21.2 Transverse momenta

This file contains the module `muli_momentum`. Its purpose is to store the actual value of the evolution parameter p_t^2 in a convenient way. We use the normalized value $p_t^2/p_{t,\max}^2$ for generating the next value of the scale, also need the square root of both p_t^2 and $p_t^2/p_{t,\max}^2$ for other purposes. That's why I store all four combinations together with $p_{t,\max}$ in an array.

21.3 Multi parton interactions

This file contains the module `muli_interactions`. The allowed interactions and their cross sections are defined here. Additionally, some coordinate transformations which annihilate divergencies of the cross sections are defined. Since the phase space border is hyperbolic, this transformations are also hyperbolic. That's why all interactions are named `x_cart` for cartesian or `x_hyp` for hyperbolic to avoid confusion.

```

21.4 VEGAS and CUBA integration routines

This file contains the module `muli_cuba`, a wrapper for the CUBA integration library. Different algorithms and settings have been tried out for the integration, including VEGAS, and this wrapper has been mainly written for that purpose.

```

21.5 Trapezoidal integration routines

This file contains the module "muli_trapezium". The name is derived from the trapezoidal integration rule. The purpose of this module is to define a binary tree `muli_trapezium_tree_t` which holds a probability function in terms of trapezoidal segments. Its leaves of type `muli_trapezium_list_t` are connected to form a list, so you can either walk the root function back and forth or pick a certain segment in logarithmic time by walking down the tree. All nodes extend `muli_trapezium_t` which holds the actual values. Those are the values of the density function, the integral from this segment to the end of the integration area and a probability function calculated from these values. All values are taken at the upper "right" bound of the segment. Additionally the differences of these values to the values of the left neighbor is stored.

`<muli_trapezium.f90>≡`

```

module muli_trapezium

  end subroutine muli_trapezium_final_interface
end interface

```

This is the base type `muli_trapezium_t`. Its component values has a first index in $\{0, \dots, \text{dim} - 1\}$, while the second index distinguishes between `r_value`, `d_value`, `r_integral`, `d_integral`, `r_probability`, `d_probability`.

21.6 Fibonacci trees

This file contains the module `muli_fibonacci_tree`. A fibonacci tree is a self-balancing binary tree. "Balanced" means that the depth of the left successor may differ from the depth of the right successor in any node by maximally one. The maximally unbalanced tree is maximally unbalanced in every node. So the number of leaves of a maximally unbalanced fibonacci tree of depth n is precisely the n th fibonacci number.

We use this tree for the adaptive quadrature. In every iteration of the algorithm, we have to pick the segment with largest integration error, cut it into pieces and calculate the new integration error for the pieces. A binary tree is obviously a good choice for soring these segments. The problem is, that we always pick leaves from the same side of the tree. So the tree must decline at one side and grow at the other side. Sorting gets less efficient and finally most of the overall CPU time gets wasted for sorting. This tree outperforms a naive binary tree significantly in this particular job.

21.7 Adaptive Quadrature

This file contains the module `muli_aq` which is an acronym for adaptive quadrature. The abstract type `aq_class` is extended and the deferred procedure `evaluate` is defined. `muli_aq` calls `evaluate` to evaluate the integrand at any point in the given range. We have tried to use a procedure pointer instead of the deferred type-bound procedure, but no compiler was able to handle procedure pointers plus `cuba` was not able to handle parameters, to wit dimensions of the integrand that should not get integrated. So we switched to this odd way of using inheritance. Meanwhile these problems got solved and we could go for a more straightforward solution, but it works fine as it is.

`aq_class` uses `muli_trapezium` to approximate the integral. It still has to do the subdivision of segments and has to check whether the precision goal is reached.

Finally, the result is written to disc using the serialization framework defined in `muli_base`. Since QCD is not expected to change frequently, the only reason to regenerate this function is a change of the used PDF set. Then you can read the integral from disc each time you run a simulation with the same PDF set.

```

```

Usually, the tree is sorted by the sum of errors. Now it shall be sorted by the right position. When at least one branch of the tree is itself a tree, i.e. each branch has got at least two leaves, then process each branch and merge the results. Now we got two sorted lists. Which one's leftmost node has got the lowest value of `r_position`? That one shall be the beginning of the merged list `lin_list`. Everything is prepared for the algorithm: `lin_list` is the beginning

of the sorted list, `last_node` is its end. `left_node` and `right_node` are the left-most nodes of the remainders of `left_list` and `right_list`. The latter will get stripped from left to right, until one of them ends. Then, either `left_list` or `right_list` is completely merged into `lin_list`. The other one gets appended to `lin_list`. In the second part of the big if clause, the tree has got two leaves at most. Is it more than one? There, `fib_tree` is a single leaf with an allocated "content" component of type `multi_trapezium_t`. If "content" is not type-compatible with `multi_trapezium_t`, then this whole conversion cannot succeed. We allocate a new node of type `multi_trapezium_list_t`. This list does not contain the content of `fib_tree`, it *is* a copy of the content, for `multi_trapezium_list_t` is an extension of `multi_trapezium_t`. In the next step, each branch of `fib_tree` is a single leaf. We could call this subroutine for each branch, but we do copy and paste for each branch instead. Finally we append one list to the other, the lowest value of `r_position` comes first.

21.8 Integrands for Multiple Interactions

This file contains the module `muli_dsigma`. Its only type `muli_dsigma_t` provides an integrand to `aq_class`. The actual integrand is the normalized differential cross section of a QCD $2 \rightarrow 2$ process $1/\sigma_0 \times d^3\sigma/(dp_T^2 dx_1 dx_2)$. We need a root function of this integrand in terms of p_T , so we have to integrate out x_1 and x_2 and have to approximate the root function of the leftover variable p_T . Integration of x_1 and x_2 is done by CUBA, the root function is approximated by `muli_aq`.

21.9 MC Integrations for QCD $2 \rightarrow 2$ processes

This file contains the module `multi_mcint` which is the Monte Carlo generator for QCD $2 \rightarrow 2$ interactions at given evolution parameter and given stratus. While `multi_t` takes care of generating the evolution parameter and the stratus, this module is about bookkeeping the strati and implementing a downstream importance sampling. The evolution parameter is a measure of transferred momentum and a “stratus” is a PDF category or, to be more precise, is whether the incoming partons are gluons or sea quarks or valence quarks.

The importance sampling then subdivides the phase space of variables $\{x_1, x_2, p_T\}$ into n^3 regions such that each region holds approximately n interactions. Thus,

we can generate a phase space point very quickly just by randomly picking a region, randomly picking a point within this region and comparing its exact cross section with the mean cross section for this actual evolution parameter and the actual stratus times the area of the picked phase space region.

The mean values must be generated in the module `muli_dsigma` before and are given to the procedure `sample_inclusive_generate_hit`. Finally the generated subregions should be written to a file via `write_to_marker` and then reused for each later WHIZARD run.

The type `sample_inclusive_t` holds the 16 strati, while the type `sample_int_kind_t` represents a single stratus, `sample_3d_t` is the whole $\{x_1, x_2, p_T\}$ phase space for each stratus, `sample_2d_t` is the $\{x_1, x_2\}$ plane with a slice of p_T and `sample_region_t` finally is a phase space region.

21.10 Proton remnants

This file contains the module `muli_remnant`. All bookkeeping of the proton remnants and twin quarks is done here. Furthermore, reweighting of the PDFs to derive remnant PDFs is done here.

```

  !!!

```

```

!!! This file contains the module "muli" which is the multiple parton
!!! interactions interface module to WHIZARD. muli is supposed to run together
!!! with initial state radiation. Both share a momentum evolution variable and
!!! compete for beam momentum, so the generation of this scale variable must
!!! be fully transparent to WHIZARD. That's why the corresponding procedures
!!! are here, while all other work like phase space integration, flavour
!!! generation and treatment of the beam remnant is put into muli_dsigma,
!!! muli_mcint and muli_remnant respectively.

```

```

!!! qcd_2_2_type is a container class for properties of qcd 2->2 interactions.
!!! It holds a very condensed internal representation and offers a convenient
!!! set of TBP to query all aspects without the burden of the generator
!!! internals.

```

```

!!! multi_t then is an extension of qcd_2_2_type that adds generator
!!! internals like random number generator, integrated cross-sections, the
!!! actual Monte Carlo generator for flavour genertation and beam remnants in
!!! tao_rnd, dsigma, samples and beam respectively.

Chapter 22

User Plugin Support

Here we collect interface code that enables the user to inject his own code into the WHIZARD workflow. The code uses data types defined elsewhere, and is referenced in the `eval_trees` module.

These are the modules:

user_code_interface Generic support and specific additions.

sf_user Handle user-defined structure functions.

22.1 User Code Interface

```
<user_code_interface.f90>≡  
  <File header>  
  
  module user_code_interface  
  
    use iso_c_binding !NODEP!  
    <Use kinds>  
    <Use strings>  
    use diagnostics  
    use c_particles  
    use os_interface  
  
    <Standard module head>  
  
    <User Code: public>  
  
    <User Code: variables>  
  
    <User Code: interfaces>  
  
    contains  
  
    <User Code: procedures>  
  
  end module user_code_interface
```

22.1.1 User Code Management

This data structure globally holds the filehandle of the user-code library:

```
<User Code: public>≡  
  public :: has_user_lib  
  
<User Code: variables>≡  
  type(dlaccess_t), save :: user_lib_handle  
  logical, save :: has_user_lib = .false.  
  type(string_t), save :: user
```

Compile, link and load user code files. Dlopen all user-provided libraries, included the one just compiled (if any).

By default, we are looking for a library `user.so/dylib`. If this is not present, try `user.f90` and compile it. This can be overridden.

In detail: First, compile all sources explicitly specified on the command line. Then collect all libraries specified on the command line, including `user.so` if it was generated. If there is still no code, check for an existing `user.f90` and compile this. Link everything into a `user.la` libtool library. When done, dlopen all libraries that we have so far.

```
<User Code: public>+≡  
  public :: user_code_init
```

```

22.1.2 Interfaces for user-defined functions

The following functions represent user-defined real observables. There may be one or two particles as argument, the result is a real value.

```
<User Code: public>+≡
  public :: user_obs_int_unary
  public :: user_obs_int_binary
  public :: user_obs_real_unary
  public :: user_obs_real_binary

<User Code: interfaces>≡
  abstract interface
    function user_obs_int_unary (prt1) result (ival) bind(C)
      use iso_c_binding !NODEP!
```

```

        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1
        integer(c_int) :: ival
    end function user_obs_int_unary
end interface

abstract interface
    function user_obs_int_binary (prt1, prt2) result (ival) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        integer(c_int) :: ival
    end function user_obs_int_binary
end interface

abstract interface
    function user_obs_real_unary (prt1) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1
        real(c_double) :: rval
    end function user_obs_real_unary
end interface

abstract interface
    function user_obs_real_binary (prt1, prt2) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        real(c_double) :: rval
    end function user_obs_real_binary
end interface

```

The following function takes an array of C-compatible particles and return a single value. The particle array represents a subevent. For C interoperability, we have to use an assumed-size array, hence the array size has to be transferred explicitly.

The cut function returns an `int`, which we should interpret as a logical value (nonzero=true).

```

<User Code: public>+≡
    public :: user_cut_fun

<User Code: interfaces>+≡
    abstract interface
        function user_cut_fun (prt, n_prt) result (iflag) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt
            integer(c_int), intent(in) :: n_prt
            integer(c_int) :: iflag
        end function user_cut_fun
    end interface

```

The event-shape function returns a real value.

```

<User Code: public>+≡
    public :: user_event_shape_fun

<User Code: interfaces>+≡
    abstract interface
        function user_event_shape_fun (prt, n_prt) result (rval) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt
            integer(c_int), intent(in) :: n_prt
            real(c_double) :: rval
        end function user_event_shape_fun
    end interface

```

22.1.3 Interfaces for user-defined interactions

The following procedure interfaces pertain to user-defined interactions, e.g., spectra or structure functions.

This subroutine retrieves the basic information for setting up the interaction and event generation. All parameters are `intent(inout)`, so we can provide default values. `n_in` and `n_out` are the number of incoming and outgoing particles, respectively. `n_states` is the total number of distinct states that should be generated (counting all states of the incoming particles). `n_col` is the maximal number of color entries a particle can have. `n_dim` is the number of input parameters, i.e., integration dimensions, that the structure function call requires for computing kinematics and matrix elements. `n_var` is the number of variables (e.g., momentum fractions) that the structure function call has to transfer from the kinematics to the dynamics evaluation.

```

<User Code: public>+≡
    public :: user_int_info

<User Code: interfaces>+≡
    abstract interface
        subroutine user_int_info (n_in, n_out, n_states, n_col, n_dim, n_var) &
            bind(C)
            use iso_c_binding !NODEP!
            integer(c_int), intent(inout) :: n_in, n_out, n_states, n_col
            integer(c_int), intent(inout) :: n_dim, n_var
        end subroutine user_int_info
    end interface

```

This subroutine retrieves the settings for the quantum number mask of a given particle index in the interaction. A nonzero value indicates that the corresponding quantum number is to be ignored. The lock index is the index of a particle that the current particle is related to. The relation applies if quantum numbers of one of the locked particles are summed over. (This is intended for helicity.)

```

<User Code: public>+≡
    public :: user_int_mask

```

```

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_mask (i_prt, m_flv, m_hel, m_col, i_lock) bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(in) :: i_prt
      integer(c_int), intent(inout) :: m_flv, m_hel, m_col, i_lock
    end subroutine user_int_mask
  end interface

```

This subroutine retrieves the quantum numbers for the particle index `i_prt` in state `i_state`. The `flv` value is a PDG code. The `hel` value is an integer helicity (twice the helicity for fermions). The `col` array is an array which has at most `n_col` entries (see above). All parameters are `intent(inout)` since default values exist. In particular, if a mask entry is set by the previous procedure, the corresponding quantum number is ignored anyway.

```

<User Code: public>+≡
  public :: user_int_state

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_state (i_state, i_prt, flv, hel, col) bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(in) :: i_state, i_prt
      integer(c_int), intent(inout) :: flv, hel
      integer(c_int), dimension(*), intent(inout) :: col
    end subroutine user_int_state
  end interface

```

This subroutine takes an array of particle objects with array length `n_in` and an array of input parameters between 0 and 1 with array length `n_dim`. It returns an array of particle objects with array length `n_out`. In addition, it returns an array of internal variables (e.g., momentum fractions, Jacobian) with array length `n_var` that is used by the following subroutine for evaluating the dynamics, i.e., the matrix elements.

```

<User Code: public>+≡
  public :: user_int_kinematics

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_kinematics (prt_in, rval, prt_out, xval) bind(C)
      use iso_c_binding !NODEP!
      use c_particles !NODEP!
      type(c_prt_t), dimension(*), intent(in) :: prt_in
      real(c_double), dimension(*), intent(in) :: rval
      type(c_prt_t), dimension(*), intent(inout) :: prt_out
      real(c_double), dimension(*), intent(out) :: xval
    end subroutine user_int_kinematics
  end interface

```

This subroutine takes the array of variables (e.g., momentum fractions) with length `n_var` which has been generated by the previous subroutine and a real variable, the energy scale of the event. It returns an array of matrix-element

values, one entry for each quantum state `n_states`. The ordering of matrix elements must correspond to the ordering of states.

```

<User Code: public>+≡
    public :: user_int_evaluate

<User Code: interfaces>+≡
    abstract interface
        subroutine user_int_evaluate (xval, scale, fval) bind(C)
            use iso_c_binding !NODEP!
            real(c_double), dimension(*), intent(in) :: xval
            real(c_double), intent(in) :: scale
            real(c_double), dimension(*), intent(out) :: fval
        end subroutine user_int_evaluate
    end interface

```

22.2 User Plugin for Structure Functions

This variant gives access to user-defined structure functions or spectra.

22.2.1 The module

```

<sf_user.f90>≡
    <File header>

    module sf_user

        use, intrinsic :: iso_c_binding !NODEP!
        <Use kinds>
        <Use strings>
        use io_units
        use format_defs, only: FMT_17
        use diagnostics
        use c_particles
        use lorentz
        use subevents
        use user_code_interface
        use pdg_arrays
        use model_data
        use flavors
        use helicities
        use colors
        use quantum_numbers
        use state_matrices
        use polarizations
        use interactions
        use sf_aux
        use sf_base

        <Standard module head>

        <SF user: public>

```

```

<SF user: types>

contains

<SF user: procedures>

end module sf_user

```

22.2.2 The user structure function data block

The data block holds the procedure pointers that are used for retrieving static information, as well as the actual evaluation.

```

<SF user: public>≡
    public :: user_data_t

<SF user: types>≡
    type, extends(sf_data_t) :: user_data_t
        private
        type(string_t) :: name
        integer :: n_in
        integer :: n_out
        integer :: n_tot
        integer :: n_states
        integer :: n_col
        integer :: n_dim
        integer :: n_var
        integer, dimension(2) :: pdg_in
        class(model_data_t), pointer :: model => null ()
        procedure(user_int_info), nopass, pointer :: info => null ()
        procedure(user_int_mask), nopass, pointer :: mask => null ()
        procedure(user_int_state), nopass, pointer :: state => null ()
        procedure(user_int_kinematics), nopass, pointer :: kinematics => null ()
        procedure(user_int_evaluate), nopass, pointer :: evaluate => null ()
    contains
        <SF user: user data: TBP>
    end type user_data_t

```

Assign procedure pointers from a dynamically loaded library, given the specified name.

We have to distinguish three cases: (1) Both beams are affected, and the user spectrum implements both beams. There is a single data object. (2) Both beams are affected, and the user spectrum applies to single beams. Fill two different objects. (3) A single beam is affected.

```

<SF User: public>≡
    public :: sf_user_data_init

<SF User: procedures>≡
    subroutine sf_user_data_init (data, name, flv, model)

```

22.2.4 The user structure function

For maximal flexibility, user structure functions separate kinematics from dynamics just as the PDF interface does. (JRR: Ok, I guess this now done for all structure functions, right?) We create `c_prt_t` particle objects from the incoming momenta (all other quantum numbers are irrelevant) and call the user-supplied kinematics function to compute the outgoing momenta, along with other variables that will be needed for matrix element evaluation. If known, we use the mass squared computed above. !!! JRR: WK please check (#529) I don't know actually whether this really fits into the setup done by WK.

```

```

22.2.5 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

<SF user: user: TBP>+≡
  procedure :: complete_kinematics => user_complete_kinematics
<SF user: procedures>+≡
  subroutine user_complete_kinematics (sf_int, x, f, r, rb, map)
    !!! JRR: WK please check (#529)
    !!! This cannot be correct, as the CIRCE1 structure function has
    !!! twice the variables (2->4 instead of 1->2 splitting)
    class(user_t), intent(inout) :: sf_int
    real(default), dimension(:), intent(out) :: x
    real(default), intent(out) :: f

Chapter 23

BLHA Interface

The code in this chapter implements support for the BLHA record that communicates data for NLO processes.

These are the modules:

blha_config

blha_interface

blha_driver

23.1 Module definition

These modules implement the communication with one loop matrix element providers according to the Binoth LesHouches Accord Interface. The actual matrix element(s) are loaded as a dynamic library.

The module is split into a configuration interface which manages configuration and handles the request and contract files, a module which interfaces the OLP matrix elements and a driver.

```

The BLHA-interface conventions require the quantity $S_{ij} = \langle M_{i,+} | T_i T_j | M_{i,-} \rangle$ to be produced, where i is the position of the splitting gluon. However, $\tilde{M} = \langle M_{i,-} | M_{i,+} \rangle$ is needed. This can be obtained using color conservation, $\sum_j T_j |M\rangle = 0$, so that

$$\sum_{j \neq i} S_{ij} = -\langle M_{i,+} | T_i^2 | M_{i,-} \rangle = -C_A \langle M_{i,+} | M_{i,-} \rangle = -C_A \tilde{M}^*$$

According to BLHA conventions, the real part of S_{ij} is located at positions $2i + 2nj$ in the output array, where n denotes the number of external particles and the enumeration of particles starts at zero. The subsequent position, i.e. $2i + 2nj + 1$ is designated to the imaginary part of S_{ij} . Note that, since the first array position is 1, the implemented position association deviates from the above one in the addition of 1.

Chapter 25

FKS Subtraction Scheme

The code in this chapter implements the FKS subtraction scheme for use with WHIZARD.

These are the modules:

fks_regions Given a process definition, identify singular regions in the associated phase space.

virtual Handle the virtual correction matrix element.

real_subtraction Handle the real-subtraction matrix element.

nlo_data Manage the subtraction objects.

phs_fks Phase-space parameterization with modifications for the FKS scheme.

This chapter deals with next-to-leading order contributions to cross sections. Basically, there are three major issues to be addressed: The creation of the $N+1$ -particle flavor structure, the construction of the $N+1$ -particle phase space and the actual calculation of the real- and virtual-subtracted matrix elements. The first is dealt with using the **auto_components** class, and it will be shown that the second and third issue are connected in FKS subtraction.

25.1 Brief outline of FKS subtraction

In the current state, this discussion is only concerned with lepton collisions. For hadron collisions, renormalization of parton distributions has to be taken into account. Further, for QCD corrections, initial-state radiation is necessarily present. However, most quantities have so far been only constructed for final-state emissions

The aim is to calculate the next-to-leading order cross section according to

$$d\sigma_{\text{NLO}} = \mathcal{B} + \mathcal{V} + \mathcal{R}d\Phi_{\text{rad}}.$$

Analytically, the divergences, in terms of poles in the complex quantity $\varepsilon = 2 - d/2$, cancel. However, this is in general only valid in an arbitrary, complex number of dimensions. This is, roughly, the content of the KLN-theorem. WHIZARD, as any other numerical program, is confined to four dimensions. We will assume

that the KLN-theorem is valid and that there exist subtraction terms \mathcal{C} such that

$$d\sigma_{\text{NLO}} = \mathcal{B} + \underbrace{\mathcal{V} + \mathcal{C}}_{\text{finite}} + \underbrace{\mathcal{R} - \mathcal{C}}_{\text{finite}},$$

i.e. the subtraction terms correspond to the divergent limits of the real and virtual matrix element.

Because \mathcal{C} subtracts the divergences of \mathcal{R} as well as those of \mathcal{V} , it suffices to consider one of them, so we focus on \mathcal{R} . For this purpose, \mathcal{R} is rewritten,

$$\mathcal{R} = \frac{1}{\xi^2} \frac{1}{1-y} (\xi^2(1-y)\mathcal{R}) = \frac{1}{\xi^2} \frac{1}{1-y} \tilde{\mathcal{R}},$$

with $\xi = (2k_{\text{rad}}^0)/\sqrt{s}$ and $y = \cos\theta$, where k_{rad}^0 denotes the energy of the radiated parton and θ is the angle between emitter and radiated parton. $\tilde{\mathcal{R}}$ is finite, therefore the whole singularity structure is contained in the prefactor $\xi^{-2}(1-y)^{-1}$. Combined with the d-dimensional phase space element,

$$\frac{d^{d-1}k}{2k^0(2\pi)^{d-1}} = \frac{s^{1-\varepsilon}}{(4\pi)^{d-1}} \xi^{1-2\varepsilon} (1-y)^{-\varepsilon} d\xi dy d\Omega^{d-2},$$

this yields

$$d\Phi_{\text{rad}}\mathcal{R} = dy(1-y)^{-1-\varepsilon} d\xi \xi^{-1-2\varepsilon} \tilde{R}.$$

This can further be rewritten in terms of plus-distributions,

$$\begin{aligned} \xi^{-1-2\varepsilon} &= -\frac{1}{2\varepsilon} \delta(\xi) + \left(\frac{1}{\xi}\right)_+ - 2\varepsilon \left(\frac{\log \xi}{\xi}\right)_+ + \mathcal{O}(\varepsilon^2), \\ (1-y)^{-1-\varepsilon} &= -\frac{2^{-\varepsilon}}{\varepsilon} \delta(1-y) + \left(\frac{1}{1-y}\right)_+ - \varepsilon \left(\frac{1}{1-y}\right)_+ \log(1-y) + \mathcal{O}(\varepsilon^2), \end{aligned}$$

(imagine that all this is written inside of integrals, which are spared for ease of notation) such that

$$\begin{aligned} d\Phi_{\text{rad}}\mathcal{R} &= -\frac{1}{2\varepsilon} dy(1-y)^{-1-\varepsilon} \tilde{R}(0, y) - d\xi \left[\frac{2^{-\varepsilon}}{\varepsilon} \left(\frac{1}{\xi}\right)_+ - 2 \left(\frac{\log \xi}{\xi}\right)_+ \right] \tilde{R}(\xi, 1) \\ &\quad + dy d\xi \left(\frac{1}{\xi}\right)_+ \left(\frac{1}{1-y}\right)_+ \tilde{R}(\xi, y) + \mathcal{O}(\varepsilon). \end{aligned}$$

The summand in the second line is of order $\mathcal{O}(1)$ and is the only one to reproduce $\mathcal{R}\xi, y$. It thus constitutes the sum of the real matrix element and the corresponding counterterms. The first summand consequently consists of the subtraction terms to the virtual matrix elements. Above formula thus allows to calculate all quantities to render the matrix elements finite.

alr	flst_alr	emi	ftuple_list

4	[-11,11,2,-2,2,-2]	5	(5,6)

Table 25.1: List of singular regions. The particles are represented by their PDG codes. The third column contains the emitter for the specific singular region. For the process involving an additional gluon, the gluon can either be emitted from one of the quarks or from the first gluon. Each emitter yields the same list of fundamental tuples, five in total. The last singular region corresponds to the process where the gluon splits up into two quarks. Here, there is only one fundamental tuple, corresponding to a singular configuration of the momenta of the additional quarks.

25.2 Identifying singular regions

In the FKS subtraction scheme, the phase space is decomposed into disjoint singular regions, such that

$$\sum_i \mathcal{S}_i + \sum_{ij} \mathcal{S}_{ij} = 1. \quad (25.1)$$

The quantities \mathcal{S}_i and \mathcal{S}_{ij} are functions of phase space corresponding to a pair of particles indices which can make up a divergent phase space region. We call such an index pair a fundamental tuple. For example, the process $e^+ e^- \rightarrow u \bar{u} g$ has two singular regions, (3, 5) and (4, 5), indicating that the gluon can be soft or collinear with respect to either the quark or the anti-quark. Therefore, the functions \mathcal{S}_{ij} have to be chosen in such a way that their contribution makes up most of (25.1) in phase-space configurations where (final-state) particle j is collinear to particle i or/and particle j is soft. The functions \mathcal{S}_i is the corresponding quantity for initial-state divergences.

As a singular region we understand the collection of real flavor structures associated with an emitter and a list of all possible fundamental tuples. As an example, consider the process $e^+ e^- \rightarrow u \bar{u} g$. At next-to-leading order, processes with an additionally radiated particle have to be considered. In this case, these are $e^+ e^- \rightarrow u \bar{u}, g g$, and $e^+ e^- \rightarrow u \bar{u} u \bar{u}$ (or the same process with any other quark). Table 25.2 sums up all possible singular regions for this problem.

Thus, during the preparation of a NLO-calculation, the possible singular regions have to be identified. `fkf_regions.f90` deals with this issue.

alr	ftuple	emitter	flst_alr
1	(3, 5)	5	[-11,11,-2,21,2,21]
2	(4, 5)	5	[-11,11,2,21,-2,21]
3	(3, 6)	5	[-11,11,-2,21,2,21]
4	(4, 6)	5	[-11,11,2,21,-2,21]
5	(5, 6)	5	[-11,11,2,-2,21,21]
6	(5, 6)	5	[-11,11,2,-2,2,-2]

```

Class for working with the flavor specification arrays.

```

<fks regions: public>+≡
    public :: flv_structure_t

<fks regions: types>+≡
    type :: flv_structure_t
        integer, dimension(:), allocatable :: flst
        integer :: nlegs
        logical, dimension(:), allocatable :: massive
        logical, dimension(:), allocatable :: colored
    contains
    <fks regions: flv structure: TBP>
    end type flv_structure_t

```

Returns `true` if the two particles at position `i` and `j` in the flavor array can originate from the same splitting. For this purpose, the function first checks

whether the splitting is allowed at all. If this is the case, the emitter is removed from the flavor array. If the resulting array is equivalent to the Born flavor structure `flv_born`, the pair is accepted as a valid splitting.

```

(fks regions: flv structure: TBP)≡
  procedure :: valid_pair => flv_structure_valid_pair

(fks regions: procedures)+≡
  function flv_structure_valid_pair &
    (flv_real,i,j, flv_born, model) result (valid)
    class(flv_structure_t), intent(in) :: flv_real
    integer, intent(in) :: i,j
    type(flv_structure_t), intent(in) :: flv_born
    type(model_data_t), intent(in) :: model
    logical :: valid
    integer :: k, n_orig
    type(flv_structure_t) :: flv_test
    integer, dimension(:), allocatable :: flv_orig, flv_orig2
    valid = .false.

```

First check whether the splitting is possible. The array `flv_orig` contains all particles which share a vertex with the particles at position `i` and `j`. If its size is equal to zero, no splitting is possible and the subroutine is exited.

```

(fks regions: procedures)+≡
  call model%match_vertex &
    (flv_real%flst(i), flv_real%flst(j), flv_orig)
  n_orig = size (flv_orig)
  if (n_orig == 0) then
    return
  else

```

For a quark emitting a gluon, `flv_orig` contains the PDG code of the anti-quark. To be on the safe side, a second array is created, which contains both the positively and negatively signed PDG codes. Then, the original tuple (i, j) is removed from the real flavor structure and the particles in `flv_orig2` are inserted. If the resulting Born configuration is equal to the underlying Born configuration, up to a permutation of final-state particles, the tuple (i, j) is accepted as valid.

```

(fks regions: procedures)+≡
  allocate (flv_orig2 (2*n_orig))
  flv_orig2 (1:n_orig) = flv_orig
  flv_orig2 (n_orig+1:2*n_orig) = -flv_orig
  do k = 1, 2*n_orig
    flv_test = flv_real%insert_particle (i,j,flv_orig2(k))
    valid = flv_born == flv_test
    if (valid) return
  end do
end if
end function flv_structure_valid_pair

```

This function checks whether two flavor arrays are the same up to a permutation of the final-state particles

```

In case of a $g \rightarrow gg$ or $g \rightarrow qq$ splitting, the factor

$$\frac{2E_{\text{em}}}{E_{\text{em}} + E_{\text{rad}}}$$

is multiplied to the real matrix element. This way, the symmetry of the splitting is used and only one singular region has to be taken into account. However, the factor ensures that there is only a soft singularity if the radiated parton becomes soft.

end function region_data_get_svalue_soft

```

This subroutine starts with a specification of N - and $N + 1$ -particle configurations, `flst_born` and `flst_real`, saved in `reg_data`. From these, it creates a list of fundamental tuples, a list of emitters and a list containing the $N + 1$ -particle configuration, rearranged in such a way that the emitter-radiation pair is last (`flst_alr`). For the $e^+e^- \rightarrow u\bar{u}g$ - example, the generated objects are

shown in table 25.2. Note that at this point, `flst_alr` is arranged in such a way that the emitter can only be equal to $n_{legs} - 1$ for final-state radiation or 0, 1, or 2 for initial-state radiation. Further, it occurs that regions can be equivalent. For example in table 25.2 the regions corresponding to `alr = 1` and `alr = 3` as well as `alr = 2` and `alr = 4` describe the same physics and are therefore equivalent.

The virtual-subtracted matrix element is given by the equation

$$\mathcal{V} = \frac{\alpha_s}{2\pi} \left(\mathcal{Q}\mathcal{B} + \sum \mathcal{I}_{ij}\mathcal{B}_{ij} + \mathcal{V}_{fin} \right), \quad (25.2)$$

where the quantity \mathcal{Q} is given by

$$\begin{aligned} \mathcal{Q} = \sum_{i=1}^n \left[\gamma'_{fi} - \log \frac{s}{Q^2} \left(\gamma_{fi} - 2C_{fi} \log \frac{2E_i}{\sqrt{s}} \right) \right. \\ \left. + 2C_{fi} \log^2 \frac{2E_i}{\sqrt{s}} - 2\gamma_{fi} \frac{2E_i}{\sqrt{s}} \right] \\ - \log \frac{\mu_F^2}{Q^2} (\gamma_{f+} + \gamma_{f-}). \end{aligned} \quad (25.3)$$

The expressions for \mathcal{I}_{ij} can be found in equations (25.4), (25.5), (25.6), depending on whether the particles involved in the radiation process are massive or massless.

```

The following code implements the \mathcal{I}_{ij} -function appearing in eq. blub. They are defined as follows:

Massless-Massless Case

$$\begin{aligned}\mathcal{I}_{ij} = & \frac{1}{2} \log^2 \frac{s}{Q^2} + \log \frac{s}{Q^2} \log \frac{k_i k_j}{2E_i E_j} - \text{Li}_2 \left(\frac{k_i k_j}{2E_i E_j} \right) \\ & + \frac{1}{2} \log^2 \frac{k_i k_j}{2E_i E_j} - \log \left(1 - \frac{k_i k_j}{2E_i E_j} \right) \log \frac{k_i k_j}{2E_i E_j}.\end{aligned}\quad (25.4)$$

Massive-Massive Case

$$\mathcal{I}_{ij} = -\frac{1}{2} I_0(k_i, k_j) \log \frac{Q^2}{s} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (25.5)$$

with

$$I_0(k_i, k_j) = \frac{1}{\beta} \log \frac{1+\beta}{1-\beta}, \quad \beta = \sqrt{1 - \frac{k_i^2 k_j^2}{(k_i \cdot k_j)^2}}$$

and a rather involved expression for I_ϵ :

$$\begin{aligned}I_\epsilon(k_i, k_j) = & (K(z_j) - K(z_i)) \frac{1 - \vec{\beta}_i \cdot \vec{\beta}_j}{\sqrt{a(1-b)}}, \\ \vec{\beta}_i = & \frac{\vec{k}_i}{k_i^0}, \\ a = & \beta_i^2 + \beta_j^2 - 2\vec{\beta}_i \cdot \vec{\beta}_j, \\ x_i = & \frac{\beta_i^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a}, \\ x_j = & \frac{\beta_j^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a} = 1 - x_i, \\ b = & \frac{\beta_i^2 \beta_j^2 - (\vec{\beta}_i \cdot \vec{\beta}_j)^2}{a}, \\ c = & \sqrt{\frac{b}{4a}}, \\ z_+ = & \frac{1 + \sqrt{1-b}}{\sqrt{b}}, \\ z_- = & \frac{1 - \sqrt{1-b}}{\sqrt{b}}, \\ z_i = & \frac{\sqrt{x_i^2 + 4c^2} - x_i}{2c}, \\ z_j = & \frac{\sqrt{x_j^2 + 4c^2} + x_j}{2c}, \\ K(z) = & -\frac{1}{2} \log^2 \frac{(z - z_-)(z_+ - z)}{(z_+ + z)(z_- + z)} - 2\text{Li}_2 \left(\frac{2z_-(z_+ - z)}{(z_+ - z_-)(z_- + z)} \right) \\ & - 2\text{Li}_2 \left(-\frac{2z_+(z_- + z)}{(z_+ - z_-)(z_+ - z)} \right)\end{aligned}$$

Massive-Massless Case

$$\mathcal{I}_{ij} = \frac{1}{2} \left[\log^2 \frac{Q}{s} - \frac{\pi^2}{6} \right] - \frac{1}{2} I_0(k_i, k_j) \log \frac{Q^2}{s} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (25.6)$$

with

$$I_0(p, k) = \log \frac{(\hat{p} \cdot \hat{k})^2}{\hat{k}^2},$$

$$I_\epsilon(p, k) = -2 \left[\frac{1}{4} \log^2 \frac{1-\beta}{1+\beta} + \log \frac{\hat{p} \cdot \hat{k}}{1+\beta} \log \frac{\hat{p} \cdot \hat{k}}{1-\beta} + Li_2 \left(1 - \frac{\hat{p} \cdot \hat{k}}{1+\beta} \right) + Li_2 \left(1 - \frac{\hat{p} \cdot \hat{k}}{1-\beta} \right) \right]$$

using

$$\hat{p} = \frac{p}{p^0}, \quad \hat{k} = \frac{k}{k^0}, \quad \beta = \frac{|\vec{k}|}{k_0}.$$

Soft subtraction terms

In the soft limit, the real matrix element behaves as

$$\mathcal{R}_{\text{soft}} = 4\pi\alpha_s \left[\sum_{i \neq j} \mathcal{B}_{ij} \frac{k_i \cdot k_j}{(k_i \cdot k)(k_j \cdot k)} - \mathcal{B} \sum_i \frac{k_i^2}{(k_i \cdot k)^2} C_i \right],$$

where k denotes the momentum of the emitted parton. The quantity \mathcal{B}_{ij} is called the color-correlated Born matrix element defined as

$$\mathcal{B}_{ij} = \frac{1}{2s} \sum_{\substack{\text{colors} \\ \text{spins}}} \mathcal{M}_{\{c_k\}} \left(\mathcal{M}_{\{c_k\}}^\dagger \right)_{\substack{c_i \rightarrow c'_i \\ c_j \rightarrow c'_j}} T_{c_i, c'_i}^a T_{c_j, c'_j}^a.$$

```

⟨real subtraction: types⟩≡

    allocate (sub_soft%momentum_matrix &
              (nlegs_born, nlegs_born))
  end subroutine soft_subtraction_init

```

The treatment of the momentum k follows the discussion about the soft limit of the partition functions (ref????). The parton momentum is pulled out, $k = E\hat{k}$. In fact, we will substitute \hat{k} for k throughout the code, because the energy will factor out of the equation when the soft \mathcal{S} -function is multiplied. The soft momentum is a unit vector, because $k^2 = (k^0)^2 - (\hat{k}^0)^2 \hat{k}^2 = 0$.

```

        q02 = 4* vector4_get_component (p_born(1), 0) * &
            vector4_get_component (p_born(2), 0)
        sub_soft%value(alr) = 4/q02 * (1-y) * sub_soft%value(alr)
    end subroutine soft_subtraction_compute

```

We have to multiply this with $\xi^2(1-y)$. Further, when applying the soft S -function, the energy of the radiated particle is factored out. Thus we have $\xi^2/E_{em}^2(1-y) = 4/q_0^2(1-y)$.

⟨nlo data: soft subtraction computation⟩≡

Computes the quantity $\mathcal{K}_{ij} = \frac{k_i \cdot k_j}{(k_i \cdot k)(k_j \cdot k)}$.

25.5.1 Collinear and soft-collinear subtraction terms

This data type deals with the calculation of the collinear and soft-collinear contribution to the cross section.

