For the following tests, we define a simple implementation of the abstract `prc_core_t`, designed such as to complement the `prc_test_t` process definition type.

Note that it is not given that the actual process is defined as `prc_test_t` type. We enforce this by calling `prc_test_create_library`. The driver component in the process core will then become of type `prc_test_t`.

```

<Processes: public>+≡
    public :: test_t

```

```

<Processes: test types>≡
  type, extends (prc_core_t) :: test_t
  contains
    procedure :: write => test_write
    procedure :: needs_mcset => test_needs_mcset
    procedure :: get_n_terms => test_get_n_terms
    procedure :: is_allowed => test_is_allowed
    procedure :: compute_hard_kinematics => test_compute_hard_kinematics
    procedure :: compute_eff_kinematics => test_compute_eff_kinematics
    procedure :: recover_kinematics => test_recover_kinematics
    procedure :: compute_amplitude => test_compute_amplitude
  end type test_t

<Processes: tests>+≡
  subroutine test_write (object, unit)
    class(test_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(3x,A)") "test type implementing prc_test"
  end subroutine test_write

```

This process type always needs a MC parameter set and a single term. This only state is always allowed.

```

<Processes: tests>+≡
  function test_needs_mcset (object) result (flag)
    class(test_t), intent(in) :: object
    logical :: flag
    flag = .true.
  end function test_needs_mcset

  function test_get_n_terms (object) result (n)
    class(test_t), intent(in) :: object
    integer :: n
    n = 1
  end function test_get_n_terms

  function test_is_allowed (object, i_term, f, h, c) result (flag)
    class(test_t), intent(in) :: object
    integer, intent(in) :: i_term, f, h, c
    logical :: flag
    flag = .true.
  end function test_is_allowed

```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

```

<Processes: tests>+≡
  subroutine test_compute_hard_kinematics &
    (object, p_seed, i_term, int_hard, core_state)
    class(test_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(in) :: p_seed
    integer, intent(in) :: i_term

```

```

type(interaction_t), intent(inout) :: int_hard
class(prc_core_state_t), intent(inout), allocatable :: core_state
call int_hard%set_momenta (p_seed)
end subroutine test_compute_hard_kinematics

```

This procedure is not called for `test_t`, just a placeholder.

```

<Processes: tests>+≡
subroutine test_compute_eff_kinematics &
  (object, i_term, int_hard, int_eff, core_state)
class(test_t), intent(in) :: object
integer, intent(in) :: i_term
type(interaction_t), intent(in) :: int_hard
type(interaction_t), intent(inout) :: int_eff
class(prc_core_state_t), intent(inout), allocatable :: core_state
end subroutine test_compute_eff_kinematics

```

Transfer the incoming momenta of `p_seed` directly to the effective interaction, and vice versa for the outgoing momenta.

`int_hard` is left untouched since `int_eff` is an alias (via pointer) to it.

```

<Processes: tests>+≡
subroutine test_recover_kinematics &
  (object, p_seed, int_hard, int_eff, core_state)
class(test_t), intent(in) :: object
type(vector4_t), dimension(:), intent(inout) :: p_seed
type(interaction_t), intent(inout) :: int_hard
type(interaction_t), intent(inout) :: int_eff
class(prc_core_state_t), intent(inout), allocatable :: core_state
integer :: n_in
n_in = int_eff%get_n_in ()
call int_eff%set_momenta (p_seed(1:n_in), outgoing = .false.)
p_seed(n_in+1:) = int_eff%get_momenta (outgoing = .true.)
end subroutine test_recover_kinematics

```

Compute the amplitude. The driver ignores all quantum numbers and, in fact, returns a constant. Nevertheless, we properly transfer the momentum vectors.

```

<Processes: tests>+≡
function test_compute_amplitude &
  (object, j, p, f, h, c, fac_scale, ren_scale, alpha_qcd_forced, core_state) &
result (amp)
class(test_t), intent(in) :: object
integer, intent(in) :: j
type(vector4_t), dimension(:), intent(in) :: p
integer, intent(in) :: f, h, c
real(default), intent(in) :: fac_scale, ren_scale
real(default), intent(in), allocatable :: alpha_qcd_forced
class(prc_core_state_t), intent(inout), allocatable, optional :: core_state
complex(default) :: amp
real(default), dimension(:,:), allocatable :: parray
integer :: i, n_tot
select type (driver => object%driver)
type is (prc_test_t)
  if (driver%scattering) then

```

```

        n_tot = 4
    else
        n_tot = 3
    end if
    allocate (parray (0:3,n_tot))
    forall (i = 1:n_tot) parray(:,i) = vector4_get_components (p(i))
    amp = driver%get_amplitude (parray)
end select
end function test_compute_amplitude

```

Write an empty process object

The most trivial test is to write an uninitialized process object.

```

<Processes: execute tests>≡
    call test (processes_1, "processes_1", &
        "write an empty process object", &
        u, results)

<Processes: tests>+≡
    subroutine processes_1 (u)
        integer, intent(in) :: u
        type(process_t) :: process

        write (u, "(A)")  "* Test output: processes_1"
        write (u, "(A)")  "* Purpose: display an empty process object"
        write (u, "(A)")

        call process%write (.false., u)

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: processes_1"

    end subroutine processes_1

```

Initialize a process object

Initialize a process and display it.

```

<Processes: execute tests>+≡

```

Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

27.4 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

`<process_stacks.f90>`≡
<File header>

```

module process_stacks

<Use strings>
  use io_units
  use format_utils, only: write_separator
  use unit_tests
  use diagnostics
  use os_interface
  use sm_qcd
  use model_data
  use rng_base
  use variables
  use observables
  use process_libraries
  use prc_test
  use processes

```

```

    <Standard module head>

    <Process stacks: public>

    <Process stacks: types>

contains

    <Process stacks: procedures>

    <Process stacks: tests>

end module process_stacks

```

27.4.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```

<Process stacks: public>≡
    public :: process_entry_t

<Process stacks: types>≡
    type, extends (process_t) :: process_entry_t
        type(process_entry_t), pointer :: next => null ()
    end type process_entry_t

```

27.4.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

The process stack can be linked to another one. This allows us to work with stacks of local scope.

```

<Process stacks: public>+≡
    public :: process_stack_t

<Process stacks: types>+≡
    type :: process_stack_t
        integer :: n = 0
        type(process_entry_t), pointer :: first => null ()
        type(var_list_t), pointer :: var_list => null ()
        type(process_stack_t), pointer :: next => null ()
    contains
        <Process stacks: process stack: TBP>
    end type process_stack_t

```

Finalize partly: deallocate the process stack and variable list entries, but keep the variable list as an empty object. This way, the variable list links are kept.

```

(Process stacks: process stack: TBP)≡
  procedure :: clear => process_stack_clear

(Process stacks: procedures)≡
  subroutine process_stack_clear (stack)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), pointer :: process
    if (associated (stack%var_list)) then
      call stack%var_list%final ()
    end if
    do while (associated (stack%first))
      process => stack%first
      stack%first => process%next
      call process%final ()
      deallocate (process)
    end do
    stack%n = 0
  end subroutine process_stack_clear

```

Finalizer. Clear and deallocate the variable list.

```

(Process stacks: process stack: TBP)+≡
  procedure :: final => process_stack_final

(Process stacks: procedures)+≡
  subroutine process_stack_final (object)
    class(process_stack_t), intent(inout) :: object
    call object%clear ()
    if (associated (object%var_list)) then
      deallocate (object%var_list)
    end if
  end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

(Process stacks: process stack: TBP)+≡
  procedure :: write => process_stack_write

(Process stacks: procedures)+≡
  recursive subroutine process_stack_write (object, unit, pacify)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: pacify
    type(process_entry_t), pointer :: process
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    select case (object%n)
    case (0)
      write (u, "(1x,A)") "Process stack: [empty]"
      call write_separator (u, 2)
    case default
      write (u, "(1x,A)") "Process stack:"
      process => object%first
    end select
  end subroutine process_stack_write

```

```

        do while (associated (process))
            call process%write (.false., u, pacify = pacify)
            process => process%next
        end do
    end select
    if (associated (object%next)) then
        write (u, "(1x,A)") "[Processes from context environment:]"
        call object%next%write (u, pacify)
    end if
end subroutine process_stack_write

```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write_var_list => process_stack_write_var_list
<Process stacks: procedures>+≡
    subroutine process_stack_write_var_list (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        if (associated (object%var_list)) then
            call var_list_write (object%var_list, unit)
        end if
    end subroutine process_stack_write_var_list

```

Short output.

```

<Process stacks: process stack: TBP>+≡
    procedure :: show => process_stack_show
<Process stacks: procedures>+≡
    recursive subroutine process_stack_show (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)
        select case (object%n)
        case (0)
        case default
            process => object%first
            do while (associated (process))
                call process%show (u, verbose=.false.)
                process => process%next
            end do
        end select
        if (associated (object%next)) call object%next%show ()
    end subroutine process_stack_show

```

27.4.3 Link

Link the current process stack to a global one.

```

<Process stacks: process stack: TBP>+≡
    procedure :: link => process_stack_link

```

```

<Process stacks: procedures>+≡
  subroutine process_stack_link (local_stack, global_stack)
    class(process_stack_t), intent(inout) :: local_stack
    type(process_stack_t), intent(in), target :: global_stack
    local_stack%next => global_stack
  end subroutine process_stack_link

```

Initialize the process variable list and link the main variable list to it.

```

<Process stacks: process stack: TBP>+≡
  procedure :: init_var_list => process_stack_init_var_list

<Process stacks: procedures>+≡
  subroutine process_stack_init_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(inout), optional :: var_list
    allocate (stack%var_list)
    if (present (var_list)) call var_list%link (stack%var_list)
  end subroutine process_stack_init_var_list

```

Link the process variable list to a global variable list.

```

<Process stacks: process stack: TBP>+≡
  procedure :: link_var_list => process_stack_link_var_list

<Process stacks: procedures>+≡
  subroutine process_stack_link_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in), target :: var_list
    call stack%var_list%link (var_list)
  end subroutine process_stack_link_var_list

```

27.4.4 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

<Process stacks: process stack: TBP>+≡
  procedure :: push => process_stack_push

<Process stacks: procedures>+≡
  subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    process%next => stack%first
    stack%first => process
    process => null ()
    stack%n = stack%n + 1
  end subroutine process_stack_push

```

Initialize process variables for a given process ID, without setting values.

```

<Process stacks: process stack: TBP>+≡
  procedure :: init_result_vars => process_stack_init_result_vars

```

```

<Process stacks: procedures>+≡
  subroutine process_stack_init_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    call var_list_init_num_id (stack%var_list, id)
    call var_list_init_process_results (stack%var_list, id)
  end subroutine process_stack_init_result_vars

```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```

<Process stacks: process stack: TBP>+≡
  procedure :: fill_result_vars => process_stack_fill_result_vars

<Process stacks: procedures>+≡
  subroutine process_stack_fill_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    type(process_t), pointer :: process
    process => stack%get_process_ptr (id)
    if (associated (process)) then
      call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
      if (process%has_integral ()) then
        call var_list_init_process_results (stack%var_list, id, &
          integral = process%get_integral (), &

      end if
    else
      call msg_bug ("process_stack_fill_result_vars: unknown process ID")
    end if
  end subroutine process_stack_fill_result_vars

```

27.4.5 Data Access

Tell if a process exists.

```

<Process stacks: process stack: TBP>+≡
  procedure :: exists => process_stack_exists

<Process stacks: procedures>+≡
  function process_stack_exists (stack, id) result (flag)
    class(process_stack_t), intent(in) :: stack
    type(string_t), intent(in) :: id
    logical :: flag
    type(process_t), pointer :: process
    process => stack%get_process_ptr (id)
    flag = associated (process)
  end function process_stack_exists

```

Return a pointer to a process with specific ID. Look also at a linked stack, if necessary.

```

<Process stacks: process stack: TBP>+≡

```

```

    procedure :: get_process_ptr => process_stack_get_process_ptr
  <Process stacks: procedures>+≡
    recursive function process_stack_get_process_ptr (stack, id) result (ptr)
      class(process_stack_t), intent(in) :: stack
      type(string_t), intent(in) :: id
      type(process_t), pointer :: ptr
      type(process_entry_t), pointer :: entry
      ptr => null ()
      entry => stack%first
      do while (associated (entry))
        if (entry%get_id () == id) then
          ptr => entry%process_t
          return
        end if
        entry => entry%next
      end do
      if (associated (stack%next)) ptr => stack%next%get_process_ptr (id)
    end function process_stack_get_process_ptr

```

27.4.6 Unit tests

```

  <Process stacks: public>+≡
    public :: process_stacks_test

  <Process stacks: tests>≡
    subroutine process_stacks_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
    <Process stacks: execute tests>
    end subroutine process_stacks_test

```

Write an empty process stack

The most trivial test is to write an uninitialized process stack.

```

  <Process stacks: execute tests>≡
    call test (process_stacks_1, "process_stacks_1", &
      "write an empty process stack", &
      u, results)

  <Process stacks: tests>+≡
    subroutine process_stacks_1 (u)
      integer, intent(in) :: u
      type(process_stack_t) :: stack

      write (u, "(A)")  "* Test output: process_stacks_1"
      write (u, "(A)")  "* Purpose: display an empty process stack"
      write (u, "(A)")

      call stack%write (u)

      write (u, "(A)")
      write (u, "(A)")  "* Test output end: process_stacks_1"

```

```
end subroutine process_stacks_1
```

Fill a process stack

Fill a process stack with two (identical) processes.

```
<Process stacks: execute tests>+≡
  call test (process_stacks_2, "process_stacks_2", &
    "fill a process stack", &
    u, results)

<Process stacks: tests>+≡
  subroutine process_stacks_2 (u)

call stack2%push (process)

write (u, "(A)")  "* Show linked stacks"
write (u, "(A)")

call stack2%write (u)

write (u, "(A)")
write (u, "(A)")  "* Cleanup"

call stack2%final ()
call stack1%final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: process_stacks_4"

end subroutine process_stacks_4

```

Chapter 28

Event Implementation

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

event_transforms Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

decays Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

showers Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

events Combine all pieces to generate full events.

eio_raw Raw I/O for complete events.

28.1 Abstract Event Transforms

```
<event_transforms.f90>≡  
  <File header>  
  
  module event_transforms  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use format_utils, only: write_separator  
    use unit_tests
```

```

use diagnostics
use os_interface
use sm_qcd
use model_data
use state_matrices
use interactions
use particles
use subevents
use process_libraries
use prc_core
use prc_test
use rng_base
use mci_base
use mci_midpoint
use phs_base
use phs_single
use processes
use process_stacks
use powheg

<Standard module head>

<Event transforms: public>

<Event transforms: types>

<Event transforms: interfaces>

contains

<Event transforms: procedures>

<Event transforms: tests>

end module event_transforms

```

28.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified setting that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include `previous` and `next` pointers.

```

<Event transforms: public>≡
    public :: evt_t

<Event transforms: types>≡
    type, abstract :: evt_t

```

```

type(process_t), pointer :: process => null ()
type(process_instance_t), pointer :: process_instance => null ()
class(model_data_t), pointer :: model => null ()
class(rng_t), allocatable :: rng
integer :: rejection_count = 0
logical :: particle_set_exists = .false.
type(particle_set_t) :: particle_set
class(evt_t), pointer :: previous => null ()
class(evt_t), pointer :: next => null ()
contains
  <Event transforms: evt: TBP>
end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡
  procedure :: final => evt_final
  procedure :: base_final => evt_final

<Event transforms: procedures>≡
  subroutine evt_final (object)
    class(evt_t), intent(inout) :: object
    if (allocated (object%rng)) call object%rng%final ()
    if (object%particle_set_exists) &
      call object%particle_set%final ()
  end subroutine evt_final

<Event transforms: evt: TBP>+≡
  procedure (evt_write), deferred :: write

<Event transforms: interfaces>≡
  abstract interface
    subroutine evt_write (evt, unit, verbose, more_verbose, testflag)
      import
      class(evt_t), intent(in) :: evt
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose, more_verbose, testflag
    end subroutine evt_write
  end interface

```

Output. We can print r.n.g. info.

```

<Event transforms: evt: TBP>+≡
  procedure :: base_write => evt_base_write

<Event transforms: procedures>+≡
  subroutine evt_base_write (evt, unit, testflag, show_set)
    class(evt_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag, show_set
    integer :: u
    logical :: show
    u = given_output_unit (unit)
    show = .true.; if (present (show_set)) show = show_set
    if (associated (evt%process)) then

```

```

        write (u, "(3x,A,A,A)") "Associated process: '", &
            char (evt%process%get_id ()), "'"
    end if
    if (allocated (evt%rng)) then
        call evt%rng%write (u, 1)
        write (u, "(3x,A,I0)") "Number of tries = ", evt%rejection_count
    end if
    if (show) then
        if (evt%particle_set_exists) then
            call write_separator (u)
            call evt%particle_set%write (u, testflag)
        end if
    end if
end subroutine evt_base_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

```

(Event transforms: evt: TBP)+≡
    procedure :: connect => evt_connect
    procedure :: base_connect => evt_connect

(Event transforms: procedures)+≡
    subroutine evt_connect (evt, process_instance, model, process_stack)
        class(evt_t), intent(inout), target :: evt
        type(process_instance_t), intent(in), target :: process_instance
        class(model_data_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        evt%process => process_instance%process
        evt%process_instance => process_instance
        evt%model => model
        call evt%process%make_rng (evt%rng)
    end subroutine evt_connect

```

Reset internal state.

