  !C-----
  !C      KTCLUS: written by Mike Seymour, July 1992.
  !C      Last modified November 2000.
  !C      Please send comments or suggestions to Mike.Seymour@rl.ac.uk
  !C
  !C      This is a general-purpose kt clustering package.
  !C      It can handle ee, ep and pp collisions.
  !C      It is loosely based on the program of Siggi Bethke.
  !C
  !C      The time taken (on a 10MIP machine) is (0.2microsec)*N**3
  !C      where N is the number of particles.
  !C      Over 90 percent of this time is used in subroutine KTPMIN, which
  !C      simply finds the minimum member of a one-dimensional array.
  !C      It is well worth thinking about optimization: on the SPARCstation
  !C      a factor of two increase was obtained simply by increasing the
  !C      optimization level from its default value.
  !C
  !C      The approach is to separate the different stages of analysis.
  !C      KTCLUS does all the clustering and records a merging history.
  !C      It returns a simple list of the y values at which each merging
  !C      occurred. Then the following routines can be called to give extra
  !C      information on the most recently analysed event.
  !C      KTCLUR is identical but includes an R parameter, see below.
  !C      KTYCUT gives the number of jets at each given YCUT value.
  !C      KTYSUB gives the number of sub-jets at each given YCUT value.
  !C      KTBEBAM gives same info as KTCLUS but only for merges with the beam
  !C      KTJOIN gives same info as KTCLUS but for merges of sub-jets.
  !C      KTRECO reconstructs the jet momenta at a given value of YCUT.
  !C      It also gives information on which jets at scale YCUT belong to
  !C      which macro-jets at scale YMAC, for studying sub-jet properties.
  !C      KTIINCL reconstructs the jet momenta according to the inclusive jet
  !C      definition of Ellis and Soper.
  !C      KTISUB, KTIJOI and KTIREC are like KTYSUB, KTJOIN and KTRECO,
  !C      except that they only apply to one inclusive jet at a time,
  !C      with the pt of that jet automatically used for ECUT.
  !C      KTWICH gives a list of which particles ended up in which jets.
  !C      KTWCHS gives the same thing, but only for subjets.
  !C      Note that the numbering of jets used by these two routines is
  !C      guaranteed to be the same as that used by KTRECO.
  !C
  !C      The collision type and analysis type are indicated by the first
  !C      argument of KTCLUS. IMODE=<TYPE><ANGLE><MONO><RECOM> where
  !C      TYPE:  1=>ee, 2=>ep with p in -z direction, 3=>pe, 4=>pp
  !C      ANGLE: 1=>angular kt def., 2=>DeltaR, 3=>f(DeltaEta,DeltaPhi)
  !C              where f()=2(cosh(eta)-cos(phi)) is the QCD emission metric
  !C      MONO:  1=>derive relative pseudoparticle angles from jets
  !C              2=>monotonic definitions of relative angles
  !C      RECOM: 1=>E recombination scheme, 2=>pt scheme, 3=>pt**2 scheme
  !C

```

```

!C      There are also abbreviated forms for the most common combinations:
!C      IMODE=1 => E scheme in e+e-                      (=1111)
!C           2 => E scheme in ep                          (=2111)
!C           3 => E scheme in pe                          (=3111)
!C           4 => E scheme in pp                          (=4111)
!C           5 => covariant E scheme in pp                (=4211)
!C           6 => covariant pt-scheme in pp                (=4212)
!C           7 => covariant monotonic pt**2-scheme in pp  (=4223)
!C
!C      KTRECO no longer needs to reconstruct the momenta according to the
!C      same recombination scheme in which they were clustered. Its first
!C      argument gives the scheme, taking the same values as RECOM above.
!C
!C      Note that unlike previous versions, all variables which hold y
!C      values have been named in a consistent way:
!C      Y() is the output scale at which jets were merged,
!C      YCUT is the input scale at which jets should be counted, and
!C      jet-momenta reconstructed etc,
!C      YMAC is the input macro-jet scale, used in determining whether
!C      or not each jet is a sub-jet.
!C      The original scheme defined in our papers is equivalent to always
!C      setting YMAC=1.
!C      Whenever a YCUT or YMAC variable is used, it is rounded down
!C      infinitesimally, so that for example, setting YCUT=Y(2) refers
!C      to the scale where the event is 2-jet, even if rounding errors
!C      have shifted its value slightly.
!C
!C      An R parameter can be used in hadron-hadron collisions by
!C      calling KTCLUR instead of KTCLUS. This is as suggested by
!C      Ellis and Soper, but implemented slightly differently,
!C      as in M.H. Seymour, LU TP 94/2 (submitted to Nucl. Phys. B.).
!C      R**2 multiplies the single Kt everywhere it is used.
!C      Calling KTCLUR with R=1 is identical to calling KTCLUS.
!C      R plays a similar role to the jet radius in a cone-type algorithm,
!C      but is scaled up by about 40% (ie R=0.7 in a cone algorithm is
!C      similar to this algorithm with R=1).
!C      Note that R.EQ.1 must be used for the e+e- and ep versions,
!C      and is strongly recommended for the hadron-hadron version.
!C      However, R values smaller than 1 have been found to be useful for
!C      certain applications, particularly the mass reconstruction of
!C      highly-boosted colour-singlets such as high-pt hadronic Ws,
!C      as in M.H. Seymour, LU TP 93/8 (to appear in Z. Phys. C.).
!C      Situations in which R<1 is useful are likely to also be those in
!C      which the inclusive reconstruction method is more useful.
!C
!C      Also included is a set of routines for doing Lorentz boosts:
!C      KTLBST finds the boost matrix to/from the cm frame of a 4-vector
!C      KTRROT finds the rotation matrix from one vector to another
!C      KTMUL multiplies together two matrices
!C      KTMUL multiplies a vector by a matrix
!C      KTINVT inverts a transformation matrix (nb NOT a general 4 by 4)
!C      KTFRAM boosts a list of vectors between two arbitrary frames
!C      KTBREI boosts a list of vectors between the lab and Breit frames
!C      KTHADR boosts a list of vectors between the lab and hadronic cmf

```

```

!C      The last two need the momenta in the +z direction of the lepton
!C      and hadron beams, and the 4-momentum of the outgoing lepton.
!C

CKKW (pseudo) weights

The type `ckkw_pseudo_shower_weights_t` gives the (relative) weights for different clusterings of the final particles, as given in Eq. (2.7) of hep-ph/0503281v1. Each particle has a binary labelling (power of 2) (first particle = 1, second particle = 2, third particle = 4, ...). Each recombination therefore corresponds to an integer, that is not a power of 2. For multiple subsequent recombinations, no different weights for different sequences of clustering are stored. It is assumed that the weight of a multiply recombined state is a combination of the states with one fewer recombination and that these states' contributions are proportional to their weights. For a $2 - > n$ event, the weights array thus has the size $2^{(2+n)-1}$. The `weights_by_type` array gives the weights depending on the type of the particle, the first index is the same as for weights, the second index gives the type of the new mother particle:

- 0: uncolored (γ , Z , W , Higgs)
- 1: colored (quark)
- 2: gluon
- 3: squark
- 4: gluino

`alphaS` gives the value for α_s used in the generation of the matrix element. This is needed for the reweighting using the values for a running α_s at the scales of the clusterings.

Chapter 17

Events

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

event_transforms Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

decays Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

showers (not re-activated yet) Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

events Combine all pieces to generate full events.

17.1 Abstract Event Transforms

```
(event_transforms.f90)≡  
  <File header>  
  
  module event_transforms  
  
    <Use kinds>

⟨Standard module head⟩

⟨Event transforms: public⟩

⟨Event transforms: types⟩

⟨Event transforms: interfaces⟩

contains

⟨Event transforms: procedures⟩

⟨Event transforms: tests⟩

end module event_transforms

```

17.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified setting that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include a `previous` and `next` pointers.

```

⟨Event transforms: public⟩≡
  public :: evt_t

⟨Event transforms: types⟩≡
  type, abstract :: evt_t
    type(process_t), pointer :: process => null ()
    type(process_instance_t), pointer :: process_instance => null ()
    type(model_t), pointer :: model => null ()

```

```

class(rng_t), allocatable :: rng
integer :: rejection_count = 0
logical :: particle_set_exists = .false.
type(particle_set_t) :: particle_set
class(evt_t), pointer :: previous => null ()
class(evt_t), pointer :: next => null ()
contains
  <Event transforms: evt: TBP>
end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡
  procedure :: final => evt_final
  procedure :: base_final => evt_final

<Event transforms: procedures>≡
  subroutine evt_final (object)
    class(evt_t), intent(inout) :: object
    if (allocated (object%rng)) call object%rng%final ()
    if (object%particle_set_exists) &
      call particle_set_final (object%particle_set)
  end subroutine evt_final

```

Output. We can print r.n.g. info.

```

<Event transforms: evt: TBP>+≡
  procedure :: base_write => evt_write

<Event transforms: procedures>+≡
  subroutine evt_write (object, unit, verbose, testflag)
    class(evt_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, testflag
    integer :: u
    u = output_unit (unit)
    if (associated (object%process)) then
      write (u, "(3x,A,A,A)") "Associated process: '", &
        char (object%process%get_id ()), "'"
    end if
    if (allocated (object%rng)) then
      call object%rng%write (u, 1)
      write (u, "(3x,A,I0)") "Number of tries = ", object%rejection_count
    end if
    if (object%particle_set_exists) then
      call write_separator (u)
      call particle_set_write (object%particle_set, u, testflag)
    end if
  end subroutine evt_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

```

(Event transforms: evt: TBP)+≡
  procedure :: connect => evt_connect
  procedure :: base_connect => evt_connect

(Event transforms: procedures)+≡
  subroutine evt_connect (evt, process_instance, model, process_stack)
    class(evt_t), intent(inout), target :: evt
    type(process_instance_t), intent(in), target :: process_instance
    type(model_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    evt%process => process_instance%process
    evt%process_instance => process_instance
    evt%model => model
    call evt%process%make_rng (evt%rng)
  end subroutine evt_connect

```

Reset internal state.

```

(Event transforms: evt: TBP)+≡
  procedure :: reset => evt_reset
  procedure :: base_reset => evt_reset

(Event transforms: procedures)+≡
  subroutine evt_reset (evt)
    class(evt_t), intent(inout) :: evt
    evt%rejection_count = 0
    evt%particle_set_exists = .false.
  end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_prepare_new_event), deferred :: prepare_new_event

(Event transforms: interfaces)≡
  interface
    subroutine evt_prepare_new_event (evt, i_mci, i_term)
      import
      class(evt_t), intent(inout) :: evt
      integer, intent(in) :: i_mci, i_term
    end subroutine evt_prepare_new_event
  end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)

```

```

import
class(evt_t), intent(inout) :: evt
real(default), intent(out) :: probability
end subroutine evt_generate_weighted
end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted
(Event transforms: procedures)+≡
  subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set
(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_make_particle_set
  end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

(Event transforms: evt: TBP)+≡

```

```

    procedure :: set_particle_set => evt_set_particle_set
  <Event transforms: procedures>+≡
    subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
      class(evt_t), intent(inout) :: evt
      type(particle_set_t), intent(in) :: particle_set
      integer, intent(in) :: i_term, i_mci
      call evt%prepare_new_event (i_mci, i_term)
      evt%particle_set = particle_set
      evt%particle_set_exists = .true.
    end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. (We need two interactions, one with color summed over, and one with the probability distributed among flows.)

We use the two values from the random number generator for factorizing the state. For testing purposes, we can provide those numbers explicitly.

```

  <Event transforms: evt: TBP>+≡
    procedure :: factorize_interactions => evt_factorize_interactions
  <Event transforms: procedures>+≡
    subroutine evt_factorize_interactions &
      (evt, int_matrix, int_flows, factorization_mode, keep_correlations, r)
      class(evt_t), intent(inout) :: evt
      type(interaction_t), intent(in), target :: int_matrix, int_flows
      integer, intent(in) :: factorization_mode
      logical, intent(in) :: keep_correlations
      real(default), dimension(:), intent(in), optional :: r
      real(default), dimension(2) :: x
      if (present (r)) then
        if (size (r) == 2) then
          x = r
        else
          call msg_bug ("event factorization: size of r array must be 2")
        end if
      else
        call evt%rng%generate (x)
      end if
      call particle_set_init (evt%particle_set, evt%particle_set_exists, &
        int_matrix, int_flows, factorization_mode, x, &
        keep_correlations, keep_virtual=.true.)
      evt%particle_set_exists = .true.
    end subroutine evt_factorize_interactions

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

```

  <Event transforms: evt: TBP>+≡

```

```

    procedure :: tag_incoming => evt_tag_incoming
  <Event transforms: procedures>+≡
    subroutine evt_tag_incoming (evt)
      class(evt_t), intent(inout) :: evt
      integer :: i_term, n_in
      integer, dimension(:), allocatable :: beam_index, in_index
      n_in = evt%process%get_n_in ()
      i_term = 1
      allocate (beam_index (n_in))
      call evt%process_instance%get_beam_index (i_term, beam_index)
      call particle_set_reset_status (evt%particle_set, &
        beam_index, PRT_BEAM)
      allocate (in_index (n_in))
      call evt%process_instance%get_in_index (i_term, in_index)
      call particle_set_reset_status (evt%particle_set, &
        in_index, PRT_INCOMING)
    end subroutine evt_tag_incoming

```

17.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

  <Event transforms: public>+≡
    public :: evt_trivial_t

  <Event transforms: types>+≡
    type, extends (evt_t) :: evt_trivial_t
      contains
      <Event transforms: evt trivial: TBP>
    end type evt_trivial_t

```

The finalizer is trivial. Some output:

```

  <Event transforms: evt trivial: TBP>≡
    procedure :: write => evt_trivial_write

  <Event transforms: procedures>+≡
    subroutine evt_trivial_write (object, unit, verbose, testflag)
      class(evt_trivial_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose, testflag
      integer :: u
      u = output_unit (unit)
      call write_separator_double (u)
      write (u, "(1x,A)") "Event transform: trivial (hard process)"
      call write_separator (u)
      call object%base_write (u, testflag = testflag)
    end subroutine evt_trivial_write

```

Nothing to do here:

```

  <Event transforms: evt trivial: TBP>+≡
    procedure :: prepare_new_event => evt_trivial_prepare_new_event

```

```

<Event transforms: procedures>+≡
  subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
  end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: generate_weighted => evt_trivial_generate_weighted

<Event transforms: procedures>+≡
  subroutine evt_trivial_generate_weighted (evt, probability)
    class(evt_trivial_t), intent(inout) :: evt
    real(default), intent(out) :: probability
    probability = 1
  end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: make_particle_set => evt_trivial_make_particle_set

<Event transforms: procedures>+≡
  subroutine evt_trivial_make_particle_set &
    (evt, factorization_mode, keep_correlations, r)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    integer :: i_term
    type(interaction_t), pointer :: int_matrix, int_flows
    if (evt%process_instance%is_complete_event ()) then
      call evt%process_instance%select_i_term (i_term)
      int_matrix => evt%process_instance%get_matrix_int_ptr (i_term)
      int_flows => evt%process_instance%get_flows_int_ptr (i_term)
      call evt%factorize_interactions (int_matrix, int_flows, &
        factorization_mode, keep_correlations, r)
      call evt%tag_incoming ()
    else
      call msg_bug ("Event factorization: event is incomplete")
    end if
  end subroutine evt_trivial_make_particle_set

```

17.1.3 Unit tests

```

<Event transforms: public>+≡
  public :: event_transforms_test

<Event transforms: tests>≡
  subroutine event_transforms_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Event transforms: execute tests>

```

```
end subroutine event_transforms_test
```

Test trivial event transform

The trivial transform, as an instance of the abstract transform, does nothing but to trigger event generation for an elementary process.

```
(Event transforms: execute tests)≡
  call test (event_transforms_1, "event_transforms_1", &
    "trivial event transform", &
    u, results)

(Event transforms: tests)+≡

    <Decays: interfaces>

contains

    <Decays: procedures>

    <Decays: tests>

end module decays

```

17.2.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

<Decays: types>≡
    type, abstract :: any_config_t
    contains
    <Decays: any config: TBP>
    end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
    procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
    interface
        subroutine any_config_final (object)
            import
            class(any_config_t), intent(inout) :: object
        end subroutine any_config_final
    end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
    procedure (any_config_write), deferred :: write

```

```

<Decays: interfaces>+≡
  interface
    subroutine any_config_write (object, unit, indent, verbose)
      import
      class(any_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
    end subroutine any_config_write
  end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_config_t
    class(any_config_t), allocatable :: c
  end type particle_config_t

```

17.2.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above. This also works around a compiler bug in gfortran.

```

<Decays: types>+≡
  type, abstract :: any_t
    contains
    <Decays: any: TBP>
  end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final

<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
      class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
      import
      class(any_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent

```

```

        end subroutine any_write
    end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
    type :: particle_out_t
        class(any_t), allocatable :: c
    end type particle_out_t

```

17.2.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+≡
    type :: decay_term_config_t
        type(particle_config_t), dimension(:), allocatable :: prt
        contains
        <Decays: decay term config: TBP>
    end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>≡
    procedure :: final => decay_term_config_final

<Decays: procedures>≡
    recursive subroutine decay_term_config_final (object)
        class(decay_term_config_t), intent(inout) :: object
        integer :: i
        if (allocated (object%prt)) then
            do i = 1, size (object%prt)
                if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
            end do
        end if
    end subroutine decay_term_config_final

```

Output, with optional indentation

```

<Decays: decay term config: TBP>+≡
    procedure :: write => decay_term_config_write

<Decays: procedures>+≡
    recursive subroutine decay_term_config_write (object, unit, indent, verbose)
        class(decay_term_config_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        logical, intent(in), optional :: verbose
        integer :: i, j, u, ind
        logical :: verb
        u = output_unit (unit)
        ind = 0; if (present (indent)) ind = indent
        verb = .true.; if (present (verbose)) verb = verbose

```

```

call write_indent (u, ind)
write (u, "(1x,A)", advance="no") "Final state:"
do i = 1, size (object%prt)
  select type (prt_config => object%prt(i)%c)
  type is (stable_config_t)
    write (u, "(1x,A)", advance="no") &
      char (flavor_get_name (prt_config%flv(1)))
    do j = 2, size (prt_config%flv)
      write (u, "(:',A)", advance="no") &
        char (flavor_get_name (prt_config%flv(j)))
    end do
  type is (unstable_config_t)
    write (u, "(1x,A)", advance="no") &
      char (flavor_get_name (prt_config%flv))
  end select
end do
write (u, *)
if (verb) then
  do i = 1, size (object%prt)
    call object%prt(i)%c%write (u, ind)
  end do
end if
end subroutine decay_term_config_write

```

Initialize, given a set of flavors. For each flavor, we must indicate whether the particle is stable. The second index of the flavor array runs over alternatives for each decay product; alternatives are allowed only if the decay product is itself stable.

(Decays: decay term config: TBP)+≡

```

17.2.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```

<Decays: types>+≡
  type :: decay_root_config_t
    type(string_t) :: process_id
    type(process_t), pointer :: process => null ()
    type(model_t), pointer :: model => null ()
    type(decay_term_config_t), dimension(:), allocatable :: term_config
  contains
    <Decays: decay root config: TBP>
  end type decay_root_config_t

```

The finalizer is recursive since there may be cascade decays.

```

<Decays: decay root config: TBP>≡
  procedure :: final => decay_root_config_final

```

```

<Decays: procedures>+≡
recursive subroutine decay_root_config_final (object)
  class(decay_root_config_t), intent(inout) :: object
  integer :: i
  if (allocated (object%term_config)) then
    do i = 1, size (object%term_config)
      call object%term_config(i)%final ()
    end do
  end if
end subroutine decay_root_config_final

```

The output routine is also recursive, and it contains an adjustable indentation.

```

<Decays: decay root config: TBP>+≡
  procedure :: write => decay_root_config_write
  procedure :: write_header => decay_root_config_write_header
  procedure :: write_terms => decay_root_config_write_terms

<Decays: procedures>+≡

```

Declare a decay term, given an array of flavors.

<Decays: decay root config: TBP>+≡

```

procedure :: init_term => decay_root_config_init_term

```

<Decays: procedures>+≡

```

recursive subroutine decay_root_config_init_term &
  (decay, i, flv, stable, model, process_stack)
  class(decay_root_config_t), intent(inout) :: decay
  integer, intent(in) :: i
  type(flavor_t), dimension(:,:), intent(in) :: flv
  logical, dimension(:), intent(in) :: stable
  type(model_t), intent(in), target :: model
  type(process_stack_t), intent(in), optional :: process_stack
  call decay%term_config(i)%init (flv, stable, model, process_stack)
end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing

particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

```

<Decays: decay root config: TBP>+≡
  procedure :: connect => decay_root_config_connect

<Decays: procedures>+≡
  recursive subroutine decay_root_config_connect &
    (decay, process, model, process_stack, process_instance)
    class(decay_root_config_t), intent(out) :: decay
    type(process_t), intent(in), target :: process
    type(model_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(process_instance_t), intent(in), optional, target :: process_instance
    type(connected_state_t), pointer :: connected_state
    type(interaction_t), pointer :: int

      call decay%term_config(i)%compute ()
    end do
  end subroutine decay_root_config_compute

```

17.2.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```
<Decays: types>+≡
  type, abstract :: decay_gen_t
    type(decay_term_t), dimension(:), allocatable :: term
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
  contains
    <Decays: decay gen: TBP>
  end type decay_gen_t
```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```
<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_root_t
    type(decay_root_config_t), pointer :: config => null ()
  contains
    <Decays: decay root: TBP>
  end type decay_root_t
```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```
<Decays: decay gen: TBP>≡
  procedure :: base_final => decay_gen_final

<Decays: procedures>+≡
  recursive subroutine decay_gen_final (object)
    class(decay_gen_t), intent(inout) :: object
    integer :: i
    if (allocated (object%term)) then
      do i = 1, size (object%term)
        call object%term(i)%final ()
      end do
    end if
  end subroutine decay_gen_final
```

No extra finalization for the decay root.

```
<Decays: decay root: TBP>≡
  procedure :: final => decay_root_final

<Decays: procedures>+≡
  subroutine decay_root_final (object)
    class(decay_root_t), intent(inout) :: object
    call object%base_final ()
  end subroutine decay_root_final
```

Output.

```

<Decays: decay root: TBP>+≡
  procedure :: write => decay_root_write

<Decays: procedures>+≡
  subroutine decay_root_write (object, unit)
    class(decay_root_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    if (associated (object%config)) then
      call object%config%write (unit, verbose = .false.)
    else
      write (u, "(1x,A)") "Final-state decay tree: [not configured]"
    end if
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI      = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI      = [undefined]"
    end if
    if (object%selected_term > 0) then
      write (u, "(3x,A,I0)") "Selected term    = ", object%selected_term
      call object%term(object%selected_term)%write (u, 1)
    else
      write (u, "(3x,A)") "Selected term    = [undefined]"
    end if
  end subroutine decay_root_write

```

Write the process instances, recursively.

```

<Decays: decay gen: TBP>+≡
  procedure :: write_process_instances => decay_gen_write_process_instances

<Decays: procedures>+≡
  recursive subroutine decay_gen_write_process_instances (decay, unit, verbose)
    class(decay_gen_t), intent(in) :: decay

  type(process_instance_t), intent(in), target :: process_instance
  call decay_root%base_init (config%term_config)
  decay_root%config => config
  decay_root%process_instance => process_instance
  call decay_root%make_term_rng (config%process)
  call decay_root%link_term_interactions ()
end subroutine decay_root_init

```

Implement random-number generators for unstable decay selection in all terms. This is not recursive.

We also make use of the fact that `process` is a pointer; the (state of the RNG factory inside the) target process will be modified by the rng-spawning method, but not the pointer.

```

<Decays: decay gen: TBP>+≡
  procedure :: make_term_rng => decay_gen_make_term_rng

<Decays: procedures>+≡
subroutine decay_gen_make_term_rng (decay, process)
  class(decay_gen_t), intent(inout) :: decay
  type(process_t), intent(in), pointer :: process
  integer :: i
  do i = 1, size (decay%term)
    call decay%term(i)%make_rng (process)
  end do
end subroutine decay_gen_make_term_rng

```

Recursively link interactions of the enclosed decay terms to the corresponding terms in the current process instance.

Note: A bug in nagfor requires the extra `i_term` variable.

```

<Decays: decay gen: TBP>+≡
  procedure :: link_term_interactions => decay_gen_link_term_interactions

```

```

<Decays: procedures>+≡
recursive subroutine decay_gen_link_term_interactions (decay)
  class(decay_gen_t), intent(inout) :: decay
  integer :: i, i_term
  type(interaction_t), pointer :: trace
  associate (instance => decay%process_instance)
    do i = 1, size (decay%term)
      i_term = i
      trace => instance%get_trace_int_ptr (i_term)
      call decay%term(i_term)%link_interactions (trace)
    end do
  end associate
end subroutine decay_gen_link_term_interactions

```

Select a decay chain: decay modes and process components.

```

<Decays: decay root: TBP>+≡
  procedure :: select_chain => decay_root_select_chain

<Decays: procedures>+≡
subroutine decay_root_select_chain (decay_root)
  class(decay_root_t), intent(inout) :: decay_root
  if (decay_root%selected_term > 0) then
    call decay_root%term(decay_root%selected_term)%select_chain ()
  else
    call msg_bug ("Decays: no term selected for parent process")
  end if
end subroutine decay_root_select_chain

```

Generate a decay tree, i.e., for the selected term in the parent process, recursively generate a decay event for all unstable particles.

Factor out the trace of the connected state of the parent process. This trace should not be taken into account for unweighting the decay chain, since it was already used for unweighting the parent event, or it determines the overall event weight.

```

<Decays: decay root: TBP>+≡
  procedure :: generate => decay_root_generate

<Decays: procedures>+≡
subroutine decay_root_generate (decay_root)
  class(decay_root_t), intent(inout) :: decay_root
  type(connected_state_t), pointer :: connected_state

  else
    call msg_bug ("Decays: no term selected for parent process")
  end if
end subroutine decay_root_generate

```

17.2.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

```

<Decays: types>+≡
  type, extends (decay_root_config_t) :: decay_config_t
    real(default) :: weight = 0
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: mci_selector
  contains
    <Decays: decay_config: TBP>
  end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay_config: TBP>≡
  procedure :: write => decay_config_write

<Decays: procedures>+≡
  recursive subroutine decay_config_write (object, unit, indent, verbose)
    class(decay_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, ind
    u = output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,A)") "Decay:"
    call object%write_header (unit, indent)
    call write_indent (u, ind)
    write (u, 2) "branching ratio =", object%weight * 100
    call write_indent (u, ind)
    write (u, 1) "partial width  =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs)    =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel)    =", object%rel_error
1   format (3x,A,ES19.12)
2   format (3x,A,F11.6,1x,'%')
    call object%write_terms (unit, indent, verbose)
  end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should

be used instead.

```

<Decays: decay config: TBP>+≡
    procedure :: connect => decay_config_connect

<Decays: procedures>+≡
    recursive subroutine decay_config_connect &
        (decay, process, model, process_stack, process_instance)
        class(decay_config_t), intent(out) :: decay
        type(process_t), intent(in), target :: process
        type(model_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        type(process_instance_t), intent(in), optional, target :: process_instance
        real(default), dimension(:), allocatable :: integral_mci
        integer :: i, n_mci
        call decay%decay_root_config_t%connect (process, model, process_stack)
        decay%integral = process%get_integral ()
        decay%abs_error = process%get_error ()
        if (process%cm_frame ()) then
            call msg_fatal ("Decay process " // char (process%get_id ()) &
                // ": unusable because rest frame is fixed.")
        end if
        n_mci = process%get_n_mci ()
        allocate (integral_mci (n_mci))
        do i = 1, n_mci
            integral_mci(i) = process%get_integral_mci (i)
        end do
        call decay%mc_selector%init (integral_mci)
    end subroutine decay_config_connect

```

Compute embedded branchings and the relative error. This method does not apply to the decay root.

```

<Decays: decay config: TBP>+≡
    procedure :: compute => decay_config_compute

<Decays: procedures>+≡
    recursive subroutine decay_config_compute (decay)
        class(decay_config_t), intent(inout) :: decay
        call decay%decay_root_config_t%compute ()
        if (decay%integral == 0) then
            call decay%write ()
            call msg_fatal ("Decay configuration: partial width is zero")
        end if
        decay%rel_error = decay%abs_error / decay%integral
    end subroutine decay_config_compute

```

17.2.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

<Decays: types>+≡

```

```

type, extends (decay_gen_t) :: decay_t
  type(decay_config_t), pointer :: config => null ()
  class(rng_t), allocatable :: rng
contains
  <Decays: decay: TBP>
end type decay_t

```

The finalizer is recursive.

```

<Decays: decay: TBP>≡
  procedure :: final => decay_final

<Decays: procedures>+≡
  recursive subroutine decay_final (object)
    class(decay_t), intent(inout) :: object
    integer :: i
    call object%base_final ()
    do i = 1, object%config%process%get_n_mci ()
      call object%process_instance%final_simulation (i)
    end do
    call object%process_instance%final ()
    deallocate (object%process_instance)
  end subroutine decay_final

```

Output.

```

<Decays: decay: TBP>+≡
  procedure :: write => decay_write

<Decays: procedures>+≡
  recursive subroutine decay_write (object, unit, indent, recursive)
    class(decay_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent, recursive
    integer :: u, ind
    u = output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call object%config%write (unit, indent, verbose = .false.)
    if (allocated (object%rng)) then
      call object%rng%write (u, ind + 1)
    end if
    call write_indent (u, ind)
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI    = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI    = [undefined]"
    end if
    call write_indent (u, ind)
    if (object%selected_term > 0) then
      write (u, "(3x,A,I0)") "Selected term  = ", object%selected_term
      call object%term(object%selected_term)%write (u, ind + 1)
    else
      write (u, "(3x,A)") "Selected term  = [undefined]"
    end if
  end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
  procedure :: init => decay_init

<Decays: procedures>+≡
  recursive subroutine decay_init (decay, config)
    class(decay_t), intent(out) :: decay
    type(decay_config_t), intent(in), target :: config
    integer :: i
    call decay%base_init (config%term_config)
    decay%config => config
    allocate (decay%process_instance)
    call decay%process_instance%init (decay%config%process)
    call decay%process_instance%setup_event_data (decay%config%model)
    do i = 1, decay%config%process%get_n_mci ()
      call decay%process_instance%init_simulation (i)
    end do
    call decay%config%process%make_rng (decay%rng)
    call decay%make_term_rng (decay%config%process)
  end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
  procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
  recursive subroutine decay_link_interactions (decay, i_prt, trace)
    class(decay_t), intent(inout) :: decay
    integer, intent(in) :: i_prt
    type(interaction_t), intent(in), target :: trace
    type(interaction_t), pointer :: beam_int
    integer :: n_in, n_vir
    beam_int => decay%process_instance%get_beam_int_ptr ()
    n_in = interaction_get_n_in (trace)
    n_vir = interaction_get_n_vir (trace)
    call interaction_set_source_link (beam_int, 1, trace, &
      n_in + n_vir + i_prt)
    call decay%link_term_interactions ()
  end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
  procedure :: select_chain => decay_select_chain

```

```

⟨Decays: procedures⟩+≡
recursive subroutine decay_select_chain (decay)
  class(decay_t), intent(inout) :: decay
  real(default) :: x
  integer :: i
  call decay%rng%generate (x)
  decay%selected_mci = decay%config%mc_selector%select (x)
  call decay%process_instance%choose_mci (decay%selected_mci)
  call decay%process_instance%select_i_term (decay%selected_term)
  do i = 1, size (decay%term)
    call decay%term(i)%select_chain ()
  end do
end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

⟨Decays: decay: TBP⟩+≡
procedure :: generate => decay_generate

⟨Decays: procedures⟩+≡
recursive subroutine decay_generate (decay)
  class(decay_t), intent(inout) :: decay
  type(isolated_state_t), pointer :: isolated_state
  integer :: i
  call decay%process_instance%receive_beam_momenta ()
  call decay%config%process%generate_unweighted_event &
    (decay%process_instance, decay%selected_mci)
  if (signal_is_pending ()) return
  call decay%process_instance%evaluate_event_data ()
  isolated_state => &
    decay%process_instance%get_isolated_state_ptr (decay%selected_term)
  call isolated_state%normalize_matrix_by_trace ()
  do i = 1, size (decay%term)
    call decay%term(i)%generate ()
    if (signal_is_pending ()) return
  end do
end subroutine decay_generate

```

17.2.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```

⟨Decays: types⟩+≡
type, extends (any_config_t) :: stable_config_t
  type(flavor_t), dimension(:), allocatable :: flv
contains
  ⟨Decays: stable config: TBP⟩

```

```
end type stable_config_t
```

The finalizer is empty:

```
<Decays: stable config: TBP>≡
  procedure :: final => stable_config_final

<Decays: procedures>+≡
  subroutine stable_config_final (object)
    class(stable_config_t), intent(inout) :: object
  end subroutine stable_config_final
```

Output.