```

<real subtraction: types>+≡
type :: coll_subtraction_t
  real(default), dimension(:), allocatable :: value
  real(default), dimension(:), allocatable :: value_soft
  integer :: n_alr
  real(default), dimension(0:3,0:3) :: b_munu
  real(default) , dimension(0:3,0:3) :: k_perp_matrix
contains
  <real subtraction: coll sub: TBP>
end type coll_subtraction_t

```

```

<real subtraction: coll sub: TBP>≡
procedure :: init => coll_subtraction_init

```

```

<real subtraction: procedures>+≡
subroutine coll_subtraction_init (coll_sub, n_alr)
class(coll_subtraction_t), intent(inout) :: coll_sub
integer, intent(in) :: n_alr
coll_sub%n_alr = n_alr
allocate (coll_sub%value (n_alr))
allocate (coll_sub%value_soft (n_alr))
end subroutine coll_subtraction_init

```

To compute the collinear limit of \mathcal{R} , we follow the original FKS-paper. Here, the real amplitude is supposed to factorize in the collinear limit. considering a splitting $g \rightarrow g(i)g(j)$,

$$\mathcal{A}^{(n)}(h_i, h_j, \{h_l\}) \xrightarrow{i||j} g_s \sum_{d_e} \sum_{h_e} C(d_e, b, c) S_{gg}^{h_e h_i h_j}(z) \mathcal{A}_{d_e}^{(n-1)}(h_e, \{h_l\})$$

Explain quantities. Evaluating this expression leads to

$$|\mathcal{A}^{(n)}(h_i, h_j, \{h_l\})|^2 \xrightarrow{i||j} |\mathcal{N}^{(n)}(h_i, h_j, \{h_l\})|^2 + \mathcal{R}(h_i, h_j, \{h_l\})^2,$$

where \mathcal{R} contains all contributions with spin-correlated amplitudes, i.e. terms like $\mathcal{A}_{d_e}^{(n-1)}(+, \{h_l\}) \left(\mathcal{A}_{d_e}^{(n-1)}(-, \{h_l\}) \right)^*$. Explicitly,

$$\sum_{h_i, h_j, \{h_l\}} \sum_{\{d_l\}} |\mathcal{N}^{(n)}(h_i, h_j, \{h_l\})|^2 = \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{gg}(z) |\mathcal{A}^{(n-1)}|^2,$$

and

$$\begin{aligned} \sum_{h_i, h_j, \{h_l\}} \sum_{\{d_l\}} \mathcal{R}(h_i, h_j, \{h_l\}) &= 32\pi\alpha_s C_A z(1-z) \\ &\times \underbrace{\operatorname{Re} \left\{ \frac{\langle ij \rangle}{[ij]} \sum_{\{h_l\}} \sum_{d_e, \{d_l\}} \mathcal{A}_{d_e}^{(n-1)}(+, \{h_l\}) \left(\mathcal{A}_{d_e}^{(n-1)}(-, \{h_l\}) \right)^* \right\}}_{-\tilde{\mathcal{M}}^{(n-1)}/(2k_i \cdot k_j)}. \end{aligned}$$

This yields

$$\mathcal{M}^{(n)} \xrightarrow{i||j} \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{gg}(z) \mathcal{M}^{(n-1)} - \frac{16\pi\alpha_s}{k_i \cdot k_j} C_A z(1-z) \tilde{\mathcal{M}}^{(n-1)}. \quad (25.7)$$

The equivalent expression for a $g \rightarrow qq$ -splitting is given by

$$\mathcal{M}^{(n)} \xrightarrow{i||j} \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{qg}(z) \mathcal{M}^{(n-1)} + \frac{16\pi\alpha_s}{k_i \cdot k_j} T_F z(1-z) \tilde{\mathcal{M}}^{(n-1)}. \quad (25.8)$$

<real subtraction: coll sub: TBP>+≡

`procedure :: compute => coll_subtraction_compute`

<real subtraction: procedures>+≡

```
subroutine coll_subtraction_compute &
  (coll_sub, sregion, p_born, sqme_born, sqme_born_sc, &
   xi, alpha_s, alr, soft_in)
  class(coll_subtraction_t), intent(inout) :: coll_sub
  type(singular_region_t), intent(in) :: sregion
  type(vector4_t), intent(in), dimension(:) :: p_born
  real(default), intent(in) :: sqme_born
  real(default), intent(in) :: sqme_born_sc
  real(default), intent(in) :: xi, alpha_s
  integer, intent(in) :: alr
```

The function obtains a flag to indicate whether the limit to be computed is also soft. Moreover, this consideration explains the structure of the code. In the soft limit, we find $z \rightarrow 0$ as well as $\xi \rightarrow 0$. However, the quantity z/ξ is finite, because

$$\frac{z}{\xi} = \frac{p_{rad}^0}{\bar{p}_{em}^0} \frac{q^0}{2p_{em}^0} = \frac{q^0}{2\bar{p}_{em}^0}.$$

Thus, all expressions are written in terms of this well-behaved quantity. Recalling that there is a prefactor of $(\xi^2 z)^{-1}$, it is necessary to expand with z once.

25.5.3 The real contribution to the cross section

In each singular region α , the real contribution to σ is given by the second summand of eqn. ??,

$$\sigma_{\text{real}}^{\alpha} = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 dy \int_0^{\xi_{\text{max}}} d\xi \left(\frac{1}{\xi} \right)_+ \left(\frac{1}{1-y} \right) + \underbrace{\frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1-y)\xi^2 \mathcal{R}^{\alpha}(\Phi_{n+1})]}_{\substack{g^{\alpha}(\xi, y) \\ (25.9)}}.$$

Writing out the plus-distribution and introducing $\tilde{\xi} = \xi/\xi_{\text{max}}$ to set the upper integration limit to 1, this turns out to be equal to

$$\begin{aligned} \sigma_{\text{real}}^{\alpha} = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 \frac{dy}{1-y} \left\{ \int_0^1 d\tilde{\xi} \left[\frac{g^{\alpha}(\tilde{\xi}\xi_{\text{max}}, y)}{\tilde{\xi}} - \underbrace{\frac{g^{\alpha}(0, y)}{\tilde{\xi}}}_{\text{soft}} - \underbrace{\frac{g^{\alpha}(\tilde{\xi}\xi_{\text{max}}, 1)}{\tilde{\xi}}}_{\text{coll.}} + \underbrace{\frac{g^{\alpha}(0, 1)}{\tilde{\xi}}}_{\text{coll.}+\text{soft}} \right] \right. \\ \left. + [\log \xi_{\text{max}}(y)g^{\alpha}(0, y) - \log \xi_{\text{max}}(1)g^{\alpha}(0, 1)] \right\}. \end{aligned} \quad (25.10)$$

This formula is implemented in `compute_sqme_real_fin`

The fks phase space type contains the wood phase space and separately the in- and outgoing momenta for the real process and the corresponding Born momenta. Additionally, there are the variables ξ, ξ_{max}, y and ϕ which are used to create the real phase space, as well as the jacobian and its corresponding soft and collinear limit. Lastly, the array `ch_to_em` connects each channel with an emitter.

25.7.1 Creation of the real phase space - FSR

At this point, the Born phase space has been generated, as well as the three random variables ξ , y and ϕ . The question is how the real phase space is generated for a final-state emission configuration. We work with two different sets of momenta, the Born configuration $\{\bar{k}_\oplus, \bar{k}_\ominus, \bar{k}_1, \dots, \bar{k}_n\}$ and the real configuration $\{k_\oplus, k_\ominus, k_1, \dots, k_n, k_{n+1}\}$. We define the momentum of the emitter to be on the n -th position and the momentum of the radiated particle to be at position $n+1$. The magnitude of the spatial component of k is denoted by \underline{k} .

For final-state emissions, it is $\bar{k}_\oplus = k_\oplus$ and $\bar{k}_\ominus = k_\ominus$. Thus, the center-of-mass systems coincide and it is

$$q = \sum_{i=1}^n \bar{k}_i = \sum_{i=1}^{n+1} k_i, \quad (25.11)$$

with $\vec{q} = 0$ and $q^2 = (q^0)^2$.

We want to construct the real phase space from the Born phase space using three random numbers. They are defined as follows:

- $\xi = \frac{2k_{n+1}^0}{\sqrt{s}} \in [0, \xi_{max}]$, where k_{n+1} denotes the four-momentum of the radiated particle.
- $y = \cos \theta = \frac{\vec{k}_n \cdot \vec{k}_{n+1}}{\underline{k}_n \underline{k}_{n+1}}$ is the splitting angle.
- The angle between the two splitting particles in the transversal plane, $\phi \in [0, 2\pi]$.

Further, $k_{rec} = \sum_{i=1}^{n-1} k_i$ denotes the sum of all recoiling momenta.

end function compute_beta_massive

```

The momentum of the radiated particle is computed according to

$$\underline{k}_n = \frac{q^2 - M_{\text{rec}}^2 - 2q^0 \underline{k}_{n+1}}{2(q^0 - \underline{k}_{n+1}(1-y))}, \quad (25.12)$$

with $k = k_n + k_{n+1}$ and $M_{\text{rec}}^2 = k_{\text{rec}}^2 = (q - k)^2$. Because of $\bar{\mathbf{k}}_n \parallel \mathbf{k}_n + \mathbf{k}_{n+1}$ we find $M_{\text{rec}}^2 = (q - \bar{k}_n)^2$. Equation ?? follows from the fact that $(\mathbf{k} - \mathbf{k}_n)^2 = \mathbf{k}_{n+1}^2$, which is equivalent to $\mathbf{k}_n \cdot \mathbf{k} = \frac{1}{2}(k_n^2 + k^2 - k_{n+1}^2)$. \mathbf{k}_n and \mathbf{k}_{n+1} are obtained by first setting up vectors parallel to $\bar{\mathbf{k}}_n$,

$$\mathbf{k}'_n = \underline{k}_n \frac{\bar{\mathbf{k}}_n}{\bar{k}_n}, \quad \mathbf{k}'_{n+1} = \underline{k}_{n+1} \frac{\bar{\mathbf{k}}_n}{\bar{k}_n},$$

and then rotating these vectors by an amount of $\cos \psi_n = \frac{\mathbf{k}_n \cdot \mathbf{k}}{\bar{k}_n \underline{k}}$. The emitted particle cannot have more momentum than the emitter has in the Born phase space. Thus, there is an upper bound for ξ , determined by the condition $k_{n+1}^0 = \bar{k}_n$, which is equal to

$$\xi_{\text{max}} = \frac{2}{\bar{k}_n} q^0.$$

Chapter 26

Model Handling and Features

These modules deal with process definitions and physics models.

These modules use the `model_data` methods to automatically generate process definitions.

auto_components Generic process-definition generator. We can specify a basic process or initial particle(s) and some rules to extend this process, given a model definition with particle names and vertex structures.

radiation_generator Applies the generic generator to the specific problem of generating NLO corrections in a restricted setup.

Model construction:

eval_trees Implementation of the generic `expr_t` type for the concrete evaluation of expressions that access user variables.

This module is actually part of the Sindarin language implementation, and should be moved elsewhere. Currently, the `models` module relies on it.

models Extends the `model_data_t` structure by user-variable objects for easy access, and provides the means to read a model definition from file.

slha_interface Read/write a SUSY model in the standardized SLHA format. The format defines fields and parameters, but no vertices.

26.1 Automatic generation of process components

This module provides the functionality for automatically generating radiation corrections or decays, provided as lists of PDG codes.

```
<auto_components.f90>≡  
  <File header>  
  
  module auto_components

  end module auto_components
```

26.1.1 Constraints: Abstract types

An abstract type that denotes a constraint on the automatically generated states. The concrete objects are applied as visitor objects at certain hooks during the splitting algorithm.

```
<Auto components: types>≡  
  type, abstract :: split_constraint_t  
    contains  
    <Auto components: split constraint: TBP>  
  end type split_constraint_t
```

By default, all checks return true.

```
<Auto components: split constraint: TBP>≡  
  procedure :: check_before_split => split_constraint_check_before_split  
  procedure :: check_before_insert => split_constraint_check_before_insert  
  procedure :: check_before_record => split_constraint_check_before_record
```

```

<Auto components: procedures>≡
  subroutine split_constraint_check_before_split (c, table, pl, k, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: k
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_split

  subroutine split_constraint_check_before_insert (c, table, pa, pl, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_array_t), intent(in) :: pa
    type(pdg_list_t), intent(inout) :: pl
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_insert

  subroutine split_constraint_check_before_record (c, table, pl, n_loop, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_record

```

A transparent wrapper, so we can collect constraints of different type.

```

<Auto components: types>+≡
  type :: split_constraint_wrap_t
    class(split_constraint_t), allocatable :: c
  end type split_constraint_wrap_t

```

A collection of constraints.

```

<Auto components: public>≡
  public :: split_constraints_t

<Auto components: types>+≡
  type :: split_constraints_t
    class(split_constraint_wrap_t), dimension(:), allocatable :: cc
    contains
    <Auto components: split constraints: TBP>
  end type split_constraints_t

```

Initialize the constraints set with a specific number of elements.

```

<Auto components: split constraints: TBP>≡
  procedure :: init => split_constraints_init

<Auto components: procedures>+≡
  subroutine split_constraints_init (constraints, n)
    class(split_constraints_t), intent(out) :: constraints
    integer, intent(in) :: n

```

```

        allocate (constraints%cc (n))
    end subroutine split_constraints_init

```

Set a constraint.

```

<Auto components: split constraints: TBP>+≡
    procedure :: set => split_constraints_set

<Auto components: procedures>+≡
    subroutine split_constraints_set (constraints, i, c)
        class(split_constraints_t), intent(inout) :: constraints
        integer, intent(in) :: i
        class(split_constraint_t), intent(in) :: c
        allocate (constraints%cc(i)%c, source = c)
    end subroutine split_constraints_set

```

Apply checks.

```

    check_before_split is applied to the particle list that we want to split.
    check_before_insert is applied to the particle list pl that is to replace the
    particle pa that is split. This check may transform the particle list.
    check_before_record is applied to the complete new particle list that re-
    sults from splitting before it is recorded.

<Auto components: split constraints: TBP>+≡
    procedure :: check_before_split => split_constraints_check_before_split

        if (.not. passed) return
    end do
end subroutine split_constraints_check_before_record

```

26.1.2 Specific constraints

Number of particles

Specific constraint: The number of particles plus the number of loops, if any, must remain less than the given limit. Note that the number of loops is defined only when we are recording the entry.

```

<Auto components: types>+≡
    type, extends (split_constraint_t) :: constraint_n_tot
    private
    integer :: n_max = 0
    contains
    procedure :: check_before_split => constraint_n_tot_check_before_split
    procedure :: check_before_record => constraint_n_tot_check_before_record
end type constraint_n_tot

<Auto components: public>+≡
    public :: constrain_n_tot

<Auto components: procedures>+≡
    function constrain_n_tot (n_max) result (c)
    integer, intent(in) :: n_max
    type(constraint_n_tot) :: c
    c%n_max = n_max
end function constrain_n_tot

subroutine constraint_n_tot_check_before_split (c, table, pl, k, passed)
    class(constraint_n_tot), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: k
    logical, intent(out) :: passed
    passed = pl%get_size () < c%n_max
end subroutine constraint_n_tot_check_before_split

```

```

subroutine constraint_n_tot_check_before_record (c, table, pl, n_loop, passed)
  class(constraint_n_tot), intent(in) :: c
  class(ps_table_t), intent(in) :: table
  type(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n_loop
  logical, intent(out) :: passed
  passed = pl%get_size () + n_loop <= c%n_max
end subroutine constraint_n_tot_check_before_record

```

Number of loops

Specific constraint: The number of loops is limited, independent of the total number of particles.

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_n_loop
  private
  integer :: n_loop_max = 0
  contains
  procedure :: check_before_record => constraint_n_loop_check_before_record
end type constraint_n_loop

<Auto components: public>+≡
  public :: constrain_n_loop

<Auto components: procedures>+≡
  function constrain_n_loop (n_loop_max) result (c)
    integer, intent(in) :: n_loop_max
    type(constraint_n_loop) :: c
    c%n_loop_max = n_loop_max
  end function constrain_n_loop

  subroutine constraint_n_loop_check_before_record &
    (c, table, pl, n_loop, passed)
    class(constraint_n_loop), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    passed = n_loop <= c%n_loop_max
  end subroutine constraint_n_loop_check_before_record

```

Particles allowed in splitting

Specific constraint: The entries in the particle list ready for insertion are matched to a given list of particle patterns. If a match occurs, the entry is replaced by the corresponding pattern. If there is no match, the check fails.

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_insert
  private
  type(pdg_list_t) :: pl_match

```

```

contains
  procedure :: check_before_insert => constraint_insert_check_before_insert
end type constraint_insert

<Auto components: public>+≡
  public :: constrain_insert

<Auto components: procedures>+≡
  function constrain_insert (pl_match) result (c)
    type(pdg_list_t), intent(in) :: pl_match
    type(constraint_insert) :: c
    c%pl_match = pl_match
  end function constrain_insert

  subroutine constraint_insert_check_before_insert (c, table, pa, pl, passed)
    class(constraint_insert), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_array_t), intent(in) :: pa
    type(pdg_list_t), intent(inout) :: pl
    logical, intent(out) :: passed
    call pl%match_replace (c%pl_match, passed)
  end subroutine constraint_insert_check_before_insert

```

Particles required in final state

Specific constraint: The entries in the recorded state must be a superset of the entries in the given list (for instance, the lowest-order state).

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_require
  private
  type(pdg_list_t) :: pl
  contains
  procedure :: check_before_record => constraint_require_check_before_record
end type constraint_require

```

We check the current state by matching all particle entries against the stored particle list, and crossing out the particles in the latter list when a match is found. The constraint passed if all entries have been crossed out.

For an `if_table` in particular, we check the final state only.

```

<Auto components: public>+≡
  public :: constrain_require

<Auto components: procedures>+≡
  function constrain_require (pl) result (c)
    type(pdg_list_t), intent(in) :: pl
    type(constraint_require) :: c
    c%pl = pl
  end function constrain_require

  subroutine constraint_require_check_before_record &
    (c, table, pl, n_loop, passed)
    class(constraint_require), intent(in) :: c

```

```

class(ps_table_t), intent(in) :: table

  class(ps_table_t), intent(in) :: table
  type(pdg_array_t), intent(in) :: pa
  type(pdg_list_t), intent(inout) :: pl
  logical, intent(out) :: passed
  passed = .not. (pl .match. pa)
end subroutine constraint_radiation_check_before_insert

```

Mass sum

Specific constraint: The sum of masses within the particle list must be smaller than a given limit. For in/out state combinations, we check initial and final state separately.

If we specify `margin` in the initialization, the sum must be strictly less than the limit minus the given margin (which may be zero). If not, equality is allowed.

```
(Auto components: public)+≡
    public :: constrain_mass_sum

(Auto components: types)+≡
    type, extends (split_constraint_t) :: constraint_mass_sum
    private
        real(default) :: mass_limit = 0
        logical :: strictly_less = .false.
        real(default) :: margin = 0

    end type constraint_in_state

<Auto components: procedures>+≡
    function constrain_in_state (pl) result (c)
        type(pdg_list_t), intent(in) :: pl
        type(constraint_in_state) :: c
        c%pl = pl
    end function constrain_in_state

    subroutine constraint_in_state_check_before_record &
        (c, table, pl, n_loop, passed)
        class(constraint_in_state), intent(in) :: c
        class(ps_table_t), intent(in) :: table
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: n_loop
        logical, intent(out) :: passed
        integer :: i
        select type (table)
        type is (if_table_t)
            passed = .false.
            do i = 1, 2
                if (.not. (c%pl .match. pl%get (i))) return
            end do
        end select
        passed = .true.
    end subroutine constraint_in_state_check_before_record

```

26.1.3 Tables of states

Automatically generate a list of possible process components for a given initial set (a single massive particle or a preset list of states).

The set of process components are generated by recursive splitting, applying constraints on the fly that control and limit the process. The generated states are accumulated in a table that we can read out after completion.

```

⟨Auto components: types⟩+≡
  type, extends (pdg_list_t) :: ps_entry_t
    integer :: n_loop = 0
    integer :: n_rad = 0
    type(ps_entry_t), pointer :: previous => null ()
    type(ps_entry_t), pointer :: next => null ()
  end type ps_entry_t

```

This is the wrapper type for the decay tree for the list of final states and the final array. First, an abstract base type:

```

⟨Auto components: public⟩+≡
  public :: ps_table_t

⟨Auto components: types⟩+≡
  type, abstract :: ps_table_t
    private
      class(model_data_t), pointer :: model => null ()
      logical :: loops = .false.
      type(ps_entry_t), pointer :: first => null ()
      type(ps_entry_t), pointer :: last => null ()
    contains
      ⟨Auto components: ps table: TBP⟩
  end type ps_table_t

```

The extensions: one for decay, one for generic final states. The decay-state table stores the initial particle. The final-state table is indifferent, and the initial/final state table treats the first two particles in its list as incoming antiparticles.

```

⟨Auto components: public⟩+≡
  public :: ds_table_t
  public :: if_table_t

⟨Auto components: types⟩+≡
  type, extends (ps_table_t) :: ds_table_t
    private
      integer :: pdg_in = 0
    contains
      ⟨Auto components: ds table: TBP⟩
  end type ds_table_t

  type, extends (ps_table_t) :: fs_table_t
    contains
      ⟨Auto components: fs table: TBP⟩
  end type fs_table_t

  type, extends (fs_table_t) :: if_table_t
    contains

```

```

    <Auto components: if table: TBP>
end type if_table_t

```

Finalizer: we must deallocate the embedded list.

```

<Auto components: ps table: TBP>≡
    procedure :: final => ps_table_final

<Auto components: procedures>+≡
    subroutine ps_table_final (object)

        call pl_in%init (1)
        call pl_in%set (1, [pdg_in])
        call table%split (pl_in, 0, constraints)
    end subroutine ds_table_make

```

Split all entries in a growing table, starting from a table that may already contain states. Add and record split states on the fly.

```

<Auto components: fs table: TBP>+≡
    procedure :: radiate => fs_table_radiate

```

```

<Auto components: procedures>+≡
subroutine fs_table_radiate (table, constraints)
  class(fs_table_t), intent(inout) :: table
  type(split_constraints_t) :: constraints
  type(ps_entry_t), pointer :: current
  integer :: i, s
  logical :: passed
  current => table%first
  do while (associated (current))
    call table%split (current, 0, constraints, record = .true.)
    current => current%next
  end do
end subroutine fs_table_radiate

```

26.1.5 Splitting algorithm

Recursive splitting. First of all, we record the current `pdg_list` in the table, subject to `constraints`, if requested. We also record copies of the list marked as loop corrections.

When we record a particle list, we sort it first.

If there is room for splitting, We take a PDG array list and the index of an element, and split this element in all possible ways. The split entry is inserted into the list, which we split further.

The recursion terminates whenever the split array would have a length greater than n_{\max} .

```

<Auto components: ps table: TBP>+≡
procedure :: split => ps_table_split

<Auto components: procedures>+≡
recursive subroutine ps_table_split (table, pl, n_rad, constraints, &
  record)
  class(ps_table_t), intent(inout) :: table
  class(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n_rad
  type(split_constraints_t), intent(in) :: constraints
  logical, intent(in), optional :: record
  integer :: n_loop, i
  logical :: passed
  type(vertex_iterator_t) :: vit
  integer, dimension(:), allocatable :: pdg1
  integer, dimension(:), allocatable :: pdg2
  if (present (record)) then
    if (record) then
      n_loop = 0
      INCR_LOOPS: do
        call table%record_sorted (pl, n_loop, n_rad, constraints, passed)
        if (.not. passed) exit INCR_LOOPS
        if (.not. table%loops) exit INCR_LOOPS
        n_loop = n_loop + 1
      end do INCR_LOOPS
    end if
  end if
end if

```

```

do i = 1, pl%get_size ()
  call constraints%check_before_split (table, pl, i, passed)
  if (passed) then
    pdg1 = pl%get (i)
    call vit%init (table%model, pdg1)
    SCAN_VERTICES: do
      call vit%get_next_match (pdg2)
      if (allocated (pdg2)) then
        call table%insert (pl, n_rad, i, pdg2, constraints)
      else
        exit SCAN_VERTICES
      end if
    end do SCAN_VERTICES
  end if
end do
end subroutine ps_table_split

```

The worker part: insert the list of particles found by vertex matching in place of entry *i* in the PDG list. Then split/record further.

The *n_in* parameter tells the replacement routine to insert the new particles after entry *n_in*. Otherwise, they follow index *i*.

(Auto components: ps table: TBP)+≡

```

procedure :: insert => ps_table_insert

```

(Auto components: procedures)+≡

```

recursive subroutine ps_table_insert &

      constraints, record = .true.)
  end if
end subroutine ps_table_insert

```

Special case: If we are splitting an initial particle, there is slightly more to do. We loop over the particles from the vertex match and replace the initial particle by each of them in turn. The remaining particles must be appended after the second initial particle, so they will end up in the out state. This is done by providing the *n_in* argument to the base method as an optional argument.

Note that we must call the base-method procedure explicitly, so the `table` argument keeps its dynamic type as `if_table` inside this procedure.

```

<Auto components: if table: TBP>+≡
  procedure :: insert => if_table_insert

<Auto components: procedures>+≡
  recursive subroutine if_table_insert &
    (table, pl, n_rad, i, pdg, constraints, n_in)
    class(if_table_t), intent(inout) :: table

26.1.6 Tools

Compute the mass sum for a PDG list object, counting the entries with indices between (including) `n1` and `n2`. Rely on the requirement that if an entry is a PDG array, this array must be degenerate in mass.

(Auto components: procedures)+≡

```

function mass_sum (pl, n1, n2, model) result (m)
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n1, n2
    class(model_data_t), intent(in), target :: model
    integer, dimension(:), allocatable :: pdg
    real(default) :: m
    type(field_data_t), pointer :: prt
    integer :: i
    m = 0
    do i = n1, n2
        pdg = pl%get (i)
        prt => model%get_field_ptr (pdg(1))
        m = m + prt%get_mass ()
    end do
end function mass_sum

```

Invert a PDG array, replacing particles by antiparticles. This depends on the model.

(Auto components: procedures)+≡

```

function invert_pdg_array (pa, model) result (pa_inv)
    type(pdg_array_t), intent(in) :: pa
    class(model_data_t), intent(in), target :: model
    type(pdg_array_t) :: pa_inv
    type(field_data_t), pointer :: prt
    integer :: i, pdg
    pa_inv = pa
    do i = 1, pa_inv%get_length ()
        pdg = pa_inv%get (i)
        prt => model%get_field_ptr (pdg)
        if (prt%has_antiparticle ()) call pa_inv%set (i, -pdg)
    end do
end function invert_pdg_array

```

26.1.7 Access results

Return the number of generated decays.

```
<Auto components: ps table: TBP>+≡
  procedure :: get_length => ps_table_get_length

<Auto components: procedures>+≡
  function ps_table_get_length (ps_table) result (n)
    class(ps_table_t), intent(in) :: ps_table
    integer :: n
    type(ps_entry_t), pointer :: entry
    n = 0
    entry => ps_table%first
    do while (associated (entry))
      n = n + 1
      entry => entry%next
    end do
  end function ps_table_get_length
```

Return an allocated array of decay products (PDG codes). If requested, return also the loop and radiation order count.

```
<Auto components: ps table: TBP>+≡
  procedure :: get_pdg_out => ps_table_get_pdg_out

<Auto components: procedures>+≡
  subroutine ps_table_get_pdg_out (ps_table, i, pa_out, n_loop, n_rad)
    class(ps_table_t), intent(in) :: ps_table
    integer, intent(in) :: i
    type(pdg_array_t), dimension(:), allocatable, intent(out) :: pa_out
    integer, intent(out), optional :: n_loop, n_rad
    type(ps_entry_t), pointer :: entry
    integer :: n, j
    n = 0
    entry => ps_table%first
    FIND_ENTRY: do while (associated (entry))
      n = n + 1
      if (n == i) then
        allocate (pa_out (entry%get_size ()))

26.3 Sindarin Expression Implementation

This module defines expressions of all kinds, represented in a tree structure, for repeated evaluation. This provides an implementation of the `expr_base` abstract type.

We have two flavors of expressions: one with particles and one without particles. The latter version is used for defining cut/selection criteria and for online analysis.

```

26.3.1 Tree nodes

The evaluation tree consists of branch nodes (unary and binary) and of leaf nodes, originating from a common root. The node object should be polymorphic. For the time being, polymorphism is emulated here. This means that we have to maintain all possibilities that the node may hold, including associated procedures as pointers.

The following parameter values characterize the node. Unary and binary operators have sub-nodes. The other are leaf nodes. Possible leafs are literal constants or named-parameter references.

<Eval trees: types>≡

```
integer, parameter :: EN_UNKNOWN = 0, EN_UNARY = 1, EN_BINARY = 2
integer, parameter :: EN_CONSTANT = 3, EN_VARIABLE = 4
integer, parameter :: EN_CONDITIONAL = 5, EN_BLOCK = 6

case (V_STR); allocate (node%sval)
end select
allocate (node%value_is_known)
node%value_is_known = .false.
end subroutine eval_node_allocate_value

```

Initialize a block node which contains, in addition to the expression to be evaluated, a variable definition. The result type is not yet assigned, because we can compile the enclosed expression only after the var list is set up.

Note that the node always allocates a new variable list and appends it to the current one. Thus, if the variable redefines an existing one, it only shadows it but does not reset it. Any side-effects are therefore absent and need not be undone outside the block.

If the flag `new` is set, a variable is (re)declared. This must not be done for intrinsic variables. Vice versa, if the variable is not existent, the `new` flag is required.

(Eval trees: procedures)+≡

```

subroutine eval_node_init_block (node, name, type, var_def, var_list)
type(eval_node_t), intent(out), target :: node
type(string_t), intent(in) :: name
integer, intent(in) :: type

  end if
  call eval_node_allocate_value (node)
  node%arg0 => arg

```

```
end subroutine eval_node_set_expr
```

Initialize a conditional. There are three branches: the condition (evaluates to logical) and the two alternatives (evaluate both to the same arbitrary type).

(Eval trees: procedures)+≡

```
subroutine eval_node_init_conditional (node, result_type, cond, arg1, arg2)
  type(eval_node_t), intent(out) :: node
  integer, intent(in) :: result_type
  type(eval_node_t), intent(in), target :: cond, arg1, arg2
  node%type = EN_CONDITIONAL
  node%tag = "cond"
  node%result_type = result_type
  call eval_node_allocate_value (node)
  node%arg0 => cond
  node%arg1 => arg1
  node%arg2 => arg2
end subroutine eval_node_init_conditional
```

Initialize a recording command (which evaluates to a logical constant). The first branch is the ID of the analysis object to be filled, the optional branches 1 to 4 are the values to be recorded.

If the event-weight pointer is null, we record values with unit weight. Otherwise, we use the value pointed to as event weight.

There can be up to four arguments which represent x , y , Δy , Δx . Therefore, this is the only node type that may fill four sub-nodes.

(Eval trees: procedures)+≡

```
subroutine eval_node_init_record_cmd &
  (node, event_weight, id, arg1, arg2, arg3, arg4)
  type(eval_node_t), intent(out) :: node
  real(default), pointer :: event_weight
  type(eval_node_t), intent(in), target :: id
  type(eval_node_t), intent(in), optional, target :: arg1, arg2, arg3, arg4
  call eval_node_init_log (node, .true.)
  node%type = EN_RECORD_CMD
  node%rval => event_weight
  node%tag = "record_cmd"
  node%arg0 => id
  if (present (arg1)) then
    node%arg1 => arg1
    if (present (arg2)) then
      node%arg2 => arg2
      if (present (arg3)) then
        node%arg3 => arg3
        if (present (arg4)) then
          node%arg4 => arg4
        end if
      end if
    end if
  end if
end if
end if
end if
end if
end subroutine eval_node_init_record_cmd
```

Initialize a node for operations on subevents. The particle lists (one or two) are inserted as `arg1` and `arg2`. We allocated particle pointers as temporaries for iterating over particle lists. The procedure pointer which holds the function to evaluate for the subevents (e.g., combine, select) is also initialized.

(Eval trees: procedures)+≡

```

subroutine eval_node_init_prt_fun_unary (node, arg1, name, proc)
  type(eval_node_t), intent(out) :: node
  type(eval_node_t), intent(in), target :: arg1
  type(string_t), intent(in) :: name
  procedure(unary_sev) :: proc
  node%type = EN_PRT_FUN_UNARY
  node%tag = name
  node%result_type = V_SEV
  call eval_node_allocate_value (node)
  node%arg1 => arg1
  allocate (node%index, source = 0)
  allocate (node%prt1)
  node%op1_sev => proc
end subroutine eval_node_init_prt_fun_unary

subroutine eval_node_init_prt_fun_binary (node, arg1, arg2, name, proc)
  type(eval_node_t), intent(out) :: node
  type(eval_node_t), intent(in), target :: arg1, arg2
  type(string_t), intent(in) :: name
  procedure(binary_sev) :: proc
  node%type = EN_PRT_FUN_BINARY
  node%tag = name
  node%result_type = V_SEV
  call eval_node_allocate_value (node)
  node%arg1 => arg1

```

If particle functions depend upon a condition (or an expression is evaluated), the observables that can be evaluated for the given particles have to be thrown on the local variable stack. This is done here. Each observable is initialized with the particle pointers which have been allocated for the node.

The integer variable that is referred to by the `Index` pseudo-observable is always known when it is referred to.

```

<Eval trees: procedures>+≡

26.3.2 Operation types

For the operations associated to evaluation tree nodes, we define abstract interfaces for all cases.

Particles/subevents are transferred by-reference, to avoid unnecessary copying. Therefore, subroutines instead of functions. (Furthermore, the function version of `unary_prt` triggers an obscure bug in nagfor 5.2(649) [invalid C code].)

(Eval trees: interfaces)≡

```

abstract interface
  logical function unary_log (arg)
    import eval_node_t
    type(eval_node_t), intent(in) :: arg
  end function unary_log

```

```

end interface
abstract interface
    integer function unary_int (arg)
        import eval_node_t
        type(eval_node_t), intent(in) :: arg
    end function unary_int
end interface
abstract interface
    real(default) function unary_real (arg)
        import default
        import eval_node_t
        type(eval_node_t), intent(in) :: arg
    end function unary_real
end interface

26.3.3 Specific operators

Our expression syntax contains all Fortran functions that make sense. These functions have to be provided in a form that they can be used in procedures pointers, and have the abstract interfaces above. For some intrinsic functions, we could use specific versions provided by Fortran directly. However, this has two drawbacks: (i) We should work with the values instead of the eval-nodes as argument, which complicates the interface; (ii) more importantly, the **default** real type need not be equivalent to double precision. This would, at least, introduce system dependencies. Finally, for operators there are no specific versions.

Therefore, we write wrappers for all possible functions, at the expense of some overhead.

Binary numerical functions

<Eval trees: procedures>+≡

```

integer function add_ii (en1, en2) result (y)
  type(eval_node_t), intent(in) :: en1, en2
  y = en1%ival + en2%ival
end function add_ii

real(default) function add_ir (en1, en2) result (y)
  type(eval_node_t), intent(in) :: en1, en2
  y = en1%ival + en2%rval
end function add_ir

complex(default) function add_ic (en1, en2) result (y)
  type(eval_node_t), intent(in) :: en1, en2
  y = en1%ival + en2%cval
end function add_ic

real(default) function add_ri (en1, en2) result (y)
  type(eval_node_t), intent(in) :: en1, en2
  y = en1%rval + en2%ival

    call eval_node_evaluate (en0)
    lval = .not. en0%lval
    if (lval) exit
end do
end function no_p

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

<Eval trees: procedures>+≡

```

Binary particle-list functions

This joins two subevents, stored in the evaluation nodes `en1` and `en2`. If `en0` is also present, it amounts to a logical test returning true or false for every pair of particles. A particle of the second list gets a mask entry only if it passes the test for all particles of the first list.

```

<Eval trees: procedures>+≡
subroutine join_pp (subvt, en1, en2, en0)
    type(subvt_t), intent(inout) :: subvt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:), allocatable :: mask2
    integer :: i, j, n1, n2
    n1 = subvt_get_length (en1%pval)
    n2 = subvt_get_length (en2%pval)
    allocate (mask2 (n2))
    mask2 = .true.
    if (present (en0)) then
        do i = 1, n1
            en0%index = i
            en0%prt1 = subvt_get_prt (en1%pval, i)
            do j = 1, n2
                en0%prt2 = subvt_get_prt (en2%pval, j)
                call eval_node_evaluate (en0)
                mask2(j) = mask2(j) .and. en0%lval
            end do
        end do
    end if
end subroutine join_pp

```

```

        end do
    end do
end if
    call subevt_join (subevt, en1%pval, en2%pval, mask2)
end subroutine join_pp

```

Combine two subevents, i.e., make a list of composite particles built from all possible particle pairs from the two lists. If `en0` is present, create a mask which is true only for those pairs that pass the test.

(Eval trees: procedures)+≡

```

subroutine combine_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:,:), allocatable :: mask12
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    if (present (en0)) then
        allocate (mask12 (n1, n2))
        do i = 1, n1
            en0%index = i
            en0%prt1 = subevt_get_prt (en1%pval, i)
            do j = 1, n2
                en0%prt2 = subevt_get_prt (en2%pval, j)
                call eval_node_evaluate (en0)
                mask12(i,j) = en0%lval
            end do
        end do
        call subevt_combine (subevt, en1%pval, en2%pval, mask12)
    else
        call subevt_combine (subevt, en1%pval, en2%pval)
    end if
end subroutine combine_pp

```

Combine all particles of the first argument. If `en0` is present, create a mask which is true only for those particles that pass the test w.r.t. all particles in the second argument. If `en0` is absent, the second argument is ignored.

(Eval trees: procedures)+≡

```

subroutine collect_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:), allocatable :: mask1
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    allocate (mask1 (n1))
    mask1 = .true.
    if (present (en0)) then

```

Binary string functions

Currently, the only string operation is concatenation.

<Eval trees: procedures>+≡

```
subroutine concat_ss (string, en1, en2)
  type(string_t), intent(out) :: string
  type(eval_node_t), intent(in) :: en1, en2
  string = en1%sval // en2%sval
end subroutine concat_ss
```

26.3.4 Compiling the parse tree

The evaluation tree is built recursively by following a parse tree. Debug option:

<Eval trees: variables>≡

```
logical, parameter :: debug = .false.
```

Evaluate an expression. The requested type is given as an optional argument; default is numeric (integer or real).

<Eval trees: procedures>+≡

```
recursive subroutine eval_node_compile_genexpr &
  (en, pn, var_list, result_type)
  type(eval_node_t), pointer :: en
  type(parse_node_t), intent(in) :: pn
  type(var_list_t), intent(in), target :: var_list
  integer, intent(in), optional :: result_type
  if (debug) then
    print *, "read genexpr"; call parse_node_write (pn)
  end if
  if (present (result_type)) then
    select case (result_type)
    case (V_INT, V_REAL, V_CMPLX)
      call eval_node_compile_expr (en, pn, var_list)
    case (V_LOG)

```

```

Numeric expressions

This procedure compiles a numerical expression. This is a single term or a sum or difference of terms. We have to account for all combinations of integer and real arguments. If both are constant, we immediately do the calculation and allocate a constant node.

(Eval trees: procedures)+≡

```

```

Real, complex and integer values are numeric literals with an optional unit attached. In case of an integer, the unit actually makes it a real value in disguise. The signed version of real values is not possible in generic expressions; it is a special case for numeric constants in model files (see below). We do not introduce signed versions of complex values.

```

Compile a variable, with or without a specified type. Take the list of variables, look for the name and make a node with a pointer to the value. If no type is provided, the variable is numeric, and the stored value determines whether it is real or integer.

We explicitly demand that the variable is defined, so we do not accidentally point to variables that are declared only later in the script but have come into existence in a previous compilation pass.

Variables may actually be anonymous, these are expressions in disguise. In that case, the expression replaces the variable name in the parse tree, and we allocate an ordinary expression node in the eval tree.

Variables of type V_PDG (pdg-code array) are not treated here. They are handled by `eval_node_compile_cvariable`.

This user observable behaves like a variable. We link the node to the generic user-observable entry in the variable list. The syntax element has an argument which provides the name of the user variable, this is stored as an eval-node alongside with the variable. When the variable value is used, the user-supplied external function is called and provides the (real) result value.

Variable definition

A block expression contains a variable definition (first argument) and an expression where the definition can be used (second argument). The `result_type` decides which type of expression is expected for the second argument. For numeric variables, if there is a mismatch between real and integer type, insert an

extra node for type conversion.

Conditionals

A conditional has the structure `if lexpr then expr else expr`. So we first evaluate the logical expression, then depending on the result the first or second expression. Note that the second expression is mandatory.

The `result_type`, if present, defines the requested type of the `then` and `else` clauses. Default is numeric (int/real). If there is a mismatch between real and integer result types, insert conversion nodes.

(Eval trees: procedures) +=

```

Comparisons

Up to the loop, this is easy. There is always at least one comparison. This is evaluated, and the result is the logical node **en**. If it is constant, we keep its second sub-node as **en2**. (Thus, at the very end **en2** has to be deleted if **en** is (still) constant.)

If there is another comparison, we first check if the first comparison was constant. In that case, there are two possibilities: (i) it was true. Then, its right-hand side is compared with the new right-hand side, and the result replaces the previous one which is deleted. (ii) it was false. In this case, the result of the whole comparison is false, and we can exit the loop without evaluating anything else.

Now assume that the first comparison results in a valid branch, its second sub-node kept as **en2**. We first need a copy of this, which becomes the new left-hand side. If **en2** is constant, we make an identical constant node **en1**. Otherwise, we make **en1** an appropriate pointer node. Next, the first branch is saved as **en0** and we evaluate the comparison between **en1** and the a right-hand side. If this turns out to be constant, there are again two possibilities: (i) true, then we revert to the previous result. (ii) false, then the wh

```

This takes two extra arguments: **en1**, the left-hand-side of the comparison, is already allocated and evaluated. **en2** (the right-hand side) and **en** (the result) are allocated by the routine. **pn** is the parse node which contains the operator and the right-hand side as subnodes.

If the result of the comparison is constant, **en1** is deleted but **en2** is kept, because it may be used in a subsequent comparison. **en** then becomes a constant. If the result is variable, **en** becomes a branch node which refers to **en1** and **en2**.

end subroutine eval_node_compile_pterm

```

A particle-list value is a PDG-code array, a particle identifier, a variable, a (grouped) pexpr, a block pexpr, a conditional, or a particle-list function.

The `cexpr` node is responsible for transforming a constant PDG-code array into a subevent. It takes the code array as its first argument, the event subevent as its second argument, and the requested particle type (incoming/outgoing) as its zero-th argument. The result is the list of particles in the event that match the code array.

Particle functions

This combines the treatment of 'join', 'combine', 'collect', 'cluster', 'select', and 'extract' which all have the same syntax. The one or two argument nodes are allocated. If there is a condition, the condition node is also allocated as a logical expression, for which the variable list is augmented by the appropriate (unary/binary) observables.

(Eval trees: procedures)+≡

```

```

        // "for logical, integer, real, and string values only")
    end select
    j = j + 1
    en_branch => en_branch%arg2
end do
else
    allocate (arg(0))
end if
if (autoformat) then
    string = sprintf (trim (fmt), arg)
else
    string = sprintf (en_fmt%sval, arg)
end if
end subroutine evaluate_sprintf

```

26.3.5 Auxiliary functions for the compiler

Issue an error that the current node could not be compiled because of type mismatch:

```

<Eval trees: procedures>+≡
subroutine eval_type_error (pn, string, t)
    type(parse_node_t), intent(in) :: pn
    character(*), intent(in) :: string
    integer, intent(in) :: t
    type(string_t) :: type
    select case (t)
    case (V_NONE); type = "(none)"
    case (V_LOG); type = "'logical'"
    case (V_INT); type = "'integer'"
    case (V_REAL); type = "'real'"
    case (V_CMPLX); type = "'complex'"
    case default; type = "(unknown)"
    end select
    call parse_node_write (pn)
    call msg_fatal (" The " // string // &
        " operation is not defined for the given argument type " // &
        char (type))
end subroutine eval_type_error

```

If two numerics are combined, the result is integer if both arguments are integer, if one is integer and the other real or both are real, than its argument is real, otherwise complex.

```

<Eval trees: procedures>+≡
function numeric_result_type (t1, t2) result (t)
    integer, intent(in) :: t1, t2
    integer :: t
    if (t1 == V_INT .and. t2 == V_INT) then
        t = V_INT
    else if (t1 == V_INT .and. t2 == V_REAL) then
        t = V_REAL
    else if (t1 == V_REAL .and. t2 == V_INT) then
        t = V_REAL
    end if
end function numeric_result_type

```

```

else if (t1 == V_REAL .and. t2 == V_REAL) then
    t = V_REAL
else
    t = V_CMPLX
end if
end function numeric_result_type

```

26.3.6 Evaluation

Evaluation is done recursively. For leaf nodes nothing is to be done.

Evaluating particle-list functions: First, we evaluate the particle lists. If a condition is present, we assign the particle pointers of the condition node to the allocated particle entries in the parent node, keeping in mind that the observables in the variable stack used for the evaluation of the condition also contain pointers to these entries. Then, the assigned procedure is evaluated, which sets the subevent in the parent node. If required, the procedure evaluates the condition node once for each (pair of) particles to determine the result.

(Eval trees: procedures)+≡

```

26.3.7 Evaluation syntax

We have two different flavors of the syntax: with and without particles.