```

(Event transforms: evt: TBP)+≡
    procedure :: reset => evt_reset
    procedure :: base_reset => evt_reset

(Event transforms: procedures)+≡
    subroutine evt_reset (evt)
        class(evt_t), intent(inout) :: evt
        evt%rejection_count = 0
        evt%particle_set_exists = .false.
    end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

(Event transforms: evt: TBP)+≡
    procedure (evt_prepare_new_event), deferred :: prepare_new_event

```

```

(Event transforms: interfaces)+≡
interface
  subroutine evt_prepare_new_event (evt, i_mci, i_term)
    import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
  end subroutine evt_prepare_new_event
end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)
      import
      class(evt_t), intent(inout) :: evt
      real(default), intent(out) :: probability
    end subroutine evt_generate_weighted
  end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted

(Event transforms: procedures)+≡
  subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set

(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_make_particle_set
end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

(Event transforms: evt: TBP)+≡
  procedure :: set_particle_set => evt_set_particle_set

(Event transforms: procedures)+≡
  subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
    class(evt_t), intent(inout) :: evt
    type(particle_set_t), intent(in) :: particle_set
    integer, intent(in) :: i_term, i_mci
    call evt%prepare_new_event (i_mci, i_term)
    evt%particle_set = particle_set
    evt%particle_set_exists = .true.
  end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. (We need two interactions, one with color summed over, and one with the probability distributed among flows.)

We use the two values from the random number generator for factorizing the state. For testing purposes, we can provide those numbers explicitly.

```

(Event transforms: evt: TBP)+≡
  procedure :: factorize_interactions => evt_factorize_interactions

(Event transforms: procedures)+≡
  subroutine evt_factorize_interactions &
    (evt, int_matrix, int_flows, factorization_mode, keep_correlations, r)
    class(evt_t), intent(inout) :: evt
    type(interaction_t), intent(in), target :: int_matrix, int_flows
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    real(default), dimension(2) :: x
    if (present (r)) then
      if (size (r) == 2) then
        x = r
      else
        call msg_bug ("event factorization: size of r array must be 2")
      end if
    end if
  end subroutine

```

```

        end if
    else
        call evt%rng%generate (x)
    end if
    call evt%particle_set%init (evt%particle_set_exists, &
        int_matrix, int_flows, factorization_mode, x, &
        keep_correlations, keep_virtual=.true.)
    evt%particle_set_exists = .true.
end subroutine evt_factorize_interactions

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

```

<Event transforms: evt: TBP>+≡
    procedure :: tag_incoming => evt_tag_incoming
<Event transforms: procedures>+≡
    subroutine evt_tag_incoming (evt)
        class(evt_t), intent(inout) :: evt
        integer :: i_term, n_in
        integer, dimension(:), allocatable :: beam_index, in_index
        n_in = evt%process%get_n_in ()
        i_term = 1
        allocate (beam_index (n_in))
        call evt%process_instance%get_beam_index (i_term, beam_index)
        call evt%particle_set%reset_status (beam_index, PRT_BEAM)
        allocate (in_index (n_in))
        call evt%process_instance%get_in_index (i_term, in_index)
        call evt%particle_set%reset_status (in_index, PRT_INCOMING)
    end subroutine evt_tag_incoming

```

28.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

<Event transforms: public>+≡
    public :: evt_trivial_t
<Event transforms: types>+≡
    type, extends (evt_t) :: evt_trivial_t
        contains
        <Event transforms: evt trivial: TBP>
    end type evt_trivial_t

```

The finalizer is trivial. Some output:

```

<Event transforms: evt trivial: TBP>≡
    procedure :: write => evt_trivial_write

```

```

(Event transforms: procedures)+≡
subroutine evt_trivial_write (evt, unit, verbose, more_verbose, testflag)
  class(evt_trivial_t), intent(in) :: evt
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: verbose, more_verbose, testflag
  integer :: u
  u = given_output_unit (unit)
  call write_separator (u, 2)
  write (u, "(1x,A)") "Event transform: trivial (hard process)"
  call write_separator (u)
  call evt%base_write (u, testflag = testflag)
end subroutine evt_trivial_write

```

Nothing to do here:

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: prepare_new_event => evt_trivial_prepare_new_event

(Event transforms: procedures)+≡
subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
  class(evt_trivial_t), intent(inout) :: evt
  integer, intent(in) :: i_mci, i_term
  call evt%reset ()
end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: generate_weighted => evt_trivial_generate_weighted

(Event transforms: procedures)+≡
subroutine evt_trivial_generate_weighted (evt, probability)
  class(evt_trivial_t), intent(inout) :: evt

```

28.2.5 Hadronization Event Transform

This is the type for the hadronization event transform. It does not depend on the specific hadronization implementation of `hadrons_t`.

```

<Hadrons: public>+≡
  public :: evt_hadrons_t

<Hadrons: types>+≡
  type, extends (evt_t) :: evt_hadrons_t
    class(hadrons_t), allocatable :: hadrons
    type(shower_settings_t) :: settings
    type(model_t), pointer :: model_hadrons => null()
    type(qcd_t), pointer :: qcd_t => null()
  contains
    <Hadrons: evt hadrons: TBP>
  end type evt_hadrons_t

```

Initialize the parameters. The `model_hadrons` is supposed to be the SM variant that contains all hadrons that may be generated in the shower.

```

<Hadrons: evt hadrons: TBP>≡
  procedure :: init => evt_hadrons_init

```

```

<Hadrons: procedures>+≡
subroutine evt_hadrons_init (evt, settings, model_hadrons, method)
  class(evt_hadrons_t), intent(out) :: evt
  type(shower_settings_t), target, intent(in) :: settings
  type(model_t), intent(in), target :: model_hadrons
  type(string_t), intent(in) :: method
  evt%settings = settings
  evt%model_hadrons => model_hadrons
  ! TODO: (bcn 2015-03-27) method should be part of hadronization settings
  select case (char (method))
  case ("PYTHIA6")
    allocate (hadrons_pythia6_t :: evt%hadrons)
  case ("PYTHIA8")
    allocate (hadrons_pythia8_t :: evt%hadrons)
  case default
    call msg_fatal ("Hadronization method " // char (method) // &
      " not implemented.")
  end select
  call evt%hadrons%init (evt%settings, model_hadrons)
end subroutine evt_hadrons_init

```

Output.

```

<Hadrons: evt hadrons: TBP>+≡
  procedure :: write => evt_hadrons_write

<Hadrons: procedures>+≡
subroutine evt_hadrons_write (evt, unit, verbose, more_verbose, testflag)
  class(evt_hadrons_t), intent(in) :: evt
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: verbose, more_verbose, testflag
  integer :: u
  u = given_output_unit (unit)
  call write_separator (u, 2)
  write (u, "(1x,A)") "Event transform: hadronization"
  call write_separator (u)

      (u, summary = .true., compressed = .true.)
  call write_separator (u)
  call evt%settings%write (u)
end subroutine evt_hadrons_write

```

Here we take the particle set from the previous event transform and apply the hadronization. The result is stored in the `evt%hadrons` object. We always return a probability of unity as we don't have the analytic weight of the hadronization. Invalid events have to be discarded by the caller which is why we mark the particle set as invalid.

```

<Hadrons: evt hadrons: TBP>+≡
  procedure :: generate_weighted => evt_hadrons_generate_weighted

<Hadrons: procedures>+≡

28.3.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

⟨Decays: types⟩≡
  type, abstract :: any_config_t
  contains
    ⟨Decays: any config: TBP⟩
  end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
  procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
  interface
    subroutine any_config_final (object)
      import
        class(any_config_t), intent(inout) :: object
    end subroutine any_config_final
  end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
  procedure (any_config_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_config_write (object, unit, indent, verbose)
      import
        class(any_config_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        logical, intent(in), optional :: verbose
    end subroutine any_config_write
  end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_config_t
    class(any_config_t), allocatable :: c
  end type particle_config_t

```

28.3.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above. This also works around a compiler bug in gfortran.

```

<Decays: types>+≡
  type, abstract :: any_t
    contains
      <Decays: any: TBP>
  end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final

```

```

<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
      class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
      import
      class(any_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
    end subroutine any_write
  end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_out_t
    class(any_t), allocatable :: c
  end type particle_out_t

```

28.3.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+≡

```

28.3.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```

<Decays: types>+≡
    type :: decay_root_config_t
        type(string_t) :: process_id
        type(process_t), pointer :: process => null ()
        class(model_data_t), pointer :: model => null ()
        type(decay_term_config_t), dimension(:), allocatable :: term_config
    contains
        <Decays: decay root config: TBP>
    end type decay_root_config_t

```

The finalizer is recursive since there may be cascade decays.

```

<Decays: decay root config: TBP>≡
    procedure :: final => decay_root_config_final

<Decays: procedures>+≡
    recursive subroutine decay_root_config_final (object)
        class(decay_root_config_t), intent(inout) :: object
        integer :: i
        if (allocated (object%term_config)) then
            do i = 1, size (object%term_config)
                call object%term_config(i)%final ()
            end do
        end if
    end subroutine decay_root_config_final

```

The output routine is also recursive, and it contains an adjustable indentation.

```

<Decays: decay root config: TBP>+≡
    procedure :: write => decay_root_config_write
    procedure :: write_header => decay_root_config_write_header

<Decays: procedures>+≡
    recursive subroutine decay_root_config_init_term &
        (decay, i, flv, stable, model, process_stack)
        class(decay_root_config_t), intent(inout) :: decay
        integer, intent(in) :: i

```

```

type(flavor_t), dimension(:,:), intent(in) :: flv
logical, dimension(:), intent(in) :: stable
class(model_data_t), intent(in), target :: model
type(process_stack_t), intent(in), optional :: process_stack
call decay%term_config(i)%init (flv, stable, model, process_stack)
end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

<Decays: decay root config: TBP>+≡

```

procedure :: connect => decay_root_config_connect

```

<Decays: procedures>+≡

```

recursive subroutine decay_root_config_connect &
  (decay, process, model, process_stack, process_instance)
class(decay_root_config_t), intent(out) :: decay
type(process_t), intent(in), target :: process
class(model_data_t), intent(in), target :: model
type(process_stack_t), intent(in), optional :: process_stack
type(process_instance_t), intent(in), optional, target :: process_instance
type(connected_state_t), pointer :: connected_state
type(interaction_t), pointer :: int
type(flavor_t), dimension(:,:), allocatable :: flv
logical, dimension(:), allocatable :: stable
integer :: i

      call decay%term_config(i)%compute ()
    end do
  end subroutine decay_root_config_compute
```

28.3.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```
<Decays: types>+≡
  type, abstract :: decay_gen_t
    type(decay_term_t), dimension(:), allocatable :: term
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
  contains
    <Decays: decay gen: TBP>
  end type decay_gen_t
```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```
<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_root_t
    type(decay_root_config_t), pointer :: config => null ()
  contains
    <Decays: decay root: TBP>
  end type decay_root_t
```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```
<Decays: decay gen: TBP>≡
  procedure :: base_final => decay_gen_final

<Decays: procedures>+≡
  recursive subroutine decay_gen_final (object)
    class(decay_gen_t), intent(inout) :: object
    integer :: i
    if (allocated (object%term)) then
      do i = 1, size (object%term)
```

```

        call object%term(i)%final ()
      end do
    end if
  end subroutine decay_gen_final

```

No extra finalization for the decay root.

```

<Decays: decay root: TBP>≡
  procedure :: final => decay_root_final

<Decays: procedures>+≡
  subroutine decay_root_final (object)
    class(decay_root_t), intent(inout) :: object
    call object%base_final ()
  end subroutine decay_root_final

```

Output.

```

<Decays: decay root: TBP>+≡
  procedure :: write => decay_root_write

<Decays: procedures>+≡
  subroutine decay_root_write (object, unit)
    class(decay_root_t), intent(in) :: object

    end if
    if (decay%selected_term > 0) then
      call decay%term(decay%selected_term)%write_process_instances (unit, verb)
    end if
  end subroutine decay_gen_write_process_instances

```

Generic initializer. All can be done recursively.

```

<Decays: decay gen: TBP>+≡
  procedure :: base_init => decay_gen_init

<Decays: procedures>+≡
  recursive subroutine decay_gen_init (decay, term_config)
    class(decay_gen_t), intent(out) :: decay
    type(decay_term_config_t), dimension(:), intent(in), target :: term_config
    integer :: i
    allocate (decay%term (size (term_config)))
    do i = 1, size (decay%term)
      call decay%term(i)%init (term_config(i))
    end do
  end subroutine decay_gen_init

```

Specific initializer. We assign the configuration object, which should correspond to a completely initialized decay configuration tree. We also connect to an existing process instance. Then, we recursively link the child interactions to the parent process.

```

<Decays: decay root: TBP>+≡
  procedure :: init => decay_root_init

<Decays: procedures>+≡
  subroutine decay_root_init (decay_root, config, process_instance)
    class(decay_root_t), intent(out) :: decay_root
    type(decay_root_config_t), intent(in), target :: config
    type(process_instance_t), intent(in), target :: process_instance
    call decay_root%base_init (config%term_config)
    decay_root%config => config
    decay_root%process_instance => process_instance
    call decay_root%make_term_rng (config%process)
    call decay_root%link_term_interactions ()
  end subroutine decay_root_init

```

Implement random-number generators for unstable decay selection in all terms. This is not recursive.

We also make use of the fact that `process` is a pointer; the (state of the RNG factory inside the) target process will be modified by the `rng-spawning` method, but not the pointer.

```

<Decays: decay gen: TBP>+≡
  procedure :: make_term_rng => decay_gen_make_term_rng

```

```

<Decays: procedures>+≡
  subroutine decay_gen_make_term_rng (decay, process)
    class(decay_gen_t), intent(inout) :: decay
    type(process_t), intent(in), pointer :: process
    integer :: i
    do i = 1, size (decay%term)
      call decay%term(i)%make_rng (process)
    end do
  end subroutine decay_gen_make_term_rng

```

Recursively link interactions of the enclosed decay terms to the corresponding terms in the current process instance.

Note: A bug in nagfor requires the extra `i_term` variable.

```

<Decays: decay gen: TBP>+≡
  procedure :: link_term_interactions => decay_gen_link_term_interactions

<Decays: procedures>+≡
  recursive subroutine decay_gen_link_term_interactions (decay)
    class(decay_gen_t), intent(inout) :: decay
    integer :: i, i_term
    type(interaction_t), pointer :: trace
    associate (instance => decay%process_instance)
      do i = 1, size (decay%term)
        i_term = i
        trace => instance%get_trace_int_ptr (i_term)
        call decay%term(i_term)%link_interactions (trace)
      end do
    end associate
  end subroutine decay_gen_link_term_interactions

```

Select a decay chain: decay modes and process components.

