i
  type(internal_link_t), intent(in) :: link
  i = link%i
end function internal_link_get_index

```

Return the list length

```

<Interactions: procedures>+≡
function internal_link_list_get_length (link_list) result (length)

```

```

integer :: length
type(internal_link_list_t), intent(in) :: link_list
length = link_list%length
end function internal_link_list_get_length

```

7.6.3 The interaction type

An interaction is an entangled system of particles. Thus, the interaction object consists of two parts: the subevent, and the quantum state which technically is a trie. The subnode levels beyond the trie root node are in correspondence to the subevent, so both should be traversed in parallel.

The subevent is implemented as an allocatable array of four-momenta. The first `n_in` particles are incoming, `n_vir` particles in-between can be kept for bookkeeping, and the last `n_out` particles are outgoing.

Distinct interactions are linked by their particles: for each particle, we have the possibility of links to corresponding particles in other interactions. Furthermore, for bookkeeping purposes we have a self-link array `relations` where the parent-child relations are kept, and a flag array `resonant` which is set for an intermediate resonance.

Each momentum is associated with masks for flavor, color, and helicity. If a mask entry is set, the associated quantum number is to be ignored for that particle. If any mask has changed, the flag `update` is set.

We can have particle pairs locked together. If this is the case, the corresponding mask entries are bound to be equal. This is useful for particles that go through the interaction.

The interaction tag serves bookkeeping purposes. In particular, it identifies links in printout.

```

<Interactions: public>+≡
public :: interaction_t

<Interactions: types>+≡
type :: interaction_t
private
integer :: tag = 0
type(state_matrix_t) :: state_matrix
integer :: n_in = 0
integer :: n_vir = 0
integer :: n_out = 0
integer :: n_tot = 0
logical, dimension(:), allocatable :: p_is_known
type(vector4_t), dimension(:), allocatable :: p
type(external_link_t), dimension(:), allocatable :: source
type(internal_link_list_t), dimension(:), allocatable :: parents
type(internal_link_list_t), dimension(:), allocatable :: children
logical, dimension(:), allocatable :: resonant
type(quantum_numbers_mask_t), dimension(:), allocatable :: mask
integer, dimension(:), allocatable :: hel_lock
logical :: update_state_matrix = .false.
logical :: update_values = .false.
end type interaction_t

```

Initialize the particle array with a fixed size. The first `n_in` particles are incoming, the rest outgoing. Masks are optional. There is also an optional tag. The interaction still needs fixing the values, but that is to be done after all branches have been added.

Interaction tags are assigned consecutively, using a `saved` variable local to this procedure. If desired, we can provide a seed for the interaction tags. Such a seed should be positive. The default seed is one. `tag=0` indicates an empty interaction.

If `set_relations` is set and true, we establish parent-child relations for all incoming and outgoing particles. Virtual particles are skipped; this option is normally used only for interactions without virtual particles.

```

<Interactions: public>+=
  public :: interaction_init

<Interactions: procedures>+=
  subroutine interaction_init &
    (int, n_in, n_vir, n_out, &
     tag, resonant, mask, hel_lock, set_relations, store_values)

```

7.6.4 Methods inherited from the state matrix member

Until F2003 is standard, we cannot implement inheritance directly. Therefore, we need wrappers for “inherited” methods.

Make a new branch in the state matrix if it does not yet exist. This is not just a wrapper but it introduces the interaction mask: where a quantum number is masked, it is not transferred but set undefined. After this, the value array has to be updated.

```

<Interactions: public>+≡
    public :: interaction_add_state

<Interactions: procedures>+≡
    subroutine interaction_add_state &
        (int, qn, index, value, sum_values, counter_index, me_index)
        type(interaction_t), intent(inout) :: int
        type(quantum_numbers_t), dimension(:), intent(in) :: qn
        integer, intent(in), optional :: index
        complex(default), intent(in), optional :: value
        logical, intent(in), optional :: sum_values
        integer, intent(in), optional :: counter_index
        integer, intent(out), optional :: me_index
        type(quantum_numbers_t), dimension(size(qn)) :: qn_tmp
        qn_tmp = qn
        call quantum_numbers_undefine (qn_tmp, int%mask)
        call state_matrix_add_state &
            (int%state_matrix, qn_tmp, index, value, sum_values, &
             counter_index, me_index)
        int%update_values = .true.
    end subroutine interaction_add_state

```

Freeze the quantum state: First collapse the quantum state, i.e., remove quantum numbers if any mask has changed, then fix the array of value pointers.

```

<Interactions: public>+≡
    public :: interaction_freeze

<Interactions: procedures>+≡
    subroutine interaction_freeze (int)
        type(interaction_t), intent(inout) :: int
        if (int%update_state_matrix) then
            call state_matrix_collapse (int%state_matrix, int%mask)
            int%update_state_matrix = .false.
            int%update_values = .true.
        end if
        if (int%update_values) then
            call state_matrix_freeze (int%state_matrix)
            int%update_values = .false.
        end if
    end subroutine interaction_freeze

```

```

        end if
    end subroutine interaction_freeze

```

Return true if the state matrix is empty.

```

<Interactions: public>+=
    public :: interaction_is_empty

<Interactions: procedures>+=
    function interaction_is_empty (int) result (flag)
        logical :: flag
        type(interaction_t), intent(in) :: int
        flag = state_matrix_is_empty (int%state_matrix)
    end function interaction_is_empty

```

Get the number of values stored in the state matrix:

```

<Interactions: public>+=
    public :: interaction_get_n_matrix_elements

<Interactions: procedures>+=
    function interaction_get_n_matrix_elements (int) result (n)
        integer :: n
        type(interaction_t), intent(in) :: int
        n = state_matrix_get_n_matrix_elements (int%state_matrix)
    end function interaction_get_n_matrix_elements

```

Get the norm of the state matrix (if the norm has been taken out, otherwise this would be unity).

```

<Interactions: public>+=
    public :: interaction_get_norm

<Interactions: procedures>+=
    function interaction_get_norm (int) result (norm)
        real(default) :: norm
        type(interaction_t), intent(in) :: int
        norm = state_matrix_get_norm (int%state_matrix)
    end function interaction_get_norm

```

Get the quantum number array that corresponds to a given index.

```

<Interactions: public>+=
    public :: interaction_get_quantum_numbers

<Interactions: procedures>+=
    function interaction_get_quantum_numbers (int, i) result (qn)
        type(quantum_numbers_t), dimension(:), allocatable :: qn
        type(interaction_t), intent(in), target :: int
        integer, intent(in) :: i
        allocate (qn (state_matrix_get_depth (int%state_matrix)))
        qn = state_matrix_get_quantum_numbers (int%state_matrix, i)
    end function interaction_get_quantum_numbers

```

Get the matrix element that corresponds to a set of quantum numbers, a given index, or return the whole array.

```

<Interactions: public>+=
    public :: interaction_get_matrix_element

```

```

<Interactions: procedures>+≡
function interaction_get_matrix_element (int, i) result (me)
  complex(default) :: me
  type(interaction_t), intent(in) :: int
  integer, intent(in) :: i
  me = state_matrix_get_matrix_element (int%state_matrix, i)
end function interaction_get_matrix_element

```

Set the complex value(s) stored in the quantum state.

```

<Interactions: public>+≡
public :: interaction_set_matrix_element

<Interactions: interfaces>+≡
interface interaction_set_matrix_element
  module procedure interaction_set_matrix_element_qn
  module procedure interaction_set_matrix_element_all
  module procedure interaction_set_matrix_element_array
  module procedure interaction_set_matrix_element_single
  module procedure interaction_set_matrix_element_clone
end interface

```

Indirect access via the quantum number array:

```

<Interactions: procedures>+≡
subroutine interaction_set_matrix_element_qn (int, qn, val)
  type(interaction_t), intent(inout) :: int
  type(quantum_numbers_t), dimension(:), intent(in) :: qn
  complex(default), intent(in) :: val
  call state_matrix_set_matrix_element (int%state_matrix, qn, val)
end subroutine interaction_set_matrix_element_qn

```

Set all entries of the matrix-element array to a given value.

```

<Interactions: procedures>+≡
subroutine interaction_set_matrix_element_all (int, value)
  type(interaction_t), intent(inout) :: int
  complex(default), intent(in) :: value
  call state_matrix_set_matrix_element (int%state_matrix, value)
end subroutine interaction_set_matrix_element_all

```

Set the matrix-element array directly.

```

<Interactions: procedures>+≡
subroutine interaction_set_matrix_element_array (int, value)
  type(interaction_t), intent(inout) :: int
  complex(default), dimension(:), intent(in) :: value
  call state_matrix_set_matrix_element (int%state_matrix, value)
end subroutine interaction_set_matrix_element_array

pure subroutine interaction_set_matrix_element_single (int, i, value)
  type(interaction_t), intent(inout) :: int
  integer, intent(in) :: i
  complex(default), intent(in) :: value
  call state_matrix_set_matrix_element (int%state_matrix, i, value)
end subroutine interaction_set_matrix_element_single

```

Clone from another (matching) interaction.

```
<Interactions: procedures>+≡  
  subroutine interaction_set_matrix_element_clone (int, int1)  
    type(interaction_t), intent(inout) :: int  
    type(interaction_t), intent(in) :: int1  
    call state_matrix_set_matrix_element (int%state_matrix, int1%state_matrix)  
  end subroutine interaction_set_matrix_element_clone
```

Get the indices of any diagonal matrix elements.

```
<Interactions: public>+≡  
  public :: interaction_get_diagonal_entries  
  
<Interactions: procedures>+≡  
  subroutine interaction_get_diagonal_entries (int, i)  
    type(interaction_t), intent(in) :: int  
    integer, dimension(:), allocatable, intent(out) :: i  
    call state_matrix_get_diagonal_entries (int%state_matrix, i)  
  end subroutine interaction_get_diagonal_entries
```

Renormalize the state matrix by its trace, if nonzero. The renormalization is reflected in the state-matrix norm.

```
<Interactions: public>+≡  
  public :: interaction_normalize_by_trace  
  
<Interactions: procedures>+≡  
  subroutine interaction_normalize_by_trace (int)  
    type(interaction_t), intent(inout) :: int  
    call state_matrix_normalize_by_trace (int%state_matrix)  
  end subroutine interaction_normalize_by_trace
```

Analogous, but renormalize by maximal (absolute) value.

```
<Interactions: public>+≡  
  public :: interaction_normalize_by_max  
  
<Interactions: procedures>+≡  
  subroutine interaction_normalize_by_max (int)  
    type(interaction_t), intent(inout) :: int  
    call state_matrix_normalize_by_max (int%state_matrix)  
  end subroutine interaction_normalize_by_max
```

Return the maximum absolute value of color indices.

```
<Interactions: public>+≡  
  public :: interaction_get_max_color_value  
  
<Interactions: procedures>+≡  
  function interaction_get_max_color_value (int) result (cmax)  
    integer :: cmax  
    type(interaction_t), intent(in) :: int  
    cmax = state_matrix_get_max_color_value (int%state_matrix)  
  end function interaction_get_max_color_value
```

Factorize the state matrix into single-particle state matrices, the branch selection depending on a (random) value between 0 and 1; optionally also return a correlated state matrix.

```

<Interactions: public>+≡
    public :: interaction_factorize
<Interactions: procedures>+≡
    subroutine interaction_factorize &
        (int, mode, x, ok, single_state, correlated_state, qn_in)
        type(interaction_t), intent(in), target :: int
        integer, intent(in) :: mode
        real(default), intent(in) :: x
        logical, intent(out) :: ok
        type(state_matrix_t), &
            dimension(:), allocatable, intent(out) :: single_state
        type(state_matrix_t), intent(out), optional :: correlated_state
        type(quantum_numbers_t), dimension(:), intent(in), optional :: qn_in
        call state_matrix_factorize &
            (int%state_matrix, mode, x, ok, single_state, correlated_state, qn_in)
    end subroutine interaction_factorize

```

Sum all matrix element values

```

<Interactions: public>+≡
    public :: interaction_sum
<Interactions: procedures>+≡
    function interaction_sum (int) result (value)
        complex(default) :: value
        type(interaction_t), intent(in) :: int
        value = state_matrix_sum (int%state_matrix)
    end function interaction_sum

```

Append new states which are color-contracted versions of the existing states. The matrix element index of each color contraction coincides with the index of its origin, so no new matrix elements are generated. After this operation, no `freeze` must be performed anymore.

```

<Interactions: public>+≡
    public :: interaction_add_color_contractions
<Interactions: procedures>+≡
    subroutine interaction_add_color_contractions (int)
        type(interaction_t), intent(inout) :: int
        call state_matrix_add_color_contractions (int%state_matrix)
    end subroutine interaction_add_color_contractions

```

Multiply matrix elements from two interactions. Choose the elements as given by the integer index arrays, multiply them and store the sum of products in the indicated matrix element. The suffixes mean: c=conjugate first factor; f=include weighting factor.

```

<Interactions: public>+≡
    public :: interaction_evaluate_product

end if
end subroutine interaction_set_flavored_values

```

7.6.7 Handling Linked interactions

Store relations between corresponding particles within one interaction. The first particle is the parent, the second one the child. Links are established in both directions.

These relations have no effect on the propagation of momenta etc., they are rather used for mother-daughter relations in event output.

(Interactions: public)+≡

```
public :: interaction_relate
```

(Interactions: procedures)+≡

```

subroutine interaction_relate (int, i1, i2)
  type(interaction_t), intent(inout), target :: int
  integer, intent(in) :: i1, i2
  if (i1 /= 0 .and. i2 /= 0) then
    call internal_link_list_append (int%children(i1), i2)
    call internal_link_list_append (int%parents(i2), i1)
  end if
end subroutine interaction_relate

```

Transfer internal parent-child relations defined within interaction `int1` to a new interaction `int` where the particle indices are mapped to. Some particles in `int1` may have no image in `int`. In that case, a child entry maps to zero, and we skip this relation.

Also transfer resonance flags.

(Interactions: public)+≡

```
public :: interaction_transfer_relations
```

(Interactions: procedures)+≡

```

subroutine interaction_transfer_relations (int1, int2, map)
  type(interaction_t), intent(in) :: int1
  type(interaction_t), intent(inout), target :: int2
  integer, dimension(:), intent(in) :: map
  type(internal_link_t), pointer :: link
  integer :: i, k
  do i = 1, size (map)
    link => internal_link_list_get_first_ptr (int1%parents(i))
    do while (associated (link))
      k = internal_link_get_index (link)

```

```

        call interaction_relate (int2, map(k), map(i))
        call internal_link_advance (link)
    end do
    if (map(i) /= 0) then
        int2%resonant(map(i)) = int1%resonant(i)
    end if
end do
end subroutine interaction_transfer_relations

```

Make up internal parent-child relations for the particle(s) that are connected to a new interaction `int`.

If `resonant` is defined and true, the connections are marked as resonant in the result interaction

```

<Interactions: public>+≡
    public :: interaction_relate_connections

<Interactions: procedures>+≡
    subroutine interaction_relate_connections &

  integer :: i
  do i = 1, int%n_tot
    call pacify (int%p(i), acc)
  end do
end subroutine interaction_pacify_momenta

```

7.6.8 Recovering connections

When creating an evaluator for two interactions, we have to know by which particles they are connected. The connection indices can be determined if we have two linked interactions. We assume that `int1` is the source and `int2` the target, so the connections of interest are stored within `int2`. A connection is found if either the source is `int1`, or the (ultimate) source of a particle within `int2` coincides with the (ultimate) source of a particle within `int1`. The result is an array of index pairs.

To make things simple, we scan the interaction twice, once for counting hits, then allocate the array, then scan again and store the connections.

The connections are scanned for `int2`, which has sources in `int1`. It may happen that the order of connections is interchanged (crossed). We require the indices in `int1` to be sorted, so we reorder both index arrays correspondingly before returning them. (After this, the indices in `int2` may be out of order.)

```

<Interactions: public>+≡
public :: find_connections

<Interactions: procedures>+≡
subroutine find_connections (int1, int2, n, connection_index)

```

7.6.9 Test

Generate an interaction of a polarized virtual photon and a colored quark which may be either up or down. Remove the quark polarization. Generate another interaction for the quark radiating a photon and link this to the first interaction.

The radiation ignores polarization; transfer this information to the first interaction to simplify it. Then, transfer the momentum to the radiating quark and perform a splitting.

7.7 Matrix element evaluation

The `evaluator_t` type is an extension of the `interaction_t` type. It represents either a density matrix as the square of a transition matrix element, or the product of two density matrices. Usually, some quantum numbers are summed over in the result.

The `interaction_t` subobject represents a multi-particle interaction with incoming, virtual, and outgoing particles and the associated (not necessarily diagonal) density matrix of quantum state. When the evaluator is initialized, this interaction is constructed from the input interaction(s).

In addition, the initialization process sets up a multiplication table. For each matrix element of the result, it states which matrix elements are to be taken from the input interaction(s), multiplied (optionally, with an additional weight factor) and summed over.

Eventually, to a processes we associate a chain of evaluators which are to be evaluated sequentially. The physical event and its matrix element value(s) can be extracted from the last evaluator in such a chain.

Evaluators are constructed only once (as long as this is possible) during an initialization step. Then, for each event, momenta are computed and transferred among evaluators using the links within the interaction subobject. The multiplication tables enable fast evaluation of the result without looking at quantum numbers anymore.

```

<evaluators.f90>≡
  <File header>

```

```

  module evaluators

```

```

    <Use kinds>
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use lorentz !NODEP!
    use models
    use flavors
    use colors
    use helicities

```

```

    use quantum_numbers
    use state_matrices
    use interactions

    <Standard module head>

    <Evaluators: public>

    <Evaluators: parameters>

    <Evaluators: types>

    <Evaluators: interfaces>

    contains

    <Evaluators: procedures>

    end module evaluators

```

7.7.1 Array of pairings

The evaluator contains an array of `pairing_array` objects. This makes up the multiplication table.

Each pairing array contains two list of matrix element indices and a list of numerical factors. The matrix element indices correspond to the input interactions. The corresponding matrix elements are to be multiplied and optionally multiplied by a factor. The results are summed over to yield one specific matrix element of the result evaluator.

```

<Evaluators: types>≡
    type :: pairing_array_t
        integer, dimension(:), allocatable :: i1, i2
        complex(default), dimension(:), allocatable :: factor
    end type pairing_array_t

<Evaluators: procedures>≡
    elemental subroutine pairing_array_init (pa, n, has_i2, has_factor)
        type(pairing_array_t), intent(out) :: pa
        integer, intent(in) :: n
        logical, intent(in) :: has_i2, has_factor
        allocate (pa%i1 (n))
        if (has_i2) allocate (pa%i2 (n))
        if (has_factor) allocate (pa%factor (n))
    end subroutine pairing_array_init

```

7.7.2 The evaluator type

Possible variants of evaluators:

```

<Evaluators: parameters>≡
    integer, parameter :: &

```

```

EVAL_UNDEFINED = 0, &
EVAL_PRODUCT = 1, &
EVAL_SQUARED_FLOWS = 2, &
EVAL_SQUARE_WITH_COLOR_FACTORS = 3, &
EVAL_COLOR_CONTRACTION = 4, &
EVAL_IDENTITY = 5, &
EVAL_QN_SUM = 6

```

The evaluator type contains the result interaction and an array of pairing lists, one for each matrix element in the result interaction.

```

⟨Evaluators: public⟩≡
  public :: evaluator_t

⟨Evaluators: types⟩+≡
  type :: evaluator_t
  private
  integer :: type = EVAL_UNDEFINED
  type(interaction_t), pointer :: int_in1 => null ()
  type(interaction_t), pointer :: int_in2 => null ()
  type(interaction_t) :: int
  type(pairing_array_t), dimension(:), allocatable :: pairing_array
  contains
  ⟨Evaluators: evaluator: TBP⟩
end type evaluator_t

```

Output.

```

⟨Evaluators: public⟩+≡
  public :: evaluator_write

```

7.7.3 Auxiliary structures for evaluator creation

Creating an evaluator that properly handles all quantum numbers requires some bookkeeping. In this section, we define several auxiliary types and methods that organize and simplify this task. More structures are defined within the specific initializers (as local types and internal subroutines).

These types are currently implemented in a partial object-oriented way: We define some basic methods for initialization etc. here, but the evaluator routines below do access their internals as well. This simplifies some things such as index addressing using array slices, at the expense of losing some clarity.

Index mapping

Index mapping are abundant when constructing an evaluator. To have arrays of index mappings, we define this:

```

(Evaluators: types)+≡
  type :: index_map_t
    integer, dimension(:), allocatable :: entry
  end type index_map_t

(Evaluators: procedures)+≡
  elemental subroutine index_map_init (map, n)
    type(index_map_t), intent(out) :: map
    integer, intent(in) :: n
    allocate (map%entry (n))
  end subroutine index_map_init

(Evaluators: procedures)+≡
  function index_map_exists (map) result (flag)
    logical :: flag
    type(index_map_t), intent(in) :: map
    flag = allocated (map%entry)
  end function index_map_exists

(Evaluators: interfaces)+≡
  interface size
    module procedure index_map_size
  end interface

(Evaluators: procedures)+≡
  function index_map_size (map) result (s)
    integer :: s
    type(index_map_t), intent(in) :: map
    if (allocated (map%entry)) then
      s = size (map%entry)
    else
      s = 0
    end if
  end function index_map_size

(Evaluators: interfaces)+≡
  interface assignment(=)
    module procedure index_map_assign_int
    module procedure index_map_assign_array
  end interface

```

```

(Evaluators: procedures)+≡
  elemental subroutine index_map_assign_int (map, ival)
    type(index_map_t), intent(inout) :: map
    integer, intent(in) :: ival
    map%entry = ival
  end subroutine index_map_assign_int

  subroutine index_map_assign_array (map, array)
    type(index_map_t), intent(inout) :: map
    integer, dimension(:), intent(in) :: array
    map%entry = array
  end subroutine index_map_assign_array

(Evaluators: procedures)+≡
  elemental subroutine index_map_set_entry (map, i, ival)
    type(index_map_t), intent(inout) :: map
    integer, intent(in) :: i
    integer, intent(in) :: ival
    map%entry(i) = ival
  end subroutine index_map_set_entry

(Evaluators: procedures)+≡
  elemental function index_map_get_entry (map, i) result (ival)
    integer :: ival
    type(index_map_t), intent(in) :: map
    integer, intent(in) :: i
    ival = map%entry(i)
  end function index_map_get_entry

```

Index mapping (two-dimensional)

This is a variant with a square matrix instead of an array.