```

<Eval trees: variables>+≡
    type(syntax_t), target, save :: syntax_expr
    type(syntax_t), target, save :: syntax_pexpr

```

These are for testing only and may be removed:

```

<Eval trees: public>≡
    public :: syntax_expr_init
    public :: syntax_pexpr_init

<Eval trees: procedures>+≡
    subroutine syntax_expr_init ()
        type(ifile_t) :: ifile
        call define_expr_syntax (ifile, particles=.false., analysis=.false.)
        call syntax_init (syntax_expr, ifile)
        call ifile_final (ifile)
    end subroutine syntax_expr_init

    subroutine syntax_pexpr_init ()
        type(ifile_t) :: ifile
        call define_expr_syntax (ifile, particles=.true., analysis=.false.)
        call syntax_init (syntax_pexpr, ifile)
        call ifile_final (ifile)
    end subroutine syntax_pexpr_init

<Eval trees: public>+≡
    public :: syntax_expr_final
    public :: syntax_pexpr_final

<Eval trees: procedures>+≡
    subroutine syntax_expr_final ()
        call syntax_final (syntax_expr)
    end subroutine syntax_expr_final

    subroutine syntax_pexpr_final ()
        call syntax_final (syntax_pexpr)
    end subroutine syntax_pexpr_final

```

```

end subroutine syntax_pexpr_final

<Eval trees: public>+≡
public :: syntax_pexpr_write

<Eval trees: procedures>+≡
subroutine syntax_pexpr_write (unit)
  integer, intent(in), optional :: unit
  call syntax_write (syntax_pexpr, unit)
end subroutine syntax_pexpr_write

<Eval trees: public>+≡

26.3.9 The evaluation tree

The evaluation tree contains the initial variable list and the root node.

```

<Eval trees: public>+≡
    public :: eval_tree_t

<Eval trees: types>+≡
    type, extends (expr_t) :: eval_tree_t
    private
        type(parse_node_t), pointer :: pn => null ()
        type(var_list_t) :: var_list
        type(eval_node_t), pointer :: root => null ()
    contains
        <Eval trees: eval tree: TBP>
    end type eval_tree_t

```

Init from stream, using a temporary parse tree.

```

<Eval trees: procedures>+≡
    subroutine eval_tree_init_stream &
        (eval_tree, stream, var_list, subvt, result_type)
        type(eval_tree_t), intent(out), target :: eval_tree
        type(stream_t), intent(inout), target :: stream
        type(var_list_t), intent(in), target :: var_list
        type(subvt_t), intent(in), target, optional :: subvt
        integer, intent(in), optional :: result_type
        type(parse_tree_t) :: parse_tree
        type(parse_node_t), pointer :: nd_root
        integer :: type
        type = V_REAL; if (present (result_type)) type = result_type
        select case (type)
        case (V_INT, V_REAL, V_CMPLX)
            call parse_tree_init_expr (parse_tree, stream, present (subvt))
        case (V_LOG)
            call parse_tree_init_lexpr (parse_tree, stream, present (subvt))
        case (V_SEV)
            call parse_tree_init_pexpr (parse_tree, stream)
        case (V_PDG)
            call parse_tree_init_cexpr (parse_tree, stream)
        case (V_STR)
            call parse_tree_init_sexpr (parse_tree, stream, present (subvt))
        end select

  rewind (u)
  md5sum_et = md5sum (u)
  close (u)
end function eval_tree_get_md5sum

```

26.3.10 Direct evaluation

These procedures create an eval tree and evaluate it on-the-fly, returning only the final value. The evaluation must yield a well-defined value, unless the `is_known` flag is present, which will be set accordingly.

end subroutine eval_tree_unknown

```

26.3.11 Factory Type

Since `eval_tree_t` is an implementation of `expr_t`, we also need a matching factory type and build method.

```

<Eval trees: public>+≡
    public :: eval_tree_factory_t

<Eval trees: types>+≡
    type, extends (expr_factory_t) :: eval_tree_factory_t
    private
        type(parse_node_t), pointer :: pn => null ()
    contains
        <Eval trees: eval tree factory: TBP>
    end type eval_tree_factory_t

```

Output: delegate to the output of the embedded parse node.

```

<Eval trees: eval tree factory: TBP>≡
    procedure :: write => eval_tree_factory_write

<Eval trees: procedures>+≡
    subroutine eval_tree_factory_write (expr_factory, unit)
        class(eval_tree_factory_t), intent(in) :: expr_factory
        integer, intent(in), optional :: unit
        if (associated (expr_factory%pn)) then
            call parse_node_write_rec (expr_factory%pn, unit)
        end if
    end subroutine eval_tree_factory_write

```

Initializer: take a parse node and hide it thus from the environment.

```

<Eval trees: eval tree factory: TBP>+≡
    procedure :: init => eval_tree_factory_init

```

```

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_init (expr_factory, pn)
    class(eval_tree_factory_t), intent(out) :: expr_factory
    type(parse_node_t), intent(in), pointer :: pn
    expr_factory%pn => pn
  end subroutine eval_tree_factory_init

```

Factory method: allocate expression with correct eval tree type. If the stored parse node is not associate, don't allocate.

```

<Eval trees: eval tree factory: TBP>+≡
  procedure :: build => eval_tree_factory_build

<Eval trees: procedures>+≡

26.4 Physics Models

A model object represents a physics model. It contains a table of particle data, a list of parameters, and a vertex table. The list of parameters is a variable list which includes the real parameters (which are pointers to the particle data table) and PDG array variables for the particles themselves. The vertex list is used for phase-space generation, not for calculating the matrix element.

The actual numeric model data are in the base type `model_data_t`, as part of the `qft` section. We implement the `model_t` as an extension of this, for convenient direct access to the base-type methods via inheritance. (Alternatively, we could delegate these calls explicitly.) The extension contains administrative additions, such as the methods for recalculating derived data and keeping the parameter set consistent. It thus acts as a proxy of the actual model-data object towards the WHIZARD package. There are further proxy objects, such as the `parameter_t` array which provides the interface to the actual numeric parameters.

Model definitions are read from model files. Therefore, this module contains a parser for model files. The parameter definitions (derived parameters) are Sindarin expressions.

The models, as read from file, are stored in a model library which is a simple list of model definitions. For setting up a process object we should make a copy (an instance) of a model, which gets the current parameter values from the global variable list.

26.4.1 Module

`<models.f90>`≡

    <Models: interfaces>

    <Models: variables>

contains

    <Models: procedures>

    <Models: tests>

end module models

```

26.4.2 Physics Parameters

A parameter has a name, a value. Derived parameters also have a definition in terms of other parameters, which is stored as an `eval_tree`. External parameters are set by an external program.

This parameter object should be considered as a proxy object. The parameter name and value are stored in a corresponding `modelpar_data_t` object which is located in a `model_data_t` object. The latter is a component of the `model_t` handler. Methods of `parameter_t` can be delegated to the `par_data_t` component.

The `pn` component is a pointer to the parameter definition inside the model parse tree. It allows us to recreate the `eval_tree` when making copies (instances) of the parameter object.

```

<Models: parameters>≡
    integer, parameter :: PAR_NONE = 0
    integer, parameter :: PAR_INDEPENDENT = 1, PAR_DERIVED = 2
    integer, parameter :: PAR_EXTERNAL = 3

<Models: types>≡
    type :: parameter_t
    private
        integer :: type = PAR_NONE
        class(modelpar_data_t), pointer :: data => null ()
        type(parse_node_t), pointer :: pn => null ()
        class(expr_t), allocatable :: expr
    contains
        <Models: parameter: TBP>
    end type parameter_t

```

Initialization depends on parameter type. Independent parameters are initialized by a constant value or a constant numerical expression (which may contain a unit). Derived parameters are initialized by an arbitrary numerical expression, which makes use of the current variable list. The expression is evaluated by the function `parameter_reset`.

This implementation supports only real parameters and real values.

```

<Models: parameter: TBP>≡
  procedure :: init_independent_value => parameter_init_independent_value
  procedure :: init_independent => parameter_init_independent
  procedure :: init_derived => parameter_init_derived
  procedure :: init_external => parameter_init_external

<Models: procedures>≡
  subroutine parameter_init_independent_value (par, par_data, name, value)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    real(default), intent(in) :: value
    par%type = PAR_INDEPENDENT
    par%data => par_data
    call par%data%init (name, value)
  end subroutine parameter_init_independent_value

  subroutine parameter_init_independent (par, par_data, name, pn)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    type(parse_node_t), intent(in), target :: pn
    par%type = PAR_INDEPENDENT
    par%pn => pn
    allocate (eval_tree_t :: par%expr)
    select type (expr => par%expr)
    type is (eval_tree_t)
      call expr%init_numeric_value (pn)
    end select
    par%data => par_data
    call par%data%init (name, par%expr%get_real ())
  end subroutine parameter_init_independent

  subroutine parameter_init_derived (par, par_data, name, pn, var_list)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    type(parse_node_t), intent(in), target :: pn
    type(var_list_t), intent(in), target :: var_list
    par%type = PAR_DERIVED
    par%pn => pn
    allocate (eval_tree_t :: par%expr)
    select type (expr => par%expr)
    type is (eval_tree_t)
      call expr%init_expr (pn, var_list=var_list)
    end select
    par%data => par_data
    call par%expr%evaluate ()
  end subroutine parameter_init_derived

```

```

        call par%data%init (name, par%expr%get_real ())
    end subroutine parameter_init_derived

subroutine parameter_init_external (par, par_data, name)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    par%type = PAR_EXTERNAL
    par%data => par_data
    call par%data%init (name, 0._default)
end subroutine parameter_init_external

```

The finalizer is needed for the evaluation tree in the definition.

```

<Models: parameter: TBP>+≡
    procedure :: final => parameter_final

<Models: procedures>+≡
    subroutine parameter_final (par)
        class(parameter_t), intent(inout) :: par
        if (allocated (par%expr)) then
            call par%expr%final ()
        end if
    end subroutine parameter_final

```

All derived parameters should be recalculated if some independent parameters have changed:

```

<Models: parameter: TBP>+≡
    procedure :: reset_derived => parameter_reset_derived

<Models: procedures>+≡
    subroutine parameter_reset_derived (par)
        class(parameter_t), intent(inout) :: par
        select case (par%type)
        case (PAR_DERIVED)
            call par%expr%evaluate ()
            par%data = par%expr%get_real ()
        end select
    end subroutine parameter_reset_derived

```

Output. [We should have a formula format for the eval tree, suitable for input and output!]

```

<Models: parameter: TBP>+≡
    procedure :: write => parameter_write

<Models: procedures>+≡
    subroutine parameter_write (par, unit, write_defs)
        class(parameter_t), intent(in) :: par
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: write_defs
        logical :: defs
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        defs = .false.; if (present (write_defs)) defs = write_defs
    end subroutine parameter_write

```

```

select case (par%type)
case (PAR_INDEPENDENT)
    write (u, "(3x,A)", advance="no") "parameter"
case (PAR_DERIVED)
    write (u, "(3x,A)", advance="no") "derived"
case (PAR_EXTERNAL)
    write (u, "(3x,A)", advance="no") "external"
end select
call par%data%write (u)
select case (par%type)

            call par%data%show (l, u)
        end if
    end subroutine parameter_show

```

26.4.3 Model Object

A model object holds all information about parameters, particles, and vertices. For models that require an external program for parameter calculation, there is the pointer to a function that does this calculation, given the set of independent and derived parameters.

As explained above, the type inherits from `model_data_t`, which is the actual storage for the model data.

When reading a model, we create a parse tree. Parameter definitions are available via parse nodes. Since we may need those later when making model instances, we keep the whole parse tree in the model definition (but not in the instances).

```

<Models: public>≡
    public :: model_t

```

```

<Models: types>+=
  type, extends (model_data_t) :: model_t
    private
      character(32) :: md5sum = ""
      type(parameter_t), dimension(:), allocatable :: par
      integer :: max_par_name_length = 0
      integer :: max_field_name_length = 0
      type(var_list_t) :: var_list
      type(string_t) :: dlname
      procedure(model_init_external_parameters), nopass, pointer :: &
        init_external_parameters => null ()
      type(dlaccess_t) :: dlaccess
      type(parse_tree_t) :: parse_tree
    contains
      <Models: model: TBP>
    end type model_t

```

This is the interface for a procedure that initializes the calculation of external parameters, given the array of all parameters.

```

<Models: interfaces>=
  abstract interface
    subroutine model_init_external_parameters (par) bind (C)
      import
      real(c_default_float), dimension(*), intent(inout) :: par
    end subroutine model_init_external_parameters
  end interface

```

Initialization: Specify the number of parameters, particles, vertices and allocate memory. If an associated DL library is specified, load this library.

```

<Models: model: TBP>=
  generic :: init => model_init
  procedure, private :: model_init

<Models: procedures>+=
  subroutine model_init &
    (model, name, libname, os_data, n_par, n_prt, n_vtx)
    class(model_t), intent(inout) :: model
    type(string_t), intent(in) :: name, libname
    type(os_data_t), intent(in) :: os_data

Make a copy of a parameter. We assume that the `model_data_t` parameter arrays have already been copied, so names and values are available in the current model, and can be used as targets. The eval tree should not be copied, since it should refer to the new variable list. The safe solution is to make use of the above initializers, which also take care of the building a new variable list.

```

        n_par, n_prt, n_vtx)
      call model_list%import (current, model)
    end if
  end subroutine model_list_add

```

Read a new model from file and add to the list, if it does not yet exist. Finalize the model by allocating the vertex table. Return a pointer to the new model. If unsuccessful, return the original pointer.

The model is always inserted in the last link of a chain of model lists. This way, we avoid loading models twice from different contexts. When a model is modified, we should first allocate a local copy.

```

26.4.7 Model instances

A model instance is a copy of a model object. The parameters are true copies. The particle data and the variable list pointers should point to the copy, so modifying the parameters has only a local effect. Hence, we build them up explicitly. The vertex array is also rebuilt, it contains particle pointers. Finally, the vertex hash table can be copied directly since it contains no pointers.

The `multiplicity` entry depends on the association of the `mass_data` entry and therefore has to be set at the end.

The instance must carry the `target` attribute.

Parameters: the `copy_parameter` method essentially copies the parameter decorations (parse node, expression etc.). The current parameter values are part of the `model_data_t` base type and are copied afterwards via its `copy_from` method.

```

<Models: model: TBP>+≡
    procedure :: init_instance => model_copy

    use constants  
    use string_utils, only: upper_case  
    use unit_tests  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF  
    use diagnostics  
    use os_interface  
    use ifiles  
    use lexers  
    use syntax_rules  
    use parser  
    use variables  
    use models  
  
    <Standard module head>  
  
    <SLHA: public>  
  
    <SLHA: parameters>  
  
    <SLHA: variables>  
  
    save  
  
    contains  
  
    <SLHA: procedures>  
  
    <SLHA: tests>  
  
  end module slha_interface
```

26.5.1 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a

data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

    end subroutine define_slha_syntax

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed

somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

```

<SLHA: public>+=
    public :: lexer_init_slha

<SLHA: procedures>+=
    subroutine lexer_init_slha (lexer)
        type(lexer_t), intent(out) :: lexer

SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is not defined in the block, we use the previous value from the model variable list. For the basic parameters we have to do a small recalculation, since SLHA uses

the G_F - α - m_Z scheme, while WHIZARD derives them from G_F , m_W , and m_Z .

```

26.5.6 API

Read the SLHA file, parse it, and interpret the parse tree. The model parameters retrieved from the file will be inserted into the appropriate model, which is loaded and modified in the background. The pointer to this model is returned as the last argument.

<SLHA: public>+≡

```

Chapter 27

Integration and Process Objects

This is the central part of the WHIZARD package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

subvt_expr This enables process observables as (abstract) expressions, to be evaluated for each process call.

parton_states A `parton_state_t` object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

processes Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: `prc_core` for matrix-element evaluation, `prc_core_def` for the associated configuration and driver, `sf_base` for beams and structure-functions, `phs_base` for phase space, and `mci_base` for integration and event generation.

process_stacks Process stacks collect process objects.

27.1 Process observables

We define an abstract `subvt_expr_t` object as an extension of the `subvt_t` type. The object contains a local variable list, variable instances (as targets for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the `subvt`.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression `selection` which determines whether the object passes user-defined cuts.

The intention is that we fill the `subvt_t` base object and compute the variables once we have evaluated a kinematical phase space point (or a complete

event). We then evaluate the expressions and can use the results in further calculations.

The `process_expr_t` extension contains furthermore scale and weight expressions. The `event_expr_t` extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

Note that there are unit tests, but they are deferred to the `expr_tests` module.

            call object%selection%final ()
        end if
    end subroutine subvt_expr_final

```

27.1.2 Initialization

Initialization: define local variables and establish pointers.

The common variables are `sqrts` (the nominal beam energy, fixed), `sqrts_hat` (the actual energy), `n_in`, `n_out`, and `n_tot` for the subevt. With the exception of `sqrts`, all are implemented as pointers to subobjects.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure (subevt_expr_setup_vars), deferred :: setup_vars
  procedure :: base_setup_vars => subevt_expr_setup_vars
<Subevt expr: procedures>+≡
  subroutine subevt_expr_setup_vars (expr, sqrts)
    class(subevt_expr_t), intent(inout), target :: expr
    real(default), intent(in) :: sqrts
    call expr%var_list%final ()
    call var_list_append_real (expr%var_list, &
      var_str ("sqrts"), sqrts, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_real_ptr (expr%var_list, &
      var_str ("sqrts_hat"), expr%sqrts_hat, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_in"), expr%n_in, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_out"), expr%n_out, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_tot"), expr%n_tot, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
  end subroutine subevt_expr_setup_vars

```

Append the subevent expr (its base-type core) itself to the variable list, if it is not yet present.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure :: setup_var_self => subevt_expr_setup_var_self
<Subevt expr: procedures>+≡
  subroutine subevt_expr_setup_var_self (expr)
    class(subevt_expr_t), intent(inout), target :: expr
    if (.not. expr%var_list%contains (var_str ("@evt"))) then
      call var_list_append_subevt_ptr &
        (expr%var_list, &
        var_str ("@evt"), expr%subevt_t, &
        is_known = expr%subevt_filled, &
        locked = .true., verbose = .false., intrinsic=.true.)
    end if
  end subroutine subevt_expr_setup_var_self

```

Link a variable list to the local one. This could be done event by event, but before evaluating expressions.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure :: link_var_list => subevt_expr_link_var_list

```

```

<Subvt expr: procedures>+≡
  subroutine subvt_expr_link_var_list (expr, var_list)
    class(subvt_expr_t), intent(inout) :: expr
    type(var_list_t), intent(in), target :: var_list
    call expr%var_list%link (var_list)
  end subroutine subvt_expr_link_var_list

```

Compile the selection expression. If there is no expression, the build method won't allocate the expression object.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: setup_selection => subvt_expr_setup_selection

<Subvt expr: procedures>+≡
  subroutine subvt_expr_setup_selection (expr, ef_cuts)
    class(subvt_expr_t), intent(inout), target :: expr
    class(expr_factory_t), intent(in) :: ef_cuts
    call ef_cuts%build (expr%selection)
    if (allocated (expr%selection)) then
      call expr%setup_var_self ()
      call expr%selection%setup_lexpr (expr%var_list)
      expr%has_selection = .true.
    end if
  end subroutine subvt_expr_setup_selection

```

27.1.3 Evaluation

Reset to initial state, i.e., mark the subvt as invalid.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: reset => subvt_expr_reset
  procedure :: base_reset => subvt_expr_reset

<Subvt expr: procedures>+≡
  subroutine subvt_expr_reset (expr)
    class(subvt_expr_t), intent(inout) :: expr
    expr%subvt_filled = .false.
  end subroutine subvt_expr_reset

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: base_evaluate => subvt_expr_evaluate

<Subvt expr: procedures>+≡
  subroutine subvt_expr_evaluate (expr, passed)
    class(subvt_expr_t), intent(inout) :: expr
    logical, intent(out) :: passed
    if (expr%has_selection) then
      call expr%selection%evaluate ()
      if (expr%selection%is_known ()) then
        passed = expr%selection%get_log ()
      else
        call msg_error ("Evaluate selection expression: result undefined")
      end if
    end if
  end subroutine subvt_expr_evaluate

```

```

        passed = .false.
    end if
else
    passed = .true.
end if
end subroutine subevt_expr_evaluate

```

27.1.4 Implementation for partonic events

This implementation contains the expressions that we can evaluate for the partonic process during integration.

```

⟨Subevt expr: public⟩≡
    public :: parton_expr_t

⟨Subevt expr: types⟩+≡
    type, extends (subevt_expr_t) :: parton_expr_t
        integer, dimension(:), allocatable :: i_beam

27.1.5 Implementation for full events

This implementation contains the expressions that we can evaluate for the full event. It also contains data that pertain to the event, suitable for communication with external event formats. These data simultaneously serve as pointer targets for the variable lists hidden in the expressions (eval trees).

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

```

27.2 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states, depending on the the beam setup allows. The result is used for integration.

The `matrix` evaluator is the counterpart of `trace` which is kept exclusive in all observable quantum numbers. The `flows` evaluator is furthermore exclusive in colors, but neglecting all color interference. The `matrix` and `flows` evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. However, this causes memory corruption in gfortran 4.6.3. The extra `has_XXX` flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the `processes` module below.

```

    contains

    <Parton states: procedures>

    end module parton_states

```

27.2.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

<Parton states: types>≡
  type, abstract :: parton_state_t
    logical :: has_trace = .false.
    logical :: has_matrix = .false.
    logical :: has_flows = .false.
    type(evaluator_t) :: trace
    type(evaluator_t) :: matrix
    type(evaluator_t) :: flows
  contains
    <Parton states: parton state: TBP>
  end type parton_state_t

```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both implemented as a pointer. The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```

<Parton states: public>≡
  public :: isolated_state_t

<Parton states: types>+≡
  type, extends (parton_state_t) :: isolated_state_t
    logical :: sf_chain_is_allocated = .false.
    type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()

```

```

    logical :: int_is_allocated = .false.
    type(interaction_t), pointer :: int_eff => null ()
contains
  <Parton states: isolated state: TBP>
end type isolated_state_t

```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

```

<Parton states: types>+≡
  public :: connected_state_t
<Parton states: types>+≡
  type, extends (parton_state_t) :: connected_state_t
    logical :: has_flows_sf = .false.
    type(evaluator_t) :: flows_sf
    logical :: has_expr = .false.
    type(parton_expr_t) :: expr
contains
  <Parton states: connected state: TBP>
end type connected_state_t

```

Output: each evaluator is written only when it is active. The `sf_chain` is only written if it is explicitly allocated.

```

```

27.2.2 Common Initialization

Initialize the isolated parton state. In this version, the effective structure-function chain `sf_chain_eff` and the effective interaction `int_eff` both are trivial pointers to the seed structure-function chain and to the hard interaction, respectively.

```

(Parton states: isolated state: TBP)≡
  procedure :: init => isolated_state_init_pointers

(Parton states: procedures)+≡
  subroutine isolated_state_init_pointers (state, sf_chain, int)
    class(isolated_state_t), intent(out) :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(interaction_t), intent(in), target :: int
    state%sf_chain_eff => sf_chain
    state%int_eff => int
  end subroutine isolated_state_init_pointers

```

27.2.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask_in`.

There are two options: explicitly computing the color factor table (`use_cf` false; `nc` defined), or taking the color factor table from the hard matrix element data.

```

(Parton states: isolated state: TBP)+≡

```

```

procedure :: setup_square_trace => isolated_state_setup_square_trace
<Parton states: procedures>+≡
  subroutine isolated_state_setup_square_trace (state, core, qn_mask_in, &
    col)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), dimension(:), intent(in) :: qn_mask_in
    integer, dimension(:), intent(in) :: col
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    associate (data => core%data)
      allocate (qn_mask (data%n_in + data%n_out))
      qn_mask(:data%n_in) = &
        new_quantum_numbers_mask (.false., .true., .false.) &
        .or. qn_mask_in
      qn_mask(data%n_in+1:) = &
        new_quantum_numbers_mask (.true., .true., .true.)
    if (core%use_color_factors) then
      call evaluator_init_square (state%trace, &
        state%int_eff, qn_mask, &
        data%cf_index, data%color_factors, col, nc=core%nc)
    else
      call evaluator_init_square (state%trace, &
        state%int_eff, qn_mask, nc=core%nc)
    end if
    end associate
    state%has_trace = .true.
  end subroutine isolated_state_setup_square_trace

```

Setup the evaluator for the transition matrix, exclusive in helicities where this is requested.

For all unstable final-state particles we keep polarization according to the applicable decay options. If the process is a decay itself, this applies also to the initial state.

For all polarized final-state particles, we keep polarization including off-diagonal entries. We drop helicity completely for unpolarized final-state particles.

For the initial state, if the particle has not been handled yet, we apply the provided `qn_mask_in` which communicates the beam properties.

```

<Parton states: isolated state: TBP>+≡
  procedure :: setup_square_matrix => isolated_state_setup_square_matrix
<Parton states: procedures>+≡
  subroutine isolated_state_setup_square_matrix &
    (state, core, model, qn_mask_in, col)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    class(model_data_t), intent(in), target :: model
    type(quantum_numbers_mask_t), dimension(:), intent(in) :: qn_mask_in
    integer, dimension(:), intent(in) :: col
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    type(flavor_t), dimension(:), allocatable :: flv
    integer :: i
    logical :: helmask, helmask_hd

```

```

associate (data => core%data)
  allocate (qn_mask (data%n_in + data%n_out))
  allocate (flv (data%n_flv))
  do i = 1, data%n_in + data%n_out
    call flavor_init (flv, data%flv_state(i,:), model)
    if ((data%n_in == 1 .or. i > data%n_in) &
        .and. any (.not. flavor_is_stable (flv))) then
      helmask = all (flavor_decays_isotropically (flv))
      helmask_hd = all (flavor_decays_diagonal (flv))
      qn_mask(i) = new_quantum_numbers_mask (.false., .true., helmask, &
        mask_hd = helmask_hd)
    else if (i > data%n_in) then
      helmask = all (.not. flavor_is_polarized (flv))
      qn_mask(i) = new_quantum_numbers_mask (.false., .true., helmask)
    else
      qn_mask(i) = new_quantum_numbers_mask (.false., .true., .false.) &
        .or. qn_mask_in(i)
    end if
  end do
  if (core%use_color_factors) then
    call evaluator_init_square (state%matrix, &
      state%int_eff, qn_mask, &
      data%cf_index, data%color_factors, col, nc=core%nc)
  else
    call evaluator_init_square (state%matrix, state%int_eff, &
      qn_mask, nc=core%nc)
  end if
end associate
state%has_matrix = .true.
end subroutine isolated_state_setup_square_matrix

```

This procedure initializes the evaluator that computes the contributions to color flows, neglecting color interference. The incoming-particle mask can be used to sum over incoming flavor.

Helicity handling: see above.

(Parton states: isolated state: TBP)+≡

```

procedure :: setup_square_flows => isolated_state_setup_square_flows

```

(Parton states: procedures)+≡

```

subroutine isolated_state_setup_square_flows (state, core, model, qn_mask_in)
  class(isolated_state_t), intent(inout), target :: state

end associate
state%has_flows = .true.
end subroutine isolated_state_setup_square_flows

```

27.2.4 Evaluator initialization: connected state

Setup a trace evaluator as a product of two evaluators (incoming state, effective interaction). In the result, all quantum numbers are summed over.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`.

The `resonant` flag applies if we want to construct a decay chain. The resonance property can propagate to the final event output.

(Parton states: connected state: TBP)≡

```

    procedure :: setup_connected_trace => connected_state_setup_connected_trace

```

(Parton states: procedures)+≡

```

    subroutine connected_state_setup_connected_trace &
        (state, isolated, int, resonant)
        class(connected_state_t), intent(inout), target :: state
        type(isolated_state_t), intent(in), target :: isolated
        type(interaction_t), intent(in), optional, target :: int
        logical, intent(in), optional :: resonant
        type(quantum_numbers_mask_t) :: mask
        type(interaction_t), pointer :: src_int
        mask = new_quantum_numbers_mask (.true., .true., .true.)
        if (present (int)) then
            src_int => int
        else
            src_int => isolated%sf_chain_eff%get_out_int_ptr ()
        end if
        call evaluator_init_product &
            (state%trace, src_int, isolated%trace, mask, mask, &
                connections_are_resonant = resonant)
        state%has_trace = .true.
    end subroutine connected_state_setup_connected_trace

```

Setup a matrix evaluator as a product of two evaluators (incoming state, effective interaction). In the intermediate state, color and helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

```

(Parton states: connected state: TBP)+≡
  procedure :: setup_connected_matrix => connected_state_setup_connected_matrix

(Parton states: procedures)+≡
  subroutine connected_state_setup_connected_matrix &
    (state, isolated, int, resonant)
    class(connected_state_t), intent(inout), target :: state
    type(isolated_state_t), intent(in), target :: isolated
    type(interaction_t), intent(in), optional, target :: int
    logical, intent(in), optional :: resonant
    type(quantum_numbers_mask_t) :: mask
    type(interaction_t), pointer :: src_int
    mask = new_quantum_numbers_mask (.false., .true., .true.)
    if (present (int)) then
      src_int => int
    else
      src_int => isolated%sf_chain_eff%get_out_int_ptr ()
    end if
    call evaluator_init_product &
      (state%matrix, src_int, isolated%matrix, mask, &
       connections_are_resonant = resonant)
    state%has_matrix = .true.
  end subroutine connected_state_setup_connected_matrix

```

Setup a matrix evaluator as a product of two evaluators (incoming state, effective interaction). In the intermediate state, only helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`, after creating an intermediate interaction that includes a correlated color state. We assume that for a caller-provided `int`, this is not necessary.

```

(Parton states: connected state: TBP)+≡
  procedure :: setup_connected_flows => connected_state_setup_connected_flows

(Parton states: procedures)+≡
  subroutine connected_state_setup_connected_flows &
    (state, isolated, int, resonant)
    class(connected_state_t), intent(inout), target :: state
    type(isolated_state_t), intent(in), target :: isolated
    type(interaction_t), intent(in), optional, target :: int
    logical, intent(in), optional :: resonant
    type(quantum_numbers_mask_t) :: mask
    type(interaction_t), pointer :: src_int
    mask = new_quantum_numbers_mask (.false., .false., .true.)
    if (present (int)) then
      src_int => int
    else
      src_int => isolated%sf_chain_eff%get_out_int_ptr ()
      call evaluator_init_color_contractions (state%flows_sf, src_int)
    end if
  end subroutine connected_state_setup_connected_flows

```

```

        state%has_flows_sf = .true.
        src_int => evaluator_get_int_ptr (state%flows_sf)
    end if
    call evaluator_init_product &
        (state%flows, src_int, isolated%flows, mask, &
         connections_are_resonant = resonant)
    state%has_flows = .true.
end subroutine connected_state_setup_connected_flows

```

27.2.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

(Parton states: connected state: TBP)+≡

```

    procedure :: setup_subevt => connected_state_setup_subevt

```

(Parton states: procedures)+≡

```

subroutine connected_state_setup_subevt (state, sf_chain, f_beam, f_in, f_out)
    class(connected_state_t), intent(inout), target :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(flavor_t), dimension(:), intent(in) :: f_beam, f_in, f_out
    integer :: n_beam, n_in, n_out, n_vir, n_tot, i, j
    integer, dimension(:), allocatable :: i_beam, i_in, i_out
    integer :: sf_out_i
    type(interaction_t), pointer :: int, sf_int
    int => evaluator_get_int_ptr (state%trace)
    sf_int => sf_chain%get_out_int_ptr ()
    n_beam = size (f_beam)
    n_in = size (f_in)
    n_out = size (f_out)
    n_vir = interaction_get_n_vir (int)
    n_tot = interaction_get_n_tot (int)
    allocate (i_beam (n_beam), i_in (n_in), i_out (n_out))
    i_beam = [(i, i = 1, n_beam)]
    do j = 1, n_in
        sf_out_i = sf_chain%get_out_i (j)
        i_in(j) = interaction_find_link (int, sf_int, sf_out_i)
    end do
    i_out = [(i, i = n_vir + 1, n_tot)]

  call state%expr%get_in_index (i_in)
end subroutine connected_state_get_in_index

```

27.3 Complete Elementary Processes

This module combines hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the **computed** state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the **observed** state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible subsequent decay processes on the parton level, which are full-fledged process objects themselves.

27.3.1 The Process Object

A process object is the workspace for creating process instances for event generation. After initialization, its contents are filled by integration passes which shape the integration grids and compute cross sections. Processes are set up initially from user-level configuration data. After calculating integrals and thus developing integration grid data, the program may use a process object or a copy of it for the purpose of generating events

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The **type** determines whether we are considering a decay or a scattering process.

The **meta** object describes the process and its environment. All contents become fixed when the object is initialized.

The **config** object holds physical and technical configuration data that have been obtained during process initialization, and which are common to all process components.

The individual process components are configured in the **component** objects. These objects contain more configuration parameters and workspace, as needed for the specific process variant.

The **term** objects describe parton configurations which are technically used as phase-space points. Each process component may split into several terms with distinct kinematics and particle content. Furthermore, each term may project on a different physical state, e.g., by particle recombination. The **term** object provides the framework for this projection, for applying cuts, weight, and thus completing the process calculation.

The **beam_config** object describes the incoming particles, either the decay mother or the scattering beams. It also contains the structure-function information.

The **mci_entry** objects configure a MC input parameter set and integrator, each. The number of parameters depends on the process component and on the beam and structure-function setup.

```

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam_data_t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by extending the code in the `beams` module.

```

```

We complete the kinematics configuration after the beam setup, but before we configure the chain of structure functions. The reason is that we need the total energy `sqrts` for the kinematics, but the structure-function setup requires the number of channels, which depends on the kinematics configuration. For instance, the kinematics module may return the need for parameterizing an s-channel resonance.

```

```

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

```

MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

    (process%config, process%component, process%beam_config)
end do
end subroutine process_compute_md5sum

```

Integration and event generation

The sampler test should just evaluate the squared matrix element `n_calls` times, discarding the results, and return. This can be done before integration, e.g., for timing estimates.

```

<Processes: process: TBP>+≡
  procedure :: sampler_test => process_sampler_test

<Processes: procedures>+≡
  subroutine process_sampler_test (process, instance, i_mci, n_calls)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout), target :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_calls
    call process%mci_entry(i_mci)%sampler_test (instance, n_calls)
  end subroutine process_sampler_test

```

Integrate the process, using a previously initialized process instance. We select one of the available MCI integrators by its index `i_mci` and thus integrate over (structure functions and) phase space for the associated (group of) process component(s).

The finalizer should be called after all integration passes have been completed. It will, for instance, write a summary of the integration results.

`integrate_dummy` does a “dummy” integration in the sense that nothing is done but just empty integration results appended.

```

<Processes: process: TBP>+≡
  procedure :: integrate => process_integrate
  procedure :: final_integration => process_final_integration
  procedure :: integrate_dummy => process_integrate_dummy

<Processes: procedures>+≡
  subroutine process_integrate (process, instance, i_mci, n_it, n_calls, &
    adapt_grids, adapt_weights, final, pacify)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_it
    integer, intent(in) :: n_calls

```

```

logical, intent(in), optional :: adapt_grids
logical, intent(in), optional :: adapt_weights
logical, intent(in), optional :: final, pacify
call process%mci_entry(i_mci)%integrate (instance, n_it, n_calls, &
      adapt_grids, adapt_weights, final, pacify, i_mci)
call instance%display_real_kinematics (i_mci)
end subroutine process_integrate

subroutine process_final_integration (process, i_mci)
  class(process_t), intent(inout) :: process
  integer, intent(in) :: i_mci
  call process%mci_entry(i_mci)%final_integration ()
end subroutine process_final_integration

            end if
        end do
    end subroutine process_write_state_summary

```

Prepare event generation for the specified MCI entry. This implies, in particular, checking the phase-space file.

```

<Processes: process: TBP>+≡
    procedure :: prepare_simulation => process_prepare_simulation

<Processes: procedures>+≡
    subroutine process_prepare_simulation (process, i_mci)
        class(process_t), intent(inout) :: process
        integer, intent(in) :: i_mci
        call process%mc_entry(i_mci)%prepare_simulation ()
    end subroutine process_prepare_simulation

```

Generate a weighted event. We select one of the available MCI integrators by its index `i_mci` and thus generate an event for the associated (group of) process

component(s). The arguments exactly correspond to the initializer and finalizer above.

The resulting event is stored in the `process_instance` object, which also holds the workspace of the integrator.

Note: The `process` object is declared `intent(inout)` because it contains the random-number state, which changes for each event. Otherwise, all volatile data are inside the `instance` object.

```

(Processes: process: TBP)+≡
  procedure :: generate_weighted_event => process_generate_weighted_event
  procedure :: generate_unweighted_event => process_generate_unweighted_event

(Processes: procedures)+≡
  subroutine process_generate_weighted_event (process, instance, i_mci)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%generate_weighted_event (instance)
  end subroutine process_generate_weighted_event

  subroutine process_generate_unweighted_event (process, instance, i_mci)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%generate_unweighted_event (instance)
  end subroutine process_generate_unweighted_event

```

This replaces the event generation methods for the situation that the process instance object has been filled by other means (i.e., reading and/or recalculating its contents). We just have to fill in missing MCI data, especially the event weight.

```

(Processes: process: TBP)+≡

    end function process_get_md5sum_cfg

```

27.3.2 Metadata

This information describes the process and its environment. It is fixed upon initialization.

The `id` string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The `num_id` is meaningful if nonzero. It is used for communication with external programs or file standards which do not support string IDs.

The `run_id` string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The `var_list` is a snapshot of the variable list, taken at the point where the process was initialized.

The `lib` pointer accesses the process library where the process definition and the process driver are located.

The `lib_index` is the index of entry in the process library that corresponds to the current process.

The `component_id` array identifies the individual process components.

The `component_description` is an array of human-readable strings that characterize the process components, for instance `a, b => c, d`.

The `active` mask array marks those components which are active. The others are skipped.

```
<Processes: process part types>≡
  type :: process_metadata_t
  private
  integer :: type = PRC_UNKNOWN
  type(string_t) :: id
  integer :: num_id = 0
  type(string_t) :: run_id

27.3.3 Generic Configuration Data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the variable list.

The number **n_in** is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number **n_components** is the number of components that constitute the current process.

The number **n_terms** is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number **n_mci** is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI

configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The `model` pointer identifies the physics model and its parameters. This is a pointer to an external object.

The `rng_factory` component spawns independent random-number generators for use in integration, event generation, and event postprocessing.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the `effective_state` subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The `md5sum` is taken and used to verify the process configuration when re-reading data from file.

```

<Processes: process part types>+=
  type :: process_config_data_t
    private
      integer :: n_in = 0
      integer :: n_components = 0
      integer :: n_terms = 0
      integer :: n_mci = 0
      type(os_data_t) :: os_data
      class(rng_factory_t), allocatable :: rng_factory

        end if
    else
        call write_separator (u)
        write (u, "(3x,A)") "Expressions (cut, scales, weight): [not shown]"
    end if
    if (config%md5sum /= "") then
        call write_separator (u)
        write (u, "(3x,A,A,A)") "MD5 sum (config) = '", config%md5sum, "'"
    end if
end subroutine process_config_data_write

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

The model that we import here should be an instance of the global model. If we create the instance outside, we can make it an extension of the basic `model_data_t`. This will allow us to synchronize the variable list with the model. Using a pointer instead of an allocatable, we can guarantee the `target` attribute.

The RNG factory object is imported by moving the allocation.

```

<Processes: process config data: TBP>+=
    procedure :: init => process_config_data_init

<Processes: procedures>+=
    subroutine process_config_data_init &
        (config, meta, os_data, qcd, rng_factory, model)
        class(process_config_data_t), intent(out) :: config
        type(process_metadata_t), intent(in) :: meta
        type(os_data_t), intent(in) :: os_data
        type(qcd_t), intent(in) :: qcd
        class(rng_factory_t), intent(inout), allocatable :: rng_factory
        class(model_data_t), intent(inout), pointer :: model
        config%n_in = meta%lib%get_n_in (meta%id)
        config%n_components = size (meta%component_id)
        config%os_data = os_data
        config%qcd = qcd
        call move_alloc (from = rng_factory, to = config%rng_factory)
        config%model_name = model%get_name ()
        config%model => model
        model => null ()
    end subroutine process_config_data_init

```

Since the captured model is a separate object allocated via a pointer, we need a finalizer.

```

<Processes: process config data: TBP>+=
    procedure :: final => process_config_data_final

<Processes: procedures>+=
    subroutine process_config_data_final (config)
        class(process_config_data_t), intent(inout) :: config

```

```

    if (associated (config%model)) then
        call config%model%final ()
        deallocate (config%model)
    end if
end subroutine process_config_data_final

```

Compute the MD5 sum of the configuration data. This encodes, in particular, the model and the expressions for cut, scales, weight, etc. It should not contain the IDs and number of components, etc., since the MD5 sum should be useful for integrating individual components.

This is done only once. If the MD5 sum is nonempty, the calculation is skipped.

```

<Processes: process config data: TBP>+≡
    procedure :: compute_md5sum => process_config_data_compute_md5sum

<Processes: procedures>+≡
    subroutine process_config_data_compute_md5sum (config)

        if (config%md5sum == "") then
            u = free_unit ()
            open (u, status = "scratch", action = "readwrite")
            call config%write (u, counters = .false., os_data = .false., &
                rng_factory = .false., model = .true., expressions = .true.)
            rewind (u)
            config%md5sum = md5sum (u)
            close (u)
        end if
    end subroutine process_config_data_compute_md5sum

```

27.3.4 Beam configuration

The object `data` holds all details about the initial beam configuration. The allocatable array `sf` holds the structure-function configuration blocks. There are `n_strfun` entries in the structure-function chain (not counting the initial beam object). We maintain `n_channel` independent parameterizations of this chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is `n_sfpar`.

The flag `azimuthal_dependence` tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag `lab_is_cm_frame` is obvious.

```

<Processes: process part types>+≡
    type :: process_beam_config_t
        private
        type(beam_data_t) :: data
        integer :: n_strfun = 0
        integer :: n_channel = 1
        integer :: n_sfpar = 0
        type(sf_config_t), dimension(:), allocatable :: sf

```

```

    type(sf_channel_t), dimension(:), allocatable :: sf_channel
    logical :: azimuthal_dependence = .false.

        counter%total = counter%total + 1
    end subroutine process_counter_record

```

27.3.5 Multi-channel integration

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly

the values that apply to the current pass. Previous values are archived in the **results** object.

The **counter** receives the counter statistics from the associated process instance, for diagnostics.

The **results** object records results, broken down in passes and iterations.