```

<Decays: decay root: TBP>+≡
  procedure :: select_chain => decay_root_select_chain

<Decays: procedures>+≡
  subroutine decay_root_select_chain (decay_root)
    class(decay_root_t), intent(inout) :: decay_root
    if (decay_root%selected_term > 0) then
      call decay_root%term(decay_root%selected_term)%select_chain ()
    else
      call msg_bug ("Decays: no term selected for parent process")
    end if
  end subroutine decay_root_select_chain

```

Generate a decay tree, i.e., for the selected term in the parent process, recursively generate a decay event for all unstable particles.

Factor out the trace of the connected state of the parent process. This trace should not be taken into account for unweighting the decay chain, since it was already used for unweighting the parent event, or it determines the overall event weight.

```

<Decays: decay root: TBP>+≡
  procedure :: generate => decay_root_generate

```

```

<Decays: procedures>+≡
  subroutine decay_root_generate (decay_root)
    class(decay_root_t), intent(inout) :: decay_root
    type(connected_state_t), pointer :: connected_state
    if (decay_root%selected_term > 0) then
      connected_state => decay_root%process_instance%get_connected_state_ptr &
        (decay_root%selected_term)
      call connected_state%normalize_matrix_by_trace ()
      call decay_root%term(decay_root%selected_term)%generate ()
    else
      call msg_bug ("Decays: no term selected for parent process")
    end if
  end subroutine decay_root_generate

```

28.3.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

The flavor component should be identical to the flavor component of the parent particle (*unstable* object).

```

<Decays: types>+≡
  type, extends (decay_root_config_t) :: decay_config_t
    type(flavor_t) :: flv
    real(default) :: weight = 0
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: mci_selector
  contains
    <Decays: decay config: TBP>
  end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
  procedure :: write => decay_config_write

<Decays: procedures>+≡
  recursive subroutine decay_config_write (object, unit, indent, verbose)
    class(decay_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,A)") "Decay:"
    call object%write_header (unit, indent)
    call write_indent (u, ind)

```

```

        write (u, 2) "branching ratio =", object%weight * 100
        call write_indent (u, ind)
        write (u, 1) "partial width  =", object%integral
        call write_indent (u, ind)
        write (u, 1) "error (abs)    =", object%abs_error
        call write_indent (u, ind)
        write (u, 1) "error (rel)    =", object%rel_error
1   format (3x,A,ES19.12)
2   format (3x,A,F11.6,1x,'%')
        call object%write_terms (unit, indent, verbose)
    end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should be used instead.

```

<Decays: decay config: TBP>+≡
    procedure :: connect => decay_config_connect

<Decays: procedures>+≡
    recursive subroutine decay_config_connect &
        (decay, process, model, process_stack, process_instance)
        class(decay_config_t), intent(out) :: decay
        type(process_t), intent(in), target :: process
        class(model_data_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        type(process_instance_t), intent(in), optional, target :: process_instance
        real(default), dimension(:), allocatable :: integral_mci
        integer :: i, n_mci
        call decay%decay_root_config_t%connect (process, model, process_stack)
        decay%integral = process%get_integral ()
        decay%abs_error = process%get_error ()
        if (process%cm_frame ()) then
            call msg_fatal ("Decay process " // char (process%get_id ()) &
                // ": unusable because rest frame is fixed.")
        end if
        n_mci = process%get_n_mci ()
        allocate (integral_mci (n_mci))
        do i = 1, n_mci
            integral_mci(i) = process%get_integral_mci (i)
        end do
        call decay%mci_selector%init (integral_mci)
    end subroutine decay_config_connect

```

Set the flavor entry, which repeats the flavor of the parent unstable particle.

```

<Decays: decay config: TBP>+≡
    procedure :: set_flv => decay_config_set_flv

<Decays: procedures>+≡
    subroutine decay_config_set_flv (decay, flv)
        class(decay_config_t), intent(inout) :: decay

```

```

    type(flavor_t), intent(in) :: flv
    decay%flv = flv
end subroutine decay_config_set_flv

```

Compute embedded branchings and the relative error. This method does not apply to the decay root.

```

⟨Decays: decay config: TBP⟩+≡
    procedure :: compute => decay_config_compute

⟨Decays: procedures⟩+≡
    recursive subroutine decay_config_compute (decay)
        class(decay_config_t), intent(inout) :: decay
        call decay%decay_root_config_t%compute ()
        if (.not. vanishes (decay%integral)) then
            decay%rel_error = decay%abs_error / decay%integral
        else
            decay%rel_error = 0
        end if
    end subroutine decay_config_compute

```

28.3.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

⟨Decays: types⟩+≡
    type, extends (decay_gen_t) :: decay_t
        type(decay_config_t), pointer :: config => null ()
        class(rng_t), allocatable :: rng
    contains
        ⟨Decays: decay: TBP⟩
    end type decay_t

```

The finalizer is recursive.

```

⟨Decays: decay: TBP⟩≡
    procedure :: final => decay_final

⟨Decays: procedures⟩+≡
    recursive subroutine decay_final (object)
        class(decay_t), intent(inout) :: object
        integer :: i
        call object%base_final ()
        do i = 1, object%config%process%get_n_mci ()
            call object%process_instance%final_simulation (i)
        end do
        call object%process_instance%final ()
        deallocate (object%process_instance)
    end subroutine decay_final

```

Output.

```

<Decays: decay: TBP>+≡
  procedure :: write => decay_write

<Decays: procedures>+≡
  recursive subroutine decay_write (object, unit, indent, recursive)
    class(decay_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent, recursive
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call object%config%write (unit, indent, verbose = .false.)
    if (allocated (object%rng)) then
      call object%rng%write (u, ind + 1)
    end if
    call write_indent (u, ind)
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI      = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI      = [undefined]"
    end if
    call write_indent (u, ind)
    if (object%selected_term > 0) then
      write (u, "(3x,A,I0)") "Selected term    = ", object%selected_term
      call object%term(object%selected_term)%write (u, ind + 1)
    else
      write (u, "(3x,A)") "Selected term    = [undefined]"
    end if
  end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
  procedure :: init => decay_init

<Decays: procedures>+≡
  recursive subroutine decay_init (decay, config)
    class(decay_t), intent(out) :: decay
    type(decay_config_t), intent(in), target :: config
    integer :: i
    call decay%base_init (config%term_config)
    decay%config => config
    allocate (decay%process_instance)
    call decay%process_instance%init (decay%config%process)
    call decay%process_instance%setup_event_data (decay%config%model)
    do i = 1, decay%config%process%get_n_mci ()
      call decay%process_instance%init_simulation (i)
    end do
    call decay%config%process%make_rng (decay%rng)
    call decay%make_term_rng (decay%config%process)
  end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
  procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
  recursive subroutine decay_link_interactions (decay, i_prt, trace)
    class(decay_t), intent(inout) :: decay
    integer, intent(in) :: i_prt
    type(interaction_t), intent(in), target :: trace
    type(interaction_t), pointer :: beam_int
    integer :: n_in, n_vir
    beam_int => decay%process_instance%get_beam_int_ptr ()
    n_in = trace%get_n_in ()
    n_vir = trace%get_n_vir ()
    call beam_int%set_source_link (1, trace, &
      n_in + n_vir + i_prt)
    call decay%link_term_interactions ()
  end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
  procedure :: select_chain => decay_select_chain

<Decays: procedures>+≡
  recursive subroutine decay_select_chain (decay)
    class(decay_t), intent(inout) :: decay
    real(default) :: x
    integer :: i
    call decay%rng%generate (x)
    decay%selected_mci = decay%config%mc_selector%select (x)
    call decay%process_instance%choose_mci (decay%selected_mci)
    call decay%process_instance%select_i_term (decay%selected_term)
    do i = 1, size (decay%term)
      call decay%term(i)%select_chain ()
    end do
  end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

<Decays: decay: TBP>+≡
  procedure :: generate => decay_generate

```

```

<Decays: procedures>+≡
recursive subroutine decay_generate (decay)
  class(decay_t), intent(inout) :: decay
  type(isolated_state_t), pointer :: isolated_state
  integer :: i
  call decay%process_instance%receive_beam_momenta ()
  call decay%config%process%generate_unweighted_event &
    (decay%process_instance, decay%selected_mci)
  if (signal_is_pending ()) return
  call decay%process_instance%evaluate_event_data ()
  isolated_state => &
    decay%process_instance%get_isolated_state_ptr (decay%selected_term)
  call isolated_state%normalize_matrix_by_trace ()
  do i = 1, size (decay%term)
    call decay%term(i)%generate ()
    if (signal_is_pending ()) return
  end do
end subroutine decay_generate

```

28.3.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```

<Decays: types>+≡
type, extends (any_config_t) :: stable_config_t
  type(flavor_t), dimension(:), allocatable :: flv
contains
  <Decays: stable config: TBP>
end type stable_config_t

```

The finalizer is empty:

```

<Decays: stable config: TBP>≡
  procedure :: final => stable_config_final

<Decays: procedures>+≡
  subroutine stable_config_final (object)
    class(stable_config_t), intent(inout) :: object
  end subroutine stable_config_final

```

Output.

```

<Decays: stable config: TBP>+≡
  procedure :: write => stable_config_write

<Decays: procedures>+≡
recursive subroutine stable_config_write (object, unit, indent, verbose)
  class(stable_config_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent
  logical, intent(in), optional :: verbose
  integer :: u, i, ind
  u = given_output_unit (unit)
  ind = 0; if (present (indent)) ind = indent
  call write_indent (u, ind)
  write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"

```

```

write (u, "(1x,A)", advance = "no") char (object%flv(1)%get_name ())
do i = 2, size (object%flv)
  write (u, "(:',A)", advance = "no") &
    char (object%flv(i)%get_name ())
end do
write (u, *)
end subroutine stable_config_write

```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```

<Decays: stable config: TBP>+≡
  procedure :: init => stable_config_init

<Decays: procedures>+≡
  subroutine stable_config_init (config, flv)
    class(stable_config_t), intent(out) :: config
    type(flavor_t), dimension(:), intent(in) :: flv
    integer, dimension (size (flv)) :: pdg
    logical, dimension (size (flv)) :: mask
    integer :: i
    pdg = flv%get_pdg ()
    mask(1) = .true.
    forall (i = 2 : size (pdg))
      mask(i) = all (pdg(i) /= pdg(1:i-1))
    end forall
    allocate (config%flv (count (mask)))
    config%flv = pack (flv, mask)
  end subroutine stable_config_init

```

Here is the corresponding object instance. Except for the pointer to the configuration, there is no content.

```

<Decays: types>+≡
  type, extends (any_t) :: stable_t
    type(stable_config_t), pointer :: config => null ()
  contains
    <Decays: stable: TBP>
  end type stable_t

```

The finalizer does nothing.

```

<Decays: stable: TBP>≡
  procedure :: final => stable_final

<Decays: procedures>+≡
  subroutine stable_final (object)
    class(stable_t), intent(inout) :: object
  end subroutine stable_final

```

We can delegate output to the configuration object.

```

<Decays: stable: TBP>+≡
  procedure :: write => stable_write

```

```

<Decays: procedures>+≡
  subroutine stable_write (object, unit, indent)
    class(stable_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    call object%config%write (unit, indent)
  end subroutine stable_write

```

Initializer: just assign the configuration.

```

<Decays: stable: TBP>+≡
  procedure :: init => stable_init

<Decays: procedures>+≡
  subroutine stable_init (stable, config)
    class(stable_t), intent(out) :: stable
    type(stable_config_t), intent(in), target :: config
    stable%config => config
  end subroutine stable_init

```

28.3.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: types>+≡
  type, extends (any_config_t) :: unstable_config_t
    type(flavor_t) :: flv
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: selector
    type(decay_config_t), dimension(:), allocatable :: decay_config
  contains
    <Decays: unstable config: TBP>
  end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
  procedure :: final => unstable_config_final

<Decays: procedures>+≡
  recursive subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%final ()
      end do
    end if
  end subroutine

```

```
end subroutine unstable_config_final
```

Output. Since this may be recursive, we include indentation.

```
<Decays: unstable config: TBP>+≡
  procedure :: write => unstable_config_write

<Decays: procedures>+≡
  recursive subroutine unstable_config_write (object, unit, indent, verbose)
    class(unstable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    logical :: verb
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
      char (object%flv%get_name ())
    call write_indent (u, ind)
    write (u, 1) "total width =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs) =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel) =", object%rel_error
1  format (5x,A,ES19.12)
    if (verb .and. allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%write (u, ind + 1)
      end do
    end if
  end subroutine unstable_config_write
```

Initializer. For the unstable particle, the flavor is unique.

```
<Decays: unstable config: TBP>+≡
  procedure :: init => unstable_config_init

<Decays: procedures>+≡
  subroutine unstable_config_init (config, flv)
    class(unstable_config_t), intent(out) :: config
    type(flavor_t), intent(in) :: flv
    config%flv = flv
  end subroutine unstable_config_init
```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```
<Decays: unstable config: TBP>+≡
  procedure :: init_decays => unstable_config_init_decays
```

```

<Decays: procedures>+≡
recursive subroutine unstable_config_init_decays &
  (unstable, decay_id, model, process_stack)
  class(unstable_config_t), intent(inout) :: unstable
  type(string_t), dimension(:), intent(in) :: decay_id
  class(model_data_t), intent(in), target :: model
  type(process_stack_t), intent(in), optional :: process_stack
  integer :: i
  allocate (unstable%decay_config (size (decay_id)))
  do i = 1, size (decay_id)
    associate (decay => unstable%decay_config(i))
      if (present (process_stack)) then
        call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
          model, process_stack)
      else
        call decay%init (model, decay_id(i))
      end if
      call decay%set_flg (unstable%flv)
    end associate
  end do
end subroutine unstable_config_init_decays

```

Compute the total width and branching ratios, initializing the decay selector.

```

<Decays: unstable config: TBP>+≡
  procedure :: compute => unstable_config_compute

<Decays: procedures>+≡
recursive subroutine unstable_config_compute (unstable)
  class(unstable_config_t), intent(inout) :: unstable
  integer :: i
  do i = 1, size (unstable%decay_config)
    call unstable%decay_config(i)%compute ()
  end do
  unstable%integral = sum (unstable%decay_config%integral)
  if (unstable%integral <= 0) then
    call unstable%write ()
    call msg_fatal ("Decay configuration: computed total width is zero")
  end if
  unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
  unstable%rel_error = unstable%abs_error / unstable%integral
  call unstable%selector%init (unstable%decay_config%integral)
  do i = 1, size (unstable%decay_config)
    unstable%decay_config(i)%weight &
      = unstable%selector%get_weight (i)
  end do
end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: types>+≡
type, extends (any_t) :: unstable_t

  end subroutine unstable_generate

```

28.3.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+≡
  type, extends (connected_state_t) :: decay_chain_entry_t
    integer :: index = 0
    type(decay_config_t), pointer :: config => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
    type(decay_chain_entry_t), pointer :: previous => null ()
  end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This

allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: types>+≡
  type :: decay_chain_t
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_term = 0
    type(evaluator_t) :: correlated_trace
    type(decay_chain_entry_t), pointer :: last => null ()
  contains
    <Decays: decay chain: TBP>
  end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay chain: TBP>≡
  procedure :: final => decay_chain_final

<Decays: procedures>+≡
  subroutine decay_chain_final (object)
    class(decay_chain_t), intent(inout) :: object
    type(decay_chain_entry_t), pointer :: entry
    do while (associated (object%last))
      entry => object%last
      object%last => entry%previous
      call entry%final ()
      deallocate (entry)
    end do
    call object%correlated_trace%final ()
  end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

<Decays: decay chain: TBP>+≡
  procedure :: write => decay_chain_write

<Decays: procedures>+≡
  subroutine decay_chain_write (object, unit)
    class(decay_chain_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    write (u, "(1x,A)") "Decay chain:"
    call write_entries (object%last)
    call write_separator (u, 2)
    write (u, "(1x,A)") "Evaluator (correlated trace of the decay chain):"
    call write_separator (u)
    call object%correlated_trace%write (u)
    call write_separator (u, 2)
  contains