```
<Decays: stable config: TBP>+≡
  procedure :: write => stable_config_write

<Decays: procedures>+≡
  recursive subroutine stable_config_write (object, unit, indent, verbose)
    class(stable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    u = output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"
    write (u, "(1x,A)", advance = "no") char (flavor_get_name (object%flv(1)))
    do i = 2, size (object%flv)
      write (u, "(:',A)", advance = "no") &
        char (flavor_get_name (object%flv(i)))
    end do
    write (u, *)
  end subroutine stable_config_write
```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```
<Decays: stable config: TBP>+≡
  procedure :: init => stable_config_init

<Decays: procedures>+≡
  subroutine stable_config_init (config, flv)
    class(stable_config_t), intent(out) :: config
    type(flavor_t), dimension(:), intent(in) :: flv
    integer, dimension (size (flv)) :: pdg
    logical, dimension (size (flv)) :: mask
    integer :: i
    pdg = flavor_get_pdg (flv)
    mask(1) = .true.
    forall (i = 2 : size (pdg))
      mask(i) = all (pdg(i) /= pdg(1:i-1))
    end forall
    allocate (config%flv (count (mask)))
    config%flv = pack (flv, mask)
  end subroutine stable_config_init
```

Here is the corresponding object instance. Except for the pointer to the configuration, there is no content.

```

<Decays: types>+≡
  type, extends (any_t) :: stable_t
    type(stable_config_t), pointer :: config => null ()
    contains
      <Decays: stable: TBP>
    end type stable_t

```

The finalizer does nothing.

```

<Decays: stable: TBP>≡
  procedure :: final => stable_final

<Decays: procedures>+≡
  subroutine stable_final (object)
    class(stable_t), intent(inout) :: object
  end subroutine stable_final

```

We can delegate output to the configuration object.

```

<Decays: stable: TBP>+≡
  procedure :: write => stable_write

<Decays: procedures>+≡
  subroutine stable_write (object, unit, indent)
    class(stable_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    call object%config%write (unit, indent)
  end subroutine stable_write

```

Initializer: just assign the configuration.

```

<Decays: stable: TBP>+≡
  procedure :: init => stable_init

<Decays: procedures>+≡
  subroutine stable_init (stable, config)
    class(stable_t), intent(out) :: stable
    type(stable_config_t), intent(in), target :: config
    stable%config => config
  end subroutine stable_init

```

17.2.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: types>+≡
  type, extends (any_config_t) :: unstable_config_t
    type(flavor_t) :: flv

```

```

    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: selector
    type(decay_config_t), dimension(:), allocatable :: decay_config
contains
  <Decays: unstable config: TBP>
end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
  procedure :: final => unstable_config_final

<Decays: procedures>+≡
  recursive subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%final ()
      end do
    end if
  end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
  procedure :: write => unstable_config_write

<Decays: procedures>+≡
  recursive subroutine unstable_config_write (object, unit, indent, verbose)
    class(unstable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    logical :: verb
    u = output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
      char (flavor_get_name (object%flv))
    call write_indent (u, ind)
    write (u, 1) "total width =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs) =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel) =", object%rel_error
1  format (5x,A,ES19.12)
    if (verb .and. allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%write (u, ind + 1)
      end do
    end if
  end subroutine unstable_config_write

```

Initializer. For the unstable particle, the flavor is unique.

```

<Decays: unstable config: TBP>+≡
  procedure :: init => unstable_config_init

<Decays: procedures>+≡
  subroutine unstable_config_init (config, flv)
    class(unstable_config_t), intent(out) :: config
    type(flavor_t), intent(in) :: flv
    config%flv = flv
  end subroutine unstable_config_init

```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```

<Decays: unstable config: TBP>+≡
  procedure :: init_decays => unstable_config_init_decays

<Decays: procedures>+≡
  recursive subroutine unstable_config_init_decays &
    (unstable, decay_id, model, process_stack)
    class(unstable_config_t), intent(inout) :: unstable
    type(string_t), dimension(:), intent(in) :: decay_id
    type(model_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    integer :: i
    allocate (unstable%decay_config (size (decay_id)))
    do i = 1, size (decay_id)
      associate (decay => unstable%decay_config(i))
        if (present (process_stack)) then
          call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
            model, process_stack)
        else
          call decay%init (model, decay_id(i))
        end if
      end associate
    end do
  end subroutine unstable_config_init_decays

```

Compute the total width and branching ratios, initializing the decay selector.

```

<Decays: unstable config: TBP>+≡
  procedure :: compute => unstable_config_compute

<Decays: procedures>+≡
  recursive subroutine unstable_config_compute (unstable)
    class(unstable_config_t), intent(inout) :: unstable
    integer :: i
    do i = 1, size (unstable%decay_config)
      call unstable%decay_config(i)%compute ()
    end do
    unstable%integral = sum (unstable%decay_config%integral)
    if (unstable%integral <= 0) then

```

```

        call unstable%write ()
        call msg_fatal ("Decay configuration: computed total width is zero")
    end if
    unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
    unstable%rel_error = unstable%abs_error / unstable%integral
    call unstable%selector%init (unstable%decay_config%integral)
    do i = 1, size (unstable%decay_config)
        unstable%decay_config(i)%weight &
            = unstable%selector%get_weight (i)
    end do
end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: types>+≡
type, extends (any_t) :: unstable_t
    type(unstable_config_t), pointer :: config => null ()
    class(rng_t), allocatable :: rng
    integer :: selected_decay = 0
    type(decay_t), dimension(:), allocatable :: decay
contains
    <Decays: unstable: TBP>
end type unstable_t

```

Recursive finalizer.

```

<Decays: unstable: TBP>≡
    procedure :: final => unstable_final

<Decays: procedures>+≡
recursive subroutine unstable_final (object)
    class(unstable_t), intent(inout) :: object

    recursive subroutine unstable_generate (unstable)
        class(unstable_t), intent(inout) :: unstable
        call unstable%decay(unstable%selected_decay)%generate ()
    end subroutine unstable_generate

```

17.2.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle

decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+=
  type, extends (connected_state_t) :: decay_chain_entry_t
    integer :: index = 0
    type(decay_config_t), pointer :: config => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
    type(decay_chain_entry_t), pointer :: previous => null ()
  end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: types>+=
  type :: decay_chain_t
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_term = 0
    type(evaluator_t) :: correlated_trace
    type(decay_chain_entry_t), pointer :: last => null ()
  contains
    <Decays: decay_chain: TBP>
  end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay_chain: TBP>=
  procedure :: final => decay_chain_final

<Decays: procedures>+=
  subroutine decay_chain_final (object)
    class(decay_chain_t), intent(inout) :: object
    type(decay_chain_entry_t), pointer :: entry
    do while (associated (object%last))
      entry => object%last
      object%last => entry%previous
      call entry%final ()
      deallocate (entry)
    end do
    call evaluator_final (object%correlated_trace)
  end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

<Decays: decay chain: TBP>+≡
  procedure :: write => decay_chain_write

<Decays: procedures>+≡
  subroutine decay_chain_write (object, unit)
    class(decay_chain_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    call write_separator_double (u)
    write (u, "(1x,A)") "Decay chain:"
    call write_entries (object%last)
    call write_separator_double (u)
    write (u, "(1x,A)") "Evaluator (correlated trace of the decay chain):"
    call write_separator (u)
    call object%correlated_trace%write (u)
    call write_separator_double (u)
contains
  recursive subroutine write_entries (entry)
    type(decay_chain_entry_t), intent(in), pointer :: entry
    if (associated (entry)) then
      call write_entries (entry%previous)
      call write_separator_double (u)
      write (u, "(1x,A,I0)") "Decay #", entry%index
      call entry%config%write_header (u)
      write (u, "(3x,A,I0)") "Selected MCI    = ", entry%selected_mci
      write (u, "(3x,A,I0)") "Selected term  = ", entry%selected_term
      call entry%config%term_config(entry%selected_term)%write (u, indent=1)
      call entry%write (u)
    end if
  end subroutine write_entries
end subroutine decay_chain_write

```

Build a decay chain, recursively following the selected decays and terms in a decay tree. Before start, we finalize the chain, deleting any previous contents.

```

<Decays: decay chain: TBP>+≡
  procedure :: build => decay_chain_build

<Decays: procedures>+≡
  subroutine decay_chain_build (chain, decay_root)
    class(decay_chain_t), intent(inout), target :: chain
    type(decay_root_t), intent(in) :: decay_root
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    type(interaction_t), pointer :: int_last_decay
    call chain%final ()
    if (decay_root%selected_term > 0) then

      chain%selected_term = decay_root%selected_term
      call chain%build_term_entries (decay_root%term(decay_root%selected_term))
    end if
    int_last_decay => chain%last%get_matrix_int_ptr ()
    allocate (qn_mask (interaction_get_n_tot (int_last_decay)))

```

```

call quantum_numbers_mask_init (qn_mask, &
    mask_f = .true., mask_c = .true., mask_h = .true.)
call evaluator_init_qn_sum (chain%correlated_trace, int_last_decay, qn_mask)
end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable particles.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_term_entries (chain, term)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_term_t), intent(in) :: term
    integer :: i
    do i = 1, size (term%particle_out)
      select type (unstable => term%particle_out(i)%c)
        type is (unstable_t)
          if (unstable%selected_decay > 0) then
            call chain%build_decay_entries &
              (unstable%decay(unstable%selected_decay))
          end if
        end select
      end do
    end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_decay_entries => decay_chain_build_decay_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_decay_entries (chain, decay)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_t), intent(in) :: decay
    type(decay_chain_entry_t), pointer :: entry
    type(connected_state_t), pointer :: previous_state
    type(isolated_state_t), pointer :: current_decay
    allocate (entry)
    if (associated (chain%last)) then

```

```

    entry%previous => chain%last
    entry%index = entry%previous%index + 1
    previous_state => entry%previous%connected_state_t
else
    entry%index = 1
    previous_state => &
        chain%process_instance%get_connected_state_ptr (chain%selected_term)
end if
entry%config => decay%config
entry%selected_mci = decay%selected_mci

    (current_decay, previous_state%get_flows_int_ptr ())
chain%last => entry
call chain%build_term_entries (decay%term(decay%selected_term))
end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

```

<Decays: decay chain: TBP>+≡
    procedure :: evaluate => decay_chain_evaluate

<Decays: procedures>+≡

Read in the LHE file opened in unit u and add the final particles to the `particle_set`, the outgoing particles of the existing `particle_set` are set to be virtual before the outgoing particles from the LHEF are added to the `particle_set` as outgoing particles. At the same time, it is searched for pairs of existing and new particles with equal momenta and PDG code, these pairs are marked as connected. All remaining existing former outgoing particles are set to be the mothers of all remaining new outgoing particles.

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations might be useful. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid.

Matching and hadronization functions

The HEPUP (event) common block is needed for the interface to the shower. Filling of it is triggered by some output file formats. If these are not present, the common block is filled with some dummy information. Be generous with the number of processes in HEPUP so that PYTHIA only rarely needs to be reinitialized in case events with higher process ids are generated.

    ⟨Events: tests⟩  
  
  end module events
```

17.4.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The `safety_factor` reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The `sigma` and `n` values, if nontrivial, allow for reweighting the events according to the requested `norm_mode`.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the `event_expr_t` objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

(Events: types)≡

```

type :: event_config_t
  logical :: unweighted = .false.
  integer :: norm_mode = NORM_UNDEFINED
  integer :: factorization_mode = FM_IGNORE_HELICITY
  logical :: keep_correlations = .false.

17.4.3 The event type

Each event has a single elementary process as its core. This process may be dressed by a shower, a decay chain etc. For this core we implement pointers to a process instance.

The actual (dressed) event record is implemented as a **particle_set** object.

A list of event transforms (class **evt_t**) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The **particle_set** pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the **ref** value is the number in the file, while the **prc** value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of **alt** values is copied from an array of alternative event records. These values should represent calculated values.

The **sqme** and **weight** values mirror corresponding values in the **expr** sub-object. The idea is that when generating or reading events, the event record is filled first, then the **expr** object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the **expr** subobject. In particular, evaluating the event-selection expression sets the **passed** flag. Furthermore, the **expr** subobject collects data that can be used in the analysis and should be written to file, including copies of **sqme** and **weight**.

```

17.4.4 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```

<Events: event: TBP>+≡
  procedure :: basic_init => event_init

<Events: procedures>+≡
  subroutine event_init (event, var_list, n_alt)

```

```

class(event_t), intent(out) :: event
type(var_list_t), intent(in), optional :: var_list
integer, intent(in), optional :: n_alt
type(string_t) :: norm_string
logical :: polarized_events
if (present (var_list)) then
    event%config%unweighted = var_list_get_lval (var_list, &
        var_str ("?unweighted"))
    norm_string = var_list_get_sval (var_list, &
        var_str ("sample_normalization"))
    event%config%norm_mode = &
        event_normalization_mode (norm_string, event%config%unweighted)
    polarized_events = &
        var_list_get_lval (var_list, var_str ("?polarized_events"))
    if (polarized_events) then
        event%config%factorization_mode = FM_SELECT_HELICITY
    else
        event%config%factorization_mode = FM_IGNORE_HELICITY
    end if
    if (event%config%unweighted) then
        event%config%safety_factor = var_list_get_rval (var_list, &
            var_str ("safety_factor"))
    end if
else
    event%config%norm_mode = NORM_SIGMA
end if
if (present (n_alt)) then
    event%n_alt = n_alt
    allocate (event%sqme_alt (n_alt))
    allocate (event%weight_alt (n_alt))
    call event%expr%init (n_alt)
end if
allocate (evt_trivial_t :: event%transform_first)
event%transform_last => event%transform_first
end subroutine event_init

```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

(Events: event: TBP)+≡

```

procedure :: set_sigma => event_set_sigma
procedure :: set_n => event_set_n

```

(Events: procedures)+≡

```

elemental subroutine event_set_sigma (event, sigma)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: sigma
    event%config%sigma = sigma
end subroutine event_set_sigma

```

```

elemental subroutine event_set_n (event, n)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: n
    event%config%n = n

```

```
end subroutine event_set_n
```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```
<Events: event: TBP>+≡
  procedure :: import_transform => event_import_transform

<Events: procedures>+≡
  subroutine event_import_transform (event, evt)
    class(event_t), intent(inout) :: event
    class(evt_t), intent(inout), pointer :: evt
    event%transform_last%next => evt
    evt%previous => event%transform_last
    event%transform_last => evt
    evt => null ()
  end subroutine event_import_transform
```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to **event** subobjects, therefore the **target** attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```
<Events: event: TBP>+≡
  procedure :: connect => event_connect

<Events: procedures>+≡
  subroutine event_connect (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    type(model_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(string_t) :: id
    integer :: num_id
    class(evt_t), pointer :: evt
    event%process => process_instance%process
    event%instance => process_instance
    id = event%process%get_id ()
    if (id /= "") call event%expr%set_process_id (id)
    num_id = event%process%get_num_id ()
    if (num_id /= 0) call event%expr%set_process_num_id (num_id)
    call event%expr%setup_vars (event%process%get_sqrts ())
    call event%expr%link_var_list (event%process%get_var_list_ptr ())
    call event%process%make_rng (event%rng)
```

```

    evt => event%transform_first
  do while (associated (evt))
    call evt%connect (process_instance, model, process_stack)
    evt => evt%next
  end do
end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
  procedure :: set_selection => event_set_selection
  procedure :: set_reweight => event_set_reweight
  procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡
  subroutine event_set_selection (event, pn_selection)
    class(event_t), intent(inout) :: event
    type(parse_node_t), intent(in), pointer :: pn_selection
    event%config%pn_selection => pn_selection
  end subroutine event_set_selection

  subroutine event_set_reweight (event, pn_reweight)
    class(event_t), intent(inout) :: event
    type(parse_node_t), intent(in), pointer :: pn_reweight
    event%config%pn_reweight => pn_reweight
  end subroutine event_set_reweight

  subroutine event_set_analysis (event, pn_analysis)
    class(event_t), intent(inout) :: event
    type(parse_node_t), intent(in), pointer :: pn_analysis
    event%config%pn_analysis => pn_analysis
  end subroutine event_set_analysis

```

Create evaluation trees from the parse trees. The `target` attribute is required because the expressions contain pointers to event subobjects.

```

<Events: event: TBP>+≡
  procedure :: setup_expressions => event_setup_expressions

<Events: procedures>+≡
  subroutine event_setup_expressions (event)
    class(event_t), intent(inout), target :: event
    call event%expr%setup_selection (event%config%pn_selection)
    call event%expr%setup_analysis (event%config%pn_analysis)
    call event%expr%setup_reweight (event%config%pn_reweight)
  end subroutine event_setup_expressions

```

17.4.5 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

<Events: event: TBP>+≡
  procedure :: evaluate_transforms => event_evaluate_transforms

<Events: procedures>+≡
  subroutine event_evaluate_transforms (event, r)
    class(event_t), intent(inout) :: event

      .and. event%weight_alt_is_known
  end if
end subroutine event_check

```

17.4.8 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we accept the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
procedure :: generate => event_generate

<Events: procedures>+≡
subroutine event_generate (event, i_mci, r)
  class(event_t), intent(inout) :: event
  integer, intent(in) :: i_mci
  real(default), dimension(:), intent(in), optional :: r
  call event%reset ()
  event%selected_i_mci = i_mci
  if (event%config%unweighted) then
    call event%process%generate_unweighted_event (event%instance, i_mci)
    if (signal_is_pending ()) return
    call event%instance%evaluate_event_data ()
    call event%instance%normalize_weight ()
  else
    call event%process%generate_weighted_event (event%instance, i_mci)
    if (signal_is_pending ()) return
    call event%instance%evaluate_event_data ()
  end if
  event%selected_channel = event%instance%get_channel ()
  call event%import_instance_results ()
  call event%accept_sqme_prc ()
  call event%update_normalization ()
  call event%accept_weight_prc ()
  call event%evaluate_transforms (r)

```

```

        if (signal_is_pending ()) return
        call event%check ()
    end subroutine event_generate

```

Get a copy of the particle set belonging to the hard process.

```

<Events: event: TBP>+≡
    procedure :: get_particle_set_hard_proc => event_get_particle_set_hard_proc

<Events: procedures>+≡
    subroutine event_get_particle_set_hard_proc (event, pset)
        class(event_t), intent(in) :: event
        type(particle_set_t), intent(out) :: pset
        class(evt_t), pointer :: evt
        evt => event%transform_first
        pset = evt%particle_set
    end subroutine event_get_particle_set_hard_proc

```

17.4.9 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
    procedure :: select => event_select

<Events: procedures>+≡
    subroutine event_select (event, i_mci, i_term, channel)
        class(event_t), intent(inout) :: event
        integer, intent(in) :: i_mci, i_term, channel
        if (associated (event%instance)) then
            event%selected_i_mci = i_mci
            event%selected_i_term = i_term
            event%selected_channel = channel
        else
            call msg_bug ("Event: select term: process instance undefined")
        end if
    end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. Thus, with the current implementation, event readers can only be used for reading hard events. However, once we have reconstructed the master process, we may apply all event transforms to generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
    procedure :: set_particle_set_hard_proc => event_set_particle_set_hard_proc

<Events: procedures>+≡
    subroutine event_set_particle_set_hard_proc (event, particle_set)
        class(event_t), intent(inout) :: event
        type(particle_set_t), intent(in) :: particle_set
        class(evt_t), pointer :: evt
        evt => event%transform_first

```

```

    call evt%set_particle_set (particle_set, &
        event%selected_i_mci, event%selected_i_term)
    event%particle_set => evt%particle_set
    call event%accept_particle_set ()
    evt => evt%next
    do while (associated (evt))
        call evt%reset ()
        evt => evt%next
    end do
end subroutine event_set_particle_set_hard_proc

```

Mark the particle set as existing, assuming that it has just been filled somehow.

```

<Events: event: TBP>+≡
    procedure :: accept_particle_set => event_accept_particle_set

<Events: procedures>+≡
    subroutine event_accept_particle_set (event)
        class(event_t), intent(inout) :: event
        event%particle_set_exists = .true.
    end subroutine event_accept_particle_set

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

<Events: event: TBP>+≡
    procedure :: recalculate => event_recalculate

<Events: procedures>+≡
    subroutine event_recalculate &
        (event, update_sqme, weight_factor, recover_beams)
        class(event_t), intent(inout) :: event
        logical, intent(in) :: update_sqme
        real(default), intent(in), optional :: weight_factor
        logical, intent(in), optional :: recover_beams
        integer :: i_mci, i_term, channel
        if (event%particle_set_exists) then
            i_mci = event%selected_i_mci

```

```

i_term = event%selected_i_term

Chapter 18

Matrix Element Implementations

In this chapter, we define concrete implementations for the workflow, from matrix-element code generation via matrix-element access to integration and event generation.

18.1 Template matrix elements

Here, we provide template matrix elements that are in structure very similar to O'MEGA matrix elements, but do not need its infrastructure. Per default, the matrix elements are flat, i.e. they have the constant value one. Analogous to the O'MEGA implementation, this section implements the interface to the templates (via the makefile) and the driver.

```
<prc_template_me.f90>≡  
  <File header>  
  
  module prc_template_me  
  
    use iso_c_binding !NODEP!  
    use kinds !NODEP!  
    <Use file utils>  
    <Use strings>  
    use limits, only: TAB !NODEP!  
    use diagnostics !NODEP!  
    use unit_tests  
    use os_interface  
    use lorentz !NODEP!  
    use flavors  
    use sm_qcd  
    use interactions  
    use variables  
    use models  
  
    use process_constants  
    use prclib_interfaces
```

```

    use prc_core_def
    use particle_specifiers
    use process_libraries
    use prc_core

    <Standard module head>

    <Template matrix elements: public>

    <Template matrix elements: types>

    <Template matrix elements: interfaces>

    contains

    <Template matrix elements: procedures>

    <Template matrix elements: tests>

    end module prc_template_me

```

18.1.1 Process definition

For the process definition we implement an extension of the `prc_core_def_t` abstract type.

```

<Template matrix elements: public>≡
    public :: template_me_def_t

<Template matrix elements: types>≡
    type, extends (prc_core_def_t) :: template_me_def_t
    contains
    <Template matrix elements: template ME def: TBP>
    end type template_me_def_t

<Template matrix elements: template ME def: TBP>≡
    procedure, nopass :: type_string => template_me_def_type_string

<Template matrix elements: procedures>≡
    function template_me_def_type_string () result (string)
        type(string_t) :: string
        string = "template"
    end function template_me_def_type_string

```

Initialization: allocate the writer for the template matrix element. Also set any data for this process that the writer needs.

```

<Template matrix elements: template ME def: TBP>+≡
    procedure :: init => template_me_def_init

<Template matrix elements: procedures>+≡
    subroutine template_me_def_init &
        (object, model, prt_in, prt_out, unity)
        class(template_me_def_t), intent(out) :: object
        type(model_t), intent(in), target :: model
        type(string_t), dimension(:), intent(in) :: prt_in
    end subroutine

```

```

    type(string_t), dimension(:), intent(in) :: prt_out
    logical, intent(in) :: unity
    allocate (template_me_writer_t :: object%writer)
    select type (writer => object%writer)
    type is (template_me_writer_t)
        call writer%init (model, prt_in, prt_out, unity)
    end select
end subroutine template_me_def_init

```

Write/read process- and method-specific data.

```

<Template matrix elements: template ME def: TBP>+≡
    procedure :: write => template_me_def_write

```

```

<Template matrix elements: procedures>+≡
    subroutine template_me_def_write (object, unit)
        class(template_me_def_t), intent(in) :: object
        integer, intent(in) :: unit
        select type (writer => object%writer)
        type is (template_me_writer_t)
            call writer%write (unit)
        end select
    end subroutine template_me_def_write

```

```

<Template matrix elements: template ME def: TBP>+≡
    procedure :: read => template_me_def_read

```

```

<Template matrix elements: procedures>+≡
    subroutine template_me_def_read (object, unit)
        class(template_me_def_t), intent(out) :: object
        integer, intent(in) :: unit
        call msg_bug &
            ("WHIZARD template process definition: input not supported (yet)")
    end subroutine template_me_def_read

```

Allocate the driver for template matrix elements.

```

<Template matrix elements: template ME def: TBP>+≡
    procedure :: allocate_driver => template_me_def_allocate_driver

```

```

<Template matrix elements: procedures>+≡
    subroutine template_me_def_allocate_driver (object, driver, basename)
        class(template_me_def_t), intent(in) :: object
        class(prc_core_driver_t), intent(out), allocatable :: driver
        type(string_t), intent(in) :: basename
        allocate (template_me_driver_t :: driver)
    end subroutine template_me_def_allocate_driver

```

We need code:

```

<Template matrix elements: template ME def: TBP>+≡
    procedure, nopass :: needs_code => template_me_def_needs_code

```

```

<Template matrix elements: procedures>+≡
function template_me_def_needs_code () result (flag)
    logical :: flag
    flag = .true.
end function template_me_def_needs_code

```

These are the features that a template matrix element provides.

```

<Template matrix elements: template ME def: TBP>+≡
procedure, nopass :: get_features => template_me_def_get_features

<Template matrix elements: procedures>+≡
subroutine template_me_def_get_features (features)
    type(string_t), dimension(:), allocatable, intent(out) :: features
    allocate (features (6))
    features = [ &
        var_str ("init"), &
        var_str ("update_alpha_s"), &
        var_str ("is_allowed"), &
        var_str ("new_event"), &
        var_str ("get_amplitude")]
end subroutine template_me_def_get_features

```

The interface of the specific features.

```

<Template matrix elements: interfaces>≡
abstract interface
    subroutine init_t (par) bind(C)
        import
        real(c_default_float), dimension(*), intent(in) :: par
    end subroutine init_t
end interface

abstract interface
    subroutine update_alpha_s_t (alpha_s) bind(C)
        import
        real(c_default_float), intent(in) :: alpha_s
    end subroutine update_alpha_s_t
end interface

abstract interface
    subroutine is_allowed_t (flv, hel, col, flag) bind(C)
        import
        integer(c_int), intent(in) :: flv, hel, col
        logical(c_bool), intent(out) :: flag
    end subroutine is_allowed_t
end interface

abstract interface
    subroutine new_event_t (p) bind(C)
        import
        real(c_default_float), dimension(0:3,*), intent(in) :: p
    end subroutine new_event_t
end interface

```

```

abstract interface
  subroutine get_amplitude_t (flv, hel, col, amp) bind(C)
    import
    integer(c_int), intent(in) :: flv, hel, col
    complex(c_default_complex), intent(out):: amp
  end subroutine get_amplitude_t
end interface

```

Connect the template matrix element features with the process driver.

```

<Template matrix elements: template ME def: TBP>+≡
  procedure :: connect => template_me_def_connect

<Template matrix elements: procedures>+≡
  subroutine template_me_def_connect (def, lib_driver, i, proc_driver)
    class(template_me_def_t), intent(in) :: def
    class(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i
    class(prc_core_driver_t), intent(inout) :: proc_driver
    integer(c_int) :: pid, fid
    type(c_funptr) :: fptr
    select type (proc_driver)
    type is (template_me_driver_t)
      pid = i
      fid = 1
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%init)
      fid = 2
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%update_alpha_s)
      fid = 3
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%is_allowed)
      fid = 4
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%new_event)
      fid = 5
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%get_amplitude)
    end select
  end subroutine template_me_def_connect

```

18.1.2 The Template Matrix element writer

Unlike O'MEGA, the template matrix element is directly written by the main WHIZARD program, so there will be no entry in the makefile for calling an external program. The template matrix element writer is responsible for writing interfaces and wrappers.

```

<Template matrix elements: types>+≡
  type, extends (prc_writer_f_module_t) :: template_me_writer_t
    type(model_t), pointer :: model => null ()
    type(string_t) :: model_name
    logical :: unity

```

```

    type(string_t), dimension(:), allocatable :: prt_in
    type(string_t), dimension(:), allocatable :: prt_out
    integer :: n_in
    integer :: n_out
    integer :: n_tot
contains
    <Template matrix elements: template ME writer: TBP>
end type template_me_writer_t

```

The reported type is the same as for the `template_me_def_t` type.

```

<Template matrix elements: template ME writer: TBP>≡
    procedure, nopass :: type_name => template_me_writer_type_name
<Template matrix elements: procedures>+≡
    function template_me_writer_type_name () result (string)
        type(string_t) :: string
        string = "template"
    end function template_me_writer_type_name

```

Taking into account the prefix for template ME module names.

```

<Template matrix elements: template ME writer: TBP>+≡
    procedure, nopass :: get_module_name => template_me_writer_get_module_name
<Template matrix elements: procedures>+≡
    function template_me_writer_get_module_name (id) result (name)
        type(string_t) :: name
        type(string_t), intent(in) :: id
        name = "tpr_" // id
    end function template_me_writer_get_module_name

```

Output. This is called by `template_me_def_write`.

```

<Template matrix elements: template ME writer: TBP>+≡
    procedure :: write => template_me_writer_write
<Template matrix elements: procedures>+≡
    subroutine template_me_writer_write (object, unit)
        class(template_me_writer_t), intent(in) :: object
        integer, intent(in) :: unit
        integer :: i, j
        write (unit, "(5x,A,I0)") "# incoming part. = ", object%n_in
        write (unit, "(7x,A)", advance="no") &
            "    Initial state: "
        do i = 1, object%n_in - 1
            write (unit, "(1x,A)", advance="no") char (object%prt_in(i))
        end do
        write (unit, "(1x,A)") char (object%prt_in(object%n_in))
        write (unit, "(5x,A,I0)") "# outgoing part. = ", object%n_out
        write (unit, "(7x,A)", advance="no") &
            "    Final state:  "
        do j = 1, object%n_out - 1
            write (unit, "(1x,A)", advance="no") char (object%prt_out(i))
        end do
        write (unit, "(1x,A)") char (object%prt_out(object%n_out))
        write (unit, "(5x,A,I0)") "# part. (total) = ", object%n_tot
    end subroutine template_me_writer_write

```

```
end subroutine template_me_writer_write
```

Initialize with process data.