```

(Evaluators: types)+≡
  type :: index_map2_t
    integer :: s = 0
    integer, dimension(:,:), allocatable :: entry
  end type index_map2_t

(Evaluators: procedures)+≡
  elemental subroutine index_map2_init (map, n)
    type(index_map2_t), intent(out) :: map
    integer, intent(in) :: n
    map%s = n
    allocate (map%entry (n, n))
  end subroutine index_map2_init

(Evaluators: procedures)+≡
  function index_map2_exists (map) result (flag)
    logical :: flag
    type(index_map2_t), intent(in) :: map
    flag = allocated (map%entry)
  end function index_map2_exists

```

```

end function index_map2_exists

<Evaluators: interfaces>+≡
interface size
  module procedure index_map2_size
end interface

<Evaluators: procedures>+≡
function index_map2_size (map) result (s)
  integer :: s
  type(index_map2_t), intent(in) :: map
  s = map%s
end function index_map2_size

<Evaluators: interfaces>+≡
interface assignment(=)
  module procedure index_map2_assign_int
end interface

<Evaluators: procedures>+≡
elemental subroutine index_map2_assign_int (map, ival)
  type(index_map2_t), intent(inout) :: map
  integer, intent(in) :: ival
  map%entry = ival
end subroutine index_map2_assign_int

<Evaluators: procedures>+≡
elemental subroutine index_map2_set_entry (map, i, j, ival)
  type(index_map2_t), intent(inout) :: map
  integer, intent(in) :: i, j
  integer, intent(in) :: ival
  map%entry(i,j) = ival
end subroutine index_map2_set_entry

<Evaluators: procedures>+≡
elemental function index_map2_get_entry (map, i, j) result (ival)
  integer :: ival
  type(index_map2_t), intent(in) :: map
  integer, intent(in) :: i, j
  ival = map%entry(i,j)
end function index_map2_get_entry

```

Auxiliary structures: particle mask

This is a simple container of a logical array.

```

<Evaluators: types>+≡
type :: prt_mask_t
  logical, dimension(:), allocatable :: entry
end type prt_mask_t

```

```

<Evaluators: procedures>+≡
  subroutine prt_mask_init (mask, n)
    type(prt_mask_t), intent(out) :: mask
    integer, intent(in) :: n
    allocate (mask%entry (n))
  end subroutine prt_mask_init

```

```

<Evaluators: interfaces>+≡
  interface size
    module procedure prt_mask_size
  end interface

```

```

<Evaluators: procedures>+≡
  function prt_mask_size (mask) result (s)
    integer :: s
    type(prt_mask_t), intent(in) :: mask
    s = size (mask%entry)
  end function prt_mask_size

```

Quantum number containers

Trivial transparent containers:

```

<Evaluators: types>+≡
  type :: qn_list_t
    type(quantum_numbers_t), dimension(:,:), allocatable :: qn
  end type qn_list_t

  type :: qn_mask_array_t
    type(quantum_numbers_mask_t), dimension(:), allocatable :: mask
  end type qn_mask_array_t

```

Auxiliary structures: connection entries

This type is used as intermediate storage when computing the product of two evaluators or the square of an evaluator. The quantum-number array **qn** corresponds to the particles common to both interactions, but irrelevant quantum numbers (color) masked out. The index arrays **index_in** determine the entries in the input interactions that contribute to this connection. **n_index** is the size of these arrays, and **count** is used while filling the entries. Finally, the quantum-number arrays **qn_in_list** are the actual entries in the input interaction that contribute. In the product case, they exclude the connected quantum numbers.

Each evaluator has its own **connection_table** which contains an array of **connection_entry** objects, but also has stuff that specifically applies to the evaluator type. Hence, we do not generalize the **connection_table_t** type.

The filling procedure **connection_entry_add_state** is specific to the various evaluator types.

```

<Evaluators: types>+≡
  type :: connection_entry_t
    type(quantum_numbers_t), dimension(:), allocatable :: qn_conn

```

```

integer, dimension(:), allocatable :: n_index
integer, dimension(:), allocatable :: count
type(index_map_t), dimension(:), allocatable :: index_in
type(qn_list_t), dimension(:), allocatable :: qn_in_list
end type connection_entry_t

```

(Evaluators: procedures)+≡

```

subroutine connection_entry_init &
  (entry, n_count, n_map, qn_conn, count, n_rest)
  type(connection_entry_t), intent(out) :: entry
  integer, intent(in) :: n_count, n_map
  type(quantum_numbers_t), dimension(:), intent(in) :: qn_conn
  integer, dimension(n_count), intent(in) :: count
  integer, dimension(n_count), intent(in) :: n_rest
  integer :: i
  allocate (entry%qn_conn (size (qn_conn)))
  allocate (entry%n_index (n_count))
  allocate (entry%count (n_count))

Color handling

For managing color-factor computation, we introduce this local type. The `index` is the index in the color table that corresponds to a given matrix element index in the input interaction. The `col` array stores the color assignments in rows. The `factor` array associates a complex number with each pair of arrays in the color table. The `factor_is_known` array reveals whether a given factor is known already or still has to be computed.

(Evaluators: types)+≡

```

type :: color_table_t
    integer, dimension(:), allocatable :: index
    type(color_t), dimension(:, :), allocatable :: col
    logical, dimension(:, :), allocatable :: factor_is_known
    complex(default), dimension(:, :), allocatable :: factor
end type color_table_t

```

This is the initializer. We extract the color states from the given state matrices, establish index mappings between the two states (implemented by the array `me_index`), make an array of color states, and initialize the color-factor table. The latter is two-dimensional (includes interference) and not yet filled.

(Evaluators: procedures)+≡

```

subroutine color_table_init (color_table, state, n_tot)
    type(color_table_t), intent(out) :: color_table
    type(state_matrix_t), intent(in) :: state
    integer, intent(in) :: n_tot
    type(state_iterator_t) :: it
    type(quantum_numbers_t), dimension(:), allocatable :: qn
    type(state_matrix_t) :: state_col
    integer :: index, n_col_state
    allocate (color_table%index &
        (state_matrix_get_n_matrix_elements (state)))
    color_table%index = 0

        end if
      end do
    end do
  end if
end subroutine color_table_write

```

This subroutine sets color factors, based on information from the hard matrix element: the list of pairs of color-flow indices (in the basis of the matrix element code), the list of corresponding factors, and the list of mappings from the matrix element index in the input interaction to the color-flow index in the hard matrix element object.

We first determine the mapping of color-flow indices from the hard matrix element code to the current color table. The mapping could be nontrivial because the latter is derived from iterating over a state matrix, which may return states in non-canonical order. The translation table can be determined because we have, for the complete state matrix, both the mapping to the hard interac-

tion (the input `col_index_hi`) and the mapping to the current color table (the component `color_table%index`).

Once this mapping is known, we scan the list of index pairs `color_flow_index` and translate them to valid color-table index pairs. For this pair, the color factor is set using the corresponding entry in the list `col_factor`.

(Evaluators: procedures)+≡

```
subroutine color_table_set_color_factors (color_table, &
    col_flow_index, col_factor, col_index_hi)
    type(color_table_t), intent(inout) :: color_table
    integer, dimension(:,:), intent(in) :: col_flow_index
    complex(default), dimension(:), intent(in) :: col_factor
    integer, dimension(:), intent(in) :: col_index_hi
    integer, dimension(:), allocatable :: hi_to_ct
    integer :: n_cflow
    integer :: hi_index, me_index, ct_index, cf_index
    integer, dimension(2) :: hi_index_pair, ct_index_pair
    n_cflow = size (col_index_hi)
    if (size (color_table%index) /= n_cflow) &
        call msg_bug ("Mismatch between hard matrix element and color table")
    allocate (hi_to_ct (n_cflow))
    do me_index = 1, size (color_table%index)
        ct_index = color_table%index(me_index)
        hi_index = col_index_hi(me_index)
        hi_to_ct(hi_index) = ct_index
    end do
    do cf_index = 1, size (col_flow_index, 2)
        hi_index_pair = col_flow_index(:,cf_index)
        ct_index_pair = hi_to_ct(hi_index_pair)
        color_table%factor(ct_index_pair(1), ct_index_pair(2)) = &
            col_factor(cf_index)
        color_table%factor_is_known(ct_index_pair(1), ct_index_pair(2)) = .true.
    end do
end subroutine color_table_set_color_factors
```

This function returns a color factor, given two indices which point to the matrix elements of the initial state matrix. Internally, we can map them to the corresponding indices in the color table. As a side effect, we store the color factor in the color table for later lookup. (I.e., this function is impure.)

(Evaluators: procedures)+≡

```
function color_table_get_color_factor (color_table, index1, index2, nc) &
    result (factor)
    real(default) :: factor
    type(color_table_t), intent(inout) :: color_table

    color_table%factor(i1,i2) = factor
    color_table%factor_is_known(i1,i2) = .true.
!    print *, "    computed : ", factor
end if
end function color_table_get_color_factor

```

7.7.4 Creating an evaluator: Matrix multiplication

The evaluator for matrix multiplication is the most complicated variant.

The initializer takes two input interactions and constructs the result evaluator, which consists of the interaction and the multiplication table for the product (or convolution) of the two. Normally, the input interactions are connected by one or more common particles (e.g., decay, structure function convolution).

In the result interaction, quantum numbers of the connections can be summed over. This is determined by the `qn_mask_conn` argument. The `qn_mask_rest` argument is its analog for the other particles within the result interaction. (E.g., for the trace of the state matrix, all quantum numbers are summed over.) Finally, the `connections_are_resonant` argument tells whether the connecting particles should be marked as resonant in the final event record. This is useful for decays.

The algorithm consists of the following steps:

1. **find_connections**: Find the particles which are connected, i.e., common to both input interactions. Either they are directly linked, or both are linked to a common source.
2. **compute_index_bounds_and_mappings**: Compute the mappings of particle indices from the input interactions to the result interaction. There is a separate mapping for the connected particles.
3. **accumulate_connected_states**: Create an auxiliary state matrix which lists the possible quantum numbers for the connected particles. When building this matrix, count the number of times each assignment is contained in any of the input states and, for each of the input states, record the index of the matrix element within the new state matrix. For the connected particles, reassign color indices such that no color state is present twice in different color-index assignment. Note that helicity assignments of the connected state can be (and will be) off-diagonal, so no spin correlations are lost in decays.

Do this for both input interactions.

4. **allocate_connection_entries**: Allocate a table of connections. Each table row corresponds to one state in the auxiliary matrix, and to multiple states of the input interactions. It collects all states of the unconnected particles in the two input interactions that are associated with the particular state (quantum-number assignment) of the connected particles.

5. **fill_connection_table**: Fill the table of connections by scanning both input interactions. When copying states, reassign color indices for the unconnected particles such that they match between all involved particle sets (interaction 1, interaction 2, and connected particles).
6. **make_product_interaction**: Scan the table of connections we have just built. For each entry, construct all possible pairs of states of the unconnected particles and combine them with the specific connected-particle state. This is a possible quantum-number assignment of the result interaction. Now mask all quantum numbers that should be summed over, and append this to the result state matrix. Record the matrix element index of the result. We now have the result interaction.
7. **make_pairing_array**: First allocate the pairing array with the number of entries of the result interaction. Then scan the table of connections again. For each entry, record the indices of the matrix elements which have to be multiplied and summed over in order to compute this particular matrix element. This makes up the multiplication table.
8. **record_links**: Transfer all source pointers from the input interactions to the result interaction. Do the same for the internal parent-child relations and resonance assignments. For the connected particles, make up appropriate additional parent-child relations. This allows for fetching momenta from other interactions when a new event is filled, and to reconstruct the event history when the event is analyzed.

After all this is done, for each event, we just have to evaluate the pairing arrays (multiplication tables) in order to compute the result matrix elements in their proper positions. The quantum-number assignments remain fixed from now on.

```

7.7.5 Creating an evaluator: square

The generic initializer for an evaluator that squares a matrix element. Depending on the provided mask, we select the appropriate specific initializer for either diagonal or non-diagonal helicity density matrices.

```

(Evaluators: public)+≡
  public :: evaluator_init_square

(Evaluators: procedures)+≡
  subroutine evaluator_init_square (eval, int_in, qn_mask, &
    col_flow_index, col_factor, col_index_hi, expand_color_flows, nc)
    type(evaluator_t), intent(out), target :: eval

    else
      call evaluator_init_square_nondiag (eval, int_in, qn_mask, &
        col_flow_index, col_factor, col_index_hi, expand_color_flows, nc)
    end if
  end subroutine evaluator_init_square

```

Color-summed squared matrix (diagonal helicities)

The initializer for an evaluator that squares a matrix element, including color factors. The mask must be such that off-diagonal matrix elements are excluded.

If `color_flows` is set, the evaluator keeps color-flow entries separate and drops all interfering color structures. The color factors are set to unity in this case.

There is only one input interaction. The quantum-number mask is an array, one entry for each particle, so they can be treated individually. For academic

purposes, we allow for the number of colors being different from three (but 3 is the default).

The algorithm is analogous to multiplication, with a few notable differences:

1. The connected particles are known, the correspondence is one-to-one. All particles are connected, and the mapping of indices is trivial, which simplifies the following steps.
2. **accumulate_connected_states**: The matrix of connected states encompasses all particles, but color indices are removed. However, ghost states are still kept separate from physical color states. No color-index reassignment is necessary.
3. The table of connections contains single index and quantum-number arrays instead of pairs of them. They are paired with themselves in all possible ways.
4. **make_squared_interaction**: Now apply the predefined quantum-numbers mask, which usually collects all color states (physical and ghosts), and possibly a helicity sum.
5. **make_pairing_array**: For each pair of input states, compute the color factor (including a potential ghost-parity sign) and store this in the pairing array together with the matrix-element indices for multiplication.
6. **record_links**: This is again trivial due to the one-to-one correspondence.

```

Color-summed squared matrix (support nodiagonal helicities)

The initializer for an evaluator that squares a matrix element, including color factors. Unless requested otherwise by the quantum-number mask, the result contains off-diagonal matrix elements. (The input interaction must be diagonal since it represents an amplitude, not a density matrix.)

There is only one input interaction. The quantum-number mask is an array, one entry for each particle, so they can be treated individually. For academic purposes, we allow for the number of colors being different from three (but 3 is the default).

The algorithm is analogous to the previous one, with some additional complications due to the necessity to loop over two helicity indices.

Copy with additional contracted color states

This evaluator involves no square or multiplication, its matrix elements are just copies of the (single) input interaction. However, the state matrix of the interaction contains additional states that have color indices contracted. This is used for copies of the beam or structure-function interactions that need to match the hard interaction also in the case where its color indices coincide.

Auxiliary procedure for initialization

This will become a standard procedure in F2008. The result is true if the number of true values in the mask is odd. We use the function for determining the ghost parity of a quantum-number array.

```

<Evaluators: procedures>+≡
    function parity (mask)
        logical :: parity
        logical, dimension(:) :: mask
        integer :: i
        parity = .false.
        do i = 1, size (mask)
            if (mask(i)) parity = .not. parity
        end do
    end function parity

```

7.7.6 Accessing contents

Return the interaction component, as a pointer to avoid any copying.

```

<Evaluators: public>+≡
    public :: evaluator_get_int_ptr

<Evaluators: procedures>+≡
    function evaluator_get_int_ptr (eval) result (int)
        type(interaction_t), pointer :: int
        type(evaluator_t), intent(in), target :: eval
        int => eval%int
    end function evaluator_get_int_ptr

```

7.7.7 Inherited procedures

Return true if the state matrix within the interaction is empty.

```

<Evaluators: public>+≡
    public :: evaluator_is_empty

<Evaluators: procedures>+≡
    function evaluator_is_empty (eval) result (flag)

        call interaction_final (eval%int)
    end subroutine evaluator_final

```

7.7.9 Creating an evaluator: identity

The identity evaluator creates a copy of the first input evaluator; the second input is not used.

All particles link back to the input evaluator and the internal relations are copied. As evaluation does take a shortcut by cloning the matrix elements, the pairing array is not used and does not have to be set up.

```

<Evaluators: public>+≡
    public :: evaluator_init_identity

<Evaluators: interfaces>+≡

7.7.11 Evaluation

When the input interactions (which are pointed to in the pairings stored within the evaluator) are filled with values, we can activate the evaluator, i.e., calculate the result values which are stored in the interaction.

The evaluation of matrix elements can be done in parallel. A `forall` construct is not appropriate, however. We would need `do concurrent` here. Nevertheless, the evaluation functions are marked as `pure`.

```

<Evaluators: public>+≡
  public :: evaluator_evaluate

<Evaluators: procedures>+≡
  subroutine evaluator_evaluate (eval)
    type(evaluator_t), intent(inout), target :: eval
    integer :: i
    select case (eval%type)
    case (EVAL_PRODUCT)
      do i = 1, size(eval%pairing_array)
        call interaction_evaluate_product (eval%int, i, &
          eval%int_in1, eval%int_in2, &
          eval%pairing_array(i)%i1, eval%pairing_array(i)%i2)
      end do
    case (EVAL_SQUARE_WITH_COLOR_FACTORS)
      do i = 1, size(eval%pairing_array)
        call interaction_evaluate_product_cf (eval%int, i, &
          eval%int_in1, eval%int_in1, &
          eval%pairing_array(i)%i1, eval%pairing_array(i)%i2, &
          eval%pairing_array(i)%factor)
      end do

      end do
    case (EVAL_IDENTITY)
      call interaction_set_matrix_element (eval%int, eval%int_in1)
    end select
  end subroutine

```

```

case (EVAL_QN_SUM)
  do i = 1, size (eval%pairing_array)
    call interaction_evaluate_sum (eval%int, i, &
      eval%int_in1, eval%pairing_array(i)%i1)
  end do
end select
end subroutine evaluator_evaluate

```

7.7.12 Test

Test: Create two interactions. The interactions are twofold connected. The first connection has a helicity index that is kept, the second connection has a helicity index that is summed over. Concatenate the interactions in an evaluator, which thus contains a result interaction. Fill the input interactions with values, activate the evaluator and print the result.

Chapter 8

Particles

In this chapter, we deal with particles which have well-defined quantum numbers. While within interactions, all correlations are manifest, a particle array is derived by selecting a particular quantum number set. This involves tracing over all other particles, as far as polarization is concerned. Thus, a particle has definite flavor, color, and a single-particle density matrix for polarization.

8.1 Polarization

Particle polarization is determined by a particular quantum state which has just helicity information. For defining polarizations, we adopt the phase convention for a spin-1/2 particle that

$$\rho = \frac{1}{2}(1 + \vec{\alpha} \cdot \vec{\sigma}) \quad (8.1)$$

with the polarization axis $\vec{\alpha}$. Using this, we define

1. Trivial polarization: $\vec{\alpha} = 0$. [This is unpolarized, but distinct from the particular undefined polarization matrix which has the same meaning.]
2. Circular polarization: $\vec{\alpha}$ points in $\pm z$ direction.
3. Transversal polarization: $\vec{\alpha}$ points orthogonal to the z direction, with a phase ϕ that is 0 for the x axis, and $\pi/2 = 90^\circ$ for the y axis. For antiparticles, the phase switches sign, corresponding to complex conjugation.
4. Axis polarization, where we explicitly give $\vec{\alpha}$.

For higher spin, we retain this definition, but apply it to the two components with maximum and minimum weight. For massless particles, this is sufficient. For massive particles, we add the possibilities:

5. Longitudinal polarization: Only the 0-component is set. This is possible only for bosons.
6. Diagonal polarization: Explicitly specify all components in the helicity basis.

Obviously, this does not exhaust the possible density matrices for higher spin, but it should cover all practical applications.

```

    <Polarizations: types>

    <Polarizations: interfaces>

    contains

    <Polarizations: procedures>

  end module polarizations

```

8.1.1 The polarization type

This is not an extension, but rather a restriction of the quantum state. Flavor and color are ignored, there is just a one-particle helicity density matrix.

```

<Polarizations: public>≡
  public :: polarization_t

<Polarizations: types>≡
  type :: polarization_t
    logical :: polarized = .false.
    integer :: spin_type = 0
    integer :: multiplicity = 0
    type(state_matrix_t) :: state
  end type polarization_t

```

8.1.2 Basic initializer and finalizer

We need the particle flavor for determining the allowed helicity values. The density matrix is not set, but prepared to be filled later. This is private.

```

<Polarizations: procedures>≡
  elemental subroutine polarization_init (pol, flv)
    type(polarization_t), intent(out) :: pol
    type(flavor_t), intent(in) :: flv
    pol%spin_type = flavor_get_spin_type (flv)
    pol%multiplicity = flavor_get_multiplicity (flv)
    call state_matrix_init (pol%state, store_values = .true.)
  end subroutine polarization_init

```

The finalizer has to be public. The quantum state contains memory allocated to pointers.

```

<Polarizations: public>+≡

8.1.6 Specific initializers

Unpolarized particle, no helicity labels in the density matrix. The value is specified as $1/N$, where N is the multiplicity.

Exception: for left-handed or right-handed particles (neutrinos), polarization is always circular with fraction unity.

```

```

The following three modes are useful mainly for spin-1/2 particle and massless particles of any nonzero spin. Only the highest-weight components are filled.