```

```

recursive subroutine write_entries (entry)
  type(decay_chain_entry_t), intent(in), pointer :: entry
  if (associated (entry)) then
    call write_entries (entry%previous)
    call write_separator (u, 2)
    write (u, "(1x,A,I0)") "Decay #", entry%index
    call entry%config%write_header (u)
    write (u, "(3x,A,I0)") "Selected MCI    = ", entry%selected_mci
    write (u, "(3x,A,I0)") "Selected term  = ", entry%selected_term
    call entry%config%term_config(entry%selected_term)%write (u, indent=1)
    call entry%write (u)
  end if
end subroutine write_entries
end subroutine decay_chain_write

```

Build a decay chain, recursively following the selected decays and terms in a decay tree. Before start, we finalize the chain, deleting any previous contents.

```

<Decays: decay chain: TBP>+≡
  procedure :: build => decay_chain_build

<Decays: procedures>+≡
  subroutine decay_chain_build (chain, decay_root)
    class(decay_chain_t), intent(inout), target :: chain
    type(decay_root_t), intent(in) :: decay_root
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    type(interaction_t), pointer :: int_last_decay
    call chain%final ()
    if (decay_root%selected_term > 0) then
      chain%process_instance => decay_root%process_instance
      chain%selected_term = decay_root%selected_term
      call chain%build_term_entries (decay_root%term(decay_root%selected_term))
    end if
    int_last_decay => chain%last%get_matrix_int_ptr ()
    allocate (qn_mask (int_last_decay%get_n_tot ()))
    call qn_mask%init (mask_f = .true., mask_c = .true., mask_h = .true.)
    call chain%correlated_trace%init_qn_sum (int_last_decay, qn_mask)
  end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable particles.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_term_entries (chain, term)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_term_t), intent(in) :: term
    integer :: i
    do i = 1, size (term%particle_out)
      select type (unstable => term%particle_out(i)%c)
      type is (unstable_t)
        if (unstable%selected_decay > 0) then
          call chain%build_decay_entries &
            (unstable%decay(unstable%selected_decay))
        end if
      end select
    end do
  end subroutine decay_chain_build_term_entries

```

```

        end if
    end select
end do
end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

<Decays: decay chain: TBP>+≡
    procedure :: build_decay_entries => decay_chain_build_decay_entries

<Decays: procedures>+≡
    recursive subroutine decay_chain_build_decay_entries (chain, decay)
        class(decay_chain_t), intent(inout) :: chain
        type(decay_t), intent(in) :: decay
        type(decay_chain_entry_t), pointer :: entry
        type(connected_state_t), pointer :: previous_state
        type(isolated_state_t), pointer :: current_decay
        type(helicity_t) :: hel
        type(quantum_numbers_t) :: qn_filter_conn
        allocate (entry)
        if (associated (chain%last)) then
            entry%previous => chain%last
            entry%index = entry%previous%index + 1
            previous_state => entry%previous%connected_state_t
        else
            entry%index = 1
            previous_state => &
                chain%process_instance%get_connected_state_ptr (chain%selected_term)
        end if
        entry%config => decay%config
        entry%selected_mci = decay%selected_mci
        entry%selected_term = decay%selected_term
        current_decay => decay%process_instance%get_isolated_state_ptr &
            (decay%selected_term)
        call entry%setup_connected_trace &
            (current_decay, previous_state%get_trace_int_ptr (), resonant=.true.)
        if (entry%config%flv%has_decay_helicity ()) then
            call hel%init (entry%config%flv%get_decay_helicity ())
            call qn_filter_conn%init (hel)
            call entry%setup_connected_matrix &
                (current_decay, previous_state%get_matrix_int_ptr (), &

```

```

        resonant=.true., qn_filter_conn = qn_filter_conn)
    call entry%setup_connected_flows &
        (current_decay, previous_state%get_flows_int_ptr (), &
        resonant=.true., qn_filter_conn = qn_filter_conn)
else
    call entry%setup_connected_matrix &
        (current_decay, previous_state%get_matrix_int_ptr (), &
        resonant=.true.)
    call entry%setup_connected_flows &
        (current_decay, previous_state%get_flows_int_ptr (), &
        resonant=.true.)
end if
chain%last => entry
call chain%build_term_entries (decay%term(decay%selected_term))
end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

```

<Decays: decay chain: TBP>+≡
    procedure :: evaluate => decay_chain_evaluate

<Decays: procedures>+≡
    subroutine decay_chain_evaluate (chain)
        class(decay_chain_t), intent(inout) :: chain
        call evaluate (chain%last)
        call chain%correlated_trace%receive_momenta ()
        call chain%correlated_trace%evaluate ()
    contains
        recursive subroutine evaluate (entry)
            type(decay_chain_entry_t), intent(inout), pointer :: entry
            if (associated (entry)) then
                call evaluate (entry%previous)
                call entry%receive_kinematics ()
                call entry%evaluate_trace ()
                call entry%evaluate_event_data ()
            end if
        end subroutine evaluate
    end subroutine decay_chain_evaluate

```

Return the probability of a decay chain. This is given as the trace of the density matrix with intermediate helicity correlations, normalized by the product of the uncorrelated density matrix traces. This works only if an event has been evaluated and the `correlated_trace` evaluator is filled. By definition, this evaluator has only one matrix element, and this must be real.

```

<Decays: decay chain: TBP>+≡
    procedure :: get_probability => decay_chain_get_probability

<Decays: procedures>+≡
    function decay_chain_get_probability (chain) result (x)

```

```

class(decay_chain_t), intent(in) :: chain
real(default) :: x
x = real (chain%correlated_trace%get_matrix_element (1))
end function decay_chain_get_probability

```

28.3.12 Decay as Event Transform

The `evt_decay` object combines decay configuration, decay tree, and chain in a single object, as an implementation of the `evt` (event transform) abstract type.

```

<Decays: public>≡
  public :: evt_decay_t

<Decays: types>+≡
  type, extends (evt_t) :: evt_decay_t
    type(decay_root_config_t) :: decay_root_config
    type(decay_root_t) :: decay_root
    type(decay_chain_t) :: decay_chain
  contains
    <Decays: evt decay: TBP>
  end type evt_decay_t

```

Output. We display the currently selected decay tree, which includes configuration data, and the decay chain, i.e., the evaluators.

```

<Decays: evt decay: TBP>≡
  procedure :: write => evt_decay_write

<Decays: procedures>+≡
  subroutine evt_decay_write (evt, unit, verbose, more_verbose, testflag)
    class(evt_decay_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, more_verbose, testflag
    logical :: verb, verb2
    integer :: u
    u = given_output_unit (unit)
    verb = .true.; if (present (verbose)) verb = verbose
    verb2 = .false.; if (present (more_verbose)) verb2 = more_verbose
    call write_separator (u, 2)
    write (u, "(1x,A)") "Event transform: partonic decays"
    call write_separator (u, 2)
    call evt%base_write (u)
    if (verb) then
      call write_separator (u)
      call evt%decay_root%write (u)
      if (verb2) then
        call evt%decay_chain%write (u)
        call evt%decay_root%write_process_instances (u, verb)
      end if
    else
      call write_separator (u, 2)
    end if
  end subroutine evt_decay_write

```

Connect with a process instance and process. This initializes the decay configuration. The process stack is used to look for process objects that implement daughter decays.

When all processes are assigned, configure the decay tree instance, using the decay tree configuration. First obtain the branching ratios, then allocate the decay tree. This is done once for all events.

```

<Decays: evt decay: TBP>+≡
  procedure :: connect => evt_decay_connect

<Decays: procedures>+≡
  subroutine evt_decay_connect (evt, process_instance, model, process_stack)
    class(evt_decay_t), intent(inout), target :: evt
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    call evt%base_connect (process_instance, model)
    call evt%decay_root_config%connect (process_instance%process, &
      model, process_stack, process_instance)
    call evt%decay_root_config%compute ()
    call evt%decay_root%init (evt%decay_root_config, evt%process_instance)
  end subroutine evt_decay_connect

```

Prepare a new event: Select a decay chain and build the corresponding chain object.

```

<Decays: evt decay: TBP>+≡
  procedure :: prepare_new_event => evt_decay_prepare_new_event

<Decays: procedures>+≡
  subroutine evt_decay_prepare_new_event (evt, i_mci, i_term)
    class(evt_decay_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
    evt%decay_root%selected_mci = i_mci
    evt%decay_root%selected_term = i_term
    call evt%decay_root%select_chain ()
    call evt%decay_chain%build (evt%decay_root)
  end subroutine evt_decay_prepare_new_event

```

Generate a weighted event and assign the resulting weight (probability). We use a chain initialized by the preceding subroutine, fill it with momenta and evaluate.

```

<Decays: evt decay: TBP>+≡
  procedure :: generate_weighted => evt_decay_generate_weighted

<Decays: procedures>+≡
  subroutine evt_decay_generate_weighted (evt, probability)
    class(evt_decay_t), intent(inout) :: evt
    real(default), intent(out) :: probability
    call evt%decay_root%generate ()
    if (signal_is_pending ()) return
    call evt%decay_chain%evaluate ()
    probability = evt%decay_chain%get_probability ()
  end subroutine evt_decay_generate_weighted

```

To create a usable event, we have to transform the interaction into a particle set; this requires factorization for the correlated density matrix, according to the factorization mode.

```

<Decays: evt_decay: TBP>+≡
    procedure :: make_particle_set => evt_decay_make_particle_set

<Decays: procedures>+≡
    subroutine evt_decay_make_particle_set &
        (evt, factorization_mode, keep_correlations, r)

    end module shower

```

28.4.1 Configuration Parameters

POWHEG_TESTING allows to disable the parton shower for validation and testing of the POWHEG procedure.

```

<Shower: parameters>≡
    logical, parameter :: DEBUG_EVT_SHOWER = .false.
    logical, parameter :: POWHEG_TESTING = .false.
    logical, parameter :: TEST_SUDAKOV = .false.
    logical, parameter :: TO_FILE = .false.

```

28.4.2 Event Transform

The event transforms can do more than mere showering. Especially, it may reweight showered events to fixed-order matrix elements. The `model_hadrons` is supposed to be the SM variant that contains all hadrons that can be generated in the shower.

```

<Shower: public>≡
    public :: evt_shower_t

<Shower: types>≡
    type, extends (evt_t) :: evt_shower_t
        type(shower_settings_t) :: settings
        class(shower_base_t), allocatable :: shower
        type(model_t), pointer :: model_hadrons => null ()
        type(powheg_t) :: powheg
        class(matching_settings_t), allocatable :: matching_settings
        class(matching_data_t), allocatable :: data

    end subroutine evt_shower_prepare_new_event

```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations is under construction. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid. This procedure directly takes the (MLM) matching into account.

28.5.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The **safety_factor** reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The **sigma** and **n** values, if nontrivial, allow for reweighting the events according to the requested **norm_mode**.

Various **parse_node_t** objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the **event_expr_t** objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

⟨Events: types⟩≡

```

28.5.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event_base` module. The core manages the main (dressed) particle set pointer and the current values for weights and sqme. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters.

When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

The `sqme` and `weight` values mirror corresponding values in the `expr` subobject. The idea is that when generating or reading events, the event record is filled first, then the `expr` object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the `expr` subobject. In particular, evaluating the event-selection expression sets the `passed` flag. Furthermore, the `expr` subobject collects data that can be used in the analysis and should be written to file, including copies of `sqme` and `weight`.

```

```

28.5.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```
<Events: event: TBP>+≡
  procedure :: basic_init => event_init
<Events: procedures>+≡
  subroutine event_init (event, var_list, n_alt)
    class(event_t), intent(out) :: event
    type(var_list_t), intent(in), optional :: var_list
    integer, intent(in), optional :: n_alt
    type(string_t) :: norm_string
    logical :: polarized_events
    if (present (n_alt)) then
      call event%base_init (n_alt)
      call event%expr%init (n_alt)
    else
      call event%base_init (0)
    end if
    if (present (var_list)) then
      event%config%unweighted = var_list%get_lval (&
        var_str ("?unweighted"))
      norm_string = var_list%get_sval (&
        var_str ("sample_normalization"))
      event%config%norm_mode = &
        event_normalization_mode (norm_string, event%config%unweighted)
      polarized_events = &
        var_list%get_lval (var_str ("?polarized_events"))
      if (polarized_events) then
        event%config%factorization_mode = FM_SELECT_HELICITY
      else
        event%config%factorization_mode = FM_IGNORE_HELICITY
      end if
      if (event%config%unweighted) then
        event%config%safety_factor = var_list%get_rval (&
          var_str ("safety_factor"))
      end if
    else
      event%config%norm_mode = NORM_SIGMA
    end if
    allocate (evt_trivial_t :: event%transform_first)
    event%transform_last => event%transform_first
  end subroutine event_init
```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

```
<Events: event: TBP>+≡
```

```

    procedure :: set_sigma => event_set_sigma
    procedure :: set_n => event_set_n

    <Events: procedures>+≡
    elemental subroutine event_set_sigma (event, sigma)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: sigma
        event%config%sigma = sigma
    end subroutine event_set_sigma

    elemental subroutine event_set_n (event, n)
        class(event_t), intent(inout) :: event
        integer, intent(in) :: n
        event%config%n = n
    end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

    <Events: event: TBP>+≡
    procedure :: import_transform => event_import_transform

    <Events: procedures>+≡
    subroutine event_import_transform (event, evt)
        class(event_t), intent(inout) :: event
        class(evt_t), intent(inout), pointer :: evt
        event%transform_last%next => evt
        evt%previous => event%transform_last
        event%transform_last => evt
        evt => null ()
    end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

    <Events: event: TBP>+≡
    procedure :: connect => event_connect

    <Events: procedures>+≡
    subroutine event_connect (event, process_instance, model, process_stack)
        class(event_t), intent(inout), target :: event
        type(process_instance_t), intent(in), target :: process_instance
        class(model_data_t), intent(in), target :: model

```

```

type(process_stack_t), intent(in), optional :: process_stack
type(string_t) :: id

```

28.5.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

<Events: event: TBP>+≡
  procedure :: evaluate_transforms => event_evaluate_transforms

<Events: procedures>+≡
  subroutine event_evaluate_transforms (event, r)
    class(event_t), intent(inout) :: event
    real(default), dimension(:), intent(in), optional :: r
    class(evt_t), pointer :: evt

    end if
  end subroutine event_check

```

28.5.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we accept the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
  procedure :: generate => event_generate

<Events: procedures>+≡
  subroutine event_generate (event, i_mci, r)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci
    real(default), dimension(:), intent(in), optional :: r
    call event%reset ()
    event%selected_i_mci = i_mci
    if (event%config%unweighted) then
      call event%process%generate_unweighted_event (event%instance, i_mci)
      if (signal_is_pending ()) return
      call event%instance%evaluate_event_data ()
      call event%instance%normalize_weight ()
    else
      call event%process%generate_weighted_event (event%instance, i_mci)

28.5.8 Recovering an event

Select MC group, term, and integration channel.

```
<Events: event: TBP>+≡
  procedure :: select => event_select

<Events: procedures>+≡
  subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
    if (associated (event%instance)) then
      event%selected_i_mci = i_mci
      event%selected_i_term = i_term
      event%selected_channel = channel
    else
      call msg_bug ("Event: select term: process instance undefined")
    end if
  end subroutine event_select
```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. The event reader may either read in the transformed event separately, or apply all event transforms to the hard particle set to (re)generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```
<Events: event: TBP>+≡
  procedure :: set_hard_particle_set => event_set_hard_particle_set

<Events: procedures>+≡
  subroutine event_set_hard_particle_set (event, particle_set)
    class(event_t), intent(inout) :: event
    type(particle_set_t), intent(in) :: particle_set
    class(evt_t), pointer :: evt
    evt => event%transform_first
    call evt%set_particle_set (particle_set, &
      event%selected_i_mci, event%selected_i_term)
    call event%link_particle_set (evt%particle_set)
    evt => evt%next
    do while (associated (evt))
      call evt%reset ()
      evt => evt%next
    end do
  end subroutine event_set_hard_particle_set
```

Set the α_s value that should be used in a recalculation. This should be called only if we explicitly want to override the QCD setting of the process core.

```
<Events: event: TBP>+≡
  procedure :: set_alpha_qcd_forced => event_set_alpha_qcd_forced

<Events: procedures>+≡
  subroutine event_set_alpha_qcd_forced (event, alpha_qcd)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: alpha_qcd
```

```

    if (allocated (event%alpha_qcd_forced)) then
        event%alpha_qcd_forced = alpha_qcd
    else
        allocate (event%alpha_qcd_forced, source = alpha_qcd)
    end if
end subroutine event_set_alpha_qcd_forced

```

Analogously, for the common scale. This forces also renormalization and factorization scale.