```
<Template matrix elements: template ME writer: TBP>+=
  procedure :: init => template_me_writer_init

<Template matrix elements: procedures>+=
  subroutine template_me_writer_init (writer, model, &
    prt_in, prt_out, unity)
    class(template_me_writer_t), intent(out) :: writer
    type(model_t), intent(in), target :: model
    type(string_t), dimension(:), intent(in) :: prt_in
    type(string_t), dimension(:), intent(in) :: prt_out
    logical, intent(in) :: unity
    writer%model => model
    writer%model_name = model%get_name ()
    writer%n_in = size (prt_in)
    writer%n_out = size (prt_out)
    writer%n_tot = size (prt_in) + size (prt_out)
    allocate (writer%prt_in (size (prt_in)), source = prt_in)
    allocate (writer%prt_out (size (prt_out)), source = prt_out)
    writer%unity = unity
  end subroutine template_me_writer_init
```

The makefile is the driver file for the test matrix elements.

```
<Template matrix elements: template ME writer: TBP>+=
  procedure :: write_makefile_code => template_me_write_makefile_code

<Template matrix elements: procedures>+=
  subroutine template_me_write_makefile_code (writer, unit, id, os_data, testflag)
    class(template_me_writer_t), intent(in) :: writer

18.1.3 Driver

```

<Template matrix elements: types>+≡
type, extends (prc_core_driver_t) :: template_me_driver_t
    procedure(init_t), nopass, pointer :: &
        init => null ()
    procedure(update_alpha_s_t), nopass, pointer :: &
        update_alpha_s => null ()
    procedure(is_allowed_t), nopass, pointer :: &
        is_allowed => null ()
    procedure(new_event_t), nopass, pointer :: &
        new_event => null ()
    procedure(get_amplitude_t), nopass, pointer :: &
        get_amplitude => null ()
contains
<Template matrix elements: template ME driver: TBP>
end type template_me_driver_t

```

The reported type is the same as for the `template_me_def_t` type.

```

<Template matrix elements: template ME driver: TBP>≡
    procedure, nopass :: type_name => template_me_driver_type_name

<Template matrix elements: procedures>+≡
    function template_me_driver_type_name () result (string)
        type(string_t) :: string
        string = "template"
    end function template_me_driver_type_name

```

18.1.4 High-level process definition

This procedure wraps the details filling a process-component definition entry as appropriate for an template matrix element.

NOTE: For calling the `import_component` method, we must explicitly address the `process_def_t` parent object. The natural way to call the method of the extended type triggers a bug in gfortran 4.6. The string array arguments `prt_in` and `prt_out` become corrupted and cause a segfault.

```

<Template matrix elements: public>+≡
    public :: template_me_make_process_component

<Template matrix elements: procedures>+≡
    subroutine template_me_make_process_component (entry, component_index, &
        model, model_name, prt_in, prt_out, unity)
        class(process_def_entry_t), intent(inout) :: entry
        integer, intent(in) :: component_index
        type(string_t), intent(in) :: model_name
        type(model_t), intent(in), target :: model
        type(string_t), dimension(:), intent(in) :: prt_in
        type(string_t), dimension(:), intent(in) :: prt_out
        logical, intent(in) :: unity
        class(prc_core_def_t), allocatable :: def
        allocate (template_me_def_t :: def)
        select type (def)
        type is (template_me_def_t)
            call def%init (model, prt_in, prt_out, unity)
        end select
        call entry%process_def_t%import_component (component_index, &
            n_out = size (prt_out), &
            prt_in = new_prt_spec (prt_in), &
            prt_out = new_prt_spec (prt_out), &
            method = var_str ("template"), &
            variant = def)
    end subroutine template_me_make_process_component

```

18.1.5 The `prc_template_me_t` wrapper

This is an instance of the generic `prc_core_t` object. It contains a pointer to the process definition (`template_me_def_t`), a data component (`process_constants_t`), and the matrix-element driver (`template_me_driver_t`).

```

<Template matrix elements: public>+≡

```

```

public :: prc_template_me_t
<Template matrix elements: types>+≡
type, extends (prc_core_t) :: prc_template_me_t
    real(default), dimension(:), allocatable :: par
contains
    <Template matrix elements: prc template ME: TBP>
end type prc_template_me_t

```

The workspace associated to a `prc_template_me_t` object contains a single flag. The flag is used to suppress re-evaluating the matrix element for each quantum-number combination, after the first amplitude belonging to a given kinematics has been computed.

We can also store the value of a running coupling once it has been calculated for an event. The default value is negative, which indicates an undefined value in this context.

```

<Template matrix elements: types>+≡
type, extends (workspace_t) :: template_me_state_t
    logical :: new_kinematics = .true.
    real(default) :: alpha_qcd = -1
contains
    procedure :: write => template_me_state_write
end type template_me_state_t

```

```

<Template matrix elements: procedures>+≡
subroutine template_me_state_write (object, unit)
    class(template_me_state_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(3x,A,L1)") "Template ME state: new kinematics = ", &
        object%new_kinematics
end subroutine template_me_state_write

```

Allocate the workspace with the above specific type.

```

<Template matrix elements: prc template ME: TBP>≡
procedure :: allocate_workspace => prc_template_me_allocate_workspace

<Template matrix elements: procedures>+≡
subroutine prc_template_me_allocate_workspace (object, tmp)
    class(prc_template_me_t), intent(in) :: object
    class(workspace_t), intent(inout), allocatable :: tmp
    allocate (template_me_state_t :: tmp)
end subroutine prc_template_me_allocate_workspace

```

The following procedures are inherited from the base type as deferred, thus must be implemented. The corresponding unit tests are skipped here; the procedures are tested when called from the `processes` module.

Output: print just the ID of the associated matrix element. Then display any stored parameters.

```

<Template matrix elements: prc template ME: TBP>+≡
procedure :: write => prc_template_me_write

```

```

<Template matrix elements: procedures>+≡
subroutine prc_template_me_write (object, unit)
  class(prc_template_me_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u, i
  u = output_unit (unit)
  write (u, "(3x,A)", advance="no") "Template process core:"
  if (object%data_known) then
    write (u, "(1x,A)" char (object%data%id)
  else
    write (u, "(1x,A)" "[undefined]"
  end if
  if (allocated (object%par)) then
    write (u, "(3x,A)" "Parameter array:"
    do i = 1, size (object%par)
      write (u, "(5x,I0,1x,ES17.10)" i, object%par(i)
    end do
  end if
end subroutine prc_template_me_write

```

Temporarily store the parameter array inside the `prc_template_me` object, so we can use it later during the actual initialization.

```

<Template matrix elements: prc template ME: TBP>+≡
procedure :: set_parameters => prc_template_me_set_parameters

<Template matrix elements: procedures>+≡
subroutine prc_template_me_set_parameters (prc_template_me, model)
  class(prc_template_me_t), intent(inout) :: prc_template_me
  type(model_t), intent(in), target, optional :: model
  if (present (model)) then
    if (allocated (prc_template_me%par)) deallocate (prc_template_me%par)
    call model_parameters_to_c_array (model, prc_template_me%par)
  end if
end subroutine prc_template_me_set_parameters

```

To fully initialize the process core, we perform base initialization, then initialize the external matrix element code.

This procedure overrides the `init` method of the base type, which we nevertheless can access via its binding `base_init`. When done, we have an allocated driver. The driver will call the `init` procedure for the external matrix element, and thus transfer the parameter set to where it finally belongs.

```

<Template matrix elements: prc template ME: TBP>+≡
procedure :: init => prc_template_me_init

<Template matrix elements: procedures>+≡
subroutine prc_template_me_init (object, def, lib, id, i_component)
  class(prc_template_me_t), intent(inout) :: object
  class(prc_core_def_t), intent(in), target :: def
  type(process_library_t), intent(in), target :: lib
  type(string_t), intent(in) :: id
  integer, intent(in) :: i_component
  call object%base_init (def, lib, id, i_component)
  call object%activate_parameters ()

```

```
end subroutine prc_template_me_init
```

Activate the stored parameters by transferring them to the external matrix element.

```
<Template matrix elements: prc template ME: TBP>+=
  procedure :: activate_parameters => prc_template_me_activate_parameters

<Template matrix elements: procedures>+=
  subroutine prc_template_me_activate_parameters (object)
    class (prc_template_me_t), intent(inout) :: object
    if (allocated (object%driver)) then
      if (allocated (object%par)) then
        select type (driver => object%driver)
          type is (template_me_driver_t)
            if (associated (driver%init)) call driver%init (object%par)
          end select
        else
          call msg_bug ("prc_template_me_activate: parameter set is not allocated")
        end if
      else
        call msg_bug ("prc_template_me_activate: driver is not allocated")
      end if
    end subroutine prc_template_me_activate_parameters
```

The template ME process is an independent process which needs its own Monte Carlo parameter set for integration.

```
<Template matrix elements: prc template ME: TBP>+=
  procedure :: needs_mcset => prc_template_me_needs_mcset

<Template matrix elements: procedures>+=
  function prc_template_me_needs_mcset (object) result (flag)
    class(prc_template_me_t), intent(in) :: object
    logical :: flag
    flag = .true.
  end function prc_template_me_needs_mcset
```

There is only one term for this tree-level process.

```
<Template matrix elements: prc template ME: TBP>+=
  procedure :: get_n_terms => prc_template_me_get_n_terms

<Template matrix elements: procedures>+=
  function prc_template_me_get_n_terms (object) result (n)
    class(prc_template_me_t), intent(in) :: object
    integer :: n
    n = 1
  end function prc_template_me_get_n_terms
```

Tell whether a particular combination of flavor, helicity, color is allowed. Here we have to consult the matrix-element driver.

```
<Template matrix elements: prc template ME: TBP>+=
  procedure :: is_allowed => prc_template_me_is_allowed
```

```

<Template matrix elements: procedures>+≡
function prc_template_me_is_allowed (object, i_term, f, h, c) result (flag)
    class(prc_template_me_t), intent(in) :: object
    integer, intent(in) :: i_term, f, h, c
    logical :: flag
    logical(c_bool) :: cflag
    select type (driver => object%driver)
    type is (template_me_driver_t)
        call driver%is_allowed (f, h, c, cflag)
        flag = cflag
    end select
end function prc_template_me_is_allowed

```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

We reset the `new_kinematics` flag, so that the next call to `compute_amplitude` will evaluate the matrix element.

```

<Template matrix elements: prc template ME: TBP>+≡
procedure :: compute_hard_kinematics => &
    prc_template_me_compute_hard_kinematics

<Template matrix elements: procedures>+≡
subroutine prc_template_me_compute_hard_kinematics &
    (object, p_seed, i_term, int_hard, tmp)
    class(prc_template_me_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(in) :: p_seed
    integer, intent(in) :: i_term
    type(interaction_t), intent(inout) :: int_hard
    class(workspace_t), intent(inout), allocatable :: tmp
    call interaction_set_momenta (int_hard, p_seed)
    if (allocated (tmp)) then
        select type (tmp)
        type is (template_me_state_t); tmp%new_kinematics = .true.
        end select
    end if
end subroutine prc_template_me_compute_hard_kinematics

```

This procedure is not called for `prc_template_me_t`, just a placeholder.

```

<Template matrix elements: prc template ME: TBP>+≡
procedure :: compute_eff_kinematics => &
    prc_template_me_compute_eff_kinematics

<Template matrix elements: procedures>+≡
subroutine prc_template_me_compute_eff_kinematics &
    (object, i_term, int_hard, int_eff, tmp)
    class(prc_template_me_t), intent(in) :: object
    integer, intent(in) :: i_term

    type(interaction_t), intent(inout) :: int_eff
    class(workspace_t), intent(inout), allocatable :: tmp
end subroutine prc_template_me_compute_eff_kinematics

```

Recover the momenta within the hard interaction. For tree-level processes, this is a trivial copy of the incoming seed and outgoing effective momenta. The effective interaction is a pointer to the hard interaction, so the latter is ignored.

```

<Template matrix elements: prc template ME: TBP>+=
  procedure :: recover_kinematics => prc_template_me_recover_kinematics

<Template matrix elements: tests>=
  subroutine prc_template_me_recover_kinematics &
    (object, p_seed, int_hard, int_eff, tmp)
    class(prc_template_me_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(inout) :: p_seed
    type(interaction_t), intent(inout) :: int_hard
    type(interaction_t), intent(inout) :: int_eff
    class(workspace_t), intent(inout), allocatable :: tmp
    integer :: n_in
    n_in = interaction_get_n_in (int_eff)
    call interaction_set_momenta (int_eff, p_seed(1:n_in), outgoing = .false.)
    p_seed(n_in+1:) = interaction_get_momenta (int_eff, outgoing = .true.)
  end subroutine prc_template_me_recover_kinematics

```

Compute the amplitude. For the tree-level process, we can ignore the scale settings. The term index j is also irrelevant.

We first call `new_event` for the given momenta (which we must unpack), then retrieve the amplitude value for the given quantum numbers.

If the `tmp` status flag is present, we can make sure that we call `new_event` only once for a given kinematics. After the first call, we unset the `new_kinematics` flag.

```

<Template matrix elements: prc template ME: TBP>+=
  procedure :: compute_amplitude => prc_template_me_compute_amplitude

<Template matrix elements: procedures>+=
  function prc_template_me_compute_amplitude &
    (object, j, p, f, h, c, fac_scale, ren_scale, tmp) result (amp)

        amp = camp
    else
        amp = 0
    end if
end select
end function prc_template_me_compute_amplitude

```

We do not overwrite the `prc_core_t` routine for α_s .

18.1.6 Test

This is the master for calling self-test procedures. There is a separate test for testing O'MEGA diagram generation as this depends on a working analysis setup.

```

<Template matrix elements: public>+≡
    public :: prc_template_me_test

<Template matrix elements: tests>+≡
    subroutine prc_template_me_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Template matrix elements: execute tests>
    end subroutine prc_template_me_test

```

Generate, compile and load a simple process matrix element

The process is $e^+e^- \rightarrow \mu^+\mu^-$ for vanishing masses and $e = 0.3$. We initialize the process, build the library, and compute a particular matrix element for momenta of unit energy and right-angle scattering. The matrix element, as it happens, is equal to e^2 . (Note that are no conversion factors applied, so this result is exact.)

For GNU `make`, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

```

<Template matrix elements: execute tests>≡
    call test (prc_template_me_1, "prc_template_me_1", &
        "build and load simple template process", &
        u, results)

18.2 O'MEGA Interface

The standard method for process computation with WHIZARD is the O'MEGA matrix element generator.

This section implements the interface to the code generator (via the makefile) and the driver for the features provided by the O'MEGA matrix element.

```

<prc_omega.f90>≡
  <File header>

  module prc_omega

    use iso_c_binding !NODEP!
    use kinds !NODEP!
    <Use file utils>
    <Use strings>
    use limits, only: TAB !NODEP!
    use diagnostics !NODEP!
    use unit_tests
    use os_interface
    use lorentz !NODEP!
    use sm_qcd
    use interactions
    use variables
    use models

    use process_constants
    use prclib_interfaces
    use prc_core_def
    use particle_specifiers
    use process_libraries
    use prc_core

    <Standard module head>

    <Omega interface: public>

    <Omega interface: types>

    <Omega interface: interfaces>

    contains

    <Omega interface: procedures>

    <Omega interface: tests>

  end module prc_omega

```

18.2.1 Process definition

For the process definition we implement an extension of the `prc_core_def_t` abstract type.

```
<Omega interface: public>≡
    public :: omega_def_t

<Omega interface: types>≡
    type, extends (prc_core_def_t) :: omega_def_t
    contains
    <Omega interface: omega def: TBP>
    end type omega_def_t

<Omega interface: omega def: TBP>≡
    procedure, nopass :: type_string => omega_def_type_string

<Omega interface: procedures>≡
    function omega_def_type_string () result (string)
        type(string_t) :: string
        string = "omega"
    end function omega_def_type_string
```

Initialization: allocate the writer for the O'MEGA matrix element. Also set any data for this process that the writer needs.

```
<Omega interface: omega def: TBP>+≡
    procedure :: init => omega_def_init

<Omega interface: procedures>+≡
    subroutine omega_def_init (object, model_name, prt_in, prt_out, &
        restrictions, openmp_support, report_progress, extra_options, &
        diags, diags_color)
        class(omega_def_t), intent(out) :: object
        type(string_t), intent(in) :: model_name
        type(string_t), dimension(:), intent(in) :: prt_in
        type(string_t), dimension(:), intent(in) :: prt_out
        type(string_t), intent(in), optional :: restrictions
        logical, intent(in), optional :: openmp_support
        logical, intent(in), optional :: report_progress
        logical, intent(in), optional :: diags, diags_color
        type(string_t), intent(in), optional :: extra_options
        allocate (omega_writer_t :: object%writer)
        select type (writer => object%writer)
            type is (omega_writer_t)
                call writer%init (model_name, prt_in, prt_out, &
                    restrictions, openmp_support, report_progress, &
                    extra_options, diags, diags_color)
            end select
    end subroutine omega_def_init
```

Write/read process- and method-specific data.

```
<Omega interface: omega def: TBP>+≡
    procedure :: write => omega_def_write
```

```

<Omega interface: procedures>+≡
  subroutine omega_def_write (object, unit)
    class(omega_def_t), intent(in) :: object
    integer, intent(in) :: unit
    select type (writer => object%writer)
    type is (omega_writer_t)
      call writer%write (unit)
    end select
  end subroutine omega_def_write

<Omega interface: omega def: TBP>+≡
  procedure :: read => omega_def_read

<Omega interface: procedures>+≡
  subroutine omega_def_read (object, unit)
    class(omega_def_t), intent(out) :: object
    integer, intent(in) :: unit
    call msg_bug ("O'Mega process definition: input not supported yet")
  end subroutine omega_def_read

```

Allocate the driver for O'MEGAmatrix elements.

```

<Omega interface: omega def: TBP>+≡
  procedure :: allocate_driver => omega_def_allocate_driver

<Omega interface: procedures>+≡
  subroutine omega_def_allocate_driver (object, driver, basename)
    class(omega_def_t), intent(in) :: object
    class(prc_core_driver_t), intent(out), allocatable :: driver
    type(string_t), intent(in) :: basename
    allocate (omega_driver_t :: driver)
  end subroutine omega_def_allocate_driver

```

We need code:

```

<Omega interface: omega def: TBP>+≡
  procedure, nopass :: needs_code => omega_def_needs_code

<Omega interface: procedures>+≡
  function omega_def_needs_code () result (flag)
    logical :: flag
    flag = .true.
  end function omega_def_needs_code

```

These are the features that an O'MEGA matrix element provides.

```

<Omega interface: omega def: TBP>+≡
  procedure, nopass :: get_features => omega_def_get_features

<Omega interface: procedures>+≡
  subroutine omega_def_get_features (features)
    type(string_t), dimension(:), allocatable, intent(out) :: features
    allocate (features (6))
    features = [ &
      var_str ("init"), &
      var_str ("update_alpha_s"), &

```

```

        var_str ("reset_helicity_selection"), &
        var_str ("is_allowed"), &
        var_str ("new_event"), &
        var_str ("get_amplitude")]
end subroutine omega_def_get_features

```

The interface of the specific features.

(Omega interface: interfaces)≡

```

abstract interface
  subroutine init_t (par) bind(C)
    import
    real(c_default_float), dimension(*), intent(in) :: par
  end subroutine init_t
end interface

abstract interface
  subroutine update_alpha_s_t (alpha_s) bind(C)
    import
    real(c_default_float), intent(in) :: alpha_s
  end subroutine update_alpha_s_t
end interface

abstract interface
  subroutine reset_helicity_selection_t (threshold, cutoff) bind(C)
    import
    real(c_default_float), intent(in) :: threshold
    integer(c_int), intent(in) :: cutoff
  end subroutine reset_helicity_selection_t
end interface

abstract interface
  subroutine is_allowed_t (flv, hel, col, flag) bind(C)
    import
    integer(c_int), intent(in) :: flv, hel, col
    logical(c_bool), intent(out) :: flag
  end subroutine is_allowed_t
end interface

abstract interface
  subroutine new_event_t (p) bind(C)
    import
    real(c_default_float), dimension(0:3,*), intent(in) :: p
  end subroutine new_event_t
end interface

abstract interface
  subroutine get_amplitude_t (flv, hel, col, amp) bind(C)
    import
    integer(c_int), intent(in) :: flv, hel, col
    complex(c_default_complex), intent(out):: amp
  end subroutine get_amplitude_t
end interface

```

Connect the O'MEGA features with the process driver.

```

<Omega interface: omega def: TBP>+≡
  procedure :: connect => omega_def_connect

<Omega interface: procedures>+≡
  subroutine omega_def_connect (def, lib_driver, i, proc_driver)
    class(omega_def_t), intent(in) :: def
    class(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i

      call c_f_procpointer (fptr, proc_driver%get_amplitude)
    end select
  end subroutine omega_def_connect

```

18.2.2 The O'MEGA writer

The O'MEGA writer is responsible for inserting the appropriate lines in the make-file that call O'MEGA, and for writing interfaces and wrappers.

```

<Omega interface: types>+≡
  type, extends (prc_writer_f_module_t) :: omega_writer_t
    type(string_t) :: model_name
    type(string_t) :: process_mode
    type(string_t) :: process_string
    type(string_t) :: restrictions
    logical :: openmp_support = .false.
    logical :: report_progress = .false.
    logical :: diags = .false.
    logical :: diags_color = .false.
    type(string_t) :: extra_options
  contains

```

```

    <Omega interface: omega writer: TBP>
end type omega_writer_t

```

The reported type is the same as for the omega_def_t type.

```

<Omega interface: omega writer: TBP>≡
    procedure, nopass :: type_name => omega_writer_type_name

<Omega interface: procedures>+≡
    function omega_writer_type_name () result (string)
        type(string_t) :: string

```

18.2.4 High-level process definition

This procedure wraps the details filling a process-component definition entry as appropriate for an O'MEGA matrix element.

NOTE: For calling the `import_component` method, we must explicitly address the `process_def_t` parent object. The natural way to call the method of the extended type triggers a bug in gfortran 4.6. The string array arguments `prt_in` and `prt_out` become corrupted and cause a segfault.

```

<Omega interface: public>+≡
  public :: omega_make_process_component

<Omega interface: procedures>+≡
  subroutine omega_make_process_component (entry, component_index, &
    model_name, prt_in, prt_out, restrictions, openmp_support, &
    report_progress, extra_options, diags, diags_color)
    class(process_def_entry_t), intent(inout) :: entry
    integer, intent(in) :: component_index
    type(string_t), intent(in) :: model_name
    type(string_t), dimension(:), intent(in) :: prt_in
    type(string_t), dimension(:), intent(in) :: prt_out
    type(string_t), intent(in), optional :: restrictions
    logical, intent(in), optional :: openmp_support
    logical, intent(in), optional :: report_progress

```

```

logical, intent(in), optional :: diags, diags_color
type(string_t), intent(in), optional :: extra_options
class(prc_core_def_t), allocatable :: def
allocate (omega_def_t :: def)
select type (def)
type is (omega_def_t)
    call def%init (model_name, prt_in, prt_out, &
        restrictions, openmp_support, report_progress, &
        extra_options, diags, diags_color)
end select
call entry%process_def_t%import_component (component_index, &
    n_out = size (prt_out), &
    prt_in = new_prt_spec (prt_in), &
    prt_out = new_prt_spec (prt_out), &
    method = var_str ("omega"), &
    variant = def)
end subroutine omega_make_process_component

```

18.2.5 The prc_omega_t wrapper

This is an instance of the generic `prc_core_t` object. It contains a pointer to the process definition (`omega_def_t`), a data component (`process_constants_t`), and the matrix-element driver (`omega_driver_t`).

```

<Omega interface: public>+≡
    public :: prc_omega_t

<Omega interface: types>+≡
    type, extends (prc_core_t) :: prc_omega_t
        real(default), dimension(:), allocatable :: par
        type(helicity_selection_t) :: helicity_selection
        type(qcd_t) :: qcd
    contains
        <Omega interface: prc omega: TBP>
    end type prc_omega_t

```

The workspace associated to a `prc_omega_t` object contains a single flag. The flag is used to suppress re-evaluating the matrix element for each quantum-number combination, after the first amplitude belonging to a given kinematics has been computed.

We can also store the value of a running coupling once it has been calculated for an event. The default value is negative, which indicates an undefined value in this context.

```

<Omega interface: types>+≡
    type, extends (workspace_t) :: omega_state_t
        logical :: new_kinematics = .true.
        real(default) :: alpha_qcd = -1
    contains
        procedure :: write => omega_state_write
    end type omega_state_t

```

```

<Omega interface: procedures>+≡
subroutine omega_state_write (object, unit)
  class(omega_state_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u
  u = output_unit (unit)
  write (u, "(3x,A,L1)") "0'Mega state: new kinematics = ", &
    object%new_kinematics
end subroutine omega_state_write

```

Allocate the workspace with the above specific type.

```

<Omega interface: prc omega: TBP>≡
  procedure :: allocate_workspace => prc_omega_allocate_workspace

<Omega interface: procedures>+≡
subroutine prc_omega_allocate_workspace (object, tmp)
  class(prc_omega_t), intent(in) :: object
  class(workspace_t), intent(inout), allocatable :: tmp
  allocate (omega_state_t :: tmp)
end subroutine prc_omega_allocate_workspace

```

The following procedures are inherited from the base type as deferred, thus must be implemented. The corresponding unit tests are skipped here; the procedures are tested when called from the `processes` module.

Output: print just the ID of the associated matrix element. Then display any stored parameters and the helicity selection data. (The latter are printed only if active.)

```

<Omega interface: prc omega: TBP>+≡
  procedure :: write => prc_omega_write

<Omega interface: procedures>+≡
subroutine prc_omega_write (object, unit)
  class(prc_omega_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u, i
  u = output_unit (unit)
  write (u, "(3x,A)", advance="no") "0'Mega process core:"
  if (object%data_known) then
    write (u, "(1x,A)") char (object%data%id)
  else
    write (u, "(1x,A)") "[undefined]"
  end if
  if (allocated (object%par)) then
    write (u, "(3x,A)") "Parameter array:"
    do i = 1, size (object%par)
      write (u, "(5x,I0,1x,ES17.10)") i, object%par(i)
    end do
  end if
  call object%helicity_selection%write (u)
  call object%qcd%write (u)
end subroutine prc_omega_write

```

Temporarily store the parameter array inside the `prc_omega` object, so we can use it later during the actual initialization. Also store threshold and cutoff for helicity selection.

```

<Omega interface: prc_omega: TBP>+=
  procedure :: set_parameters => prc_omega_set_parameters

<Omega interface: procedures>+=
  subroutine prc_omega_set_parameters (prc_omega, model, &
    helicity_selection, qcd, use_color_factors)
    class(prc_omega_t), intent(inout) :: prc_omega
    type(model_t), intent(in), target, optional :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    logical, intent(in), optional :: use_color_factors
    if (present (model)) then
      if (allocated (prc_omega%par)) deallocate (prc_omega%par)
      call model_parameters_to_c_array (model, prc_omega%par)
    end if
    if (present (helicity_selection)) then
      prc_omega%helicity_selection = helicity_selection
    end if
    if (present (qcd)) then
      prc_omega%qcd = qcd
    end if
    if (present (use_color_factors)) then
      prc_omega%use_color_factors = use_color_factors
    end if
  end subroutine prc_omega_set_parameters

```

To fully initialize the process core, we perform base initialization, then initialize the external matrix element code.

This procedure overrides the `init` method of the base type, which we nevertheless can access via its binding `base_init`. When done, we have an allocated driver. The driver will call the `init` procedure for the external matrix element, and thus transfer the parameter set to where it finally belongs.

If requested, we initialize the helicity selection counter.

```

<Omega interface: prc_omega: TBP>+=
  procedure :: init => prc_omega_init

<Omega interface: procedures>+=
  subroutine prc_omega_init (object, def, lib, id, i_component)
    class(prc_omega_t), intent(inout) :: object
    class(prc_core_def_t), intent(in), target :: def
    type(process_library_t), intent(in), target :: lib
    type(string_t), intent(in) :: id
    integer, intent(in) :: i_component
    call object%base_init (def, lib, id, i_component)
    call object%activate_parameters ()
  end subroutine prc_omega_init

```

Activate the stored parameters by transferring them to the external matrix element. Also reset the helicity selection, if requested.

```

<Omega interface: prc_omega: TBP>+=

```

```

    procedure :: activate_parameters => prc_omega_activate_parameters
<Omega interface: procedures>+≡
    subroutine prc_omega_activate_parameters (object)
        class (prc_omega_t), intent(inout) :: object
        if (allocated (object%driver)) then
            if (allocated (object%par)) then
                select type (driver => object%driver)
                type is (omega_driver_t)
                    if (associated (driver%init)) call driver%init (object%par)
                end select
            else
                call msg_bug ("prc_omega_activate: parameter set is not allocated")
            end if
            call object%reset_helicity_selection ()
        else
            call msg_bug ("prc_omega_activate: driver is not allocated")
        end if
    end subroutine prc_omega_activate_parameters

```

The O'MEGA process is an independent process which needs its own Monte Carlo parameter set for integration.

```

<Omega interface: prc omega: TBP>+≡

        logical :: flag
        flag = .true.
    end function prc_omega_needs_mcset

```

There is only one term for this tree-level process.

```

<Omega interface: prc omega: TBP>+≡
    procedure :: get_n_terms => prc_omega_get_n_terms
<Omega interface: procedures>+≡
    function prc_omega_get_n_terms (object) result (n)
        class(prc_omega_t), intent(in) :: object
        integer :: n
        n = 1
    end function prc_omega_get_n_terms

```

Tell whether a particular combination of flavor, helicity, color is allowed. Here we have to consult the matrix-element driver.

```

<Omega interface: prc omega: TBP>+≡
    procedure :: is_allowed => prc_omega_is_allowed
<Omega interface: procedures>+≡
    function prc_omega_is_allowed (object, i_term, f, h, c) result (flag)
        class(prc_omega_t), intent(in) :: object
        integer, intent(in) :: i_term, f, h, c
        logical :: flag
        logical(c_bool) :: cflag

```

```

select type (driver => object%driver)
type is (omega_driver_t)
  call driver%is_allowed (f, h, c, cflag)
  flag = cflag
end select
end function prc_omega_is_allowed

```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

We reset the `new_kinematics` flag, so that the next call to `compute_amplitude` will evaluate the matrix element.

```

<Omega interface: prc omega: TBP>+=
  procedure :: compute_hard_kinematics => prc_omega_compute_hard_kinematics

<Omega interface: procedures>+=
  subroutine prc_omega_compute_hard_kinematics &
    (object, p_seed, i_term, int_hard, tmp)
    class(prc_omega_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(in) :: p_seed
    integer, intent(in) :: i_term
    type(interaction_t), intent(inout) :: int_hard
    class(workspace_t), intent(inout), allocatable :: tmp
    call interaction_set_momenta (int_hard, p_seed)
    if (allocated (tmp)) then
      select type (tmp)
        type is (omega_state_t); tmp%new_kinematics = .true.
      end select
    end if
  end subroutine prc_omega_compute_hard_kinematics

```

This procedure is not called for `prc_omega_t`, just a placeholder.