Circular polarization: The density matrix of the two highest-weight states

is

$$\rho(f) = \frac{1 - |f|}{2} \mathbf{1} + |f| \times \begin{cases} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, & f > 0; \\ \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, & f < 0, \end{cases}$$

If the polarization fraction $|f|$ is unity, we need only one entry in the density matrix.

```

    end subroutine polarization_init_circular

```

Transversal polarization is analogous to circular, but we get a density matrix

$$\rho(f, \phi) = \frac{1 - |f|}{2} \mathbf{1} + \frac{|f|}{2} \begin{pmatrix} 1 & e^{-i\phi} \\ e^{i\phi} & 1 \end{pmatrix}.$$

The phase is $\phi = 0$ for the x -axis, $\phi = 90^\circ$ for the y axis as polarization vector. For an antiparticle, the phase switches sign, and for $f < 0$, the off-diagonal elements switch sign.

```

(Polarizations: public)+≡
    public :: polarization_init_transversal

```

```

(Polarizations: procedures)+≡
subroutine polarization_init_transversal (pol, flv, phi, fraction)

  real(default), intent(in) :: phi, fraction
  call polarization_init_axis &
    (pol, flv, fraction * (/ cos (phi), sin (phi), 0._default/))
end subroutine polarization_init_transversal

```

For axis polarization, we again set only the entries with maximum weight.

$$\rho(f, \phi) = \frac{1}{2} \begin{pmatrix} 1 + \alpha_3 & \alpha_1 - i\alpha_2 \\ \alpha_1 + i\alpha_2 & 1 - \alpha_3 \end{pmatrix}.$$

For an antiparticle, α_2 switches sign (complex conjugate).

end module particles

```

8.2.1 The particle type

Particle status codes

The overall status codes (incoming/outgoing etc.) are inherited from the module `subevents`.

Polarization status:

```

<Particles: parameters>≡
    integer, parameter, public :: PRT_UNPOLARIZED = 0
    integer, parameter, public :: PRT_DEFINITE_HELICITY = 1
    integer, parameter, public :: PRT_GENERIC_POLARIZATION = 2

```

Definition

The quantum numbers are flavor (from which invariant particle properties can be derived), color, and polarization. The particle may be unpolarized. In this

case, `hel` and `pol` are unspecified. If it has a definite helicity, the `hel` component is defined. If it has a generic polarization, the `pol` component is defined. For each particle we store the four-momentum and the invariant mass squared, i.e., the squared norm of the four-momentum. There is also an optional list of parent and child particles, for bookkeeping in physical events.

```

(Particles: public)≡
    public :: particle_t

(Particles: types)≡
    type :: particle_t
    private
        integer :: status = PRT_UNDEFINED
        integer :: polarization = PRT_UNPOLARIZED
        type(flavor_t) :: flv
        type(color_t) :: col
        type(helicity_t) :: hel
        type(polarization_t) :: pol
        type(vector4_t) :: p = vector4_null
        real(default) :: p2 = 0
        integer, dimension(:), allocatable :: parent
        integer, dimension(:), allocatable :: child
    end type particle_t

```

Particle initializers:

```

(Particles: interfaces)≡
    interface particle_init
        module procedure particle_init_particle
        module procedure particle_init_state
    !     module procedure particle_init_hepmc
    end interface

```

Copy a particle. (Deep copy) The excludes the parent-child relations.

```

(Particles: procedures)≡
    subroutine particle_init_particle (prt_out, prt_in)
        type(particle_t), intent(out) :: prt_out
        type(particle_t), intent(in) :: prt_in
        prt_out%status = prt_in%status
        prt_out%polarization = prt_in%polarization
        prt_out%flv = prt_in%flv
        prt_out%col = prt_in%col
        prt_out%hel = prt_in%hel
        prt_out%pol = prt_in%pol
        prt_out%p = prt_in%p
        prt_out%p2 = prt_in%p2
    end subroutine particle_init_particle

```

Initialize a particle using a single-particle state matrix which determines flavor, color, and polarization. The state matrix must have unique flavor and color. The factorization mode determines whether the particle is unpolarized, has definite helicity, or generic polarization. This mode is translated into the polarization status.

```

(Particles: procedures)+≡

```

```

subroutine particle_init_state (prt, state, status, mode)
  type(particle_t), intent(out) :: prt
  type(state_matrix_t), intent(in) :: state
  integer, intent(in) :: status, mode
  type(state_iterator_t) :: it
  prt%status = status

  case (FM_FACTOR_HELICITY)
    call polarization_init_state_matrix (prt%pol, state)
    prt%polarization = PRT_GENERIC_POLARIZATION
  end select
end subroutine particle_init_state

```

Initialize a particle from a HepMC particle object. The model is necessary for making a fully qualified flavor component. We have the additional flag `polarized` which tells whether the polarization information should be interpreted or ignored, and the lookup array of barcodes. Note that the lookup array is searched linearly, a possible bottleneck for large particle arrays. If necessary, the barcode array could be replaced by a hash table.

8.2.2 Particle sets

A particle set is what is usually called an event: an array of particles. The individual particle entries carry momentum, quantum numbers, polarization, and optionally connections. There is (also optionally) a correlated state-density matrix that maintains spin correlations that are lost in the individual particle entries.

```

(Particles: public) +=
  public :: particle_set_t

(Particles: types) +=
  type :: particle_set_t
  !   private
  integer :: n_beam = 0
  integer :: n_in = 0
  integer :: n_vir = 0
  integer :: n_out = 0
  integer :: n_tot = 0
  type(particle_t), dimension(:), allocatable :: prt
  type(state_matrix_t) :: correlated_state
end type particle_set_t

```

A particle set can be initialized from an interaction or from a HepMC event record.

```

(Particles: public)+≡
    public :: particle_set_init
(Particles: interfaces)+≡
    interface particle_set_init
        module procedure particle_set_init_interaction
    !     module procedure particle_set_init_hepmc
    end interface

```

When a particle set is initialized from a given interaction, we have to determine the branch within the original state matrix that fixes the particle quantum numbers. This is done with the appropriate probabilities, based on a random number `x`. The `mode` determines whether the individual particles become unpolarized, or take a definite (diagonal) helicity, or acquire single-particle polarization matrices. The flag `keep_correlations` tells whether the spin-correlation matrix is to be calculated and stored in addition to the particles. The flag `keep_virtual` tells whether virtual particles should be dropped. Note that if virtual particles are dropped, the spin-correlation matrix makes no sense, and parent-child relations are not set.

For a correct disentangling of color and flavor (in the presence of helicity), we consider two interactions. `int` has no color information, and is used to select a flavor state. Consequently, we trace over helicities here. `int_flows` contains color-flow and potentially helicity information, but is useful only after the flavor combination has been chosen. So this interaction is used to select helicity and color, but restricted to the selected flavor combination.

`int` and `int_flows` may be identical if there is only a single (or no) color flow. If there is just a single flavor combination, `x(1)` can be set to zero.

The current algorithm of evaluator convolution requires that the beam particles are assumed outgoing (in the beam interaction) and become virtual in all derived interactions. In the particle set they should be re-identified as incoming. The optional integer `n_incoming` can be used to perform this correction.

The flag `is_valid` is false if factorization of the state is not possible, in particular if the squared matrix element is zero.

```

(Particles: procedures)+≡
    subroutine particle_set_init_interaction &
        (particle_set, is_valid, int, int_flows, mode, x, &
         keep_correlations, keep_virtual, n_incoming)

    end if
end subroutine particle_set_write

```

8.2.3 I/O formats

Here, we define input/output of particle sets in various formats. This is the right place since particle sets contain most of the event information.

All write/read routines take as first argument the object, as second argument the I/O unit which in this case is a mandatory argument. Then follow further event data.

Internal binary format

This format is supposed to contain the complete information, so the particle data set can be fully reconstructed. The exception is the model part of the particle flavors; this is unassigned for the flavor values read from file.

```

(Particles: public) +=
    public :: particle_set_write_raw
    public :: particle_set_read_raw

(Particles: procedures) +=
    subroutine particle_set_write_raw (particle_set, u)
        type(particle_set_t), intent(in) :: particle_set
        integer, intent(in) :: u
        integer :: i
        write (u) &
            particle_set%n_beam, particle_set%n_in, &
            particle_set%n_vir, particle_set%n_out
        write (u) particle_set%n_tot
        do i = 1, particle_set%n_tot
            call particle_write_raw (particle_set%prt(i), u)
        end do
        call state_matrix_write_raw (particle_set%correlated_state, u)
    end subroutine particle_set_write_raw

    subroutine particle_set_read_raw (particle_set, u, iostat)
        type(particle_set_t), intent(out) :: particle_set
        integer, intent(in) :: u
        integer, intent(out) :: iostat

end do
call state_matrix_read_raw (particle_set%correlated_state, u, iostat=iostat)
end subroutine particle_set_read_raw

```

HepMC format

The master output function fills a HepMC GenEvent object that is already initialized, but has no vertices in it.

We first set up the vertex lists and enter the vertices into the HepMC event. Then, we assign first all incoming particles and then all outgoing particles to their associated vertices. Particles which have neither parent nor children entries (this should not happen) are dropped.

Finally, we insert the beam particles. If there are none, use the incoming particles instead.

Reconstruct the momenta within an interaction object from a particle set. We start from the incoming particles, which should be stored at the beginning. (The number of incoming particles is provided separately, so we do not need to analyze the interaction or particle set for this.) We follow their children down the tree until the interaction is exhausted.

This implies that the particle set may contain a longer tree (e.g., decay chains) than the interaction. The remainder of the tree is simply ignored.

The detailed ordering of the subsequent sub-interactions may differ between the interaction and the particle set. However, within each sub-interaction, the ordering of particles must match.

This reconstructs the hard interaction from a particle set. First the particle set is reduced to the incoming partons, then we add the direct children of those. The interaction and particle set should match in their array sizes. If we find a permutation of the particle flavors that matches one of the given flavor states, the assignment of momenta is made accordingly.

Given a particle set with an arbitrary ordering of particles, we need the permutation that yields an ordering that is present in the state matrix. This can be found by examining the flavor table. The result is a permutation of the PDG array that matches a row in the flavor table. If ok is returned false, no match was found.

This procedure reconstructs an array of vertex indices from the parent-child information in the particle entries, according to the HepMC scheme. For each particle, we determine which vertex it comes from and which vertex it goes to. We return the two arrays and the maximum vertex index.

For each particle in the list, we first check its parents. If for any parent the vertex where it goes to is already known, this vertex index is assigned as the current 'from' vertex. Otherwise, a new index is created, assigned as the current 'from' vertex, and as the 'to' vertex for all parents.

Then, the analogous procedure is done for the children.

    use flavors  
    use colors  
    use polarizations  
    use quantum_numbers  
    use state_matrices  
    use interactions  
  
    <Standard module head>  
  
    <Beams: public>  
  
    <Beams: types>  
  
    <Beams: interfaces>  
  
    contains  
  
    <Beams: procedures>  
  
  end module beams
```

9.1.1 Beam data

The beam data type contains beam data for one or two beams, depending on whether we are dealing with beam collisions or particle decay. In addition, it holds the c.m. energy `sqrts`, the Lorentz transformation `L` that transforms the c.m. system into the lab system, and the pair of c.m. momenta.

```

(Beams: public)≡
    public :: beam_data_t

(Beams: types)≡
    type :: beam_data_t
        logical :: initialized = .false.
        integer :: n = 0
        type(flavor_t), dimension(:), allocatable :: flv
        real(default), dimension(:), allocatable :: mass
        type(polarization_t), dimension(:), allocatable :: pol
        logical :: lab_is_cm_frame = .true.
        type(vector4_t), dimension(:), allocatable :: p_cm
        type(vector4_t), dimension(:), allocatable :: p
        type(lorentz_transformation_t), pointer :: L_cm_to_lab => null ()
        real(default) :: sqrts = 0
        character(32) :: md5sum = ""
    contains
        (Beams: beam data: TBP)
    end type beam_data_t

```

Generic initializer. This is called by the specific initializers below. Initialize either for decay or for collision.

```

(Beams: procedures)≡
    subroutine beam_data_init (beam_data, n)
        type(beam_data_t), intent(out) :: beam_data
        integer, intent(in) :: n
        beam_data%n = n
        allocate (beam_data%flv (n))
        allocate (beam_data%mass (n))
        allocate (beam_data%pol (n))
        allocate (beam_data%p_cm (n))
        allocate (beam_data%p (n))
        beam_data%initialized = .true.
    end subroutine beam_data_init

```

Finalizer: needed for the polarization components of the beams.

```

(Beams: public)+≡
    public :: beam_data_final

(Beams: procedures)+≡
    subroutine beam_data_final (beam_data)

  end if
end do
call beam_data_compute_md5sum (beam_data)
if (logging) call beam_data_write (beam_data)
end subroutine beam_data_finish_initialization

```

The MD5 sum is stored within the beam-data record, so it can be checked for integrity in subsequent runs.

(Beams: procedures)+≡

```

subroutine beam_data_compute_md5sum (beam_data)
  type(beam_data_t), intent(inout) :: beam_data
  integer :: unit
  unit = free_unit ()
  open (unit = unit, status = "scratch", action = "readwrite")
  call beam_data_write (beam_data, unit, write_md5sum = .false., &
    verbose = .true.)
  rewind (unit)
  beam_data%md5sum = md5sum (unit)
  close (unit)
end subroutine beam_data_compute_md5sum

```

9.1.3 Initializers: decays

This is the simplest one: decay in rest frame. We need just flavor and polarization. Color is inferred from flavor. Beam momentum and c.m. momentum coincide.

(Beams: public)+≡

```

public :: beam_data_init_decay

```

(Beams: procedures)+≡

```

subroutine beam_data_init_decay &
  (beam_data, flv, pol, p_cm, theta, phi)
  type(beam_data_t), intent(out) :: beam_data
  type(flavor_t), dimension(1), intent(in) :: flv
  type(polarization_t), dimension(1), intent(in), optional :: pol
  real(default), intent(in), optional :: p_cm, theta, phi
  real(default), dimension(1) :: m
  type(polarization_t), dimension(1) :: polarization
  m = flavor_get_mass (flv)
  if (present (pol)) then
    call beam_data_init_sqrts &
      (beam_data, m(1), flv, pol, p_cm, theta, phi)
  else
    call polarization_init_trivial (polarization(1), flv(1))
    call beam_data_init_sqrts &

```

```

        (beam_data, m(1), flv, polarization, p_cm, theta, phi)
    end if
end subroutine beam_data_init_decay

```

9.1.4 Data access

Post-initialization changes to the polarization:

```

(Beams: public)+≡
    public :: beam_data_set_polarization
    public :: beam_data_kill_polarization

(Beams: procedures)+≡
    subroutine beam_data_set_polarization (beam_data, pol)
        type(beam_data_t), intent(inout) :: beam_data
        type(polarization_t), dimension(:), intent(in) :: pol
        integer :: i
        if (size (pol) /= beam_data%n) call msg_bug ( &
            "beam_data_set_polarization_pol: initial state multiplicity mismatch")
        !do i = 1, beam_data%n
        !    call polarization_final (beam_data%pol(i))
        !end do
        beam_data%pol = pol
        call beam_data_compute_md5sum (beam_data)
    end subroutine beam_data_set_polarization

    subroutine beam_data_kill_polarization (beam_data)
        type(beam_data_t), intent(inout) :: beam_data
        if (beam_data%n == 1) then
            call polarization_init_trivial (beam_data%pol(1), beam_data%flv(1))
        else
            call polarization_init_unpolarized (beam_data%pol(1), beam_data%flv(1))
            call polarization_init_unpolarized (beam_data%pol(2), beam_data%flv(2))
        end if
    end subroutine beam_data_kill_polarization

```

9.1.5 Sanity check

After the beams have been set, the initial-particle masses may have been modified. This can be checked here.

```

(Beams: public)+≡
    public :: beam_data_masses_are_consistent

(Beams: procedures)+≡
    function beam_data_masses_are_consistent (beam_data) result (flag)
        logical :: flag
        type(beam_data_t), intent(in) :: beam_data
        flag = all (beam_data%mass == flavor_get_mass (beam_data%flv))
    end function beam_data_masses_are_consistent

```

9.1.6 The beams type

Beam objects are interaction objects that contain the actual beam data including polarization and density matrix. For collisions, the beam object actually contains two beams.

```

(Beams: public)+≡
    public :: beam_t

(Beams: types)+≡
    type :: beam_t
    private
        type(interaction_t) :: int
    end type beam_t

```

The constructor contains code that converts beam data into the (entangled) particle-pair quantum state. First, we set the number of particles and polarization mask. (The polarization mask is handed over to all later interactions, so if helicity is diagonal or absent, this fact is used when constructing the hard-interaction events.) Then, we construct the entangled state that combines helicity, flavor and color of the two particles (where flavor and color are unique, while several helicity states are possible). Then, we transfer this state together with the associated values from the spin density matrix into the `interaction_t` object.

```

(Beams: public)+≡
    public :: beam_init

(Beams: procedures)+≡
    subroutine beam_init (beam, beam_data)
        type(beam_t), intent(out) :: beam

```

10.1.1 Momentum splitting

Let us consider first an incoming parton with momentum k and invariant mass squared $s = k^2$ that splits into two partons with momenta q, p and invariant masses $t = q^2$ and $u = p^2$. (This is an abuse of the Mandelstam notation. t is actually the momentum transfer, assuming that p is radiated and q initiates the hard process.) The energy is split among the partons such that if $E = k^0$, we have $q^0 = xE$ and $p^0 = \bar{x}E$, where $\bar{x} \equiv 1 - x$.

We define the angle θ as the polar angle of p w.r.t. the momentum axis of the incoming momentum k . Ignoring azimuthal angle, we can write the four-momenta in the basis (E, p_T, p_L) as

$$k = \begin{pmatrix} E \\ 0 \\ p \end{pmatrix}, \quad p = \begin{pmatrix} \bar{x}E \\ \bar{x}\bar{p}\sin\theta \\ \bar{x}\bar{p}\cos\theta \end{pmatrix}, \quad q = \begin{pmatrix} xE \\ -\bar{x}\bar{p}\sin\theta \\ p - \bar{x}\bar{p}\cos\theta \end{pmatrix}, \quad (10.1)$$

where the first two mass-shell conditions are

$$p^2 = E^2 - s, \quad \bar{p}^2 = E^2 - \frac{u}{\bar{x}^2}. \quad (10.2)$$

The second condition implies that, for positive u , $\bar{x}^2 > u/E^2$, or equivalently

$$x < 1 - \sqrt{u}/E. \quad (10.3)$$

We are interested in the third mass-shell conditions: s and u are fixed, so we need t as a function of $\cos\theta$:

$$t = -2\bar{x}(E^2 - p\bar{p}\cos\theta) + s + u. \quad (10.4)$$

Solving for $\cos\theta$, we get

$$\cos\theta = \frac{2\bar{x}E^2 + t - s - u}{2\bar{x}p\bar{p}}. \quad (10.5)$$

We can compute $\sin^2\theta$ numerically as $\sin^2\theta = 1 - \cos^2\theta$, but it is important to reexpress this in view of numerical stability. To this end, we first determine the bounds for t . The cosine must be between -1 and 1 , so the bounds are

$$t_0 = -2\bar{x}(E^2 + p\bar{p}) + s + u, \quad (10.6)$$

$$t_1 = -2\bar{x}(E^2 - p\bar{p}) + s + u. \quad (10.7)$$

Computing $\sin^2\theta$ from $\cos\theta$ above, we observe that the numerator is a quadratic polynomial in t which has the zeros t_0 and t_1 , while the common denominator is given by $(2\bar{x}p\bar{p})^2$. Hence, we can write

$$\sin^2\theta = -\frac{(t - t_0)(t - t_1)}{(2\bar{x}p\bar{p})^2} \quad \text{and} \quad \cos\theta = \frac{(t - t_0) + (t - t_1)}{4\bar{x}p\bar{p}}, \quad (10.8)$$

which is free of large cancellations near $t = t_0$ or $t = t_1$.

If all is massless, i.e., $s = u = 0$, this simplifies to

$$t_0 = -4\bar{x}E^2, \quad t_1 = 0, \quad (10.9)$$

$$\sin^2\theta = -\frac{t}{\bar{x}E^2} \left(1 + \frac{t}{4\bar{x}E^2}\right), \quad \cos\theta = 1 + \frac{t}{2\bar{x}E^2}. \quad (10.10)$$

Here is the implementation. First, we define a container for the kinematical integration limits and some further data.

```

<SF aux: public>≡
  public :: splitting_data_t

<SF aux: types>≡
  type :: splitting_data_t
    private
      logical :: collinear = .false.

    contains
      <SF aux: splitting data: TBP>
    end type splitting_data_t

```

I/O for debugging:

```

<SF aux: splitting data: TBP>≡
  procedure :: write => splitting_data_write

<SF aux: procedures>≡
  subroutine splitting_data_write (d, unit)
    class(splitting_data_t), intent(in) :: d
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit); if (u < 0) return
    write (u, "(A)") "Splitting data:"
    write (u, "(2x,A,L1)") "collinear = ", d%collinear
1   format (2x,A,1x,ES15.8)
    write (u, 1) "x0  =", d%x0
    write (u, 1) "x   =", d%x
    write (u, 1) "xb  =", d%xb
    write (u, 1) "x1  =", d%x1
    write (u, 1) "t0  =", d%t0
    write (u, 1) "t   =", d%t
    write (u, 1) "t1  =", d%t1
    write (u, 1) "phi0 =", d%phi0
    write (u, 1) "phi  =", d%phi
    write (u, 1) "phi1 =", d%phi1
    write (u, 1) "E    =", d%E
    write (u, 1) "p    =", d%p
    write (u, 1) "pb   =", d%pb
    write (u, 1) "s    =", d%s
    write (u, 1) "u    =", d%u
    write (u, 1) "m2   =", d%m2
  end subroutine splitting_data_write

```

10.1.2 Constant data

This is the initializer for the data. The input consists of the incoming momentum, its invariant mass squared, and the invariant mass squared of the radiated particle. m_2 is the *physical* mass squared of the outgoing particle. The t bounds depend on the chosen x value and cannot be determined yet.

```

(SF aux: splitting data: TBP)+≡
  procedure :: init => splitting_data_init

(SF aux: procedures)+≡
  subroutine splitting_data_init (d, k, mk2, mr2, mo2, collinear)
    class(splitting_data_t), intent(out) :: d
    type(vector4_t), intent(in) :: k
    real(default), intent(in) :: mk2, mr2, mo2
    logical, intent(in), optional :: collinear
    if (present (collinear)) d%collinear = collinear
    d%E = energy (k)
    d%x1 = 1 - sqrt (max (mr2, 0._default)) / d%E
    d%p = sqrt (d%E**2 - mk2)
    d%s = mk2
    d%u = mr2
    d%m2 = mo2
  end subroutine splitting_data_init

```

Retrieve the x bounds, if needed for x sampling. Generating an x value is done by the caller, since this is the part that depends on the nature of the structure function.

```

(SF aux: splitting data: TBP)+≡
  procedure :: get_x_bounds => splitting_get_x_bounds

(SF aux: procedures)+≡
  function splitting_get_x_bounds (d) result (x)
    class(splitting_data_t), intent(in) :: d
    real(default), dimension(2) :: x
    x = (/ d%x0, d%x1 /)
  end function splitting_get_x_bounds

```

Now set the momentum fraction and compute t_0 and t_1 .