```

<Events: event: TBP>+≡
    procedure :: set_scale_forced => event_set_scale_forced

<Events: procedures>+≡
    subroutine event_set_scale_forced (event, scale)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: scale
        if (allocated (event%scale_forced)) then
            event%scale_forced = scale
        else
            allocate (event%scale_forced, source = scale)
        end if
    end subroutine event_set_scale_forced

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

<Events: event: TBP>+≡
    procedure :: recalculate => event_recalculate

<Events: procedures>+≡
    subroutine event_recalculate &
        (event, update_sqme, weight_factor, recover_beams)

28.6 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the `events` module which provides the concrete implementation of `event_base`. The other I/O formats access only the methods that are defined in `event_base`.

```

<eio_raw.f90>≡
  <File header>

  module eio_raw

    use kinds
    use io_units
    <Use strings>
    use unit_tests
    use diagnostics

    use lorentz
    use variables
    use model_data
    use particles
    use event_base
    use eio_data
    use eio_base
    use events

    <Standard module head>

    <EIO raw: public>

    <EIO raw: parameters>

    <EIO raw: types>

    contains

    <EIO raw: procedures>

```

```
⟨EIO raw: tests⟩
```

```
end module eio_raw
```

28.6.1 File Format Version

This is the current default file version.

```
⟨EIO raw: parameters⟩≡
```

```
integer, parameter :: CURRENT_FILE_VERSION = 2
```

The user may change this number; this should force some compatibility mode for reading and writing. In any case, the file version stored in a event file that we read has to match the expected file version.

History of version numbers:

1. Format for WHIZARD 2.2.0 to 2.2.3. No version number stored in the raw file.
2. Format from 2.2.4 on. File contains version number. The file contains the transformed particle set (if applicable) after the hard-process particle set.

28.6.2 Type

Note the file version number. The default may be reset during initialization, which should enforce some compatibility mode.

```
⟨EIO raw: public⟩≡
```

```
public :: eio_raw_t
```

```
⟨EIO raw: types⟩≡
```

```

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

The `passed` flag is not written. This allow us to apply different selection criteria upon rereading.

write (u, "(A)")
write (u, "(A)")  "* Test output end: eio_raw_2"

end subroutine eio_raw_2

```

28.7 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```

<user_files.f90>≡
  <File header>

  module user_files

    <Use strings>
    use io_units
    use diagnostics
    use ifiles
    use analysis

    <Standard module head>

    <User files: public>

    <User files: types>

    <User files: interfaces>

    contains

    <User files: procedures>

```

```
end module user_files
```

28.7.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡
type :: file_t
  private
  type(string_t) :: name
  integer :: unit = -1
  logical :: reading = .false.
  logical :: writing = .false.
  type(file_t), pointer :: prev => null ()
  type(file_t), pointer :: next => null ()
end type file_t
```

The initializer opens the file.

```
<User files: procedures>≡
subroutine file_init (file, name, action, status, position)
  type(file_t), intent(out) :: file
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position
  file%unit = free_unit ()
  file%name = name
  open (unit = file%unit, file = char (file%name), &
        action = action, status = status, position = position)
  select case (action)
  case ("read")
    file%reading = .true.
  case ("write")
    file%writing = .true.
  case ("readwrite")
    file%reading = .true.
    file%writing = .true.
  end select
end subroutine file_init
```

The finalizer closes it.

```
<User files: procedures>+≡
subroutine file_final (file)
  type(file_t), intent(inout) :: file
  close (unit = file%unit)
  file%unit = -1
end subroutine file_final
```

Check if a file is open with correct status.

```
<User files: procedures>+≡
function file_is_open (file, action) result (flag)
  logical :: flag
```

```

type(file_t), intent(in) :: file
character(*), intent(in) :: action
select case (action)
case ("read")
    flag = file%reading
case ("write")
    flag = file%writing
case ("readwrite")
    flag = file%reading .and. file%writing
case default
    call msg_bug ("Checking file '" // char (file%name) &
        // "': illegal action specifier")
end select
end function file_is_open

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the `advancing` option.

<User files: procedures>+≡

```

subroutine file_write_string (file, string, advancing)
type(file_t), intent(in) :: file
type(string_t), intent(in), optional :: string
logical, intent(in), optional :: advancing
if (file%writing) then
    if (present (string)) then
        if (present (advancing)) then
            if (advancing) then
                write (file%unit, "(A)") char (string)
            else
                write (file%unit, "(A)", advance="no") char (string)
            end if
        else
            write (file%unit, "(A)") char (string)
        end if
    else
        write (file%unit, *)
    end if
else
    call msg_error ("Writing to file: File '" // char (file%name) &
        // "' is not open for writing.")
end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

<User files: procedures>+≡

```

subroutine file_write_ifile (file, ifile)
type(file_t), intent(in) :: file
type(ifile_t), intent(in) :: ifile
type(line_p) :: line
call line_init (line, ifile)
do while (line_is_associated (line))
    call file_write_string (file, line_get_string_advance (line))
end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
  subroutine file_write_analysis (file, tag)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: tag
    if (file%writing) then
      if (present (tag)) then
        call analysis_write (tag, unit = file%unit)
      else
        call analysis_write (unit = file%unit)
      end if
    else
      call msg_error ("Writing analysis to file: File ' " // char (file%name) &
        // "' is not open for writing.")
    end if
  end subroutine file_write_analysis

```

28.7.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
  public :: file_list_t

<User files: types>+≡
  type :: file_list_t
    type(file_t), pointer :: first => null ()
    type(file_t), pointer :: last => null ()
  end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
  public :: file_list_final

<User files: procedures>+≡
  subroutine file_list_final (file_list)
    type(file_list_t), intent(inout) :: file_list
    type(file_t), pointer :: current
    do while (associated (file_list%first))
      current => file_list%first
      file_list%first => current%next
      call file_final (current)
      deallocate (current)
    end do
    file_list%last => null ()
  end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```

<User files: procedures>+≡
  function file_list_get_file_ptr (file_list, name) result (current)

```

```

type(file_t), pointer :: current
type(file_list_t), intent(in) :: file_list
type(string_t), intent(in) :: name
current => file_list%first
do while (associated (current))
    if (current%name == name) return
    current => current%next
end do
end function file_list_get_file_ptr

```

Check if a file is open, public version:

```

<User files: public>+≡
public :: file_list_is_open

<User files: procedures>+≡
function file_list_is_open (file_list, name, action) result (flag)
    logical :: flag
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action
    type(file_t), pointer :: current
    current => file_list_get_file_ptr (file_list, name)
    if (associated (current)) then
        flag = file_is_open (current, action)
    else
        flag = .false.
    end if
end function file_list_is_open

```

Append a new file entry, i.e., open this file. Error if it is already open.

```

<User files: public>+≡
public :: file_list_open

<User files: procedures>+≡
subroutine file_list_open (file_list, name, action, status, position)
    type(file_list_t), intent(inout) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    type(file_t), pointer :: current
    if (.not. associated (file_list_get_file_ptr (file_list, name))) then
        allocate (current)
        call msg_message ("Opening file '" // char (name) // "' for output")
        call file_init (current, name, action, status, position)
        if (associated (file_list%last)) then
            file_list%last%next => current
            current%prev => file_list%last
        else
            file_list%first => current
        end if
        file_list%last => current
    else
        call msg_error ("Opening file: File '" // char (name) &
            // "' is already open.")
    end if
end subroutine file_list_open

```

```
end subroutine file_list_open
```

Delete a file entry, i.e., close this file. Error if it is not open.

```
<User files: public>+≡
public :: file_list_close

<User files: procedures>+≡
subroutine file_list_close (file_list, name)
  type(file_list_t), intent(inout) :: file_list
  type(string_t), intent(in) :: name
  type(file_t), pointer :: current
  current => file_list_get_file_ptr (file_list, name)
  if (associated (current)) then
    if (associated (current%prev)) then
      current%prev%next => current%next
    else
      file_list%first => current%next
    end if
    if (associated (current%next)) then
      current%next%prev => current%prev
    else
      file_list%last => current%prev
    end if
    call msg_message ("Closing file '" // char (name) // "' for output")
    call file_final (current)
    deallocate (current)
  else
    call msg_error ("Closing file: File '" // char (name) &
      // "' is not open.")
  end if
end subroutine file_list_close
```

Write a string to file. Error if it is not open.

```
<User files: public>+≡
public :: file_list_write

<User files: interfaces>≡
interface file_list_write
  module procedure file_list_write_string
  module procedure file_list_write_ifile
end interface

<User files: procedures>+≡
subroutine file_list_write_string (file_list, name, string, advancing)

```

28.8.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn, is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

28.8.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

(RT data: types)≡

```
type :: rt_parse_nodes_t
  type(parse_node_t), pointer :: cuts_lexpr => null ()
  type(parse_node_t), pointer :: scale_expr => null ()
  type(parse_node_t), pointer :: fac_scale_expr => null ()
  type(parse_node_t), pointer :: ren_scale_expr => null ()
  type(parse_node_t), pointer :: weight_expr => null ()
  type(parse_node_t), pointer :: selection_lexpr => null ()
  type(parse_node_t), pointer :: reweight_expr => null ()
  type(parse_node_t), pointer :: analysis_lexpr => null ()
  type(parse_node_p), dimension(:), allocatable :: alt_setup
```

```

contains
  <RT data: rt_parse_nodes: TBP>
end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt_parse_nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

<RT data: procedures>≡
  subroutine rt_parse_nodes_clear (rt_pn, name)
    class(rt_parse_nodes_t), intent(inout) :: rt_pn
    type(string_t), intent(in) :: name
    select case (char (name))
    case ("cuts")
      rt_pn%cuts_lexpr => null ()
    case ("scale")
      rt_pn%scale_expr => null ()
    case ("factorization_scale")
      rt_pn%fac_scale_expr => null ()
    case ("renormalization_scale")
      rt_pn%ren_scale_expr => null ()
    case ("weight")
      rt_pn%weight_expr => null ()
    case ("selection")
      rt_pn%selection_lexpr => null ()
    case ("reweight")
      rt_pn%reweight_expr => null ()
    case ("analysis")
      rt_pn%analysis_lexpr => null ()
    end select
  end subroutine rt_parse_nodes_clear

```

Output for the parse nodes.

```

<RT data: rt_parse_nodes: TBP>+≡
  procedure :: write => rt_parse_nodes_write

<RT data: procedures>+≡
  subroutine rt_parse_nodes_write (object, unit)
    class(rt_parse_nodes_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)

```

```

    call global%beam_structure%final_mom ()
end subroutine rt_data_clear_beams

```

28.8.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

```

  (global%var_list, var_str ("?openmp_logging"), &
   .true., intrinsic=.true.)
end subroutine set_openmp_defaults

```

28.8.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init

<RT data: procedures>+≡
  subroutine rt_data_local_init (local, global, env)
    class(rt_data_t), intent(inout), target :: local
    type(rt_data_t), intent(in), target :: global
    integer, intent(in), optional :: env
    local%context => global
    call local%process_stack%link (global%process_stack)
    call local%process_stack%init_var_list (local%var_list)
    call local%process_stack%link_var_list (global%var_list)
    call var_list_append_string &
      (local%var_list, var_str ("$model_name"), var_str (""), &
       intrinsic=.true.)
    call local%init_pointer_variables ()
    local%fallback_model => global%fallback_model
    local%radiation_model => global%radiation_model
    local%os_data = global%os_data
    local%logfile = global%logfile
    call local%model_list%link (global%model_list)
    local%model => global%model
    if (associated (local%model)) then
      call local%model%link_var_list (local%var_list)
    end if
  end subroutine rt_data_local_init

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
  procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: procedures>+≡
  subroutine rt_data_init_pointer_variables (local)
    class(rt_data_t), intent(inout), target :: local
    logical, target, save :: known = .true.
    call var_list_append_string_ptr &
      (local%var_list, var_str ("fc"), local%os_data%fc, known, &
        intrinsic=.true.)
    call var_list_append_string_ptr &
      (local%var_list, var_str ("fcflags"), local%os_data%fcflags, known, &
        intrinsic=.true.)
  end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: activate => rt_data_activate

<RT data: procedures>+≡
  subroutine rt_data_activate (local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), pointer :: global
    global => local%context
    if (associated (global)) then
      local%lexer => global%lexer
      call global%copy_globals (local)
      local%os_data = global%os_data
      local%logfile = global%logfile
      if (associated (global%prclib)) then
        local%prclib => &
          local%prclib_stack%get_library_ptr (global%prclib%get_name ())
      end if
      call local%import_values ()
      call local%process_stack%link (global%process_stack)
      local%it_list = global%it_list
      local%beam_structure = global%beam_structure
      local%pn = global%pn
      if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
      if (allocated (global%sample_fmt)) then
        allocate (local%sample_fmt (size (global%sample_fmt)), &

```

```

        source = global%sample_fmt)
    end if
    local%out_files => global%out_files
    local%model => global%model
    local%model_is_copy = .false.
else if (.not. associated (local%model)) then
    local%model => local%preload_model
    local%model_is_copy = .false.
end if
if (associated (local%model)) then
    call local%model%link_var_list (local%var_list)
    call var_list_set_string (local%var_list, var_str ("model_name"), &
        local%model%get_name (), is_known = .true.)
else
    call var_list_set_string (local%var_list, var_str ("model_name"), &
        var_str (""), is_known = .false.)
end if
end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
    procedure :: deactivate => rt_data_deactivate

<RT data: procedures>+≡
    subroutine rt_data_deactivate (local, global, keep_local)
        class(rt_data_t), intent(inout), target :: local
        class(rt_data_t), intent(inout), optional, target :: global
        logical, intent(in), optional :: keep_local
        type(string_t) :: global_model, local_model
        logical :: same_model, delete
        delete = .true.; if (present (keep_local)) delete = .not. keep_local
        if (present (global)) then
            if (associated (global%model) .and. associated (local%model)) then
                global_model = global%model%get_name ()
                local_model = local%model%get_name ()
                same_model = global_model == local_model
            else
                same_model = .false.
            end if
            if (delete) then
                call local%process_stack%clear ()
                call local%unselect_model ()
                call local%unset_values ()
            else if (associated (local%model)) then
                call local%ensure_model_copy ()
            end if
        end if
    end subroutine

```

```

        if (.not. same_model .and. global_model /= "") then
            call msg_message ("Restoring model '" // char (global_model) // "'")
        end if
        if (associated (global%model)) then
            call global%model%link_var_list (global%var_list)
        end if
        call global%restore_globals (local)
    else
        call local%unselect_model ()
    end if
end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
    procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
    subroutine rt_data_copy_globals (global, local)
        class(rt_data_t), intent(in) :: global
        class(rt_data_t), intent(inout) :: local
        local%prclib_stack = global%prclib_stack
    end subroutine rt_data_copy_globals

```

This restores global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡
    procedure :: restore_globals => rt_data_restore_globals

<RT data: procedures>+≡
    subroutine rt_data_restore_globals (global, local)
        class(rt_data_t), intent(inout) :: global
        class(rt_data_t), intent(in) :: local
        global%prclib_stack = local%prclib_stack
    end subroutine rt_data_restore_globals

```

28.8.8 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
    procedure :: final => rt_data_global_final

<RT data: procedures>+≡
    subroutine rt_data_global_final (global)
        class(rt_data_t), intent(inout) :: global
        call global%process_stack%final ()
        call global%prclib_stack%final ()
    !    call global%delete_model_copy ()
        call global%model_list%final ()
        call global%var_list%final (follow_link=.false.)
        if (associated (global%out_files)) then

```

```

        call file_list_final (global%out_files)
        deallocate (global%out_files)
    end if
end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡
    procedure :: local_final => rt_data_local_final

<RT data: procedures>+≡
    subroutine rt_data_local_final (local)
        class(rt_data_t), intent(inout) :: local
        call local%process_stack%clear ()
!       call local%delete_model_copy ()
        call local%model_list%final ()
        call local%var_list%final (follow_link=.false.)
    end subroutine rt_data_local_final