```

<Omega interface: prc omega: TBP>+=
  procedure :: compute_eff_kinematics => prc_omega_compute_eff_kinematics

<Omega interface: procedures>+=
  subroutine prc_omega_compute_eff_kinematics &
    (object, i_term, int_hard, int_eff, tmp)
    class(prc_omega_t), intent(in) :: object
    integer, intent(in) :: i_term
    type(interaction_t), intent(in) :: int_type
    type(interaction_t), intent(inout) :: int_eff
    class(workspace_t), intent(inout), allocatable :: tmp
  end subroutine prc_omega_compute_eff_kinematics

```

Recover the momenta within the hard interaction. For tree-level processes, this is a trivial copy of the incoming seed and outgoing effective momenta. The effective interaction is a pointer to the hard interaction, so the latter is ignored.

```

<Omega interface: prc omega: TBP>+=
  procedure :: recover_kinematics => prc_omega_recover_kinematics

<Omega interface: tests>=
  subroutine prc_omega_recover_kinematics &
    (object, p_seed, int_hard, int_eff, tmp)

```

```

class(prc_omega_t), intent(in) :: object
type(vector4_t), dimension(:), intent(inout) :: p_seed
type(interaction_t), intent(inout) :: int_hard
type(interaction_t), intent(inout) :: int_eff
class(workspace_t), intent(inout), allocatable :: tmp
integer :: n_in
n_in = interaction_get_n_in (int_eff)
call interaction_set_momenta (int_eff, p_seed(1:n_in), outgoing = .false.)
p_seed(n_in+1:) = interaction_get_momenta (int_eff, outgoing = .true.)
end subroutine prc_omega_recover_kinematics

```

Reset the helicity selection counters and start counting zero helicities. We assume that the `helicity_selection` object is allocated. Otherwise, reset and switch off helicity counting.

In the test routine, the driver is allocated but the driver methods are not. Therefore, guard against a disassociated method.

```

<Omega interface: prc omega: TBP>+≡
  procedure :: reset_helicity_selection => prc_omega_reset_helicity_selection

<Omega interface: procedures>+≡
  subroutine prc_omega_reset_helicity_selection (object)
    class(prc_omega_t), intent(inout) :: object
    select type (driver => object%driver)
      type is (omega_driver_t)
        if (associated (driver%reset_helicity_selection)) then
          if (object%helicity_selection%active) then
            call driver%reset_helicity_selection &
              (real (object%helicity_selection%threshold, &
                c_default_float), &
              int (object%helicity_selection%cutoff, c_int))
          else
            call driver%reset_helicity_selection &
              (0._c_default_float, 0_c_int)
          end if
        end if
      end select
    end subroutine prc_omega_reset_helicity_selection

```

Compute the amplitude. For the tree-level process, we can ignore the scale settings. The term index `j` is also irrelevant.

We first call `new_event` for the given momenta (which we must unpack), then retrieve the amplitude value for the given quantum numbers.

If the `tmp` status flag is present, we can make sure that we call `new_event` only once for a given kinematics. After the first call, we unset the `new_kinematics` flag.

The `is_allowed` query is not redundant, since the status may change during the run if helicities are switched off.

```

<Omega interface: prc omega: TBP>+≡
  procedure :: compute_amplitude => prc_omega_compute_amplitude

<Omega interface: procedures>+≡
  function prc_omega_compute_amplitude &
    (object, j, p, f, h, c, fac_scale, ren_scale, tmp) result (amp)

```

```

      select type (tmp)
        type is (omega_state_t)
          alpha = tmp%alpha_qcd
        end select
      end if
    end function prc_omega_get_alpha_s

```

18.2.6 Test

This is the master for calling self-test procedures. There is a separate test for testing O'MEGA diagram generation as this depends on a working analysis setup.

```

<Omega interface: public>+=
  public :: prc_omega_test

<Omega interface: tests>+=
  subroutine prc_omega_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Omega interface: execute tests>
  end subroutine prc_omega_test

<Omega interface: public>+=
  public :: prc_omega_diags_test

<Omega interface: tests>+=
  subroutine prc_omega_diags_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Omega interface: execute diags tests>
  end subroutine prc_omega_diags_test

```

Generate, compile and load a simple process matrix element

The process is $e^+e^- \rightarrow \mu^+\mu^-$ for vanishing masses and $e = 0.3$. We initialize the process, build the library, and compute a particular matrix element for momenta of unit energy and right-angle scattering. The matrix element, as it happens, is equal to e^2 . (Note that are no conversion factors applied, so this result is exact.)

For GNU make, makeflags is set to -j1. This eliminates a potential clash with a -j<n> flag if this test is called from a parallel make.

(Omega interface: execute tests)≡

```

Check prc_omega_t wrapper and options

The process is $e^-e^+ \rightarrow e^-e^+$ for vanishing masses and $e = 0.3$. We build the library using the high-level procedure `omega_make_process_component` and the “black box” `prc_omega_t` object. Two variants with different settings for restrictions and OpenMP.

For GNU make, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

```

Chapter 19

Event I/O

In this chapter we provide a generic handler for event I/O and the various implementations: raw, HepMC, Les Houches, etc.

19.1 Event Sample Data

We define a simple and transparent container for (meta)data that are associated with an event sample.

```
<eio_data.f90>≡  
<File header>  
  
module eio_data  
  
    use kinds !NODEP!  
<Use file utils>  
<Use strings>  
    use diagnostics !NODEP!  
    use unit_tests  
  
    use events  
  
<EIO data: public>  
  
<EIO data: types>  
  
contains  
  
<EIO data: procedures>  
  
<EIO data: tests>  
  
end module eio_data
```

19.1.1 Event Sample Data

These are data that apply to an event sample as a whole. They are given in an easily portable form (no fancy structure) and are used for initializing event

formats.

There are two MD5 sums here. `md5sum_proc` depends only on the definition of the contributing processes. A sample with matching checksum can be rescanned with modified model parameters, beam structure etc, to recalculate observables. `md5sum_config` includes all relevant data. Rescanning a sample with matching checksum will produce identical observables. (A third checksum might be added which depends on the event sample itself. This is not needed, so far.)

If alternate weights are part of the event sample (`n_alt` nonzero), there is a configuration MD5 sum for each of them.

```

(EIO data: public)≡
  public :: event_sample_data_t

(EIO data: types)≡
  type :: event_sample_data_t

19.2 Abstract I/O Handler

This module defines an abstract object for event I/O and the associated methods.

There are `output` and `input` methods which write or read a single event from/to the I/O stream, respectively. The I/O stream itself may be a file, a common block, or an externally linked structure, depending on the concrete implementation.

A `write` method prints the current content of the implementation-dependent event record in human-readable form.

The `init_in/init_out` and `final` prepare and finalize the I/O stream, respectively. There is also a `switch_inout` method which turns an input stream into an output stream where events can be appended.

Optionally, output files can be split in chunks of well-defined size. The `split_out` method takes care of this.

```

<eio_base.f90>≡
  <File header>

  module eio_base

    use kinds !NODEP!
    <Use file utils>
    <Use strings>
    use diagnostics !NODEP!
    use unit_tests

    use lorentz !NODEP!
    use models
    use particles
    use beams
    use processes
    use events
    use eio_data

    <Standard module head>

    <EIO base: public>

    <EIO base: types>

    <EIO base: interfaces>

    <EIO base: test types>

    contains

    <EIO base: procedures>

    <EIO base: tests>

  end module eio_base

```

19.2.1 Process pointer

For handling multiple processes, we need an array of process pointers. This requires a wrapper:

```

<EIO base: public>≡
  public :: process_ptr_t

<EIO base: types>≡
  type :: process_ptr_t
    type(process_t), pointer :: ptr => null ()
  end type process_ptr_t

```

19.2.2 Type

We can assume that most implementations will need the file extension as a fixed string and, if they support file splitting, the current file index.

```
<EIO base: public>+≡
    public :: eio_t

<EIO base: types>+≡
    type, abstract :: eio_t
        type(string_t) :: sample
        type(string_t) :: extension
        type(string_t) :: filename
        logical :: split = .false.
        integer :: split_n_evt = 0
        integer :: split_index = 0
    contains
        <EIO base: eio: TBP>
    end type eio_t
```

Write to screen. If possible, this should display the contents of the current event, i.e., the last one that was written or read.

```
<EIO base: eio: TBP>≡
    procedure (eio_write), deferred :: write

<EIO base: interfaces>≡
    abstract interface
        subroutine eio_write (object, unit)
            import
            class(eio_t), intent(in) :: object
            integer, intent(in), optional :: unit
        end subroutine eio_write
    end interface
```

Finalize. This should write/read footer data and close input/output channels.

```
<EIO base: eio: TBP>+≡
    procedure (eio_final), deferred :: final

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_final (object)
            import
            class(eio_t), intent(inout) :: object
        end subroutine eio_final
    end interface
```

Determine splitting parameters from the event sample data.

```
<EIO base: eio: TBP>+≡
    procedure :: set_splitting => eio_set_splitting

<EIO base: procedures>≡
    subroutine eio_set_splitting (eio, data)
        class(eio_t), intent(inout) :: eio
        type(event_sample_data_t), intent(in) :: data
        eio%split = data%split_n_evt > 0
```

```

    if (eio%split) then
        eio%split_n_evt = data%split_n_evt
        eio%split_index = data%split_index
    end if
end subroutine eio_set_splitting

```

Generate a filename, taking a possible split index into account.

```

<EIO base: eio: TBP>+≡
    procedure :: set_filename => eio_set_filename

<EIO base: procedures>+≡
    subroutine eio_set_filename (eio)
        class(eio_t), intent(inout) :: eio
        character(32) :: buffer
        if (eio%split) then
            write (buffer, "(I0,'.')") eio%split_index
            eio%filename = eio%sample // "." // trim (buffer) // eio%extension
        else
            eio%filename = eio%sample // "." // eio%extension
        end if
    end subroutine eio_set_filename

```

Initialize for output. We provide process pointers. This should open an event file if appropriate and write header data. Some methods may require event sample data.

```

<EIO base: eio: TBP>+≡
    procedure (eio_init_out), deferred :: init_out

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_init_out (eio, sample, process_ptr, data, success)
            import
            class(eio_t), intent(inout) :: eio
            type(string_t), intent(in) :: sample
            type(process_ptr_t), dimension(:), intent(in) :: process_ptr
            type(event_sample_data_t), intent(in), optional :: data
            logical, intent(out), optional :: success
        end subroutine eio_init_out
    end interface

```

Initialize for input. We provide process names. This should open an event file if appropriate and read header data. The md5sum can be used to check the integrity of the configuration, it it provides a checksum to compare with. In case the extension has changed the extension is also given as an argument.

The data argument is intent(inout): we may read part of it and keep other parts and/or check them against the data in the file.

```

<EIO base: eio: TBP>+≡
    procedure (eio_init_in), deferred :: init_in

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_init_in (eio, sample, process_ptr, data, success, extension)
            import

```

```

        class(eio_t), intent(inout) :: eio
        type(string_t), intent(in) :: sample
        type(string_t), intent(in), optional :: extension
        type(process_ptr_t), dimension(:), intent(in) :: process_ptr
        type(event_sample_data_t), intent(inout), optional :: data
        logical, intent(out), optional :: success
    end subroutine eio_init_in
end interface

```

Re-initialize for output. This should change the status of any event file from input to output and position it for appending new events.

```

<EIO base: eio: TBP>+≡
    procedure (eio_switch_inout), deferred :: switch_inout

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_switch_inout (eio, success)
            import
            class(eio_t), intent(inout) :: eio
            logical, intent(out), optional :: success
        end subroutine eio_switch_inout
    end interface

```

This is similar: split the output, i.e., close the current file and open a new one. The default implementation does nothing. For the feature to work, an implementation must override this.

```

<EIO base: eio: TBP>+≡
    procedure :: split_out => eio_split_out

<EIO base: procedures>+≡
    subroutine eio_split_out (eio)
        class(eio_t), intent(inout) :: eio
    end subroutine eio_split_out

```

Output an event. All data can be taken from the `event` record. The index `i_prc` identifies the process among the processes that are contained in the current sample. The `reading` flag, if present, indicates that the event was read from file, not generated.

```

<EIO base: eio: TBP>+≡
    procedure (eio_output), deferred :: output

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_output (eio, event, i_prc, reading)
            import
            class(eio_t), intent(inout) :: eio
            type(event_t), intent(in), target :: event
            integer, intent(in) :: i_prc
            logical, intent(in), optional :: reading
        end subroutine eio_output
    end interface

```

Input an event. This should fill all event data that cannot be inferred from the associated process.

The input is broken down into two parts. First we read the `i_prc` index. So we know which process to expect in the subsequent event. If we have reached end of file, we also will know. Then, we read the event itself.

The parameter `iostat` is supposed to be set as the Fortran standard requires, negative for EOF and positive for error.

```

<EIO base: eio: TBP>+≡
  procedure (eio_input_i_prc), deferred :: input_i_prc
  procedure (eio_input_event), deferred :: input_event

<EIO base: interfaces>+≡
  abstract interface
    subroutine eio_input_i_prc (eio, i_prc, iostat)
      import
      class(eio_t), intent(inout) :: eio
      integer, intent(out) :: i_prc
      integer, intent(out) :: iostat
    end subroutine eio_input_i_prc
  end interface

  abstract interface
    subroutine eio_input_event (eio, event, iostat)
      import
      class(eio_t), intent(inout) :: eio
      type(event_t), intent(inout), target :: event
      integer, intent(out) :: iostat
    end subroutine eio_input_event
  end interface

```

19.2.3 Unit tests

```

<EIO base: public>+≡
  public :: eio_base_test

<EIO base: tests>≡
  subroutine eio_base_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <EIO base: execute tests>
  end subroutine eio_base_test

```

Test type for event I/O

The contents simulate the contents of an external file. We have the `sample` string as the file name, `sqrts` and the array of `process_ids` as metadata, and the array of momenta `event_p` as the list of events. The second index is the event index. The `event_i` component is the pointer to the current event, `event_n` is the total number of stored events.

```

<EIO base: test types>≡
  type, extends (eio_t) :: eio_test_t

```

```

    real(default) :: sqrts
    type(string_t) :: process_id
    integer :: event_n = 0
    integer :: event_i = 0
    integer :: i_prc = 0
    type(vector4_t), dimension(:,,:), allocatable :: event_p
contains
    <EIO base: eio test: TBP>
end type eio_test_t

```

Write to screen. Pretend that this is an actual event format.

```

<EIO base: eio test: TBP>≡
    procedure :: write => eio_test_write

<EIO base: procedures>+≡
    subroutine eio_test_write (object, unit)
        class(eio_test_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = output_unit (unit)
        write (u, "(1x,A)") "Test event stream"
        write (u, "(3x,A,A,A)") "Process ID = ", char (object%process_id), ""
        write (u, "(3x,A,ES19.12)") "sqrts      = ", object%sqrts
        if (object%event_i /= 0) then
            write (u, "(1x,A,I0,A)") "Event #", object%event_i, ":"
            do i = 1, size (object%event_p, 1)
                call vector4_write (object%event_p(i, object%event_i), u)
            end do
        end if
    end subroutine eio_test_write

```

Finalizer. For the test case, we just reset the event count, but keep the stored “events”. For the real implementations, the events would be stored on an external medium, so we would delete the object contents.

```

<EIO base: eio test: TBP>+≡
    procedure :: final => eio_test_final

<EIO base: procedures>+≡
    subroutine eio_test_final (object)
        class(eio_test_t), intent(inout) :: object
        object%event_i = 0
    end subroutine eio_test_final

```

Initialization: We store the process IDs and the energy from the beam-data object. We also allocate the momenta (i.e., the simulated event record) for a fixed maximum size of 10 events, 2 momenta each. There is only a single process.

```

<EIO base: eio test: TBP>+≡
    procedure :: init_out => eio_test_init_out

<EIO base: procedures>+≡
    subroutine eio_test_init_out (eio, sample, process_ptr, data, success)
        class(eio_test_t), intent(inout) :: eio

```

```

type(string_t), intent(in) :: sample
type(process_ptr_t), dimension(:), intent(in) :: process_ptr
type(event_sample_data_t), intent(in), optional :: data
logical, intent(out), optional :: success
type(beam_data_t), pointer :: beam_data
eio%sample = sample
eio%process_id = process_ptr(1)%ptr%get_id ()
beam_data => process_ptr(1)%ptr%get_beam_data_ptr ()
eio%sqrts = beam_data_get_sqrts (beam_data)
eio%event_n = 0
eio%event_i = 0
allocate (eio%event_p (2, 10))
if (present (success)) success = .true.
end subroutine eio_test_init_out

```

Initialization for input. Nothing to do for the test type.

```

<EIO base: eio test: TBP>+≡
  procedure :: init_in => eio_test_init_in

<EIO base: procedures>+≡
  subroutine eio_test_init_in &

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the prc values for weight and sqme, since these are the values just computed. On input, we store the values as ref values. The caller can then decide whether to recompute values and thus obtain distinct prc values, or just accept them.

19.5 HEP Common Blocks

Long ago, to transfer data between programs one had to set up a common block and link both programs as libraries to the main executable. The HEP community standardizes several of those common blocks.

The modern way of data exchange uses data files with standard formats. However, the LHEF standard data format derives from a common block (actually, two).

WHIZARD used to support those common blocks, and LHEF was implemented via writing/reading blocks. We still keep this convention, but intend to eliminate common blocks (or any other static storage) from the workflow in the future. This will gain flexibility towards concurrent running of program images.

We encapsulate everything here in a module. The module holds the variables which are part of the common block.

Note: This code is taken essentially unchanged from WHIZARD 2.1 and does not (yet) provide unit tests.

```

<hep_common.f90>≡
<File header>

module hep_common

  use kinds !NODEP!
  <Use file utils>
  <Use strings>
  use diagnostics !NODEP!

  use lorentz !NODEP!
  use flavors
  use colors
  use polarizations
  use models
  use particles
  use subevents
  use processes

  <Standard module head>

```

```

    <HEP common: public>

    <HEP common: interfaces>

    <HEP common: parameters>

    <HEP common: variables>

    <HEP common: common blocks>

contains

    <HEP common: procedures>

end module hep_common

```

19.5.1 Event characteristics

The maximal number of particles in an event record.

```

<HEP common: parameters>≡
    integer, parameter :: MAXNUP = 500

```

The number of particles in this event.

```

<HEP common: variables>≡
    integer :: NUP

```

The process ID for this event.

```

<HEP common: variables>+≡
    integer :: IDPRUP

```

The weight of this event (± 1 for unweighted events).

```

<HEP common: variables>+≡
    double precision :: XWGTUP

```

The factorization scale that is used for PDF calculation (-1 if undefined).

```

<HEP common: variables>+≡
    double precision :: SCALUP

```

The QED and QCD couplings α used for this event (-1 if undefined).

```

<HEP common: variables>+≡
    double precision :: AQEDUP
    double precision :: AQCDUP

```

19.5.2 Particle characteristics

The PDG code:

```

<HEP common: variables>+≡
    integer, dimension(MAXNUP) :: IDUP

```

The status code. Incoming: -1 , outgoing: $+1$. Intermediate t-channel propagator: -2 (currently not used by WHIZARD). Intermediate resonance whose mass should be preserved: 2 . Intermediate resonance for documentation: 3 (currently not used). Beam particles: -9 .

```

<HEP common: variables>+≡
    integer, dimension(MAXNUP) :: ISTUP

```

Index of first and last mother.

```
<HEP common: variables>+≡  
integer, dimension(2,MAXNUP) :: MOTHUP
```

Color line index of the color and anticolor entry for the particle. The standard recommends using large numbers; we start from MAXNUP+1.

```
<HEP common: variables>+≡  
integer, dimension(2,MAXNUP) :: ICOLUP
```

Momentum, energy, and invariant mass: (p_x, p_y, p_z, E, M) . For space-like particles, M is the negative square root of the absolute value of the invariant mass.

```
<HEP common: variables>+≡  
double precision, dimension(5,MAXNUP) :: PUP
```

Invariant lifetime (distance) from production to decay in mm.

```
<HEP common: variables>+≡  
double precision, dimension(MAXNUP) :: VTIMUP
```

Cosine of the angle between the spin-vector and a particle and the 3-momentum of its mother, given in the lab frame. If undefined/unpolarized: 9.

```
<HEP common: variables>+≡  
double precision, dimension(MAXNUP) :: SPINUP
```

19.5.3 The HEPRUP common block

This common block is filled once per run.

Run characteristics

The maximal number of different processes.

```
<HEP common: parameters>+≡  
integer, parameter :: MAXPUP = 100
```

The beam PDG codes.

```
<HEP common: variables>+≡  
integer, dimension(2) :: IDBMUP
```

The beam energies in GeV.

```
<HEP common: variables>+≡  
double precision, dimension(2) :: EBMUP
```

The PDF group and set for the two beams. (Undefined: use -1; LHAPDF: use group = 0).

```
<HEP common: variables>+≡  
integer, dimension(2) :: PDFGUP  
integer, dimension(2) :: PDFSUP
```

The (re)weighting model. 1: events are weighted, the shower generator (SHG) selects processes according to the maximum weight (in pb) and unweights events. 2: events are weighted, the SHG selects processes according to their cross section (in pb) and unweights events. 3: events are unweighted and simply run through the SHG. 4: events are weighted, and the SHG keeps the weight. Negative numbers: negative weights are allowed (and are reweighted to ± 1 by the SHG, if allowed).

WHIZARD only supports modes 3 and 4, as the SHG is not given control over process selection. This is consistent with writing events to file, for offline showering.

```
<HEP common: variables>+≡
  integer :: IDWTUP
```

The number of different processes.

```
<HEP common: variables>+≡
  integer :: NPRUP
```

Process characteristics

Cross section and error in pb. (Cross section is needed only for IDWTUP = 2, so here both values are given for informational purposes only.)

```
<HEP common: variables>+≡
  double precision, dimension(MAXPUP) :: XSECUP
  double precision, dimension(MAXPUP) :: XERRUP
```

Maximum weight, i.e., the maximum value that XWGTUP can take. Also unused for the supported weighting models. It is ± 1 for unweighted events.

```
<HEP common: variables>+≡
  double precision, dimension(MAXPUP) :: XMAXUP
```

Internal ID of the selected process, matches IDPRUP below.

```
<HEP common: variables>+≡
  integer, dimension(MAXPUP) :: LPRUP
```

The common block

```
<HEP common: common blocks>≡
  common /HEPRUP/ &
    IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP, &
    XSECUP, XERRUP, XMAXUP, LPRUP
  save /HEPRUP/
```

Fill the run characteristics of the common block. The initialization sets the beam properties, number of processes, and weighting model.

```
<HEP common: public>≡
  public :: heprup_init
```

```
<HEP common: procedures>≡
  subroutine heprup_init &
    (beam_pdg, beam_energy, n_processes, unweighted, negative_weights)
    integer, dimension(2), intent(in) :: beam_pdg
    real(default), dimension(2), intent(in) :: beam_energy
    integer, intent(in) :: n_processes
    logical, intent(in) :: unweighted
    logical, intent(in) :: negative_weights
    IDBMUP = beam_pdg
    EBMUP = beam_energy
    PDFGUP = -1
    PDFSUP = -1
    if (unweighted) then
      IDWTUP = 3
```

```

else
  IDWTUP = 4
end if
if (negative_weights) IDWTUP = - IDWTUP
NPRUP = n_processes
end subroutine heprup_init

```

Extract parameters from the common block. We leave it to the caller to specify which parameters it actually needs.

PDFGUP and PDFSUP are not extracted. IDWTUP=1,2 are not supported by WHIZARD, but correspond to weighted events.

```

<HEP common: public>+≡
  public :: heprup_get_run_parameters

<HEP common: procedures>+≡
  subroutine heprup_get_run_parameters &
    (beam_pdg, beam_energy, n_processes, unweighted, negative_weights)

```

19.5.5 Run parameter output (other formats)

This routine writes the initialization block according to the LHEF standard. It uses the current contents of the HEPRUP block.

```
<HEP common: public>+≡
    public :: heprup_write_lhef

<HEP common: procedures>+≡
    subroutine heprup_write_lhef (unit)
        integer, intent(in), optional :: unit
        integer :: u, i
        u = output_unit (unit); if (u < 0) return
        write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
            IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
        do i = 1, NPRUP
            write (u, "(3(1x,ES17.10),1x,I0)") &
                XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
        end do
    end subroutine heprup_write_lhef
```

This routine is a complete dummy at the moment. It uses the current contents of the HEPRUP block. At the end, it should depend on certain input flags for the different ASCII event formats.

```
<HEP common: public>+≡
    public :: heprup_write_ascii

<HEP common: procedures>+≡
    subroutine heprup_write_ascii (unit)
        integer, intent(in), optional :: unit
        integer :: u, i
        u = output_unit (unit); if (u < 0) return
        write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
            IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
        do i = 1, NPRUP
            write (u, "(3(1x,ES17.10),1x,I0)") &
                XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
        end do
    end subroutine heprup_write_ascii
```

Run parameter input (LHEF)

In a LHEF file, the parameters are written in correct order on separate lines, but we should not count on the precise format. List-directed input should just work.

```
<HEP common: public>+≡
    public :: heprup_read_lhef

<HEP common: procedures>+≡
    subroutine heprup_read_lhef (u)
        integer, intent(in) :: u
        integer :: i
        read (u, *) &
            IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
```

```

do i = 1, NPRUP
  read (u, *) &
    XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
end do
end subroutine heprup_read_lhef

```

19.5.6 The HEPEUP common block

```

<HEP common: common blocks>+≡
common /HEPEUP/ &
  NUP, IDPRUP, XWGTUP, SCALUP, AQEDUP, AQCDUP, &
  IDUP, ISTUP, MOTHUP, ICOLUP, PUP, VTIMUP, SPINUP
save /HEPEUP/

```

Initialization

Fill the event characteristics of the common block. The initialization sets only the number of particles and initializes the rest with default values. The other routine sets the optional parameters.

```

<HEP common: public>+≡
public :: hepeup_init
public :: hepeup_set_event_parameters

<HEP common: procedures>+≡
subroutine hepeup_init (n_tot)
  integer, intent(in) :: n_tot
  NUP = n_tot
  IDPRUP = 0
  XWGTUP = 1
  SCALUP = -1
  AQEDUP = -1
  AQCDUP = -1
end subroutine hepeup_init

subroutine hepeup_set_event_parameters &
  (proc_id, weight, scale, alpha_qed, alpha_qcd)
  integer, intent(in), optional :: proc_id
  real(default), intent(in), optional :: weight, scale, alpha_qed, alpha_qcd
  if (present (proc_id)) IDPRUP = proc_id
  if (present (weight)) XWGTUP = weight
  if (present (scale)) SCALUP = scale
  if (present (alpha_qed)) AQEDUP = alpha_qed
  if (present (alpha_qcd)) AQCDUP = alpha_qcd
end subroutine hepeup_set_event_parameters

```

Extract event information. The caller determines the parameters.

```

<HEP common: public>+≡
public :: hepeup_get_event_parameters

```

```

<HEP common: procedures>+≡
subroutine hepeup_get_event_parameters &
    (proc_id, weight, scale, alpha_qed, alpha_qcd)
    integer, intent(out), optional :: proc_id
    real(default), intent(out), optional :: weight, scale, alpha_qed, alpha_qcd
    if (present (proc_id)) proc_id = IDPRUP
    if (present (weight)) weight = XWGTUP
    if (present (scale)) scale = SCALUP
    if (present (alpha_qed)) alpha_qed = AQEDUP
    if (present (alpha_qcd)) alpha_qcd = AQCDUP
end subroutine hepeup_get_event_parameters

```

Particle data

Below we need the particle status codes which are actually defined in the subevents module.

Set the entry for a specific particle. All parameters are set with the exception of lifetime and spin, where default values are stored.

```

<HEP common: public>+≡
public :: hepeup_set_particle

<HEP common: procedures>+≡
subroutine hepeup_set_particle (i, pdg, status, parent, col, p, m2)
    integer, intent(in) :: i
    integer, intent(in) :: pdg, status
    integer, dimension(:), intent(in) :: parent
    type(vector4_t), intent(in) :: p
    integer, dimension(2), intent(in) :: col
    real(default), intent(in) :: m2
    if (i > MAXNUP) then
        call msg_error (arr=[ &
            var_str ("Too many particles in HEPEUP common block. " // &
                "If this happened "), &
            var_str ("during event output, your events will be " // &
                "invalid; please consider "), &
            var_str ("switching to a modern event format like HEPMC. " // &
                "If you are not "), &
            var_str ("using an old, HEPEUP based format and " // &
                "nevertheless get this error,"), &
            var_str ("please notify the WHIZARD developers,") ])
        return
    end if

end if
PUP(1:3,i) = vector3_get_components (space_part (p))
PUP(4,i) = energy (p)
PUP(5,i) = sign (sqrt (abs (m2)), m2)
VTIMUP(i) = 0
SPINUP(i) = 9
end subroutine hepeup_set_particle

```

Set the lifetime, actually $c\tau$ measured in mm, where τ is the invariant lifetime.

```

<HEP common: public>+≡
    public :: hepeup_set_particle_lifetime

<HEP common: procedures>+≡
    subroutine hepeup_set_particle_lifetime (i, lifetime)
        integer, intent(in) :: i
        real(default), intent(in) :: lifetime
        VTIMUP(i) = lifetime
    end subroutine hepeup_set_particle_lifetime

```

Set the particle spin entry. We need the cosine of the angle of the spin axis with respect to the three-momentum of the parent particle.

If the particle has a full polarization density matrix given, we need the particle momentum and polarization as well as the mother-particle momentum. The polarization is transformed into a spin vector (which is sensible only for spin-1/2 or massless particles), which then is transformed into the lab frame (by a rotation of the 3-axis to the particle momentum axis). Finally, we compute the scalar product of this vector with the mother-particle three-momentum.

This puts severe restrictions on the applicability of this definition, and Lorentz invariance is lost. Unfortunately, the Les Houches Accord requires this computation.

```

<HEP common: public>+≡
    public :: hepeup_set_particle_spin

<HEP common: interfaces>≡
    interface hepeup_set_particle_spin
        module procedure hepeup_set_particle_spin_pol
    end interface

<HEP common: procedures>+≡
    subroutine hepeup_set_particle_spin_pol (i, p, pol, p_mother)

```

```

integer, intent(in) :: i
type(vector4_t), intent(in) :: p
type(polarization_t), intent(in) :: pol
type(vector4_t), intent(in) :: p_mother
type(vector3_t) :: s3, p3
type(vector4_t) :: s4
s3 = vector3_moving (polarization_get_axis (pol))
p3 = space_part (p)
s4 = rotation_to_2nd (3, p3) * vector4_moving (0._default, s3)
SPINUP(i) = enclosed_angle_ct (s4, p_mother)
end subroutine hepeup_set_particle_spin_pol

```

Extract particle data. The caller decides which ones to retrieve.

Status codes: beam remnants share the status code with virtual particles. However, for the purpose of WHIZARD we should identify them. We use the PDG code for this.

```

<HEP common: public>+≡

      end if
    end subroutine hepeup_get_particle

```

19.5.7 The HEPEVT common block

For the LEP Monte Carlos, a standard common block has been proposed in AKV89. We strongly recommend its use. (The description is an abbreviated transcription of AKV89, Vol. 3, pp. 327-330).

NMXHEP is the maximum number of entries:

```

<HEP common: variables>+≡
  integer, parameter :: NMXHEP = 4000

```

NEVHEP is normally the event number, but may take special values as follows:

0 the program does not keep track of event numbers. -1 a special initialization record. -2 a special final record.