[The calculation of t_1 is subject to numerical problems. The exact formula is ($s = m_i^2$, $u = m_r^2$)

$$t_1 = -2\bar{x}E^2 + m_i^2 + m_r^2 + 2\bar{x}\sqrt{E^2 - m_i^2}\sqrt{E^2 - m_r^2/\bar{x}^2}. \quad (10.11)$$

The structure-function paradigm is useful only if $E \gg m_i, m_r$. In a Taylor expansion for large E , the leading term cancels. The expansion of the square roots (to subleading order) yields

$$t_1 = xm_i^2 - \frac{x}{\bar{x}}m_r^2. \quad (10.12)$$

There are two cases of interest: $m_i = m_o$ and $m_r = 0$,

$$t_1 = xm_o^2 \quad (10.13)$$

and $m_i = m_r$ and $m_o = 0$,

$$t_1 = -\frac{x^2}{\bar{x}} m_i^2. \quad (10.14)$$

In both cases, $t_1 \leq m_o^2$.]

That said, it turns out that taking the t_1 evaluation at face value leads to less problems than the approximation. We express the angles in terms of $t - t_0$ and $t - t_1$. Numerical noise in t_1 can then be tolerated.

```

<SF aux: splitting data: TBP>+≡
  procedure :: set_t_bounds => splitting_set_t_bounds

<SF aux: procedures>+≡
  elemental subroutine splitting_set_t_bounds (d, x, xb)
    class(splitting_data_t), intent(inout) :: d
    real(default), intent(in), optional :: x, xb
    real(default) :: tp, tm
    if (present (x)) d%x = x
    if (present (xb)) d%xb = xb
    if (d%xb /= 0) then
      d%pb = sqrt (max (d%E**2 - d%u / d%xb**2, 0._default))
    else
      d%pb = 0
    end if
    tp = -2 * d%xb * d%E**2 + d%s + d%u
    tm = -2 * d%xb * d%p * d%pb
    d%t0 = tp + tm
    d%t1 = tp - tm
    d%t = d%t1
  end subroutine splitting_set_t_bounds

```

10.1.3 Sampling recoil

Compute a value for the momentum transfer t , using a random number r . We assume a logarithmic distribution for $t - m^2$, corresponding to the propagator $1/(t - m^2)$ with the physical mass m for the outgoing particle. Optionally, we can narrow the kinematical bounds.

If all three masses in the splitting vanish, the upper limit for t is zero. In that case, the t value is set to zero and the splitting will be collinear.

```

<SF aux: splitting data: TBP>+≡
  procedure :: sample_t => splitting_sample_t

<SF aux: procedures>+≡
  subroutine splitting_sample_t (d, r, t0, t1)
    class(splitting_data_t), intent(inout) :: d
    real(default), intent(in) :: r
    real(default), intent(in), optional :: t0, t1
    real(default) :: tt0, tt1, tt0m, tt1m
    if (d%collinear) then
      d%t = d%t1
    else
      tt0 = d%t0; if (present (t0)) tt0 = max (t0, tt0)
      tt1 = d%t1; if (present (t1)) tt1 = min (t1, tt1)
      tt0m = tt0 - d%m2

```

```

        tt1m = tt1 - d%m2
        if (tt0m < 0 .and. tt1m < 0 .and. abs(tt0m) > &
            epsilon(tt0m) .and. abs(tt1m) > epsilon(tt0m)) then
            d%t = d%m2 + tt0m * exp (r * log (tt1m / tt0m))
        else
            d%t = tt1
        end if
    end if
end subroutine splitting_sample_t

```

The inverse operation: Given t , we recover the value of r that would have produced this value.

```

<SF aux: splitting data: TBP>+≡
    procedure :: inverse_t => splitting_inverse_t
<SF aux: procedures>+≡
    subroutine splitting_inverse_t (d, r, t0, t1)
        class(splitting_data_t), intent(in) :: d
        real(default), intent(out) :: r
        real(default), intent(in), optional :: t0, t1
        real(default) :: tt0, tt1, tt0m, tt1m
        if (d%collinear) then
            r = 0
        else
            tt0 = d%t0; if (present (t0)) tt0 = max (t0, tt0)
            tt1 = d%t1; if (present (t1)) tt1 = min (t1, tt1)
            tt0m = tt0 - d%m2
            tt1m = tt1 - d%m2
            if (tt0m < 0 .and. tt1m < 0) then
                r = log ((d%t - d%m2) / tt0m) / log (tt1m / tt0m)
            else
                r = 0
            end if
        end if
    end subroutine splitting_inverse_t

```

This is trivial, but provided for convenience:

```

<SF aux: splitting data: TBP>+≡
    procedure :: sample_phi => splitting_sample_phi
<SF aux: procedures>+≡
    subroutine splitting_sample_phi (d, r)
        class(splitting_data_t), intent(inout) :: d
        real(default), intent(in) :: r
        if (d%collinear) then
            d%phi = 0
        else
            d%phi = (1-r) * d%phi0 + r * d%phi1
        end if
    end subroutine splitting_sample_phi

```

Inverse:

```

<SF aux: splitting data: TBP>+≡
    procedure :: inverse_phi => splitting_inverse_phi

```

```

<SF aux: procedures>+≡
subroutine splitting_inverse_phi (d, r)
  class(splitting_data_t), intent(in) :: d
  real(default), intent(out) :: r
  if (d%collinear) then
    r = 0
  else
    r = (d%phi - d%phi0) / (d%phi1 - d%phi0)
  end if
end subroutine splitting_inverse_phi

```

10.1.4 Splitting

In this function, we actually perform the splitting. The incoming momentum k is split into (if no recoil) $q_1 = (1 - x)k$ and $q_2 = xk$.

Apart from the splitting data, we need the incoming momentum k , the momentum transfer t , and the azimuthal angle ϕ . The momentum fraction x is already known here.

Alternatively, we can split without recoil. The azimuthal angle is irrelevant, and the momentum transfer is always equal to the upper limit t_1 , so the polar angle is zero. Obviously, if there are nonzero masses it is not possible to keep both energy-momentum conservation and at the same time all particles on shell. We choose for dropping the on-shell condition here.

```

<SF aux: splitting data: TBP>+≡
procedure :: split_momentum => splitting_split_momentum

<SF aux: procedures>+≡
function splitting_split_momentum (d, k) result (q)
  class(splitting_data_t), intent(in) :: d
  type(vector4_t), dimension(2) :: q
  type(vector4_t), intent(in) :: k
  real(default) :: st2, ct2, st, ct, cp, sp
  type(lorentz_transformation_t) :: rot
  real(default) :: tt0, tt1, den
  type(vector3_t) :: kk, q1, q2
  if (d%collinear) then
    if (d%s == 0 .and. d%u == 0) then
      q(1) = d%xb * k
      q(2) = d%x * k
    else
      kk = space_part (k)
      q1 = d%xb * (d%pb / d%p) * kk
      q2 = kk - q1
      q(1) = vector4_moving (d%xb * d%E, q1)
      q(2) = vector4_moving (d%x * d%E, q2)
    end if
  else
    den = 2 * d%xb * d%p * d%pb
    tt0 = max (d%t - d%t0, 0._default)
    tt1 = min (d%t - d%t1, 0._default)
    if (den**2 <= epsilon(den)) then
      st2 = 1
    end if
  end if
end function splitting_split_momentum

```

```

else
  st2 = - (tt0 * tt1) / den ** 2
end if
if (st2 > 1) then
  st2 = 1
end if
ct2 = 1 - st2
st = sqrt (max (st2, 0._default))
ct = sqrt (max (ct2, 0._default))
sp = sin (d%phi)
cp = cos (d%phi)
rot = rotation_to_2nd (3, space_part (k))
q1 = vector3_moving (d%xb * d%pb * (/ st * cp, st * sp, ct /))
q2 = vector3_moving (d%p, 3) - q1
q(1) = rot * vector4_moving (d%xb * d%E, q1)
q(2) = rot * vector4_moving (d%x * d%E, q2)
end if
end function splitting_split_momentum

```

Momenta generated by splitting will in general be off-shell. They are on-shell only if they are collinear and massless. This subroutine puts them on shell by brute force, violating either momentum or energy conservation. The direction of three-momentum is always retained.

If the energy is below mass shell, we return a zero momentum.

```

<SF aux: parameters>≡
  integer, parameter, public :: KEEP_ENERGY = 0, KEEP_MOMENTUM = 1

<SF aux: public>+≡
  public :: on_shell

<SF aux: procedures>+≡
  elemental subroutine on_shell (p, m2, keep)
    type(vector4_t), intent(inout) :: p
    real(default), intent(in) :: m2
    integer, intent(in) :: keep
    real(default) :: E, E2, pn
    select case (keep)
    case (KEEP_ENERGY)
      E = energy (p)
      E2 = E ** 2
      if (E2 >= m2) then
        pn = sqrt (E2 - m2)
        p = vector4_moving (E, pn * direction (space_part (p)))
      else
        p = vector4_null
      end if
    case (KEEP_MOMENTUM)
      E = sqrt (space_part (p) ** 2 + m2)
      p = vector4_moving (E, space_part (p))
    end select
  end subroutine on_shell

```

10.1.5 Recovering the splitting

This is the inverse problem. We have on-shell momenta and want to deduce the splitting parameters x , t , and ϕ .

```

(SF aux: splitting data: TBP)+≡

  function splitting_get_x (sd) result (x)
    class(splitting_data_t), intent(in) :: sd
    real(default) :: x
    x = sd%x
  end function splitting_get_x

```

10.1.7 Unit tests

```

<SF aux: public>+≡
  public :: sf_aux_test

<SF aux: tests>≡
  subroutine sf_aux_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <SF aux: execute tests>
  end subroutine sf_aux_test

```

Momentum splitting: massless radiation

Compute momentum splitting for generic kinematics. It turns out that for $x = 0.5$, where $t - m^2$ is the geometric mean between its upper and lower bounds (this can be directly seen from the logarithmic distribution in the function `sample_t` for $r \equiv x = 1 - x = 0.5$), we arrive at an exact number $t = -0.15$ for the given input values.

```

<SF aux: execute tests>≡

```

```

Momentum splitting: massless parton

Compute momentum splitting for generic kinematics. It turns out that for $x = 0.5$, where $t - m^2$ is the geometric mean between its upper and lower bounds, we arrive at an exact number $t = -0.36$ for the given input values.

```

10.2 Mappings for structure functions

In this module, we provide a wrapper for useful mappings of the unit square that we can apply to a pair of structure functions.

In some cases it is useful, or even mandatory, to map the MC input parameters nontrivially onto a pair of structure functions for the two beams. In all cases considered here, instead of x_1 and x_2 as parameters for the beams, we generate one parameter for the product $x_1 x_2$ (so it directly corresponds to \sqrt{s}) and one parameter related to the quotient.

```
<sf_mappings.f90>≡  
  <File header>  
  
  module sf_mappings  
  
    <Use kinds>  
    <Use file utils>  
    use diagnostics !NODEP!  
    use unit_tests  
  
    <Standard module head>  
  
    <SF mappings: public>  
  
    <SF mappings: parameters>  
  
    <SF mappings: types>  
  
    <SF mappings: interfaces>  
  
    contains  
  
    <SF mappings: procedures>  
  
    <SF mappings: tests>  
  
  end module sf_mappings
```

10.2.1 Base type

First, we define an abstract base type for the mapping. In all cases we need to store the indices of the parameters on which the mapping applies. Additional parameters can be stored in the extensions of this type.

```
<SF mappings: public>≡  
  public :: sf_mapping_t  
  
<SF mappings: types>≡  
  type, abstract :: sf_mapping_t  
    integer, dimension(:), allocatable :: i  
    contains  
    <SF mappings: sf mapping: TBP>  
  end type sf_mapping_t
```

The output routine is deferred:

```

<SF mappings: sf mapping: TBP>≡
  procedure (sf_mapping_write), deferred :: write

<SF mappings: interfaces>≡
  abstract interface
    subroutine sf_mapping_write (object, unit)
      import
      class(sf_mapping_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine sf_mapping_write
  end interface

```

Initializer for the base type. The array of parameter indices is allocated but initialized to zero.

```

<SF mappings: sf mapping: TBP>+≡
  procedure :: base_init => sf_mapping_base_init

<SF mappings: procedures>≡
  subroutine sf_mapping_base_init (mapping, n_par)
    class(sf_mapping_t), intent(out) :: mapping
    integer, intent(in) :: n_par
    allocate (mapping%i (n_par))
    mapping%i = 0
  end subroutine sf_mapping_base_init

```

Computation: the values **p** are the input parameters, the values **r** are the output parameters. The Jacobian is **f**. We modify only the two parameters indicated by the indices **i**.

```

<SF mappings: sf mapping: TBP>+≡
  procedure (sf_mapping_compute), deferred :: compute

<SF mappings: interfaces>+≡
  abstract interface
    subroutine sf_mapping_compute (mapping, r, f, p)
      import
      class(sf_mapping_t), intent(in) :: mapping
      real(default), dimension(:), intent(out) :: r
      real(default), intent(out) :: f
      real(default), dimension(:), intent(in) :: p
    end subroutine sf_mapping_compute
  end interface

```

The inverse mapping. Use **r** to reconstruct **p** and also compute **f**.

```

<SF mappings: sf mapping: TBP>+≡
  procedure (sf_mapping_inverse), deferred :: inverse

<SF mappings: interfaces>+≡
  abstract interface
    subroutine sf_mapping_inverse (mapping, r, f, p)
      import
      class(sf_mapping_t), intent(in) :: mapping
      real(default), dimension(:), intent(in) :: r
      real(default), intent(out) :: f
    end subroutine sf_mapping_inverse
  end interface

```

```

        real(default), dimension(:), intent(out) :: p
    end subroutine sf_mapping_inverse
end interface

```

10.2.2 Integral

This is a consistency check for the self-tests: the integral over the unit square should be unity. We estimate this by a simple binning and adding up the values; this should be sufficient for a self-test.

The argument is the requested number of sampling points. We take the square root for binning in both dimensions, so the precise number might be different.

```

<SF mappings: sf mapping: TBP>+≡
    procedure :: integral => sf_mapping_integral

<SF mappings: procedures>+≡
    function sf_mapping_integral (mapping, n_calls) result (integral)
        class(sf_mapping_t), intent(in) :: mapping
        integer, intent(in) :: n_calls
        real(default) :: integral
        integer :: n_bin, i, j
        real(default), dimension(2) :: p, r
        real(default) :: dx, f, s
        n_bin = nint (sqrt (real (n_calls)))
        dx = 1._default / n_bin
        s = 0
        do i = 1, n_bin
            p(1) = i * dx - dx/2
            do j = 1, n_bin
                p(2) = j * dx - dx/2
                call mapping%compute (r, f, p)
                s = s + f
            end do
        end do
        integral = s / n_bin / n_bin
    end function sf_mapping_integral

```

10.2.3 Implementation: standard mapping

This maps the unit square (r_1, r_2) such that p_1 is the product $r_1 r_2$, while p_2 is related to the ratio.

```

<SF mappings: public>+≡
    public :: sf_s_mapping_t

<SF mappings: types>+≡
    type, extends (sf_mapping_t) :: sf_s_mapping_t
        logical :: power_set = .false.
        real(default) :: power = 1._default
    contains
        <SF mappings: sf standard mapping: TBP>
    end type sf_s_mapping_t

```

Output.

```
<SF mappings: sf standard mapping: TBP>≡
  procedure :: write => sf_s_mapping_write

<SF mappings: procedures>+≡
  subroutine sf_s_mapping_write (object, unit)
    class(sf_s_mapping_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(1x,A)", advance="no") "map"
    if (any (object%i /= 0)) then
      write (u, "('(',IO,',',IO,')')", advance="no") object%i
    end if
    write (u, "(A,F7.5,A)" ": standard (" , object%power, ")")
  end subroutine sf_s_mapping_write
```

Initialize: index pair and power parameter.

```
<SF mappings: sf standard mapping: TBP>+≡
  procedure :: init => sf_s_mapping_init

<SF mappings: procedures>+≡
  subroutine sf_s_mapping_init (mapping, power)
    class(sf_s_mapping_t), intent(out) :: mapping
    real(default), intent(in), optional :: power
    call mapping%base_init (2)
    if (present (power)) then
      mapping%power_set = .true.
      mapping%power = power
    end if
  end subroutine sf_s_mapping_init
```

Apply mapping.

```
<SF mappings: sf standard mapping: TBP>+≡
  procedure :: compute => sf_s_mapping_compute

<SF mappings: procedures>+≡
  subroutine sf_s_mapping_compute (mapping, r, f, p)
    class(sf_s_mapping_t), intent(in) :: mapping
    real(default), dimension(:), intent(out) :: r
    real(default), intent(out) :: f
    real(default), dimension(:), intent(in) :: p
    real(default), dimension(2) :: r2
    integer :: j
    if (mapping%power_set) then
      call map_unit_square (r2, f, p(mapping%i), mapping%power)
    else
      call map_unit_square (r2, f, p(mapping%i))
    end if
    do j = 1, 2
      r(mapping%i(j)) = r2(j)
    end do
  end subroutine sf_s_mapping_compute
```

Apply inverse.

```

<SF mappings: sf standard mapping: TBP>+≡
  procedure :: inverse => sf_s_mapping_inverse

<SF mappings: procedures>+≡
  subroutine sf_s_mapping_inverse (mapping, r, f, p)
    class(sf_s_mapping_t), intent(in) :: mapping
    real(default), dimension(:), intent(in) :: r
    real(default), intent(out) :: f
    real(default), dimension(:), intent(out) :: p
    real(default), dimension(2) :: p2
    integer :: j
    if (mapping%power_set) then
      call map_unit_square_inverse (r(mapping%i), f, p2, mapping%power)
    else
      call map_unit_square_inverse (r(mapping%i), f, p2)
    end if
    do j = 1, 2
      p(mapping%i(j)) = p2(j)
    end do
  end subroutine sf_s_mapping_inverse

```

10.2.4 Basic formulas

This mapping of the unit square is appropriate in particular for structure functions which are concentrated at the lower end. Instead of a rectangular grid, one set of grid lines corresponds to constant parton c.m. energy. The other set is chosen such that the jacobian is only mildly singular ($\ln x$ which is zero at $x = 1$), corresponding to an initial concentration of sampling points at the maximum energy. If **power** is greater than one (the default), points are also concentrated at the lower end.

The formula is (**power**= α):

$$r_1 = (p_1^{p_2})^\alpha \quad (10.15)$$

$$r_2 = (p_1^{1-p_2})^\alpha \quad (10.16)$$

$$f = \alpha^2 p_1^{\alpha-1} |\log p_1| \quad (10.17)$$

and for the default case $\alpha = 1$:

$$r_1 = p_1^{p_2} \quad (10.18)$$

$$r_2 = p_1^{1-p_2} \quad (10.19)$$

$$f = |\log p_1| \quad (10.20)$$

```

<SF mappings: procedures>+≡
  subroutine map_unit_square (r, factor, p, power)
    real(default), dimension(2), intent(out) :: r
    real(default), intent(out) :: factor
    real(default), dimension(2), intent(in) :: p
    real(default), intent(in), optional :: power
    real(default) :: xx, yy
    factor = 1

```

```

xx = p(1)
yy = p(2)
if (present(power)) then
  if (p(1) > 0 .and. power > 1) then
    xx = p(1)**power
    factor = factor * power * xx / p(1)
  end if
end if
if (xx /= 0) then
  r(1) = xx ** yy
  r(2) = xx / r(1)
  factor = factor * abs (log (xx))
else
  r = 0
end if
end subroutine map_unit_square

```

This is the inverse mapping.

(SF mappings: procedures)+≡

```

subroutine map_unit_square_inverse (r, factor, p, power)
  real(kind=default), dimension(2), intent(in) :: r
  real(kind=default), intent(out) :: factor
  real(kind=default), dimension(2), intent(out) :: p
  real(kind=default), intent(in), optional :: power
  real(kind=default) :: lg, xx, yy
  factor = 1
  xx = r(1) * r(2)
  if (xx /= 0) then
    lg = log (xx)
    yy = log (r(1)) / lg
    p(2) = yy
    factor = factor * abs (lg)
    if (present(power)) then
      p(1) = xx**(1._default/power)
      factor = factor * power * xx / p(1)
    else
      p(1) = xx
    end if
  else
    p = 0
  end if
end subroutine map_unit_square_inverse

```

Structure-function channels

A structure-function chain parameterization (channel) may contain a mapping that applies to multiple structure functions. This is described by an extension of the `sf_mapping_t` type. In addition, it may contain mappings that apply to (other) individual structure functions. The details of these mappings are implementation-specific.