```

28.8.9 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
    procedure :: read_model => rt_data_read_model

<RT data: procedures>+≡
    subroutine rt_data_read_model (global, name, model)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name
        type(model_t), pointer, intent(out) :: model
        type(string_t) :: filename
        filename = name // ".mdl"
        call global%model_list%read_model &
            (name, filename, global%os_data, model)
    end subroutine rt_data_read_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
    procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: procedures>+≡
    subroutine rt_data_init_fallback_model (global, name, filename)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name, filename
        call global%model_list%read_model &

```

```

        (name, filename, global%os_data, global%fallback_model)
    end subroutine rt_data_init_fallback_model

```

Initialize the radiation model. This model is used by a radiation-generator algorithm which is part of the NLO machinery. It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
    procedure :: init_radiation_model => rt_data_init_radiation_model

<RT data: procedures>+≡
    subroutine rt_data_init_radiation_model (global, name, filename)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name, filename
        call global%model_list%read_model &
            (name, filename, global%os_data, global%radiation_model)
    end subroutine rt_data_init_radiation_model

```

Activate a model: assign the current-model pointer and set the model name in the variable list. If necessary, read the model from file. Link the global variable list to the model variable list.

```

<RT data: rt data: TBP>+≡
    procedure :: select_model => rt_data_select_model

<RT data: procedures>+≡
    subroutine rt_data_select_model (global, name)
        class(rt_data_t), intent(inout), target :: global
        type(string_t), intent(in) :: name
        logical :: same_model
        if (associated (global%model)) then
            same_model = global%model%get_name () == name
        else
            same_model = .false.
        end if
        if (.not. same_model) then
            ! call global%delete_model_copy ()
            global%model => global%model_list%get_model_ptr (name)
            if (.not. associated (global%model)) then
                call global%read_model (name, global%model)
                global%model_is_copy = .false.
            else if (associated (global%context)) then
                global%model_is_copy = &
                    global%model_list%model_exists (name, follow_link=.false.)
            else
                global%model_is_copy = .false.
            end if
        end if
        if (associated (global%model)) then
            call global%model%link_var_list (global%var_list)
            call var_list_set_string (global%var_list, var_str (" $model_name"), &
                name, is_known = .true.)
            call msg_message ("Switching to model '" // char (name) // "'")
        else
            call var_list_set_string (global%var_list, var_str (" $model_name"), &

```

```

        var_str (""), is_known = .false.)
    end if
end subroutine rt_data_select_model

```

Remove the model link and unset the model name variable.

```

<RT data: rt data: TBP>+≡
    procedure :: unselect_model => rt_data_unselect_model

  <RT data: execute tests>
  end subroutine rt_data_test

```

Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```

<RT data: rt data: TBP>+≡
  procedure :: fix_system_dependencies => rt_data_fix_system_dependencies

```

```

28.9 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

This module provides no new types, just procedures.

```
<dispatch.f90>≡  
<File header>  
  
module dispatch  
  
  <Use kinds>  
    use kinds, only: i16, double  
  <Use strings>

```

28.9.3 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```
<Dispatch: public>+≡
    public :: dispatch_core

<Dispatch: procedures>+≡
    subroutine dispatch_core (core, core_def, model, &
        helicity_selection, qcd, use_color_factors)
        class(prc_core_t), allocatable, intent(inout) :: core
        class(prc_core_def_t), intent(in) :: core_def
        class(model_data_t), intent(in), target, optional :: model
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        type(qcd_t), intent(in), optional :: qcd
        logical, intent(in), optional :: use_color_factors
        select type (core_def)
        type is (prc_test_def_t)
            allocate (test_t :: core)
        type is (template_me_def_t)
            allocate (prc_template_me_t :: core)
            select type (core)
            type is (prc_template_me_t)
                call core%set_parameters (model)
            end select
        class is (omega_def_t)
            if (.not. allocated (core)) allocate (prc_omega_t :: core)
            select type (core)
            type is (prc_omega_t)
                call core%set_parameters (model, &
                    helicity_selection, qcd, use_color_factors)
            end select
        type is (gosam_def_t)
            if (.not. allocated (core)) allocate (prc_gosam_t :: core)
            select type (core)
            type is (prc_gosam_t)
                call core%set_parameters (qcd, use_color_factors)
            end select
        type is (openloops_def_t)
            if (.not. allocated (core)) allocate (prc_openloops_t :: core)
            select type (core)
            type is (prc_openloops_t)
                call core%set_parameters (qcd, use_color_factors)
            end select
        class default
            call msg_bug ("Process core: unexpected process definition type")
        end select
    end subroutine dispatch_core
```

28.9.4 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

<Dispatch: public>+≡

```
public :: dispatch_core_update
public :: dispatch_core_restore
```

<Dispatch: procedures>+≡

```
subroutine dispatch_core_update (core, model, helicity_selection, qcd, &
    saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(model_data_t), intent(in), optional, target :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    class(prc_core_t), allocatable, intent(inout), optional :: saved_core
    if (present (saved_core)) then
        allocate (saved_core, source = core)
    end if

```

28.9.8 Random-number generator

Allocate a random-number generator factory according to the variable `$rng_method`, using the current seed in the global record. We take only the lower 15 bits of the seed, so the actual value fits into a positive 16-bit signed integer.

Since we want to guarantee that all random-number generators in a run are independent, we increment the global seed by one after creating the rng factory. If the user wants to have identical sequences, he can always set the seed manually, before it is used.

```

<Dispatch: public>+≡
    public :: dispatch_rng_factory

<Dispatch: procedures>+≡
    subroutine dispatch_rng_factory (rng_factory, global, local_input)
        class(rng_factory_t), allocatable, intent(inout) :: rng_factory

```

28.9.9 Structure function configuration data

This data type is a container for transferring structure-function specific data from the `dispatch_sf_data` to the `dispatch_sf_channels` subroutine.

```

<Dispatch: public>+≡
    public :: sf_prop_t

<Dispatch: types>≡
    type :: sf_prop_t
        real(default), dimension(2) :: isr_eps = 1
    end type sf_prop_t

```

Allocate a structure-function configuration object according to the `sf_method` string.

The `sf_prop` object can be used to transfer structure-function specific data up and to the `dispatch_sf_channels` subroutine below, so they can be used for particular mappings.

The `global` object is intent(inout) because the RNG generator seed may change during initialization.

The `pdg_in` array is the array of incoming flavors, corresponding to the upstream structure function or the beam array. This will be checked for the structure function in question and replaced by the outgoing flavors. The `pdg_prc` array is the array of incoming flavors (beam index, component index) for the hard process.

```

<Dispatch: public>+≡
    public :: dispatch_sf_data

<Dispatch: procedures>+≡
    subroutine dispatch_sf_data (data, sf_method, i_beam, sf_prop, global, &

This is an auxiliary procedure, used by the beam-structure expansion: tell for a given structure function name, whether it corresponds to a pair spectrum ($n = 2$), a single-particle structure function ($n = 1$), or nothing ($n = 0$). Though `energy_scan` can in principle also be a pair spectrum, it always has only one parameter.

end function strfun_mode

```

Dispatch a whole structure-function chain, given beam data and beam structure data.

This could be done generically, but we should look at the specific combination of structure functions in order to select appropriate mappings.

The `beam_structure` argument gets copied because we want to expand it to canonical form (one valid structure-function entry per record) before proceeding further.

The `pdg_prc` argument is the array of incoming flavors. The first index is the beam index, the second one the process component index. Each element is itself a PDG array, notrivial if there is a flavor sum for the incoming state of this component.

The dispatcher is divided in two parts. The first part configures the structure function data themselves. After this, we can configure the phase space for the elementary process.

(Dispatch: public)+≡

```
public :: dispatch_sf_config
```

(Dispatch: procedures)+≡

```
subroutine dispatch_sf_config (sf_config, sf_prop, global, pdg_prc)
  type(sf_config_t), dimension(:), allocatable, intent(out) :: sf_config
  type(sf_prop_t), intent(out) :: sf_prop
  type(rt_data_t), intent(inout) :: global
  type(beam_structure_t) :: beam_structure
  class(sf_data_t), allocatable :: sf_data
  type(pdg_array_t), dimension(:,:), intent(in) :: pdg_prc
  type(string_t), dimension(:), allocatable :: prt_in
  type(pdg_array_t), dimension(:), allocatable :: pdg_in
  type(flavor_t) :: flv_in
  integer :: n_beam, n_record, i
  beam_structure = global%beam_structure
  call beam_structure%expand (strfun_mode)
  n_record = beam_structure%get_n_record ()
  allocate (sf_config (n_record))
  n_beam = beam_structure%get_n_beam ()
  if (n_beam > 0) then
    allocate (prt_in (n_beam), pdg_in (n_beam))
    prt_in = beam_structure%get_prt ()
    do i = 1, n_beam
      call flv_in%init (prt_in(i), global%model)
      pdg_in(i) = flv_in%get_pdg ()
    end do
  else
    n_beam = size (pdg_prc, 1)
    allocate (pdg_in (n_beam))
    pdg_in = pdg_prc(:,1)
  end if
  do i = 1, n_record
    call dispatch_sf_data (sf_data, &
      beam_structure%get_name (i), &
      beam_structure%get_i_entry (i), &
      sf_prop, global, pdg_in, pdg_prc)
    call sf_config(i)%init (beam_structure%get_i_entry (i), sf_data)
    deallocate (sf_data)
  end do
end subroutine dispatch_sf_config
```

The second part configures channel mappings, using some conditions from the

phase space configuration. If there are no structure functions, we enable a default setup with a single (dummy) structure-function channel. Otherwise, we look at the channel collection that we got from the phase-space configuration step. Each entry should be translated into an independent structure-function channel, where typically there is one default entry, which could be mapped using a standard s-channel mapping if the structure function setup recommends this, and other entries with s-channel resonances. The latter need to be translated into global mappings from the structure-function chain.

28.9.11 QCD coupling

Allocate the `alpha` (running coupling) component of the `qcd` block with a concrete implementation, depending on the variable settings in the `global` record.

If a fixed α_s is requested, we do not allocate the `qcd%alpha` object. In this case, the matrix element code will just take the model parameter as-is, which implies fixed α_s . If the object is allocated, the α_s value is computed and updated for each matrix-element call.

```

end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

                     // "' : active process library undefined")
    end if
  end subroutine process_configuration_record

```

28.10.2 Test

This is the master for calling self-test procedures.

```

<Process configurations: public>+≡
  public :: process_configurations_test

<Process configurations: tests>≡
  subroutine process_configurations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Process configurations: execute tests>
  end subroutine process_configurations_test

```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

```

<Process configurations: public>+≡
  public :: prepare_test_library

```

(Process configurations: tests)+≡

```
subroutine prepare_test_library (global, libname, mode, procname)
  type(rt_data_t), intent(inout), target :: global
  type(string_t), intent(in) :: libname
  integer, intent(in) :: mode
  type(string_t), intent(in), dimension(:), optional :: procname
  type(prclib_entry_t), pointer :: lib
  type(string_t) :: prc_name
  type(string_t), dimension(:), allocatable :: prt_in, prt_out
  integer :: n_components
  type(process_configuration_t) :: prc_config

28.11 Compilation

This module manages compilation and loading of process libraries. It is needed as a separate module because integration depends on it.

```
<compilations.f90>≡  
  <File header>  
  
  module compilations  
  
    <Use strings>  
    use io_units  
    use unit_tests  
    use system_defs, only: TAB  
    use diagnostics  
    use os_interface  
    use md5  
    use variables  
    use model_data  
    use models  
    use process_libraries  
    use prclib_stacks  
    use rt_data  
    use process_configurations  
  
    <Standard module head>  
  
    <Compilations: public>  
  
    <Compilations: types>  
  
    contains  
  
    <Compilations: procedures>  
  
    <Compilations: tests>  
  
  end module compilations
```

28.11.1 The data type

The compilation item handles the compilation and loading of a single process library.

```
<Compilations: types>≡  
  type :: compilation_item_t  
    type(string_t) :: libname  
    type(string_t) :: static_external_tag  
    type(process_library_t), pointer :: lib => null ()  
    logical :: recompile_library = .false.  
  contains  
    <Compilations: compilation item: TBP>  
  end type compilation_item_t
```

Initialize:

```
<Compilations: compilation item: TBP>≡
  procedure :: init => compilation_item_init

<Compilations: procedures>≡
  subroutine compilation_item_init (comp, libname, stack, var_list)
    class(compilation_item_t), intent(out) :: comp
    type(string_t), intent(in) :: libname
    type(prclib_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in) :: var_list
    comp%libname = libname
    comp%lib => stack%get_library_ptr (comp%libname)
    if (.not. associated (comp%lib)) then
      call msg_fatal ("Process library '" // char (comp%libname) &
        // "' has not been declared.")
    end if
    comp%recompile_library = &
      var_list%get_lval (var_str ("?recompile_library"))
  end subroutine compilation_item_init
```

Compile the current library. The force flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

```
<Compilations: compilation item: TBP>+≡
  procedure :: compile => compilation_item_compile

<Compilations: procedures>+≡
  subroutine compilation_item_compile (comp, model, os_data, force, recompile)
    class(compilation_item_t), intent(inout) :: comp
    class(model_data_t), intent(in), target :: model
    type(os_data_t), intent(in) :: os_data
    logical, intent(in) :: force, recompile
    if (associated (comp%lib)) then
      call msg_message ("Process library '" &
        // char (comp%libname) // "': compiling ...")
      call comp%lib%configure (os_data)
      if (signal_is_pending ()) return
      call comp%lib%compute_md5sum (model)
      call comp%lib%write_makefile (os_data, force)
      if (signal_is_pending ()) return
      if (force) then
        call comp%lib%clean (os_data, distclean = .false.)
        if (signal_is_pending ()) return
      end if
      call comp%lib%write_driver (force)
      if (signal_is_pending ()) return
      if (recompile) then
        call comp%lib%load (os_data, keep_old_source = .true.)
        if (signal_is_pending ()) return
      end if
      call comp%lib%update_status (os_data)
    end if
  end subroutine compilation_item_compile
```

Load the current library, just after compiling it.

```
<Compilations: compilation item: TBP>+≡  
  procedure :: load => compilation_item_load  
  
<Compilations: procedures>+≡  
  subroutine compilation_item_load (comp, os_data)  
    class(compilation_item_t), intent(inout) :: comp  
    type(os_data_t), intent(in) :: os_data  
    if (associated (comp%lib)) then  
      call comp%lib%load (os_data)  
    end if  
  end subroutine compilation_item_load
```

Message as a separate call:

```
<Compilations: compilation item: TBP>+≡  
  procedure :: success => compilation_item_success  
  
<Compilations: procedures>+≡  
  subroutine compilation_item_success (comp)  
    class(compilation_item_t), intent(in) :: comp  
    if (associated (comp%lib)) then  
      call msg_message ("Process library '" // char (comp%libname) &  
        // "': ... success.")  
    else  
      call msg_fatal ("Process library '" // char (comp%libname) &  
        // "': ... failure.")  
    end if  
  end subroutine compilation_item_success
```

28.11.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```
<Compilations: public>≡  
  public :: compile_library  
  
<Compilations: procedures>+≡  
  subroutine compile_library (libname, global)  
    type(string_t), intent(in) :: libname  
    type(rt_data_t), intent(inout), target :: global  
    type(compilation_item_t) :: comp  
    logical :: force, recompile  
    force = &  
      global%var_list%get_lval (var_str ("?rebuild_library"))  
    recompile = &  
      global%var_list%get_lval (var_str ("?recompile_library"))  
    if (associated (global%model)) then  
      call comp%init (libname, global%prclib_stack, global%var_list)  
      call comp%compile (global%model, global%os_data, force, recompile)  
      if (signal_is_pending ()) return
```

```

        call comp%load (global%os_data)
        if (signal_is_pending ()) return
    else
        call msg_fatal ("Process library compilation: " &
            // " model is undefined.")
    end if
    call comp%success ()
end subroutine compile_library

```

28.11.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```

<Compilations: types>+≡
    type :: compilation_t
    private
        type(string_t) :: exe_name
        type(string_t), dimension(:), allocatable :: lib_name
    contains
        <Compilations: compilation: TBP>
    end type compilation_t

```

Output.

```

<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write

<Compilations: procedures>+≡
    subroutine compilation_write (object, unit)
        class(compilation_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Compilation object:"
        write (u, "(3x,3A)") "executable          = '", &
            char (object%exe_name), "'
        write (u, "(3x,A)", advance="no") "process libraries ="
        do i = 1, size (object%lib_name)
            write (u, "(1x,3A)", advance="no") "' ", char (object%lib_name(i)), "'
        end do
        write (u, *)
    end subroutine compilation_write

```

Initialize: we know the names of the executable and of the libraries.

```

<Compilations: compilation: TBP>+≡
    procedure :: init => compilation_init

<Compilations: procedures>+≡
    subroutine compilation_init (compilation, exe_name, lib_name)
        class(compilation_t), intent(out) :: compilation
        type(string_t), intent(in) :: exe_name
        type(string_t), dimension(:), intent(in) :: lib_name
        compilation%exe_name = exe_name

```

```

        allocate (compilation%lib_name (size (lib_name)))
        compilation%lib_name = lib_name
    end subroutine compilation_init

```

Write the dispatcher subroutine for the compiled libraries. Also write a subroutine which returns the names of the compiled libraries.