```

<HEP common: variables>+≡
  integer :: NEVHEP

```

NHEP holds the number of entries for this event.

```

<HEP common: variables>+≡
  integer :: NHEP

```

The entry ISTHEP(N) gives the status code for the Nth entry, with the following semantics: 0 a null entry. 1 an existing entry, which has not decayed or fragmented. 2 a decayed or fragmented entry, which is retained for event history information. 3 documentation line. 4- 10 reserved for future standards. 11-200 at the disposal of each model builder. 201- at the disposal of users.

```

<HEP common: variables>+≡
  integer, dimension(NMXHEP) :: ISTHEP

```

The Particle Data Group has proposed standard particle codes, which are to be stored in IDHEP(N).

```

<HEP common: variables>+≡
  integer, dimension(NMXHEP) :: IDHEP

```

JMOHEP(1,N) points to the mother of the Nth entry, if any. It is set to zero for initial entries. JMOHEP(2,N) points to the second mother, if any.

```

<HEP common: variables>+≡
  integer, dimension(2, NMXHEP) :: JMOHEP

```

JDAHEP(1,N) and JDAHEP(2,N) point to the first and last daughter of the Nth entry, if any. These are zero for entries which have not yet decayed. The other daughters are stored in between these two.

```
<HEP common: variables>+≡
    integer, dimension(2, NMXHEP) :: JDAHEP
```

In PHEP we store the momentum of the particle, more specifically this means that PHEP(1,N), PHEP(2,N), and PHEP(3,N) contain the momentum in the x , y , and z direction (as defined by the machine people), measured in GeV/c. PHEP(4,N) contains the energy in GeV and PHEP(5,N) the mass in GeV/ c^2 . The latter may be negative for spacelike partons.

```
<HEP common: variables>+≡
    double precision, dimension(5, NMXHEP) :: PHEP
```

Finally VHEP is the place to store the position of the production vertex. VHEP(1,N), VHEP(2,N), and VHEP(3,N) contain the x , y , and z coordinate (as defined by the machine people), measured in mm. VHEP(4,N) contains the production time in mm/c.

```
<HEP common: variables>+≡
    double precision, dimension(4, NMXHEP) :: VHEP
```

As an amendment to the proposed standard common block HEPEVT, we also have a polarisation common block HEPSPN, as described in AKV89. SHEP(1,N), SHEP(2,N), and SHEP(3,N) give the x , y , and z component of the spinvector s of a fermion in the fermions restframe.

Furthermore, we add the polarization of the corresponding outgoing particles:

```
<HEP common: variables>+≡
    integer, dimension(NMXHEP) :: hepevt_pol
```

By convention, SHEP(4,N) is always 1. All this is taken from StdHep 4.06 manual and written using Fortran90 conventions.

```
<HEP common: common blocks>+≡
    common /HEPEVT/ &
        NEVHEP, NHEP, ISTHEP, IDHEP, &
        JMOHEP, JDAHEP, PHEP, VHEP
    save /HEPEVT/
```

Here we store HEPEVT parameters of the WHIZARD 1 realization which are not part of the HEPEVT common block.

```
<HEP common: variables>+≡
    integer :: hepevt_n_out, hepevt_n_remnants
```

```
<HEP common: variables>+≡
    double precision :: hepevt_weight, hepevt_function_value
    double precision :: hepevt_function_ratio
```

Filling HEPEVT: If the event count is not provided, set NEVHEP to zero. If the event count is -1 or -2, the record corresponds to initialization and finalization, and the event is irrelevant.

Note that the event count may be larger than 2^{31} (2 GEvents). In that case, cut off the upper bits since NEVHEP is probably limited to default integer.

```

<HEP common: public>+≡
  public :: hepevt_init
  public :: hepevt_set_event_parameters

<HEP common: procedures>+≡
  subroutine hepevt_init (n_tot, n_out)
    integer, intent(in) :: n_tot, n_out
    NHEP                = n_tot
    NEVHEP              = 0
    hepevt_n_out        = n_out
    hepevt_n_remnants = 0
    hepevt_weight       = 1
    hepevt_function_value = 0
    hepevt_function_ratio = 1
  end subroutine hepevt_init

  subroutine hepevt_set_event_parameters &
    (weight, function_value, function_ratio, i_evt)
    integer, intent(in), optional :: i_evt
    real(default), intent(in), optional :: weight, function_value, &
      function_ratio
    if (present (i_evt)) NEVHEP = i_evt
    if (present (weight)) hepevt_weight = weight
    if (present (function_value)) hepevt_function_value = &
      function_value
    if (present (function_ratio)) hepevt_function_ratio = &
      function_ratio
  end subroutine hepevt_set_event_parameters

```

Set the entry for a specific particle. All parameters are set with the exception of lifetime and spin, where default values are stored.

```

<HEP common: public>+≡
  public :: hepevt_set_particle

```

This routine writes event output according to the HEPEVT standard. It uses the current contents of the HEPEVT block and some additional parameters according to the standard in WHIZARD 1. For the long ASCII format, the value of the sample function (i.e. the product of squared matrix element, structure functions and phase space factor is printed out). The option of reweighting matrix elements with respect to some reference cross section is not implemented in WHIZARD 2 for this event format, therefore the second entry in the long ASCII format (the function ratio) is always one. The ATHENA format is an implementation of the HEPEVT format that is readable by the ATLAS ATHENA software framework. It is very similar to the WHIZARD 1 HEPEVT format, except that it contains an event counter, a particle counter inside the event, and has the HEPEVT ISTHEP status before the PDG code. The MOKKA format is a special ASCII format that contains the information to be parsed to the MOKKA LC fast simulation software.

19.5.11 Data Transfer: particle sets

The WHIZARD format for handling particle data in events is `particle_set_t`. We have to interface this to the common blocks.

We first create a new particle set that contains only the particles that are supported by the LHEF format. These are: beam, incoming, resonant, outgoing. We drop particles with unknown, virtual or beam-remnant status.

From this set we fill the common block. Event information such as process ID and weight is not transferred here; this has to be done by the caller. The spin information is set only if the particle has a unique mother, and if its polarization is fully defined.

```

<HEP common: public>+≡
    public :: hepeup_from_particle_set

<HEP common: procedures>+≡
    subroutine hepeup_from_particle_set (particle_set, keep_beams)
        type(particle_set_t), intent(in), target :: particle_set

                end select
            end if
        end do
        call particle_set_final (pset_hepevt)
    end subroutine

```

```
end subroutine hepeup_from_particle_set
```

Input. The particle set should be allocated properly, but we replace the particle contents.

If there are no beam particles in the event, we try to reconstruct beam particles and beam remnants. We assume for simplicity that the beam particles, if any, are the first two particles. If they are absent, the first two particles should be the incoming partons.

```
<HEP common: public>+≡
```

```
public :: hepeup_to_particle_set
```

```
<HEP common: procedures>+≡
```

    end if
else
    call msg_bug ("HEPEUP: event incomplete")
end if
end subroutine hepeup_from_event

```

Reverse.

Note: The current implementation sets the particle set of the hard process and is therefore not useful if the event on file is dressed. This should be reconsidered.

Note: setting of scale or alpha is not yet supported by the `event_t` object. Ticket #628.

19.7 LHEF Input/Output

The LHEF event record is standardized. It is an ASCII format. We try our best at using it for both input and output.

Input an event. Upon input of `i_prc`, we can just read in the whole HEPEUP common block. These data are known to come first. The `i_prc` value can be deduced from the IDPRUP value by a table lookup.

Reading the common block bypasses the `cstream` which accesses the input unit. This is consistent with the LHEF specification. After the common-block data have been swallowed, we can resume reading from stream.

We don't catch actual I/O errors. However, we return a negative value in `iostat` if we reached the terminating `</LesHouchesEvents>` tag.

```

```

Since we have already read the event information from file, this input routine can transfer the common-block contents to the event record. Also, we read any further information in the event record.

Since LHEF doesn't give this information, we must assume that the MCI group, term, and channel can all be safely set to 1. This works if there is only one MCI group and term. The channel doesn't matter for the matrix element.

```

        beam_pdg = data%pdg_beam, &
        beam_energy = data%energy_beam)
    if (data%unweighted) then
        data%norm_mode = NORM_UNIT
    else
        data%norm_mode = NORM_SIGMA
    end if
    do i = 1, n_proc
        call heprup_get_process_parameters (i, &
            process_id = data%proc_num_id(i), &
            cross_section = data%cross_section(i), &
            error = data%error(i))
    end do
end subroutine eio_lhef_read_init_10

```

19.7.6 Version-Specific Code: 2.0

This is the init information for the 2.0 format, after the HEPRUP data. We have the following tags:

- **generator** Generator name and version.
- **xsecinfo** Cross section and weights data. We have the total cross section and number of events (assuming that the event file is intact), but information on minimum and maximum weights is not available before the file is complete. We just write the mandatory tags. (Note that the default values of the other tags describe a uniform unit weight, but we can determine most values only after the sample is complete.)
- **cutsinfo** This optional tag is too specific to represent the possibilities of WHIZARD, so we skip it.
- **procinfo** This optional tag is useful for giving details of NLO calculations. Skipped.
- **mergetype** Optional, also not applicable.

```

<EIO LHEF: eio_lhef: TBP>+≡
  procedure :: write_init_20 => eio_lhef_write_init_20

<EIO LHEF: procedures>+≡
  subroutine eio_lhef_write_init_20 (eio, data)

```

This is additional event-specific information for the 3.0 format, after the HEP-EUP data. We can specify weights, starting from the master weight and adding alternative weights. The weight tags are already allocated, so we just have to transfer the weight values to strings, assemble them and write them to file. All weights are collected in a single tag.

Note: If efficiency turns out to be an issue, we may revert to traditional character buffer writing. However, we need to know the maximum length.

```

<EIO LHEF: eio lhef: TBP>+≡
  procedure :: write_event_30 => eio_lhef_write_event_30

<EIO LHEF: procedures>+≡
  subroutine eio_lhef_write_event_30 (eio, event)
    class(eio_lhef_t), intent(in) :: eio

      call eio%tag_weights%write (trim (s), u); write (u, *)
    end if
  end subroutine eio_lhef_write_event_30

```

Read extra event data. If there is a `weights` tag and if there was a `weightinfo` entry labeled `sqme_prc`, we extract the corresponding entry from the weights

string and store this as the event's squared matrix-element value. Other tags, including tags written by the above writer, are skipped.

```

19.8 HepMC events

This section provides the interface to the HepMC C++ library for handling Monte-Carlo events.

Each C++ class of HepMC that we use is mirrored by a Fortran type, which contains as its only component the C pointer to the C++ object.

Each C++ method of HepMC that we use has a C wrapper function. This function takes a pointer to the host object as its first argument. Further arguments are either C pointers, or in the case of simple types (integer, real),

interoperable C/Fortran objects.

The C wrapper functions have explicit interfaces in the Fortran module. They are called by Fortran wrapper procedures. These are treated as methods of the corresponding Fortran type.

```

<hepmc_interface.f90>≡
  <File header>

  module hepmc_interface

    use iso_c_binding !NODEP!
    <Use kinds>
    <Use strings>
    <Use file utils>
    use constants !NODEP!
    use lorentz !NODEP!
    use unit_tests
    use models
    use flavors
    use colors
    use helicities
    use quantum_numbers
    use polarizations

    <Standard module head>

    <HepMC interface: public>

    <HepMC interface: types>

    <HepMC interface: interfaces>

    contains

    <HepMC interface: procedures>

    <HepMC interface: tests>

  end module hepmc_interface

```

19.8.1 Interface check

This function can be called in order to verify that we are using the actual HepMC library, and not the dummy version.

```

<HepMC interface: interfaces>≡
  interface
    logical(c_bool) function hepmc_available () bind(C)
      import
    end function hepmc_available
  end interface

  <HepMC interface: public>≡
    public :: hepmc_is_available

```

```

<HepMC interface: procedures>≡
  function hepmc_is_available () result (flag)
    logical :: flag
    flag = hepmc_available ()
  end function hepmc_is_available

```

19.8.2 FourVector

The C version of four-vectors is often transferred by value, and the associated procedures are all inlined. The wrapper needs to transfer by reference, so we create FourVector objects on the heap which have to be deleted explicitly. The input is a `vector4_t` or `vector3_t` object from the `lorentz` module.

```

<HepMC interface: public>+≡
  public :: hepmc_four_vector_t

<HepMC interface: types>≡
  type :: hepmc_four_vector_t
  private
  type(c_ptr) :: obj
  end type hepmc_four_vector_t

```

In the C constructor, the zero-component (fourth argument) is optional; if missing, it is set to zero. The Fortran version has initializer form and takes either a three-vector or a four-vector. A further version extracts the four-vector from a HepMC particle object.

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_four_vector_xyz (x, y, z) bind(C)
      import
      real(c_double), value :: x, y, z
    end function new_four_vector_xyz
  end interface
  interface

    end subroutine hepmc_four_vector_to_vector4

```

19.8.3 Polarization

Polarization objects are temporarily used for assigning particle polarization. We add a flag `polarized`. If this is false, the polarization is not set and should not be transferred to `hepmc_particle` objects.

```

<HepMC interface: public>+≡
    public :: hepmc_polarization_t
<HepMC interface: types>+≡
    type :: hepmc_polarization_t
        private
        logical :: polarized = .false.
        type(c_ptr) :: obj
    end type hepmc_polarization_t

```

Constructor. The C wrapper takes polar and azimuthal angle as arguments. The Fortran version allows for either a complete polarization density matrix, or for a definite (diagonal) helicity.

HepMC does not allow to specify the degree of polarization, therefore we have to map it to either 0 or 1. We choose 0 for polarization less than 0.5 and 1 for polarization greater than 0.5. Even this simplification works only for spin-1/2 and for massless particles; massive vector bosons cannot be treated this way. In particular, zero helicity is always translated as unpolarized.

```

(HepMC interface: interfaces)+≡
  interface
    type(c_ptr) function new_polarization (theta, phi) bind(C)
      import
      real(c_double), value :: theta, phi

```

19.8.6 Vertex-particle-in iterator

This iterator iterates over all incoming particles in an vertex. We store a pointer to the vertex in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

```

<HepMC interface: public>+≡
  public :: hepmc_vertex_particle_in_iterator_t

<HepMC interface: types>+≡
  type :: hepmc_vertex_particle_in_iterator_t
  private
  type(c_ptr) :: obj
  type(c_ptr) :: v_obj
end type hepmc_vertex_particle_in_iterator_t

```

Constructor. The iterator is initialized at the first particle in the vertex.

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function &
      new_vertex_particles_in_const_iterator (v_obj) bind(C)
    import
    type(c_ptr), value :: v_obj
    end function new_vertex_particles_in_const_iterator
  end interface

<HepMC interface: public>+≡
  public :: hepmc_vertex_particle_in_iterator_init

<HepMC interface: procedures>+≡
  subroutine hepmc_vertex_particle_in_iterator_init (it, v)
    type(hepmc_vertex_particle_in_iterator_t), intent(out) :: it
    type(hepmc_vertex_t), intent(in) :: v
    it%obj = new_vertex_particles_in_const_iterator (v%obj)
    it%v_obj = v%obj
  end subroutine hepmc_vertex_particle_in_iterator_init

```

Destructor. Necessary because the iterator is allocated on the heap.

```

<HepMC interface: interfaces>+≡
  interface
    subroutine vertex_particles_in_const_iterator_delete (it_obj) bind(C)
    import
    type(c_ptr), value :: it_obj
    end subroutine vertex_particles_in_const_iterator_delete
  end interface

```

```

<HepMC interface: public>+≡
    public :: hepmc_vertex_particle_in_iterator_final

19.8.8 GenEvent

The main object of HepMC is a GenEvent. The object is filled by GenVertex objects, which in turn contain GenParticle objects.

```
<HepMC interface: public>+≡
  public :: hepmc_event_t

<HepMC interface: types>+≡
  type :: hepmc_event_t
  private
  type(c_ptr) :: obj
end type hepmc_event_t
```

Constructor. Arguments are process ID (integer) and event ID (integer).

The Fortran version has initializer form.

```
<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_gen_event (proc_id, event_id) bind(C)
    import
    integer(c_int), value :: proc_id, event_id
    end function new_gen_event
  end interface

<HepMC interface: public>+≡
  public :: hepmc_event_init

<HepMC interface: procedures>+≡
  subroutine hepmc_event_init (evt, proc_id, event_id)
    type(hepmc_event_t), intent(out) :: evt
    integer, intent(in), optional :: proc_id, event_id
    integer(c_int) :: pid, eid
    pid = 0; if (present (proc_id)) pid = proc_id
    eid = 0; if (present (event_id)) eid = event_id
    evt%obj = new_gen_event (pid, eid)
  end subroutine hepmc_event_init
```

Destructor.

```
<HepMC interface: interfaces>+≡
  interface
    subroutine gen_event_delete (evt_obj) bind(C)
    import
    type(c_ptr), value :: evt_obj
    end subroutine gen_event_delete
  end interface

```

```
end interface
```

19.8.9 Event-particle iterator

This iterator iterates over all particles in an event. We store a pointer to the event in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

```
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_t
<HepMC interface: types>+≡
  type :: hepmc_event_particle_iterator_t
  private
    type(c_ptr) :: obj
    type(c_ptr) :: evt_obj
  end type hepmc_event_particle_iterator_t
```

Constructor. The iterator is initialized at the first particle in the event.

```
<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_event_particle_const_iterator (evt_obj) bind(C)
    import
      type(c_ptr), value :: evt_obj
    end function new_event_particle_const_iterator
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_init
<HepMC interface: procedures>+≡
  subroutine hepmc_event_particle_iterator_init (it, evt)
    type(hepmc_event_particle_iterator_t), intent(out) :: it
    type(hepmc_event_t), intent(in) :: evt
    it%obj = new_event_particle_const_iterator (evt%obj)
    it%evt_obj = evt%obj
  end subroutine hepmc_event_particle_iterator_init
```

Destructor. Necessary because the iterator is allocated on the heap.

```
<HepMC interface: interfaces>+≡
  interface
    subroutine event_particle_const_iterator_delete (it_obj) bind(C)
    import
      type(c_ptr), value :: it_obj
    end subroutine event_particle_const_iterator_delete
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_final
<HepMC interface: procedures>+≡
  subroutine hepmc_event_particle_iterator_final (it)
    type(hepmc_event_particle_iterator_t), intent(inout) :: it
    call event_particle_const_iterator_delete (it%obj)
  end subroutine hepmc_event_particle_iterator_final
```

Increment

```
<HepMC interface: interfaces>+≡
  interface
    subroutine event_particle_const_iterator_advance (it_obj) bind(C)
      import
      type(c_ptr), value :: it_obj
    end subroutine event_particle_const_iterator_advance
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_advance
<HepMC interface: procedures>+≡
  subroutine hepmc_event_particle_iterator_advance (it)
    type(hepmc_event_particle_iterator_t), intent(inout) :: it
    call event_particle_const_iterator_advance (it%obj)
  end subroutine hepmc_event_particle_iterator_advance
```

Reset to the beginning

```
<HepMC interface: interfaces>+≡
  interface
    subroutine event_particle_const_iterator_reset (it_obj, evt_obj) bind(C)
      import
      type(c_ptr), value :: it_obj, evt_obj
    end subroutine event_particle_const_iterator_reset
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_reset
<HepMC interface: procedures>+≡
  subroutine hepmc_event_particle_iterator_reset (it)
    type(hepmc_event_particle_iterator_t), intent(inout) :: it
    call event_particle_const_iterator_reset (it%obj, it%evt_obj)
  end subroutine hepmc_event_particle_iterator_reset
```

Test: return true as long as we are not past the end.

```
<HepMC interface: interfaces>+≡
  interface
    function event_particle_const_iterator_is_valid &
      (it_obj, evt_obj) result (flag) bind(C)
      import
      logical(c_bool) :: flag
      type(c_ptr), value :: it_obj, evt_obj
    end function event_particle_const_iterator_is_valid
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_is_valid
<HepMC interface: procedures>+≡
  function hepmc_event_particle_iterator_is_valid (it) result (flag)
    logical :: flag
    type(hepmc_event_particle_iterator_t), intent(in) :: it
    flag = event_particle_const_iterator_is_valid (it%obj, it%evt_obj)
  end function hepmc_event_particle_iterator_is_valid
```

Return the particle pointed to by the iterator. (The particle object should not be finalized, since it contains merely a pointer to the particle which is owned by the vertex.)

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function event_particle_const_iterator_get (it_obj) bind(C)
    import
    type(c_ptr), value :: it_obj
    end function event_particle_const_iterator_get
  end interface
<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_get
<HepMC interface: procedures>+≡
  function hepmc_event_particle_iterator_get (it) result (prt)
    type(hepmc_particle_t) :: prt
    type(hepmc_event_particle_iterator_t), intent(in) :: it
    prt%obj = event_particle_const_iterator_get (it%obj)
  end function hepmc_event_particle_iterator_get

```

19.8.10 I/O streams

There is a specific I/O stream type for handling the output of GenEvent objects (i.e., Monte Carlo event samples) to file. Opening the file is done by the constructor, closing by the destructor.

```

<HepMC interface: public>+≡
  public :: hepmc_iostream_t
<HepMC interface: types>+≡
  type :: hepmc_iostream_t
  private
  type(c_ptr) :: obj
  end type hepmc_iostream_t

```

Constructor for an output stream associated to a file.

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_io_gen_event_out (filename) bind(C)
    import
    character(c_char), dimension(*), intent(in) :: filename
    end function new_io_gen_event_out
  end interface
<HepMC interface: public>+≡
  public :: hepmc_iostream_open_out
<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_open_out (iostream, filename)
    type(hepmc_iostream_t), intent(out) :: iostream
    type(string_t), intent(in) :: filename
    iostream%obj = new_io_gen_event_out (char (filename) // c_null_char)
  end subroutine hepmc_iostream_open_out

```

Constructor for an input stream associated to a file.

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_io_gen_event_in (filename) bind(C)
    import
      character(c_char), dimension(*), intent(in) :: filename
    end function new_io_gen_event_in
  end interface
<HepMC interface: public>+≡
  public :: hepmc_iostream_open_in
<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_open_in (iostream, filename)
    type(hepmc_iostream_t), intent(out) :: iostream
    type(string_t), intent(in) :: filename
    iostream%obj = new_io_gen_event_in (char (filename) // c_null_char)
  end subroutine hepmc_iostream_open_in

```

Destructor:

```

<HepMC interface: interfaces>+≡
  interface
    subroutine io_gen_event_delete (io_obj) bind(C)
    import
      type(c_ptr), value :: io_obj
    end subroutine io_gen_event_delete
  end interface
<HepMC interface: public>+≡
  public :: hepmc_iostream_close
<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_close (iostream)
    type(hepmc_iostream_t), intent(inout) :: iostream
    call io_gen_event_delete (iostream%obj)
  end subroutine hepmc_iostream_close

```

Write a single event to the I/O stream.

```

<HepMC interface: interfaces>+≡
  interface
    subroutine io_gen_event_write_event (io_obj, evt_obj) bind(C)
    import
      type(c_ptr), value :: io_obj, evt_obj
    end subroutine io_gen_event_write_event
  end interface
<HepMC interface: public>+≡
  public :: hepmc_iostream_write_event
<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_write_event (iostream, evt)
    type(hepmc_iostream_t), intent(inout) :: iostream
    type(hepmc_event_t), intent(in) :: evt
    call io_gen_event_write_event (iostream%obj, evt%obj)
  end subroutine hepmc_iostream_write_event

```

Read a single event from the I/O stream. Return true if successful.

```

<HepMC interface: interfaces>+≡
  interface
    logical(c_bool) function io_gen_event_read_event (io_obj, evt_obj) bind(C)
    import
    type(c_ptr), value :: io_obj, evt_obj
    end function io_gen_event_read_event
  end interface
<HepMC interface: public>+≡
  public :: hepmc_iostream_read_event
<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_read_event (iostream, evt, ok)
    type(hepmc_iostream_t), intent(inout) :: iostream
    type(hepmc_event_t), intent(in) :: evt
    logical, intent(out) :: ok
    ok = io_gen_event_read_event (iostream%obj, evt%obj)
  end subroutine hepmc_iostream_read_event

```

19.8.11 Unit tests

This test example is an abridged version from the build-from-scratch example in the HepMC distribution. We create two vertices for $p \rightarrow q$ PDF splitting, then a vertex for a $qq \rightarrow W^- g$ hard-interaction process, and finally a vertex for $W^- \rightarrow qq$ decay. The setup is for LHC kinematics.

Extending the original example, we set color flow for the incoming quarks and polarization for the outgoing photon. For the latter, we have to define a particle-data object for the photon, so a flavor object can be correctly initialized.

```

<HepMC interface: public>+≡
  public :: hepmc_test

19.9 HepMC Output

The HepMC event record is standardized. It is an ASCII format. We try our best at using it for both input and output.

```

19.11 STDHEP File Formats

Here, we implement the two existing STDHEP file formats, one based on the HEPRUP/HEPEUP common blocks, the other based on the HEPEVT common block. The second one is actually the standard STDHEP format.

```

<eio_stdhep.f90>≡
  <File header>

  module eio_stdhep

    use kinds !NODEP!
    <Use file utils>
    <Use strings>
    use diagnostics !NODEP!
    use unit_tests

```

```

    use lorentz !NODEP!
    use models
    use particles
    use beams
    use processes
    use events
    use eio_data
    use eio_base
    use hep_common
    use hep_events

    <Standard module head>

    <EIO stdhep: public>

    <EIO stdhep: types>

    <EIO stdhep: variables>

    contains

    <EIO stdhep: procedures>

    <EIO stdhep: tests>

    end module eio_stdhep

```

19.11.1 Type

```

<EIO stdhep: public>≡
    public :: eio_stdhep_t

<EIO stdhep: types>≡
    type, abstract, extends (eio_t) :: eio_stdhep_t
        logical :: writing = .false.
        integer :: unit = 0
        logical :: keep_beams = .false.
        integer(i64) :: n_events_expected = 0
    contains
        <EIO stdhep: eio stdhep: TBP>
    end type eio_stdhep_t

<EIO stdhep: public>+≡
    public :: eio_stdhep_hepevt_t

<EIO stdhep: types>+≡
    type, extends (eio_stdhep_t) :: eio_stdhep_hepevt_t
    end type eio_stdhep_hepevt_t

<EIO stdhep: public>+≡
    public :: eio_stdhep_hepeup_t

```

```

<EIO stdhep: types>+≡
  type, extends (eio_stdhep_t) :: eio_stdhep_hepeup_t
end type eio_stdhep_hepeup_t

```

19.11.2 Specific Methods

Set parameters that are specifically used with STDHEP file formats.

```

<EIO stdhep: eio stdhep: TBP>≡
  procedure :: set_parameters => eio_stdhep_set_parameters

<EIO stdhep: procedures>≡
  subroutine eio_stdhep_set_parameters (eio, keep_beams, extension)
    class(eio_stdhep_t), intent(inout) :: eio
    logical, intent(in), optional :: keep_beams
    type(string_t), intent(in), optional :: extension
    if (present (keep_beams)) eio%keep_beams = keep_beams
    if (present (extension)) then
      eio%extension = extension
    else
      select type (eio)
        type is (eio_stdhep_hepevt_t)
          eio%extension = "stdhep"
        type is (eio_stdhep_hepeup_t)
          eio%extension = "up.stdhep"
      end select
    end if
  end subroutine eio_stdhep_set_parameters

```

19.11.3 Common Methods

Output. This is not the actual event format, but a readable account of the current object status.

```

<EIO stdhep: eio stdhep: TBP>+≡
  procedure :: write => eio_stdhep_write

<EIO stdhep: procedures>+≡

Output an event. Write first the event indices, then weight and two values of the squared matrix element: `sqme_ref` is the value stored in the event record, and `sqme_prc` is the one stored in the process instance. (They can differ: when recalculating, the former is read from file and the latter is the result of the new calculation.)

For the alternative entries, the `sqme` value is always obtained by a new calculation, and thus qualifies as `sqme_prc`.

```

20.0.5 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

<SLHA: parameters>≡

```
integer, parameter :: MODE_SKIP = 0, MODE_DATA = 1, MODE_INFO = 2
```

<SLHA: procedures>≡

```
subroutine slha_preprocess (stream, ifile)
  type(stream_t), intent(inout), target :: stream
  type(ifile_t), intent(out) :: ifile
  type(string_t) :: buffer, line, item
  integer :: iostat
  integer :: mode
  mode = MODE
  SCAN_FILE: do
    call stream_get_record (stream, buffer, iostat)
    select case (iostat)
    case (0)
      call split (buffer, line, "#")
      if (len_trim (line) == 0) cycle SCAN_FILE
      select case (char (extract (line, 1, 1)))
      case ("B", "b")
        mode = check_block_handling (line)
        call ifile_append (ifile, line // "$")
      case ("D", "d")
        mode = MODE_DATA
        call ifile_append (ifile, line // "$")
      case (" ")
        select case (mode)
        case (MODE_DATA)

        call ifile_append (ifile, "KEY '-'")
        call ifile_append (ifile, "KEY '+'")
        call ifile_append (ifile, "SEQ block_info = INFO info_line '$'")
    end subroutine define_slha_syntax

```

```

call ifile_append (ifile, "KEY INFO")
call ifile_append (ifile, "SEQ info_line = integer string_literal")
call ifile_append (ifile, "QUO string_literal = '""'...'""')
call ifile_append (ifile, "SEQ decay_def = " &
    // "DECAY decay_spec '$' decay_data*")
call ifile_append (ifile, "KEY DECAY")
call ifile_append (ifile, "SEQ decay_spec = pdg_code data_item")
call ifile_append (ifile, "ALT pdg_code = signed_integer | integer")
call ifile_append (ifile, "SEQ signed_integer = sign integer")
call ifile_append (ifile, "SEQ decay_data = DATA decay_line '$'")
call ifile_append (ifile, "SEQ decay_line = data_item integer pdg_code+")
end subroutine define_slha_syntax

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

```

<SLHA: public>+≡
    public :: lexer_init_slha

<SLHA: procedures>+≡
    subroutine lexer_init_slha (lexer)
        type(lexer_t), intent(out) :: lexer
        call lexer_init (lexer, &
            comment_chars = "#", &
            quote_chars = "'", &
            quote_match = "'", &
            single_chars = "+-=$", &
            special_class = [ "" ], &
            keyword_list = syntax_get_keyword_list_ptr (syntax_slha), &
            upper_case_keywords = .true.) ! $
    end subroutine lexer_init_slha

```

20.0.7 Interpreter

Find blocks

From the parse tree, find the node that represents a particular block. If **required** is true, issue an error if not found. Since **block_name** is always invoked with capital letters, we have to capitalize **pn_block_name**.

```

<SLHA: procedures>+≡
    function slha_get_block_ptr &
        (parse_tree, block_name, required) result (pn_block)
        type(parse_node_t), pointer :: pn_block
        type(parse_tree_t), intent(in) :: parse_tree
        type(string_t), intent(in) :: block_name
        logical, intent(in) :: required
        type(parse_node_t), pointer :: pn_root, pn_block_spec, pn_block_name
        pn_root => parse_tree_get_root_ptr (parse_tree)
        pn_block => parse_node_get_sub_ptr (pn_root)
        do while (associated (pn_block))
            select case (char (parse_node_get_rule_key (pn_block)))

```

```

        case ("block_def")
            pn_block_spec => parse_node_get_sub_ptr (pn_block, 2)
            pn_block_name => parse_node_get_sub_ptr (pn_block_spec)

Transfer data from variables to SLHA

Get a real/integer parameter with index i from the variable list and write it to the current output file. In the integer case, we account for the fact that the variable is type real. If it does not exist, do nothing.

(SLHA: procedures)+≡

```
subroutine write_integer_data_item (u, code, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  integer :: item
  if (var_list_exists (var_list, name)) then
    item = nint (var_list_get_rval (var_list, name))
    call write_integer_parameter (u, code, item, comment)
  end if
end subroutine write_integer_data_item

subroutine write_real_data_item (u, code, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  real(default) :: item
  if (var_list_exists (var_list, name)) then
    item = var_list_get_rval (var_list, name)
    call write_real_parameter (u, code, item, comment)
  end if
end subroutine write_real_data_item
```

Get a real data item with two integer indices from the variable list and write it to the current output file. If it does not exist, do nothing.

<SLHA: procedures>+≡

```
subroutine write_matrix_element (u, code1, code2, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code1, code2
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  real(default) :: item
  if (var_list_exists (var_list, name)) then
    item = var_list_get_rval (var_list, name)
    call write_real_matrix_element (u, code1, code2, item, comment)
  end if
end subroutine write_matrix_element
```

20.0.8 Auxiliary function

Write a block header.

<SLHA: procedures>+≡

```
subroutine write_block_header (u, name, comment)
  integer, intent(in) :: u
  character(*), intent(in) :: name, comment
  write (u, "(A,1x,A,3x,'#',1x,A)") "BLOCK", name, comment
end subroutine write_block_header
```

Extract a real parameter that may be defined real or integer, signed or unsigned.

<SLHA: procedures>+≡

```
function get_real_parameter (pn_item) result (var)
  real(default) :: var
  type(parse_node_t), intent(in), target :: pn_item
  type(parse_node_t), pointer :: pn_sign, pn_var
  integer :: sign
  select case (char (parse_node_get_rule_key (pn_item)))
  case ("signed_number")

SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is not defined in the block, we use the previous value from the model variable list. For the basic parameters we have to do a small recalculation, since SLHA uses the G_F - α - m_Z scheme, while WHIZARD derives them from G_F , m_W , and m_Z .