The `sf_channel_t` type combines this information. It contains an array of map codes, one for each structure-function entry. The code values are:

none MC input parameters r directly become energy fractions x

single default mapping for a single structure-function entry

multi/s map $r \rightarrow x$ such that one MC input parameter is \hat{s}/s

multi/resonance as before, adapted to s-channel resonance (not implemented yet)

multi/on-shell as before, adapted to an on-shell particle in the s channel (not implemented yet)

```

⟨SF mappings: parameters⟩≡
  integer, parameter :: SFMAP_NONE = 0
  integer, parameter :: SFMAP_SINGLE = 1
  integer, parameter :: SFMAP_MULTI_S = 2
  integer, parameter :: SFMAP_MULTI_RES = 3
  integer, parameter :: SFMAP_MULTI_ONS = 4

```

Then, it contains an allocatable entry for the multi mapping. This entry holds the MC-parameter indices on which the mapping applies (there may be more than one MC parameter per structure-function entry) and any parameters associated with the mapping.

There can be only one multi-mapping per channel.

```

⟨SF mappings: public⟩+≡
  public :: sf_channel_t

⟨SF mappings: types⟩+≡
  type :: sf_channel_t
    integer, dimension(:), allocatable :: map_code
    class(sf_mapping_t), allocatable :: multi_mapping
    contains
    ⟨SF mappings: sf channel: TBP⟩
  end type sf_channel_t

```

The output format prints a single character for each structure-function entry and, if applicable, an account of the mapping parameters.

```

⟨SF mappings: sf channel: TBP⟩≡
  procedure :: write => sf_channel_write

⟨SF mappings: procedures⟩+≡
  subroutine sf_channel_write (object, unit)
    class(sf_channel_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit)
    if (allocated (object%map_code)) then
      do i = 1, size (object%map_code)
        select case (object%map_code (i))
          case (SFMAP_NONE)
            write (u, "(1x,A)", advance="no") "-"

```

```

        case (SFMAP_SINGLE)
            write (u, "(1x,A)", advance="no") "+"
        case (SFMAP_MULTI_S)
            write (u, "(1x,A)", advance="no") "s"
        case (SFMAP_MULTI_RES)
            write (u, "(1x,A)", advance="no") "r"
        case (SFMAP_MULTI_ONS)
            write (u, "(1x,A)", advance="no") "o"
        end select
    end do
else
    write (u, "(1x,A)", advance="no") "-"
end if
if (allocated (object%multi_mapping)) then
    write (u, "(1x, '/')", advance="no")
    call object%multi_mapping%write (u)
else
    write (u, *)
end if
end subroutine sf_channel_write

```

Initializer for a single `sf_channel` object.

```

<SF mappings: sf channel: TBP>+≡
    procedure :: init => sf_channel_init

<SF mappings: procedures>+≡
    subroutine sf_channel_init (channel, n_strfun)
        class(sf_channel_t), intent(out) :: channel
        integer, intent(in) :: n_strfun
        allocate (channel%map_code (n_strfun))
        channel%map_code = SFMAP_NONE
    end subroutine sf_channel_init

```

Assignment. This merely copies intrinsic assignment, but apparently the latter is bugged in gfortran 4.6.3, causing memory corruption.

```

<SF mappings: sf channel: TBP>+≡
    generic :: assignment (=) => sf_channel_assign
    procedure :: sf_channel_assign

<SF mappings: procedures>+≡
    subroutine sf_channel_assign (copy, original)
        class(sf_channel_t), intent(out) :: copy
        type(sf_channel_t), intent(in) :: original
        allocate (copy%map_code (size (original%map_code)))
        copy%map_code = original%map_code
        if (allocated (original%multi_mapping)) then
            allocate (copy%multi_mapping, source = original%multi_mapping)
        end if
    end subroutine sf_channel_assign

```

This initializer allocates an array of channels with common number of structure-function entries, therefore it is not a type-bound procedure.

```

<SF mappings: public>+≡
    public :: allocate_sf_channels

```

```

<SF mappings: procedures>+≡
subroutine allocate_sf_channels (channel, n_channel, n_strfun)
  type(sf_channel_t), dimension(:), intent(out), allocatable :: channel
  integer, intent(in) :: n_channel
  integer, intent(in) :: n_strfun
  integer :: c
  allocate (channel (n_channel))
  do c = 1, n_channel
    call channel(c)%init (n_strfun)
  end do
end subroutine allocate_sf_channels

```

This marks a given subset of indices as single-mapping.

```

<SF mappings: sf channel: TBP>+≡
  procedure :: activate_mapping => sf_channel_activate_mapping

<SF mappings: procedures>+≡
subroutine sf_channel_activate_mapping (channel, i_sf)
  class(sf_channel_t), intent(inout) :: channel
  integer, dimension(:), intent(in) :: i_sf
  channel%map_code(i_sf) = SFMAP_SINGLE
end subroutine sf_channel_activate_mapping

```

This sets an s-channel multichannel mapping. The length of the `i_sf` array must be 2. The parameter indices are not yet set.

```

<SF mappings: sf channel: TBP>+≡
  procedure :: set_s_mapping => sf_channel_set_s_mapping

<SF mappings: procedures>+≡
subroutine sf_channel_set_s_mapping (channel, i_sf, power)
  class(sf_channel_t), intent(inout) :: channel
  integer, dimension(:), intent(in) :: i_sf
  real(default), intent(in), optional :: power
  channel%map_code(i_sf) = SFMAP_MULTI_S
  allocate (sf_s_mapping_t :: channel%multi_mapping)
  select type (mapping => channel%multi_mapping)
    type is (sf_s_mapping_t)
      call mapping%init (power)
    end select
end subroutine sf_channel_set_s_mapping

```

Return true if the mapping code at position `i_sf` is `SFMAP_SINGLE`.

```

<SF mappings: sf channel: TBP>+≡
  procedure :: is_single_mapping => sf_channel_is_single_mapping

<SF mappings: procedures>+≡
function sf_channel_is_single_mapping (channel, i_sf) result (flag)
  class(sf_channel_t), intent(in) :: channel
  integer, intent(in) :: i_sf
  logical :: flag
  flag = channel%map_code(i_sf) == SFMAP_SINGLE
end function sf_channel_is_single_mapping

```

Return true if the mapping code at position `i_sf` is any of the `SFMAP_MULTI` mappings.

```

<SF mappings: sf channel: TBP>+≡
  procedure :: is_multi_mapping => sf_channel_is_multi_mapping
<SF mappings: procedures>+≡
  function sf_channel_is_multi_mapping (channel, i_sf) result (flag)
    class(sf_channel_t), intent(in) :: channel
    integer, intent(in) :: i_sf
    logical :: flag
    select case (channel%map_code(i_sf))
    case (SFMAP_NONE, SFMAP_SINGLE)
      flag = .false.
    case default
      flag = .true.
    end select
  end function sf_channel_is_multi_mapping

```

Return true if there is any nontrivial mapping in any of the channels.

Note: we provide an explicit public function. gfortran 4.6.3 has problems with the alternative implementation as a type-bound procedure for an array base object.

```

<SF mappings: public>+≡
  public :: any_sf_channel_has_mapping
<SF mappings: procedures>+≡
  function any_sf_channel_has_mapping (channel) result (flag)
    type(sf_channel_t), dimension(:), intent(in) :: channel
    logical :: flag
    integer :: c
    flag = .false.
    do c = 1, size (channel)
      flag = flag .or. any (channel(c)%map_code /= SFMAP_NONE)
    end do
  end function any_sf_channel_has_mapping

```

Set a parameter index for an active multi mapping. We assume that the index array is allocated properly.

```

<SF mappings: sf channel: TBP>+≡
  procedure :: set_par_index => sf_channel_set_par_index
<SF mappings: procedures>+≡
  subroutine sf_channel_set_par_index (channel, j, i_par)
    class(sf_channel_t), intent(inout) :: channel
    integer, intent(in) :: j
    integer, intent(in) :: i_par
    channel%multi_mapping%i(j) = i_par
  end subroutine sf_channel_set_par_index

```

10.2.5 Unit tests

```

<SF mappings: public>+≡
  public :: sf_mappings_test

```

```

<SF mappings: tests>≡
  subroutine sf_mappings_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <SF mappings: execute tests>
  end subroutine sf_mappings_test

```

Check standard mapping

Probe the standard mapping of the unit square for different parameter values. Also calculates integrals. For a finite number of bins, they differ slightly from 1, but the result is well-defined because we are not using random points.

```

10.3.1 Abstract structure-function data type

This type should hold all configuration data for a specific type of structure function. The base object is empty; the implementations will fill it.

⟨SF base: public⟩≡

```
public :: sf_data_t
```

⟨SF base: types⟩≡

```
type, abstract :: sf_data_t
```

```
contains
```

⟨SF base: sf data: TBP⟩

```
end type sf_data_t
```

Output.

⟨SF base: sf data: TBP⟩≡

```
procedure (sf_data_write), deferred :: write
```

⟨SF base: interfaces⟩≡

```
abstract interface
```

```
subroutine sf_data_write (data, unit, verbose)
```

```

import
class(sf_data_t), intent(in) :: data
integer, intent(in), optional :: unit
logical, intent(in), optional :: verbose
end subroutine sf_data_write
end interface

```

Return the number of input parameters that determine the structure function.

```

⟨SF base: sf data: TBP⟩+≡
  procedure (sf_data_get_int), deferred :: get_n_par

⟨SF base: interfaces⟩+≡
  abstract interface
    function sf_data_get_int (data) result (n)
      import
      class(sf_data_t), intent(in) :: data
      integer :: n
    end function sf_data_get_int
  end interface

```

Return the outgoing particle PDG codes for the current setup.

```

⟨SF base: sf data: TBP⟩+≡
  procedure (sf_data_get_pdg_out), deferred :: get_pdg_out

⟨SF base: interfaces⟩+≡
  abstract interface
    function sf_data_get_pdg_out (data) result (pdg_out)
      import
      class(sf_data_t), intent(in) :: data
      integer, dimension(:), allocatable :: pdg_out
    end function sf_data_get_pdg_out
  end interface

```

Allocate a matching structure function interaction object and properly initialize it.

Note: We should insist on `intent(out)` for the second argument, but gfortran 4.6.3 does not like it. In any case, the interaction should enter this deallocated.

```

⟨SF base: sf data: TBP⟩+≡
  procedure (sf_data_allocate_sf_int), deferred :: allocate_sf_int

⟨SF base: interfaces⟩+≡
  abstract interface
    subroutine sf_data_allocate_sf_int (data, sf_int)
      import
      class(sf_data_t), intent(in) :: data
      class(sf_int_t), intent(inout), allocatable :: sf_int
    end subroutine sf_data_allocate_sf_int
  end interface

```

10.3.2 Structure-function chain configuration

This is the data type that the `processes` module uses for setting up its structure-function chain. For each structure function described by the beam data, there is an entry. The `i` array indicates the beam(s) to which this structure function applies, and the `data` object contains the actual configuration data.

```

<SF base: public>+=
  public :: sf_config_t
<SF base: types>+=
  type :: sf_config_t
    integer, dimension(:), allocatable :: i
    class(sf_data_t), allocatable :: data
  contains
    <SF base: sf config: TBP>
  end type sf_config_t

```

Output:

```

<SF base: sf config: TBP>=
  procedure :: write => sf_config_write
<SF base: procedures>=
  subroutine sf_config_write (object, unit)
    class(sf_config_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    if (allocated (object%i)) then
      write (u, "(1x,A,2(1x,I0))") "Structure-function configuration: &
        &beam(s)", object%i
      if (allocated (object%data)) call object%data%write (u)
    else
      write (u, "(1x,A)") "Structure-function configuration: [undefined]"
    end if
  end subroutine sf_config_write

```

Initialize.

```

<SF base: sf config: TBP>+=
  procedure :: init => sf_config_init
<SF base: procedures>+=
  subroutine sf_config_init (sf_config, i_beam, sf_data)
    class(sf_config_t), intent(out) :: sf_config
    integer, dimension(:), intent(in) :: i_beam
    class(sf_data_t), intent(in) :: sf_data
    allocate (sf_config%i (size (i_beam)), source = i_beam)
    allocate (sf_config%data, source = sf_data)
  end subroutine sf_config_init

```

10.3.3 Structure-function instance

The `sf_int_t` data type contains an `interaction_t` object (it is an extension of this type) and a pointer to the `sf_data_t` configuration data. This interaction,

or copies of it, is used to implement structure-function kinematics and dynamics in the context of process evaluation.

The status code `status` tells whether the interaction is undefined, has defined kinematics (but matrix elements invalid), or is completely defined. There is also a status code for failure. The implementation is responsible for updating the status.

The entries `mi2`, `mr2`, and `mo2` hold the squared invariant masses of the incoming, radiated, and outgoing particle, respectively. They are supposed to be set upon initialization, but could also be varied event by event.

If the radiated or outgoing mass is nonzero, we may need to apply an on-shell projection. The projection mode is stored as `on_shell_mode`.

The array `beam_index` is the list of beams on which this structure function applies (1, 2, or both). The arrays `incoming`, `radiated`, and `outgoing` contain the indices of the respective particle sets within the interaction, for convenient lookup. The array `par_index` indicates the MC input parameters that this entry will use up in the structure-function chain.

In the abstract base type, we do not implement the data pointer. This allows us to restrict its type in the implementations.

```

<SF base: public>+≡
  public :: sf_int_t

<SF base: types>+≡
  type, abstract, extends (interaction_t) :: sf_int_t
    integer :: status = SF_UNDEFINED
    real(default), dimension(:), allocatable :: mi2
    real(default), dimension(:), allocatable :: mr2
    real(default), dimension(:), allocatable :: mo2
    integer :: on_shell_mode = KEEP_ENERGY
    logical :: qmin_defined = .false.
    logical :: qmax_defined = .false.
    real(default), dimension(:), allocatable :: qmin
    real(default), dimension(:), allocatable :: qmax
    integer, dimension(:), allocatable :: beam_index
    integer, dimension(:), allocatable :: incoming
    integer, dimension(:), allocatable :: radiated
    integer, dimension(:), allocatable :: outgoing
    integer, dimension(:), allocatable :: par_index
  contains
    <SF base: sf_int: TBP>
  end type sf_int_t

```

Status codes. The codes that refer to links, masks, and connections, apply to structure-function chains only.

The status codes are public.

```

<SF base: parameters>≡
  integer, parameter, public :: SF_UNDEFINED = 0
  integer, parameter, public :: SF_INITIAL = 1
  integer, parameter, public :: SF_DONE_LINKS = 2
  integer, parameter, public :: SF_FAILED_MASK = 3
  integer, parameter, public :: SF_DONE_MASK = 4
  integer, parameter, public :: SF_FAILED_CONNECTIONS = 5
  integer, parameter, public :: SF_DONE_CONNECTIONS = 6

```

```

integer, parameter, public :: SF_SEED_KINEMATICS = 10
integer, parameter, public :: SF_FAILED_KINEMATICS = 11
integer, parameter, public :: SF_DONE_KINEMATICS = 12
integer, parameter, public :: SF_FAILED_EVALUATION = 13
integer, parameter, public :: SF_EVALUATED = 20

```

Write a string version of the status code:

```

(SF base: procedures)+≡
subroutine write_sf_status (status, u)
  integer, intent(in) :: status
  integer, intent(in) :: u
  select case (status)
  case (SF_UNDEFINED)
    write (u, "(1x,'[',A,']')") "undefined"
  case (SF_INITIAL)
    write (u, "(1x,'[',A,']')") "initialized"

            type(string_t) :: string
        end function sf_int_type_string
    end interface

```

Output of the concrete object. We should not forget to call the output routine for the base type.

```

<SF base: sf_int: TBP>+≡
    procedure (sf_int_write), deferred :: write
<SF base: interfaces>+≡
    abstract interface
        subroutine sf_int_write (object, unit)
            import
            class(sf_int_t), intent(in) :: object
            integer, intent(in), optional :: unit
        end subroutine sf_int_write
    end interface

```

Basic initialization: set the invariant masses for the particles and initialize the interaction. The caller should then add states to the interaction and freeze it.

The dimension of the mask should be equal to the sum of the dimensions of the mass-squared arrays, which determine incoming, radiated, and outgoing particles, respectively.

Optionally, we can define minimum and maximum values for the momentum transfer to the outgoing particle(s). If all masses are zero, this is actually required for non-collinear splitting.

```

<SF base: sf_int: TBP>+=

```

Initialization. This proceeds via an abstract data object, which for the actual implementation should have the matching concrete type. Since all implementations have the same signature, we can prepare a deferred procedure. The data object will become the target of a corresponding pointer within the `sf_int_t` implementation.

This should call the previous procedure.

```

⟨SF base: sf_int: TBP⟩+≡
  procedure (sf_int_init), deferred :: init

⟨SF base: interfaces⟩+≡
  abstract interface
    subroutine sf_int_init (sf_int, data)

```

Complete the structure-function kinematics, derived from an input parameter (array) r between 0 and 1. The interaction momenta are calculated, and we return x (the momentum fraction), and f (the Jacobian factor for the map $r \rightarrow x$), if `map` is set.

If the `map` flag is unset, r and x values will coincide, and f will become unity. If it is set, the structure-function implementation chooses a convenient mapping from r to x with Jacobian f .

In the `inverse_kinematics` variant, we exchange the intent of `x` and `r`. The momenta are calculated only if the optional flag `set_momenta` is present and set.

```

```

Single splitting: compute momenta, given x input parameters. We assume that the incoming momentum is set. The status code is set to `SF_FAILED_KINEMATICS` if the x array does not correspond to a valid momentum configuration. Otherwise, it is updated to `SF_DONE_KINEMATICS`.

We force the outgoing particle on-shell. The on-shell projection is determined by the `on_shell_mode`. The radiated particle should already be on shell.

The inverse procedure: we compute the x array from the momentum configuration.

NOTE: Here and above, the single-particle case is treated in detail, allowing for non-collinearity and non-vanishing masses and nontrivial momentum-transfer bounds. For the pair case, we currently implement only collinear splitting and assume massless particles. This should be improved.

        allocate (value_array (sf_int%get_n_states ()))
        call sf_int%compute_values (value_array, x, scale, E)
        value = value_array(i_state)
    else
        value = 0
    end if
end subroutine sf_int_compute_value

```

10.3.6 Structure-function instance

This is a wrapper for `sf_int_t` objects, such that we can build an array with different structure-function types. The structure-function contains an array (a sequence) of `sf_int_t` objects.

The object, it holds the evaluator that connects the preceding part of the structure-function chain to the current interaction.

It also stores the input and output parameter values for the contained structure function. The `r` array has a second dimension, corresponding to the mapping channels in a multi-channel configuration. There is a Jacobian entry `f` for each channel. The corresponding logical array `mapping` tells whether we apply the mapping appropriate for the current structure function in this channel. The `x` parameter values (energy fractions) are common to all channels.

(SF base: types)+≡

```

    type :: sf_instance_t
        class(sf_int_t), allocatable :: int
        type(evaluator_t) :: eval
        real(default), dimension(:,:), allocatable :: r
        real(default), dimension(:), allocatable :: f
    end type sf_instance_t

```

```

        logical, dimension(:), allocatable :: m
        real(default), dimension(:), allocatable :: x
    end type sf_instance_t

```

10.3.7 Structure-function chain

A chain is an array of structure functions `sf`, initiated by a beam setup. We do not use this directly for evaluation, but create instances with copies of the contained interactions.

`n_par` is the total number of MC input parameters that is necessary for completely determining the structure-function chain.

```

<SF base: public>+≡
    public :: sf_chain_t

<SF base: types>+≡
    type, extends (beam_t) :: sf_chain_t
        type(beam_data_t), pointer :: beam_data => null ()
        integer :: n_in = 0
        integer :: n_strfun = 0
        integer :: n_par = 0
        type(sf_instance_t), dimension(:), allocatable :: sf
    contains
        <SF base: sf chain: TBP>
    end type sf_chain_t

```

Finalizer.

```

<SF base: sf chain: TBP>≡
    procedure :: final => sf_chain_final

<SF base: procedures>+≡
    subroutine sf_chain_final (object)
        class(sf_chain_t), intent(inout) :: object
        integer :: i
        if (allocated (object%sf)) then
            do i = 1, size (object%sf, 1)
                associate (sf => object%sf(i))
                    if (allocated (sf%int)) then
                        call sf%int%final ()
                    end if
                end associate
            end do
        end if
        call beam_final (object%beam_t)
    end subroutine sf_chain_final

```

Output.

```

<SF base: sf chain: TBP>+≡
    procedure :: write => sf_chain_write

```

<SF base: procedures>+≡

```

subroutine sf_chain_write (object, unit)
  class(sf_chain_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u, i, c
  u = output_unit (unit)
  write (u, "(1x,A)") "Incoming particles / structure-function chain:"
  if (associated (object%beam_data)) then
    write (u, "(3x,A,I0)") "n_in      = ", object%n_in
    write (u, "(3x,A,I0)") "n_strfun  = ", object%n_strfun
    write (u, "(3x,A,I0)") "n_par      = ", object%n_par
    call beam_data_write (object%beam_data, u)
    call write_separator (u)
    call beam_write (object%beam_t, u)
    if (allocated (object%sf)) then
      do i = 1, object%n_strfun
        associate (sf => object%sf(i))
          call write_separator (u)
          if (allocated (sf%int)) then
            call sf%int%write (u)
          else
            write (u, "(1x,A)") "SF instance: [undefined]"
          end if
        end associate
      end do
    end if
  else
    write (u, "(3x,A)") "[undefined]"
  end if
end subroutine sf_chain_write

```

Initialize: setup beams. The `beam_data` target must remain valid for the lifetime of the chain, since we just establish a pointer. The structure-function configuration array is used to initialize the individual structure-function entries. The target attribute is needed because the `sf_int` entries establish pointers to the configuration data.