<Compilations: compilation: TBP>+≡

```

    procedure :: write_dispatcher => compilation_write_dispatcher

```

<Compilations: procedures>+≡

```

subroutine compilation_write_dispatcher (compilation)

            // " -f " // compilation%exe_name // ".makefile")
    end subroutine compilation_make_clean_exe

```

28.11.4 API for executable compilation

This is a shorthand for compiling and loading an executable, including the enclosed libraries. The `compilation` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
    public :: compile_executable

<Compilations: procedures>+≡
    subroutine compile_executable (exename, libname, global)
        type(string_t), intent(in) :: exename
        type(string_t), dimension(:), intent(in) :: libname
        type(rt_data_t), intent(inout), target :: global

```

```

type(compilation_t) :: compilation
type(compilation_item_t) :: item
type(string_t) :: ext_libtag
logical :: force, recompile
integer :: i
ext_libtag = ""
force = &
    global%var_list%get_lval (var_str ("?rebuild_library"))
recompile = &
    global%var_list%get_lval (var_str ("?recompile_library"))
call compilation%init (exename, [libname])
if (signal_is_pending ()) return
call compilation%write_dispatcher ()
if (signal_is_pending ()) return
do i = 1, size (libname)
    call item%init (libname(i), global%prclib_stack, global%var_list)
    call item%compile (global%model, global%os_data, &
        force=force, recompile=recompile)
    ext_libtag = "" // item%lib%get_static_modelname (global%os_data)
    if (signal_is_pending ()) return
    call item%success ()
end do
call compilation%write_makefile (global%os_data, ext_libtag)
if (signal_is_pending ()) return
call compilation%make_compile (global%os_data)
if (signal_is_pending ()) return
call compilation%make_link (global%os_data)
end subroutine compile_executable

```

28.11.5 Test

This is the master for calling self-test procedures.

```

<Compilations: public>+≡
    public :: compilations_test

<Compilations: tests>≡
    subroutine compilations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Compilations: execute tests>
    end subroutine compilations_test

```

Intrinsic Matrix Element

Compile an intrinsic test matrix element (prc_test type).

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```

<Compilations: execute tests>≡
    call test (compilations_1, "compilations_1", &
        "intrinsic test processes", &
        u, results)

```

```

<Compilations: tests>+≡
subroutine compilations_1 (u)
  integer, intent(in) :: u
  type(string_t) :: libname, procname
  type(rt_data_t), target :: global

  write (u, "(A)")  "* Test output: compilations_1"
  write (u, "(A)")  "* Purpose: configure and compile test process"
  write (u, "(A)")

  call syntax_model_file_init ()

  call global%global_init ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_3"

```

```
end subroutine compilations_3
```

28.11.6 Test static build

The tests for building a static executable are separate, since they should be skipped if the WHIZARD build itself has static libraries disabled.

```
<Compilations: public>+≡
  public :: compilations_static_test

<Compilations: tests>+≡
  subroutine compilations_static_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Compilations: static tests>
  end subroutine compilations_static_test
```

External Matrix Element

Compile an external test matrix element (omega type) and incorporate this in a new static WHIZARD executable.

```
<Compilations: static tests>≡
  call test (compilations_static_1, "compilations_static_1", &
    "static executable: compilation", &
    u, results)

<Compilations: tests>+≡
  subroutine compilations_static_1 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global

call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_static_1"

```

```
end subroutine compilations_static_1
```

External Matrix Element

Compile an external test matrix element (*omega* type) and incorporate this in a new static WHIZARD executable. In this version, we use the wrapper `compile_executable` procedure.

```
(Compilations: static tests) +=
  call test (compilations_static_2, "compilations_static_2", &
    "static executable: shortcut", &
    u, results)

(Compilations: tests) +=
  subroutine compilations_static_2 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    logical :: exist
    integer :: u_file

    write (u, "(A)")  "* Test output: compilations_static_2"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library and compile"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()
    call var_list_set_log (global%var_list, var_str ("?omega_openmp"), &
      .false., is_known = .true.)

    libname = "compilations_static_2_lib"
    procname = "prc_comp_stat_2"
    exename = "compilations_static_2"

    call prepare_test_library (global, libname, 2, [procname, procname])

    call compile_executable (exename, [libname], global)

    write (u, "(A)")  "* Check executable (should be present)"
    write (u, "(A)")

    inquire (file = char (exename), exist = exist)
    write (u, "(A,A,L1)") char (exename), " exists = ", exist

    write (u, "(A)")
    write (u, "(A)")  "* Cleanup"

    u_file = free_unit ()
    open (u_file, file = char (exename), status = "old", action = "write")
    close (u_file, status = "delete")
```

```
call global%final ()
call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_static_2"

end subroutine compilations_static_2
```

28.12 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

```

28.12.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

⟨Integrations: public⟩≡
    public :: integration_t

⟨Integrations: types⟩≡
    type :: integration_t
        private
            type(string_t) :: process_id
            type(string_t) :: run_id
            type(process_t), pointer :: process => null ()
            type(var_list_t), pointer :: model_vars => null ()
            type(qcd_t) :: qcd
            logical :: rebuild_phs = .false.
            logical :: ignore_phs_mismatch = .false.
            logical :: phs_only = .false.
            logical :: process_has_me = .true.
            integer :: n_calls_test = 0
            logical :: vis_history = .true.
            type(string_t) :: history_filename
            type(string_t) :: log_filename
            logical :: combined_integration = .false.
        contains
            ⟨Integrations: integration: TBP⟩
    end type integration_t

```

28.12.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied.

```

⟨Integrations: integration: TBP⟩≡
    procedure :: create_process => integration_create_process

```

```

<Integrations: procedures>≡
subroutine integration_create_process (intg, process_id, global)
  class(integration_t), intent(out) :: intg
  type(rt_data_t), intent(inout), optional, target :: global
  type(string_t), intent(in) :: process_id
  type(process_entry_t), pointer :: process_entry
  intg%process_id = process_id
  if (present (global)) then
    allocate (process_entry)
    intg%process => process_entry%process_t
    call global%process_stack%push (process_entry)
  else
    allocate (process_t :: intg%process)
  end if
  intg%model_vars => null ()
end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the local stack directly. The intent(inout) attribute for the local data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

```

<Integrations: integration: TBP>+≡
procedure :: init_process => integration_init_process

<Integrations: procedures>+≡
subroutine integration_init_process (intg, local)
  class(integration_t), intent(inout) :: intg
  type(rt_data_t), intent(inout), target :: local
  type(string_t) :: model_name
  type(model_t), pointer :: model
  class(model_data_t), pointer :: model_instance
  class(rng_factory_t), allocatable :: rng_factory
  if (.not. local%prclib%contains (intg%process_id)) then
    call msg_fatal ("Process '" // char (intg%process_id) // "' not found" &
      // " in library '" // char (local%prclib%get_name ()) // "'")
    return
  end if
  intg%run_id = &
    local%var_list%get_sval (var_str ("$_run_id"))
  call dispatch_qcd (intg%qcd, local)
  call dispatch_rng_factory (rng_factory, local)
  model_name = local%prclib%get_model_name (intg%process_id)
  if (local%get_sval (var_str ("$_model_name")) == model_name) then
    model => local%model
  else

```

```

        model => local%model_list%get_model_ptr (model_name)
    end if
    allocate (model_t :: model_instance)
    select type (model_instance)
    type is (model_t)
        call model_instance%init_instance (model)
        intg%model_vars => model_instance%get_var_list_ptr ()
    end select
    call intg%process%init (intg%process_id, intg%run_id, &
        local%prclib, &
        local%os_data, intg%qcd, rng_factory, model_instance)
end subroutine integration_init_process

```

Initialization, third part: complete process configuration.

(Integrations: integration: TBP)+≡

```

    procedure :: setup_process => integration_setup_process

```

(Integrations: procedures)+≡

```

    subroutine integration_setup_process (intg, local, verbose)

28.12.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

<Integrations: integration: TBP>+≡
    procedure :: evaluate => integration_evaluate

<Integrations: procedures>+≡
    subroutine integration_evaluate &
        (intg, process_instance, i_mci, pass, it_list, pacify)
        class(integration_t), intent(inout) :: intg
        type(process_instance_t), intent(inout), target :: process_instance
        integer, intent(in) :: i_mci
        integer, intent(in) :: pass
        type(iterations_list_t), intent(in) :: it_list
        logical, intent(in), optional :: pacify
        integer :: n_calls, n_it
        logical :: adapt_grids, adapt_weights, final

        n_it = it_list%get_n_it (pass)
        n_calls = it_list%get_n_calls (pass)
        adapt_grids = it_list%adapt_grids (pass)
        adapt_weights = it_list%adapt_weights (pass)
        final = pass == it_list%get_n_pass ()

        call intg%process%integrate (process_instance, &
            i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
            final, pacify)

    end subroutine integration_evaluate

```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

```

<Integrations: integration: TBP>+≡
    procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: procedures>+≡
    subroutine integration_make_iterations_list (intg, it_list)

```

```

class(integration_t), intent(in) :: intg
type(iterations_list_t), intent(out) :: it_list
integer :: pass, n_pass
integer, dimension(:), allocatable :: n_it, n_calls
logical, dimension(:), allocatable :: adapt_grids, adapt_weights

```

28.12.4 API for integration objects

This initializer does everything except assigning cuts/scale/weight expressions.

<Integrations: integration: TBP>+≡

```
procedure :: init => integration_init
```

<Integrations: procedures>+≡

```

subroutine integration_init (intg, process_id, local, global, local_stack)
  class(integration_t), intent(out) :: intg
  type(string_t), intent(in) :: process_id
  type(rt_data_t), intent(inout), target :: local
  type(rt_data_t), intent(inout), optional, target :: global
  logical, intent(in), optional :: local_stack
  logical :: use_local
  use_local = .false.; if (present (local_stack)) use_local = local_stack
  if (present (global)) then
    call intg%create_process (process_id, global)
  else if (use_local) then
    call intg%create_process (process_id, local)
  else
    call intg%create_process (process_id)
  end if
  call intg%init_process (local)
  call intg%setup_process (local)
end subroutine integration_init

```

Do the integration for a single process, both warmup and final evaluation. The `eff_reset` flag is to suppress numerical noise in the graphical output of the integration history.

    end if
    call process_instance%final ()
end subroutine integration_sampler_test

```

Return the process pointer (needed by simulate):

```

<Integrations: integration: TBP>+≡
    procedure :: get_process_ptr => integration_get_process_ptr

<Integrations: procedures>+≡
    function integration_get_process_ptr (intg) result (ptr)
        class(integration_t), intent(in) :: intg
        type(process_t), pointer :: ptr
        ptr => intg%process
    end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the `global` environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the process object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

```

<Integrations: public>+≡
    public :: integrate_process

<Integrations: procedures>+≡
    subroutine integrate_process (process_id, local, global, local_stack, init_only, eff_reset)

28.12.5 Test

This is the master for calling self-test procedures.

```

<Integrations: public>+≡
    public :: integrations_test

<Integrations: tests>≡
    subroutine integrations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Integrations: execute tests>
    end subroutine integrations_test

```

```

<Integrations: public>+≡
  public :: integrations_history_test

<Integrations: tests>+≡
  subroutine integrations_history_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Integrations: execute history tests>
  end subroutine integrations_history_test

```

Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (28.1)$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (28.2)$$

f is the flux of the incoming particles with mass $m = 125 \text{ GeV}$ and energy $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (28.3)$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (28.4)$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (28.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function $f(x) = x$ for both beams. Together with the $1/x_1 x_2$ factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the m_s mass which we set to zero here.

28.13 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
(event_streams.f90)≡  
  <File header>  
  
  module event_streams  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use unit_tests  
    use diagnostics  
    use variables  
    use model_data  
    use models  
    use processes  
    use events  
    use eio_data  
    use eio_base  
    use rt_data  
    use dispatch  
  
    <Standard module head>  
  
    <Event streams: public>  
  
    <Event streams: types>  
  
    contains  
  
    <Event streams: tests>  
  
    <Event streams: procedures>  
  
  end module event_streams
```

28.13.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡  
  type :: event_stream_entry_t  
    class(eio_t), allocatable :: eio  
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```
<Event streams: public>≡  
  public :: event_stream_array_t
```

```

<Event streams: types>+≡
  type :: event_stream_array_t
    type(event_stream_entry_t), dimension(:), allocatable :: entry
    integer :: i_in = 0
  contains
    <Event streams: event stream array: TBP>
  end type event_stream_array_t

```

Output.

```

<Event streams: event stream array: TBP>≡
  procedure :: write => event_stream_array_write

<Event streams: procedures>≡
  subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event stream array:"
    if (allocated (object%entry)) then
      select case (size (object%entry))
      case (0)
        write (u, "(3x,A)") "[empty]"
      case default
        do i = 1, size (object%entry)
          if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
          call object%entry(i)%eio%write (u)
        end do
      end select
    else
      write (u, "(3x,A)") "[undefined]"
    end if
  end subroutine event_stream_array_write

```

Finalize all streams.

```

<Event streams: event stream array: TBP>+≡
  procedure :: final => event_stream_array_final

<Event streams: procedures>+≡
  subroutine event_stream_array_final (es_array)
    class(event_stream_array_t), intent(inout) :: es_array
    integer :: i
    do i = 1, size (es_array%entry)
      call es_array%entry(i)%eio%final ()
    end do
  end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

28.13.2 Unit Tests

```

<Event streams: public>+≡
    public :: event_streams_test

<Event streams: tests>≡
    subroutine event_streams_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Event streams: execute tests>
    end subroutine event_streams_test

```

Empty event stream

This should set up an empty event output stream array, including initialization, output, and finalization (which are all no-ops).

```

<Event streams: execute tests>≡
    call test (event_streams_1, "event_streams_1", &
        "empty event stream array", &
        u, results)

<Event streams: tests>+≡
    subroutine event_streams_1 (u)
        integer, intent(in) :: u
        type(event_stream_array_t) :: es_array
        type(rt_data_t) :: global
        type(event_t) :: event
        type(string_t) :: sample
        type(string_t), dimension(0) :: empty_string_array

        write (u, "(A)")  "* Test output: event_streams_1"
        write (u, "(A)")  "* Purpose: handle empty event stream array"
        write (u, "(A)")

```

```

sample = "event_streams_1"

call es_array%init (sample, empty_string_array, global)
call es_array%output (event, 42, 1)
call es_array%write (u)
call es_array%final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: event_streams_1"

end subroutine event_streams_1

```

Nontrivial event stream

Here we generate a trivial event and choose raw output as an entry in the stream array.