Chapter 21

NLO infrastructure

21.1 BLHA interface

These modules implement the communication with one loop matrix element providers according to the Binoth LesHouches Accord Interface. The actual matrix element(s) are loaded as a dynamic library.

The module is split into a configuration interface which manages configuration and handles the request and contract files, a module which interfaces the OLP matrix elements and a driver.

Chapter 22

Integration and simulation

This layer of modules is just below the top-level API. We lay out specific data types for integration and simulation and implement the corresponding algorithms as methods acting on them. This helps to keep the command-level implementation concise and simple.

22.1 Iterations

This module defines a container for the list of iterations and calls, to be submitted to integration.

```
<iterations.f90>≡  
  <File header>  
  
  module iterations  
  
    <Use strings>  
    <Use file utils>  
    use diagnostics !NODEP!  
    use unit_tests  
    use processes  
  
    <Standard module head>  
  
    <Iterations: public>  
  
    <Iterations: types>  
  
    contains  
  
    <Iterations: procedures>  
  
    <Iterations: tests>  
  
  end module iterations
```

22.1.1 The iterations list

Each integration pass has a number of iterations and a number of calls per iteration. The last pass produces the end result; the previous passes are used for adaptation.

The flags `adapt_grid` and `adapt_weight` are used only if `custom_adaptation` is set. Otherwise, default settings are used that depend on the integration pass.

```
<Iterations: types>≡
  type :: iterations_spec_t
  private
  integer :: n_it = 0
  integer :: n_calls = 0
  logical :: custom_adaptation = .false.
  logical :: adapt_grids = .false.
  logical :: adapt_weights = .false.
end type iterations_spec_t
```

We build up a list of iterations.

```
<Iterations: public>≡
  public :: iterations_list_t

<Iterations: types>+≡
  type :: iterations_list_t
  private
  integer :: n_pass = 0
  type(iterations_spec_t), dimension(:), allocatable :: pass
  contains
  <Iterations: iterations list: TBP>
end type iterations_list_t
```

Initialize an iterations list. For each pass, we have to specify the number of iterations and calls. We may provide the adaption conventions explicitly, either as character codes or as logicals.

For passes where the adaptation conventions are not specified, we use the following default setting: adapt weights and grids for all passes except the last one.

```
<Iterations: iterations list: TBP>≡
  procedure :: init => iterations_list_init

<Iterations: procedures>≡
  subroutine iterations_list_init &
    (it_list, n_it, n_calls, adapt, adapt_code, adapt_grids, adapt_weights)
    class(iterations_list_t), intent(inout) :: it_list
    integer, dimension(:), intent(in) :: n_it, n_calls
    logical, dimension(:), intent(in), optional :: adapt
    type(string_t), dimension(:), intent(in), optional :: adapt_code
    logical, dimension(:), intent(in), optional :: adapt_grids, adapt_weights
    integer :: i
    it_list%n_pass = size(n_it)
    if (allocated(it_list%pass)) deallocate(it_list%pass)
    allocate(it_list%pass(it_list%n_pass))
    it_list%pass%n_it = n_it
    it_list%pass%n_calls = n_calls
```

```

if (present (adapt)) then
  it_list%pass%custom_adaptation = adapt
  do i = 1, it_list%n_pass
    if (adapt(i)) then
      if (verify (adapt_code(i), "wg") /= 0) then
        call msg_error ("iteration specification: " &
          // "adaptation code letters must be 'w' or 'g'")
      end if
      it_list%pass(i)%adapt_grids = scan (adapt_code(i), "g") /= 0
      it_list%pass(i)%adapt_weights = scan (adapt_code(i), "w") /= 0
    end if
  end do
else if (present (adapt_grids) .and. present (adapt_weights)) then
  it_list%pass%custom_adaptation = .true.
  it_list%pass%adapt_grids = adapt_grids
  it_list%pass%adapt_weights = adapt_weights
end if
do i = 1, it_list%n_pass - 1
  if (.not. it_list%pass(i)%custom_adaptation) then
    it_list%pass(i)%adapt_grids = .true.
    it_list%pass(i)%adapt_weights = .true.
  end if
end do
end subroutine iterations_list_init

```

<Iterations: iterations list: TBP>+≡

```

  function iterations_list_get_n_pass (it_list) result (n_pass)
    class(iterations_list_t), intent(in) :: it_list
    integer :: n_pass
    n_pass = it_list%n_pass
  end function iterations_list_get_n_pass

```

Return the number of calls for a specific pass.

```

<Iterations: iterations list: TBP>+≡
  procedure :: get_n_calls => iterations_list_get_n_calls

<Iterations: procedures>+≡
  function iterations_list_get_n_calls (it_list, pass) result (n_calls)
    class(iterations_list_t), intent(in) :: it_list
    integer :: n_calls
    integer, intent(in) :: pass
    if (pass <= it_list%n_pass) then
      n_calls = it_list%pass(pass)%n_calls
    else
      n_calls = 0
    end if
  end function iterations_list_get_n_calls

```

Get the adaptation mode (automatic/custom) and, for custom adaptation, the flags for a specific pass.

```

<Iterations: iterations list: TBP>+≡
    procedure :: adapt_grids => iterations_list_adapt_grids
    procedure :: adapt_weights => iterations_list_adapt_weights

<Iterations: procedures>+≡
    function iterations_list_adapt_grids (it_list, pass) result (flag)
        logical :: flag
        class(iterations_list_t), intent(in) :: it_list
        integer, intent(in) :: pass
        if (pass <= it_list%n_pass) then
            flag = it_list%pass(pass)%adapt_grids
        else
            flag = .false.
        end if
    end function iterations_list_adapt_grids

    function iterations_list_adapt_weights (it_list, pass) result (flag)
        logical :: flag
        class(iterations_list_t), intent(in) :: it_list
        integer, intent(in) :: pass
        if (pass <= it_list%n_pass) then
            flag = it_list%pass(pass)%adapt_weights
        else
            flag = .false.
        end if
    end function iterations_list_adapt_weights

```

Return the total number of iterations / the iterations for a specific pass.

```

<Iterations: iterations list: TBP>+≡
    procedure :: get_n_it => iterations_list_get_n_it

<Iterations: procedures>+≡
    function iterations_list_get_n_it (it_list, pass) result (n_it)
        class(iterations_list_t), intent(in) :: it_list
        integer :: n_it
        integer, intent(in) :: pass
        if (pass <= it_list%n_pass) then
            n_it = it_list%pass(pass)%n_it
        else
            n_it = 0
        end if
    end function iterations_list_get_n_it

```

22.1.3 Test

This is the master for calling self-test procedures.

```

<Iterations: public>+≡
    public :: iterations_test

```

```

<Iterations: tests>≡
  subroutine iterations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Iterations: execute tests>
  end subroutine iterations_test

```

Empty list

```

<Iterations: execute tests>≡
  call test (iterations_1, "iterations_1", &
    "empty iterations list", &
    u, results)

<Iterations: tests>+≡
  subroutine iterations_1 (u)
    integer, intent(in) :: u
    type(iterations_list_t) :: it_list

    write (u, "(A)")  "* Test output: iterations_1"
    write (u, "(A)")  "* Purpose: display empty iterations list"
    write (u, "(A)")

    call it_list%write (u)

    write (u, "(A)")
    write (u, "(A)")  "* Test output end: iterations_1"

  end subroutine iterations_1

```

Fill list

```

<Iterations: execute tests>+≡
  call test (iterations_2, "iterations_2", &
    "create iterations list", &
    u, results)

<Iterations: tests>+≡
  subroutine iterations_2 (u)
    integer, intent(in) :: u
    type(iterations_list_t) :: it_list

    write (u, "(A)")  "* Test output: iterations_2"
    write (u, "(A)")  "* Purpose: fill and display iterations list"
    write (u, "(A)")

    write (u, "(A)")  "* Minimal setup (2 passes)"
    write (u, "(A)")

    call it_list%init ([2, 4], [5000, 20000])

    call it_list%write (u)
    call it_list%clear ()

```

```

write (u, "(A)")
write (u, "(A)")  "* Setup with flags (3 passes)"
write (u, "(A)")

call it_list%init ([2, 4, 5], [5000, 20000, 400], &
    [.false., .true., .true.], &
    [var_str (""), var_str ("g"), var_str ("wg")])

call it_list%write (u)

write (u, "(A)")
write (u, "(A)")  "* Extract data"
write (u, "(A)")

write (u, "(A,I0)")  "n_pass = ", it_list%get_n_pass ()
write (u, "(A)")
write (u, "(A,I0)")  "n_calls(2) = ", it_list%get_n_calls (2)
write (u, "(A)")
write (u, "(A,I0)")  "n_it(3) = ", it_list%get_n_it (3)

write (u, "(A)")
write (u, "(A)")  "* Test output end: iterations_2"

end subroutine iterations_2

```

22.2 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```

⟨user_files.f90⟩≡
  ⟨File header⟩

  module user_files

    ⟨Use strings⟩
    ⟨Use file utils⟩
    use diagnostics !NODEP!
    use ifiles
    use analysis

    ⟨Standard module head⟩

    ⟨User files: public⟩

    ⟨User files: types⟩

    ⟨User files: interfaces⟩

    contains

```

<User files: procedures>

```
end module user_files
```

22.2.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡
  type :: file_t
    private
    type(string_t) :: name
    integer :: unit = -1
    logical :: reading = .false.
    logical :: writing = .false.
    type(file_t), pointer :: prev => null ()
    type(file_t), pointer :: next => null ()
  end type file_t
```

The initializer opens the file.

```
<User files: procedures>≡
  subroutine file_init (file, name, action, status, position)
    type(file_t), intent(out) :: file
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    file%unit = free_unit ()
    file%name = name
    open (unit = file%unit, file = char (file%name), &
          action = action, status = status, position = position)
    select case (action)
    case ("read")
      file%reading = .true.
    case ("write")
      file%writing = .true.
    case ("readwrite")
      file%reading = .true.
      file%writing = .true.
    end select
  end subroutine file_init
```

The finalizer closes it.

```
<User files: procedures>+≡
  subroutine file_final (file)
    type(file_t), intent(inout) :: file
    close (unit = file%unit)
    file%unit = -1
  end subroutine file_final
```

Check if a file is open with correct status.

```
<User files: procedures>+≡
```

```

function file_is_open (file, action) result (flag)
  logical :: flag
  type(file_t), intent(in) :: file
  character(*), intent(in) :: action
  select case (action)
  case ("read")
    flag = file%reading
  case ("write")
    flag = file%writing
  case ("readwrite")
    flag = file%reading .and. file%writing
  case default
    call msg_bug ("Checking file '" // char (file%name) &
      // "' : illegal action specifier")
  end select
end function file_is_open

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the **advancing** option.

```

<User files: procedures>+≡
subroutine file_write_string (file, string, advancing)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: string
  logical, intent(in), optional :: advancing
  if (file%writing) then
    if (present (string)) then
      if (present (advancing)) then
        if (advancing) then
          write (file%unit, "(A)") char (string)
        else
          write (file%unit, "(A)", advance="no") char (string)
        end if
      else
        write (file%unit, "(A)") char (string)
      end if
    else
      write (file%unit, *)
    end if
  else
    call msg_error ("Writing to file: File '" // char (file%name) &
      // "' is not open for writing.")
  end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
subroutine file_write_ifile (file, ifile)
  type(file_t), intent(in) :: file
  type(ifile_t), intent(in) :: ifile
  type(line_p) :: line
  call line_init (line, ifile)
  do while (line_is_associated (line))
    call file_write_string (file, line_get_string_advance (line))
  end do
end subroutine file_write_ifile

```

```

        end do
    end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
    subroutine file_write_analysis (file, tag)
        type(file_t), intent(in) :: file
        type(string_t), intent(in), optional :: tag
        if (file%writing) then
            if (present (tag)) then
                call analysis_write (tag, unit = file%unit)
            else
                call analysis_write (unit = file%unit)
            end if
        else
            call msg_error ("Writing analysis to file: File ' " // char (file%name) &
                // "' is not open for writing.")
        end if
    end subroutine file_write_analysis

```

22.2.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
    public :: file_list_t

<User files: types>+≡
    type :: file_list_t
        type(file_t), pointer :: first => null ()
        type(file_t), pointer :: last => null ()
    end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
    public :: file_list_final

<User files: procedures>+≡
    subroutine file_list_final (file_list)
        type(file_list_t), intent(inout) :: file_list
        type(file_t), pointer :: current
        do while (associated (file_list%first))
            current => file_list%first
            file_list%first => current%next
            call file_final (current)
            deallocate (current)
        end do
        file_list%last => null ()
    end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```
<User files: procedures>+≡
function file_list_get_file_ptr (file_list, name) result (current)
    type(file_t), pointer :: current
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    current => file_list%first
    do while (associated (current))
        if (current%name == name) return
        current => current%next
    end do
end function file_list_get_file_ptr
```

Check if a file is open, public version:

```
<User files: public>+≡
public :: file_list_is_open

<User files: procedures>+≡
function file_list_is_open (file_list, name, action) result (flag)
    logical :: flag
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action
    type(file_t), pointer :: current
    current => file_list_get_file_ptr (file_list, name)
    if (associated (current)) then
        flag = file_is_open (current, action)
    else
        flag = .false.
    end if
end function file_list_is_open
```

Append a new file entry, i.e., open this file. Error if it is already open.

```
<User files: public>+≡
public :: file_list_open

<User files: procedures>+≡
subroutine file_list_open (file_list, name, action, status, position)
    type(file_list_t), intent(inout) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    type(file_t), pointer :: current
    if (.not. associated (file_list_get_file_ptr (file_list, name))) then
        allocate (current)
        call msg_message ("Opening file '" // char (name) // "' for output")
        call file_init (current, name, action, status, position)
        if (associated (file_list%last)) then
            file_list%last%next => current
            current%prev => file_list%last
        else
            file_list%first => current
        end if
        file_list%last => current
    else
```

```

        call msg_error ("Opening file: File '" // char (name) &
            // "' is already open.")
    end if
end subroutine file_list_open

```

Delete a file entry, i.e., close this file. Error if it is not open.

```

<User files: public>+≡
    public :: file_list_close

<User files: procedures>+≡
    subroutine file_list_close (file_list, name)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            if (associated (current%prev)) then
                current%prev%next => current%next
            else
                file_list%first => current%next
            end if
            if (associated (current%next)) then
                current%next%prev => current%prev
            else
                file_list%last => current%prev
            end if
            call msg_message ("Closing file '" // char (name) // "' for output")
            call file_final (current)
            deallocate (current)
        else
            call msg_error ("Closing file: File '" // char (name) &
                // "' is not open.")
        end if
    end subroutine file_list_close

```

Write a string to file. Error if it is not open.

```

<User files: public>+≡
    public :: file_list_write

<User files: interfaces>≡
    interface file_list_write
        module procedure file_list_write_string
        module procedure file_list_write_ifile
    end interface

<User files: procedures>+≡
    subroutine file_list_write_string (file_list, name, string, advancing)
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        type(string_t), intent(in), optional :: string
        logical, intent(in), optional :: advancing
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)

```

22.3.1 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two

objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()
    type(parse_node_t), pointer :: fac_scale_expr => null ()
    type(parse_node_t), pointer :: ren_scale_expr => null ()
    type(parse_node_t), pointer :: weight_expr => null ()
    type(parse_node_t), pointer :: selection_lexpr => null ()
    type(parse_node_t), pointer :: reweight_expr => null ()
    type(parse_node_t), pointer :: analysis_lexpr => null ()
    type(parse_node_p), dimension(:), allocatable :: alt_setup
  contains
    <RT data: rt parse nodes: TBP>
  end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

<RT data: procedures>≡
  subroutine rt_parse_nodes_clear (rt_pn, name)
    class(rt_parse_nodes_t), intent(inout) :: rt_pn
    type(string_t), intent(in) :: name
    select case (char (name))
    case ("cuts")
      rt_pn%cuts_lexpr => null ()
    case ("scale")
      rt_pn%scale_expr => null ()
    case ("factorization_scale")
      rt_pn%fac_scale_expr => null ()
    case ("renormalization_scale")
      rt_pn%ren_scale_expr => null ()
    case ("weight")
      rt_pn%weight_expr => null ()
    case ("selection")
      rt_pn%selection_lexpr => null ()
    case ("reweight")
      rt_pn%reweight_expr => null ()
    case ("analysis")
      rt_pn%analysis_lexpr => null ()
    end select
  end subroutine rt_parse_nodes_clear

```

Output for the parse nodes.

```

<RT data: rt parse nodes: TBP>+≡
  procedure :: write => rt_parse_nodes_write

<RT data: procedures>+≡
  subroutine rt_parse_nodes_write (object, unit)
    class(rt_parse_nodes_t), intent(in) :: object

```

```

integer, intent(in), optional :: unit

```

22.3.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```
<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init
<RT data: procedures>+≡
  subroutine rt_data_local_init (local, global, env)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(in), target :: global
    integer, intent(in), optional :: env
    call var_list_link (local%var_list, global%var_list)
    if (associated (global%model)) then
      call var_list_init_copies (local%var_list, &
        model_get_var_list_ptr (global%model), &
        derived_only = .true.)
    end if
    call local%init_pointer_variables ()
    local%os_data = global%os_data
    local%logfile = global%logfile
  end subroutine rt_data_local_init
```

This copies global objects, for which local modifications should be kept.

```
<RT data: rt data: TBP>+≡
  procedure :: copy_globals => rt_data_copy_globals
<RT data: procedures>+≡
  subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
    local%model_list = global%model_list
    local%prclib_stack = global%prclib_stack
    local%process_stack = global%process_stack
  end subroutine rt_data_copy_globals
```

These variables point to objects which get local copies:

```
<RT data: rt data: TBP>+≡
  procedure :: init_pointer_variables => rt_data_init_pointer_variables
<RT data: procedures>+≡
  subroutine rt_data_init_pointer_variables (local)
    class(rt_data_t), intent(inout), target :: local
    logical, target, save :: known = .true.
    call var_list_append_string_ptr &
      (local%var_list, var_str (" $fc"), local%os_data%fc, known, &
        intrinsic=.true.)
    call var_list_append_string_ptr &
      (local%var_list, var_str (" $fcflags"), local%os_data%fcflags, known, &
        intrinsic=.true.)
  end subroutine rt_data_init_pointer_variables
```

This is done at execution time: Copy data, transfer pointers. `local` has intent(inout) because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: link => rt_data_link

<RT data: procedures>+≡
  subroutine rt_data_link (local, global)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(in), target :: global
    local%lexer => global%lexer
    call global%copy_globals (local)
    local%os_data = global%os_data
    local%logfile = global%logfile
    call var_list_link (local%var_list, global%var_list)
    if (associated (global%model)) then
      local%model => &
        local%model_list%get_model_ptr (global%model%get_name ())
      call var_list_synchronize (local%var_list, &
        model_get_var_list_ptr (local%model), reset_pointers = .true.)
      call local%particle_stack%init (local%model)
    end if
    if (associated (global%prclib)) then
      local%prclib => &
        local%prclib_stack%get_library_ptr (global%prclib%get_name ())
    end if
    local%it_list = global%it_list
    local%beam_structure = global%beam_structure
    local%lhpdf_status = global%lhpdf_status
    local%pn = global%pn
    if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
    if (allocated (global%sample_fmt)) then
      allocate (local%sample_fmt (size (global%sample_fmt)), &
        source = global%sample_fmt)
    end if
    local%out_files => global%out_files
  end subroutine rt_data_link

```

Restore the previous state of data; in particular, the variable list. This applies only to model variables (which are copies); other variables are automatically restored when local variables are removed.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model

(which thus becomes separated from the model library!), and we synchronize the local variable list with it. The other local variables are also kept.

Some command (`read_slha`) reads in model variables as local entities. In this case, the original values of model variables should not be restored, but the global variable list should be synchronized. However, this matters only if the local model is identical to the global model; otherwise, restoring will apply to a different model.

Finally, model list, process library stack, and process stack are copied back. Thus, they behave like global objects: all changes in the local environment are kept in the global context. Note that these are shallow copies.

```

<RT data: rt data: TBP>+≡
  procedure :: restore => rt_data_restore

<RT data: procedures>+≡
  subroutine rt_data_restore (global, local, keep_model_vars, keep_local)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(inout) :: local
    logical, intent(in), optional :: keep_model_vars, keep_local
    logical :: same_model, restore, delete
    delete = .true.; if (present (keep_local)) delete = .not. keep_local
    if (delete) then
      call var_list_undefine (local%var_list, follow_link=.false.)
    else
      if (associated (local%model)) then
        call model_pointer_to_instance (local%model)
        call var_list_synchronize (local%var_list, &
          model_get_var_list_ptr (local%model), reset_pointers = .true.)
      end if
    end if
    if (associated (global%model)) then
      call local%particle_stack%restore_model ()
      same_model = &
        global%model%get_name () == local%model%get_name ()
      if (present (keep_model_vars) .and. same_model) then
        restore = .not. keep_model_vars
      else
        if (.not. same_model) call msg_message ("Restoring model '" // &
          char (global%model%get_name ()) // "'")
        restore = .true.
      end if
      if (restore) then
        call var_list_restore (global%var_list)
      else
        call var_list_synchronize &
          (global%var_list, model_get_var_list_ptr (global%model))
      end if
    end if
    call global%restore_globals (local)
  end subroutine rt_data_restore

```

This restores global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡
  procedure :: restore_globals => rt_data_restore_globals

```

```

<RT data: procedures>+≡
  subroutine rt_data_restore_globals (global, local)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(in) :: local
    global%model_list = local%model_list
    global%prclib_stack = local%prclib_stack
    global%process_stack = local%process_stack
  end subroutine rt_data_restore_globals

```

22.3.8 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
  procedure :: final => rt_data_global_final

<RT data: procedures>+≡
  subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
    call global%particle_stack%final ()
    call global%model_list%final ()
    call var_list_final (global%var_list)
    if (associated (global%out_files)) then
      call file_list_final (global%out_files)
      deallocate (global%out_files)
    end if
  end subroutine rt_data_global_final

```

The local copy needs a finalizer just for the variable list, which consists of local copies.

```

<RT data: rt data: TBP>+≡
  procedure :: local_final => rt_data_local_final

<RT data: procedures>+≡
  subroutine rt_data_local_final (local)
    class(rt_data_t), intent(inout) :: local
    call var_list_final (local%var_list)
  end subroutine rt_data_local_final

```

22.3.9 Filling Contents

Read a model, filling the model list component and assigning this as the current model. Copy the model variables to the global var list.

```

<RT data: rt data: TBP>+≡

    end subroutine rt_data_pacify

```

22.3.11 Test

This is the master for calling self-test procedures.

```

<RT data: public>+≡
    public :: rt_data_test

<RT data: tests>≡
    subroutine rt_data_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <RT data: execute tests>
    end subroutine rt_data_test

```

Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```
<RT data: rt data: TBP>+≡

Save and restore

Set up a local runtime data block, change some contents, restore the global block.

For a model variable, the save-restore procedure is nontrivial. We first allocate a local copy of this variable and set a pointer to the original model variable. We set a new value, update the dependent variables and synchronize them with the local variable list, if modified. When restoring the old data, we recover the model variables from the stored values and delete the local instances.

```

22.4 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

This module provides no new types, just procedures.

```

⟨dispatch.f90⟩≡
  ⟨File header⟩

  module dispatch

    ⟨Use kinds⟩
    use kinds, only: i16 !NODEP!
    ⟨Use strings⟩

22.4.1 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable.

Note: `core_def` has `intent(inout)` because gfortran 4.7.1 crashes for `intent(out)`.

```

<Dispatch: public>≡
  public :: dispatch_core_def

<Dispatch: procedures>≡
  subroutine dispatch_core_def (core_def, prt_in, prt_out, global)
    class(prc_core_def_t), allocatable, intent(inout) :: core_def
    type(string_t), dimension(:), intent(in) :: prt_in

```

```

type(string_t), dimension(:), intent(in) :: prt_out
type(rt_data_t), intent(in) :: global
type(string_t) :: method
type(string_t) :: model_name
type(string_t) :: restrictions
logical :: openmp_support
logical :: report_progress
logical :: diags, diags_color
type(string_t) :: extra_options
type(model_t), pointer :: model
model => global%model
associate (var_list => global%var_list)
  method = var_list_get_sval (var_list, var_str ("method"))
  model_name = var_list_get_sval (var_list, var_str ("model_name"))
  select case (char (method))
  case ("unit_test")
    allocate (prc_test_def_t :: core_def)
    select type (core_def)
    type is (prc_test_def_t)
      call core_def%init (model_name, prt_in, prt_out)
    end select
  case ("template")
    allocate (template_me_def_t :: core_def)
    select type (core_def)
    type is (template_me_def_t)
      call core_def%init (model, prt_in, prt_out, unity = .false.)
    end select
  case ("template_unity")
    allocate (template_me_def_t :: core_def)
    select type (core_def)
    type is (template_me_def_t)
      call core_def%init (model, prt_in, prt_out, unity = .true.)
    end select
  case ("omega")
    diags = var_list_get_lval (var_list, &
      var_str ("diags"))
    diags_color = var_list_get_lval (var_list, &
      var_str ("diags_color"))
    restrictions = var_list_get_sval (var_list, &
      var_str ("restrictions"))
    openmp_support = var_list_get_lval (var_list, &

```

```

        call msg_fatal ("Process configuration: method '" &
            // char (method) // "' not implemented")
    end select
end associate
end subroutine dispatch_core_def

```

22.4.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```

<Dispatch: public>+≡
    public :: dispatch_core

<Dispatch: procedures>+≡
    subroutine dispatch_core (core, core_def, model, &
        helicity_selection, qcd, use_color_factors)
        class(prc_core_t), allocatable, intent(inout) :: core
        class(prc_core_def_t), intent(in) :: core_def
        type(model_t), intent(in), target, optional :: model
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        type(qcd_t), intent(in), optional :: qcd
        logical, intent(in), optional :: use_color_factors
        select type (core_def)
            type is (prc_test_def_t)
                allocate (test_t :: core)
            type is (template_me_def_t)
                allocate (prc_template_me_t :: core)
                select type (core)
                    type is (prc_template_me_t)
                        call core%set_parameters (model)
                end select
            type is (omega_def_t)
                allocate (prc_omega_t :: core)
                select type (core)
                    type is (prc_omega_t)
                        call core%set_parameters (model, &
                            helicity_selection, qcd, use_color_factors)
                end select
        end select
        class default
            call msg_bug ("Process core: unexpected process definition type")
        end select
    end subroutine dispatch_core

```

22.4.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

```

<Dispatch: public>+≡
  public :: dispatch_core_update
  public :: dispatch_core_restore

<Dispatch: procedures>+≡
  subroutine dispatch_core_update (core, model, helicity_selection, qcd, &
    saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    type(model_t), intent(in), optional, target :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    class(prc_core_t), allocatable, intent(inout), optional :: saved_core
    if (present (saved_core)) then
      allocate (saved_core, source = core)
    end if
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
      call core%set_parameters (model, helicity_selection, qcd)
      call core%activate_parameters ()
    class default
      call msg_bug ("Process core update: unexpected process definition type")
    end select
  end subroutine dispatch_core_update

  subroutine dispatch_core_restore (core, saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_t), allocatable, intent(inout) :: saved_core
    call move_alloc (from = saved_core, to = core)
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
      call core%activate_parameters ()
    class default
      call msg_bug ("Process core restore: unexpected process definition type")
    end select
  end subroutine dispatch_core_restore

```

22.4.4 Integrator allocation

Allocate an integrator according to the variable \$integration_method.

```

<Dispatch: public>+≡
  public :: dispatch_mci

<Dispatch: procedures>+≡
  subroutine dispatch_mci (mci, global, process_id)
    class(mci_t), allocatable, intent(inout) :: mci
    type(rt_data_t), intent(in) :: global
    type(string_t), intent(in) :: process_id
    type(string_t) :: run_id
    type(string_t) :: integration_method

```

22.4.6 Random-number generator

Allocate a random-number generator factory according to the variable `$rng_method`, using the current seed in the global record. We take only the lower 15 bits of the seed, so the actual value fits into a positive 16-bit signed integer.

Since we want to guarantee that all random-number generators in a run are independent, we increment the global seed by one after creating the rng factory. If the user wants to have identical sequences, he can always set the seed manually, before it is used.

```

<Dispatch: public>+≡
    public :: dispatch_rng_factory

<Dispatch: procedures>+≡
    subroutine dispatch_rng_factory (rng_factory, global)
        class(rng_factory_t), allocatable, intent(out) :: rng_factory

```

```

type(rt_data_t), intent(inout) :: global
type(string_t) :: rng_method
integer :: seed
character(30) :: buffer
integer(i16) :: s
rng_method = var_list_get_sval (global%var_list, var_str ("rng_method"))

    is_known = .true.)
end subroutine dispatch_rng_factory

```

22.4.7 Structure function configuration data

This data type is a container for transferring structure-function specific data from the `dispatch_sf_data` to the `dispatch_sf_channels` subroutine.

```

<Dispatch: public>+≡
    public :: sf_prop_t

<Dispatch: types>≡
    type :: sf_prop_t
        real(default), dimension(2) :: isr_eps = 1
    end type sf_prop_t

```

Allocate a structure-function configuration object according to the `sf_method` string.