```

<Processes: process part types>+≡

```

Integrate. The instance should be initialized.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

Generate an event. The instance should be initialized, otherwise event generation is directed by the mci integrator subobject. The integrator instance is contained in a mci_work subobject of the process instance, which simultaneously serves as the sampler object. (We avoid the anti-aliasing rules if we assume that the sampling itself does not involve the integrator instance contained in the process instance.)

Regarding weighted events, we only take events which are valid, which means that they have valid kinematics and have passed cuts. Therefore, we have a rejection loop. For unweighted events, the unweighting routine should already take care of this.

27.3.6 Process Components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components can have different types. In short, `process_component_t` is a wrapper for the actual process variants.

If the `active` flag is false, we should skip this component. This happens if the associated process has vanishing matrix element.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

<Processes: process part types>+≡
type :: process_component_t
  private
  type(process_component_def_t), pointer :: config => null ()

27.3.7 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`.

In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`. This is the total number of independent entries in the density matrix. For each combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

```

<Processes: process part types>+≡
  type :: process_term_t
    integer :: i_term_global = 0
    integer :: i_component = 0
    integer :: i_term = 0
    integer :: n_allowed = 0
    integer :: n_allowed_sub_born = 0
    type(process_constants_t) :: data
    real(default) :: alpha_s = 0
    integer, dimension(:), allocatable :: flv, hel, col
    logical :: rearrange = .false.
    type(interaction_t) :: int
    type(interaction_t), pointer :: int_eff => null ()
  contains
    <Processes: process term: TBP>
  end type process_term_t

```

For the output, we skip the process constants and the tables of allowed quantum numbers. Those can also be read off from the interaction object.

```

<Processes: process term: TBP>≡
  procedure :: write => process_term_write

if (term%rearrange) then
    call interaction_final (term%int_eff)
    deallocate (term%int_eff)
end if
end subroutine process_term_final

```

Initialize the term. We copy the process constants from the `core` object and set up the `int` hard interaction accordingly.

The `alpha_s` value is useful for writing external event records. This is the constant value which may be overridden by a event-specific running value. If the model does not contain the strong coupling, the value is zero.

The `rearrange` part is commented out; this or something equivalent could become relevant for NLO algorithms.

```

(Processes: process term: TBP) +=
    procedure :: init => process_term_init

(Processes: procedures) +=
    subroutine process_term_init &
        (term, i_term_global, i_component, i_term, core, model)

        ! end if
    end subroutine process_term_init

```

We fetch the process constants which determine the quantum numbers and use

those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

```

27.3.8 Default Iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

<Processes: process: TBP>+≡
    procedure :: get_n_pass_default => process_get_n_pass_default
    procedure :: adapt_grids_default => process_adapt_grids_default
    procedure :: adapt_weights_default => process_adapt_weights_default

<Processes: procedures>+≡
    function process_get_n_pass_default (process) result (n_pass)
        class(process_t), intent(in) :: process
        integer :: n_pass
        integer :: n_eff
        type(process_component_def_t), pointer :: config
        config => process%component(1)%config
        n_eff = config%get_n_tot () - 2
        select case (n_eff)
        case (1)
            n_pass = 1

27.3.10 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```

27.3.11 Process instances

Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

`sf_chain` is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

`phs` is an instance of the phase space for the elementary process.

The array `f` contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either `sf_chain` or `phs` are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component ('owned' by the object) or as a pointer.

```

(Processes: types)+≡
  type :: kinematics_t
    integer :: n_in = 0
    integer :: n_channel = 0

        end do
    end subroutine kinematics_compute_other_channels

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

```

<Processes: kinematics: TBP>+≡
    procedure :: get_incoming_momenta => kinematics_get_incoming_momenta

<Processes: procedures>+≡
    subroutine kinematics_get_incoming_momenta (k, p)
        class(kinematics_t), intent(in) :: k
        type(vector4_t), dimension(:), intent(out) :: p

```

```

type(interaction_t), pointer :: int
integer :: i
int => k%sf_chain%get_out_int_ptr ()
do i = 1, k%n_in
    p(i) = interaction_get_momentum (int, k%sf_chain%get_out_i (i))
end do
end subroutine kinematics_get_incoming_momenta

```

This inverts the remainder of the above `compute` method. We know the momenta and recover the rest, as far as needed. If we select a channel, we can complete the inversion and reconstruct the MC parameter set.

```

  end subroutine kinematics_return_beam_momenta

```

Process component instance

The actual calculation of a sampling point is done from here.

The `config` pointer accesses the corresponding configuration in the `process` object.

The `active` flag indicates that we are currently computing this component, together with all other components that share the same MC parameter set. Inactive components are using a different MC parameter set and are not in use for this sampling point.

The `k_seed` subobject contains the kinematics (structure-function chain, phase space, etc.) that implements the ‘seed’ configuration of momenta. This version of the process kinematics is accessed by the MCI setup.

`p_seed` is the array of momenta that we compute from the MC input parameters, via the `k_seed` subobject. Depending on the process variant, these may or may not coincide with the momenta that enter the process terms associated to this component.

The `tmp` object can be used for storing intermediate results. Its precise type and contents depend on the process variant.

```

```

Compute the momenta in the hard interactions, one for each term that constitutes this process component. In simple cases this amounts to just copying momenta. In more advanced cases, we may generate distinct sets of momenta from the seed kinematics.

The interactions in the term instances are accessed individually. We may choose to calculate all terms at once together with the seed kinematics, use `component%tmp` for storage, and just fill the interactions here.

```
(Processes: component instance: TBP)+≡
  procedure :: compute_hard_kinematics => &
    component_instance_compute_hard_kinematics

(Processes: procedures)+≡
  subroutine component_instance_compute_hard_kinematics &

        end do
      end associate
    end associate
  end subroutine component_instance_compute_hard_kinematics
```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the mo-

momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

```

Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The `k_term` object is the instance of the kinematics setup (structure-function chain, phase space, etc.) that applies specifically to this term. In ordinary cases, it consists of straight pointers to the seed kinematics.

The `amp` array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The `int_hard` interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The `isolated` object holds the effective parton state for the elementary interaction. The amplitude entries are computed from `int_hard`.

The `connected` evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The `checked` flag is set once we have applied cuts on this term. The result of this is stored in the `passed` flag. Once the term has passed cuts, we calculate the various scale and weight expressions.

```

For initialization, we make use of defined assignment for the `interaction_t` type. This creates a deep copy.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (`rearrange`) as effective structure-function chain and interaction, respectively.

Finally, we set up the `subevt` component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

The `rearrange` parts are still commented out; they could become relevant for a NLO algorithm.

  end subroutine term_instance_reset

```

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain. (If we have an algorithm that uses rearrangement, it should evaluate `k_term` explicitly.)

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

end subroutine term_instance_evaluate_interaction_real

```

Return data that might be useful for external processing. The factorization scale:

```

<Processes: term instance: TBP>+≡
    procedure :: get_fac_scale => term_instance_get_fac_scale

<Processes: procedures>+≡
    function term_instance_get_fac_scale (term) result (fac_scale)
        class(term_instance_t), intent(in) :: term
        real(default) :: fac_scale
        fac_scale = term%fac_scale
    end function term_instance_get_fac_scale

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

<Processes: term instance: TBP>+≡
    procedure :: get_alpha_s => term_instance_get_alpha_s

<Processes: procedures>+≡
    function term_instance_get_alpha_s (term, component) result (alpha_s)
        class(term_instance_t), intent(in) :: term

```

```

    associate (core => component(i_component)%config%core)
        alpha_s = core%get_alpha_s (component(i_component)%tmp)
    end associate
    if (alpha_s < 0) alpha_s = term%config%alpha_s
end function term_instance_get_alpha_s

```

MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

(Processes: types)+≡

```

type :: mci_work_t
    type(process_mci_entry_t), pointer :: config => null ()
    real(default), dimension(:), allocatable :: x
    class(mci_instance_t), pointer :: mci => null ()
    type(process_counter_t) :: counter
contains
    (Processes: mci work: TBP)
end type mci_work_t

```

First write configuration data, then the current values.

(Processes: mci work: TBP)≡

```

procedure :: write => mci_work_write

```

(Processes: procedures)+≡

```

subroutine mci_work_write (mci_work, unit, testflag)
    class(mci_work_t), intent(in) :: mci_work
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A,I0,A)") "Active MCI instance #", &
        mci_work%config%i_mci, " ="
    write (u, "(2x)", advance="no")
    do i = 1, mci_work%config%n_par
        write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
        if (i == mci_work%config%n_par_sf) &
            write (u, "(1x,'|')", advance="no")
    end do
    write (u, *)
    if (associated (mci_work%mci)) then
        call mci_work%mci%write (u, pacify = testflag)
        call mci_work%counter%write (u)
    end if
end subroutine mci_work_write

```

The `mci` component may require finalization.

(Processes: mci work: TBP)+≡

```

procedure :: final => mci_work_final

```

```

<Processes: procedures>+≡
subroutine mci_work_final (mci_work)
  class(mci_work_t), intent(inout) :: mci_work
  if (associated (mci_work%mci)) then
    call mci_work%mci%final ()
    deallocate (mci_work%mci)
  end if
end subroutine mci_work_final

```

Initialize with the maximum length that we will need. Contents are not initialized.

The integrator inside the `mci_entry` object is responsible for allocating and initializing its own instance, which is referred to by a pointer in the `mci_work` object.

```

<Processes: mci work: TBP>+≡
  procedure :: init => mci_work_init

<Processes: procedures>+≡
subroutine mci_work_init (mci_work, mci_entry)
  class(mci_work_t), intent(out) :: mci_work
  type(process_mci_entry_t), intent(in), target :: mci_entry
  mci_work%config => mci_entry
  allocate (mci_work%x (mci_entry%n_par))
  if (allocated (mci_entry%mci)) then
    call mci_entry%mci%allocate_instance (mci_work%mci)
    call mci_work%mci%init (mci_entry%mci)
  end if
end subroutine mci_work_init

```

Set parameters explicitly, either all at once, or separately for the structure-function and process parts.

```

<Processes: mci work: TBP>+≡
  procedure :: set => mci_work_set
  procedure :: set_x_strfun => mci_work_set_x_strfun
  procedure :: set_x_process => mci_work_set_x_process

<Processes: procedures>+≡
subroutine mci_work_set (mci_work, x)
  class(mci_work_t), intent(inout) :: mci_work
  real(default), dimension(:), intent(in) :: x
  mci_work%x = x
end subroutine mci_work_set

subroutine mci_work_set_x_strfun (mci_work, x)
  class(mci_work_t), intent(inout) :: mci_work
  real(default), dimension(:), intent(in) :: x
  mci_work%x(1 : mci_work%config%n_par_sf) = x
end subroutine mci_work_set_x_strfun

subroutine mci_work_set_x_process (mci_work, x)
  class(mci_work_t), intent(inout) :: mci_work
  real(default), dimension(:), intent(in) :: x
  mci_work%x(mci_work%config%n_par_sf + 1 : mci_work%config%n_par) = x

```

```
end subroutine mci_work_set_x_process
```

Return the array of active components, i.e., those that correspond to the currently selected MC parameter set.

```
<Processes: mci work: TBP>+≡
  procedure :: get_active_components => mci_work_get_active_components

<Processes: procedures>+≡
  function mci_work_get_active_components (mci_work) result (i_component)
    class(mci_work_t), intent(in) :: mci_work
    integer, dimension(:), allocatable :: i_component
    allocate (i_component (size (mci_work%config%i_component)))
    i_component = mci_work%config%i_component
  end function mci_work_get_active_components
```

Return the active parameters as a simple array with correct length. Do this separately for the structure-function parameters and the process parameters.

```
<Processes: mci work: TBP>+≡
  procedure :: get_x_strfun => mci_work_get_x_strfun
  procedure :: get_x_process => mci_work_get_x_process

<Processes: procedures>+≡
  function mci_work_get_x_strfun (mci_work) result (x)
    class(mci_work_t), intent(in) :: mci_work
    real(default), dimension(mci_work%config%n_par_sf) :: x
    x = mci_work%x(1 : mci_work%config%n_par_sf)
  end function mci_work_get_x_strfun

  function mci_work_get_x_process (mci_work) result (x)
    class(mci_work_t), intent(in) :: mci_work
    real(default), dimension(mci_work%config%n_par_phs) :: x
    x = mci_work%x(mci_work%config%n_par_sf + 1 : mci_work%config%n_par)
  end function mci_work_get_x_process
```

Initialize and finalize event generation for the specified MCI entry. This also resets the counter.

```
<Processes: mci work: TBP>+≡
  procedure :: init_simulation => mci_work_init_simulation
  procedure :: final_simulation => mci_work_final_simulation

<Processes: procedures>+≡
  subroutine mci_work_init_simulation (mci_work, safety_factor)
    class(mci_work_t), intent(inout) :: mci_work
    real(default), intent(in), optional :: safety_factor
    call mci_work%mci%init_simulation (safety_factor)
    call mci_work%counter%reset ()
  end subroutine mci_work_init_simulation

  subroutine mci_work_final_simulation (mci_work)
    class(mci_work_t), intent(inout) :: mci_work
    call mci_work%mci%final_simulation ()
  end subroutine mci_work_final_simulation
```

Counter.

```

(Processes: mci work: TBP) +=
  procedure :: reset_counter => mci_work_reset_counter
  procedure :: record_call => mci_work_record_call
  procedure :: get_counter => mci_work_get_counter

(Processes: procedures) +=
  subroutine mci_work_reset_counter (mci_work)
    class(mci_work_t), intent(inout) :: mci_work
    call mci_work%counter%reset ()
  end subroutine mci_work_reset_counter

  subroutine mci_work_record_call (mci_work, status)
    class(mci_work_t), intent(inout) :: mci_work

    class(mci_work_t), intent(in) :: mci_work
    type(process_counter_t) :: counter
    counter = mci_work%counter
  end function mci_work_get_counter

```

The process instance

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `count` object records process evaluations, broken down according to status.

The `sqme` value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The `weight` value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the `sqme` value times Jacobian weights from the integration, or unity, respectively.

The `i_mci` index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The `sf_chain` subobject is a realization of the beam and structure-function configuration in the `process` object. It is not used for calculation directly but serves as the template for the sf-chain instances that are contained in the `component` objects.

The `component` subobjects determine the state of each component.

The `term` subobjects are workspace for evaluating kinematics, matrix elements, cuts etc.

The `mci_work` subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the `mci_work` array is selected by the `i_mci` index above.

```

<Processes: public>+≡
    public :: process_instance_t

<Processes: types>+≡
    type, extends (mci_sampler_t) :: process_instance_t
        type(process_t), pointer :: process => null ()
        integer :: evaluation_status = STAT_UNDEFINED
        real(default) :: sqme = 0
        real(default), dimension(:), allocatable :: sqme_real
        real(default) :: weight = 0
        real(default) :: excess = 0
        integer :: i_mci = 0
        integer :: selected_channel = 0

    contains
        <Processes: process instance: TBP>
    end type process_instance_t

```

The output routine contains a header with the most relevant information about the process, copied from `process_metadata_write`. We mark the active components by an asterisk.

The next section is the MC parameter input. The following sections are written only if the evaluation status is beyond setting the parameters, or if the `verbose` option is set.

```

<Processes: process instance: TBP>≡

                instance%term(component%config%i_term(j))%active &
                    = .true.
            end do
        end if
    end associate
end do
instance%evaluation_status = STAT_ACTIVATED
end subroutine process_instance_activate

```

Initialization connects the instance with a process. All initial information is transferred from the process object. The process object contains templates for the interaction subobjects (beam and term), but no evaluators. The initialization routine creates evaluators for the matrix element trace, other evaluators are left untouched.

The `instance` object must have the `target` attribute (also in any caller) since the initialization routine assigns various pointers to subobject of `instance`.

```

```

Subroutine of the initialization above: initialize the beam and structure-function chain template. We establish pointers to the configuration data, so `beam_config` must have a `target` attribute.

The resulting chain is not used directly for calculation. It will acquire instances which are stored in the process-component instance objects.

```

<Processes: process instance: TBP>+≡
    procedure :: setup_sf_chain => process_instance_setup_sf_chain

<Processes: procedures>+≡
    subroutine process_instance_setup_sf_chain (instance, config)
        class(process_instance_t), intent(inout) :: instance
        type(process_beam_config_t), intent(in), target :: config
        integer :: n_strfun
        n_strfun = config%n_strfun
        if (n_strfun /= 0) then
            call instance%sf_chain%init (config%data, config%sf)
        else
            call instance%sf_chain%init (config%data)
        end if
        if (config%sf_trace) then
            call instance%sf_chain%setup_tracing (config%sf_trace_file)
        end if
    end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

<Processes: process instance: TBP>+≡
    procedure :: setup_event_data => process_instance_setup_event_data

<Processes: procedures>+≡
    subroutine process_instance_setup_event_data (instance, model)
        class(process_instance_t), intent(inout), target :: instance
        class(model_data_t), intent(in), optional, target :: model
        class(model_data_t), pointer :: current_model
        integer :: i, i_component
        if (present (model)) then

```

```

        current_model => model
    else
        current_model => instance%process%config%model

        end select
    end subroutine process_instance_init_born_amps

```

Choose a MC parameter set and the corresponding integrator.

The choice persists beyond calls of the `reset` method above. This method is automatically called here.

```

<Processes: process instance: TBP>+≡
    procedure :: choose_mci => process_instance_choose_mci

<Processes: procedures>+≡
    subroutine process_instance_choose_mci (instance, i_mci)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci
        instance%i_mci = i_mci
        call instance%reset ()
    end subroutine process_instance_choose_mci

```

Explicitly set a MC parameter set. Works only if we are in initial state. We assume that the length of the parameter set is correct.

After setting the parameters, activate the components and terms that correspond to the chosen MC parameter set.

```

<Processes: process instance: TBP>+≡
    procedure :: set_mcpair => process_instance_set_mcpair

```

```

<Processes: procedures>+≡
  subroutine process_instance_set_mcpair (instance, x)
    class(process_instance_t), intent(inout) :: instance
    real(default), dimension(:), intent(in) :: x
    if (instance%evaluation_status == STAT_INITIAL) then
      associate (mci_work => instance%mci_work(instance%i_mci))
        call mci_work%set (x)
      end associate
      call instance%activate ()
    end if
  end subroutine process_instance_set_mcpair

```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The sf-chain instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```

<Processes: process instance: TBP>+≡
  procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

<Processes: procedures>+≡
  subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%receive_beam_momenta ()
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_receive_beam_momenta

```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```

<Processes: process instance: TBP>+≡
  procedure :: set_beam_momenta => process_instance_set_beam_momenta

<Processes: procedures>+≡
  subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%set_beam_momenta (p)
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_set_beam_momenta

```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```

<Processes: process instance: TBP>+≡
  procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

```

```

<Processes: procedures>+=
  subroutine process_instance_recover_beam_momenta (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    integer :: i
    if (.not. instance%process%beam_config%lab_is_cm_frame) then
      if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
        i = instance%term(i_term)%config%i_component
        call instance%component(i)%return_beam_momenta ()
      end if
    end if
  end subroutine process_instance_recover_beam_momenta

```

Explicitly choose MC integration channel. We assume here that the channel count is identical for all active components.

```

<Processes: process instance: TBP>+=
  procedure :: select_channel => process_instance_select_channel

<Processes: procedures>+=
  subroutine process_instance_select_channel (instance, channel)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    instance%selected_channel = channel
  end subroutine process_instance_select_channel

```

First step of process evaluation: set up seed kinematics. That is, for each active process component, compute a momentum array from the MC input parameters.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Processes: process instance: TBP>+=
  procedure :: compute_seed_kinematics => &
    process_instance_compute_seed_kinematics

<Processes: procedures>+=
  subroutine process_instance_compute_seed_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: channel, skip_component, i
    logical :: success
    channel = instance%selected_channel
    if (channel == 0) then
      call msg_bug ("Compute seed kinematics: undefined integration channel")
    end if
    if (present (skip_term)) then
      skip_component = instance%term(skip_term)%config%i_component
    else
      skip_component = 0
    end if
    if (instance%evaluation_status >= STAT_ACTIVATED) then
      success = .true.
      do i = 1, size (instance%component)
        if (i == skip_component) cycle

```

```

        if (instance%component(i)%active) then
            call instance%component(i)%compute_seed_kinematics &
                (instance%mc_i_work(instance%i_mci), channel, success)
            if (.not. success) exit
        end if
    end do
    if (success) then
        instance%evaluation_status = STAT_SEED_KINEMATICS
    else
        instance%evaluation_status = STAT_FAILED_KINEMATICS
    end if
end if
end if
end subroutine process_instance_compute_seed_kinematics

```

Inverse: recover missing parts of the kinematics from the momentum configuration, which we know for a single term and component. Given a channel, reconstruct the MC parameter set.

```

<Processes: process instance: TBP>+≡
    procedure :: recover_mcpars => process_instance_recover_mcpars

<Processes: procedures>+≡
    subroutine process_instance_recover_mcpars (instance, i_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_term
        integer :: channel
        integer :: i
        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
            channel = instance%selected_channel
            if (channel == 0) then
                call msg_bug ("Recover MC parameters: undefined integration channel")
            end if
            i = instance%term(i_term)%config%i_component
            call instance%component(i)%recover_mcpars &
                (instance%mc_i_work(instance%i_mci), channel)
        end if
    end subroutine process_instance_recover_mcpars

```

Second step of process evaluation: compute all momenta, for all active components, from the seed kinematics.

```

<Processes: process instance: TBP>+≡
    procedure :: compute_hard_kinematics => &
        process_instance_compute_hard_kinematics

<Processes: procedures>+≡
    subroutine process_instance_compute_hard_kinematics (instance, skip_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in), optional :: skip_term
        integer :: i
        logical :: real_phas
        if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
            do i = 1, size (instance%component)
                if (instance%component(i)%active) then
                    select case (char (instance%component(i)%config%config%get_nlo_type()))
                        case ('Born', 'Virtual')

```

```

        real_phsp = .false.
      case ('Real')
        real_phsp = .true.
      end select
      call instance%component(i)% &
        compute_hard_kinematics (instance%term, skip_term, real_phsp)
    end if
  end do
  instance%evaluation_status = STAT_HARD_KINEMATICS
end if
end subroutine process_instance_compute_hard_kinematics

```

Inverse: recover seed kinematics. We know the beam momentum configuration and the outgoing momenta of the effective interaction, for one specific term.

```

<Processes: process instance: TBP>+≡
  procedure :: recover_seed_kinematics => &
    process_instance_recover_seed_kinematics

<Processes: procedures>+≡
  subroutine process_instance_recover_seed_kinematics (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
      associate (i_component => instance%term(i_term)%config%i_component)
        call instance%component(i_component)% &
          recover_seed_kinematics (instance%term(i_term))
      end associate
    end if
  end subroutine process_instance_recover_seed_kinematics

```

Third step of process evaluation: compute the effective momentum configurations, for all active terms, from the hard kinematics.

```

<Processes: process instance: TBP>+≡
  procedure :: compute_eff_kinematics => &
    process_instance_compute_eff_kinematics

<Processes: procedures>+≡
  subroutine process_instance_compute_eff_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: i
    if (instance%evaluation_status >= STAT_HARD_KINEMATICS) then
      do i = 1, size (instance%term)
        if (present (skip_term)) then
          if (i == skip_term) cycle
        end if
        if (instance%term(i)%active) then
          call instance%term(i)% &
            compute_eff_kinematics (instance%component)
        end if
      end do
      instance%evaluation_status = STAT_EFF_KINEMATICS
    end if
  end subroutine process_instance_compute_eff_kinematics

```

Inverse: recover the hard kinematics from effective kinematics for one term, then compute effective kinematics for the other terms.

```

(Processes: process instance: TBP)+≡
    procedure :: recover_hard_kinematics => &
        process_instance_recover_hard_kinematics

(Processes: procedures)+≡
    subroutine process_instance_recover_hard_kinematics (instance, i_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_term
        integer :: i
        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
            call instance%term(i_term)%recover_hard_kinematics (instance%component)
            do i = 1, size (instance%term)
                if (i /= i_term) then
                    if (instance%term(i)%active) then
                        call instance%term(i)% &
                            compute_eff_kinematics (instance%component)
                    end if
                end if
            end do
            instance%evaluation_status = STAT_EFF_KINEMATICS
        end if
    end subroutine process_instance_recover_hard_kinematics

```

Fourth step of process evaluation: check cuts for all terms. Where successful, compute any scales and weights. Otherwise, deactivate the term. If any of the terms has passed, set the state to STAT_PASSED_CUTS.

```

(Processes: process instance: TBP)+≡
    procedure :: evaluate_expressions => &
        process_instance_evaluate_expressions

(Processes: procedures)+≡
    subroutine process_instance_evaluate_expressions (instance)
        class(process_instance_t), intent(inout) :: instance
        integer :: i
        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
            do i = 1, size (instance%term)
                if (instance%term(i)%active) then
                    call instance%term(i)%evaluate_expressions ()
                end if
            end do
            if (any (instance%term%passed)) then
                instance%evaluation_status = STAT_PASSED_CUTS
            else
                instance%evaluation_status = STAT_FAILED_CUTS
            end if
        end if
    end subroutine process_instance_evaluate_expressions

```

Fifth step of process evaluation: fill the parameters for the non-selected ,channels, that have not been used for seeding. We should do this after evaluating

cuts, since we may save some expensive calculations if the phase space point fails the cuts.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

(Processes: process instance: TBP)+≡
  procedure :: compute_other_channels => &
    process_instance_compute_other_channels

(Processes: procedures)+≡
  subroutine process_instance_compute_other_channels (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: channel, skip_component, i
    channel = instance%selected_channel
    if (channel == 0) then
      call msg_bug ("Compute other channels: undefined integration channel")
    end if
    if (present (skip_term)) then
      skip_component = instance%term(skip_term)%config%i_component
    else
      skip_component = 0
    end if
    if (instance%evaluation_status >= STAT_PASSED_CUTS) then
      do i = 1, size (instance%component)
        if (i == skip_component) cycle
        if (instance%component(i)%active) then
          call instance%component(i)%compute_other_channels &
            (instance%mci_work(instance%i_mci), channel)
        end if
      end do
    end if
  end subroutine process_instance_compute_other_channels

```

Sixth step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

```

(Processes: process instance: TBP)+≡
  procedure :: evaluate_trace => process_instance_evaluate_trace

(Processes: procedures)+≡
  subroutine process_instance_evaluate_trace (instance)
    class(process_instance_t), intent(inout) :: instance
    integer :: i, j
    integer :: n_legs
    logical :: passed
    integer :: ireg
    instance%sqme = 0
    if (instance%evaluation_status >= STAT_PASSED_CUTS) then
      do i = 1, size (instance%term)
        associate (term => instance%term(i))
          if (term%active .and. term%passed) then
            select case (char (term%nlo_data%nlo_type))
              case ('Real')

```

```

        call instance%evaluate_trace_real (term, i)
      case ('Born', 'Virtual')
        call term%evaluate_interaction (instance%component)
        call term%evaluate_trace ()
      end select
    end if
  end associate
end do
do i = 1, size (instance%component)
  associate (component => instance%component(i))
    if (component%active) then
      select case (char (component%config%config%get_nlo_type()))
      case ('Born', 'Virtual')

        instance%sqme = instance%sqme + component%sqme
        instance%evaluation_status = STAT_EVALUATED_TRACE
      end select
    end if
  end associate
end do
else
  ! failed kinematics, failed cuts: set sqme to zero
  instance%sqme = 0
end if
end if
end subroutine process_instance_evaluate_trace

```

Final step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

If `weight` is provided, we already know the kinematical event weight (the MCI weight which depends on the kinematics sampling algorithm, but not on the matrix element), so we do not need to take it from the MCI record.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate_event_data => process_instance_evaluate_event_data

<Processes: procedures>+≡
  subroutine process_instance_evaluate_event_data (instance, weight)
    class(process_instance_t), intent(inout) :: instance
    real(default), intent(in), optional :: weight
    integer :: i
    if (instance%evaluation_status >= STAT_EVALUATED_TRACE) then
      do i = 1, size (instance%term)
        associate (term => instance%term(i))
          if (term%active .and. term%passed) then
            call term%evaluate_event_data ()
          end if
        end associate
      end do
    if (present (weight)) then
      instance%weight = weight
    else
      instance%weight = &
        instance%mc_work(instance%i_mci)%mci%get_event_weight ()
      instance%excess = &

```

```

            instance%mci_work(instance%i_mci)%mci%get_event_excess ()
        end if
        instance%evaluation_status = STAT_EVENT_COMPLETE
    else
        ! failed kinematics etc.: set weight to zero
        instance%weight = 0
    end if
end subroutine process_instance_evaluate_event_data

```

For the real part of the process evaluation at NLO, trace evaluation is a bit more intricate because the phase-spaces for different emitters might be treated differently by cuts. A phase-space point is discarded if it fails the cuts for at least one emitter.

```

(Processes: process instance: TBP) +=
    procedure :: evaluate_trace_real => process_instance_evaluate_trace_real

(Processes: procedures) +=
    subroutine process_instance_evaluate_trace_real (instance, term, i)
        class(process_instance_t), intent(inout) :: instance
        type(term_instance_t), intent(inout) :: term
        integer, intent(in) :: i
        integer :: j, ireg
        integer :: nlegs
        logical :: passed

        nlegs = term%nlo_data%reg_data%nlegs_real
        ireg = 1
        instance%sqme_real = 0
        do j = 1, nlegs
            if (any (term%nlo_data%reg_data%emitters == j)) then
                call term%nlo_data%set_active_emitter (j)
                call term%evaluate_interaction (instance%component)
                if (.not. term%passed) then
                    !!! Cuts failed, leave subroutine
                    instance%evaluation_status = STAT_FAILED_CUTS
                    instance%sqme_real = 0
                    return
                end if
                call term%evaluate_trace ()

            end if
        end do
        instance%sqme = instance%sqme + sum (instance%sqme_real)
        instance%evaluation_status = STAT_EVALUATED_TRACE
    end subroutine process_instance_evaluate_trace_real

```

For unweighted event generation, we should reset the reported event weight to unity (signed) or zero. The latter case is appropriate for an event which failed for whatever reason.

```

<Processes: process instance: TBP>+≡
  procedure :: normalize_weight => process_instance_normalize_weight

<Processes: procedures>+≡
  subroutine process_instance_normalize_weight (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%weight /= 0) then
      instance%weight = sign (1._default, instance%weight)
    end if
  end subroutine process_instance_normalize_weight

```

This is a convenience routine that performs the computations of the steps 1 to 5 in a single step. The arguments are the input for `set_mcp`. After this, the evaluation status should be either `STAT_FAILED_KINEMATICS`, `STAT_FAILED_CUTS` or `STAT_EVALUATED_TRACE`.

Before calling this, we should call `choose_mci`.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate_sqme => process_instance_evaluate_sqme

<Processes: procedures>+≡
  subroutine process_instance_evaluate_sqme (instance, channel, x)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    real(default), dimension(:), intent(in) :: x
    call instance%reset ()
    call instance%set_mcp (x)
    call instance%select_channel (channel)
    call instance%compute_seed_kinematics ()
    call instance%compute_hard_kinematics ()
    call instance%compute_eff_kinematics ()
    call instance%evaluate_expressions ()
    call instance%compute_other_channels ()
    call instance%evaluate_trace ()
  end subroutine process_instance_evaluate_sqme

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

```

<Processes: process instance: TBP>+≡
  procedure :: recover => process_instance_recover

<Processes: procedures>+≡
  subroutine process_instance_recover (instance, channel, i_term, update_sqme)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    integer, intent(in) :: i_term
    logical, intent(in) :: update_sqme

```

```

call instance%activate ()
instance%evaluation_status = STAT_EFF_KINEMATICS
call instance%recover_hard_kinematics (i_term)
call instance%recover_seed_kinematics (i_term)
call instance%select_channel (channel)
call instance%recover_mcpair (i_term)
call instance%recover_beam_momenta (i_term)
call instance%compute_seed_kinematics (i_term)
call instance%compute_hard_kinematics (i_term)
call instance%compute_eff_kinematics (i_term)
call instance%compute_other_channels (i_term)
call instance%evaluate_expressions ()
if (update_sqme) call instance%evaluate_trace ()
end subroutine process_instance_recover

```

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the x array, and the f Jacobian array are exposed by the `sampler_t` object.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate => process_instance_evaluate

<Processes: procedures>+≡
  subroutine process_instance_evaluate (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call sampler%evaluate_sqme (c, x_in)
    if (sampler%is_valid ()) call sampler%fetch (val, x, f)
    call sampler%record_call ()
  end subroutine process_instance_evaluate

```

The phase-space point is valid if the event has valid kinematics and has passed the cuts.

```

<Processes: process instance: TBP>+≡
  procedure :: is_valid => process_instance_is_valid

<Processes: procedures>+≡
  function process_instance_is_valid (sampler) result (valid)
    class(process_instance_t), intent(in) :: sampler
    logical :: valid
    valid = sampler%evaluation_status >= STAT_PASSED_CUTS
  end function process_instance_is_valid

```

The `rebuild` method should rebuild the kinematics section out of the `x_in` parameter set. The integrand value `val` should not be computed, but is provided as input.

```

<Processes: process instance: TBP>+≡
  procedure :: rebuild => process_instance_rebuild

```

```

<Processes: procedures>+≡
  subroutine process_instance_rebuild (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(in) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call msg_bug ("process_instance_rebuild not implemented yet")
    x = 0
    f = 0
  end subroutine process_instance_rebuild

```

This is another method required by the `sampler_t` base type: fetch the data that are relevant for the MCI record.

```

<Processes: process instance: TBP>+≡
  procedure :: fetch => process_instance_fetch

<Processes: procedures>+≡
  subroutine process_instance_fetch (sampler, val, x, f)
    class(process_instance_t), intent(in) :: sampler
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    integer :: i, cc
    integer :: n_channel
    val = 0
    FIND_COMPONENT: do i = 1, size (sampler%component)
      associate (component => sampler%component(i))
        if (component%active) then
          associate (k => component%k_seed)
            n_channel = k%n_channel
            do cc = 1, n_channel
              call k%get_mcpair (cc, x(:,cc))
            end do
            f = k%f
            val = sampler%sqme * k%phs_factor
          end associate
        end associate
      end if
    end do FIND_COMPONENT
  end subroutine process_instance_fetch

```

Initialize and finalize event generation for the specified MCI entry.

```

<Processes: process instance: TBP>+≡
  procedure :: init_simulation => process_instance_init_simulation
  procedure :: final_simulation => process_instance_final_simulation

<Processes: procedures>+≡
  subroutine process_instance_init_simulation (instance, i_mci, safety_factor)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    real(default), intent(in), optional :: safety_factor

```

```

        call instance%mci_work(i_mci)%init_simulation (safety_factor)
    end subroutine process_instance_init_simulation

    subroutine process_instance_final_simulation (instance, i_mci)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci
        call instance%mci_work(i_mci)%final_simulation ()
    end subroutine process_instance_final_simulation

```

27.3.12 Accessing the process instance

Once the seed kinematics is complete, we can retrieve the MC input parameters for all channels, not just the seed channel.

Note: We choose the first active component. This makes sense only if the seed kinematics is identical for all active components.

```

<Processes: process instance: TBP>+≡
    procedure :: get_mcpair => process_instance_get_mcpair

<Processes: procedures>+≡
    subroutine process_instance_get_mcpair (instance, channel, x)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
        real(default), dimension(:), intent(out) :: x
        integer :: i
        if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
            do i = 1, size (instance%component)
                if (instance%component(i)%active) then
                    call instance%component(i)%k_seed%get_mcpair (channel, x)
                    return
                end if
            end do
            call msg_bug ("Process instance: get_mcpair: no active channels")
        else
            call msg_bug ("Process instance: get_mcpair: no seed kinematics")
        end if
    end subroutine process_instance_get_mcpair

```

Return true if the *sqme* value is known. This also implies that the event is kinematically valid and has passed all cuts.

```

<Processes: process instance: TBP>+≡
    procedure :: has_evaluated_trace => process_instance_has_evaluated_trace

<Processes: procedures>+≡
    function process_instance_has_evaluated_trace (instance) result (flag)
        class(process_instance_t), intent(in) :: instance
        logical :: flag
        flag = instance%evaluation_status >= STAT_EVALUATED_TRACE
    end function process_instance_has_evaluated_trace

```

Return true if the event is complete. In particular, the event must be kinematically valid, passed all cuts, and the event data have been computed.

```

<Processes: process instance: TBP>+≡

```

```

    procedure :: is_complete_event => process_instance_is_complete_event
  <Processes: procedures>+≡
    function process_instance_is_complete_event (instance) result (flag)
      class(process_instance_t), intent(in) :: instance
      logical :: flag
      flag = instance%evaluation_status >= STAT_EVENT_COMPLETE
    end function process_instance_is_complete_event

```

Select a term for the process instance which is to provide the event record.

Note: this should be done using random numbers and applying probabilities for the various terms and components that belong to the selected MCI group. The current implementation simply selects the first term for the first active component.

```

  <Processes: process instance: TBP>+≡
    procedure :: select_i_term => process_instance_select_i_term
  <Processes: procedures>+≡
    subroutine process_instance_select_i_term (instance, i_term)

end function process_instance_get_counter

```

27.3.13 Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

NB: The `recover_beams` option should be used only when the particle set originates from an external event file, and the user has asked for it. It should be switched off when reading from raw event file.

```

(Processes: process instance: TBP)+≡
  procedure :: get_trace => process_instance_get_trace
  procedure :: set_trace => process_instance_set_trace

(Processes: procedures)+≡
  subroutine process_instance_get_trace (instance, pset, i_term)
    class(process_instance_t), intent(in), target :: instance
    type(particle_set_t), intent(out) :: pset
    integer, intent(in) :: i_term
    type(interaction_t), pointer :: int
    logical :: ok
    int => instance%get_trace_int_ptr (i_term)

```

The pacify subroutine has the purpose of setting numbers to zero which are (by comparing with a **tolerance** parameter) considered equivalent with zero. We do this in some unit tests. Here, we apply this to the phase space subobject of the process instance.

```

<Processes: public>+≡
  public :: pacify

<Processes: interfaces>≡
  interface pacify
    module procedure pacify_process_instance
  end interface pacify

```

```

<Processes: procedures>+≡
  subroutine pacify_process_instance (instance)
    type(process_instance_t), intent(inout) :: instance
    integer :: i
    do i = 1, size (instance%component)
      call pacify (instance%component(i)%k_seed%phs)
    end do
  end subroutine pacify_process_instance

```

27.3.14 Unit tests

```

<Processes: public>+≡
  public :: processes_test

<Processes: tests>≡
  subroutine processes_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Processes: execute tests>
  end subroutine processes_test

```

Test process type

For the following tests, we define a simple implementation of the abstract `prc_core_t`, designed such as to complement the `prc_test_t` process definition type.

Note that it is not given that the actual process is defined as `prc_test_t` type. We enforce this by calling `prc_test_create_library`. The driver component in the process core will then become of type `prc_test_t`.

```
<Processes: public>+≡
    public :: test_t

<Processes: test types>≡
    type, extends (prc_core_t) :: test_t
    contains
        procedure :: write => test_write
        procedure :: needs_mcset => test_needs_mcset
        procedure :: get_n_terms => test_get_n_terms
        procedure :: is_allowed => test_is_allowed
        procedure :: compute_hard_kinematics => test_compute_hard_kinematics
        procedure :: compute_eff_kinematics => test_compute_eff_kinematics
        procedure :: recover_kinematics => test_recover_kinematics
        procedure :: compute_amplitude => test_compute_amplitude
    end type test_t

<Processes: tests>+≡
    subroutine test_write (object, unit)
        class(test_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)
        write (u, "(3x,A)") "test type implementing prc_test"
    end subroutine test_write
```

This process type always needs a MC parameter set and a single term. This only state is always allowed.

```
<Processes: tests>+≡
    function test_needs_mcset (object) result (flag)
        class(test_t), intent(in) :: object
        logical :: flag
        flag = .true.
    end function test_needs_mcset

    function test_get_n_terms (object) result (n)
        class(test_t), intent(in) :: object
        integer :: n
        n = 1
    end function test_get_n_terms

    function test_is_allowed (object, i_term, f, h, c) result (flag)
        class(test_t), intent(in) :: object
        integer, intent(in) :: i_term, f, h, c
        logical :: flag
        flag = .true.
```

```
end function test_is_allowed
```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

(Processes: tests)+≡

```
subroutine test_compute_hard_kinematics &
  (object, p_seed, i_term, int_hard, tmp)
  class(test_t), intent(in) :: object
  type(vector4_t), dimension(:), intent(in) :: p_seed
  integer, intent(in) :: i_term
  type(interaction_t), intent(inout) :: int_hard
  class(workspace_t), intent(inout), allocatable :: tmp
  call interaction_set_momenta (int_hard, p_seed)
end subroutine test_compute_hard_kinematics
```

This procedure is not called for `test_t`, just a placeholder.

(Processes: tests)+≡

```
subroutine test_compute_eff_kinematics &
  (object, i_term, int_hard, int_eff, tmp)
  class(test_t), intent(in) :: object
  integer, intent(in) :: i_term
  type(interaction_t), intent(in) :: int_hard
  type(interaction_t), intent(inout) :: int_eff
  class(workspace_t), intent(inout), allocatable :: tmp
end subroutine test_compute_eff_kinematics
```

Transfer the incoming momenta of `p_seed` directly to the effective interaction, and vice versa for the outgoing momenta.

`int_hard` is left untouched since `int_eff` is an alias (via pointer) to it.

(Processes: tests)+≡

```
subroutine test_recover_kinematics &
  (object, p_seed, int_hard, int_eff, tmp)
  class(test_t), intent(in) :: object
  type(vector4_t), dimension(:), intent(inout) :: p_seed
  type(interaction_t), intent(inout) :: int_hard
  type(interaction_t), intent(inout) :: int_eff
  class(workspace_t), intent(inout), allocatable :: tmp
  integer :: n_in
  n_in = interaction_get_n_in (int_eff)
  call interaction_set_momenta (int_eff, p_seed(1:n_in), outgoing = .false.)
  p_seed(n_in+1:) = interaction_get_momenta (int_eff, outgoing = .true.)
end subroutine test_recover_kinematics
```

Compute the amplitude. The driver ignores all quantum numbers and, in fact, returns a constant. Nevertheless, we properly transfer the momentum vectors.