<SF base: sf chain: TBP>+≡

```

procedure :: init => sf_chain_init

```

<SF base: procedures>+≡

```

subroutine sf_chain_init (sf_chain, beam_data, sf_config)
  class(sf_chain_t), intent(out) :: sf_chain
  type(beam_data_t), intent(in), target :: beam_data
  type(sf_config_t), dimension(:), intent(in), optional, target :: sf_config
  integer :: i
  sf_chain%beam_data => beam_data
  sf_chain%n_in = beam_data_get_n_in (beam_data)
  call beam_init (sf_chain%beam_t, beam_data)
  if (present (sf_config)) then
    sf_chain%n_strfun = size (sf_config)
    allocate (sf_chain%sf (sf_chain%n_strfun))
    do i = 1, sf_chain%n_strfun
      call sf_chain%set_strfun (i, sf_config(i)%i, sf_config(i)%data)
    end do
  end if
end subroutine sf_chain_init

```

```

        end if
    end subroutine sf_chain_init

```

Set a structure-function entry. We use the `data` input to allocate the `int` structure-function instance with appropriate type, then initialize the entry. The entry establishes a pointer to `data`.

The index `i` is the structure-function index in the chain.

```

<SF base: sf chain: TBP>+≡
    procedure :: set_strfun => sf_chain_set_strfun

        integer :: n
        n = sf_chain%n_par
    end function sf_chain_get_n_par

```

10.3.8 Auxiliary stuff

Write a separator line.

```

<SF base: procedures>+≡
    subroutine write_separator (u)
        integer, intent(in) :: u
        write (u, "(A)") repeat ("-", 72)
    end subroutine write_separator

    subroutine write_separator_double (u)
        integer, intent(in) :: u
        write (u, "(A)") repeat ("=", 72)
    end subroutine write_separator_double

```

10.3.9 Chain instances

A structure-function chain instance contains copies of the interactions in the configuration chain, suitably linked to each other and connected by evaluators.

After initialization, `out_sf` should point, for each beam, to the last structure function that affects this beam. `out_sf_i` should indicate the index of the corresponding outgoing particle within that structure-function interaction.

Analogously, `out_eval` is the last evaluator in the structure-function chain, which contains the complete set of outgoing particles. `out_eval_i` should indicate the index of the outgoing particles, within that evaluator, which will initiate the collision.

When calculating actual kinematics, we fill the `p`, `r`, and `x` arrays and the `f` factor. The `p` array denotes the MC input parameters as they come from the random-number generator. The `r` array results from applying global mappings. The `x` array results from applying structure-function local mappings. The `x` values can be interpreted directly as momentum fractions (or angle fractions, where recoil is involved). The `f` factor is the Jacobian that results from applying all mappings.

The `mapping` entry may store a global mapping that is applied to a combination of `x` values and structure functions, as opposed to mappings that affect only a single structure function. It is applied before the latter mappings, in the transformation from the `p` array to the `r` array. For parameters affected by this mapping, we should ensure that they are not involved in a local mapping.

```

<SF base: public>+≡
  public :: sf_chain_instance_t

<SF base: types>+≡
  type, extends (beam_t) :: sf_chain_instance_t
    type(sf_chain_t), pointer :: config => null ()
    integer :: status = SF_UNDEFINED
    type(sf_instance_t), dimension(:), allocatable :: sf

end subroutine sf_chain_instance_write

```

Initialize. This creates a copy of the interactions in the configuration chain, assumed to be properly initialized. In the copy, we allocate the `p` etc. arrays.

The brute-force assignment of the `sf` component would be straightforward, but at least gfortran 4.6.3 would like a more fine-grained copy. In any case, the copy is deep as far as allocatables are concerned, but for the contained `interaction_t` objects the copy is shallow, as long as we do not bind defined assignment to the type. Therefore, we have to re-assign the `interaction_t` components explicitly, this time calling the proper defined assignment. Furthermore, we allocate the parameter arrays for each structure function.

```

      end do
      chain%status = SF_INITIAL
    end if
  end subroutine sf_chain_instance_set_channel

```

Link the interactions in the chain. First, link the beam instance to its template in the configuration chain, which should have the appropriate momenta fixed.

Then, we follow the chain via the arrays `out_sf` and `out_sf_i`. The arrays are (up to) two-dimensional, the entries correspond to the beam particle(s). For each beam, the entry `out_sf` points to the last interaction that affected this beam, and `out_sf_i` is the out-particle index within that interaction. For the initial beam, `out_sf` is zero by definition.

For each entry in the chain, we scan the affected beams (one or two). We look for `out_sf` and link the out-particle there to the corresponding in-particle in the current interaction. Then, we update the entry in `out_sf` and `out_sf_i` to point to the current interaction.

```

      chain%status = SF_DONE_CONNECTIONS
    end if
  contains
  <SF base: init evaluators: find outgoing particles>
  end subroutine sf_chain_instance_init_evaluators

```

This is an internal subroutine of the previous one: After evaluators are set, trace the outgoing particles to the last evaluator. We only need the first channel, all channels are equivalent for this purpose.

For each beam, the outgoing particle is located by `out_sf` (the structure-function object where it originates) and `out_sf_i` (the index within that object). This particle is referenced by the corresponding evaluator, which in turn is referenced by the next evaluator, until we are at the end of the chain. We can trace back references by `interaction_find_link`. Knowing that `out_eval` is the index of the last evaluator, we thus determine `out_eval_i`, the index of the outgoing particle within that evaluator.

(SF base: init evaluators: find outgoing particles)≡

```
subroutine find_outgoing_particles ()
  type(interaction_t), pointer :: int, int_next
  integer :: i, j, out_sf, out_i
  chain%out_eval = size (chain%sf)
  do j = 1, size (chain%out_eval_i)
    out_sf = chain%out_sf(j)
    out_i = chain%out_sf_i(j)
    if (out_sf == 0) then
      int => beam_get_int_ptr (chain%beam_t)
      out_sf = 1
    else
      int => chain%sf(out_sf)%int%interaction_t
    end if
    do i = out_sf, chain%out_eval
      int_next => evaluator_get_int_ptr (chain%sf(i)%eval)
      out_i = interaction_find_link (int_next, int, out_i)
      int => int_next
    end do
    chain%out_eval_i(j) = out_i
  end do
end subroutine find_outgoing_particles
```

Compute the kinematics in the chain instance. We can assume that the seed momenta are set in the configuration beams. Scanning the chain, we first transfer the incoming momenta. Then, the use up the MC input parameter array `p` to compute the radiated and outgoing momenta.

In the multi-channel case, `c_sel` is the channel which we use for computing the kinematics and the `x` values. In the other channels, we invert the kinematics in order to recover the corresponding rows in the `r` array, and the Jacobian `f`.

We first apply any global mapping to transform the input `p` into the array `r`. This is then given to the structure functions which compute the final array `x` and Jacobian factors `f`, which we multiply to obtain the overall Jacobian.

end if
end subroutine sf_chain_instance_compute_kinematics

```

This is a variant of the previous procedure. We know the x parameters and reconstruct the momenta and the MC input parameters p . We do not need to select a channel.

Note: this is probably redundant, since the method we actually want starts from the momenta, recovers all x parameters, and then inverts mappings. See below `recover_kinematics`.

Recover the kinematics: assuming that the last evaluator has been filled with a valid set of momenta, we travel the momentum links backwards and fill the preceding evaluators and, as a side effect, interactions. We stop at the beam interaction.

After all momenta are set, apply the `inverse_kinematics` procedure above, suitably modified, to recover the x and p parameters and the Jacobian factors.

The `c_sel` (channel) argument is just used to mark a selected channel for the records, otherwise the recovery procedure is independent of this.

10.3.12 Test implementation: structure function

This is a template for the actual structure-function implementation which will be defined in separate modules.

Configuration data

The test structure function uses the **Test** model. It describes a scalar within an arbitrary initial particle, which is given in the initialization. The radiated particle is also a scalar, the same one, but we set its mass artificially to zero.

```

<SF base: public>+=
  public :: sf_test_data_t

<SF base: test types>=
  type, extends (sf_data_t) :: sf_test_data_t
    type(model_t), pointer :: model => null ()
    integer :: mode = 0
    type(flavor_t) :: flv_in
    type(flavor_t) :: flv_out
    type(flavor_t) :: flv_rad
    real(default) :: m = 0
    logical :: collinear = .true.
    real(default), dimension(:), allocatable :: qbounds
  contains
    <SF base: sf test data: TBP>
  end type sf_test_data_t

```

Output.

```

<SF base: sf test data: TBP>≡
  procedure :: write => sf_test_data_write

<SF base: procedures>+≡
  subroutine sf_test_data_write (data, unit, verbose)
    class(sf_test_data_t), intent(in) :: data
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose
    integer :: u
    u = output_unit (unit)
    write (u, "(1x,A)") "SF test data:"
    write (u, "(3x,A,A)") "model      = ", char (model_get_name (data%model))
    write (u, "(3x,A)", advance="no") "incoming = "
    call flavor_write (data%flv_in, u); write (u, *)
    write (u, "(3x,A)", advance="no") "outgoing  = "
    call flavor_write (data%flv_out, u); write (u, *)
    write (u, "(3x,A)", advance="no") "radiated  = "
    call flavor_write (data%flv_rad, u); write (u, *)
    write (u, "(3x,A,ES19.12)") "mass      = ", data%m
    write (u, "(3x,A,L1)") "collinear = ", data%collinear
    if (.not. data%collinear .and. allocated (data%qbounds)) then
      write (u, "(3x,A,ES19.12)") "qmin      = ", data%qbounds(1)
      write (u, "(3x,A,ES19.12)") "qmax      = ", data%qbounds(2)
    end if

end subroutine sf_test_apply

```

10.3.13 Test implementation: pair spectrum

Another template, this time for a incoming particle pair, splitting into two radiated and two outgoing particles.

Configuration data

For simplicity, the spectrum contains two mirror images of the previous structure-function configuration: the incoming and all outgoing particles are test scalars.

We have two versions, one with radiated particles, one without.

```
<SF base: test types>+≡
  type, extends (sf_data_t) :: sf_test_spectrum_data_t
    type(model_t), pointer :: model => null ()
    type(flavor_t) :: flv_in
    type(flavor_t) :: flv_out
    type(flavor_t) :: flv_rad
    logical :: with_radiation = .true.
    real(default) :: m = 0
  contains
    <SF base: sf test spectrum data: TBP>
  end type sf_test_spectrum_data_t
```

Output.

```
<SF base: sf test spectrum data: TBP>≡
  procedure :: write => sf_test_spectrum_data_write

<SF base: procedures>+≡
  subroutine sf_test_spectrum_data_write (data, unit, verbose)
    class(sf_test_spectrum_data_t), intent(in) :: data
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose
    integer :: u
    u = output_unit (unit)
    write (u, "(1x,A)") "SF test spectrum data:"
    write (u, "(3x,A,A)") "model      = ", char (model_get_name (data%model))
    write (u, "(3x,A)", advance="no") "incoming  = "
    call flavor_write (data%flv_in, u); write (u, *)
    write (u, "(3x,A)", advance="no") "outgoing  = "
    call flavor_write (data%flv_out, u); write (u, *)
    write (u, "(3x,A)", advance="no") "radiated  = "
    call flavor_write (data%flv_rad, u); write (u, *)
    write (u, "(3x,A,ES19.12)") "mass      = ", data%m
  end subroutine sf_test_spectrum_data_write
```

Initialization.

```
<SF base: sf test spectrum data: TBP>+≡
  procedure :: init => sf_test_spectrum_data_init

<SF base: procedures>+≡
  subroutine sf_test_spectrum_data_init (data, model, flv, with_radiation)
    class(sf_test_spectrum_data_t), intent(out) :: data
    type(model_t), intent(in), target :: model
    type(flavor_t), intent(in) :: flv
    logical, intent(in) :: with_radiation
    data%model => model

Structure function instance configuration

We create a structure-function chain instance which implements a configured structure-function chain. We link the momentum entries in the interactions and compute kinematics.

We do not actually connect the interactions and create evaluators. We skip this step and manually advance the status of the chain instead.

```

10.4.1 Physics

The ISR structure function is in the most crude approximation (LLA without α corrections, i.e. ϵ^0)

$$f_0(x) = \epsilon(1-x)^{-1+\epsilon} \quad \text{with} \quad \epsilon = \frac{\alpha}{\pi} q_e^2 \ln \frac{s}{m^2}, \quad (10.21)$$

where m is the mass of the incoming (and outgoing) particle, which is initially assumed on-shell.

Here, the form of ϵ results from the kinematical bounds for the momentum squared of the outgoing particle, which in the limit $m^2 \ll s$ are given by

$$t_0 = -2\bar{x}E(E+p) + m^2 \approx -\bar{x}s, \quad (10.22)$$

$$t_1 = -2\bar{x}E(E-p) + m^2 \approx xm^2, \quad (10.23)$$

so the integration over the propagator $1/(t-m^2)$ yields

$$\ln \frac{t_0 - m^2}{t_1 - m^2} = \ln \frac{s}{m^2}. \quad (10.24)$$

In $f_0(x)$, there is an integrable singularity at $x = 1$ which does not spoil the integration, but would lead to an unbounded f_{\max} . Therefore, we map this singularity like

$$x = 1 - (1-x')^{1/\epsilon} \quad (10.25)$$

such that

$$\int dx f_0(x) = \int dx' \quad (10.26)$$

The structure function has three parameters: α , m_{in} of the incoming particle and s , the hard scale. Internally, we store the exponent ϵ which is the relevant

parameter. (In conventional notation, $\epsilon = \beta/2$.) As defaults, we take the actual values of α (which is probably $\alpha(s)$), the actual mass m_{in} and the squared total c.m. energy s .

Including ϵ , ϵ^2 , and ϵ^3 corrections, the successive approximation of the ISR structure function read

$$f_0(x) = \epsilon(1-x)^{-1+\epsilon} \quad (10.27)$$

$$f_1(x) = g_1(\epsilon) f_0(x) - \frac{\epsilon}{2}(1+x) \quad (10.28)$$

$$f_2(x) = g_2(\epsilon) f_0(x) - \frac{\epsilon}{2}(1+x) - \frac{\epsilon^2}{8} \left(\frac{1+3x^2}{1-x} \ln x + 4(1+x) \ln(1-x) + 5+x \right) \quad (10.29)$$

$$f_3(x) = g_3(\epsilon) f_0(x) - \frac{\epsilon}{2}(1+x) - \frac{\epsilon^2}{8} \left(\frac{1+3x^2}{1-x} \ln x + 4(1+x) \ln(1-x) + 5+x \right) - \frac{\epsilon^3}{48} \left((1+x) [6 \text{Li}_2(x) + 12 \ln^2(1-x) - 3\pi^2] + 6(x+5) \ln(1-x) + \frac{1}{1-x} \left[\frac{3}{2}(1+8x+3x^2) \ln x + 12(1+x^2) \ln x \ln(1-x) - \frac{1}{2}(1+7x^2) \ln^2 x + \frac{1}{4}(39-24x-15x^2) \right] \right) \quad (10.30)$$

where the successive approximations to the prefactor of the leading singularity

$$g(\epsilon) = \frac{\exp\left(\epsilon(-\gamma_E + \frac{3}{4})\right)}{\Gamma(1+\epsilon)}, \quad (10.31)$$

are given by

$$g_0(\epsilon) = 1 \quad (10.32)$$

$$g_1(\epsilon) = 1 + \frac{3}{4}\epsilon \quad (10.33)$$

$$g_2(\epsilon) = 1 + \frac{3}{4}\epsilon + \frac{27-8\pi^2}{96}\epsilon^2 \quad (10.34)$$

$$g_3(\epsilon) = 1 + \frac{3}{4}\epsilon + \frac{27-8\pi^2}{96}\epsilon^2 + \frac{27-24\pi^2+128\zeta(3)}{384}\epsilon^3, \quad (10.35)$$

where, numerically

$$\zeta(3) = 1.20205690315959428539973816151 \dots \quad (10.36)$$

Although one could calculate the function $g(\epsilon)$ exactly, truncating its Taylor expansion ensures the exact normalization of the truncated structure function at each given order:

$$\int_0^1 dx f_i(x) = 1 \quad \text{for all } i. \quad (10.37)$$

Effectively, the $O(\epsilon)$ correction reduces the low- x tail of the structure function by 50% while increasing the coefficient of the singularity by $O(\epsilon)$. Relative

to this, the $O(\epsilon^2)$ correction slightly enhances $x > \frac{1}{2}$ compared to $x < \frac{1}{2}$. At $x = 0$, $f_2(x)$ introduces a logarithmic singularity which should be cut off at $x_0 = O(e^{-1/\epsilon})$: for lower x the perturbative series breaks down. The f_3 correction is slightly positive for low x values and negative near $x = 1$, where the Li_2 piece slightly softens the singularity at $x = 1$.

Instead of the definition for ϵ given above, it is customary to include a universal nonlogarithmic piece:

$$\epsilon = \frac{\alpha}{\pi} q_e^2 \left(\ln \frac{s}{m^2} - 1 \right) \quad (10.38)$$

10.4.2 Implementation

In the concrete implementation, the zeroth order mapping (10.25) is implemented, and the Jacobian is equal to $f_i(x)/f_0(x)$. This can be written as

$$\frac{f_0(x)}{f_0(x)} = 1 \quad (10.39)$$

$$\frac{f_1(x)}{f_0(x)} = 1 + \frac{3}{4}\epsilon - \frac{1-x^2}{2(1-x')} \quad (10.40)$$

$$\begin{aligned} \frac{f_2(x)}{f_0(x)} = 1 + \frac{3}{4}\epsilon + \frac{27-8\pi^2}{96}\epsilon^2 - \frac{1-x^2}{2(1-x')} \\ - \frac{(1+3x^2)\ln x + (1-x)(4(1+x)\ln(1-x) + 5+x)}{8(1-x')}\epsilon \end{aligned} \quad (10.41)$$

For $x = 1$ (i.e., numerically indistinguishable from 1), this reduces to

$$\frac{f_0(x)}{f_0(x)} = 1 \quad (10.42)$$

$$\frac{f_1(x)}{f_0(x)} = 1 + \frac{3}{4}\epsilon \quad (10.43)$$

$$\frac{f_2(x)}{f_0(x)} = 1 + \frac{3}{4}\epsilon + \frac{27-8\pi^2}{96}\epsilon^2 \quad (10.44)$$

The last line in (10.41) is zero for

$$x_{\min} = 0.00714053329734592839549879772019 \quad (10.45)$$

(Mathematica result), independent of ϵ . For x values less than this we ignore this correction because of the logarithmic singularity which should in principle be resummed.

10.4.3 The ISR data block

```

10.4.4 The ISR object

The `isr_t` data type is a $1 \rightarrow 2$ interaction, i.e., we allow for single-photon emission only (but use the multi-photon resummed radiator function). The particles are ordered as (incoming, photon, outgoing).

There is no need to handle several flavors (and data blocks) in parallel, since ISR is always applied immediately after beam collision. (ISR for partons is accounted for by the PDFs themselves.) Polarization is carried through, i.e., we retain the polarization of the incoming particle and treat the emitted photon as unpolarized. Color is trivially carried through. This implies that particles 1 and 3 should be locked together. For ISR we don't need the `q` variable.

```

<SF isr: types>+≡
    type, extends (sf_int_t) :: isr_t
        type(isr_data_t), pointer :: data => null ()
        real(default) :: x = 0
    contains
        <SF isr: isr: TBP>
    end type isr_t

```

Type string: has to here, but there is no string variable on which ISR depends. Hence, a dummy routine.

    else
      write (u, "(1x,A)") "ISR data: [undefined]"
    end if
  end subroutine isr_write

```

10.4.5 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ were trivial. The ISR structure function allows for a straightforward mapping of the unit interval. So, to leading order, the structure function value is unity, but the x value is transformed. Higher orders affect the function value.

The structure function implementation applies the above mapping to the input (random) number \mathbf{r} to generate the momentum fraction \mathbf{x} and the function value \mathbf{f} . For numerical stability reasons, we also output \mathbf{xb} , which is $\bar{x} = 1 - x$. The mapping ensures that $f = 1$ at leading order, and the higher-order corrections are well-behaved. So, the Jacobian for the kinematics is one if the mapping is applied as it is already defined within the value of the structure function. If the `no_map` flag is set, we do not apply this mapping.

```

<SF isr: isr: TBP>+≡
  procedure :: complete_kinematics => isr_complete_kinematics

<SF isr: procedures>+≡
  subroutine isr_complete_kinematics (sf_int, x, f, r, map)
    class(isr_t), intent(inout) :: sf_int
    real(default), dimension(:), intent(out) :: x
    real(default), intent(out) :: f
    real(default), dimension(:), intent(in) :: r
    logical, intent(in) :: map
    real(default) :: rb1, xb1, eps
    eps = sf_int%data%eps
    !!!
    rb1 = 1 - r(1)
    if (map) then
      if (rb1 < tiny(1._default)**eps) then
        xb1 = 0

```

```

        else
            xb1 = rb1**(1/eps)
        end if
        f = 1
    else
        xb1 = rb1
        f = xb1 ** (-1 + eps)
    end if
    x(1) = 1 - xb1
    if (size (x) == 3) x(2:3) = r(2:3)
    call sf_int%split_momentum (x, xb1)
    sf_int%data%map = map
    select case (sf_int%status)

10.4.6 ISR application

For ISR, we could in principle compute kinematics and function value in a single step. In order to be able to reweight matrix elements including structure functions we split kinematics and structure function calculation. The structure function works on a single beam, assuming that the input momentum has been set.

After splitting momenta, we set the outgoing momenta on-shell. We choose to conserve momentum, so energy conservation may be violated.