The `sf_prop` object can be used to transfer structure-function specific data up and to the `dispatch_sf_channels` subroutine below, so they can be used for particular mappings.

The `global` object is `intent(inout)` because the PDF status may change during initialization.

The `pdg_in` array is the array of incoming flavors, corresponding to the upstream structure function or the beam array. This will be checked for the structure function in question and replaced by the outgoing flavors. The `pdg_prc` array is the array of incoming flavors (beam index, component index) for the

hard process.

This is an auxiliary procedure, used by the beam-structure expansion: tell for a given structure function name, whether it corresponds to a pair spectrum ($n = 2$), a single-particle structure function ($n = 1$), or nothing ($n = 0$). Though `energy_scan` can in principle also be a pair spectrum, it always has only one parameter.

(Dispatch: procedures)+≡

            // "' not supported yet")
    end select
end function strfun_mode

```

Dispatch a whole structure-function chain, given beam data and beam structure data.

This could be done generically, but we should look at the specific combination of structure functions in order to select appropriate mappings.

The `beam_structure` argument gets copied because we want to expand it to

canonical form (one valid structure-function entry per record) before proceeding further.

The `pdg_prc` argument is the array of incoming flavors. The first index is the beam index, the second one the process component index. Each element is itself a PDG array, notrivial if there is a flavor sum for the incoming state of this component.

The dispatcher is divided in two parts. The first part configures the structure function data themselves. After this, we can configure the phase space for the elementary process.

```

```

The second part configures channel mappings, using some conditions from the phase space configuration. If there are no structure functions, we enable a

default setup with a single (dummy) structure-function channel. Otherwise, we look at the channel collection that we got from the phase-space configuration step. Each entry should be translated into an independent structure-function channel, where typically there is one default entry, which could be mapped using a standard s-channel mapping if the structure function setup recommends this, and other entries with s-channel resonances. The latter need to be translated into global mappings from the structure-function chain.

22.4.9 QCD coupling

Allocate the `alpha` (running coupling) component of the `qcd` block with a concrete implementation, depending on the variable settings in the `global` record.

If a fixed α_s is requested, we do not allocate the `qcd%alpha` object. In this case, the matrix element code will just take the model parameter as-is, which implies fixed α_s . If the object is allocated, the α_s value is computed and updated for each matrix-element call.

(Dispatch: public)+≡

```

22.5 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

`<process_configurations.f90>≡`

22.5.1 Data Type

```

    <Process configurations: public>≡
        public :: process_configuration_t

    <Process configurations: types>≡
        type :: process_configuration_t
            type(process_def_entry_t), pointer :: entry => null ()
            type(string_t) :: id
            integer :: num_id = 0
        contains
            <Process configurations: process configuration: TBP>
        end type process_configuration_t

```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

```

    <Process configurations: process configuration: TBP>≡
        procedure :: init => process_configuration_init

    <Process configurations: procedures>≡
        subroutine process_configuration_init &
            (config, prc_name, n_in, n_components, global)
            class(process_configuration_t), intent(out) :: config
            type(string_t), intent(in) :: prc_name
            integer, intent(in) :: n_in

            model = model, n_in = n_in, n_components = n_components)
    end if
end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

```

<Process configurations: process configuration: TBP>+=
    procedure :: setup_component => process_configuration_setup_component

```

22.5.2 Test

This is the master for calling self-test procedures.

```

<Process configurations: public>+≡
    public :: process_configurations_test

<Process configurations: tests>≡
    subroutine process_configurations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Process configurations: execute tests>
end subroutine process_configurations_test

```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one **prc_test** and one **omega** type) and appends this to the process library stack in the global data set.

The **mode** argument determines which processes to build.

The **procname** argument replaces the predefined **procname(s)**.

```

<Process configurations: public>+≡
    public :: prepare_test_library

```

```

<Process configurations: tests>+≡
subroutine prepare_test_library (global, libname, mode, procname)

```

Message as a separate call:

```

<Compilations: compilation item: TBP>+≡
procedure :: success => compilation_item_success

<Compilations: procedures>+≡
subroutine compilation_item_success (comp)
  class(compilation_item_t), intent(in) :: comp
  if (associated (comp%lib)) then
    call msg_message ("Process library '" // char (comp%libname) &
      // "' : ... success.")
  end if
end subroutine compilation_item_success

```

22.6.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```
<Compilations: public>≡
    public :: compile_library

<Compilations: procedures>+≡
    subroutine compile_library (libname, global)
        type(string_t), intent(in) :: libname
        type(rt_data_t), intent(inout), target :: global
        type(compilation_item_t) :: comp
        logical :: force, recompile
        force = &
            var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
        recompile = &
            var_list_get_lval (global%var_list, var_str ("?recompile_library"))
        call comp%init (libname, global%prclib_stack, global%var_list)
        call comp%compile (global%os_data, force, recompile)
        if (signal_is_pending ()) return
        call comp%load (global%os_data)
        if (signal_is_pending ()) return
        call comp%success ()
    end subroutine compile_library
```

22.6.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```
<Compilations: types>+≡
    type :: compilation_t
        private
        type(string_t) :: exe_name
        type(string_t), dimension(:), allocatable :: lib_name
        contains
        <Compilations: compilation: TBP>
    end type compilation_t
```

Output.

```
<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write

<Compilations: procedures>+≡
    subroutine compilation_write (object, unit)
        class(compilation_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = output_unit (unit)
        write (u, "(1x,A)") "Compilation object:"
```

```

write (u, "(3x,3A)") "executable          = ', &
char (object%exe_name), "'
write (u, "(3x,A)", advance="no") "process libraries ="

External Matrix Element

Compile an external test matrix element (`omega` type) and incorporate this in a new static WHIZARD executable. In this version, we use the wrapper `compile_executable` procedure.

```

22.7 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

contains

    <Integrations: procedures>

    <Integrations: tests>

end module integrations

```

22.7.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

<Integrations: public>≡
    public :: integration_t

<Integrations: types>≡
    type :: integration_t
        private
            type(string_t) :: process_id
            type(string_t) :: run_id
            type(process_t), pointer :: process => null ()
            logical :: rebuild_phs = .false.
            logical :: ignore_phs_mismatch = .false.
            logical :: phs_only = .false.
            logical :: process_has_me = .true.
            integer :: n_calls_test = 0
            logical :: vis_history = .true.
            type(string_t) :: history_filename
            type(string_t) :: log_filename
        contains
            <Integrations: integration: TBP>
    end type integration_t

```

22.7.2 Initialization

Initialization, first part: Create and initialize a process entry and push it on the stack. Only the basic process data (ID, run ID, etc.) are configured, we postpone the rest.

(Integrations: integration: TBP)≡

```
procedure :: create_process => integration_create_process
```

(Integrations: procedures)≡

```
subroutine integration_create_process (intg, process_id, global) !, verbose)
  class(integration_t), intent(out) :: intg
  type(rt_data_t), intent(inout), target :: global
  type(string_t), intent(in) :: process_id
  type(var_list_t), pointer :: var_list
  type(qcd_t) :: qcd
  class(rng_factory_t), allocatable :: rng_factory
  type(process_entry_t), pointer :: process_entry

  var_list => global%var_list
  intg%process_id = process_id
  intg%run_id = var_list_get_sval (var_list, var_str ("$_run_id"))

  call dispatch_qcd (qcd, global)
  call dispatch_rng_factory (rng_factory, global)

  allocate (process_entry)
  call process_entry%init (intg%process_id, intg%run_id, global%prclib, &
    global%os_data, qcd, rng_factory, global%model_list)
  call global%process_stack%push (process_entry)

end subroutine integration_create_process
```

Complete process configuration.

If the `process` argument is given, use it. Otherwise, take the process object from the stack.

(Integrations: integration: TBP)+≡

```
procedure :: setup_process => integration_setup_process
```

(Integrations: procedures)+≡

```

22.7.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

<Integrations: integration: TBP>+≡
  procedure :: evaluate => integration_evaluate

<Integrations: procedures>+≡
  subroutine integration_evaluate &
    (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
    integer :: n_calls, n_it
    logical :: adapt_grids, adapt_weights, final

    n_it = it_list%get_n_it (pass)

```

```

n_calls = it_list%get_n_calls (pass)
adapt_grids = it_list%adapt_grids (pass)
adapt_weights = it_list%adapt_weights (pass)
final = pass == it_list%get_n_pass ()

call intg%process%integrate (process_instance, &
    i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
    final, pacify)

end subroutine integration_evaluate

```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

```

<Integrations: integration: TBP>+≡
    procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: procedures>+≡
    subroutine integration_make_iterations_list (intg, it_list)
        class(integration_t), intent(in) :: intg
        type(iterations_list_t), intent(out) :: it_list
        integer :: pass, n_pass
        integer, dimension(:), allocatable :: n_it, n_calls
        logical, dimension(:), allocatable :: adapt_grids, adapt_weights
        n_pass = intg%process%get_n_pass_default ()
        allocate (n_it (n_pass), n_calls (n_pass))
        allocate (adapt_grids (n_pass), adapt_weights (n_pass))
        do pass = 1, n_pass
            n_it(pass)      = intg%process%get_n_it_default (pass)
            n_calls(pass)   = intg%process%get_n_calls_default (pass)
            adapt_grids(pass) = intg%process%adapt_grids_default (pass)
            adapt_weights(pass) = intg%process%adapt_weights_default (pass)
        end do
        call it_list%init (n_it, n_calls, &
            adapt_grids = adapt_grids, adapt_weights = adapt_weights)
    end subroutine integration_make_iterations_list

```

22.7.4 API for integration objects

This initializer does everything except assigning cuts/scale/weight expressions. If `ok` is false, initialization failed, and the integration should be skipped.

If `me_only` is set, prepare just matrix-element evaluation: no phase space, no iterations.

```

<Integrations: integration: TBP>+≡
    procedure :: init => integration_init

<Integrations: procedures>+≡
    subroutine integration_init (intg, process_id, global)
        class(integration_t), intent(out) :: intg
        type(string_t), intent(in) :: process_id
        type(rt_data_t), intent(inout), target :: global

```

```

        call intg%create_process (process_id, global)
        call intg%setup_process (global)
    end subroutine integration_init

```

Do the integration for a single process, both warmup and final evaluation. The `eff_reset` flag is to suppress numerical noise in the graphical output of the integration history.

(Integrations: integration: TBP)+≡

```

    procedure :: integrate => integration_integrate

```

(Integrations: procedures)+≡

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

```

Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (22.1)$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (22.2)$$

f is the flux of the incoming particles with mass $m = 125 \text{ GeV}$ and energy $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (22.3)$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (22.4)$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (22.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function $f(x) = x$ for both beams. Together with the $1/x_1x_2$ factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the m_s mass which we set to zero here.

```

22.8 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
<event_streams.f90>≡  
  <File header>  
  
  module event_streams  
  
    <Use kinds>  
    <Use strings>  
    <Use file utils>  
    use diagnostics !NODEP!  
    use unit_tests  
    use variables  
    use models  
    use processes  
    use events  
    use eio_data  
    use eio_base  
    use rt_data  
    use dispatch  
  
    <Standard module head>  
  
    <Event streams: public>  
  
    <Event streams: types>  
  
    contains  
  
    <Event streams: tests>  
  
    <Event streams: procedures>  
  
  end module event_streams
```

22.8.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡  
  type :: event_stream_entry_t  
    class(eio_t), allocatable :: eio  
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```

(Event streams: public)≡
    public :: event_stream_array_t

(Event streams: types)+≡
    type :: event_stream_array_t
        type(event_stream_entry_t), dimension(:), allocatable :: entry
        integer :: i_in = 0
    contains
        (Event streams: event stream array: TBP)
    end type event_stream_array_t

```

Output.

```

(Event streams: event stream array: TBP)≡
    procedure :: write => event_stream_array_write

(Event streams: procedures)≡
    subroutine event_stream_array_write (object, unit)
        class(event_stream_array_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = output_unit (unit)
        write (u, "(1x,A)") "Event stream array:"
        if (allocated (object%entry)) then
            select case (size (object%entry))
            case (0)
                write (u, "(3x,A)") "[empty]"
            case default
                do i = 1, size (object%entry)
                    if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
                    call object%entry(i)%eio%write (u)
                end do
            end select
        else
            write (u, "(3x,A)") "[undefined]"
        end if
    end subroutine event_stream_array_write

```

Finalize all streams.

```

(Event streams: event stream array: TBP)+≡
    procedure :: final => event_stream_array_final

(Event streams: procedures)+≡
    subroutine event_stream_array_final (es_array)
        class(event_stream_array_t), intent(inout) :: es_array
        integer :: i
        do i = 1, size (es_array%entry)
            call es_array%entry(i)%eio%final ()
        end do
    end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

22.9.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

```

<Simulations: types>+≡
  type, extends (event_t) :: entry_t
  private
  type(string_t) :: process_id
  type(string_t) :: library
  type(string_t) :: run_id
  logical :: has_integral = .false.
  real(default) :: integral = 0
  real(default) :: error = 0
  real(default) :: process_weight = 0
  logical :: valid = .false.
  type(counter_t) :: counter
  integer :: n_in = 0
  integer :: n_mci = 0
  type(mci_set_t), dimension(:), allocatable :: mci_set
  type(selector_t) :: mci_selector
  type(core_safe_t), dimension(:), allocatable :: core_safe
  type(model_t), pointer :: model => null ()
  type(qcd_t) :: qcd
  contains
  <Simulations: entry: TBP>
end type entry_t

```

Output. Write just the configuration, the event is written by a separate routine.

The `verbose` option is unused, it is required by the interface of the base-object method.

```

<Simulations: entry: TBP>≡
  procedure :: write_config => entry_write_config

```

<Simulations: procedures>+≡

```

subroutine entry_write_config (object, unit)
  class(entry_t), intent(in) :: object

      call object%core_safe(i)%core%write (u)
    end do
  end if
end subroutine entry_write_config

```

Finalizer. The instance pointer component of the `event_t` base type points to a target which we did explicitly allocate in the `entry_init` procedure. Therefore, we finalize and explicitly deallocate it here. Then we call the finalizer of the base type.

<Simulations: entry: TBP>+≡

```

procedure :: final => entry_final

```

<Simulations: procedures>+≡

```

subroutine entry_final (object)
  class(entry_t), intent(inout) :: object
  integer :: i

    do i = 1, object%n_mci
      call object%instance%final_simulation (i)
    end do
    call object%instance%final ()
    deallocate (object%instance)
  end if
  call object%event_t%final ()
end subroutine entry_final

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the `process_instance` pointer. Assign data by looking at the process object and at the environment.

If `n_alt` is set, we prepare for additional alternate sqme and weight entries.

If the process object is not found initially: if `integrate` is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If `generate` is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the `instance` and `process` pointers of the base type by the `connect` method, so we can reference them later.

<Simulations: entry: TBP>+≡

22.9.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
  type, extends (entry_t) :: alt_entry_t
  contains
    <Simulations: alt entry: TBP>
  end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage

of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

Write the current event record. If an explicit index is given, write that event record.

We implement writing to `unit` (event contents / debugging format) and writing to an `eio` event stream (storage). We include a `testflag` in order to suppress numerical noise in the testsuite.

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the `luminosity` setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the `luminosity`, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

```

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

      class(eio_t), intent(inout) :: eio
      integer, intent(in), optional :: i_prc
      integer :: current
      if (present (i_prc)) then
        current = i_prc
      else
        current = object%i_prc
      end if
      if (current > 0) then
        if (object%split_n_evt > 0) then
          if (object%counter%total > 1 .and. &
            mod (object%counter%total, object%split_n_evt) == 1) then
            call eio%split_out ()
          end if
        end if
        call eio%output (object%entry(current)%event_t, current)
      else
        call msg_fatal ("Simulation: write event: no process selected")
      end if
    end subroutine simulation_write_event_eio

```

```
end subroutine simulation_write_event_eio
```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```
<Simulations: simulation: TBP>+≡
generic :: read_event => read_event_eio
procedure :: read_event_eio => simulation_read_event_eio

<Simulations: procedures>+≡
subroutine simulation_read_event_eio (object, eio)
  class(simulation_t), intent(inout) :: object
  class(eio_t), intent(inout) :: eio
  integer :: iostat, current
  call eio%input_i_prc (current, iostat)
  select case (iostat)
  case (0)
    object%i_prc = current
    call eio%input_event (object%entry(current)%event_t, iostat)
  end select
  select case (iostat)
  case (:-1)
    object%i_prc = 0
    object%i_mci = 0
  case (1:)
    call msg_error ("Reading events: I/O error, aborting read")
    object%i_prc = 0
    object%i_mci = 0
  case default
    object%i_mci = object%entry(current)%get_i_mci ()
  end select
end subroutine simulation_read_event_eio
```

22.9.9 Event Stream Array

Write an event using an array of event I/O streams. The process index must be selected, or the current index must be available.

```
<Simulations: simulation: TBP>+≡
generic :: write_event => write_event_es_array
procedure :: write_event_es_array => simulation_write_event_es_array

<Simulations: procedures>+≡
subroutine simulation_write_event_es_array (object, es_array)
  class(simulation_t), intent(in) :: object
  class(event_stream_array_t), intent(inout) :: es_array
  integer :: i_prc, event_index
  i_prc = object%i_prc
  if (i_prc > 0) then
    event_index = object%counter%total
```

```

        call es_array%output (object%entry(i_prc)%event_t, i_prc, event_index)
    else
        call msg_fatal ("Simulation: write event: no process selected")
    end if
end subroutine simulation_write_event_es_array

```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

```

<Simulations: simulation: TBP>+≡

23.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```

⟨Commands: types⟩≡
type, abstract :: command_t
  type(parse_node_t), pointer :: pn => null ()
  class(command_t), pointer :: next => null ()
  type(parse_node_t), pointer :: pn_opt => null ()
  type(command_list_t), pointer :: options => null ()
  type(rt_data_t), pointer :: local => null ()
contains
⟨Commands: command: TBP⟩

```

```
end type command_t
```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```
<Commands: command: TBP>≡
  procedure :: final => command_final

<Commands: procedures>≡
  recursive subroutine command_final (cmd)
    class(command_t), intent(inout) :: cmd
    if (associated (cmd%options)) then
      call cmd%options%final ()
      deallocate (cmd%options)
      call cmd%local%local_final ()
      deallocate (cmd%local)
    else
      cmd%local => null ()
    end if
  end subroutine command_final
```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

```
<Commands: procedures>+≡
  subroutine dispatch_command (command, pn)
    class(command_t), intent(inout), pointer :: command

end select
command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_write), deferred :: write

⟨Commands: interfaces⟩≡
  abstract interface
    subroutine command_write (cmd, unit, indent)
      import
      class(command_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
    end subroutine command_write
  end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_compile), deferred :: compile

⟨Commands: interfaces⟩+≡
  abstract interface
    subroutine command_compile (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_compile
  end interface

```

Execute a command. This will use and/or modify the runtime data set. If the `quit` flag is set, the caller should terminate command execution.

```

<Commands: command: TBP>+≡
    procedure (command_execute), deferred :: execute

<Commands: interfaces>+≡
    abstract interface
        subroutine command_execute (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_execute
    end interface

```

23.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```

<Commands: command: TBP>+≡
    procedure :: write_options => command_write_options

<Commands: procedures>+≡
    recursive subroutine command_write_options (cmd, unit, indent)
        class(command_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: ind
        ind = 1; if (present (indent)) ind = indent + 1
        if (associated (cmd%options)) call cmd%options%write (unit, ind)
    end subroutine command_write_options

```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```

<Commands: command: TBP>+≡
    procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
    recursive subroutine command_compile_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%pn_opt)) then
            allocate (cmd%local)
            call cmd%local%local_init (global)
            call global%copy_globals (cmd%local)
            allocate (cmd%options)
            call cmd%options%compile (cmd%pn_opt, cmd%local)
            call global%restore_globals (cmd%local)
        else
            cmd%local => global
        end if
    end subroutine command_compile_options

```

```

        end if
    end subroutine command_compile_options

```

Execute options. First prepare the local environment, then execute the command list.

```

<Commands: command: TBP>+≡
    procedure :: execute_options => cmd_execute_options

<Commands: procedures>+≡
    recursive subroutine cmd_execute_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call cmd%local%link (global)
            call cmd%options%execute (cmd%local)
        end if
    end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the global environment.

```

<Commands: command: TBP>+≡
    procedure :: reset_options => cmd_reset_options

<Commands: procedures>+≡
    subroutine cmd_reset_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call global%restore (cmd%local)
        end if
    end subroutine cmd_reset_options

```

23.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_model_t
        private
        type(string_t) :: name
    contains
        <Commands: cmd model: TBP>
    end type cmd_model_t

```

Output

```

<Commands: cmd model: TBP>≡
    procedure :: write => cmd_model_write

```

```

<Commands: procedures>+≡
subroutine cmd_model_write (cmd, unit, indent)
  class(cmd_model_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,1x,'"',A,'\"') "model =", char (cmd%name)
end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed.

```

<Commands: cmd model: TBP>+≡
  procedure :: compile => cmd_model_compile

<Commands: procedures>+≡
subroutine cmd_model_compile (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_name
  type(string_t) :: filename
  pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
  cmd%name = parse_node_get_string (pn_name)
  filename = cmd%name // ".mdl"
  call global%read_model (cmd%name, filename)
end subroutine cmd_model_compile

```

Execute: Insert a pointer into the global data record and reassign the variable list.

```

<Commands: cmd model: TBP>+≡
  procedure :: execute => cmd_model_execute

<Commands: procedures>+≡
subroutine cmd_model_execute (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  logical :: new_model
  new_model = .true.
  if (associated (global%model)) then
    new_model = global%model%get_name () /= cmd%name
  end if
  if (new_model) then
    if (global%model_list%model_exists (cmd%name)) then
      call msg_message ("Switching to model '" &
        // char (cmd%name) &
        // "': reassigning model parameters")
      call global%select_model (cmd%name)
    else
      call msg_fatal ("Switching to model '" &
        // char (cmd%name) &
        // "': unknown model name")
    end if
  end if
end subroutine cmd_model_execute

```

Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_library_t
    private
      type(string_t) :: name
    contains
      <Commands: cmd library: TBP>
    end type cmd_library_t
```

Output.

```
<Commands: cmd library: TBP>≡
  procedure :: write => cmd_library_write

<Commands: procedures>+≡
  subroutine cmd_library_write (cmd, unit, indent)
    class(cmd_library_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit)
    call write_indent (u, indent)
    write (u, "(1x,A,1x,'"',A,'\"') "library =", char (cmd%name)
  end subroutine cmd_library_write
```

Compile. Get the library name.

```
<Commands: cmd library: TBP>+≡
  procedure :: compile => cmd_library_compile

<Commands: procedures>+≡
  subroutine cmd_library_compile (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd

end if
if (associated (lib) .and. .not. rebuild_library) then
    call lib%update_status (global%os_data)
end if
end subroutine cmd_library_execute

```

Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: **omega** for O'MEGA matrix elements, **test** for special processes generated by WHIZARD, **external** for using an external matrix element and **dipole** for generating dipole subtraction terms.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_process_t
private
type(string_t) :: id
integer :: n_in = 0
type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
type(parse_node_t), pointer :: pn_out => null ()
contains
⟨Commands: cmd process: TBP⟩
end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

⟨Commands: cmd process: TBP⟩≡
procedure :: write => cmd_process_write

⟨Commands: procedures⟩+≡
subroutine cmd_process_write (cmd, unit, indent)
class(cmd_process_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = output_unit (unit); if (u < 0) return
call write_indent (u, indent)

```

```

write (u, "(1x,A,A,A,I0,A)") "process: ", char (cmd%id), " (", &
size (cmd%pn_pdg_in), " -> X)"
call cmd%write_options (u, indent)
end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

⟨Commands: cmd process: TBP⟩+≡
  procedure :: compile => cmd_process_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_process_compile (cmd, global)
    class(cmd_process_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_id, pn_in, pn_codes

    pn_codes => parse_node_get_sub_ptr (pn_in)
    allocate (cmd%pn_pdg_in (cmd%n_in))
    do i = 1, cmd%n_in
      cmd%pn_pdg_in(i)%ptr => pn_codes
      pn_codes => parse_node_get_next_ptr (pn_codes)
    end do
  end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

```

        end if
      end if
    end if
  end subroutine cmd_exec_execute
```

```
end subroutine cmd_exec_execute
```

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_var_t
    private
    type(string_t) :: name
    integer :: type = V_NONE
    type(parse_node_t), pointer :: pn_value => null ()
    logical :: is_intrinsic = .false.
    logical :: is_copy = .false.
    contains
    <Commands: cmd var: TBP>
  end type cmd_var_t
```

Output. We know name, type, and properties, but not the value.

```
<Commands: cmd var: TBP>≡
  procedure :: write => cmd_var_write

<Commands: procedures>+≡
  subroutine cmd_var_write (cmd, unit, indent)
    class(cmd_var_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
```

```

write (u, "(1x,A,A,A)", advance="no") "var: ", char (cmd%name), " ("
select case (cmd%type)

SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_slha_t
  private
  type(string_t) :: file
  logical :: write_mode = .false.
  contains
  <Commands: cmd slha: TBP>
end type cmd_slha_t

```

Output.

```

<Commands: cmd slha: TBP>≡
  procedure :: write => cmd_slha_write

<Commands: procedures>+≡
  subroutine cmd_slha_write (cmd, unit, indent)
    class(cmd_slha_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "slha: file name = ", char (cmd%file)
    write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
  end subroutine cmd_slha_write

```

Compile. Read the filename and store it.

```

<Commands: cmd slha: TBP>+≡
  procedure :: compile => cmd_slha_compile

<Commands: procedures>+≡
  subroutine cmd_slha_compile (cmd, global)
    class(cmd_slha_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_key, pn_arg, pn_file
    pn_key => parse_node_get_sub_ptr (cmd%pn)
    pn_arg => parse_node_get_next_ptr (pn_key)

case default
  call parse_node_mismatch ("read_slha|write_slha", cmd%pn)
end select
cmd%file = parse_node_get_string (pn_file)
end subroutine cmd_slha_compile

```

Execute. Read or write the specified SLHA file. Behind the scenes, this will first read the WHIZARD model file, then read the SLHA file and assign the SLHA parameters as far as determined by `dispatch_slha`. Finally, the global variables are synchronized with the model. This is similar to executing `cmd_model`.

Clear values

This command clears the current values of variables or other objects, where this makes sense. It parallels the `show` command. The objects are cleared, but not deleted.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_clear_t
    private
    type(string_t), dimension(:), allocatable :: name
    contains
    <Commands: cmd clear: TBP>
  end type cmd_clear_t
```

Output: list the names of the objects to be cleared.

```
<Commands: cmd clear: TBP>≡
  procedure :: write => cmd_clear_write

<Commands: procedures>+≡
  subroutine cmd_clear_write (cmd, unit, indent)
    class(cmd_clear_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u, i
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)", advance="no") "clear: "
    if (allocated (cmd%name)) then
      do i = 1, size (cmd%name)
        write (u, "(1x,A)", advance="no") char (cmd%name(i))
      end do
      write (u, *)
    else
      write (u, "(5x,A)") "[undefined]"
    end if
  end subroutine cmd_clear_write
```

Compile. Allocate an array which is filled with the names of the objects to be cleared.

Note: there is currently no need to account for options, but we prepare for that possibility.