(Processes: tests)+≡

```
function test_compute_amplitude &
  (object, j, p, f, h, c, fac_scale, ren_scale, tmp) result (amp)
  class(test_t), intent(in) :: object
  integer, intent(in) :: j
  type(vector4_t), dimension(:), intent(in) :: p
```

```

integer, intent(in) :: f, h, c
real(default), intent(in) :: fac_scale, ren_scale
class(workspace_t), intent(inout), allocatable, optional :: tmp
complex(default) :: amp
real(default), dimension(:,:), allocatable :: parray
integer :: i, n_tot
select type (driver => object%driver)
type is (prc_test_t)
  if (driver%scattering) then
    n_tot = 4
  else
    n_tot = 3
  end if
  allocate (parray (0:3,n_tot))
  forall (i = 1:n_tot) parray(:,i) = vector4_get_components (p(i))
  amp = driver%get_amplitude (parray)
end select
end function test_compute_amplitude

```

Write an empty process object

The most trivial test is to write an uninitialized process object.

```

<Processes: execute tests>≡
  call test (processes_1, "processes_1", &
    "write an empty process object", &
    u, results)

<Processes: tests>+≡
  subroutine processes_1 (u)

```

Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also

set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```

27.4 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

```

<process_stacks.f90>≡
<File header>

module process_stacks

<Use strings>
  use io_units
  use format_utils, only: write_separator
  use unit_tests
  use diagnostics

```

```

    use os_interface
    use sm_qcd
    use model_data
    use rng_base
    use variables
    use observables
    use process_libraries
    use prc_test
    use processes

    <Standard module head>

    <Process stacks: public>

    <Process stacks: types>

    contains

    <Process stacks: procedures>

    <Process stacks: tests>

    end module process_stacks

```

27.4.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```

    <Process stacks: public>≡
        public :: process_entry_t

    <Process stacks: types>≡
        type, extends (process_t) :: process_entry_t
            type(process_entry_t), pointer :: next => null ()
        end type process_entry_t

```

27.4.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

The process stack can be linked to another one. This allows us to work with stacks of local scope.

```

    <Process stacks: public>+≡
        public :: process_stack_t

    <Process stacks: types>+≡
        type :: process_stack_t
            integer :: n = 0
            type(process_entry_t), pointer :: first => null ()

```

```

        type(var_list_t), pointer :: var_list => null ()
        type(process_stack_t), pointer :: next => null ()
contains
    <Process stacks: process stack: TBP>
end type process_stack_t

```

Finalize partly: deallocate the process stack and variable list entries, but keep the variable list as an empty object. This way, the variable list links are kept.

```

<Process stacks: process stack: TBP>≡
    procedure :: clear => process_stack_clear

<Process stacks: procedures>≡
    subroutine process_stack_clear (stack)
        class(process_stack_t), intent(inout) :: stack
        type(process_entry_t), pointer :: process
        if (associated (stack%var_list)) then
            call stack%var_list%final ()
        end if
        do while (associated (stack%first))
            process => stack%first
            stack%first => process%next
            call process%final ()
            deallocate (process)
        end do
        stack%n = 0
    end subroutine process_stack_clear

```

Finalizer. Clear and deallocate the variable list.

```

<Process stacks: process stack: TBP>+≡
    procedure :: final => process_stack_final

<Process stacks: procedures>+≡
    subroutine process_stack_final (object)
        class(process_stack_t), intent(inout) :: object
        type(process_entry_t), pointer :: process
        call object%clear ()
        if (associated (object%var_list)) then
            deallocate (object%var_list)
        end if
    end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write => process_stack_write

<Process stacks: procedures>+≡
    recursive subroutine process_stack_write (object, unit, pacify)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: pacify
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)

```

```

call write_separator (u, 2)
select case (object%n)
case (0)
    write (u, "(1x,A)" "Process stack: [empty]"
    call write_separator (u, 2)
case default
    write (u, "(1x,A)" "Process stack:"
    process => object%first
    do while (associated (process))
        call process%write (.false., u, pacify = pacify)
        process => process%next
    end do
end select
if (associated (object%next)) then
    write (u, "(1x,A)" "[Processes from context environment:]"
    call object%next%write (u, pacify)
end if
end subroutine process_stack_write

```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write_var_list => process_stack_write_var_list

<Process stacks: procedures>+≡
    subroutine process_stack_write_var_list (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        if (associated (object%var_list)) then
            call var_list_write (object%var_list, unit)
        end if
    end subroutine process_stack_write_var_list

```

Short output.

```

<Process stacks: process stack: TBP>+≡
    procedure :: show => process_stack_show

<Process stacks: procedures>+≡
    recursive subroutine process_stack_show (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)
        select case (object%n)
        case (0)
        case default
            process => object%first
            do while (associated (process))
                call process%show (u, verbose=.false.)
                process => process%next
            end do
        end select
        if (associated (object%next)) call object%next%show ()
    end subroutine process_stack_show

```

```
end subroutine process_stack_show
```

27.4.3 Link

Link the current process stack to a global one.

```
<Process stacks: process stack: TBP>+≡
  procedure :: link => process_stack_link

<Process stacks: procedures>+≡
  subroutine process_stack_link (local_stack, global_stack)
    class(process_stack_t), intent(inout) :: local_stack
    type(process_stack_t), intent(in), target :: global_stack
    local_stack%next => global_stack
  end subroutine process_stack_link
```

Initialize the process variable list and link the main variable list to it.

```
<Process stacks: process stack: TBP>+≡
  procedure :: init_var_list => process_stack_init_var_list

<Process stacks: procedures>+≡
  subroutine process_stack_init_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(inout), optional :: var_list
    allocate (stack%var_list)
    if (present (var_list)) call var_list%link (stack%var_list)
  end subroutine process_stack_init_var_list
```

Link the process variable list to a global variable list.

```
<Process stacks: process stack: TBP>+≡
  procedure :: link_var_list => process_stack_link_var_list

<Process stacks: procedures>+≡
  subroutine process_stack_link_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in), target :: var_list
    call stack%var_list%link (var_list)
  end subroutine process_stack_link_var_list
```

27.4.4 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```
<Process stacks: process stack: TBP>+≡
  procedure :: push => process_stack_push
```

```

<Process stacks: procedures>+≡
  subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    process%next => stack%first
    stack%first => process
    process => null ()
    stack%n = stack%n + 1
  end subroutine process_stack_push

```

Initialize process variables for a given process ID, without setting values.

```

<Process stacks: process stack: TBP>+≡
  procedure :: init_result_vars => process_stack_init_result_vars

<Process stacks: procedures>+≡
  subroutine process_stack_init_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    call var_list_init_num_id (stack%var_list, id)
    call var_list_init_process_results (stack%var_list, id)
  end subroutine process_stack_init_result_vars

```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```

<Process stacks: process stack: TBP>+≡
  procedure :: fill_result_vars => process_stack_fill_result_vars

<Process stacks: procedures>+≡
  subroutine process_stack_fill_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    type(process_t), pointer :: process
    process => stack%get_process_ptr (id)
    if (associated (process)) then
      call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
      if (process%has_integral ()) then
        call var_list_init_process_results (stack%var_list, id, &
          integral = process%get_integral (), &
          error = process%get_error ())
      end if
    else
      call msg_bug ("process_stack_fill_result_vars: unknown process ID")
    end if
  end subroutine process_stack_fill_result_vars

```

27.4.5 Data Access

Tell if a process exists.

```

<Process stacks: process stack: TBP>+≡
  procedure :: exists => process_stack_exists

```

```

<Process stacks: procedures>+≡
function process_stack_exists (stack, id) result (flag)
  class(process_stack_t), intent(in) :: stack
  type(string_t), intent(in) :: id
  logical :: flag
  type(process_t), pointer :: process
  process => stack%get_process_ptr (id)
  flag = associated (process)
end function process_stack_exists

```

Return a pointer to a process with specific ID. Look also at a linked stack, if necessary.

```

<Process stacks: process stack: TBP>+≡
  procedure :: get_process_ptr => process_stack_get_process_ptr

<Process stacks: procedures>+≡
recursive function process_stack_get_process_ptr (stack, id) result (ptr)
  class(process_stack_t), intent(in) :: stack
  type(string_t), intent(in) :: id
  type(process_t), pointer :: ptr
  type(process_entry_t), pointer :: entry
  ptr => null ()
  entry => stack%first
  do while (associated (entry))
    if (entry%get_id () == id) then
      ptr => entry%process_t
      return
    end if
    entry => entry%next
  end do
  if (associated (stack%next)) ptr => stack%next%get_process_ptr (id)
end function process_stack_get_process_ptr

```

27.4.6 Unit tests

```

<Process stacks: public>+≡
  public :: process_stacks_test

<Process stacks: tests>≡
  subroutine process_stacks_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Process stacks: execute tests>
  end subroutine process_stacks_test

```

Write an empty process stack

The most trivial test is to write an uninitialized process stack.

```

<Process stacks: execute tests>≡
  call test (process_stacks_1, "process_stacks_1", &
    "write an empty process stack", &
    u, results)

```

```

<Process stacks: tests>+≡
subroutine process_stacks_1 (u)
  integer, intent(in) :: u
  type(process_stack_t) :: stack

  write (u, "(A)")  "* Test output: process_stacks_1"
  write (u, "(A)")  "* Purpose: display an empty process stack"
  write (u, "(A)")

  call stack%write (u)

  write (u, "(A)")
  write (u, "(A)")  "* Test output end: process_stacks_1"

end subroutine process_stacks_1

```

Fill a process stack

Fill a process stack with two (identical) processes.

```

<Process stacks: execute tests>+≡
call test (process_stacks_2, "process_stacks_2", &
  "fill a process stack", &
  u, results)

<Process stacks: tests>+≡
subroutine process_stacks_2 (u)
  integer, intent(in) :: u
  type(process_stack_t) :: stack
  type(process_library_t), target :: lib
  type(string_t) :: libname
  type(string_t) :: procname
  type(string_t) :: run_id
  type(os_data_t) :: os_data
  type(qcd_t) :: qcd
  class(rng_factory_t), allocatable :: rng_factory
  class(model_data_t), pointer :: model
  type(process_entry_t), pointer :: process => null ()

  write (u, "(A)")  "* Test output: process_stacks_2"
  write (u, "(A)")  "* Purpose: fill a process stack"
  write (u, "(A)")

  write (u, "(A)")  "* Build, initialize and store two test processes"
  write (u, "(A)")

  libname = "process_stacks2"
  procname = libname
  call os_data_init (os_data)
  allocate (rng_test_factory_t :: rng_factory)
  call prc_test_create_library (libname, lib)

  allocate (model)
  call model%init_test ()

```

```

allocate (process)

```

Chapter 28

Event Implementation

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

event_transforms Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

decays Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

showers Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

events Combine all pieces to generate full events.

eio_raw Raw I/O for complete events.

28.1 Abstract Event Transforms

```
<event_transforms.f90>≡  
  <File header>  
  
  module event_transforms  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use format_utils, only: write_separator  
    use unit_tests
```

```

    use diagnostics
    use os_interface
    use sm_qcd
    use model_data
    use state_matrices
    use interactions
    use particles
    use subevents
    use process_libraries
    use prc_core
    use prc_test
    use rng_base
    use mci_base
    use mci_midpoint
    use phs_base
    use phs_single
    use processes
    use process_stacks

    <Standard module head>

    <Event transforms: public>

    <Event transforms: types>

    <Event transforms: interfaces>

    contains

    <Event transforms: procedures>

    <Event transforms: tests>

    end module event_transforms

```

28.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified setting that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include `previous` and `next` pointers.

```

<Event transforms: public>≡
    public :: evt_t

<Event transforms: types>≡
    type, abstract :: evt_t
    type(process_t), pointer :: process => null ()

```

```

type(process_instance_t), pointer :: process_instance => null ()
class(model_data_t), pointer :: model => null ()
class(rng_t), allocatable :: rng
integer :: rejection_count = 0
logical :: particle_set_exists = .false.
type(particle_set_t) :: particle_set
class(evt_t), pointer :: previous => null ()
class(evt_t), pointer :: next => null ()
contains
  <Event transforms: evt: TBP>
end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡
  procedure :: final => evt_final
  procedure :: base_final => evt_final

<Event transforms: procedures>≡
  subroutine evt_final (object)
    class(evt_t), intent(inout) :: object
    if (allocated (object%rng)) call object%rng%final ()
    if (object%particle_set_exists) &
      call particle_set_final (object%particle_set)
  end subroutine evt_final

```

Output. We can print r.n.g. info.

```

<Event transforms: evt: TBP>+≡
  procedure :: base_write => evt_write

<Event transforms: procedures>+≡
  subroutine evt_write (object, unit, verbose, testflag)
    class(evt_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, testflag
    integer :: u
    u = given_output_unit (unit)
    if (associated (object%process)) then
      write (u, "(3x,A,A,A)") "Associated process: ", &
        char (object%process%get_id ()), ""
    end if
    if (allocated (object%rng)) then
      call object%rng%write (u, 1)
      write (u, "(3x,A,I0)") "Number of tries = ", object%rejection_count
    end if
    if (object%particle_set_exists) then
      call write_separator (u)
      call particle_set_write (object%particle_set, u, testflag)
    end if
  end subroutine evt_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

```

(Event transforms: evt: TBP)+≡
  procedure :: connect => evt_connect
  procedure :: base_connect => evt_connect

(Event transforms: procedures)+≡
  subroutine evt_connect (evt, process_instance, model, process_stack)
    class(evt_t), intent(inout), target :: evt
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    evt%process => process_instance%process
    evt%process_instance => process_instance
    evt%model => model
    call evt%process%make_rng (evt%rng)
  end subroutine evt_connect

```

Reset internal state.

```

(Event transforms: evt: TBP)+≡
  procedure :: reset => evt_reset
  procedure :: base_reset => evt_reset

(Event transforms: procedures)+≡
  subroutine evt_reset (evt)
    class(evt_t), intent(inout) :: evt
    evt%rejection_count = 0
    evt%particle_set_exists = .false.
  end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_prepare_new_event), deferred :: prepare_new_event

(Event transforms: interfaces)≡
  interface
    subroutine evt_prepare_new_event (evt, i_mci, i_term)
      import
      class(evt_t), intent(inout) :: evt
      integer, intent(in) :: i_mci, i_term
    end subroutine evt_prepare_new_event
  end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)

```

```

import
class(evt_t), intent(inout) :: evt
real(default), intent(out) :: probability
end subroutine evt_generate_weighted
end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted
(Event transforms: procedures)+≡
  subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set
(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_make_particle_set
  end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

(Event transforms: evt: TBP)+≡

```

```

    procedure :: set_particle_set => evt_set_particle_set
  <Event transforms: procedures>+≡
    subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
      class(evt_t), intent(inout) :: evt
      type(particle_set_t), intent(in) :: particle_set
      integer, intent(in) :: i_term, i_mci
      call evt%prepare_new_event (i_mci, i_term)
      evt%particle_set = particle_set
      evt%particle_set_exists = .true.
    end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. (We need two interactions, one with color summed over, and one with the probability distributed among flows.)

We use the two values from the random number generator for factorizing the state. For testing purposes, we can provide those numbers explicitly.

```

  <Event transforms: evt: TBP>+≡
    procedure :: factorize_interactions => evt_factorize_interactions
  <Event transforms: procedures>+≡
    subroutine evt_factorize_interactions &
      (evt, int_matrix, int_flows, factorization_mode, keep_correlations, r)
      class(evt_t), intent(inout) :: evt
      type(interaction_t), intent(in), target :: int_matrix, int_flows
      integer, intent(in) :: factorization_mode
      logical, intent(in) :: keep_correlations
      real(default), dimension(:), intent(in), optional :: r
      real(default), dimension(2) :: x
      if (present (r)) then
        if (size (r) == 2) then
          x = r
        else
          call msg_bug ("event factorization: size of r array must be 2")
        end if
      else
        call evt%rng%generate (x)
      end if
      call particle_set_init (evt%particle_set, evt%particle_set_exists, &
        int_matrix, int_flows, factorization_mode, x, &
        keep_correlations, keep_virtual=.true.)
      evt%particle_set_exists = .true.
    end subroutine evt_factorize_interactions

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

```

  <Event transforms: evt: TBP>+≡

```

```

    procedure :: tag_incoming => evt_tag_incoming
  <Event transforms: procedures>+≡
    subroutine evt_tag_incoming (evt)
      class(evt_t), intent(inout) :: evt
      integer :: i_term, n_in
      integer, dimension(:), allocatable :: beam_index, in_index
      n_in = evt%process%get_n_in ()
      i_term = 1
      allocate (beam_index (n_in))
      call evt%process_instance%get_beam_index (i_term, beam_index)
      call particle_set_reset_status (evt%particle_set, &
        beam_index, PRT_BEAM)
      allocate (in_index (n_in))
      call evt%process_instance%get_in_index (i_term, in_index)
      call particle_set_reset_status (evt%particle_set, &
        in_index, PRT_INCOMING)
    end subroutine evt_tag_incoming

```

28.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

  <Event transforms: public>+≡
    public :: evt_trivial_t

  <Event transforms: types>+≡
    type, extends (evt_t) :: evt_trivial_t
      contains
      <Event transforms: evt trivial: TBP>
    end type evt_trivial_t

```

The finalizer is trivial. Some output:

```

  <Event transforms: evt trivial: TBP>≡
    procedure :: write => evt_trivial_write

  <Event transforms: procedures>+≡
    subroutine evt_trivial_write (object, unit, verbose, testflag)
      class(evt_trivial_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose, testflag
      integer :: u
      u = given_output_unit (unit)
      call write_separator (u, 2)
      write (u, "(1x,A)") "Event transform: trivial (hard process)"
      call write_separator (u)
      call object%base_write (u, testflag = testflag)
    end subroutine evt_trivial_write

```

Nothing to do here:

```

  <Event transforms: evt trivial: TBP>+≡
    procedure :: prepare_new_event => evt_trivial_prepare_new_event

```

```

<Event transforms: procedures>+≡
  subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
  end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: generate_weighted => evt_trivial_generate_weighted

<Event transforms: procedures>+≡
  subroutine evt_trivial_generate_weighted (evt, probability)
    class(evt_trivial_t), intent(inout) :: evt
    real(default), intent(out) :: probability
    probability = 1
  end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: make_particle_set => evt_trivial_make_particle_set

<Event transforms: procedures>+≡
  subroutine evt_trivial_make_particle_set &
    (evt, factorization_mode, keep_correlations, r)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    integer :: i_term
    type(interaction_t), pointer :: int_matrix, int_flows
    if (evt%process_instance%is_complete_event ()) then
      call evt%process_instance%select_i_term (i_term)
      int_matrix => evt%process_instance%get_matrix_int_ptr (i_term)
      int_flows => evt%process_instance%get_flows_int_ptr (i_term)
      call evt%factorize_interactions (int_matrix, int_flows, &
        factorization_mode, keep_correlations, r)
      call evt%tag_incoming ()
    else
      call msg_bug ("Event factorization: event is incomplete")
    end if
  end subroutine evt_trivial_make_particle_set

```

28.1.3 Unit tests

```

<Event transforms: public>+≡
  public :: event_transforms_test

<Event transforms: tests>≡
  subroutine event_transforms_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Event transforms: execute tests>

```

```
end subroutine event_transforms_test
```

Test trivial event transform

The trivial transform, as an instance of the abstract transform, does nothing but to trigger event generation for an elementary process.

```
(Event transforms: execute tests)≡
  call test (event_transforms_1, "event_transforms_1", &
    "trivial event transform", &
    u, results)

(Event transforms: tests)+≡

contains

    <Decays: procedures>

    <Decays: tests>

end module decays

```

28.2.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

<Decays: types>≡
    type, abstract :: any_config_t
    contains
    <Decays: any config: TBP>
end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
    procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
    interface
        subroutine any_config_final (object)
            import
            class(any_config_t), intent(inout) :: object
        end subroutine any_config_final
    end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
    procedure (any_config_write), deferred :: write

<Decays: interfaces>+≡
    interface
        subroutine any_config_write (object, unit, indent, verbose)

```

```

import
class(any_config_t), intent(in) :: object
integer, intent(in), optional :: unit, indent
logical, intent(in), optional :: verbose
end subroutine any_config_write
end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
type :: particle_config_t
class(any_config_t), allocatable :: c
end type particle_config_t

```

28.2.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above. This also works around a compiler bug in gfortran.

```

<Decays: types>+≡
type, abstract :: any_t
contains
  <Decays: any: TBP>
end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
procedure (any_final), deferred :: final

<Decays: interfaces>+≡
interface
  subroutine any_final (object)
    import
    class(any_t), intent(inout) :: object
  end subroutine any_final
end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
procedure (any_write), deferred :: write

<Decays: interfaces>+≡
interface
  subroutine any_write (object, unit, indent)
    import
    class(any_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
  end subroutine any_write
end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+=
  type :: particle_out_t
    class(any_t), allocatable :: c
  end type particle_out_t

```

28.2.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+=
  type :: decay_term_config_t
    type(particle_config_t), dimension(:), allocatable :: prt
    contains
    <Decays: decay term config: TBP>
  end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>=
  procedure :: final => decay_term_config_final

<Decays: procedures>=
  recursive subroutine decay_term_config_final (object)
    class(decay_term_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%prt)) then
      do i = 1, size (object%prt)
        if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
      end do
    end if
  end subroutine decay_term_config_final

```

Output, with optional indentation

```

<Decays: decay term config: TBP>+=
  procedure :: write => decay_term_config_write

<Decays: procedures>+=
  recursive subroutine decay_term_config_write (object, unit, indent, verbose)
    class(decay_term_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: i, j, u, ind
    logical :: verb
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,A)", advance="no") "Final state:"
    do i = 1, size (object%prt)
      select type (prt_config => object%prt(i)%c)

```

```

  write (u, "(1x,A)", advance="no") &
    char (flavor_get_name (prt_config%flv(1)))
  do j = 2, size (prt_config%flv)
    write (u, "(:',A)", advance="no") &
      char (flavor_get_name (prt_config%flv(j)))
  end do
type is (unstable_config_t)
  write (u, "(1x,A)", advance="no") &
    char (flavor_get_name (prt_config%flv))
end select
end do
write (u, *)
if (verb) then
  do i = 1, size (object%prt)
    call object%prt(i)%c%write (u, ind)
  end do
end if
end subroutine decay_term_config_write

```

Initialize, given a set of flavors. For each flavor, we must indicate whether the particle is stable. The second index of the flavor array runs over alternatives for each decay product; alternatives are allowed only if the decay product is itself stable.

<Decays: decay term config: TBP>+≡

procedure :: init => decay_term_config_init

  end do
end subroutine decay_term_generate

```

28.2.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```

<Decays: types>+≡
type :: decay_root_config_t
  type(string_t) :: process_id
  type(process_t), pointer :: process => null ()
  class(model_data_t), pointer :: model => null ()
  type(decay_term_config_t), dimension(:), allocatable :: term_config
contains
  <Decays: decay root config: TBP>
end type decay_root_config_t

```

The finalizer is recursive since there may be cascade decays.

```

<Decays: decay root config: TBP>≡
  procedure :: final => decay_root_config_final

<Decays: procedures>+≡
recursive subroutine decay_root_config_final (object)
  class(decay_root_config_t), intent(inout) :: object
  integer :: i
  if (allocated (object%term_config)) then

```

```

        do i = 1, size (object%term_config)
            call object%term_config(i)%final ()
        end do
    end if
end subroutine decay_root_config_final

```

The output routine is also recursive, and it contains an adjustable indentation.

(Decays: decay root config: TBP)+≡

```

procedure :: write => decay_root_config_write
procedure :: write_header => decay_root_config_write_header
procedure :: write_terms => decay_root_config_write_terms

```

(Decays: procedures)+≡

```

recursive subroutine decay_root_config_write (object, unit, indent, verbose)

        end do
    end if
end subroutine decay_root_config_write_terms

```

```

        end do
    end if
end subroutine decay_root_config_write_terms

```

Initialize for a named process and (optionally) a pre-determined number of terms.

```

<Decays: decay root config: TBP>+≡
    procedure :: init => decay_root_config_init
<Decays: procedures>+≡
    subroutine decay_root_config_init (decay, model, process_id, n_terms)
        class(decay_root_config_t), intent(out) :: decay
        class(model_data_t), intent(in), target :: model
        type(string_t), intent(in) :: process_id
        integer, intent(in), optional :: n_terms
        decay%model => model
        decay%process_id = process_id
        if (present (n_terms)) then
            allocate (decay%term_config (n_terms))
        end if
    end subroutine decay_root_config_init

```

Declare a decay term, given an array of flavors.

```

<Decays: decay root config: TBP>+≡
    procedure :: init_term => decay_root_config_init_term
<Decays: procedures>+≡
    recursive subroutine decay_root_config_init_term &
        (decay, i, flv, stable, model, process_stack)
        class(decay_root_config_t), intent(inout) :: decay
        integer, intent(in) :: i
        type(flavor_t), dimension(:,:), intent(in) :: flv
        logical, dimension(:), intent(in) :: stable
        class(model_data_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        call decay%term_config(i)%init (flv, stable, model, process_stack)
    end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

```

<Decays: decay root config: TBP>+≡

```

```

procedure :: connect => decay_root_config_connect
<Decays: procedures>+≡
recursive subroutine decay_root_config_connect &
    (decay, process, model, process_stack, process_instance)
class(decay_root_config_t), intent(out) :: decay
type(process_t), intent(in), target :: process
class(model_data_t), intent(in), target :: model
type(process_stack_t), intent(in), optional :: process_stack
type(process_instance_t), intent(in), optional, target :: process_instance
type(connected_state_t), pointer :: connected_state

do i = 1, size (decay%term_config)
    call decay%term_config(i)%compute ()
end do
end subroutine decay_root_config_compute

```

28.2.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```

<Decays: types>+≡

```

```

type, abstract :: decay_gen_t
  type(decay_term_t), dimension(:), allocatable :: term
  type(process_instance_t), pointer :: process_instance => null ()
  integer :: selected_mci = 0
  integer :: selected_term = 0
contains
  <Decays: decay gen: TBP>
end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_root_t
    type(decay_root_config_t), pointer :: config => null ()
  contains
    <Decays: decay root: TBP>
  end type decay_root_t

```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```

<Decays: decay gen: TBP>≡
  procedure :: base_final => decay_gen_final

<Decays: procedures>+≡
  recursive subroutine decay_gen_final (object)
    class(decay_gen_t), intent(inout) :: object
    integer :: i
    if (allocated (object%term)) then
      do i = 1, size (object%term)
        call object%term(i)%final ()
      end do
    end if
  end subroutine decay_gen_final

```

No extra finalization for the decay root.

```

<Decays: decay root: TBP>≡
  procedure :: final => decay_root_final

<Decays: procedures>+≡
  subroutine decay_root_final (object)
    class(decay_root_t), intent(inout) :: object
    call object%base_final ()
  end subroutine decay_root_final

```

Output.

```

<Decays: decay root: TBP>+≡
  procedure :: write => decay_root_write

<Decays: procedures>+≡
  subroutine decay_root_write (object, unit)
    class(decay_root_t), intent(in) :: object
    integer, intent(in), optional :: unit

```

```

integer :: u
u = given_output_unit (unit)
if (associated (object%config)) then
    call object%config%write (unit, verbose = .false.)
else
    write (u, "(1x,A)") "Final-state decay tree: [not configured]"
end if
if (object%selected_mci > 0) then
    write (u, "(3x,A,I0)") "Selected MCI      = ", object%selected_mci
else
    write (u, "(3x,A)") "Selected MCI      = [undefined]"
end if
if (object%selected_term > 0) then
    write (u, "(3x,A,I0)") "Selected term    = ", object%selected_term
    call object%term(object%selected_term)%write (u, 1)
else
    write (u, "(3x,A)") "Selected term    = [undefined]"
end if
end subroutine decay_root_write

```

Write the process instances, recursively.

```

<Decays: decay gen: TBP>+≡
    procedure :: write_process_instances => decay_gen_write_process_instances

<Decays: procedures>+≡
    recursive subroutine decay_gen_write_process_instances (decay, unit, verbose)
        class(decay_gen_t), intent(in) :: decay
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: verbose
        logical :: verb
        verb = .true.; if (present (verbose)) verb = verbose
        if (associated (decay%process_instance)) then
            if (verb) then
                call decay%process_instance%write (unit)
            else
                call decay%process_instance%write_header (unit)
            end if
        end if
        if (decay%selected_term > 0) then
            call decay%term(decay%selected_term)%write_process_instances (unit, verb)
        end if
    end subroutine decay_gen_write_process_instances

```

Generic initializer. All can be done recursively.

```

<Decays: decay gen: TBP>+≡
    procedure :: base_init => decay_gen_init

<Decays: procedures>+≡
    recursive subroutine decay_gen_init (decay, term_config)
        class(decay_gen_t), intent(out) :: decay
        type(decay_term_config_t), dimension(:), intent(in), target :: term_config
        integer :: i
        allocate (decay%term (size (term_config)))
        do i = 1, size (decay%term)

```

```

        call decay%term(i)%init (term_config(i))
    end do
end subroutine decay_gen_init

```

Specific initializer. We assign the configuration object, which should correspond to a completely initialized decay configuration tree. We also connect to an existing process instance. Then, we recursively link the child interactions to the parent process.

```

<Decays: decay root: TBP>+≡
    procedure :: init => decay_root_init

<Decays: procedures>+≡
    subroutine decay_root_init (decay_root, config, process_instance)
        class(decay_root_t), intent(out) :: decay_root
        type(decay_root_config_t), intent(in), target :: config
        type(process_instance_t), intent(in), target :: process_instance
        call decay_root%base_init (config%term_config)
        decay_root%config => config
        decay_root%process_instance => process_instance
        call decay_root%make_term_rng (config%process)
        call decay_root%link_term_interactions ()
    end subroutine decay_root_init

```

Implement random-number generators for unstable decay selection in all terms. This is not recursive.

We also make use of the fact that `process` is a pointer; the (state of the RNG factory inside the) target process will be modified by the rng-spawning method, but not the pointer.

```

<Decays: decay gen: TBP>+≡
    procedure :: make_term_rng => decay_gen_make_term_rng

<Decays: procedures>+≡
    subroutine decay_gen_make_term_rng (decay, process)
        class(decay_gen_t), intent(inout) :: decay
        type(process_t), intent(in), pointer :: process
        integer :: i
        do i = 1, size (decay%term)
            call decay%term(i)%make_rng (process)
        end do
    end subroutine decay_gen_make_term_rng

```

Recursively link interactions of the enclosed decay terms to the corresponding terms in the current process instance.

Note: A bug in nagfor requires the extra `i_term` variable.

```

<Decays: decay gen: TBP>+≡
    procedure :: link_term_interactions => decay_gen_link_term_interactions

<Decays: procedures>+≡
    recursive subroutine decay_gen_link_term_interactions (decay)
        class(decay_gen_t), intent(inout) :: decay
        integer :: i, i_term
        type(interaction_t), pointer :: trace
        associate (instance => decay%process_instance)

```

```

do i = 1, size (decay%term)
  i_term = i
  trace => instance%get_trace_int_ptr (i_term)
  call decay%term(i_term)%link_interactions (trace)
end do
end associate
end subroutine decay_gen_link_term_interactions

```

Select a decay chain: decay modes and process components.

```

<Decays: decay root: TBP>+≡
  procedure :: select_chain => decay_root_select_chain

<Decays: procedures>+≡
  subroutine decay_root_select_chain (decay_root)
    class(decay_root_t), intent(inout) :: decay_root
    if (decay_root%selected_term > 0) then
      call decay_root%term(decay_root%selected_term)%select_chain ()
    else
      call msg_bug ("Decays: no term selected for parent process")
    end if
  end subroutine decay_root_select_chain

```

Generate a decay tree, i.e., for the selected term in the parent process, recursively generate a decay event for all unstable particles.

Factor out the trace of the connected state of the parent process. This trace should not be taken into account for unweighting the decay chain, since it was already used for unweighting the parent event, or it determines the overall event weight.

```

<Decays: decay root: TBP>+≡
  procedure :: generate => decay_root_generate

<Decays: procedures>+≡
  subroutine decay_root_generate (decay_root)
    class(decay_root_t), intent(inout) :: decay_root
    type(connected_state_t), pointer :: connected_state
    if (decay_root%selected_term > 0) then
      connected_state => decay_root%process_instance%get_connected_state_ptr &
        (decay_root%selected_term)
      call connected_state%normalize_matrix_by_trace ()
      call decay_root%term(decay_root%selected_term)%generate ()
    else
      call msg_bug ("Decays: no term selected for parent process")
    end if
  end subroutine decay_root_generate

```

28.2.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains

the integral of the parent process and the selector for the MCI group inside this process.

```

<Decays: types>+≡
  type, extends (decay_root_config_t) :: decay_config_t
    real(default) :: weight = 0
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: mci_selector
  contains
    <Decays: decay config: TBP>
  end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
  procedure :: write => decay_config_write

<Decays: procedures>+≡
  recursive subroutine decay_config_write (object, unit, indent, verbose)
    class(decay_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,A)") "Decay:"
    call object%write_header (unit, indent)
    call write_indent (u, ind)
    write (u, 2) "branching ratio =", object%weight * 100
    call write_indent (u, ind)
    write (u, 1) "partial width   =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs)      =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel)     =", object%rel_error
1   format (3x,A,ES19.12)
2   format (3x,A,F11.6,1x,'%')
    call object%write_terms (unit, indent, verbose)
  end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should be used instead.

```

<Decays: decay config: TBP>+≡
  procedure :: connect => decay_config_connect

<Decays: procedures>+≡
  recursive subroutine decay_config_connect &

```

```

        (decay, process, model, process_stack, process_instance)
class(decay_config_t), intent(out) :: decay
type(process_t), intent(in), target :: process
class(model_data_t), intent(in), target :: model
type(process_stack_t), intent(in), optional :: process_stack
type(process_instance_t), intent(in), optional, target :: process_instance
real(default), dimension(:), allocatable :: integral_mci
integer :: i, n_mci
call decay%decay_root_config_t%connect (process, model, process_stack)
decay%integral = process%get_integral ()
decay%abs_error = process%get_error ()
if (process%cm_frame ()) then
    call msg_fatal ("Decay process " // char (process%get_id ()) &
        // ": unusable because rest frame is fixed.")
end if
n_mci = process%get_n_mci ()
allocate (integral_mci (n_mci))
do i = 1, n_mci
    integral_mci(i) = process%get_integral_mci (i)
end do
call decay%mci_selector%init (integral_mci)
end subroutine decay_config_connect

```

Compute embedded branchings and the relative error. This method does not apply to the decay root.

```

<Decays: decay config: TBP>+≡
    procedure :: compute => decay_config_compute

<Decays: procedures>+≡
    recursive subroutine decay_config_compute (decay)
        class(decay_config_t), intent(inout) :: decay
        call decay%decay_root_config_t%compute ()
        if (decay%integral == 0) then
            call decay%write ()
            call msg_fatal ("Decay configuration: partial width is zero")
        end if
        decay%rel_error = decay%abs_error / decay%integral
    end subroutine decay_config_compute

```

28.2.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

<Decays: types>+≡
    type, extends (decay_gen_t) :: decay_t
        type(decay_config_t), pointer :: config => null ()
        class(rng_t), allocatable :: rng
    contains
    <Decays: decay: TBP>

```

```
end type decay_t
```

The finalizer is recursive.

```
<Decays: decay: TBP>≡
  procedure :: final => decay_final
<Decays: procedures>+≡
  recursive subroutine decay_final (object)
    class(decay_t), intent(inout) :: object
    integer :: i
    call object%base_final ()
    do i = 1, object%config%process%get_n_mci ()
      call object%process_instance%final_simulation (i)
    end do
    call object%process_instance%final ()
    deallocate (object%process_instance)
  end subroutine decay_final
```

Output.

```
<Decays: decay: TBP>+≡
  procedure :: write => decay_write
<Decays: procedures>+≡
  recursive subroutine decay_write (object, unit, indent, recursive)
    class(decay_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent, recursive
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call object%config%write (unit, indent, verbose = .false.)
    if (allocated (object%rng)) then
      call object%rng%write (u, ind + 1)
    end if
    call write_indent (u, ind)
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI    = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI    = [undefined]"
    end if
    call write_indent (u, ind)
    if (object%selected_term > 0) then
      write (u, "(3x,A,I0)") "Selected term  = ", object%selected_term
      call object%term(object%selected_term)%write (u, ind + 1)
    else
      write (u, "(3x,A)") "Selected term  = [undefined]"
    end if
  end subroutine decay_write
```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```
<Decays: decay: TBP>+≡
  procedure :: init => decay_init
```

```

<Decays: procedures>+≡
recursive subroutine decay_init (decay, config)
  class(decay_t), intent(out) :: decay
  type(decay_config_t), intent(in), target :: config
  integer :: i
  call decay%base_init (config%term_config)
  decay%config => config
  allocate (decay%process_instance)
  call decay%process_instance%init (decay%config%process)
  call decay%process_instance%setup_event_data (decay%config%model)
  do i = 1, decay%config%process%get_n_mci ()
    call decay%process_instance%init_simulation (i)
  end do
  call decay%config%process%make_rng (decay%rng)
  call decay%make_term_rng (decay%config%process)
end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
  procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
recursive subroutine decay_link_interactions (decay, i_prt, trace)
  class(decay_t), intent(inout) :: decay
  integer, intent(in) :: i_prt
  type(interaction_t), intent(in), target :: trace
  type(interaction_t), pointer :: beam_int
  integer :: n_in, n_vir
  beam_int => decay%process_instance%get_beam_int_ptr ()
  n_in = interaction_get_n_in (trace)
  n_vir = interaction_get_n_vir (trace)
  call interaction_set_source_link (beam_int, 1, trace, &
    n_in + n_vir + i_prt)
  call decay%link_term_interactions ()
end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
  procedure :: select_chain => decay_select_chain

<Decays: procedures>+≡
recursive subroutine decay_select_chain (decay)
  class(decay_t), intent(inout) :: decay
  real(default) :: x
  integer :: i
  call decay%rng%generate (x)
  decay%selected_mci = decay%config%mc_selector%select (x)

```

```

    call decay%process_instance%choose_mci (decay%selected_mci)
    call decay%process_instance%select_i_term (decay%selected_term)
    do i = 1, size (decay%term)
        call decay%term(i)%select_chain ()
    end do
end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

<Decays: decay: TBP>+≡
    procedure :: generate => decay_generate

<Decays: procedures>+≡
    recursive subroutine decay_generate (decay)
        class(decay_t), intent(inout) :: decay
        type(isolated_state_t), pointer :: isolated_state
        integer :: i
        call decay%process_instance%receive_beam_momenta ()
        call decay%config%process%generate_unweighted_event &
            (decay%process_instance, decay%selected_mci)
        if (signal_is_pending ()) return
        call decay%process_instance%evaluate_event_data ()
        isolated_state => &
            decay%process_instance%get_isolated_state_ptr (decay%selected_term)
        call isolated_state%normalize_matrix_by_trace ()
        do i = 1, size (decay%term)
            call decay%term(i)%generate ()
            if (signal_is_pending ()) return
        end do
    end subroutine decay_generate

```

28.2.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```

<Decays: types>+≡
    type, extends (any_config_t) :: stable_config_t
        type(flavor_t), dimension(:), allocatable :: flv
    contains
        <Decays: stable config: TBP>
    end type stable_config_t

```

The finalizer is empty:

```

<Decays: stable config: TBP>≡
    procedure :: final => stable_config_final

```

```

<Decays: procedures>+≡
  subroutine stable_config_final (object)
    class(stable_config_t), intent(inout) :: object
  end subroutine stable_config_final

```

Output.

```

<Decays: stable config: TBP>+≡
  procedure :: write => stable_config_write

<Decays: procedures>+≡
  recursive subroutine stable_config_write (object, unit, indent, verbose)
    class(stable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"
    write (u, "(1x,A)", advance = "no") char (flavor_get_name (object%flv(1)))
    do i = 2, size (object%flv)
      write (u, "(':',A)", advance = "no") &
        char (flavor_get_name (object%flv(i)))
    end do
    write (u, *)
  end subroutine stable_config_write

```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```

<Decays: stable config: TBP>+≡
  procedure :: init => stable_config_init

<Decays: procedures>+≡
  subroutine stable_config_init (config, flv)
    class(stable_config_t), intent(out) :: config
    type(flavor_t), dimension(:), intent(in) :: flv
    integer, dimension (size (flv)) :: pdg
    logical, dimension (size (flv)) :: mask
    integer :: i
    pdg = flavor_get_pdg (flv)
    mask(1) = .true.
    forall (i = 2 : size (pdg))
      mask(i) = all (pdg(i) /= pdg(1:i-1))
    end forall
    allocate (config%flv (count (mask)))
    config%flv = pack (flv, mask)
  end subroutine stable_config_init

```

Here is the corresponding object instance. Except for the pointer to the configuration, there is no content.

```

<Decays: types>+≡
  type, extends (any_t) :: stable_t
    type(stable_config_t), pointer :: config => null ()

```

```

contains
  <Decays: stable: TBP>
end type stable_t

```

The finalizer does nothing.

```

<Decays: stable: TBP>≡
  procedure :: final => stable_final

<Decays: procedures>+≡
  subroutine stable_final (object)
    class(stable_t), intent(inout) :: object
  end subroutine stable_final

```

We can delegate output to the configuration object.

```

<Decays: stable: TBP>+≡
  procedure :: write => stable_write

<Decays: procedures>+≡
  subroutine stable_write (object, unit, indent)
    class(stable_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    call object%config%write (unit, indent)
  end subroutine stable_write

```

Initializer: just assign the configuration.

```

<Decays: stable: TBP>+≡
  procedure :: init => stable_init

<Decays: procedures>+≡
  subroutine stable_init (stable, config)
    class(stable_t), intent(out) :: stable
    type(stable_config_t), intent(in), target :: config
    stable%config => config
  end subroutine stable_init

```

28.2.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: types>+≡
  type, extends (any_config_t) :: unstable_config_t
    type(flavor_t) :: flv
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: selector
    type(decay_config_t), dimension(:), allocatable :: decay_config

```

```

contains
  <Decays: unstable config: TBP>≡
end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
  procedure :: final => unstable_config_final

<Decays: procedures>+≡
  recursive subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%final ()
      end do
    end if
  end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
  procedure :: write => unstable_config_write

<Decays: procedures>+≡
  recursive subroutine unstable_config_write (object, unit, indent, verbose)
    class(unstable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    logical :: verb
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
      char (flavor_get_name (object%flv))
    call write_indent (u, ind)
    write (u, 1) "total width =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs) =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel) =", object%rel_error
1  format (5x,A,ES19.12)
    if (verb .and. allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%write (u, ind + 1)
      end do
    end if
  end subroutine unstable_config_write

```

Initializer. For the unstable particle, the flavor is unique.