10.5.1 Physics

The EPA structure function for a photon inside an (elementary) particle p with energy E , mass m and charge q_p (e.g., electron) is given by ($\bar{x} \equiv 1 - x$)

$$\begin{aligned}
 f(x) = \frac{\alpha}{\pi} q_p^2 \frac{1}{x} & \left[\left(\bar{x} + \frac{x^2}{2} \right) \ln \frac{Q_{\max}^2}{Q_{\min}^2} \right. \\
 & \left. - \left(1 - \frac{x}{2} \right)^2 \ln \frac{x^2 + \frac{Q_{\max}^2}{E^2}}{x^2 + \frac{Q_{\min}^2}{E^2}} - x^2 \frac{m^2}{Q_{\min}^2} \left(1 - \frac{Q_{\min}^2}{Q_{\max}^2} \right) \right]. \quad (10.46)
 \end{aligned}$$

If no explicit Q bounds are provided, the kinematical bounds are

$$-Q_{\max}^2 = t_0 = -2\bar{x}(E^2 + p\bar{p}) + 2m^2 \approx -4\bar{x}E^2, \quad (10.47)$$

$$-Q_{\min}^2 = t_1 = -2\bar{x}(E^2 - p\bar{p}) + 2m^2 \approx -\frac{x^2}{\bar{x}}m^2. \quad (10.48)$$

The second and third terms in (10.46) are negative definite (and subleading). Noting that $\bar{x} + x^2/2$ is bounded between $1/2$ and 1 , we derive that $f(x)$ is always smaller than

$$\bar{f}(x) = \frac{\alpha}{\pi} q_p^2 \frac{L - 2 \ln x}{x} \quad \text{where} \quad L = \ln \frac{\min(4E_{\max}^2, Q_{\max}^2)}{\max(m^2, Q_{\min}^2)}, \quad (10.49)$$

where we allow for explicit Q bounds that narrow the kinematical range. Therefore, we generate this distribution:

$$\int_{x_0}^{x_1} dx \bar{f}(x) = C(x_0, x_1) \int_0^1 dx' \quad (10.50)$$

We set

$$\ln x = \frac{1}{2} \left\{ L - \sqrt{L^2 - 4 [x' \ln x_1 (L - \ln x_1) + \bar{x}' \ln x_0 (L - \ln x_0)]} \right\} \quad (10.51)$$

such that $x(0) = x_0$ and $x(1) = x_1$ and

$$\frac{dx}{dx'} = \left(\frac{\alpha}{\pi} q_p^2 \right)^{-1} x \frac{C(x_0, x_1)}{L - 2 \ln x} \quad (10.52)$$

with

$$C(x_0, x_1) = \frac{\alpha}{\pi} q_p^2 [\ln x_1 (L - \ln x_1) - \ln x_0 (L - \ln x_0)] \quad (10.53)$$

such that (10.50) is satisfied. Finally, we have

$$\int_{x_0}^{x_1} dx f(x) = C(x_0, x_1) \int_0^1 dx' \frac{f(x(x'))}{\bar{f}(x(x'))} \quad (10.54)$$

where x' is calculated from x via (10.51).

The structure of the mapping is most obvious from:

$$x'(x) = \frac{\log x (L - \log x) - \log x_0 (L - \log x_0)}{\log x_1 (L - \log x_1) - \log x_0 (L - \log x_0)}. \quad (10.55)$$

10.5.2 The EPA data block

The EPA parameters are: α , E_{\max} , m , Q_{\min} , and x_{\min} . Instead of m we can use the incoming particle PDG code as input; from this we can deduce the mass and charge.

Internally we store in addition $C_{0/1} = \frac{\alpha}{\pi} q_e^2 \ln x_{0/1} (L - \ln x_{0/1})$, the c.m. energy squared and the incoming particle mass.

10.5.3 The EPA object

The `epa_t` data type is a $1 \rightarrow 2$ interaction. We should be able to handle several flavors in parallel, since EPA is not necessarily applied immediately after beam collision: Photons may be radiated from quarks. In that case, the partons are massless and q_{\min} applies instead, so we do not need to generate several kinematical configurations in parallel.

The particles are ordered as (incoming, radiated, photon), where the photon initiates the hard interaction.

We generate an unpolarized photon and transfer initial polarization to the radiated parton. Color is transferred in the same way. !!! JRR: WK please check For EPA we don't seem to need the `q` variable.

```

<SF epa: types>+≡

10.5.5 EPA structure function

The EPA structure function allows for a straightforward mapping of the unit interval. The x value is transformed, and the mapped structure function becomes unity at its upper boundary.

The structure function implementation applies the above mapping to the input (random) number r to generate the momentum fraction x and the function value f . For numerical stability reasons, we also output xb , which is $\bar{x} = 1 - x$.

If `map` is set, the mapping is applied, otherwise it is switched off.

(EPA: procedures)≡

```

elemental subroutine strfun (f, x, xb, r, E, data, no_map)
    real(default), intent(out) :: f, x, xb
    real(default), intent(in)  :: r, E
    type(epa_data_t), intent(in) :: data

* ( data%c1 - data%c0 ) / den
end if
end subroutine strfun

```

10.5.6 EPA application

For EPA, we can in principle compute kinematics and function value in a single step. In order to be able to reweight events, kinematics and structure function application are separated. This function works on a single beam, assuming that the input momentum has been set. We need three random numbers as input: one for x , and two for the polar and azimuthal angles. Alternatively, for the no-recoil case, we can skip p_T generation; in this case, we only need one.

For obtaining splitting kinematics, we rely on the assumption that all in-particles are mass-degenerate (or there is only one), so the generated x values are identical.

```

10.6.1 Physics

The EWA structure function for a Z or W inside a fermion (lepton or quark) depends on the vector-boson polarization. We distinguish transversal (\pm) and

longitudinal (0) polarization.

$$F_+(x) = \frac{1}{16\pi^2} \frac{(v-a)^2 + (v+a)^2 \bar{x}^2}{x} \left[\ln \left(\frac{p_{\perp,\max}^2 + \bar{x}M^2}{\bar{x}M^2} \right) - \frac{p_{\perp,\max}^2}{p_{\perp,\max}^2 + \bar{x}M^2} \right] \quad (10.56)$$

$$F_-(x) = \frac{1}{16\pi^2} \frac{(v+a)^2 + (v-a)^2 \bar{x}^2}{x} \left[\ln \left(\frac{p_{\perp,\max}^2 + \bar{x}M^2}{\bar{x}M^2} \right) - \frac{p_{\perp,\max}^2}{p_{\perp,\max}^2 + \bar{x}M^2} \right] \quad (10.57)$$

$$F_0(x) = \frac{v^2 + a^2}{8\pi^2} \frac{2\bar{x}}{x} \frac{p_{\perp,\max}^2}{p_{\perp,\max}^2 + \bar{x}M^2} \quad (10.58)$$

where $p_{\perp,\max}$ is the cutoff in transversal momentum, M is the vector-boson mass, v and a are the vector and axial-vector couplings, and $\bar{x} \equiv 1-x$. Note that the longitudinal structure function is finite for large cutoff, while the transversal structure function is logarithmically divergent.

The maximal transverse momentum is given by the kinematical limit, it is

$$p_{\perp,\max} = \bar{x}\sqrt{s}/2. \quad (10.59)$$

The vector and axial couplings for a fermion branching into a W are

$$v_W = \frac{g}{2\sqrt{2}}, \quad a_W = \frac{g}{2\sqrt{2}}. \quad (10.60)$$

For Z emission, this is replaced by

$$v_Z = \frac{g}{2\cos\theta_w} (t_3 - 2q\sin^2\theta_w), \quad a_Z = \frac{g}{2\cos\theta_w} t_3, \quad (10.61)$$

where $t_3 = \pm\frac{1}{2}$ is the fermion isospin, and q its charge.

For an initial antifermion, the signs of the axial couplings are inverted. Note that a common sign change of v and a is irrelevant.

The EWA depends on the parameters g , $\sin^2\theta_w$, M_W , and M_Z . These can all be taken from the SM input, and the prefactors are calculated from those and the incoming particle type.

Since these structure functions have a $1/x$ singularity (which is not really relevant in practice, however, since the vector boson mass is finite), we map this singularity allowing for nontrivial x bounds:

$$x = \exp(\bar{r} \ln x_0 + r \ln x_1) \quad (10.62)$$

such that

$$\int_{x_0}^{x_1} \frac{dx}{x} = (\ln x_1 - \ln x_0) \int_0^1 dr. \quad (10.63)$$

As a user parameter, we have the cutoff $p_{\perp,\max}$. The divergence $1/x$ also requires a x_0 cutoff; and for completeness we introduce a corresponding x_1 . Physically, the minimal sensible value of x is M^2/s , although the approximation loses its value already at higher x values.

10.6.2 The EWA data block

The EWA parameters are: $p_{T,\max}$, c_V , c_A , and m . Instead of m we can use the incoming particle PDG code as input; from this we can deduce the mass and charges. In the initialization phase it is not yet determined whether a W or a Z is radiated, hence we set the vector and axial-vector couplings equal to the common prefactors $g/2 = e/2/\sin\theta_W$.

In principle, for EWA it would make sense to allow the user to also set the upper bound for x , x_{\max} , but we fix it to one here.

10.6.3 The EWA object

The `ewa_t` data type is a $1 \rightarrow 2$ interaction. We should be able to handle several flavors in parallel, since EWA is not necessarily applied immediately after beam collision: Photons may be radiated from quarks. In that case, the partons are massless and q_{\min} applies instead, so we do not need to generate several kinematical configurations in parallel.

The particles are ordered as (incoming, radiated, W/Z), where the W/Z initiates the hard interaction.

For EPA, we generate an unpolarized photon and transfer initial polarization to the radiated parton. Color is transferred in the same way. I do not know whether the same can/should be done for EWA, as the structure functions depend on the W/Z polarization. If we are having Z bosons, both up- and down-type fermions can participate. Otherwise, with a W^+ an up-type fermion is transferred to a down-type fermion, and the other way round.

```

10.6.4 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, the exponential mapping for the $1/x$ singularity discussed above is applied.

```

10.6.5 EWA structure function

The EWA structure function allows for a straightforward mapping of the unit interval. So, to leading order, the structure function value is unity, but the x value is transformed. Higher orders affect the function value.

The structure function implementation applies the above mapping to the input (random) number r to generate the momentum fraction x and the function value f . For numerical stability reasons, we also output xb , which is $\bar{x} = 1 - x$. The mapping ensures that $f = 1$ at leading order, and the higher-order

corrections are well-behaved.

10.6.6 EWA application

For EWA, we can compute kinematics and function value in a single step. This function works on a single beam, assuming that the input momentum has been set. We need four random numbers as input: one for x , one for Q^2 , and two for the polar and azimuthal angles. Alternatively, we can skip p_T generation; in this case, we only need one.

For obtaining splitting kinematics, we rely on the assumption that all in-particles are mass-degenerate (or there is only one), so the generated x values are identical.

```

10.7.1 Physics

Beamstrahlung is applied before ISR. The CIRCE1 implementation has a single structure function for both beams (which makes sense since it has to be switched on or off for both beams simultaneously). Nevertheless it is factorized:

The functional form in the CIRCE1 parameterization is defined for electrons or photons

$$f(x) = \alpha x^\beta (1-x)^\gamma \quad (10.64)$$

for $x < 1 - \epsilon$ (resp. $x > \epsilon$ in the photon case). In the remaining interval, the standard form is zero, with a delta singularity at $x = 1$ (resp. $x = 0$). Equivalently, the delta part may be distributed uniformly among this interval.

This latter form is implemented in the `kirke` version of the `CIRCE1` subroutines, and is used here.

The parameter ϵ is hardcoded in `CIRCE1` (set equal to 10^{-6}). Therefore, it cannot be changed in the namelist.

```
<SF circe1: public parameters>≡
  real(kind=default), parameter, public :: KIREPS = 1E-6_default
```

The other parameters are the parameterization version and revision number, the accelerator type, and the \sqrt{s} value used by `CIRCE1`. The chattiness can also be set (?).

Since the energy is distributed in a narrow region around unity (for electrons) or zero (for photons), it is advantageous to map the interval first. The mapping is controlled by the powers `beta` and `gamma` which are taken from the `CIRCE1` internal data structure.

The \sqrt{s} value, if not explicitly set, is taken from the process data. Note that interpolating \sqrt{s} is not recommended; one should rather choose one of the distinct values known to `CIRCE1`.

10.7.2 The CIRCE1 data block

The `CIRCE1` parameters are: The incoming flavors, the flags whether the photon or the lepton is the parton in the hard interaction, the flags for the generation mode (generator/mapping/no mapping), the mapping parameters β and γ , \sqrt{s} and several steering parameters: `ver`, `rev`, `acc`, `chat`.

In generator mode, the x values are actually discarded and a random number generator is used instead.

```

10.7.3 The CIRCE1 object

This is a $2 \rightarrow 4$ interaction, where, depending on the parameters, any two of the four outgoing particles are connected to the hard interactions, the others are radiated. Knowing that all particles are colorless, we do not have to deal with color.

The flavors are sorted such that the first two particles are the incoming leptons, the next two are the radiated particles, and the last two are the partons initiating the hard interaction.

CIRCE1 does not support polarized beams explicitly. For simplicity, we nevertheless carry beam polarization through to the outgoing electrons and make the photons unpolarized.

```

<SF circe1: types>+≡
  !!! JRR: WK please check

10.7.4 Kinematics

Set kinematics. If *map* is unset, the *r* and *x* values coincide, and the Jacobian $f(r)$ is trivial.

If *map* is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

10.7.5 CIRCE1 structure function

Compute the CIRCE1 structure function: either using the generator or the structure function value. In the latter case, we may employ a mapping that depends on the β, γ parameters.

The generator mode is the default and by far more useful, since there is virtually no loss in accuracy or reweighting efficiency for a process with CIRCE1 and without. The formal problem with this approach is the indeterministic integration, which is presumably harmless since the corresponding integration dimensions factorize in the VEGAS approach.

If `no_map` is set, we switch off generator and mapping.

```

<Limits: public parameters>+≡
    double precision, parameter, public :: CIRCE1_EPSILON = 1d-6

<CIRCE1: procedures>+≡
    subroutine strfun (f, x, xb, r, circe1_data, no_map)
        real(default), intent(out) :: f
        real(default), dimension(2), intent(out) :: x, xb
        real(default), dimension(2), intent(in) :: r
        type(circe1_data_t), intent(in) :: circe1_data
        logical, intent(in) :: no_map
        real(kind=default), parameter :: eps = CIRCE1_EPSILON
        real(default), dimension(2) :: fi
        if (circe1_data%generate .and. .not. no_map) then
            call circe_generate &
                (x, circe1_data%rng, circe1_data%pdg_in < 0, circe1_data%photon)
            xb = 1 - x
            f = 1
        else if (circe1_data%map .and. .not. no_map) then
            call circe_map_p (fi, x, xb, r, eps, &
                circe1_data%beta, circe1_data%gamma, circe1_data%photon)
            f = product (fi) * strfun_circe1 (x, circe1_data%pdg_in)
        else
            x = r
            xb = 1 - r
            f = strfun_circe1 (x, circe1_data%pdg_in)
        end if
    end subroutine strfun

```

Call the CIRCE1 generator. The integration variables are not used in this case. Instead, we call a random-number generator.

The CIRCE1 generator calls need the generator as argument, but not the generator state. Thus, we temporarily assign a pointer to the state to a module variable which is accessed by the generator.

```

<CIRCE1: variables>≡
    type(tao_random_state), pointer :: rng_tmp => null ()

```

```

<CIRCE1: procedures>+≡
subroutine rn_sub (r)
  double precision, intent(out) :: r
  real(default) :: x
  call tao_random_number (rng_tmp, x)
  r = x
end subroutine rn_sub

<CIRCE1: procedures>+≡
subroutine circe_generate (x, rng, anti, photon)
  logical, dimension(2), intent(in) :: anti
  logical, dimension(2), intent(in) :: photon
  real(default), dimension(2), intent(out) :: x
  real(double), dimension(2) :: xdum
  type( tao_random_state ), intent(in), target :: rng
  rng_tmp => rng
  if (all (photon)) then
    call gircgg (xdum(1), xdum(2), rn_sub)
  else if (photon(2)) then
    call girceg (xdum(1), xdum(2), rn_sub)
  else if (photon(1)) then
    call girceg (xdum(2), xdum(1), rn_sub)
  else if (.not. anti(1) .and. anti(2)) then
    call gircee (xdum(1), xdum(2), rn_sub)
  else if (anti(1) .and. .not. anti(2)) then
    call gircee (xdum(2), xdum(1), rn_sub)
  else
    call msg_bug ("CIRCE1: impossible flavor assignment")
  end if
  x = xdum
  rng_tmp => null ()
end subroutine circe_generate

```

Apply the appropriate mapping, exchanging x vs. $1 - x$ depending on the particle. This can be done for both beams simultaneously, since the parameterization factorizes.

The CIRCE1 structure function has the form of a β distribution

$$f(x) = \begin{cases} \alpha x^\beta (1-x)^\gamma & \text{for } 0 < x < x_0 \\ \alpha x_0^\beta (1-x_0)^\gamma & \text{for } x_0 < x < 1 \end{cases} \quad (10.65)$$

in the electron/positron case. In the photon case, this form holds for $1 - x$. Instead of mapping this function in one step, we consider the two factors separately, such that the mapping $y(x)$ satisfies either

$$\frac{dy}{dx} = \begin{cases} ax^\beta & \text{for } 0 < x < x_0 \\ ax_0^\beta & \text{for } x_0 < x < 1 \end{cases} \quad (10.66)$$

or

$$\frac{dy}{dx} = \begin{cases} a(1-x)^\gamma & \text{for } 0 < x < x_0 \\ a(1-x_0)^\gamma & \text{for } x_0 < x < 1 \end{cases} \quad (10.67)$$

where, typically, $\beta > 0$ and $\gamma < 0$.

Integrating this leads to

$$y = \begin{cases} a \frac{x^{1+\beta}}{a + \beta}, & x < x_0 \\ y_0 + a(x - x_0)x_0^\beta, & x > x_0 \end{cases} \quad (10.68)$$

resp.

$$y = \begin{cases} a \frac{1 - (1 - x)^{1+\gamma}}{1 + \gamma}, & x < x_0 \\ y_0 + ax_0^\gamma(x - x_0) & x > x_0 \end{cases} \quad (10.69)$$

We need the inverse mapping: The y value is taken from the random number set and has to be transformed into a x value which is fed into **CIRCE1**.

$$x = \begin{cases} \left((1 + \beta) \frac{y}{a} \right)^{\frac{1}{1+\beta}} & y < y_0 \\ x_0 + \frac{y - y_0}{ax_0^\beta} & y > y_0 \end{cases} \quad (10.70)$$

or

$$x = \begin{cases} 1 - \left(1 - (1 + \gamma) \frac{y}{a} \right)^{\frac{1}{1+\gamma}} & y < y_0 \\ x_0 + \frac{y - y_0}{a(1 - x_0)^\gamma} & y > y_0 \end{cases} \quad (10.71)$$

The boundary in y is given by

$$y_0 = a \frac{x_0^{1+\beta}}{1 + \beta} \quad \text{resp.} \quad y_0 = a \frac{1 - (1 - x_0)^{1+\gamma}}{1 + \gamma} \quad (10.72)$$

and the normalization is chosen such that $y(1) = 1$

$$a = \left(\frac{x_0^{1+\beta}}{1 + \beta} + (1 - x_0)x_0^\beta \right)^{-1} \quad (10.73)$$

or

$$a = \left(\frac{1 - (1 - x_0)^{1+\gamma}}{1 + \gamma} + (1 - x_0)^{1+\gamma} \right)^{-1} \quad (10.74)$$

$\langle \text{CIRCE1: procedures} \rangle + \equiv$

```

elemental subroutine circe_map_p (f, x, xb, r, eps, beta, gamma, photon)
  real(default), intent(out) :: f, x, xb
  real(default), intent(in) :: r
  real(default), intent(in) :: eps, beta, gamma
  logical, intent(in) :: photon
  real(default) :: rb
  if (photon) then
    rb = 1 - r
    call circe_map_s (f, xb, rb, 1-eps, beta, gamma)
    x = 1 - xb

  call circe_set_const (ay, y0, x0, gamma, invert=.true.)
  call circe_set_const (az, z0, y0, beta, invert=.false.)
  y = circe_map_x (z, z0, y0, az, beta, invert=.false.)
  x = circe_map_x (y, y0, x0, ay, gamma, invert=.true.)
  f = 1 / circe_jacobian (x, x0, ay, gamma, invert=.true.) &
      / circe_jacobian (y, y0, az, beta, invert=.false.)
end subroutine circe_map_s
```

(CIRCE1: procedures)+≡

```
pure function circe_map_x (y, y0, x0, a, power, invert) result (x)
  real(kind=default), intent(in) :: y, y0, x0, a, power
  logical, intent(in) :: invert
  real(kind=default) :: x
  if (y<=0) then
    x = 0
  else if (y>1) then
    x = 1
  else if (invert) then
    if (y<y0) then
      x = 1 - (1 - (1+power)*y/a)**(1/(1+power))
    else
      x = x0 + (y-y0)/(a*(1-x0)**power)
    end if
  else
    if (y<y0) then
      x = ((1+power)*y/a)**(1/(1+power))
    else
      x = x0 + (y-y0)/(a*x0**power)
    end if
  end if
end function circe_map_x
```

Set constants for power mappings.

(CIRCE1: procedures)+≡

```
pure subroutine circe_set_const (a, y0, x0, power, invert)
  real(default), intent(out) :: a, y0
  real(default), intent(in) :: x0, power
  logical, intent(in) :: invert
  real(default) :: tmp
  if (invert) then
    tmp = (1 - (1-x0)**(1+power)) / (1+power)
    a = 1 / (tmp + (1-x0)**(1+power))
  else
    tmp = x0**(1+power) / (1+power)
    a = 1 / (tmp + (1-x0) * x0**power)
  end if
  y0 = a * tmp
```

```
end subroutine circe_set_const
```

The Jacobian factor for the power mapping:

<CIRCE1: procedures>+≡

```
pure function circe_jacobian (x, x0, a, power, invert) result (dy_dx)
  real(kind=default), intent(in) :: x, x0, a, power
  logical, intent(in) :: invert
  real(kind=default) :: dy_dx
  if (x<=0) then
    dy_dx = a
  else if (invert) then
    if (x<x0) then
      dy_dx = a * (1-x)**power
    else
      dy_dx = a * (1-x0)**power
    end if
  else
    if (x<x0) then
      dy_dx = a * x**power
    else
      dy_dx = a * x0**power
    end if
  end if
end function circe_jacobian
```

The actual CIRCE call. The parameters are already mapped, so we can directly call the structure function.

<CIRCE1: procedures>+≡

```
function strfun_circe1 (x, pdg) result (f)
  real(default) :: f
  real(default), dimension(2), intent(in) :: x
  integer, dimension(2), intent(in) :: pdg
  if (all (x /= 0)) then
    f = kirke (dble (x(1)), dble (x(2)), pdg(1), pdg(2))
  else
    f = 0
  end if
end function strfun_circe1
```

10.7.6 CIRCE1 application

CIRCE is applied for the two beams at once. We can safely assume that no structure functions are applied before this, so the incoming particles are on-shell electrons/positrons. There will however be at some point the lumi-linker implementations, which are used as an alternative to the CIRCE1 structure function.

<SF circe1: circe1: TBP>+≡

```
procedure :: apply => circe1_apply

10.9.1 Physics

CIRCE2 describes photon spectra Beamstrahlung is applied before ISR. The CIRCE2 implementation has a single structure function for both beams (which makes sense since it has to be switched on or off for both beams simultaneously).