```

```

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_expect_t
    private
      type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
      <Commands: cmd expect: TBP>
    end type cmd_expect_t
```

Simply tell the status.

```
<Commands: cmd expect: TBP>≡
  procedure :: write => cmd_expect_write

<Commands: procedures>+≡
  subroutine cmd_expect_write (cmd, unit, indent)
    class(cmd_expect_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    if (associated (cmd%pn_lexpr)) then
      write (u, "(1x,A)") "expect: [expression associated]"
    else
      write (u, "(1x,A)") "expect: [undefined]"
    end if
  end subroutine cmd_expect_write
```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

```
<Commands: cmd expect: TBP>+≡
  procedure :: compile => cmd_expect_compile

<Commands: procedures>+≡
  subroutine cmd_expect_compile (cmd, global)
    class(cmd_expect_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_arg
    pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_arg)
    cmd%pn_lexpr => parse_node_get_sub_ptr (pn_arg)
    call cmd%compile_options (global)
  end subroutine cmd_expect_compile
```

Execute. Evaluate both arguments, print them and their difference (if numerical), and whether they agree. Record the result.

```
<Commands: cmd expect: TBP>+≡
  procedure :: execute => cmd_expect_execute
```

```

⟨Commands: procedures⟩+≡
  subroutine cmd_expect_execute (cmd, global)
    class(cmd_expect_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    logical :: success, is_known
    success = &
      eval_log (cmd%pn_lexpr, cmd%local%var_list, is_known=is_known)
    if (is_known) then
      if (success) then
        call msg_message ("expect: success")
      else

Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

⟨Commands: types⟩+≡
  type :: sentry_expr_t
    type(parse_node_p), dimension(:), allocatable :: expr
    contains
    ⟨Commands: sentry expr: TBP⟩
  end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

⟨Commands: sentry expr: TBP⟩≡
  procedure :: compile => sentry_expr_compile

⟨Commands: procedures⟩+≡
  subroutine sentry_expr_compile (sentry, pn)
    class(sentry_expr_t), intent(out) :: sentry
    type(parse_node_t), intent(in), target :: pn
    type(parse_node_t), pointer :: pn_expr, pn_extra

    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_weight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd weight: TBP⟩+≡
  procedure :: execute => cmd_weight_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_weight_execute (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%weight_expr => cmd%pn_expr
  end subroutine cmd_weight_execute

```

Selection

Define a selection expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_selection_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd selection: TBP⟩
  end type cmd_selection_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

⟨Commands: cmd selection: TBP⟩≡
  procedure :: write => cmd_selection_write

⟨Commands: procedures⟩+≡
  subroutine cmd_selection_write (cmd, unit, indent)
    class(cmd_selection_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "selection expression: [defined]"
  end subroutine cmd_selection_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd selection: TBP⟩+≡
  procedure :: compile => cmd_selection_compile

```

```

<Commands: procedures>+≡
  subroutine cmd_selection_compile (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_selection_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd selection: TBP>+≡
  procedure :: execute => cmd_selection_execute

<Commands: procedures>+≡
  subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_reweight_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd reweight: TBP>
  end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd reweight: TBP>≡
  procedure :: write => cmd_reweight_write

<Commands: procedures>+≡
  subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: compile => cmd_reweight_compile

```

```

⟨Commands: procedures⟩+≡
  subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd reweight: TBP⟩+≡
  procedure :: execute => cmd_reweight_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_reweight_execute (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%reweight_expr => cmd%pn_expr
  end subroutine cmd_reweight_execute

```

Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_alt_setup_t
  private
    type(parse_node_p), dimension(:), allocatable :: setup
  contains
    ⟨Commands: cmd alt setup: TBP⟩
  end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

⟨Commands: cmd alt setup: TBP⟩≡
  procedure :: write => cmd_alt_setup_write

⟨Commands: procedures⟩+≡
  subroutine cmd_alt_setup_write (cmd, unit, indent)
    class(cmd_alt_setup_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
  end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

⟨Commands: cmd alt setup: TBP⟩+≡
  procedure :: compile => cmd_alt_setup_compile

```

```

⟨Commands: procedures⟩+=
subroutine cmd_alt_setup_compile (cmd, global)
  class(cmd_alt_setup_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_list, pn_setup
  integer :: i
  pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
  if (associated (pn_list)) then
    allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
    i = 1
    pn_setup => parse_node_get_sub_ptr (pn_list)
    do while (associated (pn_setup))
      cmd%setup(i)%ptr => pn_setup
      i = i + 1
      pn_setup => parse_node_get_next_ptr (pn_setup)
    end do
  else
    allocate (cmd%setup (0))
  end if
end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

⟨Commands: cmd alt setup: TBP⟩+=
procedure :: execute => cmd_alt_setup_execute

⟨Commands: procedures⟩+=
subroutine cmd_alt_setup_execute (cmd, global)

    call global%process_stack%init_result_vars (cmd%process_id(i))
    pn_proc => parse_node_get_next_ptr (pn_proc)
  end do
end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

<Commands: cmd integrate: TBP>+≡

```

procedure :: execute => cmd_integrate_execute

```

<Commands: procedures>+≡

```

subroutine cmd_integrate_execute (cmd, global)

```

Plots

Declare a plot. No mandatory arguments, just options.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_plot_t
    private
    type(string_t) :: id
contains

```

```

    <Commands: cmd plot: TBP>
end type cmd_plot_t

```

Output. Just print the ID.

```

<Commands: cmd plot: TBP>≡
    procedure :: write => cmd_plot_write

<Commands: procedures>+≡
    subroutine cmd_plot_write (cmd, unit, indent)
        class(cmd_plot_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A)") "plot: ", char (cmd%id)
    end subroutine cmd_plot_write

```

Compile. Record the plot ID and initialize lower, upper bound and bin width.

```

<Commands: cmd plot: TBP>+≡
    procedure :: compile => cmd_plot_compile

<Commands: procedures>+≡
    subroutine cmd_plot_compile (cmd, global)
        class(cmd_plot_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_tag
        pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
        cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
        call cmd%init (pn_tag, global)
    end subroutine cmd_plot_compile

```

This init routine is separated because it is reused below for graph initialization.

```

<Commands: cmd plot: TBP>+≡
    procedure :: init => cmd_plot_init

<Commands: procedures>+≡
    subroutine cmd_plot_init (plot, pn_tag, global)
        class(cmd_plot_t), intent(inout) :: plot
        type(parse_node_t), intent(in), pointer :: pn_tag
        type(rt_data_t), intent(inout), target :: global
        call plot%compile_options (global)
        select case (char (parse_node_get_rule_key (pn_tag)))
            case ("analysis_id")
                plot%id = parse_node_get_string (pn_tag)
            case default
                call msg_bug ("plot: name expression not implemented (yet)")
        end select
    end subroutine cmd_plot_init

```

Command execution. This declares the plot and allocates it in the analysis store.

```

<Commands: cmd plot: TBP>+≡
    procedure :: execute => cmd_plot_execute

```

```

<Commands: procedures>+≡
  subroutine cmd_plot_execute (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options

    call graph_options_init (graph_options)
    call set_graph_options (graph_options, cmd%local%var_list)
    call drawing_options_init_plot (drawing_options)
    call set_drawing_options (drawing_options, cmd%local%var_list)

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_graph_t
    private
    type(string_t) :: id
    integer :: n_elements = 0
    type(cmd_plot_t), dimension(:), allocatable :: el
    type(string_t), dimension(:), allocatable :: element_id
  contains
    <Commands: cmd graph: TBP>
  end type cmd_graph_t

```

Output. Just print the ID.

```

<Commands: cmd graph: TBP>≡
  procedure :: write => cmd_graph_write

<Commands: procedures>+≡
  subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)") "graph: ", char (cmd%id), &
      " (", cmd%n_elements, " entries)"
  end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: compile => cmd_graph_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_compile (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
    integer :: i

    pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      cmd%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("graph: name expression not implemented (yet)")
    end select
    pn_def => parse_node_get_next_ptr (pn_term, 2)
    cmd%n_elements = parse_node_get_n_sub (pn_def)
    allocate (cmd%element_id (cmd%n_elements))
    allocate (cmd%el (cmd%n_elements))
    pn_term => parse_node_get_sub_ptr (pn_def)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%el(1)%init (pn_tag, global)
    cmd%element_id(1) = parse_node_get_string (pn_tag)
    pn_app => parse_node_get_next_ptr (pn_term)
    do i = 2, cmd%n_elements
      pn_term => parse_node_get_sub_ptr (pn_app, 2)
      pn_tag => parse_node_get_sub_ptr (pn_term)
      cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
      call cmd%el(i)%init (pn_tag, global)
      cmd%element_id(i) = parse_node_get_string (pn_tag)
      pn_app => parse_node_get_next_ptr (pn_app)
    end do

  end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: execute => cmd_graph_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_execute (cmd, global)

```

```

class(cmd_graph_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(graph_options_t) :: graph_options
type(drawing_options_t) :: drawing_options
integer :: i, type

call graph_options_init (graph_options)
call set_graph_options (graph_options, cmd%local%var_list)
call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

do i = 1, cmd%n_elements
  if (associated (cmd%el(i)%options)) then
    call cmd%el(i)%options%execute (cmd%el(i)%local)
  end if
  type = analysis_store_get_object_type (cmd%element_id(i))
  select case (type)
    case (AN_HISTOGRAM)
      call drawing_options_init_histogram (drawing_options)
    case (AN_PLOT)
      call drawing_options_init_plot (drawing_options)
  end select
  call set_drawing_options (drawing_options, cmd%local%var_list)
  if (associated (cmd%el(i)%options)) then
    call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
  end if
  call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
end do
end subroutine cmd_graph_execute

```

Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
  type :: analysis_id_t
    type(string_t) :: tag
    type(parse_node_t), pointer :: pn_sexpr => null ()
  end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_analysis_t
    private
    type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
    ⟨Commands: cmd analysis: TBP⟩
  end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

⟨Commands: cmd analysis: TBP⟩≡

```

```

    procedure :: write => cmd_analysis_write
  <Commands: procedures>+≡
    subroutine cmd_analysis_write (cmd, unit, indent)
      class(cmd_analysis_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit); if (u < 0) return
      call write_indent (u, indent)
      write (u, "(1x,A)") "analysis: [defined]"
    end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

  <Commands: cmd analysis: TBP>+≡
    procedure :: compile => cmd_analysis_compile

  <Commands: procedures>+≡
    subroutine cmd_analysis_compile (cmd, global)
      class(cmd_analysis_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
    end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

  <Commands: cmd analysis: TBP>+≡
    procedure :: execute => cmd_analysis_execute

  <Commands: procedures>+≡
    subroutine cmd_analysis_execute (cmd, global)
      class(cmd_analysis_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      global%pn%analysis_lexpr => cmd%pn_lexpr
    end subroutine cmd_analysis_execute

```

Write histograms and plots

The data type encapsulating the command:

```

  <Commands: types>+≡
    type, extends (command_t) :: cmd_write_analysis_t
      private
      type(analysis_id_t), dimension(:), allocatable :: id
      type(string_t), dimension(:), allocatable :: tag
    contains
      <Commands: cmd write analysis: TBP>
    end type cmd_write_analysis_t

```

Output. Just the keyword.

```

  <Commands: cmd write analysis: TBP>≡
    procedure :: write => cmd_write_analysis_write

```

```

<Commands: procedures>+≡
subroutine cmd_write_analysis_write (cmd, unit, indent)
  class(cmd_write_analysis_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A)") "write_analysis"
end subroutine cmd_write_analysis_write

```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: compile => cmd_write_analysis_compile

<Commands: procedures>+≡
subroutine cmd_write_analysis_compile (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
  integer :: n, i
  pn_clause => parse_node_get_sub_ptr (cmd%pn)
  pn_args => parse_node_get_sub_ptr (pn_clause, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
  call cmd%compile_options (global)
  if (associated (pn_args)) then
    n = parse_node_get_n_sub (pn_args)
    allocate (cmd%id (n))
    do i = 1, n
      pn_id => parse_node_get_sub_ptr (pn_args, i)
      if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
        cmd%id(i)%tag = parse_node_get_string (pn_id)
      else
        cmd%id(i)%pn_sexpr => pn_id
      end if
    end do
  else
    allocate (cmd%id (0))
  end if
end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

<Limits: public parameters>+≡
character(*), parameter, public :: &
  DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
  FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(5), parameter, public :: &
  FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "lo", "la" ]
character(len=3), dimension(14), parameter, public :: &
  FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
    "f95", "log", "ltp", "mpx", "pdf", "phs", "sin", "tex" ]

```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```

<Commands: cmd write analysis: TBP>+≡
    procedure :: execute => cmd_write_analysis_execute

<Commands: procedures>+≡
    subroutine cmd_write_analysis_execute (cmd, global)
        class(cmd_write_analysis_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        call write_analysis_wrap (cmd%local%var_list, global%out_files, &
            cmd%id, tag = cmd%tag)
    end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

```

<Commands: procedures>+≡
    subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
        type(var_list_t), intent(inout), target :: var_list
        type(file_list_t), intent(inout), target :: out_files
        type(analysis_id_t), dimension(:), intent(in), target :: id
        type(string_t), dimension(:), allocatable, intent(out) :: tag

  end subroutine cmd_printf_compile

```

Execute. Evaluate the string (pretending this is a `sprintf` expression) and print it.

```

⟨Commands: cmd printf: TBP⟩+≡
  procedure :: execute => cmd_printf_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_printf_execute (cmd, global)

```

```

class(cmd_printf_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(string_t) :: string, file
type(eval_tree_t) :: sprintf_expr
logical :: advance
advance = var_list_get_lval (cmd%local%var_list, &
    var_str ("?out_advance"))
file = var_list_get_sval (cmd%local%var_list, &
    var_str ("out_file"))
call eval_tree_init_sexpr (sprintf_expr, cmd%sexpr, cmd%local%var_list)
call eval_tree_evaluate (sprintf_expr)
if (eval_tree_result_is_known (sprintf_expr)) then
    string = eval_tree_get_string (sprintf_expr)
    if (len (file) == 0) then
        call msg_result (char (string))
    else
        call file_list_write (global%out_files, file, string, advance)
    end if
end if
end subroutine cmd_printf_execute

```

Record data

The expression syntax already contains a **record** keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

<Commands: types>+=
type, extends (command_t) :: cmd_record_t
private
type(parse_node_t), pointer :: pn_lexpr => null ()
contains
<Commands: cmd record: TBP>
end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

<Commands: cmd record: TBP>=
procedure :: write => cmd_record_write

<Commands: procedures>+=
subroutine cmd_record_write (cmd, unit, indent)
class(cmd_record_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)" "record"
end subroutine cmd_record_write

```

Compile. This is a hack which transforms the **record** command into a **record** expression, which we handle in the expressions module.

```

<Commands: cmd record: TBP>+=
procedure :: compile => cmd_record_compile

```

```

⟨Commands: procedures⟩+≡
  subroutine cmd_record_compile (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
    call parse_node_create_branch (pn_lexpr, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))
    call parse_node_create_branch (pn_lsinglet, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lsinglet")))
    call parse_node_append_sub (pn_lexpr, pn_lsinglet)
    call parse_node_create_branch (pn_lterm, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lterm")))
    call parse_node_append_sub (pn_lsinglet, pn_lterm)
    pn_record => parse_node_get_sub_ptr (cmd%pn)
    call parse_node_append_sub (pn_lterm, pn_record)
    cmd%pn_lexpr => pn_lexpr
  end subroutine cmd_record_compile

```

Command execution. Again, transfer this to the embedded expression and just forget the logical result.

```

⟨Commands: cmd record: TBP⟩+≡
  procedure :: execute => cmd_record_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_record_execute (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    logical :: lval
    lval = eval_log (cmd%pn_lexpr, global%var_list)
  end subroutine cmd_record_execute

```

Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_unstable_t
    private
    integer :: n_proc = 0
    type(string_t), dimension(:), allocatable :: process_id
    type(parse_node_t), pointer :: pn_prt_in => null ()
  contains
    ⟨Commands: cmd unstable: TBP⟩
  end type cmd_unstable_t

```

Output: we know the process IDs.

```

⟨Commands: cmd unstable: TBP⟩≡
  procedure :: write => cmd_unstable_write

⟨Commands: procedures⟩+≡
  subroutine cmd_unstable_write (cmd, unit, indent)
    class(cmd_unstable_t), intent(in) :: cmd

```

```

integer, intent(in), optional :: unit, indent
integer :: u, i
u = output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A,1x,I0,1x,A)", advance="no") &
      "unstable:", 1, "("
do i = 1, cmd%n_proc
  if (i > 1) write (u, "(A,1x)", advance="no") " ,"
  write (u, "(A)", advance="no") char (cmd%process_id(i))
end do
write (u, "(A)" )
end subroutine cmd_unstable_write

```

Compile. Initiate an eval tree for the decaying particle and determine the decay channel process IDs.

<Commands: cmd unstable: TBP>+≡

```

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `fs_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

Range expressions

We need a special type for storing and evaluating range expressions.

```
(Commands: parameters)≡
integer, parameter :: STEP_NONE = 0
integer, parameter :: STEP_ADD = 1
integer, parameter :: STEP_SUB = 2
integer, parameter :: STEP_MUL = 3
integer, parameter :: STEP_DIV = 4
integer, parameter :: STEP_COMP_ADD = 11
integer, parameter :: STEP_COMP_MUL = 13
```

There is an abstract base type and two implementations: scan over integers and scan over reals.

```
(Commands: types)+≡
type, abstract :: range_t
type(parse_node_t), pointer :: pn_expr => null ()
type(parse_node_t), pointer :: pn_term => null ()
type(parse_node_t), pointer :: pn_factor => null ()
type(parse_node_t), pointer :: pn_value => null ()
type(parse_node_t), pointer :: pn_literal => null ()
type(parse_node_t), pointer :: pn_beg => null ()
type(parse_node_t), pointer :: pn_end => null ()
type(parse_node_t), pointer :: pn_step => null ()
type(eval_tree_t) :: expr_beg
type(eval_tree_t) :: expr_end
type(eval_tree_t) :: expr_step
integer :: step_mode = 0
integer :: n_step = 0
contains
(Commands: range: TBP)
end type range_t
```

These are the implementations:

```
(Commands: types)+≡
type, extends (range_t) :: range_int_t
integer :: i_beg = 0
integer :: i_end = 0
integer :: i_step = 0
contains
(Commands: range int: TBP)
end type range_int_t

type, extends (range_t) :: range_real_t
real(default) :: r_beg = 0
real(default) :: r_end = 0
real(default) :: r_step = 0
real(default) :: lr_beg = 0
real(default) :: lr_end = 0
real(default) :: lr_step = 0
```

```

contains
  <Commands: range real: TBP>
end type range_real_t

```

Finalize the allocated dummy node. The other nodes are just pointers.

```

<Commands: range: TBP>≡
  procedure :: final => range_final

<Commands: procedures>+≡
  subroutine range_final (object)
    class(range_t), intent(inout) :: object
    if (associated (object%pn_expr)) then

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

```

Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

Note: for the integer/real range array, the obvious implementation as a polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are apparently broken.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_scan_t

    !!! !!! gfortran 4.7.x memory corruption
    !!! class(range_t), dimension(:), allocatable :: range
    type(range_int_t), dimension(:), allocatable :: range_int
    type(range_real_t), dimension(:), allocatable :: range_real
contains
    <Commands: cmd scan: TBP>
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

(Commands: cmd scan: TBP)≡
  procedure :: final => cmd_scan_final

(Commands: procedures)+≡
  recursive subroutine cmd_scan_final (cmd)
    class(cmd_scan_t), intent(inout) :: cmd
    type(parse_node_t), pointer :: pn_var_single, pn_decl_single
    type(string_t) :: key
    integer :: i
    if (allocated (cmd%scan_cmd)) then
      do i = 1, size (cmd%scan_cmd)
        pn_var_single => parse_node_get_sub_ptr (cmd%scan_cmd(i)%ptr)

      do i = 1, size (cmd%range_int)
        call cmd%range_int(i)%final ()
      end do
    end if
    if (allocated (cmd%range_real)) then
      do i = 1, size (cmd%range_real)
        call cmd%range_real(i)%final ()
      end do
    end if
  end subroutine cmd_scan_final

```

Output.

```

(Commands: cmd scan: TBP)+≡
  procedure :: write => cmd_scan_write

(Commands: procedures)+≡
  subroutine cmd_scan_write (cmd, unit, indent)
    class(cmd_scan_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u

```

```

u = output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A,1x,A,1x,'(,IO,')')") "scan:", char (cmd%name), &
      cmd%n_values
end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

```

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of **else if** constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_if_t
private
type(parse_node_t), pointer :: pn_if_lexpr => null ()
type(command_list_t), pointer :: if_body => null ()
type(cmd_if_t), dimension(:), pointer :: elsif_cmd => null ()
type(command_list_t), pointer :: else_body => null ()
contains
<Commands: cmd if: TBP>
end type cmd_if_t

```

Finalizer. There are no local options, therefore we can simply override the default finalizer.

```

<Commands: cmd if: TBP>≡
procedure :: final => cmd_if_final

        type(parse_node_t), pointer :: pn_code_expr => null ()
        contains
        ⟨Commands: cmd quit: TBP⟩
    end type cmd_quit_t

```

Output.

```

⟨Commands: cmd quit: TBP⟩≡
    procedure :: write => cmd_quit_write

⟨Commands: procedures⟩+≡
    subroutine cmd_quit_write (cmd, unit, indent)
        class(cmd_quit_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = output_unit (unit); if (u < 0) return
    end subroutine cmd_quit_write

```

```

        call write_indent (u, indent)
        write (u, "(1x,A,L1)") "quit: has_code = ", cmd%has_code
    end subroutine cmd_quit_write

```

Compile: allocate a quit object which serves as a placeholder.

```

<Commands: cmd quit: TBP>+≡
    procedure :: compile => cmd_quit_compile

<Commands: procedures>+≡
    subroutine cmd_quit_compile (cmd, global)
        class(cmd_quit_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_arg
        pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
        if (associated (pn_arg)) then
            cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
            cmd%has_code = .true.
        end if
    end subroutine cmd_quit_compile

```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```

<Commands: cmd quit: TBP>+≡
    procedure :: execute => cmd_quit_execute

<Commands: procedures>+≡
    subroutine cmd_quit_execute (cmd, global)
        class(cmd_quit_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        logical :: is_known
        if (cmd%has_code) then
            global%quit_code = eval_int (cmd%pn_code_expr, global%var_list, &
                is_known=is_known)
            if (.not. is_known) then
                call msg_error ("Undefined return code of quit/exit command")
            end if
        end if
        global%quit = .true.
    end subroutine cmd_quit_execute

```

23.2.2 The command list

The command list holds a list of commands and relevant global data.

```

<Commands: public>+≡
    public :: command_list_t

<Commands: types>+≡
    type :: command_list_t
        ! not private anymore as required by the whizard-c-interface
        class(command_t), pointer :: first => null ()

```

```

        class(command_t), pointer :: last => null ()
    contains
        <Commands: command list: TBP>
    end type command_list_t

```

Output.

```

<Commands: command list: TBP>≡
    procedure :: write => command_list_write
<Commands: procedures>+≡
    recursive subroutine command_list_write (cmd_list, unit, indent)
        class(command_list_t), intent(in) :: cmd_list
        integer, intent(in), optional :: unit, indent
        class(command_t), pointer :: cmd
        cmd => cmd_list%first
        do while (associated (cmd))
            call cmd%write (unit, indent)
            cmd => cmd%next
        end do
    end subroutine command_list_write

```

Append a new command to the list and free the original pointer.

```

<Commands: command list: TBP>+≡
    procedure :: append => command_list_append
<Commands: procedures>+≡
    subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
        if (associated (cmd_list%last)) then
            cmd_list%last%next => command
        else
            cmd_list%first => command
        end if
        cmd_list%last => command
        command => null ()
    end subroutine command_list_append

```

Finalize.

```

<Commands: command list: TBP>+≡
    procedure :: final => command_list_final
<Commands: procedures>+≡
    recursive subroutine command_list_final (cmd_list)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), pointer :: command
        do while (associated (cmd_list%first))
            command => cmd_list%first
            cmd_list%first => cmd_list%first%next
            call command%final ()
            deallocate (command)
        end do
        cmd_list%last => null ()
    end subroutine command_list_final

```

23.2.3 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```
(Commands: command list: TBP)+≡
  procedure :: compile => command_list_compile

(Commands: procedures)+≡
  recursive subroutine command_list_compile (cmd_list, pn, global)
    class(command_list_t), intent(inout), target :: cmd_list
    type(parse_node_t), intent(in), target :: pn
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_cmd
    class(command_t), pointer :: command
    integer :: i
    pn_cmd => parse_node_get_sub_ptr (pn)
    do i = 1, parse_node_get_n_sub (pn)
      call dispatch_command (command, pn_cmd)
      call command%compile (global)
      call cmd_list%append (command)
      call terminate_now_if_signal ()
      pn_cmd => parse_node_get_next_ptr (pn_cmd)
    end do
  end subroutine command_list_compile
```

23.2.4 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```
(Commands: command list: TBP)+≡
  procedure :: execute => command_list_execute

(Commands: procedures)+≡
  recursive subroutine command_list_execute (cmd_list, global)
    class(command_list_t), intent(in) :: cmd_list
    type(rt_data_t), intent(inout), target :: global
    class(command_t), pointer :: command
    command => cmd_list%first
    COMMAND_COND: do while (associated (command))
      call command%execute_options (global)
      call command%execute (global)
      call command%reset_options (global)
      call terminate_now_if_signal ()
      if (global%quit) exit COMMAND_COND
      command => command%next
    end do COMMAND_COND
  end subroutine command_list_execute
```

23.2.5 Command list syntax

```
<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡
    public :: syntax_cmd_list_init

<Standard module head>

<WHIZARD: public>

<WHIZARD: types>

save

```

```

contains

<WHIZARD: procedures>

end module whizard

```

23.3.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the **whizard** object. Most parameters are used for initializing the **global** state.

```

<WHIZARD: public>≡
  public :: whizard_options_t

<WHIZARD: types>≡
  type :: whizard_options_t
    type(string_t) :: preload_model
    type(string_t) :: default_lib
    type(string_t) :: preload_libraries
    logical :: rebuild_library = .false.
    logical :: recompile_library = .false.
    logical :: rebuild_user
    logical :: rebuild_phs = .false.
    logical :: rebuild_grids = .false.
    logical :: rebuild_events = .false.
  end type whizard_options_t

```

23.3.2 Parse tree stack

We collect all parse trees that we generate in the **whizard** object. To this end, we create a stack of parse trees. They must not be finalized before the **global** object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

<WHIZARD: types>+≡
  type, extends (parse_tree_t) :: pt_entry_t
    type(pt_entry_t), pointer :: previous => null ()
  end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the **last** pointer.

```

<WHIZARD: types>+≡
  type :: pt_stack_t
    type(pt_entry_t), pointer :: last => null ()
    contains
    <WHIZARD: pt stack: TBP>
  end type pt_stack_t

```

The finalizer is called at the very end.

```

<WHIZARD: pt stack: TBP>≡
  procedure :: final => pt_stack_final

```

```

<WHIZARD: procedures>≡
  subroutine pt_stack_final (pt_stack)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(pt_entry_t), pointer :: current
    do while (associated (pt_stack%last))
      current => pt_stack%last
      pt_stack%last => current%previous
      call parse_tree_final (current%parse_tree_t)
      deallocate (current)
    end do
  end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt_stack: TBP>+≡
  procedure :: push => pt_stack_push

<WHIZARD: procedures>+≡
  subroutine pt_stack_push (pt_stack, parse_tree)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(parse_tree_t), intent(out), pointer :: parse_tree
    type(pt_entry_t), pointer :: current
    allocate (current)
    parse_tree => current%parse_tree_t
    current%previous => pt_stack%last
    pt_stack%last => current
  end subroutine pt_stack_push

```

23.3.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a WHIZARD instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+≡
  public :: whizard_t

<WHIZARD: types>+≡
  type :: whizard_t
    type(whizard_options_t) :: options
    type(rt_data_t) :: global
    type(pt_stack_t) :: pt_stack
  contains
    <WHIZARD: whizard: TBP>
  end type whizard_t

```

23.3.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>≡
  procedure :: init => whizard_init

<WHIZARD: procedures>+≡
  subroutine whizard_init (whizard, options, paths, logfile)
    class(whizard_t), intent(out), target :: whizard
    type(whizard_options_t), intent(in) :: options
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
    call init_syntax_tables ()
    whizard%options = options
    call whizard%global%global_init (paths, logfile)
    call whizard%init_rebuild_flags ()
    call whizard%preload_model ()
    call whizard%preload_library ()
  end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: final => whizard_final

<WHIZARD: procedures>+≡
  subroutine whizard_final (whizard)
    class(whizard_t), intent(inout), target :: whizard
    call whizard%global%final ()
    call whizard%pt_stack%final ()
    !!! JRR: WK please check (#529)
    !   call user_code_final ()
    call final_syntax_tables ()
  end subroutine whizard_final

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: procedures>+≡
  subroutine whizard_init_rebuild_flags (whizard)
    class(whizard_t), intent(inout), target :: whizard
    associate (var_list => whizard%global%var_list, options => whizard%options)
      call var_list_append_log &
        (var_list, var_str ("?rebuild_library"), options%rebuild_library, &
          intrinsic=.true.)
      call var_list_append_log &
        (var_list, var_str ("?recompile_library"), &
          options%recompile_library, &
          intrinsic=.true.)
      call var_list_append_log &
        (var_list, var_str ("?rebuild_phase_space"), options%rebuild_phs, &

```

```

        intrinsic=.true.)
    call var_list_append_log &
        (var_list, var_str ("?rebuild_grids"), options%rebuild_grids, &
        intrinsic=.true.)
    call var_list_append_log &
        (var_list, var_str ("?rebuild_events"), options%rebuild_events, &
        intrinsic=.true.)
    end associate
end subroutine whizard_init_rebuild_flags

```

This procedure preloads a model, if a model name is given.

(WHIZARD: whizard: TBP)+≡

```

    procedure :: preload_model => whizard_preload_model

```

(WHIZARD: procedures)+≡

```

subroutine whizard_preload_model (whizard)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t) :: model_name, filename
    model_name = whizard%options%preload_model
    if (model_name /= "") then
        filename = model_name // ".mdl"
        call whizard%global%read_model (model_name, filename)
        if (associated (whizard%global%model)) then
            call msg_message ("Preloaded model: " &
                // char (model_name))
        else
            call msg_fatal ("Preloading model " // char (model_name) &
                // " failed")
        end if
    else
        call msg_message ("No model preloaded")
    end if
end subroutine whizard_preload_model

```

This procedure preloads a library, if a library name is given.

Note: This version just opens a new library with that name. It does not load (yet) an existing library on file, as previous WHIZARD versions would do.

(WHIZARD: whizard: TBP)+≡

```

    procedure :: preload_library => whizard_preload_library

```

(WHIZARD: procedures)+≡

```

subroutine whizard_preload_library (whizard)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t) :: library_name, libs
    type(string_t), dimension(:), allocatable :: libname_static
    type(prclib_entry_t), pointer :: lib_entry
    integer :: i
    call get_prclib_static (libname_static)
    do i = 1, size (libname_static)
        allocate (lib_entry)
        call lib_entry%init_static (libname_static(i))
        call whizard%global%add_prclib (lib_entry)
    end do
    libs = adjustl (whizard%options%preload_libraries)

```

```

if (libs == "" .and. whizard%options%default_lib /= "") then
  allocate (lib_entry)
  call lib_entry%init (whizard%options%default_lib)
  call whizard%global%add_prclib (lib_entry)
  call msg_message ("Preloaded library: " // &
    char (whizard%options%default_lib))
end if
SCAN_LIBS: do while (libs /= "")
  call split (libs, library_name, " ")
  if (library_name /= "") then
    allocate (lib_entry)
    call lib_entry%init (library_name)
    call whizard%global%add_prclib (lib_entry)
    call msg_message ("Preloaded library: " // char (library_name))
  end if
end do SCAN_LIBS
end subroutine whizard_preload_library

```

23.3.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

```

<WHIZARD: public>+≡
  public :: init_syntax_tables
  public :: final_syntax_tables

<WHIZARD: procedures>+≡
  subroutine init_syntax_tables ()
    call syntax_model_file_init ()
    call syntax_phs_forest_init ()
    call syntax_pexpr_init ()
    call syntax_slha_init ()
    call syntax_blha_contract_init ()
    call syntax_cmd_list_init ()
  end subroutine init_syntax_tables

  subroutine final_syntax_tables ()
    call syntax_model_file_final ()
    call syntax_phs_forest_final ()
    call syntax_pexpr_final ()
    call syntax_slha_final ()
    call syntax_blha_contract_final ()
    call syntax_cmd_list_final ()
  end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
    public :: write_syntax_tables

<WHIZARD: procedures>+≡
    subroutine write_syntax_tables ()
        integer :: unit
        character(*), parameter :: file_model = "whizard.model_file.syntax"
        character(*), parameter :: file_phs = "whizard.phase_space_file.syntax"
        character(*), parameter :: file_pexpr = "whizard.prt_expressions.syntax"
        character(*), parameter :: file_slha = "whizard.slha.syntax"
        character(*), parameter :: file_sindarin = "whizard.sindarin.syntax"
        unit = free_unit ()
        print *, "Writing file '" // file_model // "'"
        open (unit=unit, file=file_model, status="replace", action="write")
        write (unit, "(A)")  VERSION_STRING
        write (unit, "(A)")  "Syntax definition file: " // file_model
        call syntax_model_file_write (unit)
        close (unit)
        print *, "Writing file '" // file_phs // "'"
        open (unit=unit, file=file_phs, status="replace", action="write")
        write (unit, "(A)")  VERSION_STRING
        write (unit, "(A)")  "Syntax definition file: " // file_phs
        call syntax_phs_forest_write (unit)
        close (unit)
        print *, "Writing file '" // file_pexpr // "'"
        open (unit=unit, file=file_pexpr, status="replace", action="write")
        write (unit, "(A)")  VERSION_STRING
        write (unit, "(A)")  "Syntax definition file: " // file_pexpr
        call syntax_pexpr_write (unit)
        close (unit)
        print *, "Writing file '" // file_slha // "'"
        open (unit=unit, file=file_slha, status="replace", action="write")
        write (unit, "(A)")  VERSION_STRING
        write (unit, "(A)")  "Syntax definition file: " // file_slha
        call syntax_slha_write (unit)
        close (unit)
        print *, "Writing file '" // file_sindarin // "'"
        open (unit=unit, file=file_sindarin, status="replace", action="write")
        write (unit, "(A)")  VERSION_STRING
        write (unit, "(A)")  "Syntax definition file: " // file_sindarin
        call syntax_cmd_list_write (unit)
        close (unit)
    end subroutine write_syntax_tables

```

23.3.6 Execute command lists

Process commands given on the command line, stored as an ifile. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: process_ifile => whizard_process_ifile

```

```

<WHIZARD: procedures>+≡
  subroutine whizard_process_ifile (whizard, ifile, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    type(ifile_t), intent(in) :: ifile
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    call msg_message ("Reading commands given on the command line")
    call lexer_init_cmd_list (lexer)
    call stream_init (stream, ifile)
    call whizard%process_stream (stream, lexer, quit, quit_code)
    call stream_final (stream)
    call lexer_final (lexer)
  end subroutine whizard_process_ifile

```

Process standard input as a command list. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: process_stdin => whizard_process_stdin

<WHIZARD: procedures>+≡
  subroutine whizard_process_stdin (whizard, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