```

<Decays: unstable config: TBP>+≡
  procedure :: init => unstable_config_init

```

```

<Decays: procedures>+≡
  subroutine unstable_config_init (config, flv)
    class(unstable_config_t), intent(out) :: config
    type(flavor_t), intent(in) :: flv
    config%flv = flv
  end subroutine unstable_config_init

```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```

<Decays: unstable config: TBP>+≡
  procedure :: init_decays => unstable_config_init_decays

<Decays: procedures>+≡
  recursive subroutine unstable_config_init_decays &
    (unstable, decay_id, model, process_stack)
    class(unstable_config_t), intent(inout) :: unstable
    type(string_t), dimension(:), intent(in) :: decay_id
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    integer :: i
    allocate (unstable%decay_config (size (decay_id)))
    do i = 1, size (decay_id)
      associate (decay => unstable%decay_config(i))
        if (present (process_stack)) then
          call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
            model, process_stack)
        else
          call decay%init (model, decay_id(i))
        end if
      end associate
    end do
  end subroutine unstable_config_init_decays

```

Compute the total width and branching ratios, initializing the decay selector.

```

<Decays: unstable config: TBP>+≡
  procedure :: compute => unstable_config_compute

<Decays: procedures>+≡
  recursive subroutine unstable_config_compute (unstable)
    class(unstable_config_t), intent(inout) :: unstable
    integer :: i
    do i = 1, size (unstable%decay_config)
      call unstable%decay_config(i)%compute ()
    end do
    unstable%integral = sum (unstable%decay_config%integral)
    if (unstable%integral <= 0) then
      call unstable%write ()
      call msg_fatal ("Decay configuration: computed total width is zero")
    end if
    unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
    unstable%rel_error = unstable%abs_error / unstable%integral
    call unstable%selector%init (unstable%decay_config%integral)

```

```

do i = 1, size (unstable%decay_config)
  unstable%decay_config(i)%weight &
    = unstable%selector%get_weight (i)
end do
end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: types>+≡
type, extends (any_t) :: unstable_t
  type(unstable_config_t), pointer :: config => null ()
  class(rng_t), allocatable :: rng
  integer :: selected_decay = 0
  type(decay_t), dimension(:), allocatable :: decay
contains
  <Decays: unstable: TBP>
end type unstable_t

```

Recursive finalizer.

```

<Decays: unstable: TBP>≡
  procedure :: final => unstable_final

<Decays: procedures>+≡
  recursive subroutine unstable_final (object)
    class(unstable_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay)) then
      do i = 1, size (object%decay)
        call object%decay(i)%final ()
      end do
    end if
  end subroutine unstable_final

```

Output.

```

  recursive subroutine unstable_select_chain (unstable)
    class(unstable_t), intent(inout) :: unstable
    real(default) :: x
    call unstable%rng%generate (x)
    unstable%selected_decay = unstable%config%selector%select (x)
    call unstable%decay(unstable%selected_decay)%select_chain ()
  end subroutine unstable_select_chain

```

Generate a decay event.

```

<Decays: unstable: TBP>+≡
  procedure :: generate => unstable_generate

<Decays: procedures>+≡
  recursive subroutine unstable_generate (unstable)
    class(unstable_t), intent(inout) :: unstable
    call unstable%decay(unstable%selected_decay)%generate ()
  end subroutine unstable_generate

```

28.2.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+≡
  type, extends (connected_state_t) :: decay_chain_entry_t

```

```

integer :: index = 0
type(decay_config_t), pointer :: config => null ()
integer :: selected_mci = 0
integer :: selected_term = 0
type(decay_chain_entry_t), pointer :: previous => null ()
end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: types>+≡
type :: decay_chain_t
type(process_instance_t), pointer :: process_instance => null ()
integer :: selected_term = 0
type(evaluator_t) :: correlated_trace
type(decay_chain_entry_t), pointer :: last => null ()
contains
<Decays: decay chain: TBP>
end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay chain: TBP>≡
procedure :: final => decay_chain_final

<Decays: procedures>+≡
subroutine decay_chain_final (object)
class(decay_chain_t), intent(inout) :: object
type(decay_chain_entry_t), pointer :: entry
do while (associated (object%last))
entry => object%last
object%last => entry%previous
call entry%final ()
deallocate (entry)
end do
call evaluator_final (object%correlated_trace)
end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

<Decays: decay chain: TBP>+≡
procedure :: write => decay_chain_write

<Decays: procedures>+≡
subroutine decay_chain_write (object, unit)

```

```

class(decay_chain_t), intent(in) :: object
integer, intent(in), optional :: unit
integer :: u
u = given_output_unit (unit)
call write_separator (u, 2)
write (u, "(1x,A)") "Decay chain:"
call write_entries (object%last)
call write_separator (u, 2)
write (u, "(1x,A)") "Evaluator (correlated trace of the decay chain):"
call write_separator (u)
call object%correlated_trace%write (u)
call write_separator (u, 2)
contains
recursive subroutine write_entries (entry)
  type(decay_chain_entry_t), intent(in), pointer :: entry
  if (associated (entry)) then
    call write_entries (entry%previous)
    call write_separator (u, 2)
    write (u, "(1x,A,I0)") "Decay #", entry%index
    call entry%config%write_header (u)
    write (u, "(3x,A,I0)") "Selected MCI    = ", entry%selected_mci

  call evaluator_init_qn_sum (chain%correlated_trace, int_last_decay, qn_mask)
end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable

particles.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_term_entries (chain, term)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_term_t), intent(in) :: term
    integer :: i
    do i = 1, size (term%particle_out)
      select type (unstable => term%particle_out(i)%c)
        type is (unstable_t)
          if (unstable%selected_decay > 0) then
            call chain%build_decay_entries &
              (unstable%decay(unstable%selected_decay))
          end if
        end select
      end do
    end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_decay_entries => decay_chain_build_decay_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_decay_entries (chain, decay)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_t), intent(in) :: decay
    type(decay_chain_entry_t), pointer :: entry
    type(connected_state_t), pointer :: previous_state
    type(isolated_state_t), pointer :: current_decay
    allocate (entry)
    if (associated (chain%last)) then
      entry%previous => chain%last
      entry%index = entry%previous%index + 1
      previous_state => entry%previous%connected_state_t
    else
      entry%index = 1
      previous_state => &
        chain%process_instance%get_connected_state_ptr (chain%selected_term)
    end if
  end subroutine decay_chain_build_decay_entries

```

```

end if

chain%last => entry
call chain%build_term_entries (decay%term(decay%selected_term))
end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

```

<Decays: decay chain: TBP>+≡
  procedure :: evaluate => decay_chain_evaluate

<Decays: procedures>+≡
  subroutine decay_chain_evaluate (chain)
    class(decay_chain_t), intent(inout) :: chain

```

Read in the LHE file opened in unit `u` and add the final particles to the `particle_set`, the outgoing particles of the existing `particle_set` are set to be virtual before the outgoing particles from the LHEF are added to the `particle_set` as outgoing particles. At the same time, it is searched for pairs of existing and new particles with equal momenta and PDG code, these pairs are marked as connected. All remaining existing former outgoing particles are set to be the mothers of all remaining new outgoing particles.

```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations might be useful. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid.

Matching and hadronization functions

The HEPRUP (event) common block is needed for the interface to the shower. Filling of it is triggered by some output file formats. If these are not present, the common block is filled with some dummy information. Be generous with

the number of processes in HEPUP so that PYTHIA only rarely needs to be reinitialized in case events with higher process ids are generated.

28.4.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The **safety_factor** reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The **sigma** and **n** values, if nontrivial, allow for reweighting the events according to the requested **norm_mode**.

Various **parse_node_t** objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the **event_expr_t** objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

```

```

28.4.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event_base` module. The core manages the main (dressed) particle set pointer and the current values for weights and sqme. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the **ref** value is the number in the file, while the **prc** value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of **alt** values is copied from an array of alternative event records. These values should represent calculated values.

The **sqme** and **weight** values mirror corresponding values in the **expr** sub-object. The idea is that when generating or reading events, the event record is filled first, then the **expr** object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the **expr** subobject. In particular, evaluating the event-selection expression sets the **passed** flag. Furthermore, the **expr** subobject collects data that can be used in the analysis and should be written to file, including copies of **sqme** and **weight**.

```

<Events: public>≡
    public :: event_t

<Events: types>+≡
    type, extends (generic_event_t) :: event_t

```

28.4.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```
<Events: event: TBP>+≡
  procedure :: basic_init => event_init

<Events: procedures>+≡
  subroutine event_init (event, var_list, n_alt)
    class(event_t), intent(out) :: event
    type(var_list_t), intent(in), optional :: var_list
    integer, intent(in), optional :: n_alt
    type(string_t) :: norm_string
    logical :: polarized_events
    if (present (n_alt)) then
      call event%base_init (n_alt)
      call event%expr%init (n_alt)
    else
      call event%base_init (0)
    end if
    if (present (var_list)) then
      event%config%unweighted = var_list%get_lval (&
        var_str ("?unweighted"))
      norm_string = var_list%get_sval (&
        var_str ("sample_normalization"))
      event%config%norm_mode = &
        event_normalization_mode (norm_string, event%config%unweighted)
      polarized_events = &
        var_list%get_lval (var_str ("?polarized_events"))
      if (polarized_events) then
        event%config%factorization_mode = FM_SELECT_HELICITY
      else
        event%config%factorization_mode = FM_IGNORE_HELICITY
      end if
      if (event%config%unweighted) then
        event%config%safety_factor = var_list%get_rval (&
          var_str ("safety_factor"))
      end if
    else
      event%config%norm_mode = NORM_SIGMA
    end if
    allocate (evt_trivial_t :: event%transform_first)
    event%transform_last => event%transform_first
  end subroutine event_init
```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

```

<Events: event: TBP>+≡
  procedure :: set_sigma => event_set_sigma
  procedure :: set_n => event_set_n

<Events: procedures>+≡
  elemental subroutine event_set_sigma (event, sigma)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: sigma
    event%config%sigma = sigma
  end subroutine event_set_sigma

  elemental subroutine event_set_n (event, n)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: n
    event%config%n = n
  end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
  procedure :: import_transform => event_import_transform

<Events: procedures>+≡
  subroutine event_import_transform (event, evt)
    class(event_t), intent(inout) :: event
    class(evt_t), intent(inout), pointer :: evt
    event%transform_last%next => evt
    evt%previous => event%transform_last
    event%transform_last => evt
    evt => null ()
  end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

```

```

<Events: procedures>+≡
subroutine event_connect (event, process_instance, model, process_stack)
  class(event_t), intent(inout), target :: event
  type(process_instance_t), intent(in), target :: process_instance
  class(model_data_t), intent(in), target :: model
  type(process_stack_t), intent(in), optional :: process_stack
  type(string_t) :: id
  integer :: num_id
  class(evt_t), pointer :: evt
  event%process => process_instance%process
  event%instance => process_instance
  id = event%process%get_id ()
  if (id /= "") call event%expr%set_process_id (id)
  num_id = event%process%get_num_id ()
  if (num_id /= 0) call event%expr%set_process_num_id (num_id)
  call event%expr%setup_vars (event%process%get_sqrts ())
  call event%expr%link_var_list (event%process%get_var_list_ptr ())
  call event%process%make_rng (event%rng)
  evt => event%transform_first
  do while (associated (evt))
    call evt%connect (process_instance, model, process_stack)
    evt => evt%next
  end do
end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
  procedure :: set_selection => event_set_selection
  procedure :: set_reweight => event_set_reweight
  procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡
subroutine event_set_selection (event, ef_selection)
  class(event_t), intent(inout) :: event
  class(expr_factory_t), intent(in) :: ef_selection
  allocate (event%config%ef_selection, source = ef_selection)
end subroutine event_set_selection

subroutine event_set_reweight (event, ef_reweight)
  class(event_t), intent(inout) :: event
  class(expr_factory_t), intent(in) :: ef_reweight
  allocate (event%config%ef_reweight, source = ef_reweight)
end subroutine event_set_reweight

subroutine event_set_analysis (event, ef_analysis)
  class(event_t), intent(inout) :: event
  class(expr_factory_t), intent(in) :: ef_analysis
  allocate (event%config%ef_analysis, source = ef_analysis)
end subroutine event_set_analysis

```

Create evaluation trees from the parse trees. The **target** attribute is required because the expressions contain pointers to event subobjects.

```

<Events: event: TBP>+≡
  procedure :: setup_expressions => event_setup_expressions

<Events: procedures>+≡
  subroutine event_setup_expressions (event)
    class(event_t), intent(inout), target :: event
    call event%expr%setup_selection (event%config%ef_selection)
    call event%expr%setup_analysis (event%config%ef_analysis)
    call event%expr%setup_reweight (event%config%ef_reweight)
  end subroutine event_setup_expressions

```

28.4.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

<Events: event: TBP>+≡
  procedure :: evaluate_transforms => event_evaluate_transforms

<Events: procedures>+≡
  subroutine event_evaluate_transforms (event, r)
    class(event_t), intent(inout) :: event
    real(default), dimension(:), intent(in), optional :: r
    class(evt_t), pointer :: evt
    integer :: i_term
    call event%discard_particle_set ()
    call event%check ()
    if (event%instance%is_complete_event ()) then
      call event%instance%select_i_term (i_term)
      event%selected_i_term = i_term
      evt => event%transform_first
      do while (associated (evt))
        call evt%prepare_new_event &
          (event%selected_i_mci, event%selected_i_term)
        evt => evt%next
      end do
      evt => event%transform_first
      do while (associated (evt))
        call evt%generate_unweighted ()
        if (signal_is_pending ()) return
        call evt%make_particle_set (event%config%factorization_mode, &
          event%config%keep_correlations)
        if (signal_is_pending ()) return
      end do
    end if
  end subroutine event_evaluate_transforms

```

```

        if (.not. evt%particle_set_exists) exit
        evt => evt%next
    end do
    evt => event%transform_last
    if (associated (evt) .and. evt%particle_set_exists) then
        call event%link_particle_set (evt%particle_set)
    end if
end if
end if
end subroutine event_evaluate_transforms

```

Evaluate the event-related expressions, given a valid `particle_set`. If `update_sqme` is set, we use the process instance for the `sqme_prc` value. The `sqme_ref` value is always taken from the event record.

Note: without the explicit `particle_set` pointer, some gfortran 4.8 version corrupts its memory.

```

<Events: event: TBP>+≡
    procedure :: evaluate_expressions => event_evaluate_expressions

<Events: procedures>+≡
    subroutine event_evaluate_expressions (event)
    class(event_t), intent(inout) :: event
    type(particle_set_t), pointer :: particle_set
    if (event%has_valid_particle_set ()) then
        particle_set => event%get_particle_set_ptr ()
        call event%expr%fill_subevt (particle_set)
    end if
    if (event%weight_ref_is_known ()) then
        call event%expr%set (weight_ref = event%get_weight_ref ())
    end if
    if (event%weight_prc_is_known ()) then

    end if
    if (event%excess_prc_is_known ()) then
        call event%expr%set (excess_prc = event%get_excess_prc ())
    end if
    if (event%sqme_ref_is_known ()) then
        call event%expr%set (sqme_ref = event%get_sqme_ref ())
    end if
    if (event%sqme_prc_is_known ()) then
        call event%expr%set (sqme_prc = event%get_sqme_prc ())
    end if
    if (event%has_valid_particle_set ()) then
        call event%expr%evaluate &
            (event%passed, event%reweight, event%analysis_flag)
        event%selection_evaluated = .true.
    end if
    end subroutine event_evaluate_expressions

```

Set alternate `sqme` and `weight` arrays. This should be merged with the previous routine, if the expressions are allowed to refer to these values.

```

<Events: event: TBP>+≡
    procedure :: store_alt_values => event_store_alt_values

```

```

<Events: procedures>+≡
  subroutine event_store_alt_values (event)
    class(event_t), intent(inout) :: event
    if (event%weight_alt_is_known ()) then
      call event%expr%set (weight_alt = event%get_weight_alt ())
    end if
    if (event%sqme_alt_is_known ()) then
      call event%expr%set (sqme_alt = event%get_sqme_alt ())
    end if
  end subroutine event_store_alt_values

```

28.4.5 Reset to empty state

Applying this, current event contents are marked as incomplete but are not deleted. In particular, the initialization is kept.

```

<Events: event: TBP>+≡
  procedure :: reset => event_reset

<Events: procedures>+≡
  subroutine event_reset (event)
    class(event_t), intent(inout) :: event
    class(evt_t), pointer :: evt
    call event%base_reset ()
    event%selected_i_mci = 0
    event%selected_i_term = 0
    event%selected_channel = 0
    event%is_complete = .false.
    call event%expr%reset ()
    event%selection_evaluated = .false.
    event%passed = .false.
    event%analysis_flag = .false.
    if (associated (event%instance)) then
      call event%instance%reset (reset_mci = .true.)
    end if
    evt => event%transform_first
    do while (associated (evt))
      call evt%reset ()
      evt => evt%next
    end do
  end subroutine event_reset

```

28.4.6 Squared Matrix Element and Weight

Transfer the result of the process instance calculation to the event record header.

```

<Events: event: TBP>+≡
  procedure :: import_instance_results => event_import_instance_results

<Events: procedures>+≡
  subroutine event_import_instance_results (event)
    class(event_t), intent(inout) :: event
    if (associated (event%instance)) then

```

```

        if (event%instance%has_evaluated_trace ()) then
            call event%set ( &
                sqme_prc = event%instance%get_sqme (), &
                weight_prc = event%instance%get_weight (), &
                excess_prc = event%instance%get_excess () &
            )
        end if
    end if
end subroutine event_import_instance_results

```

Duplicate the instance result / the reference result in the event record.

(Events: event: TBP)+≡

```

    procedure :: accept_sqme_ref => event_accept_sqme_ref
    procedure :: accept_sqme_prc => event_accept_sqme_prc

        end if
    end subroutine event_check

```

28.4.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we

accept the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
  procedure :: generate => event_generate

<Events: procedures>+≡
  subroutine event_generate (event, i_mci, r)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci
    real(default), dimension(:), intent(in), optional :: r
    call event%reset ()
    event%selected_i_mci = i_mci
    if (event%config%unweighted) then
      call event%process%generate_unweighted_event (event%instance, i_mci)
      if (signal_is_pending ()) return
      call event%instance%evaluate_event_data ()

```

28.4.8 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
  procedure :: select => event_select

```

```

<Events: procedures>+≡
  subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
    if (associated (event%instance)) then
      event%selected_i_mci = i_mci
      event%selected_i_term = i_term
      event%selected_channel = channel
    else
      call msg_bug ("Event: select term: process instance undefined")
    end if
  end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. Thus, with the current implementation, event readers can only be used for reading hard events. However, once we have reconstructed the master process, we may apply all event transforms to generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
  procedure :: set_hard_particle_set => event_set_hard_particle_set

<Events: procedures>+≡
  subroutine event_set_hard_particle_set (event, particle_set)
    class(event_t), intent(inout) :: event
    type(particle_set_t), intent(in) :: particle_set
    class(evt_t), pointer :: evt
    evt => event%transform_first
    call evt%set_particle_set (particle_set, &
      event%selected_i_mci, event%selected_i_term)
    call event%link_particle_set (evt%particle_set)
    evt => evt%next
    do while (associated (evt))
      call evt%reset ()
      evt => evt%next
    end do
  end subroutine event_set_hard_particle_set

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have

an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

<Events: event: TBP>+≡
  procedure :: recalculate => event_recalculate

<Events: procedures>+≡
  subroutine event_recalculate &
    (event, update_sqme, weight_factor, recover_beams)

28.5 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the `events` module which provides the concrete implementation of `event_base`. The other I/O formats access only the methods that are defined in `event_base`.

`<eio_raw.f90>`≡
<File header>

```

module eio_raw

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the prc values for weight and sqme, since these are

the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

Chapter 29

Integration and simulation

This layer of modules is just below the top-level API. We lay out specific data types for integration and simulation and implement the corresponding algorithms as methods acting on them. This helps to keep the command-level implementation concise and simple.

Generic modules for connecting Sindarin with **WHIZARD**:

user_files Manage files that are accessed by user-written Sindarin code.

rt_data The main runtime data block, giving access to all features of **WHIZARD** via contained data structures or pointers.

dispatch Dynamic dispatch for various **WHIZARD** objects that have multiple implementations. The dispatcher uses data from the **rt_data** block to decide which path to follow.

More specific modules, the workhorses of **WHIZARD**. These modules use **rt_data** components and the dispatcher. They define dedicated object types for bundling lower-level data and procedures that together provide the desired functionality.

process_configurations Interpret process definitions to generate matrix-element objects and external code.

compilations Compile, link and access external matrix-element code.

integrations Manage integration runs.

event_streams Manage external event I/O.

simulations Manage simulation runs.

29.1 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```
<user_files.f90>≡
  <File header>

  module user_files

    <Use strings>
    use io_units
    use diagnostics
    use ifiles
    use analysis

    <Standard module head>

    <User files: public>

    <User files: types>

    <User files: interfaces>

    contains

    <User files: procedures>

  end module user_files
```

29.1.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡
  type :: file_t
    private
    type(string_t) :: name
    integer :: unit = -1
    logical :: reading = .false.
    logical :: writing = .false.
    type(file_t), pointer :: prev => null ()
    type(file_t), pointer :: next => null ()
  end type file_t
```

The initializer opens the file.

```
<User files: procedures>≡
  subroutine file_init (file, name, action, status, position)
    type(file_t), intent(out) :: file
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    file%unit = free_unit ()
```

```

file%name = name
open (unit = file%unit, file = char (file%name), &
      action = action, status = status, position = position)
select case (action)
case ("read")
  file%reading = .true.
case ("write")
  file%writing = .true.
case ("readwrite")
  file%reading = .true.
  file%writing = .true.
end select
end subroutine file_init

```

The finalizer closes it.

```

<User files: procedures>+≡
subroutine file_final (file)
  type(file_t), intent(inout) :: file
  close (unit = file%unit)
  file%unit = -1
end subroutine file_final

```

Check if a file is open with correct status.

```

<User files: procedures>+≡
function file_is_open (file, action) result (flag)
  logical :: flag
  type(file_t), intent(in) :: file
  character(*), intent(in) :: action
  select case (action)
case ("read")
  flag = file%reading
case ("write")
  flag = file%writing
case ("readwrite")
  flag = file%reading .and. file%writing
case default
  call msg_bug ("Checking file '" // char (file%name) &
               // "' : illegal action specifier")
  end select
end function file_is_open

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the **advancing** option.

```

<User files: procedures>+≡
subroutine file_write_string (file, string, advancing)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: string
  logical, intent(in), optional :: advancing
  if (file%writing) then
    if (present (string)) then
      if (present (advancing)) then
        if (advancing) then

```

```

        write (file%unit, "(A)" char (string))
    else
        write (file%unit, "(A)", advance="no") char (string)
    end if
else
    write (file%unit, "(A)" char (string))
end if
else
    write (file%unit, *)
end if
else
    call msg_error ("Writing to file: File '" // char (file%name) &
        // "' is not open for writing.")
end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
subroutine file_write_ifile (file, ifile)
    type(file_t), intent(in) :: file
    type(ifile_t), intent(in) :: ifile
    type(line_p) :: line
    call line_init (line, ifile)
    do while (line_is_associated (line))
        call file_write_string (file, line_get_string_advance (line))
    end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
subroutine file_write_analysis (file, tag)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: tag
    if (file%writing) then
        if (present (tag)) then
            call analysis_write (tag, unit = file%unit)
        else
            call analysis_write (unit = file%unit)
        end if
    else
        call msg_error ("Writing analysis to file: File '" // char (file%name) &
            // "' is not open for writing.")
    end if
end subroutine file_write_analysis

```

29.1.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
public :: file_list_t

```

```

<User files: types>+≡
  type :: file_list_t
    type(file_t), pointer :: first => null ()
    type(file_t), pointer :: last => null ()
  end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
  public :: file_list_final

<User files: procedures>+≡
  subroutine file_list_final (file_list)
    type(file_list_t), intent(inout) :: file_list
    type(file_t), pointer :: current
    do while (associated (file_list%first))
      current => file_list%first
      file_list%first => current%next
      call file_final (current)
      deallocate (current)
    end do
    file_list%last => null ()
  end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```

<User files: procedures>+≡
  function file_list_get_file_ptr (file_list, name) result (current)
    type(file_t), pointer :: current
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    current => file_list%first
    do while (associated (current))
      if (current%name == name) return
      current => current%next
    end do
  end function file_list_get_file_ptr

```

Check if a file is open, public version:

```

<User files: public>+≡
  public :: file_list_is_open

<User files: procedures>+≡
  function file_list_is_open (file_list, name, action) result (flag)
    logical :: flag
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action
    type(file_t), pointer :: current
    current => file_list_get_file_ptr (file_list, name)
    if (associated (current)) then
      flag = file_is_open (current, action)
    else
      flag = .false.
    end if
  end function

```

```
end function file_list_is_open
```

Append a new file entry, i.e., open this file. Error if it is already open.

```
<User files: public>+≡
```

```
public :: file_list_open
```

```
<User files: procedures>+≡
```

```
subroutine file_list_open (file_list, name, action, status, position)
  type(file_list_t), intent(inout) :: file_list
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position
  type(file_t), pointer :: current
  if (.not. associated (file_list_get_file_ptr (file_list, name))) then
    allocate (current)
    call msg_message ("Opening file '" // char (name) // "' for output")
    call file_init (current, name, action, status, position)
    if (associated (file_list%last)) then
      file_list%last%next => current
      current%prev => file_list%last
    else
      file_list%first => current
    end if
    file_list%last => current
  else
    call msg_error ("Opening file: File '" // char (name) &
      // "' is already open.")
  end if
end subroutine file_list_open
```

Delete a file entry, i.e., close this file. Error if it is not open.

```
<User files: public>+≡
```

```
public :: file_list_close
```

```
<User files: procedures>+≡
```

```
subroutine file_list_close (file_list, name)
  type(file_list_t), intent(inout) :: file_list
  type(string_t), intent(in) :: name
  type(file_t), pointer :: current
  current => file_list_get_file_ptr (file_list, name)
  if (associated (current)) then
    if (associated (current%prev)) then
      current%prev%next => current%next
    else
      file_list%first => current%next
    end if
    if (associated (current%next)) then
      current%next%prev => current%prev
    else
      file_list%last => current%prev
    end if
    call msg_message ("Closing file '" // char (name) // "' for output")
    call file_final (current)
    deallocate (current)
  else

```

```

        call msg_error ("Closing file: File '" // char (name) &
            // "' is not open.")
    end if
end subroutine file_list_close

```

Write a string to file. Error if it is not open.

```

<User files: public>+≡
    public :: file_list_write

<User files: interfaces>≡
    interface file_list_write
        module procedure file_list_write_string
        module procedure file_list_write_ifile
    end interface

<User files: procedures>+≡

```

29.2.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn, is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

29.2.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

$\langle RT\ data: types \rangle \equiv$

```
type :: rt_parse_nodes_t
  type(parse_node_t), pointer :: cuts_lexpr => null ()
  type(parse_node_t), pointer :: scale_expr => null ()
  type(parse_node_t), pointer :: fac_scale_expr => null ()
  type(parse_node_t), pointer :: ren_scale_expr => null ()
  type(parse_node_t), pointer :: weight_expr => null ()
  type(parse_node_t), pointer :: selection_lexpr => null ()
  type(parse_node_t), pointer :: reweight_expr => null ()
  type(parse_node_t), pointer :: analysis_lexpr => null ()
  type(parse_node_p), dimension(:), allocatable :: alt_setup
```

```

contains
  <RT data: rt parse nodes: TBP>
end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

<RT data: procedures>≡
  subroutine rt_parse_nodes_clear (rt_pn, name)
    class(rt_parse_nodes_t), intent(inout) :: rt_pn
    type(string_t), intent(in) :: name
    select case (char (name))
    case ("cuts")

```

```

    call global%beam_structure%final_mom ()
end subroutine rt_data_clear_beams

```

29.2.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

```

<RT data: rt data: TBP>+≡

```

29.2.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init

```

```

<RT data: procedures>+≡
subroutine rt_data_local_init (local, global, env)
  class(rt_data_t), intent(inout), target :: local
  type(rt_data_t), intent(in), target :: global
  integer, intent(in), optional :: env
  local%context => global
  call local%process_stack%link (global%process_stack)
  call local%process_stack%init_var_list (local%var_list)
  call local%process_stack%link_var_list (global%var_list)
  call var_list_append_string &
    (local%var_list, var_str ("$model_name"), var_str (""), &
     intrinsic=.true.)
  call local%init_pointer_variables ()
  local%fallback_model => global%fallback_model
  local%radiation_model => global%radiation_model
  local%os_data = global%os_data
  local%logfile = global%logfile
  call local%model_list%link (global%model_list)
  local%model => global%model
  if (associated (local%model)) then
    call local%model%link_var_list (local%var_list)
  end if
end subroutine rt_data_local_init

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
  procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: procedures>+≡
subroutine rt_data_init_pointer_variables (local)
  class(rt_data_t), intent(inout), target :: local
  logical, target, save :: known = .true.
  call var_list_append_string_ptr &
    (local%var_list, var_str ("$fc"), local%os_data%fc, known, &
     intrinsic=.true.)
  call var_list_append_string_ptr &
    (local%var_list, var_str ("$fcflags"), local%os_data%fcflags, known, &
     intrinsic=.true.)
end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+≡

```

```

    procedure :: activate => rt_data_activate

<RT data: procedures>+≡
subroutine rt_data_activate (local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), pointer :: global
    global => local%context
    if (associated (global)) then
        local%lexer => global%lexer
        call global%copy_globals (local)
        local%os_data = global%os_data
        local%logfile = global%logfile
        if (associated (global%prclib)) then
            local%prclib => &
                local%prclib_stack%get_library_ptr (global%prclib%get_name ())
        end if
        call local%import_values ()
        call local%process_stack%link (global%process_stack)
        local%it_list = global%it_list
        local%beam_structure = global%beam_structure
        local%pn = global%pn
        if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
        if (allocated (global%sample_fmt)) then
            allocate (local%sample_fmt (size (global%sample_fmt)), &
                source = global%sample_fmt)
        end if
        local%out_files => global%out_files
        local%model => global%model
        local%model_is_copy = .false.
    else if (.not. associated (local%model)) then
        local%model => local%preload_model
        local%model_is_copy = .false.
    end if
    if (associated (local%model)) then
        call local%model%link_var_list (local%var_list)
        call var_list_set_string (local%var_list, var_str ("model_name"), &
            local%model%get_name (), is_known = .true.)
    else
        call var_list_set_string (local%var_list, var_str ("model_name"), &
            var_str (""), is_known = .false.)
    end if
end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
    procedure :: deactivate => rt_data_deactivate

```

```

<RT data: procedures>+≡
subroutine rt_data_deactivate (local, global, keep_local)
  class(rt_data_t), intent(inout), target :: local
  class(rt_data_t), intent(inout), optional, target :: global
  logical, intent(in), optional :: keep_local
  type(string_t) :: global_model, local_model
  logical :: same_model, delete
  delete = .true.; if (present (keep_local)) delete = .not. keep_local
  if (present (global)) then
    if (associated (global%model) .and. associated (local%model)) then
      global_model = global%model%get_name ()
      local_model = local%model%get_name ()
      same_model = global_model == local_model
    else
      same_model = .false.
    end if
    if (delete) then
      call local%process_stack%clear ()
      call local%unselect_model ()
      call local%unset_values ()
    else if (associated (local%model)) then
      call local%ensure_model_copy ()
    end if
    if (.not. same_model .and. global_model /= "") then
      call msg_message ("Restoring model '" // char (global_model) // "'")
    end if
    if (associated (global%model)) then
      call global%model%link_var_list (global%var_list)
    end if
    call global%restore_globals (local)
  else
    call local%unselect_model ()
  end if
end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
  procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
subroutine rt_data_copy_globals (global, local)
  class(rt_data_t), intent(in) :: global
  class(rt_data_t), intent(inout) :: local
  local%prclib_stack = global%prclib_stack
end subroutine rt_data_copy_globals

```

This restores global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡
  procedure :: restore_globals => rt_data_restore_globals

<RT data: procedures>+≡
subroutine rt_data_restore_globals (global, local)
  class(rt_data_t), intent(inout) :: global

```

```

class(rt_data_t), intent(in) :: local
global%prclib_stack = local%prclib_stack
end subroutine rt_data_restore_globals

```

29.2.8 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
  procedure :: final => rt_data_global_final

<RT data: procedures>+≡
  subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
!    call global%delete_model_copy ()
    call global%model_list%final ()
    call global%var_list%final (follow_link=.false.)
    if (associated (global%out_files)) then
      call file_list_final (global%out_files)
      deallocate (global%out_files)
    end if
  end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: local_final => rt_data_local_final

<RT data: procedures>+≡
  subroutine rt_data_local_final (local)
    class(rt_data_t), intent(inout) :: local
    call local%process_stack%clear ()
!    call local%delete_model_copy ()
    call local%model_list%final ()
    call local%var_list%final (follow_link=.false.)
  end subroutine rt_data_local_final

```

29.2.9 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
  procedure :: read_model => rt_data_read_model

```

```

<RT data: procedures>+≡
subroutine rt_data_read_model (global, name, model)
  class(rt_data_t), intent(inout) :: global
  type(string_t), intent(in) :: name
  type(model_t), pointer, intent(out) :: model
  type(string_t) :: filename
  filename = name // ".mdl"
  call global%model_list%read_model &
    (name, filename, global%os_data, model)
end subroutine rt_data_read_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
  procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: procedures>+≡
subroutine rt_data_init_fallback_model (global, name, filename)
  class(rt_data_t), intent(inout) :: global
  type(string_t), intent(in) :: name, filename
  call global%model_list%read_model &
    (name, filename, global%os_data, global%fallback_model)
end subroutine rt_data_init_fallback_model

```

Initialize the radiation model. This model is used by a radiation-generator algorithm which is part of the NLO machinery. It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
  procedure :: init_radiation_model => rt_data_init_radiation_model

<RT data: procedures>+≡
subroutine rt_data_init_radiation_model (global, name, filename)
  class(rt_data_t), intent(inout) :: global
  type(string_t), intent(in) :: name, filename
  call global%model_list%read_model &
    (name, filename, global%os_data, global%radiation_model)
end subroutine rt_data_init_radiation_model

```

Activate a model: assign the current-model pointer and set the model name in the variable list. If necessary, read the model from file. Link the global variable list to the model variable list.

```

<RT data: rt data: TBP>+≡
  procedure :: select_model => rt_data_select_model

<RT data: procedures>+≡
subroutine rt_data_select_model (global, name)
  class(rt_data_t), intent(inout), target :: global
  type(string_t), intent(in) :: name
  logical :: same_model
  if (associated (global%model)) then
    same_model = global%model%get_name () == name
  else

```

```

        same_model = .false.
    end if
    if (.not. same_model) then
!      call global%delete_model_copy ()
      global%model => global%model_list%get_model_ptr (name)
      if (.not. associated (global%model)) then
          call global%read_model (name, global%model)
          global%model_is_copy = .false.
      else if (associated (global%context)) then
          global%model_is_copy = &
              global%model_list%model_exists (name, follow_link=.false.)
      else
          global%model_is_copy = .false.
      end if
    end if
    if (associated (global%model)) then
        call global%model%link_var_list (global%var_list)
        call var_list_set_string (global%var_list, var_str ("$model_name"), &
            name, is_known = .true.)
        call msg_message ("Switching to model '" // char (name) // "'")
    else
        call var_list_set_string (global%var_list, var_str ("$model_name"), &
            var_str (""), is_known = .false.)
    end if
end subroutine rt_data_select_model

```

Remove the model link and unset the model name variable.

```

<RT data: rt data: TBP>+≡
    procedure :: unselect_model => rt_data_unselect_model

<RT data: procedures>+≡
    subroutine rt_data_unselect_model (global)
        class(rt_data_t), intent(inout), target :: global
        if (associated (global%model)) then
!          call global%delete_model_copy ()
          global%model => null ()
          global%model_is_copy = .false.
          call var_list_set_string (global%var_list, var_str ("$model_name"), &
              var_str (""), is_known = .false.)
        end if
    end subroutine rt_data_unselect_model

```

Create a copy of the currently selected model and append it to the local model list. The model pointer is redirected to the copy. (Not applicable for the global model list, those models will be modified in-place.)

```

<RT data: rt data: TBP>+≡
    procedure :: ensure_model_copy => rt_data_ensure_model_copy
!    procedure :: delete_model_copy => rt_data_delete_model_copy

<RT data: procedures>+≡

29.2.10 Managing Variables

Return a pointer to the currently active variable list. If there is no model, this is the global variable list. If there is one, it is the model variable list, which should be linked to the former.

```

<RT data: rt data: TBP>+≡
  procedure :: get_var_list_ptr => rt_data_get_var_list_ptr

<RT data: procedures>+≡
  function rt_data_get_var_list_ptr (global) result (var_list)
    class(rt_data_t), intent(in), target :: global
    type(var_list_t), pointer :: var_list
    if (associated (global%model)) then
      var_list => global%model%get_var_list_ptr ()
    else
      var_list => global%var_list
    end if
  end function rt_data_get_var_list_ptr

```

Initialize a local variable: append it to the current variable list. No initial value, yet.

```

    <RT data: execute tests>
    end subroutine rt_data_test

```

Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```

<RT data: rt data: TBP>+≡

29.3 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

This module provides no new types, just procedures.

```
<dispatch.f90>≡  
<File header>  
  
module dispatch  
  
  <Use kinds>  
  use kinds, only: i16, double  
  <Use strings>

end select
end associate
end subroutine dispatch_core_def

```

29.3.3 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```

<Dispatch: public>+≡
    public :: dispatch_core

<Dispatch: procedures>+≡
    subroutine dispatch_core (core, core_def, model, &
        helicity_selection, qcd, use_color_factors)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_def_t), intent(in) :: core_def
    class(model_data_t), intent(in), target, optional :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    logical, intent(in), optional :: use_color_factors
    select type (core_def)
    type is (prc_test_def_t)
        allocate (test_t :: core)
    type is (template_me_def_t)

```

```

        allocate (prc_template_me_t :: core)
        select type (core)
        type is (prc_template_me_t)
            call core%set_parameters (model)
        end select
class is (omega_def_t)
    if (.not. allocated (core)) allocate (prc_omega_t :: core)
    select type (core)
    type is (prc_omega_t)
        call core%set_parameters (model, &
            helicity_selection, qcd, use_color_factors)
    end select
type is (gosam_def_t)
    if (.not. allocated (core)) allocate (prc_gosam_t :: core)
    select type (core)
    type is (prc_gosam_t)
        call core%set_parameters (qcd, use_color_factors)
    end select
class default
    call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

29.3.4 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

(Dispatch: public)+≡

```

public :: dispatch_core_update
public :: dispatch_core_restore

```

(Dispatch: procedures)+≡

```

subroutine dispatch_core_update (core, model, helicity_selection, qcd, &
    saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(model_data_t), intent(in), optional, target :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    class(prc_core_t), allocatable, intent(inout), optional :: saved_core
    if (present (saved_core)) then
        allocate (saved_core, source = core)
    end if
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
        call core%set_parameters (model, helicity_selection, qcd)
        call core%activate_parameters ()
    type is (prc_gosam_t)
        call msg_message ("dispatch core restore: Gosam implementation not present yet!")

```

```

```

29.3.8 Random-number generator

Allocate a random-number generator factory according to the variable `$rng_method`, using the current seed in the global record. We take only the lower 15 bits of the seed, so the actual value fits into a positive 16-bit signed integer.

Since we want to guarantee that all random-number generators in a run are independent, we increment the global seed by one after creating the rng factory. If the user wants to have identical sequences, he can always set the seed manually, before it is used.

```

<Dispatch: public>+≡
    public :: dispatch_rng_factory

<Dispatch: procedures>+≡
    subroutine dispatch_rng_factory (rng_factory, global, local_input)
        class(rng_factory_t), allocatable, intent(inout) :: rng_factory

    end subroutine dispatch_rng_factory

```

29.3.9 Structure function configuration data

This data type is a container for transferring structure-function specific data from the `dispatch_sf_data` to the `dispatch_sf_channels` subroutine.

```

<Dispatch: public>+≡
    public :: sf_prop_t

```

```

<Dispatch: types>≡
  type :: sf_prop_t
    real(default), dimension(2) :: isr_eps = 1
  end type sf_prop_t

```

Allocate a structure-function configuration object according to the `sf_method` string.

The `sf_prop` object can be used to transfer structure-function specific data up and to the `dispatch_sf_channels` subroutine below, so they can be used for particular mappings.

The `global` object is intent(inout) because the RNG generator seed may change during initialization.

The `pdg_in` array is the array of incoming flavors, corresponding to the upstream structure function or the beam array. This will be checked for the structure function in question and replaced by the outgoing flavors. The `pdg_prc` array is the array of incoming flavors (beam index, component index) for the hard process.

```

<Dispatch: public>+≡
  public :: dispatch_sf_data

```

This is an auxiliary procedure, used by the beam-structure expansion: tell for a given structure function name, whether it corresponds to a pair spectrum ($n = 2$), a single-particle structure function ($n = 1$), or nothing ($n = 0$). Though `energy_scan` can in principle also be a pair spectrum, it always has only one parameter.