10.9.2 The CIRCE2 data block

The CIRCE2 parameters are: file and collider specification, incoming (= outgoing) particles. The luminosity is returned by `cir2lm`.

```

10.9.3 The CIRCE2 object

For CIRCE2 spectra it does not make sense to describe the state matrix as a radiation interaction, even if photons originate from laser backscattering. Instead, it is a $2 \rightarrow 2$ interaction where the incoming particles are identical to the outgoing ones.

The current implementation of CIRCE2 does support polarization and classical correlations, but no entanglement, so the density matrix of the outgoing particles is diagonal. The incoming particles are unpolarized (user-defined polarization for beams is meaningless, since polarization is described by the data file). The outgoing particles are polarized or polarization-averaged, depending on user request.

When assigning matrix elements, we scan the previously initialized state matrix. For each entry, we extract helicity and call the structure function. In the unpolarized case, the helicity is undefined and replaced by value zero. In the polarized case, there are four entries. If the generator is used, only one entry is nonzero in each call. Which one, is determined by comparing with a previously (randomly, distributed by relative luminosity) selected pair of helicities.

10.9.4 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

10.9.5 CIRCE2 structure function

Compute the CIRCE2 structure function: either using the generator or the structure function value. In the latter case, we may employ a power mapping for the singular endpoint that uses some heuristics for the mapping parameters.

The generator mode is the default and by far more useful, since there is virtually no loss in accuracy or reweighting efficiency for a process with CIRCE2 and without. The formal problem with this approach is the indeterministic integration, which is presumably harmless since the corresponding integration dimensions factorize in the VEGAS approach.

In generator mode with polarized beams, for each event only one helicity is selected. (See `interaction_apply_circe2` below.) The selection is based on the relative luminosities. Hence, the function value (unity) is multiplied by the number of helicity states (four).

Similarly, in non-generator mode, the luminosity densities for the helicity states are individually normalized and must be multiplied by their luminosity fraction and multiplied by four.

If `no_map` is set, switch off generator and mapping modes.

```

<CIRCE2: procedures>≡
subroutine strfun (f, x, r, hel, data, no_map)
    real(default), intent(out) :: f
    real(default), dimension(2), intent(out) :: x
    real(default), dimension(2), intent(in) :: r
    real(default), dimension(2) :: fi
    integer, dimension(2), intent(in) :: hel
    double precision, dimension(2) :: xx
    type(circe2_data_t), intent(in) :: data
    logical, intent(in) :: no_map
    if (data%generate .and. .not. no_map) then
        rng_tmp => data%rng
        call cir2gn &
            (data%pdg(1), hel(1), data%pdg(2), hel(2), xx(1), xx(2), rn_sub)
        x = xx
        if (data%polarized) then
            f = 4
        else
            f = 1
        end if
    else
        if (no_map) then
            x = r
            fi = 1
        else
            call circe2_map (fi, x, r, data%map_mode, data%map_power)
        end if
        f = product (fi) &
            * cir2dn (data%pdg(1), hel(1), data%pdg(2), hel(2), &

```

```

                                dble (x(1)), dble (x(2)))
    if (data%polarized) then
        f = 4 * f * data%lumi_hel_frac (hel(1), hel(2))
    end if
end if
end subroutine strfun

```

The CIRCE2 calls need the generator as argument, but not the generator state. Thus, we temporarily assign a pointer to the state to a module variable which is accessed by the generator.

(CIRCE2: variables)≡
 type(tao_random_state), pointer :: rng_tmp => null ()

Here is the generator call in the form that CIRCE2 expects:

(CIRCE2: procedures)+≡
 subroutine rn_sub (r)
 double precision, intent(out) :: r
 real(default) :: x
 call tao_random_number (rng_tmp, x)
 r = x
end subroutine rn_sub

Map the random numbers to x values, using specified power mappings for both beams. This function applies to a single beam but is elemental, so it is applied to the beam pair simultaneously.

We define power mappings (modes) for $x = 0$ or, alternatively, for $x = 1$. Mode $x = -1$ means no mapping.

Near zero (photon case) a power 2...3 should be sufficient to cancel the singularity, while near one (electron) the very narrow smeared delta function requires a high power ~ 10 to be identified. Quite generically, if a low x value x_0 needs to be resolved by the mapping, a power of the order $-\frac{1}{2} \log x_0$ is appropriate.

(CIRCE2: procedures)+≡
 elemental subroutine circe2_map (f, x, r, mode, power)
 real(default), intent(out) :: f, x
 real(default), intent(in) :: r
 integer, intent(in) :: mode
 real(default), intent(in) :: power
 real(default) :: xbar, rbar
 select case (mode)
 case (0)
 if (r <= tiny(1._default)) then
 x = 0
 f = 0
 else
 x = r ** power
 f = power * x / r
 end if
 case (1)
 rbar = 1 - r
 if (rbar <= tiny(1._default)) then
 xbar = 0

```

        f = 0
    else
        xbar = rbar ** power
        f = power * xbar / rbar
    end if
    x = 1 - xbar
case default
    x = r
    f = 1
end select
end subroutine circe2_map

```

10.9.6 CIRCE2 application

This function works on both beams, assuming that the input momentum has been set. We apply the usual splitting formalism, specializing to collinear splitting, but throw away the radiated momenta.

```

        end do
    end do
    call msg_bug ("CIRCE2: helicity selection failed")
end subroutine circe2_select_hel

```

10.10 Energy-scan spectrum

This spectrum is actually a trick that allows us to plot the c.m. energy dependence of a cross section without scanning the input energy. We start with the observation that a spectrum $f(x)$, applied to one of the incoming beams only, results in a cross section

$$\sigma = \int dx f(x) \hat{\sigma}(xs). \quad (10.75)$$

We want to compute the distribution of $E = \sqrt{\hat{s}} = \sqrt{xs}$, i.e.,

$$\frac{d\sigma}{dE} = \frac{2\sqrt{x}}{\sqrt{s}} \frac{d\sigma}{dx} = \frac{2\sqrt{x}}{\sqrt{s}} f(x) \hat{\sigma}(xs), \quad (10.76)$$

so if we set

$$f(x) = \frac{\sqrt{s}}{2\sqrt{x}}, \quad (10.77)$$

we get the distribution

$$\frac{d\sigma}{dE} = \hat{\sigma}(\hat{s} = E^2). \quad (10.78)$$

If we want to start, in the first iteration, from a homogeneous energy scan, we should apply a mapping

$$x = y^2 \quad \text{with} \quad dx = 2\sqrt{x} dy, \quad (10.79)$$

which cancels out $f(x)$ apart from the numerator \sqrt{s} .

The input parameter for this spectrum applies to the energy directly. Note that the spectrum must not be applied to more than one beam, and that the total cross section is essentially meaningless (it is the area under the energy distribution).

A direct application of this procedure would, of course, result in boosted events since only one beam energy is scaled down. However, we can achieve the same effect without a boost if we scale both x values such that their product remains constant, i.e., instead of generating x and applying it for one beam, we apply \sqrt{x} for both beams.

10.10.4 Energy-scan structure function

This is the structure function for a single beam, suitably mapped.

As stated above, the mapping cancels the denominator of the structure function, so the factor is a constant. The normalization is determined such that the integral (the 'cross section' returned by WHIZARD) is unity for a unit test matrix element.

(Escan: procedures)≡

```

subroutine strfun (f, x, r, data)
    real(default), intent(out) :: f, x
    real(default), intent(in) :: r

```

```

    type(escan_data_t), intent(in) :: data
    x = r**2
    f = 1
end subroutine strfun

```

10.10.5 Energy scan application

Depending on the affected beams, we either apply the structure function to one beam, or to both beams using the square root of x_i .

There is no `no_map` flag involved since there is no mapping anyway.

```

<SF escan: escan: TBP>+=
  procedure :: apply => escan_apply

<SF escan: procedures>+=

10.11 Using beam event data

Instead of an analytic beam description, beam data may be provided in form of an event file. In its most simple form, the event file contains pairs of x values, relative to nominal beam energies. More advanced formats may include polarization, etc. The current implementation carries beam polarization through, if specified.

The code is very similar to the energy scan described above.

```

<sf_beam_events.f90>≡
<File header>

module sf_beam_events

  <Use kinds>
  <Use strings>
  <Use file utils>
  use diagnostics !NODEP!
  use lorentz !NODEP!

    integer, dimension(:), allocatable :: pdg_out
    integer :: i, n
    n = 2
    allocate (pdg_out (n))

```

```

do i = 1, n
  pdg_out(i) = flavor_get_pdg (data%flv(i))
end do
end function beam_events_data_get_pdg_out

```

Allocate the interaction record.

```

<SF beam events: beam events data: TBP>+≡
  procedure :: allocate_sf_int => beam_events_data_allocate_sf_int

<SF beam events: procedures>+≡
  subroutine beam_events_data_allocate_sf_int (data, sf_int)
    class(beam_events_data_t), intent(in) :: data
    class(sf_int_t), intent(inout), allocatable :: sf_int
    allocate (beam_events_t :: sf_int)
  end subroutine beam_events_data_allocate_sf_int

```

Output

```

<SF beam events: beam events data: TBP>+≡
  procedure :: write => beam_events_data_write

<SF beam events: procedures>+≡
  subroutine beam_events_data_write (data, unit, verbose) !, md5)
    class(beam_events_data_t), intent(in) :: data
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose
    integer :: u
    !!! JRR: WK please check: still needed?
    ! logical, intent(in), optional :: md5
    u = output_unit (unit); if (u < 0) return
    write (u, "(1x,A)") "Beam-event file data:"
    write (u, "(3x,A,A,A,A)") " prt_in = ", &
      char (flavor_get_name (data%flv(1))), &
      ", ", char (flavor_get_name (data%flv(2)))
    write (u, "(3x,A,A)") " file = '", char (data%file), "'"
    write (u, "(3x,L1)") " warn_eof = ", data%warn_eof
    write (u, "(3x,I3)") " unit = ", data%unit
  end subroutine beam_events_data_write

```

The data file needs to be opened and closed explicitly:

```

<Beam events: public>+≡
  public :: beam_events_data_open
  public :: beam_events_data_close

<Beam events: procedures>+≡
  subroutine beam_events_data_open (data)
    type(beam_events_data_t), intent(inout) :: data
    if (data%unit == 0) then

else
  write (u, "(1x,A)") "Beam events data: [undefined]"
end if
end subroutine beam_events_write

```

10.11.3 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

(SF beam events: beam events: TBP)+≡
  procedure :: complete_kinematics => beam_events_complete_kinematics

(SF beam events: procedures)+≡
  subroutine beam_events_complete_kinematics (sf_int, x, f, r, map)
    class(beam_events_t), intent(inout) :: sf_int
    real(default), dimension(:), intent(out) :: x
    real(default), intent(out) :: f
    real(default), dimension(:), intent(in) :: r
    logical, intent(in) :: map
    real(default) :: xb1
    if (map) then
      call msg_fatal ("Beam events: map flag not supported")
    else
      x(1) = r(1)

10.11.4 Beam-event file structure function

This is actually not a structure function but a routine that reads a single line from the event file. If EOF is reached, we reread from the beginning and issue a warning (unless `warn_eof` is unset).

This is a rare occasion where a conditional jump is really appropriate: we want to catch EOF, but not other I/O errors.

```
<Beam events: procedures>+≡
  subroutine read_x (x, data)
    real(default), dimension(:), intent(out) :: x
    type(beam_events_data_t), intent(in) :: data
    read (unit=data%unit, fmt=*, end=1) x
    return
1  if (data%warn_eof) &

10.12 LHAPDF

Parton distribution functions (PDFs) are available via an interface to the LHAPDF standard library.

The default PDF for protons set is chosen to be CTEQ6ll (LO fit with LO α_s).

```
<Limits: public parameters>+≡
    character(*), parameter, public :: LHAPDF_DEFAULT_PROTON = "cteq6ll.LHpdf"
    character(*), parameter, public :: LHAPDF_DEFAULT_PION   = "ABFKWPI.LHgrid"
    character(*), parameter, public :: LHAPDF_DEFAULT_PHOTON = "GSG960.LHgrid"
```

10.12.2 LHAPDF library interface

Here we specify explicit interfaces for all LHAPDF routines that we use below.

```
<SF lhpdf: interfaces>≡
```

```
interface
  subroutine InitPDFsetM (set, file)
    integer, intent(in) :: set
    character(*), intent(in) :: file
  end subroutine InitPDFsetM
end interface
```

```
<SF lhpdf: interfaces>+≡
```

```
interface
  subroutine InitPDFM (set, mem)
    integer, intent(in) :: set, mem
  end subroutine InitPDFM
end interface
```

```
<SF lhpdf: interfaces>+≡
```

```
interface
  subroutine numberPDFM (set, n_members)
    integer, intent(in) :: set
    integer, intent(out) :: n_members
  end subroutine numberPDFM
end interface
```

```
<SF lhpdf: interfaces>+≡
```

```
interface
  subroutine evolvePDFM (set, x, q, ff)
    integer, intent(in) :: set
    double precision, intent(in) :: x, q
    double precision, dimension(-6:6), intent(out) :: ff
  end subroutine evolvePDFM
end interface
```

```
<SF lhpdf: interfaces>+≡
```

```
interface
  subroutine evolvePDFphotonM (set, x, q, ff, fphot)
    integer, intent(in) :: set
    double precision, intent(in) :: x, q
    double precision, dimension(-6:6), intent(out) :: ff
    double precision, intent(out) :: fphot
  end subroutine evolvePDFphotonM
end interface
```

```

<SF lhpdf: interfaces>+≡
interface
  subroutine evolvePDFpM (set, x, q, s, scheme, ff)
    integer, intent(in) :: set
    double precision, intent(in) :: x, q, s
    integer, intent(in) :: scheme
    double precision, dimension(-6:6), intent(out) :: ff
  end subroutine evolvePDFpM
end interface

```

```

<SF lhpdf: interfaces>+≡
interface
  subroutine GetXminM (set, mem, xmin)
    integer, intent(in) :: set, mem
    double precision, intent(out) :: xmin
  end subroutine GetXminM
end interface

```

```

<SF lhpdf: interfaces>+≡
interface
  subroutine GetXmaxM (set, mem, xmax)
    integer, intent(in) :: set, mem
    double precision, intent(out) :: xmax
  end subroutine GetXmaxM
end interface

```

```

<SF lhpdf: interfaces>+≡
interface
  subroutine GetQ2minM (set, mem, q2min)
    integer, intent(in) :: set, mem
    double precision, intent(out) :: q2min
  end subroutine GetQ2minM
end interface

```

```

<SF lhpdf: interfaces>+≡
interface
  subroutine GetQ2maxM (set, mem, q2max)
    integer, intent(in) :: set, mem
    double precision, intent(out) :: q2max
  end subroutine GetQ2maxM
end interface

```

```

<SF lhpdf: interfaces>+≡
interface
  function has_photon () result(flag)
    logical :: flag
  end function has_photon
end interface

```

10.12.3 The LHAPDF status

This type holds the initialization status of the LHAPDF system. Entry 1 is for proton PDFs, entry 2 for pion PDFs, entry 3 for photon PDFs.

```
<SF lhpdf: public>≡
    public :: lhpdf_status_t

<SF lhpdf: types>≡
    type :: lhpdf_status_t
    private
        logical, dimension(3) :: initialized = .false.
    end type lhpdf_status_t

<SF lhpdf: public>+≡
    public :: lhpdf_status_reset

<SF lhpdf: procedures>≡
    subroutine lhpdf_status_reset (lhpdf_status)
        type(lhpdf_status_t), intent(inout) :: lhpdf_status
        lhpdf_status%initialized = .false.
    end subroutine lhpdf_status_reset

<SF lhpdf: procedures>+≡
    function lhpdf_status_is_initialized (lhpdf_status, set) result (flag)
        logical :: flag
        type(lhpdf_status_t), intent(in) :: lhpdf_status
        integer, intent(in), optional :: set
        if (present (set)) then
            select case (set)
                case (1:3);    flag = lhpdf_status%initialized(set)
                case default;  flag = .false.
            end select
        else
            flag = any (lhpdf_status%initialized)
        end if
    end function lhpdf_status_is_initialized

<SF lhpdf: procedures>+≡
    subroutine lhpdf_status_set_initialized (lhpdf_status, set)
        type(lhpdf_status_t), intent(inout) :: lhpdf_status
        integer, intent(in) :: set
        lhpdf_status%initialized(set) = .true.
    end subroutine lhpdf_status_set_initialized
```

10.12.4 LHAPDF initialization

Before using LHAPDF, we have to initialize it with a particular data set and member. This applies not just if we use structure functions, but also if we just use an α_s formula. The integer `set` should be 1 for proton, 2 for pion, and 3 for photon, but this is just convention.

If the particular set has already been initialized, do nothing. This implies that whenever we want to change the setup for a particular set, we have to

reset the LHAPDF status. `lhpdf_initialize` has an obvious name clash with `lhpdf_init`, the reason it works for `pdf_builtin` is that these things are outsourced to a separate module (inc. `lhpdf_status` etc.).

```

<SF lhpdf: public>+≡
  public :: lhpdf_initialize

<SF lhpdf: procedures>+≡
  subroutine lhpdf_initialize (status, set, prefix, file, member)
    type(lhpdf_status_t), intent(inout) :: status
    integer, intent(in) :: set
    type(string_t), intent(inout) :: prefix
    type(string_t), intent(inout) :: file
    integer, intent(inout) :: member
    if (lhpdf_status_is_initialized (status, set)) return
    if (prefix == "") prefix = LHAPDF_PDFSETS_PATH
    if (file == "") then
      select case (set)
        case (1); file = LHAPDF_DEFAULT_PROTON
        case (2); file = LHAPDF_DEFAULT_PION
        case (3); file = LHAPDF_DEFAULT_PHOTON
      end select
    end if
    if (data_file_exists (prefix // "/" // file)) then
      call InitPDFsetM (set, char (prefix // "/" // file))
    else
      call msg_fatal ("LHAPDF: Data file '" &
        // char (file) // "' not found in '" // char (prefix) // "'.")
      return
    end if
    if (.not. dataset_member_exists (set, member)) then
      call msg_error (" LHAPDF: Chosen member does not exist for set '" &
        // char (file) // "', using default.")
      member = 0
    end if
    call InitPDFM (set, member)
    call lhpdf_status_set_initialized (status, set)
  contains
    function data_file_exists (fq_name) result (exist)
      type(string_t), intent(in) :: fq_name
      logical :: exist
      inquire (file = char(fq_name), exist = exist)
    end function data_file_exists
    function dataset_member_exists (set, member) result (exist)
      integer, intent(in) :: set, member
      logical :: exist
      integer :: n_members
      call numberPDFM (set, n_members)
      exist = member >= 0 .and. member <= n_members
    end function dataset_member_exists
  end subroutine lhpdf_initialize

```

10.12.5 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

<SF lhpdf: lhpdf: TBP>≡
  procedure :: complete_kinematics => lhpdf_complete_kinematics

<SF lhpdf: procedures>+≡
  subroutine lhpdf_complete_kinematics (sf_int, x, f, r, map)
    class(lhpdf_t), intent(inout) :: sf_int
    real(default), dimension(:), intent(out) :: x
    real(default), intent(out) :: f
    real(default), dimension(:), intent(in) :: r
    logical, intent(in) :: map
    real(default) :: xb1
    if (map) then
      call msg_fatal ("LHAPDF: map flag not supported")
    else
      x(1) = r(1)
      f = 1
    end if
    xb1 = 1 - x(1)
    call sf_int%split_momentum (x, xb1)
    select case (sf_int%status)
    case (SF_DONE_KINEMATICS)
      sf_int%x = x(1)
    case (SF_FAILED_KINEMATICS)
      sf_int%x = 0
      f = 0
    end select
  end subroutine lhpdf_complete_kinematics

```

Compute inverse kinematics. Here, we start with the x array and compute the “input” r values and the Jacobian f . After this, we can set momenta by the same formula as for normal kinematics.

```

<SF lhpdf: lhpdf: TBP>+≡
  procedure :: inverse_kinematics => lhpdf_inverse_kinematics

<SF lhpdf: procedures>+≡
  subroutine lhpdf_inverse_kinematics (sf_int, x, f, r, map, set_momenta)
    class(lhpdf_t), intent(inout) :: sf_int
    real(default), dimension(:), intent(in) :: x
    real(default), intent(out) :: f
    real(default), dimension(:), intent(out) :: r
    logical, intent(in) :: map