```

case default
  call msg_bug ("Structure function '" // char (name) &
               // "' not supported yet")
end select
end function strfun_mode

```

Dispatch a whole structure-function chain, given beam data and beam structure data.

This could be done generically, but we should look at the specific combination of structure functions in order to select appropriate mappings.

The `beam_structure` argument gets copied because we want to expand it to canonical form (one valid structure-function entry per record) before proceeding further.

The `pdg_prc` argument is the array of incoming flavors. The first index is the beam index, the second one the process component index. Each element is itself a PDG array, notrivial if there is a flavor sum for the incoming state of this component.

The dispatcher is divided in two parts. The first part configures the structure function data themselves. After this, we can configure the phase space for the elementary process.

```

<Dispatch: public>+≡
  public :: dispatch_sf_config

<Dispatch: procedures>+≡
  subroutine dispatch_sf_config (sf_config, sf_prop, global, pdg_prc)
    type(sf_config_t), dimension(:), allocatable, intent(out) :: sf_config

    type(pdg_array_t), dimension(:,,:), intent(in) :: pdg_prc
    type(string_t), dimension(:), allocatable :: prt_in
    type(pdg_array_t), dimension(:), allocatable :: pdg_in
    type(flavor_t) :: flv_in
    integer :: n_beam, n_record, i
    beam_structure = global%beam_structure
    call beam_structure%expand (strfun_mode)
    n_record = beam_structure%get_n_record ()
    allocate (sf_config (n_record))
    n_beam = beam_structure%get_n_beam ()
    if (n_beam > 0) then
      allocate (prt_in (n_beam), pdg_in (n_beam))

```

```

    prt_in = beam_structure%get_prt ()
    do i = 1, n_beam
        call flavor_init (flv_in, prt_in(i), global%model)
        pdg_in(i) = flavor_get_pdg (flv_in)
    end do
else
    n_beam = size (pdg_prc, 1)
    allocate (pdg_in (n_beam))
    pdg_in = pdg_prc(:,1)
end if
do i = 1, n_record
    call dispatch_sf_data (sf_data, &
        beam_structure%get_name (i), &
        beam_structure%get_i_entry (i), &
        sf_prop, global, pdg_in, pdg_prc)
    call sf_config(i)%init (beam_structure%get_i_entry (i), sf_data)
    deallocate (sf_data)
end do
end subroutine dispatch_sf_config

```

The second part configures channel mappings, using some conditions from the phase space configuration. If there are no structure functions, we enable a default setup with a single (dummy) structure-function channel. Otherwise, we look at the channel collection that we got from the phase-space configuration step. Each entry should be translated into an independent structure-function channel, where typically there is one default entry, which could be mapped using a standard s-channel mapping if the structure function setup recommends this, and other entries with s-channel resonances. The latter need to be translated into global mappings from the structure-function chain.

29.3.11 QCD coupling

Allocate the `alpha` (running coupling) component of the `qcd` block with a concrete implementation, depending on the variable settings in the `global` record.

If a fixed α_s is requested, we do not allocate the `qcd%alpha` object. In this case, the matrix element code will just take the model parameter as-is, which implies fixed α_s . If the object is allocated, the α_s value is computed and updated for each matrix-element call.

```

29.4 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

```
<process_configurations.f90>≡
  <File header>

  module process_configurations

    <Use strings>
    use unit_tests
    use diagnostics

    use variables
    use models

    use particle_specifiers
    use process_libraries
    use prclib_stacks
    use prc_test
    use prc_omega
    use rt_data
    use dispatch

    use prc_gosam

    <Standard module head>

    <Process configurations: public>

    <Process configurations: types>

    contains

    <Process configurations: procedures>

    <Process configurations: tests>

  end module process_configurations
```

29.4.1 Data Type

```
<Process configurations: public>≡
  public :: process_configuration_t

<Process configurations: types>≡
  type :: process_configuration_t
    type(process_def_entry_t), pointer :: entry => null ()
    type(string_t) :: id
    integer :: num_id = 0
  contains
```

```

    <Process configurations: process configuration: TBP>
end type process_configuration_t

```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

```

<Process configurations: process configuration: TBP>≡
    procedure :: init => process_configuration_init

<Process configurations: procedures>≡
    subroutine process_configuration_init &
        (config, prc_name, n_in, n_components, global)
    class(process_configuration_t), intent(out) :: config
    type(string_t), intent(in) :: prc_name
    integer, intent(in) :: n_in
    integer, intent(in) :: n_components
    type(rt_data_t), intent(in) :: global
    type(model_t), pointer :: model

29.4.2 Test

This is the master for calling self-test procedures.

```

<Process configurations: public>+≡
  public :: process_configurations_test

<Process configurations: tests>≡
  subroutine process_configurations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Process configurations: execute tests>
  end subroutine process_configurations_test

```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

```

<Process configurations: public>+≡
  public :: prepare_test_library

<Process configurations: tests>+≡
  subroutine prepare_test_library (global, libname, mode, procname)
    type(rt_data_t), intent(inout), target :: global
    type(string_t), intent(in) :: libname
    integer, intent(in) :: mode

```

```

29.5 Compilation

This module manages compilation and loading of process libraries. It is needed as a separate module because integration depends on it.

```
<compilations.f90>≡  
  <File header>  
  
  module compilations  
  
    <Use strings>  
    use io_units  
    use unit_tests  
    use system_defs, only: TAB  
    use diagnostics  
    use os_interface  
    use md5  
    use variables  
    use model_data  
    use models  
    use process_libraries  
    use prclib_stacks  
    use rt_data  
    use process_configurations  
  
    <Standard module head>  
  
    <Compilations: public>  
  
    <Compilations: types>  
  
    contains  
  
    <Compilations: procedures>  
  
    <Compilations: tests>  
  
  end module compilations
```

29.5.1 The data type

The compilation item handles the compilation and loading of a single process library.

```
<Compilations: types>≡  
  type :: compilation_item_t  
    type(string_t) :: libname  
    type(string_t) :: static_external_tag  
    type(process_library_t), pointer :: lib => null ()  
    logical :: recompile_library = .false.  
  contains  
    <Compilations: compilation item: TBP>  
  end type compilation_item_t
```

Initialize:

```
<Compilations: compilation item: TBP>≡
  procedure :: init => compilation_item_init

<Compilations: procedures>≡
  subroutine compilation_item_init (comp, libname, stack, var_list)
    class(compilation_item_t), intent(out) :: comp
    type(string_t), intent(in) :: libname
    type(prclib_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in) :: var_list
    comp%libname = libname
    comp%lib => stack%get_library_ptr (comp%libname)
    if (.not. associated (comp%lib)) then
      call msg_fatal ("Process library '" // char (comp%libname) &
        // "' has not been declared.")
    end if
    comp%recompile_library = &
      var_list%get_lval (var_str ("?recompile_library"))
  end subroutine compilation_item_init
```

Compile the current library. The force flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

```
<Compilations: compilation item: TBP>+≡
  procedure :: compile => compilation_item_compile

<Compilations: procedures>+≡
  subroutine compilation_item_compile (comp, model, os_data, force, recompile)
    class(compilation_item_t), intent(inout) :: comp
    class(model_data_t), intent(in), target :: model
    type(os_data_t), intent(in) :: os_data
    logical, intent(in) :: force, recompile
    if (associated (comp%lib)) then
      call msg_message ("Process library '" &
        // char (comp%libname) // "': compiling ...")
      call comp%lib%configure (os_data)
      if (signal_is_pending ()) return
      call comp%lib%compute_md5sum (model)
      call comp%lib%write_makefile (os_data, force)
      if (signal_is_pending ()) return
      if (force) then
        call comp%lib%clean (os_data, distclean = .false.)
        if (signal_is_pending ()) return
      end if
      call comp%lib%write_driver (force)
      if (signal_is_pending ()) return
      if (recompile) then
        call comp%lib%load (os_data, keep_old_source = .true.)
        if (signal_is_pending ()) return
      end if
      call comp%lib%update_status (os_data)
    end if
  end subroutine compilation_item_compile
```

Load the current library, just after compiling it.

```
<Compilations: compilation item: TBP>+≡  
  procedure :: load => compilation_item_load  
  
<Compilations: procedures>+≡  
  subroutine compilation_item_load (comp, os_data)  
    class(compilation_item_t), intent(inout) :: comp  
    type(os_data_t), intent(in) :: os_data  
    if (associated (comp%lib)) then  
      call comp%lib%load (os_data)  
    end if  
  end subroutine compilation_item_load
```

Message as a separate call:

```
<Compilations: compilation item: TBP>+≡  
  procedure :: success => compilation_item_success  
  
<Compilations: procedures>+≡  
  subroutine compilation_item_success (comp)  
    class(compilation_item_t), intent(in) :: comp  
    if (associated (comp%lib)) then  
      call msg_message ("Process library '" // char (comp%libname) &  
        // "' : ... success.")  
    else  
      call msg_fatal ("Process library '" // char (comp%libname) &  
        // "' : ... failure.")  
    end if  
  end subroutine compilation_item_success
```

29.5.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```
<Compilations: public>≡  
  public :: compile_library  
  
<Compilations: procedures>+≡  
  subroutine compile_library (libname, global)  
    type(string_t), intent(in) :: libname  
    type(rt_data_t), intent(inout), target :: global  
    type(compilation_item_t) :: comp  
    logical :: force, recompile  
    force = &  
      global%var_list%get_lval (var_str ("?rebuild_library"))  
    recompile = &  
      global%var_list%get_lval (var_str ("?recompile_library"))  
    if (associated (global%model)) then  
      call comp%init (libname, global%prclib_stack, global%var_list)  
      call comp%compile (global%model, global%os_data, force, recompile)  
      if (signal_is_pending ()) return
```

```

        call comp%load (global%os_data)
        if (signal_is_pending ()) return
    else
        call msg_fatal ("Process library compilation: " &
            // " model is undefined.")
    end if
    call comp%success ()
end subroutine compile_library

```

29.5.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```

<Compilations: types>+≡
    type :: compilation_t
    private
        type(string_t) :: exe_name
        type(string_t), dimension(:), allocatable :: lib_name
    contains
        <Compilations: compilation: TBP>
    end type compilation_t

```

Output.

```

<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write

<Compilations: procedures>+≡
    subroutine compilation_write (object, unit)
        class(compilation_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Compilation object:"
        write (u, "(3x,3A)") "executable          = '", &
            char (object%exe_name), "'
        write (u, "(3x,A)", advance="no") "process libraries ="
        do i = 1, size (object%lib_name)
            write (u, "(1x,3A)", advance="no") "' ", char (object%lib_name(i)), "'
        end do
        write (u, *)
    end subroutine compilation_write

```

Initialize: we know the names of the executable and of the libraries.

```

<Compilations: compilation: TBP>+≡
    procedure :: init => compilation_init

<Compilations: procedures>+≡
    subroutine compilation_init (compilation, exe_name, lib_name)
        class(compilation_t), intent(out) :: compilation
        type(string_t), intent(in) :: exe_name
        type(string_t), dimension(:), intent(in) :: lib_name
        compilation%exe_name = exe_name

```

```

        allocate (compilation%lib_name (size (lib_name)))
        compilation%lib_name = lib_name
    end subroutine compilation_init

```

Write the dispatcher subroutine for the compiled libraries. Also write a subroutine which returns the names of the compiled libraries.

<Compilations: compilation: TBP>+≡

```

    procedure :: write_dispatcher => compilation_write_dispatcher

```

<Compilations: procedures>+≡

            // " -f " // compilation%exe_name // ".makefile")
    end subroutine compilation_make_clean_exe

```

29.5.4 API for executable compilation

This is a shorthand for compiling and loading an executable, including the enclosed libraries. The `compilation` object is used only internally.

The global data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
    public :: compile_executable

<Compilations: procedures>+≡
    subroutine compile_executable (exename, libname, global)
        type(string_t), intent(in) :: exename
        type(string_t), dimension(:), intent(in) :: libname
        type(rt_data_t), intent(inout), target :: global
        type(compilation_t) :: compilation

```

```

type(compilation_item_t) :: item
type(string_t) :: ext_libtag
logical :: force, recompile
integer :: i
ext_libtag = ""
force = &
    global%var_list%get_lval (var_str ("?rebuild_library"))
recompile = &
    global%var_list%get_lval (var_str ("?recompile_library"))
call compilation%init (exename, [libname])
if (signal_is_pending ()) return
call compilation%write_dispatcher ()
if (signal_is_pending ()) return
do i = 1, size (libname)
    call item%init (libname(i), global%prclib_stack, global%var_list)
    call item%compile (global%model, global%os_data, &
        force=force, recompile=recompile)
    ext_libtag = "" // item%lib%get_static_modelname (global%os_data)
    if (signal_is_pending ()) return
    call item%success ()
end do
call compilation%write_makefile (global%os_data, ext_libtag)
if (signal_is_pending ()) return
call compilation%make_compile (global%os_data)
if (signal_is_pending ()) return
call compilation%make_link (global%os_data)
end subroutine compile_executable

```

29.5.5 Test

This is the master for calling self-test procedures.

```

<Compilations: public>+≡
    public :: compilations_test

<Compilations: tests>≡
    subroutine compilations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Compilations: execute tests>
    end subroutine compilations_test

```

Intrinsic Matrix Element

Compile an intrinsic test matrix element (`prc_test` type).

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```

<Compilations: execute tests>≡
    call test (compilations_1, "compilations_1", &
        "intrinsic test processes", &
        u, results)

```

```

<Compilations: tests>+=
subroutine compilations_1 (u)
  integer, intent(in) :: u
  type(string_t) :: libname, procname
  type(rt_data_t), target :: global

  write (u, "(A)")  "* Test output: compilations_1"
  write (u, "(A)")  "* Purpose: configure and compile test process"
  write (u, "(A)")

  call syntax_model_file_init ()

  call global%global_init ()

  libname = "compilation_1"
  procname = "prc_comp_1"
  call prepare_test_library (global, libname, 1, [procname])

  call compile_library (libname, global)

  call global%write_libraries (u)

  call global%final ()
  call syntax_model_file_final ()

  write (u, "(A)")
  write (u, "(A)")  "* Test output end: compilations_1"

end subroutine compilations_1

```

External Matrix Element

Compile an external test matrix element (omega type)

```

<Compilations: execute tests>+=
  call test (compilations_2, "compilations_2", &
    "external process (omega)", &
    u, results)

<Compilations: tests>+=
subroutine compilations_2 (u)
  integer, intent(in) :: u
  type(string_t) :: libname, procname
  type(rt_data_t), target :: global

  write (u, "(A)")  "* Test output: compilations_2"
  write (u, "(A)")  "* Purpose: configure and compile test process"
  write (u, "(A)")

  call syntax_model_file_init ()

  call global%global_init ()
  call var_list_set_log (global%var_list, var_str ("?omega_openmp"), &
    .false., is_known = .true.)

```

```

libname = "compilation_2"
procname = "prc_comp_2"
call prepare_test_library (global, libname, 2, [procname,procname])

call compile_library (libname, global)

call global%write_libraries (u, libpath = .false.)

call global%final ()
call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_2"

end subroutine compilations_2

```

External Matrix Element

Compile an external test matrix element (omega type) and create driver files for a static executable.

```

<Compilations: execute tests>+≡
  call test (compilations_3, "compilations_3", &
    "static executable: driver", &
    u, results)

<Compilations: tests>+≡
  subroutine compilations_3 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    type(compilation_t) :: compilation
    integer :: u_file
    character(80) :: buffer

    write (u, "(A)")  "* Test output: compilations_3"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()
    call var_list_set_log (global%var_list, var_str ("?omega_omp"), &
      .false., is_known = .true.)

    libname = "compilations_3_lib"
    procname = "prc_comp_3"
    exename = "compilations_3"

    call prepare_test_library (global, libname, 2, [procname,procname])

```

```

call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_3"

```

```
end subroutine compilations_3
```

29.5.6 Test static build

The tests for building a static executable are separate, since they should be skipped if the WHIZARD build itself has static libraries disabled.

```
<Compilations: public>+≡
  public :: compilations_static_test

<Compilations: tests>+≡
  subroutine compilations_static_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Compilations: static tests>
  end subroutine compilations_static_test
```

External Matrix Element

Compile an external test matrix element (omega type) and incorporate this in a new static WHIZARD executable.

```
<Compilations: static tests>≡
  call test (compilations_static_1, "compilations_static_1", &
    "static executable: compilation", &
    u, results)

<Compilations: tests>+≡
  subroutine compilations_static_1 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    type(compilation_item_t) :: item
    type(compilation_t) :: compilation
    logical :: exist

    write (u, "(A)")  "* Test output: compilations_static_1"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library"

    call syntax_model_file_init ()

    call global%global_init ()
    call var_list_set_log (global%var_list, var_str ("?omega_openmp"), &
      .false., is_known = .true.)

    libname = "compilations_static_1_lib"
    procname = "prc_comp_stat_1"
    exename = "compilations_static_1"

    call prepare_test_library (global, libname, 2, [procname, procname])
```

```

call compilation%init (exename, [libname])

write (u, "(A)")
write (u, "(A)")  "* Write dispatcher"

call compilation%write_dispatcher ()

write (u, "(A)")
write (u, "(A)")  "* Write Makefile"

call compilation%write_makefile (global%os_data)

write (u, "(A)")
write (u, "(A)")  "* Build libraries"

call item%init (libname, global%prclib_stack, global%var_list)
call item%compile &
    (global%model, global%os_data, force=.true., recompile=.false.)
call item%success ()

write (u, "(A)")
write (u, "(A)")  "* Check executable (should be absent)"
write (u, "(A)")

call compilation%make_clean_exe (global%os_data)
inquire (file = char (exename), exist = exist)
write (u, "(A,A,L1)") char (exename), " exists = ", exist

write (u, "(A)")

call global%final ()
call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_static_1"

end subroutine compilations_static_1

```

External Matrix Element

Compile an external test matrix element (`omega` type) and incorporate this in a new static WHIZARD executable. In this version, we use the wrapper `compile_executable` procedure.

```
<Compilations: static tests>+≡
  call test (compilations_static_2, "compilations_static_2", &
    "static executable: shortcut", &
    u, results)

<Compilations: tests>+≡
  subroutine compilations_static_2 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    type(compilation_item_t) :: item
    type(compilation_t) :: compilation
    logical :: exist
    integer :: u_file

    write (u, "(A)")  "* Test output: compilations_static_2"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library and compile"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()
    call var_list_set_log (global%var_list, var_str ("?omega_omp"), &
      .false., is_known = .true.)

    libname = "compilations_static_2_lib"
    procname = "prc_comp_stat_2"
    exename = "compilations_static_2"

    call prepare_test_library (global, libname, 2, [procname,procname])

    call compile_executable (exename, [libname], global)

    write (u, "(A)")  "* Check executable (should be present)"
    write (u, "(A)")

    inquire (file = char (exename), exist = exist)
    write (u, "(A,A,L1)") char (exename), " exists = ", exist

    write (u, "(A)")
    write (u, "(A)")  "* Cleanup"

    u_file = free_unit ()
    open (u_file, file = char (exename), status = "old", action = "write")
```

```
close (u_file, status = "delete")

call global%final ()
call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_static_2"

end subroutine compilations_static_2
```

29.6 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

```
<integrations.f90>≡  
  <File header>  
  
  module integrations  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use unit_tests  
    use diagnostics  
    use os_interface  
    use cputime  
    use sm_qcd  
    use ifiles  
    use lexers  
    use parser  
    use model_data  
    use flavors  
    use pdg_arrays  
    use variables  
    use expr_base  
    use eval_trees  
    use models  
    use interactions  
    use sf_mappings  
    use sf_base  
    use phs_base  
    use mappings  
    use phs_forests  
    use phs_wood  
    use rng_base  
    use mci_base  
    use process_libraries

    use dispatch  
    use process_configurations  
    use compilations  
  
    use process_constants  
    use prc_omega  
    use prc_gosam  
    use nlo_data  
  
    <Standard module head>
```

```

    <Integrations: public>

    <Integrations: types>

contains

    <Integrations: procedures>

    <Integrations: tests>

end module integrations

```

29.6.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

<Integrations: public>≡
    public :: integration_t

<Integrations: types>≡
    type :: integration_t
    private
        type(string_t) :: process_id
        type(string_t) :: run_id
        type(process_t), pointer :: process => null ()
        type(var_list_t), pointer :: model_vars => null ()
        type(qcd_t) :: qcd
        logical :: rebuild_phs = .false.
        logical :: ignore_phs_mismatch = .false.
        logical :: phs_only = .false.
        logical :: process_has_me = .true.
        integer :: n_calls_test = 0
        logical :: vis_history = .true.
        type(string_t) :: history_filename
        type(string_t) :: log_filename
    contains
        <Integrations: integration: TBP>
    end type integration_t

```

29.6.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the `global` environment is supplied.

```

<Integrations: integration: TBP>≡
    procedure :: create_process => integration_create_process

<Integrations: procedures>≡
    subroutine integration_create_process (intg, process_id, global)
        class(integration_t), intent(out) :: intg
        type(rt_data_t), intent(inout), optional, target :: global
    end subroutine

```

```

type(string_t), intent(in) :: process_id
type(process_entry_t), pointer :: process_entry
intg%process_id = process_id
if (present (global)) then
  allocate (process_entry)
  intg%process => process_entry%process_t
  call global%process_stack%push (process_entry)
else
  allocate (process_t :: intg%process)
end if
intg%model_vars => null ()
end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the local stack directly. The intent(inout) attribute for the local data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

(Integrations: integration: TBP)+≡

```

procedure :: init_process => integration_init_process

```

(Integrations: procedures)+≡

```

subroutine integration_init_process (intg, local)
  class(integration_t), intent(inout) :: intg
  type(rt_data_t), intent(inout), target :: local
  type(string_t) :: model_name
  type(model_t), pointer :: model
  class(model_data_t), pointer :: model_instance
  class(rng_factory_t), allocatable :: rng_factory
  if (.not. local%prclib%contains (intg%process_id)) then
    call msg_fatal ("Process '" // char (intg%process_id) // "' not found" &
      // " in library '" // char (local%prclib%get_name ()) // "'")
    return
  end if
  intg%run_id = &
    local%var_list%get_sval (var_str ("$_run_id"))
  call dispatch_qcd (intg%qcd, local)
  call dispatch_rng_factory (rng_factory, local)
  model_name = local%prclib%get_model_name (intg%process_id)
  if (local%get_sval (var_str ("$_model_name")) == model_name) then
    model => local%model
  else
    model => local%model_list%get_model_ptr (model_name)
  end if
  allocate (model_t :: model_instance)
  select type (model_instance)

```

```

type is (model_t)
  call model_instance%init_instance (model)
  intg%model_vars => model_instance%get_var_list_ptr ()
end select
call intg%process%init (intg%process_id, intg%run_id, &
  local%prclib, &
  local%os_data, intg%qcd, rng_factory, model_instance)
end subroutine integration_init_process

```

Initialization, third part: complete process configuration.

(Integrations: integration: TBP)+≡

```

29.6.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

<Integrations: integration: TBP> +=
    procedure :: evaluate => integration_evaluate

<Integrations: procedures> +=
    subroutine integration_evaluate &

```

```

        (intg, process_instance, i_mci, pass, it_list, pacify)
class(integration_t), intent(inout) :: intg
type(process_instance_t), intent(inout), target :: process_instance
integer, intent(in) :: i_mci
integer, intent(in) :: pass
type(iterations_list_t), intent(in) :: it_list
logical, intent(in), optional :: pacify
integer :: n_calls, n_it
logical :: adapt_grids, adapt_weights, final

n_it = it_list%get_n_it (pass)
n_calls = it_list%get_n_calls (pass)
adapt_grids = it_list%adapt_grids (pass)
adapt_weights = it_list%adapt_weights (pass)
final = pass == it_list%get_n_pass ()

call intg%process%integrate (process_instance, &
    i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
    final, pacify)

end subroutine integration_evaluate

```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

```

<Integrations: integration: TBP>+≡
    procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: procedures>+≡
    subroutine integration_make_iterations_list (intg, it_list)
    class(integration_t), intent(in) :: intg

```

Return the process pointer (needed by simulate):

(Integrations: integration: TBP)+≡

```
procedure :: get_process_ptr => integration_get_process_ptr
```

(Integrations: procedures)+≡

```

function integration_get_process_ptr (intg) result (ptr)
    class(integration_t), intent(in) :: intg
    type(process_t), pointer :: ptr
    ptr => intg%process
end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the `global` environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the `process` object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

```

29.6.5 Test

This is the master for calling self-test procedures.

```

<Integrations: public>+≡
    public :: integrations_test

<Integrations: tests>≡
    subroutine integrations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Integrations: execute tests>
    end subroutine integrations_test

<Integrations: public>+≡
    public :: integrations_history_test

<Integrations: tests>+≡
    subroutine integrations_history_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Integrations: execute history tests>
    end subroutine integrations_history_test

```

Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (29.1)$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (29.2)$$

f is the flux of the incoming particles with mass $m = 125 \text{ GeV}$ and energy $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (29.3)$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (29.4)$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (29.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function $f(x) = x$ for both beams. Together with the $1/x_1x_2$ factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the m_s mass which we set to zero here.

```

29.7 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
(event_streams.f90)≡
  <File header>

  module event_streams

    <Use kinds>
    <Use strings>
    use io_units
    use unit_tests
    use diagnostics
    use variables
    use model_data
    use models
    use processes
    use events
    use eio_data
    use eio_base
    use rt_data
    use dispatch

    <Standard module head>

    <Event streams: public>

    <Event streams: types>

    contains

    <Event streams: tests>

    <Event streams: procedures>

  end module event_streams
```

29.7.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡
  type :: event_stream_entry_t
    class(eio_t), allocatable :: eio
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```
<Event streams: public>≡
  public :: event_stream_array_t
```

```

<Event streams: types>+≡
  type :: event_stream_array_t
    type(event_stream_entry_t), dimension(:), allocatable :: entry
    integer :: i_in = 0
  contains
    <Event streams: event stream array: TBP>
  end type event_stream_array_t

```

Output.

```

<Event streams: event stream array: TBP>≡
  procedure :: write => event_stream_array_write

<Event streams: procedures>≡
  subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event stream array:"
    if (allocated (object%entry)) then
      select case (size (object%entry))
      case (0)
        write (u, "(3x,A)") "[empty]"
      case default
        do i = 1, size (object%entry)
          if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
          call object%entry(i)%eio%write (u)
        end do
      end select
    else
      write (u, "(3x,A)") "[undefined]"
    end if
  end subroutine event_stream_array_write

```

Finalize all streams.

```

<Event streams: event stream array: TBP>+≡
  procedure :: final => event_stream_array_final

<Event streams: procedures>+≡
  subroutine event_stream_array_final (es_array)
    class(event_stream_array_t), intent(inout) :: es_array
    integer :: i
    do i = 1, size (es_array%entry)
      call es_array%entry(i)%eio%final ()
    end do
  end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

(Event streams: event stream array: TBP)+≡

            object%has_integral = .true.
        end if
    end subroutine mci_set_init

```

29.8.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

```

<Simulations: types>+≡
    type :: core_safe_t
        class(prc_core_t), allocatable :: core
    end type core_safe_t

```

29.8.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

```

<Simulations: procedures>+≡
    subroutine prepare_process &
        (process, process_id, integrate, local, global)
        type(process_t), pointer, intent(out) :: process

```

```

type(string_t), intent(in) :: process_id
logical, intent(in) :: integrate
type(rt_data_t), intent(inout), target :: local
type(rt_data_t), intent(inout), optional, target :: global
if (present (global)) then
    process => global%process_stack%get_process_ptr (process_id)
else
    process => local%process_stack%get_process_ptr (process_id)
end if
if (.not. associated (process)) then
    if (integrate) then
        call msg_message ("Simulate: process '" &
            // char (process_id) // "' needs integration")
    else
        call msg_message ("Simulate: process '" &
            // char (process_id) // "' needs initialization")
    end if
    if (present (global)) then
        call integrate_process (process_id, local, global, &
            init_only = .not. integrate)
    else
        call integrate_process (process_id, local, local_stack=.true., &
            init_only = .not. integrate)
    end if
    if (signal_is_pending ()) return
    process => global%process_stack%get_process_ptr (process_id)
    if (associated (process)) then
        if (integrate) then
            call msg_message ("Simulate: integration done")
            call global%process_stack%fill_result_vars (process_id)
        else
            call msg_message ("Simulate: process initialization done")
        end if
    else
        call msg_fatal ("Simulate: process '" &
            // char (process_id) // "' could not be initialized: aborting")
    end if
end if
end subroutine prepare_process

```

29.8.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the qcd and/or model components are present.

```

<Simulations: types>+≡
type, extends (event_t) :: entry_t
private
type(string_t) :: process_id
type(string_t) :: library
type(string_t) :: run_id
logical :: has_integral = .false.
real(default) :: integral = 0
real(default) :: error = 0
real(default) :: process_weight = 0
logical :: valid = .false.
type(counter_t) :: counter
integer :: n_in = 0
integer :: n_mci = 0
type(mci_set_t), dimension(:), allocatable :: mci_set
type(selector_t) :: mci_selector

```

Finalizer. The *instance* pointer component of the *event_t* base type points to a target which we did explicitly allocate in the *entry_init* procedure. Therefore, we finalize and explicitly deallocate it here. Then we call the finalizer of the base type.

```

<Simulations: entry: TBP>+≡
    procedure :: final => entry_final

            deallocate (object%instance)
        end if
        call object%event_t%final ()
    end subroutine entry_final

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the *process_instance* pointer. Assign data by looking at the process object and at the environment.

If *n_alt* is set, we prepare for additional alternate sqme and weight entries.

If the process object is not found initially: if *integrate* is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If *generate* is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the *instance* and *process* pointers of the base type by the *connect* method, so we can reference them later.

```

29.8.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

<Simulations: types>+≡

```

    type, extends (entry_t) :: alt_entry_t
    contains
        <Simulations: alt entry: TBP>
    end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

Write the current event record. If an explicit index is given, write that event record.

We implement writing to `unit` (event contents / debugging format) and writing to an `eio` event stream (storage). We include a `testflag` in order to suppress numerical noise in the testsuite.

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the luminosity setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the luminosity, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

NB: When reading from file, event transforms can't be applied because the process instance will not be complete. This should be fixed.

```

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

```

29.8.8 Event Stream I/O

Write an event to a generic `eio` event stream. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+≡
generic :: write_event => write_event_eio
procedure :: write_event_eio => simulation_write_event_eio

<Simulations: procedures>+≡
subroutine simulation_write_event_eio (object, eio, i_prc)
class(simulation_t), intent(in) :: object
class(eio_t), intent(inout) :: eio
integer, intent(in), optional :: i_prc
integer :: current
if (present (i_prc)) then
    current = i_prc
else
    current = object%i_prc
end if
if (current > 0) then
    if (object%split_n_evt > 0) then
        if (object%counter%total > 1 .and. &
            mod (object%counter%total, object%split_n_evt) == 1) then
            call eio%split_out ()
        end if
    end if
    call eio%output (object%entry(current)%event_t, current, pacify = object%pacify)
else
    call msg_fatal ("Simulation: write event: no process selected")
end if
end subroutine simulation_write_event_eio

```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```

<Simulations: simulation: TBP>+=
generic :: read_event => read_event_eio
procedure :: read_event_eio => simulation_read_event_eio

<Simulations: procedures>+=
subroutine simulation_read_event_eio (object, eio)
  class(simulation_t), intent(inout) :: object

    call eio%input_event (object%entry(current)%event_t, iostat)
  end select
  select case (iostat)
  case (:-1)
    object%i_prc = 0
    object%i_mci = 0
  case (1:)
    call msg_error ("Reading events: I/O error, aborting read")
    object%i_prc = 0
    object%i_mci = 0
  case default
    object%i_mci = object%entry(current)%get_i_mci ()
  end select
end subroutine simulation_read_event_eio

```

29.8.9 Event Stream Array

Write an event using an array of event I/O streams. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+=
generic :: write_event => write_event_es_array
procedure :: write_event_es_array => simulation_write_event_es_array

<Simulations: procedures>+=
subroutine simulation_write_event_es_array (object, es_array)
  class(simulation_t), intent(in) :: object
  class(event_stream_array_t), intent(inout) :: es_array
  integer :: i_prc, event_index
  i_prc = object%i_prc
  if (i_prc > 0) then
    event_index = object%counter%total
    call es_array%output (object%entry(i_prc)%event_t, i_prc, &
      event_index, pacify = object%pacify)
  else
    call msg_fatal ("Simulation: write event: no process selected")
  end if
end subroutine simulation_write_event_es_array

```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

<Simulations: simulation: TBP>+≡

```

Chapter 30

More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in init/final hooks that we can set at runtime.)

30.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
(expr_tests.f90)≡  
  <File header>  
  module expr_tests  
  
    <Use kinds>  
    <Use strings>  
    use format_defs, only: FMT_12  
    use format_utils, only: write_separator  
    use unit_tests  
    use os_interface  
    use ifiles  
    use lexers  
    use parser  
    use lorentz  
    use sm_qcd  
    use model_data  
    use interactions, only: reset_interaction_counter  
    use variables

Chapter 31

Top Level

The top level consists of

commands Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

whizard This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

main The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

whizard_c_interface Alternative top-level procedures, for use in the context of a C-compatible caller program.

31.1 Commands

This module defines the command language of the main input file.

end module commands

31.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as **options**, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```
⟨Commands: types⟩≡
  type, abstract :: command_t
    type(parse_node_t), pointer :: pn => null ()
    class(command_t), pointer :: next => null ()
    type(parse_node_t), pointer :: pn_opt => null ()
    type(command_list_t), pointer :: options => null ()
    type(rt_data_t), pointer :: local => null ()
  contains
    ⟨Commands: command: TBP⟩
  end type command_t
```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```
⟨Commands: command: TBP⟩≡
  procedure :: final => command_final

⟨Commands: procedures⟩≡
  recursive subroutine command_final (cmd)
    class(command_t), intent(inout) :: cmd
    if (associated (cmd%options)) then
      call cmd%options%final ()
      deallocate (cmd%options)
      call cmd%local%local_final ()
      deallocate (cmd%local)
```

```

else
    cmd%local => null ()
end if
end subroutine command_final

```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

(Commands: procedures)+≡

```

subroutine dispatch_command (command, pn)
    class(command_t), intent(inout), pointer :: command
    type(parse_node_t), intent(in), target :: pn
    select case (char (parse_node_get_rule_key (pn)))

    allocate (cmd_quit_t :: command)
case default
    print *, char (parse_node_get_rule_key (pn))
    call msg_bug ("Command not implemented")
end select
command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

<Commands: command: TBP>+≡
    procedure (command_write), deferred :: write

<Commands: interfaces>≡
    abstract interface
        subroutine command_write (cmd, unit, indent)
            import
            class(command_t), intent(in) :: cmd
            integer, intent(in), optional :: unit, indent
        end subroutine command_write
    end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

<Commands: command: TBP>+≡
    procedure (command_compile), deferred :: compile

<Commands: interfaces>+≡
    abstract interface
        subroutine command_compile (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_compile
    end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

<Commands: command: TBP>+≡
    procedure (command_execute), deferred :: execute

<Commands: interfaces>+≡
    abstract interface
        subroutine command_execute (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_execute
    end interface

```

31.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```
<Commands: command: TBP>+≡
  procedure :: write_options => command_write_options

<Commands: procedures>+≡
  recursive subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options
```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```
<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
  recursive subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call cmd%options%compile (cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
      call cmd%local%deactivate ()
    else
      cmd%local => global
    end if
  end subroutine command_compile_options
```

Execute options. First prepare the local environment, then execute the command list.

```
<Commands: command: TBP>+≡
  procedure :: execute_options => cmd_execute_options

<Commands: procedures>+≡
  recursive subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call cmd%local%activate ()
      call cmd%options%execute (cmd%local)
```

```

        end if
    end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

⟨Commands: command: TBP⟩+≡
    procedure :: reset_options => cmd_reset_options

⟨Commands: procedures⟩+≡
    subroutine cmd_reset_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then

        end if
    end subroutine cmd_reset_options

```

31.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_model_t
    private
        type(string_t) :: name
    contains
        ⟨Commands: cmd model: TBP⟩
    end type cmd_model_t

```

Output

```

⟨Commands: cmd model: TBP⟩≡
    procedure :: write => cmd_model_write

⟨Commands: procedures⟩+≡
    subroutine cmd_model_write (cmd, unit, indent)
        class(cmd_model_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,1x,'"',A,'\"') "model =", char (cmd%name)
    end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

```

⟨Commands: cmd model: TBP⟩+≡
    procedure :: compile => cmd_model_compile

```

```

⟨Commands: procedures⟩+=
subroutine cmd_model_compile (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_name
  type(model_t), pointer :: model
  pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
  cmd%name = parse_node_get_string (pn_name)
  model => null ()
  if (associated (global%model)) then
    if (global%model%get_name () == cmd%name) model => global%model
  end if
  if (.not. associated (model)) then
    if (global%model_list%model_exists (cmd%name)) then
      model => global%model_list%get_model_ptr (cmd%name)
    else
      call global%read_model (cmd%name, model)
    end if
  end if
  global%model => model
  if (associated (global%model)) then
    call global%model%link_var_list (global%var_list)
  end if
end subroutine cmd_model_compile

```

Execute: Insert a pointer into the global data record and reassign the variable list.

```

⟨Commands: cmd model: TBP⟩+=
procedure :: execute => cmd_model_execute

⟨Commands: procedures⟩+=
subroutine cmd_model_execute (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  call global%select_model (cmd%name)
  if (.not. associated (global%model)) &
    call msg_fatal ("Switching to model '" &
      // char (cmd%name) // "' : model not found")
end subroutine cmd_model_execute

```

Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

```

⟨Commands: types⟩+=
type, extends (command_t) :: cmd_library_t
  private
  type(string_t) :: name
contains
  ⟨Commands: cmd library: TBP⟩
end type cmd_library_t

```

Output.

```
<Commands: cmd library: TBP>≡
  procedure :: write => cmd_library_write

<Commands: procedures>+≡
  subroutine cmd_library_write (cmd, unit, indent)
    class(cmd_library_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit)
    call write_indent (u, indent)
    write (u, "(1x,A,1x,'"',A,'\"')") "library =", char (cmd%name)
  end subroutine cmd_library_write
```

Compile. Get the library name.

```
<Commands: cmd library: TBP>+≡
  procedure :: compile => cmd_library_compile

<Commands: procedures>+≡
  subroutine cmd_library_compile (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_name
    pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
    cmd%name = parse_node_get_string (pn_name)
  end subroutine cmd_library_compile
```

Execute: Initialize a new library and push it on the library stack (if it does not yet exist). Insert a pointer to the library into the global data record. Then, try to load the library unless the rebuild flag is set.

```
<Commands: cmd library: TBP>+≡
  procedure :: execute => cmd_library_execute

<Commands: procedures>+≡
  subroutine cmd_library_execute (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(prclib_entry_t), pointer :: lib_entry
    type(process_library_t), pointer :: lib
    logical :: rebuild_library
    lib => global%prclib_stack%get_library_ptr (cmd%name)
    rebuild_library = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    if (.not. (associated (lib))) then
      allocate (lib_entry)
      call lib_entry%init (cmd%name)
      lib => lib_entry%process_library_t
      call global%add_prclib (lib_entry)
    else
      call global%update_prclib (lib)
    end if
    if (associated (lib) .and. .not. rebuild_library) then
      call lib%update_status (global%os_data)
```

```

        end if
    end subroutine cmd_library_execute

```

Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_process_t
        private
        type(string_t) :: id
        integer :: n_in = 0
        type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
        type(parse_node_t), pointer :: pn_out => null ()
        contains
        ⟨Commands: cmd process: TBP⟩
    end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

⟨Commands: cmd process: TBP⟩≡
    procedure :: write => cmd_process_write

⟨Commands: procedures⟩+≡
    subroutine cmd_process_write (cmd, unit, indent)
        class(cmd_process_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A,A,I0,A)") "process: ", char (cmd%id), " (", &
            size (cmd%pn_pdg_in), " -> X)"
        call cmd%write_options (u, indent)
    end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

⟨Commands: cmd process: TBP⟩+≡
    procedure :: compile => cmd_process_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_process_compile (cmd, global)
  class(cmd_process_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_id, pn_in, pn_codes
  integer :: i
  pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
  pn_in => parse_node_get_next_ptr (pn_id, 2)
  cmd%pn_out => parse_node_get_next_ptr (pn_in, 2)
  cmd%pn_opt => parse_node_get_next_ptr (cmd%pn_out)
  call cmd%compile_options (global)
  cmd%id = parse_node_get_string (pn_id)
  cmd%n_in = parse_node_get_n_sub (pn_in)
  pn_codes => parse_node_get_sub_ptr (pn_in)
  allocate (cmd%pn_pdg_in (cmd%n_in))
  do i = 1, cmd%n_in
    cmd%pn_pdg_in(i)%ptr => pn_codes
    pn_codes => parse_node_get_next_ptr (pn_codes)
  end do
end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

```

Command execution. Generate code, write driver, compile and link. Do this for all libraries in the list.

If no library names have been given and stored while compiling this command, we collect all libraries from the current stack and compile those.

We can compile static libraries (which actually just loads them). However, we can't incorporate in a generated executable.

<Commands: cmd compile: TBP>+≡

```

procedure :: execute => cmd_compile_execute

```

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer.

After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_slha_t
    private
    type(string_t) :: file
    logical :: write_mode = .false.
    contains
    ⟨Commands: cmd slha: TBP⟩
end type cmd_slha_t

```

Output.

```

⟨Commands: cmd slha: TBP⟩≡
    procedure :: write => cmd_slha_write

⟨Commands: procedures⟩+≡
    subroutine cmd_slha_write (cmd, unit, indent)
        class(cmd_slha_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A)") "slha: file name = ", char (cmd%file)
        write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
    end subroutine cmd_slha_write

```

Compile. Read the filename and store it.

```

⟨Commands: cmd slha: TBP⟩+≡
    procedure :: compile => cmd_slha_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_slha_compile (cmd, global)
        class(cmd_slha_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_key, pn_arg, pn_file
        pn_key => parse_node_get_sub_ptr (cmd%pn)
        pn_arg => parse_node_get_next_ptr (pn_key)
        pn_file => parse_node_get_sub_ptr (pn_arg)
        call cmd%compile_options (global)
    end subroutine cmd_slha_compile

```

```

cmd%pn_opt => parse_node_get_next_ptr (pn_arg)
select case (char (parse_node_get_key (pn_key)))
case ("read_slha")
    cmd%write_mode = .false.
case ("write_slha")
    cmd%write_mode = .true.
case default
    call parse_node_mismatch ("read_slha|write_slha", cmd%pn)
end select
cmd%file = parse_node_get_string (pn_file)
end subroutine cmd_slha_compile

```

Execute. Read or write the specified SLHA file. Behind the scenes, this will first read the WHIZARD model file, then read the SLHA file and assign the SLHA parameters as far as determined by `dispatch_slha`. Finally, the global variables are synchronized with the model. This is similar to executing `cmd_model`.

Clear values

This command clears the current values of variables or other objects, where this makes sense. It parallels the `show` command. The objects are cleared, but not deleted.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_clear_t
    private
    type(string_t), dimension(:), allocatable :: name
contains
    <Commands: cmd clear: TBP>
end type cmd_clear_t

```

Output: list the names of the objects to be cleared.

```

<Commands: cmd clear: TBP>≡
    procedure :: write => cmd_clear_write

<Commands: procedures>+≡
subroutine cmd_clear_write (cmd, unit, indent)
    class(cmd_clear_t), intent(in) :: cmd

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

⟨Commands: types⟩+≡

Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

⟨Commands: types⟩+≡
  type :: sentry_expr_t
    type(parse_node_p), dimension(:), allocatable :: expr
  contains
    ⟨Commands: sentry expr: TBP⟩
  end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

⟨Commands: sentry expr: TBP⟩≡
  procedure :: compile => sentry_expr_compile

```

<Commands: procedures>+≡

```

subroutine sentry_expr_compile (sentry, pn)
  class(sentry_expr_t), intent(out) :: sentry
  type(parse_node_t), intent(in), target :: pn
  type(parse_node_t), pointer :: pn_expr, pn_extra
  integer :: n_expr, i
  n_expr = parse_node_get_n_sub (pn)
  allocate (sentry%expr (n_expr))
  if (n_expr > 0) then
    i = 0
    pn_expr => parse_node_get_sub_ptr (pn)
    pn_extra => parse_node_get_next_ptr (pn_expr)
    do i = 1, n_expr
      sentry%expr(i)%ptr => pn_expr
      if (associated (pn_extra)) then
        pn_expr => parse_node_get_sub_ptr (pn_extra, 2)
        pn_extra => parse_node_get_next_ptr (pn_extra)
      end if
    end do
  end if
end subroutine sentry_expr_compile

```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

```
subroutine cmd_beams_pol_density_compile (cmd, global)
  class(cmd_beams_pol_density_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_pol_spec, pn_smatrix
  integer :: i
  pn_pol_spec => parse_node_get_sub_ptr (cmd%pn, 3)
  call cmd%compile_options (global)
  cmd%n_in = parse_node_get_n_sub (pn_pol_spec)
  allocate (cmd%smatrix (cmd%n_in))
  pn_smatrix => parse_node_get_sub_ptr (pn_pol_spec)
  do i = 1, cmd%n_in
    call cmd%smatrix(i)%compile (pn_smatrix)
    pn_smatrix => parse_node_get_next_ptr (pn_smatrix)
  end do
end subroutine cmd_beams_pol_density_compile
```

Command execution: Fill polarization density matrices. No check yet, the matrices are checked and normalized when the actual beam object is created, just before integration. For intermediate storage, we use the `beam_structure` object in the `global` data set.

(Commands: cmd beams pol density: TBP)+≡

```
procedure :: execute => cmd_beams_pol_density_execute
```

(Commands: procedures)+≡

```
subroutine cmd_beams_pol_density_execute (cmd, global)
  class(cmd_beams_pol_density_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(smatrix_t) :: smatrix
  integer :: i
  call global%beam_structure%init_pol (cmd%n_in)
  do i = 1, cmd%n_in
    call cmd%smatrix(i)%evaluate (smatrix, global)
    call global%beam_structure%set_smatrix (i, smatrix)
  end do
end subroutine cmd_beams_pol_density_execute
```

Beam polarization fraction

In addition to the polarization density matrix, we can independently specify the polarization fraction for one or both beams.

(Commands: types)+≡

```
type, extends (command_t) :: cmd_beams_pol_fraction_t
private
integer :: n_in = 0
```

```

        type(parse_node_p), dimension(:), allocatable :: expr
contains
    <Commands: cmd beams pol fraction: TBP>
end type cmd_beams_pol_fraction_t

```

Output.

```

<Commands: cmd beams pol fraction: TBP>≡
    procedure :: write => cmd_beams_pol_fraction_write

<Commands: procedures>+≡
    subroutine cmd_beams_pol_fraction_write (cmd, unit, indent)
        class(cmd_beams_pol_fraction_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        select case (cmd%n_in)
        case (1)
            write (u, "(1x,A)") "beams polarization fraction: 1 [decay]"
        case (2)
            write (u, "(1x,A)") "beams polarization fraction: 2 [scattering]"
        case default
            write (u, "(1x,A)") "beams polarization fraction: [undefined]"
        end select
    end subroutine cmd_beams_pol_fraction_write

```

Compile. Find and assign the parse nodes.

Note: local environments are not yet supported.

```

<Commands: cmd beams pol fraction: TBP>+≡
    procedure :: compile => cmd_beams_pol_fraction_compile

<Commands: procedures>+≡
    subroutine cmd_beams_pol_fraction_compile (cmd, global)
        class(cmd_beams_pol_fraction_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_frac_spec, pn_expr
        integer :: i
        pn_frac_spec => parse_node_get_sub_ptr (cmd%pn, 3)
        call cmd%compile_options (global)
        cmd%n_in = parse_node_get_n_sub (pn_frac_spec)
        allocate (cmd%expr (cmd%n_in))
        pn_expr => parse_node_get_sub_ptr (pn_frac_spec)

    call expr%evaluate ()
    if (expr%is_known ()) then
      pol_f(i) = expr%get_real ()
    else
      call msg_fatal ("beams polarization fraction: undefined value")
    end if
    call expr%final ()
  end do
  call global%beam_structure%set_pol_f (pol_f)
end subroutine cmd_beams_pol_fraction_execute

```

Beam momentum

This is completely analogous to the previous command, hence we can use inheritance.

```

<Commands: types>+≡
type, extends (cmd_beams_pol_fraction_t) :: cmd_beams_momentum_t
contains
  <Commands: cmd beams momentum: TBP>
end type cmd_beams_momentum_t

```

Output.

```

<Commands: cmd beams momentum: TBP>≡
procedure :: write => cmd_beams_momentum_write

<Commands: procedures>+≡
subroutine cmd_beams_momentum_write (cmd, unit, indent)
  class(cmd_beams_momentum_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  select case (cmd%n_in)
  case (1)
    write (u, "(1x,A)") "beams momentum: 1 [decay]"
  case (2)
    write (u, "(1x,A)") "beams momentum: 2 [scattering]"
  case default
    write (u, "(1x,A)") "beams momentum: [undefined]"
  end select

```

```
end subroutine cmd_beams_momentum_write
```

Compile: inherited.

Command execution: Not inherited, but just the error string and the final command are changed.

<Commands: cmd beams momentum: TBP>+≡

```
procedure :: execute => cmd_beams_momentum_execute
```

<Commands: procedures>+≡

```
subroutine cmd_beams_momentum_execute (cmd, global)

```

Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_alt_setup_t
  private
  type(parse_node_p), dimension(:), allocatable :: setup
  contains
  ⟨Commands: cmd alt setup: TBP⟩
  end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

⟨Commands: cmd alt setup: TBP⟩≡
  procedure :: write => cmd_alt_setup_write

⟨Commands: procedures⟩+≡
  subroutine cmd_alt_setup_write (cmd, unit, indent)
    class(cmd_alt_setup_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
  end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

⟨Commands: cmd alt setup: TBP⟩+≡
  procedure :: compile => cmd_alt_setup_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_alt_setup_compile (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_list, pn_setup
    integer :: i
    pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
    if (associated (pn_list)) then

```

```

        allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
        i = 1
        pn_setup => parse_node_get_sub_ptr (pn_list)
        do while (associated (pn_setup))
            cmd%setup(i)%ptr => pn_setup
            i = i + 1
            pn_setup => parse_node_get_next_ptr (pn_setup)
        end do
    else
        allocate (cmd%setup (0))
    end if
end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

<Commands: cmd alt setup: TBP>+≡
    procedure :: execute => cmd_alt_setup_execute

<Commands: procedures>+≡
    subroutine cmd_alt_setup_execute (cmd, global)
        class(cmd_alt_setup_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (allocated (global%pn%alt_setup)) deallocate (global%pn%alt_setup)
        allocate (global%pn%alt_setup (size (cmd%setup)), source = cmd%setup)
    end subroutine cmd_alt_setup_execute

```

Integration

Integrate several processes, consecutively with identical parameters.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_integrate_t
    private
        integer :: n_proc = 0
        type(string_t), dimension(:), allocatable :: process_id
    contains
        <Commands: cmd integrate: TBP>
    end type cmd_integrate_t

```

Output: we know the process IDs.

```

<Commands: cmd integrate: TBP>≡
    procedure :: write => cmd_integrate_write

<Commands: procedures>+≡
    subroutine cmd_integrate_write (cmd, unit, indent)

        integer :: u, i
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)", advance="no") "integrate ("
        do i = 1, cmd%n_proc
            if (i > 1) write (u, "(A,1x)", advance="no") ", "
            write (u, "(A)", advance="no") char (cmd%process_id(i))
        end do
    end subroutine cmd_integrate_write

```

```

        end do
        write (u, "(A)" ) " "
    end subroutine cmd_integrate_write

```

Compile.

```

<Commands: cmd integrate: TBP>+≡
    procedure :: compile => cmd_integrate_compile

<Commands: procedures>+≡
    subroutine cmd_integrate_compile (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_proclist, pn_proc
        integer :: i
        pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
        cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
        call cmd%compile_options (global)
        cmd%n_proc = parse_node_get_n_sub (pn_proclist)
        allocate (cmd%process_id (cmd%n_proc))
        pn_proc => parse_node_get_sub_ptr (pn_proclist)
        do i = 1, cmd%n_proc
            cmd%process_id(i) = parse_node_get_string (pn_proc)
            call global%process_stack%init_result_vars (cmd%process_id(i))
            pn_proc => parse_node_get_next_ptr (pn_proc)
        end do
    end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

<Commands: cmd integrate: TBP>+≡
    procedure :: execute => cmd_integrate_execute

<Commands: procedures>+≡
    subroutine cmd_integrate_execute (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        integer :: i
        do i = 1, cmd%n_proc
            call integrate_process (cmd%process_id(i), cmd%local, global)
            call global%process_stack%fill_result_vars (cmd%process_id(i))
            if (signal_is_pending ()) return
        end do
    end subroutine cmd_integrate_execute

```

Observables

Declare an observable. After the declaration, it can be used to record data, and at the end one can retrieve average and error.

```
<Commands: types>+≡
    type, extends (command_t) :: cmd_observable_t
        private
        type(string_t) :: id
        contains
        <Commands: cmd observable: TBP>
    end type cmd_observable_t
```

Output. We know the ID.

```
<Commands: cmd observable: TBP>≡
    procedure :: write => cmd_observable_write

<Commands: procedures>+≡
    subroutine cmd_observable_write (cmd, unit, indent)
        class(cmd_observable_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A)") "observable: ", char (cmd%id)
    end subroutine cmd_observable_write
```

Compile. Just record the observable ID.

```
<Commands: cmd observable: TBP>+≡
    procedure :: compile => cmd_observable_compile

<Commands: procedures>+≡
    subroutine cmd_observable_compile (cmd, global)
        class(cmd_observable_t), intent(inout) :: cmd

      plot%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("plot: name expression not implemented (yet)")
    end select
  end subroutine cmd_plot_init
```

Command execution. This declares the plot and allocates it in the analysis store.

```
<Commands: cmd plot: TBP>+≡
  procedure :: execute => cmd_plot_execute
```

```

<Commands: procedures>+≡
subroutine cmd_plot_execute (cmd, global)
  class(cmd_plot_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  type(graph_options_t) :: graph_options
  type(drawing_options_t) :: drawing_options

  var_list => cmd%local%get_var_list_ptr ()
  call graph_options_init (graph_options)
  call set_graph_options (graph_options, var_list)
  call drawing_options_init_plot (drawing_options)
  call set_drawing_options (drawing_options, var_list)

  call analysis_init_plot (cmd%id, graph_options, drawing_options)
end subroutine cmd_plot_execute

```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_graph_t
  private
  type(string_t) :: id
  integer :: n_elements = 0
  type(cmd_plot_t), dimension(:), allocatable :: el
  type(string_t), dimension(:), allocatable :: element_id
  contains
  <Commands: cmd graph: TBP>
end type cmd_graph_t

```

Output. Just print the ID.

```

<Commands: cmd graph: TBP>≡
procedure :: write => cmd_graph_write

<Commands: procedures>+≡
subroutine cmd_graph_write (cmd, unit, indent)
  class(cmd_graph_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u

  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,A,A,I0,A)" "graph: ", char (cmd%id), &
    " (", cmd%n_elements, " entries)"
end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: compile => cmd_graph_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_compile (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
    integer :: i

    pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      cmd%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("graph: name expression not implemented (yet)")
    end select
    pn_def => parse_node_get_next_ptr (pn_term, 2)
    cmd%n_elements = parse_node_get_n_sub (pn_def)
    allocate (cmd%element_id (cmd%n_elements))
    allocate (cmd%el (cmd%n_elements))
    pn_term => parse_node_get_sub_ptr (pn_def)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%el(1)%init (pn_tag, global)
    cmd%element_id(1) = parse_node_get_string (pn_tag)
    pn_app => parse_node_get_next_ptr (pn_term)
    do i = 2, cmd%n_elements
      pn_term => parse_node_get_sub_ptr (pn_app, 2)
      pn_tag => parse_node_get_sub_ptr (pn_term)
      cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
      call cmd%el(i)%init (pn_tag, global)
      cmd%element_id(i) = parse_node_get_string (pn_tag)
      pn_app => parse_node_get_next_ptr (pn_app)
    end do

  end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: execute => cmd_graph_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_execute (cmd, global)

```

```

class(cmd_graph_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(var_list_t), pointer :: var_list
type(graph_options_t) :: graph_options
type(drawing_options_t) :: drawing_options
integer :: i, type

var_list => cmd%local%get_var_list_ptr ()
call graph_options_init (graph_options)
call set_graph_options (graph_options, var_list)
call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

do i = 1, cmd%n_elements
  if (associated (cmd%el(i)%options)) then
    call cmd%el(i)%options%execute (cmd%el(i)%local)
  end if
  type = analysis_store_get_object_type (cmd%element_id(i))
  select case (type)
  case (AN_HISTOGRAM)
    call drawing_options_init_histogram (drawing_options)
  case (AN_PLOT)
    call drawing_options_init_plot (drawing_options)
  end select
  call set_drawing_options (drawing_options, var_list)
  if (associated (cmd%el(i)%options)) then
    call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
  end if
  call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
end do
end subroutine cmd_graph_execute

```

Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
  type :: analysis_id_t
  type(string_t) :: tag
  type(parse_node_t), pointer :: pn_sexpr => null ()
end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_analysis_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  ⟨Commands: cmd analysis: TBP⟩
end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```
<Commands: cmd analysis: TBP>≡  
  procedure :: write => cmd_analysis_write  
  
<Commands: procedures>+≡  
  subroutine cmd_analysis_write (cmd, unit, indent)  
    class(cmd_analysis_t), intent(in) :: cmd  
    integer, intent(in), optional :: unit, indent  
    integer :: u  
    u = given_output_unit (unit); if (u < 0) return  
    call write_indent (u, indent)  
    write (u, "(1x,A)") "analysis: [defined]"  
  end subroutine cmd_analysis_write
```

Compile. Simply store the parse (sub)tree.

```
<Commands: cmd analysis: TBP>+≡  
  procedure :: compile => cmd_analysis_compile  
  
<Commands: procedures>+≡  
  subroutine cmd_analysis_compile (cmd, global)  
    class(cmd_analysis_t), intent(inout) :: cmd  
    type(rt_data_t), intent(inout), target :: global  
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)  
  end subroutine cmd_analysis_compile
```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```
<Commands: cmd analysis: TBP>+≡  
  procedure :: execute => cmd_analysis_execute  
  
<Commands: procedures>+≡  
  subroutine cmd_analysis_execute (cmd, global)  
    class(cmd_analysis_t), intent(inout) :: cmd  
    type(rt_data_t), intent(inout), target :: global  
    global%pn%analysis_lexpr => cmd%pn_lexpr  
  end subroutine cmd_analysis_execute
```

Write histograms and plots

The data type encapsulating the command:

```
<Commands: types>+≡  
  type, extends (command_t) :: cmd_write_analysis_t  
    private  
    type(analysis_id_t), dimension(:), allocatable :: id  
    type(string_t), dimension(:), allocatable :: tag  
  contains  
    <Commands: cmd write analysis: TBP>  
  end type cmd_write_analysis_t
```

Output. Just the keyword.

```
<Commands: cmd write analysis: TBP>≡  
  procedure :: write => cmd_write_analysis_write
```

```

<Commands: procedures>+≡
subroutine cmd_write_analysis_write (cmd, unit, indent)
  class(cmd_write_analysis_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A)") "write_analysis"
end subroutine cmd_write_analysis_write

```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: compile => cmd_write_analysis_compile

<Commands: procedures>+≡
subroutine cmd_write_analysis_compile (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
  integer :: n, i
  pn_clause => parse_node_get_sub_ptr (cmd%pn)
  pn_args => parse_node_get_sub_ptr (pn_clause, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
  call cmd%compile_options (global)
  if (associated (pn_args)) then
    n = parse_node_get_n_sub (pn_args)
    allocate (cmd%id (n))
    do i = 1, n
      pn_id => parse_node_get_sub_ptr (pn_args, i)
      if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
        cmd%id(i)%tag = parse_node_get_string (pn_id)
      else
        cmd%id(i)%pn_sexpr => pn_id
      end if
    end do
  else
    allocate (cmd%id (0))
  end if
end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

<Commands: parameters>+≡
character(*), parameter, public :: &
  DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
  FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(5), parameter, public :: &
  FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "lo", "la" ]
character(len=3), dimension(14), parameter, public :: &
  FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
    "f95", "log", "ltp", "mpx", "pdf", "phs", "sin", "tex" ]

```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```

<Commands: cmd write analysis: TBP>+≡
    procedure :: execute => cmd_write_analysis_execute

<Commands: procedures>+≡
    subroutine cmd_write_analysis_execute (cmd, global)
        class(cmd_write_analysis_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(var_list_t), pointer :: var_list
        var_list => cmd%local%get_var_list_ptr ()
        call write_analysis_wrap (var_list, global%out_files, &
            cmd%id, tag = cmd%tag)
    end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

```

<Commands: procedures>+≡
    subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
        type(var_list_t), intent(inout), target :: var_list
        type(file_list_t), intent(inout), target :: out_files
        type(analysis_id_t), dimension(:), intent(in), target :: id

      end if
    end if
  end subroutine cmd_printf_execute

```

Record data

The expression syntax already contains a `record` keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_record_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  ⟨Commands: cmd record: TBP⟩
  end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

⟨Commands: cmd record: TBP⟩≡
  procedure :: write => cmd_record_write

⟨Commands: procedures⟩+≡
  subroutine cmd_record_write (cmd, unit, indent)
    class(cmd_record_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u

```

```

    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "record"
end subroutine cmd_record_write

```

Compile. This is a hack which transforms the `record` command into a `record` expression, which we handle in the `expressions` module.

```

⟨Commands: cmd record: TBP⟩+≡
    procedure :: compile => cmd_record_compile

⟨Commands: procedures⟩+≡

```

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

            // char (parse_node_get_rule_key (pn)) &
            // "' not implemented")
    end select
end subroutine range_init

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

```

Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

Note: for the integer/real range array, the obvious implementation as a polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are apparently broken.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_scan_t
    private
    type(string_t) :: name
    integer :: n_values = 0
    type(parse_node_t), dimension(:), allocatable :: scan_cmd
    !!! !!! gfortran 4.7.x memory corruption
    !!! class(range_t), dimension(:), allocatable :: range
    type(range_int_t), dimension(:), allocatable :: range_int
    type(range_real_t), dimension(:), allocatable :: range_real
    contains
    <Commands: cmd scan: TBP>
  end type cmd_scan_t
```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```
<Commands: cmd scan: TBP>≡
  procedure :: final => cmd_scan_final

<Commands: procedures>+≡
  recursive subroutine cmd_scan_final (cmd)
    class(cmd_scan_t), intent(inout) :: cmd

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local

environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

```

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of **else if** constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

⟨Commands: types⟩+≡

                // "neither branch will be executed")
        end subroutine error_undecided
    end subroutine cmd_if_execute

```

Include another command-list file

The include command allocates a local parse tree. This must not be deleted before the command object itself is deleted, since pointers may point to subobjects of it.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_include_t
    private
        type(string_t) :: file
        type(command_list_t), pointer :: command_list => null ()
        type(parse_tree_t) :: parse_tree
    contains
        <Commands: cmd include: TBP>
    end type cmd_include_t

```

Finalizer: delete the command list. No options, so we can simply override the default finalizer.

```

<Commands: cmd include: TBP>≡
    procedure :: final => cmd_include_final

<Commands: procedures>+≡
    subroutine cmd_include_final (cmd)
        class(cmd_include_t), intent(inout) :: cmd
        call parse_tree_final (cmd%parse_tree)
        if (associated (cmd%command_list)) then
            call cmd%command_list%final ()
            deallocate (cmd%command_list)
        end if
    end subroutine cmd_include_final

```

Write: display the command list as-is, if allocated.

```

<Commands: cmd include: TBP>+≡
    procedure :: write => cmd_include_write

<Commands: procedures>+≡
    subroutine cmd_include_write (cmd, unit, indent)
        class(cmd_include_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u, ind
        u = given_output_unit (unit)
        ind = 0; if (present (indent)) ind = indent
        call write_indent (u, indent)
    end subroutine cmd_include_write

```

```

write (u, "(A,A,A,A)") "include ", "'", char (cmd%file), "'"
if (associated (cmd%command_list)) then
    call cmd%command_list%write (u, ind + 1)
end if
end subroutine cmd_include_write

```

Compile file contents: First parse the file, then immediately compile its contents.
Use the global data set.

```

<Commands: cmd include: TBP>+≡
    procedure :: compile => cmd_include_compile

<Commands: procedures>+≡
    subroutine cmd_include_compile (cmd, global)
        class(cmd_include_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_arg, pn_file
        type(string_t) :: file
        logical :: exist
        integer :: u
        type(stream_t), target :: stream
        type(lexer_t) :: lexer
        pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
        pn_file => parse_node_get_sub_ptr (pn_arg)
        file = parse_node_get_string (pn_file)
        inquire (file=char(file), exist=exist)
        if (exist) then
            cmd%file = file
        else
            cmd%file = global%os_data%whizard_cutspath // "/" // file
            inquire (file=char(cmd%file), exist=exist)
            if (.not. exist) then
                call msg_error ("Include file '" // char (file) // "' not found")
                return
            end if
        end if
        u = free_unit ()
        call lexer_init_cmd_list (lexer, global%lexer)
        call stream_init (stream, char (cmd%file))
        call lexer_assign_stream (lexer, stream)
        call parse_tree_init (cmd%parse_tree, syntax_cmd_list, lexer)
        call stream_final (stream)
        call lexer_final (lexer)
        close (u)
        allocate (cmd%command_list)
        call cmd%command_list%compile (parse_tree_get_root_ptr (cmd%parse_tree), &
            global)
    end subroutine cmd_include_compile

```

Execute file contents in the global context.

```

<Commands: cmd include: TBP>+≡
    procedure :: execute => cmd_include_execute

<Commands: procedures>+≡
    subroutine cmd_include_execute (cmd, global)

```

```

class(cmd_include_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
if (associated (cmd%command_list)) then
  call msg_message &
    ("Including Sindarin from '" // char (cmd%file) // "'")
  call cmd%command_list%execute (global)
  call msg_message &
    ("End of included '" // char (cmd%file) // "'")
end if
end subroutine cmd_include_execute

```

Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_quit_t
  private
  logical :: has_code = .false.
  type(parse_node_t), pointer :: pn_code_expr => null ()
contains
  <Commands: cmd quit: TBP>
end type cmd_quit_t

```

Output.

```

<Commands: cmd quit: TBP>≡
  procedure :: write => cmd_quit_write

<Commands: procedures>+≡
  subroutine cmd_quit_write (cmd, unit, indent)
    class(cmd_quit_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,L1)") "quit: has_code = ", cmd%has_code
  end subroutine cmd_quit_write

```

Compile: allocate a quit object which serves as a placeholder.

```

<Commands: cmd quit: TBP>+≡
  procedure :: compile => cmd_quit_compile

<Commands: procedures>+≡
  subroutine cmd_quit_compile (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_arg
    pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
    if (associated (pn_arg)) then
      cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
      cmd%has_code = .true.
    end if
  end if

```

```
end subroutine cmd_quit_compile
```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```
<Commands: cmd quit: TBP>+≡
  procedure :: execute => cmd_quit_execute

<Commands: procedures>+≡
  subroutine cmd_quit_execute (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    logical :: is_known
    var_list => global%get_var_list_ptr ()
    if (cmd%has_code) then
      global%quit_code = eval_int (cmd%pn_code_expr, var_list, &
        is_known=is_known)
      if (.not. is_known) then
        call msg_error ("Undefined return code of quit/exit command")
      end if
    end if
    global%quit = .true.
  end subroutine cmd_quit_execute
```

31.1.6 The command list

The command list holds a list of commands and relevant global data.

```
<Commands: public>+≡
  public :: command_list_t

<Commands: types>+≡
  type :: command_list_t
    ! not private anymore as required by the whizard-c-interface
    class(command_t), pointer :: first => null ()
    class(command_t), pointer :: last => null ()
  contains
    <Commands: command list: TBP>
  end type command_list_t
```

Output.

```
<Commands: command list: TBP>≡
  procedure :: write => command_list_write

<Commands: procedures>+≡
  recursive subroutine command_list_write (cmd_list, unit, indent)
    class(command_list_t), intent(in) :: cmd_list
    integer, intent(in), optional :: unit, indent
    class(command_t), pointer :: cmd
    cmd => cmd_list%first
    do while (associated (cmd))
```

```

        call cmd%write (unit, indent)
        cmd => cmd%next
    end do
end subroutine command_list_write

```

Append a new command to the list and free the original pointer.

```

<Commands: command list: TBP>+≡
    procedure :: append => command_list_append

<Commands: procedures>+≡
    subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
        if (associated (cmd_list%last)) then
            cmd_list%last%next => command
        else
            cmd_list%first => command
        end if
        cmd_list%last => command
        command => null ()
    end subroutine command_list_append

```

Finalize.

```

<Commands: command list: TBP>+≡
    procedure :: final => command_list_final

<Commands: procedures>+≡
    recursive subroutine command_list_final (cmd_list)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), pointer :: command
        do while (associated (cmd_list%first))
            command => cmd_list%first
            cmd_list%first => cmd_list%first%next
            call command%final ()
            deallocate (command)
        end do
        cmd_list%last => null ()
    end subroutine command_list_final

```

31.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```

<Commands: command list: TBP>+≡
    procedure :: compile => command_list_compile

<Commands: procedures>+≡
    recursive subroutine command_list_compile (cmd_list, pn, global)
        class(command_list_t), intent(inout), target :: cmd_list
        type(parse_node_t), intent(in), target :: pn
        type(rt_data_t), intent(inout), target :: global

```

```

type(parse_node_t), pointer :: pn_cmd
class(command_t), pointer :: command
integer :: i
pn_cmd => parse_node_get_sub_ptr (pn)
do i = 1, parse_node_get_n_sub (pn)
    call dispatch_command (command, pn_cmd)
    call command%compile (global)
    call cmd_list%append (command)
    call terminate_now_if_signal ()
    pn_cmd => parse_node_get_next_ptr (pn_cmd)
end do
end subroutine command_list_compile

```

31.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```

<Commands: command list: TBP>+≡
    procedure :: execute => command_list_execute

<Commands: procedures>+≡
    recursive subroutine command_list_execute (cmd_list, global)
        class(command_list_t), intent(in) :: cmd_list
        type(rt_data_t), intent(inout), target :: global
        class(command_t), pointer :: command
        command => cmd_list%first
        COMMAND_COND: do while (associated (command))
            call command%execute_options (global)
            call command%execute (global)
            call command%reset_options (global)
            call terminate_now_if_signal ()
            if (global%quit) exit COMMAND_COND
            command => command%next
        end do COMMAND_COND
    end subroutine command_list_execute

```

31.1.9 Command list syntax

```

<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡
    public :: syntax_cmd_list_init

<Commands: procedures>+≡
    subroutine syntax_cmd_list_init ()
        type(ifile_t) :: ifile
        call define_cmd_list_syntax (ifile)
    end subroutine

```

```

        call syntax_init (syntax_cmd_list, ifile)
        call ifile_final (ifile)
    end subroutine syntax_cmd_list_init

    <Commands: public>+≡
        public :: syntax_cmd_list_final

    <Commands: procedures>+≡
        subroutine syntax_cmd_list_final ()
            call syntax_final (syntax_cmd_list)
        end subroutine syntax_cmd_list_final

    <Commands: public>+≡
        public :: syntax_cmd_list_write

    <Commands: procedures>+≡
        subroutine syntax_cmd_list_write (unit)
            integer, intent(in), optional :: unit
            call syntax_write (syntax_cmd_list, unit)
        end subroutine syntax_cmd_list_write

    <Commands: procedures>+≡

Compile Process

Read a model, then declare a process and compile the library. The process library is allocated explicitly. For the process definition, We take the default (`unit_test`) method. There is no external code, so compilation of the library is merely a formal status change.

```

⟨Standard module head⟩

⟨WHIZARD: public⟩

⟨WHIZARD: types⟩

    save

contains

⟨WHIZARD: procedures⟩

end module whizard

```

31.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```

⟨WHIZARD: public⟩≡
    public :: whizard_options_t

⟨WHIZARD: types⟩≡
    type :: whizard_options_t
        type(string_t) :: preload_model
        type(string_t) :: default_lib
        type(string_t) :: preload_libraries
        logical :: rebuild_library = .false.
        logical :: recompile_library = .false.
        logical :: rebuild_user
        logical :: rebuild_phs = .false.
        logical :: rebuild_grids = .false.
        logical :: rebuild_events = .false.
    end type whizard_options_t

```

31.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

⟨WHIZARD: types⟩+≡
    type, extends (parse_tree_t) :: pt_entry_t
        type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the `last` pointer.

```

⟨WHIZARD: types⟩+≡
    type :: pt_stack_t
        type(pt_entry_t), pointer :: last => null ()

```

```

contains
  <WHIZARD: pt_stack: TBP>
end type pt_stack_t

```

The finalizer is called at the very end.

```

<WHIZARD: pt_stack: TBP>≡
  procedure :: final => pt_stack_final

<WHIZARD: procedures>≡
  subroutine pt_stack_final (pt_stack)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(pt_entry_t), pointer :: current
    do while (associated (pt_stack%last))
      current => pt_stack%last
      pt_stack%last => current%previous
      call parse_tree_final (current%parse_tree_t)
      deallocate (current)
    end do
  end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt_stack: TBP>+≡
  procedure :: push => pt_stack_push

<WHIZARD: procedures>+≡
  subroutine pt_stack_push (pt_stack, parse_tree)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(parse_tree_t), intent(out), pointer :: parse_tree
    type(pt_entry_t), pointer :: current
    allocate (current)
    parse_tree => current%parse_tree_t
    current%previous => pt_stack%last
    pt_stack%last => current
  end subroutine pt_stack_push

```

31.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a `WHIZARD` instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+≡
  public :: whizard_t

```

```

<WHIZARD: types>+=
  type :: whizard_t
    type(whizard_options_t) :: options
    type(rt_data_t) :: global
    type(pt_stack_t) :: pt_stack
  contains
    <WHIZARD: whizard: TBP>
  end type whizard_t

```

31.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>=
  procedure :: init => whizard_init

<WHIZARD: procedures>+=
  subroutine whizard_init (whizard, options, paths, logfile)
    class(whizard_t), intent(out), target :: whizard
    type(whizard_options_t), intent(in) :: options
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
    call init_syntax_tables ()
    whizard%options = options
    call whizard%global%global_init (paths, logfile)
    call whizard%init_rebuild_flags ()
    call whizard%preload_model ()
    call whizard%preload_library ()
    call whizard%global%init_fallback_model &
      (var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))
    call whizard%global%init_radiation_model &
      (var_str ("SM_rad"), var_str ("SM_rad.mdl"))
  end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+=
  procedure :: final => whizard_final

<WHIZARD: procedures>+=
  subroutine whizard_final (whizard)
    class(whizard_t), intent(inout), target :: whizard
    call whizard%global%final ()
    call whizard%pt_stack%final ()
    !!! JRR: WK please check (#529)
    !   call user_code_final ()
    call final_syntax_tables ()
  end subroutine whizard_final

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+=
  procedure :: init_rebuild_flags => whizard_init_rebuild_flags

```

```

<WHIZARD: procedures>+≡
subroutine whizard_init_rebuild_flags (whizard)
  class(whizard_t), intent(inout), target :: whizard
  associate (var_list => whizard%global%var_list, options => whizard%options)
    call var_list_append_log &
      (var_list, var_str ("?rebuild_library"), options%rebuild_library, &
        intrinsic=.true.)
    call var_list_append_log &
      (var_list, var_str ("?recompile_library"), &
        options%recompile_library, &
        intrinsic=.true.)
    call var_list_append_log &
      (var_list, var_str ("?rebuild_phase_space"), options%rebuild_phs, &
        intrinsic=.true.)
    call var_list_append_log &
      (var_list, var_str ("?rebuild_grids"), options%rebuild_grids, &
        intrinsic=.true.)
    call var_list_append_log &
      (var_list, var_str ("?rebuild_events"), options%rebuild_events, &
        intrinsic=.true.)
  end associate
end subroutine whizard_init_rebuild_flags

```

This procedure preloads a model, if a model name is given.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: preload_model => whizard_preload_model

<WHIZARD: procedures>+≡
subroutine whizard_preload_model (whizard)
  class(whizard_t), intent(inout), target :: whizard
  type(string_t) :: model_name
  model_name = whizard%options%preload_model
  if (model_name /= "") then
    call whizard%global%read_model (model_name, whizard%global%preload_model)
    whizard%global%model => whizard%global%preload_model
    if (associated (whizard%global%model)) then
      call whizard%global%model%link_var_list (whizard%global%var_list)
      call msg_message ("Preloaded model: " &
        // char (model_name))
    else
      call msg_fatal ("Preloading model " // char (model_name) &
        // " failed")
    end if
  else
    call msg_message ("No model preloaded")
  end if
end subroutine whizard_preload_model

```

This procedure preloads a library, if a library name is given.

Note: This version just opens a new library with that name. It does not load (yet) an existing library on file, as previous WHIZARD versions would do.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: preload_library => whizard_preload_library

```

```

<WHIZARD: procedures>+≡
subroutine whizard_preload_library (whizard)
  class(whizard_t), intent(inout), target :: whizard

  type(string_t), dimension(:), allocatable :: libname_static
  type(prclib_entry_t), pointer :: lib_entry
  integer :: i
  call get_prclib_static (libname_static)
  do i = 1, size (libname_static)
    allocate (lib_entry)
    call lib_entry%init_static (libname_static(i))
    call whizard%global%add_prclib (lib_entry)
  end do
  libs = adjustl (whizard%options%preload_libraries)
  if (libs == "" .and. whizard%options%default_lib /= "") then
    allocate (lib_entry)
    call lib_entry%init (whizard%options%default_lib)
    call whizard%global%add_prclib (lib_entry)
    call msg_message ("Preloaded library: " // &
      char (whizard%options%default_lib))
  end if
SCAN_LIBS: do while (libs /= "")
  call split (libs, library_name, " ")
  if (library_name /= "") then
    allocate (lib_entry)
    call lib_entry%init (library_name)
    call whizard%global%add_prclib (lib_entry)
    call msg_message ("Preloaded library: " // char (library_name))
  end if
end do SCAN_LIBS
end subroutine whizard_preload_library

```

31.2.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

```

<WHIZARD: public>+≡
  public :: init_syntax_tables
  public :: final_syntax_tables

<WHIZARD: procedures>+≡
subroutine init_syntax_tables ()
  call syntax_model_file_init ()
  call syntax_phs_forest_init ()
  call syntax_pexpr_init ()

```

```

    call syntax_slha_init ()
    call syntax_blha_contract_init ()
    call syntax_cmd_list_init ()
end subroutine init_syntax_tables

subroutine final_syntax_tables ()
    call syntax_model_file_final ()
    call syntax_phs_forest_final ()
    call syntax_pexpr_final ()
    call syntax_slha_final ()
    call syntax_blha_contract_final ()
    call syntax_cmd_list_final ()
end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
    public :: write_syntax_tables

<WHIZARD: procedures>+≡
    subroutine write_syntax_tables ()
        integer :: unit
        character(*), parameter :: file_model = "whizard.model_file.syntax"
        character(*), parameter :: file_phs = "whizard.phase_space_file.syntax"
        character(*), parameter :: file_pexpr = "whizard.prt_expressions.syntax"
        character(*), parameter :: file_slha = "whizard.slha.syntax"
        character(*), parameter :: file_sindarin = "whizard.sindarin.syntax"
        unit = free_unit ()
        print *, "Writing file '" // file_model // "'"
        open (unit=unit, file=file_model, status="replace", action="write")

    end do COMMAND_LOOP
    print *
    call lexer_final (lexer)
  end subroutine whizard_shell

```

31.2.8 Self-tests

For those self-tests, we need some auxiliary routines that provide an environment. The environment depends on things that are not available at the level of the module that we want to test.

Testbed for event I/O

This subroutine prepares a test process with a single event. All objects are allocated via anonymous pointers, because we want to recover the pointers and delete the objects in a separate procedure.

<WHIZARD: procedures>+≡

```
subroutine prepare_eio_test (event, unweighted, n_alt)
  use variables
  use model_data
  use event_base
  class(generic_event_t), intent(inout), pointer :: event
  logical, intent(in), optional :: unweighted
  integer, intent(in), optional :: n_alt
  type(model_data_t), pointer :: model
  type(var_list_t) :: var_list
  type(process_t), pointer :: process
  type(process_instance_t), pointer :: process_instance

  allocate (model)
  call model%init_test ()

  allocate (process)
  allocate (process_instance)

  call prepare_test_process (process, process_instance, model)
  call process_instance%setup_event_data ()

  call model%final ()
  deallocate (model)

  allocate (event_t :: event)
  select type (event)
  type is (event_t)
    if (present (unweighted)) then
      call var_list_append_log (var_list, &
        var_str ("?unweighted"), unweighted, &
        intrinsic = .true.)
    else
      call var_list_append_log (var_list, &
        var_str ("?unweighted"), .true., &
        intrinsic = .true.)
    end if
    call var_list_append_string (var_list, &
      var_str ("$_sample_normalization"), &
      var_str ("auto"), intrinsic = .true.)
    call event%basic_init (var_list, n_alt)
    call event%connect (process_instance, process%get_model_ptr ())
    call var_list%final ()
  end select
end subroutine prepare_eio_test
```

Recover those pointers, finalize the objects and deallocate.

<WHIZARD: procedures>+≡

```

subroutine cleanup_eio_test (event)
  use model_data
  use event_base
  class(generic_event_t), intent(inout), pointer :: event
  type(process_t), pointer :: process
  type(process_instance_t), pointer :: process_instance
  select type (event)
  type is (event_t)
    process => event%get_process_ptr ()
    process_instance => event%get_process_instance_ptr ()
    call cleanup_test_process (process, process_instance)
    deallocate (process_instance)
    deallocate (process)
    call event%final ()
  end select
  deallocate (event)
end subroutine cleanup_eio_test

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

<WHIZARD: prepare testbed>≡
  eio_prepare_test => prepare_eio_test
  eio_cleanup_test => cleanup_eio_test

```

Any Model

This procedure reads any model from file and, optionally, assigns a var-list pointer.

```

<WHIZARD: procedures>+≡
  subroutine prepare_whizard_model (model, name, vars)
  <Use strings>
    use os_interface
    use model_data
    use var_base
    use models
    class(model_data_t), intent(inout), pointer :: model
    type(string_t), intent(in) :: name
    class(vars_t), pointer, intent(out), optional :: vars
    type(os_data_t) :: os_data
    call syntax_model_file_init ()
    call os_data_init (os_data)
    allocate (model_t :: model)
    select type (model)
    type is (model_t)
      call model%read (name // ".mdl", os_data)
      if (present (vars)) then
        vars => model%get_var_list_ptr ()
      end if
    end select
  end subroutine prepare_whizard_model

```

Cleanup after use. Includes deletion of the model-file syntax.

```

<WHIZARD: procedures>+≡
  subroutine cleanup_whizard_model (model)
    use model_data
    use models
    class(model_data_t), intent(inout), pointer :: model
    call model%final ()
    deallocate (model)
    call syntax_model_file_final ()
  end subroutine cleanup_whizard_model

```

Assign those procedures to appropriate pointers (module variables) in the `model_testbed` module, so they can be called as if they were module procedures.

```

<WHIZARD: prepare testbed>+≡
  prepare_model => prepare_whizard_model
  cleanup_model => cleanup_whizard_model

```

Fallback model: hadrons

Some event format tests require the hadronic SM implementation, which has to be read from file. We provide the functionality here, so the tests do not depend on model I/O.

```

<WHIZARD: procedures>+≡
  subroutine prepare_fallback_model (model)
    use model_data
    class(model_data_t), intent(inout), pointer :: model
    call prepare_whizard_model (model, var_str ("SM_hadrons"))
  end subroutine prepare_fallback_model

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

<WHIZARD: prepare testbed>+≡
  eio_prepare_fallback_model => prepare_fallback_model
  eio_cleanup_fallback_model => cleanup_model

```

Procedure for Checking

This is for developers only, but needs a well-defined interface.

```

<WHIZARD: public>+≡