```

<Event streams: execute tests>+≡
  call test (event_streams_2, "event_streams_2", &
    "nontrivial event stream array", &
    u, results)

<Event streams: tests>+≡

            object%error = process%get_error (i_mci)
            object%has_integral = .true.
        end if
    end subroutine mci_set_init

```

28.14.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

```

<Simulations: types>+≡
    type :: core_safe_t
        class(prc_core_t), allocatable :: core
    end type core_safe_t

```

28.14.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

```

<Simulations: procedures>+≡
    subroutine prepare_process &
        (process, process_id, integrate, local, global)
        type(process_t), pointer, intent(out) :: process

```

```

type(string_t), intent(in) :: process_id
logical, intent(in) :: integrate
type(rt_data_t), intent(inout), target :: local
type(rt_data_t), intent(inout), optional, target :: global
if (present (global)) then
    process => global%process_stack%get_process_ptr (process_id)
else
    process => local%process_stack%get_process_ptr (process_id)
end if
if (.not. associated (process)) then
    if (integrate) then
        call msg_message ("Simulate: process '" &
            // char (process_id) // "' needs integration")
    else
        call msg_message ("Simulate: process '" &
            // char (process_id) // "' needs initialization")
    end if
    if (present (global)) then
        call integrate_process (process_id, local, global, &
            init_only = .not. integrate)
    else
        call integrate_process (process_id, local, local_stack=.true., &
            init_only = .not. integrate)
    end if
    if (signal_is_pending ()) return
    process => global%process_stack%get_process_ptr (process_id)
    if (associated (process)) then
        if (integrate) then
            call msg_message ("Simulate: integration done")
            call global%process_stack%fill_result_vars (process_id)
        else
            call msg_message ("Simulate: process initialization done")
        end if
    else
        call msg_fatal ("Simulate: process '" &
            // char (process_id) // "' could not be initialized: aborting")
    end if
end if
end subroutine prepare_process

```

28.14.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the qcd and/or model components are present.

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the *process_instance* pointer. Assign data by looking at the process object and at the environment.

If *n_alt* is set, we prepare for additional alternate sqme and weight entries.

If the process object is not found initially: if *integrate* is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If *generate* is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the *instance* and *process* pointers of the base type by the *connect* method, so we can reference them later.

28.14.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
type, extends (entry_t) :: alt_entry_t
contains
  <Simulations: alt entry: TBP>
end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

Write the current event record. If an explicit index is given, write that event record.

We implement writing to `unit` (event contents / debugging format) and writing to an `eio` event stream (storage). We include a `testflag` in order to suppress numerical noise in the testsuite.

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the `luminosity` setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the `luminosity`, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

  if (simulation%i_prc /= 0) then
    i_mci = simulation%entry(simulation%i_prc)%select_mci ()
  end if
end function simulation_select_mci
```

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

NB: When reading from file, event transforms can't be applied because the process instance will not be complete. This should be fixed.

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

      end if
    end subroutine simulation_write_event_eio

```

```
end subroutine simulation_write_event_eio
```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```
<Simulations: simulation: TBP>+≡
generic :: read_event => read_event_eio
procedure :: read_event_eio => simulation_read_event_eio

<Simulations: procedures>+≡
subroutine simulation_read_event_eio (object, eio)

Chapter 29

More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in init/final hooks that we can set at runtime.)

29.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
<expr_tests.f90>≡  
  <File header>  
  module expr_tests  
  
    <Use kinds>  
    <Use strings>  
    use format_defs, only: FMT_12  
    use format_utils, only: write_separator  
    use unit_tests  
    use os_interface  
    use ifiles  
    use lexers  
    use parser  
    use lorentz  
    use sm_qcd  
    use model_data  
    use interactions, only: reset_interaction_counter  
    use variables  
    use expr_base  
    use eval_trees  
    use models  
    use subevents  
    use subvt_expr  
    use phs_base  
    use rng_base
```

```

use mci_base
use process_libraries
use prc_test
use prc_core
use processes
use events

```

⟨Standard module head⟩

Chapter 30

Top Level

The top level consists of

commands Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

whizard This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

main The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

whizard_c_interface Alternative top-level procedures, for use in the context of a C-compatible caller program.

30.1 Commands

This module defines the command language of the main input file.

```
<commands.f90>≡

end module commands

30.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as **options**, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```
⟨Commands: types⟩≡
  type, abstract :: command_t
    type(parse_node_t), pointer :: pn => null ()
    class(command_t), pointer :: next => null ()
    type(parse_node_t), pointer :: pn_opt => null ()
    type(command_list_t), pointer :: options => null ()
    type(rt_data_t), pointer :: local => null ()
  contains
    ⟨Commands: command: TBP⟩
  end type command_t
```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```
⟨Commands: command: TBP⟩≡
  procedure :: final => command_final

⟨Commands: procedures⟩≡
  recursive subroutine command_final (cmd)
    class(command_t), intent(inout) :: cmd
    if (associated (cmd%options)) then
      call cmd%options%final ()
      deallocate (cmd%options)
      call cmd%local%local_final ()
```

```

        deallocate (cmd%local)
    else
        cmd%local => null ()
    end if
end subroutine command_final

```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

(Commands: procedures)+≡

```

subroutine dispatch_command (command, pn)
    class(command_t), intent(inout), pointer :: command

```

case ("cmd_if")
  allocate (cmd_if_t :: command)
case ("cmd_include")
  allocate (cmd_include_t :: command)
case ("cmd_quit")
  allocate (cmd_quit_t :: command)
case default
  print *, char (parse_node_get_rule_key (pn))
  call msg_bug ("Command not implemented")
end select
command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

<Commands: command: TBP>+≡
  procedure (command_write), deferred :: write

<Commands: interfaces>≡
  abstract interface
    subroutine command_write (cmd, unit, indent)
      import
      class(command_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
    end subroutine command_write
  end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

<Commands: command: TBP>+≡
  procedure (command_compile), deferred :: compile

<Commands: interfaces>+≡
  abstract interface
    subroutine command_compile (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_compile
  end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

<Commands: command: TBP>+≡
  procedure (command_execute), deferred :: execute

<Commands: interfaces>+≡
  abstract interface
    subroutine command_execute (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_execute
  end interface

```

30.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```
<Commands: command: TBP>+≡
  procedure :: write_options => command_write_options

<Commands: procedures>+≡
  recursive subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options
```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```
<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
  recursive subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call cmd%options%compile (cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
      call cmd%local%deactivate ()
    else
      cmd%local => global
    end if
  end subroutine command_compile_options
```

Execute options. First prepare the local environment, then execute the command list.

```
<Commands: command: TBP>+≡
  procedure :: execute_options => cmd_execute_options

<Commands: procedures>+≡
  recursive subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call cmd%local%activate ()
      call cmd%options%execute (cmd%local)
```

```

        end if
    end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

⟨Commands: command: TBP⟩+≡
    procedure :: reset_options => cmd_reset_options

⟨Commands: procedures⟩+≡
    subroutine cmd_reset_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call cmd%local%deactivate (global)
        end if
    end subroutine cmd_reset_options

```

30.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_model_t
        private
        type(string_t) :: name
    contains
        ⟨Commands: cmd model: TBP⟩
    end type cmd_model_t

```

Output

```

⟨Commands: cmd model: TBP⟩≡
    procedure :: write => cmd_model_write

⟨Commands: procedures⟩+≡
    subroutine cmd_model_write (cmd, unit, indent)
        class(cmd_model_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,1x,'"',A,'\"') "model =", char (cmd%name)
    end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

```

⟨Commands: cmd model: TBP⟩+≡
    procedure :: compile => cmd_model_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_model_compile (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_name
  type(model_t), pointer :: model
  pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
  cmd%name = parse_node_get_string (pn_name)
  model => null ()
  if (associated (global%model)) then
    if (global%model%get_name () == cmd%name) model => global%model
  end if
  if (.not. associated (model)) then
    if (global%model_list%model_exists (cmd%name)) then
      model => global%model_list%get_model_ptr (cmd%name)
    else
      call global%read_model (cmd%name, model)
    end if
  end if
  global%model => model
  if (associated (global%model)) then
    call global%model%link_var_list (global%var_list)
  end if
end subroutine cmd_model_compile

```

Execute: Insert a pointer into the global data record and reassign the variable list.

```

⟨Commands: cmd model: TBP⟩+≡
  procedure :: execute => cmd_model_execute

⟨Commands: procedures⟩+≡
subroutine cmd_model_execute (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  call global%select_model (cmd%name)
  if (.not. associated (global%model)) &
    call msg_fatal ("Switching to model '" &
      // char (cmd%name) // "' : model not found")
end subroutine cmd_model_execute

```

Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_library_t
  private
  type(string_t) :: name
contains
  ⟨Commands: cmd library: TBP⟩
end type cmd_library_t

```

Output.

```
<Commands: cmd library: TBP>≡
  procedure :: write => cmd_library_write

<Commands: procedures>+≡
  subroutine cmd_library_write (cmd, unit, indent)
    class(cmd_library_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit)
    call write_indent (u, indent)
    write (u, "(1x,A,1x,'"',A,'\"')") "library =", char (cmd%name)
  end subroutine cmd_library_write
```

Compile. Get the library name.

```
<Commands: cmd library: TBP>+≡
  procedure :: compile => cmd_library_compile

<Commands: procedures>+≡
  subroutine cmd_library_compile (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_name
    pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
    cmd%name = parse_node_get_string (pn_name)
  end subroutine cmd_library_compile
```

Execute: Initialize a new library and push it on the library stack (if it does not yet exist). Insert a pointer to the library into the global data record. Then, try to load the library unless the rebuild flag is set.

```
<Commands: cmd library: TBP>+≡
  procedure :: execute => cmd_library_execute

<Commands: procedures>+≡
  subroutine cmd_library_execute (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(prclib_entry_t), pointer :: lib_entry
    type(process_library_t), pointer :: lib
    logical :: rebuild_library
    lib => global%prclib_stack%get_library_ptr (cmd%name)
    rebuild_library = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    if (.not. (associated (lib))) then
      allocate (lib_entry)
      call lib_entry%init (cmd%name)
      lib => lib_entry%process_library_t
      call global%add_prclib (lib_entry)
    else
      call global%update_prclib (lib)
    end if
    if (associated (lib) .and. .not. rebuild_library) then
      call lib%update_status (global%os_data)
```

```

        end if
    end subroutine cmd_library_execute

```

Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_process_t
        private
        type(string_t) :: id
        integer :: n_in = 0
        type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
        type(parse_node_t), pointer :: pn_out => null ()
        contains
        ⟨Commands: cmd process: TBP⟩
    end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

⟨Commands: cmd process: TBP⟩≡
    procedure :: write => cmd_process_write

⟨Commands: procedures⟩+≡
    subroutine cmd_process_write (cmd, unit, indent)
        class(cmd_process_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A,A,I0,A)") "process: ", char (cmd%id), " (", &
            size (cmd%pn_pdg_in), " -> X)"
        call cmd%write_options (u, indent)
    end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

⟨Commands: cmd process: TBP⟩+≡
    procedure :: compile => cmd_process_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_process_compile (cmd, global)
  class(cmd_process_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_id, pn_in, pn_codes
  integer :: i
  pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
  pn_in => parse_node_get_next_ptr (pn_id, 2)
  cmd%pn_out => parse_node_get_next_ptr (pn_in, 2)
  cmd%pn_opt => parse_node_get_next_ptr (cmd%pn_out)
  call cmd%compile_options (global)
  cmd%id = parse_node_get_string (pn_id)
  cmd%n_in = parse_node_get_n_sub (pn_in)
  pn_codes => parse_node_get_sub_ptr (pn_in)
  allocate (cmd%pn_pdg_in (cmd%n_in))
  do i = 1, cmd%n_in
    cmd%pn_pdg_in(i)%ptr => pn_codes
    pn_codes => parse_node_get_next_ptr (pn_codes)
  end do
end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

```

```

Command execution. Generate code, write driver, compile and link. Do this for all libraries in the list.

If no library names have been given and stored while compiling this command, we collect all libraries from the current stack and compile those.

We can compile static libraries (which actually just loads them). However, we can't incorporate in a generated executable.

<Commands: cmd compile: TBP>+≡

```
procedure :: execute => cmd_compile_execute
```

<Commands: procedures>+≡

```
subroutine cmd_compile_execute (cmd, global)
  class(cmd_compile_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(string_t), dimension(:), allocatable :: libname, libname_static
  integer :: i
  if (allocated (cmd%libname)) then
    allocate (libname (size (cmd%libname)))
    libname = cmd%libname
  else
    call cmd%local%prclib_stack%get_names (libname)
  end if
  if (cmd%make_executable) then
    call get_prclib_static (libname_static)
    do i = 1, size (libname)
      if (any (libname_static == libname(i))) then
        call msg_fatal ("Compile: can't include static library '" &
          // char (libname(i)) // "'")
      end if
    end do
    call compile_executable (cmd%exec_name, libname, cmd%local)
  else
    do i = 1, size (libname)
      call compile_library (libname(i), cmd%local)
    end do
  end if
end subroutine cmd_compile_execute
```

This is the interface to the external procedure which returns the names of all static libraries which are part of the executable. (The default is none.) The routine must allocate the array.

<Commands: public>≡

```
public :: get_prclib_static
```

<Commands: interfaces>+≡

```
interface
  subroutine get_prclib_static (libname)
    import
    type(string_t), dimension(:), intent(inout), allocatable :: libname
  end subroutine get_prclib_static
end interface
```

Execute a shell command

The argument is a string expression.

```

    end if
  end if
end if
end subroutine cmd_exec_execute

```

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

```

SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_slha_t
    private
    type(string_t) :: file
    logical :: write_mode = .false.
contains
<Commands: cmd slha: TBP>

```

```
end type cmd_slha_t
```

Output.

```
<Commands: cmd slha: TBP>≡
  procedure :: write => cmd_slha_write

<Commands: procedures>+≡
  subroutine cmd_slha_write (cmd, unit, indent)
    class(cmd_slha_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "slha: file name = ", char (cmd%file)
    write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
  end subroutine cmd_slha_write
```

Compile. Read the filename and store it.

```
<Commands: cmd slha: TBP>+≡
  procedure :: compile => cmd_slha_compile

<Commands: procedures>+≡
  subroutine cmd_slha_compile (cmd, global)
    class(cmd_slha_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_key, pn_arg, pn_file
    pn_key => parse_node_get_sub_ptr (cmd%pn)

```

Clear values

This command clears the current values of variables or other objects, where this makes sense. It parallels the `show` command. The objects are cleared, but not deleted.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_clear_t
    private
      type(string_t), dimension(:), allocatable :: name
    contains
      <Commands: cmd clear: TBP>
    end type cmd_clear_t
```

Output: list the names of the objects to be cleared.

```
<Commands: cmd clear: TBP>≡
  procedure :: write => cmd_clear_write

<Commands: procedures>+≡
  subroutine cmd_clear_write (cmd, unit, indent)
    class(cmd_clear_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u, i
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)", advance="no") "clear: "
    if (allocated (cmd%name)) then
      do i = 1, size (cmd%name)
        write (u, "(1x,A)", advance="no") char (cmd%name(i))

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

⟨Commands: types⟩+=
    type, extends (command_t) :: cmd_expect_t
        private
            type(parse_node_t), pointer :: pn_lexpr => null ()
        contains
            ⟨Commands: cmd expect: TBP⟩
        end type cmd_expect_t

```

Simply tell the status.

```

⟨Commands: cmd expect: TBP⟩=
    procedure :: write => cmd_expect_write

⟨Commands: procedures⟩+=
    subroutine cmd_expect_write (cmd, unit, indent)
        class(cmd_expect_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        if (associated (cmd%pn_lexpr)) then
            write (u, "(1x,A)") "expect: [expression associated]"
        else
            write (u, "(1x,A)") "expect: [undefined]"
        end if
    end subroutine cmd_expect_write

```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

```

⟨Commands: cmd expect: TBP⟩+=
    procedure :: compile => cmd_expect_compile

⟨Commands: procedures⟩+=
    subroutine cmd_expect_compile (cmd, global)
        class(cmd_expect_t), intent(inout) :: cmd

Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

<Commands: types>+≡
    type :: sentry_expr_t
        type(parse_node_p), dimension(:), allocatable :: expr
        contains
        <Commands: sentry expr: TBP>
    end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

<Commands: sentry expr: TBP>≡
    procedure :: compile => sentry_expr_compile

<Commands: procedures>+≡
    subroutine sentry_expr_compile (sentry, pn)
        class(sentry_expr_t), intent(out) :: sentry
        type(parse_node_t), intent(in), target :: pn
        type(parse_node_t), pointer :: pn_expr, pn_extra
        integer :: n_expr, i
        n_expr = parse_node_get_n_sub (pn)
        allocate (sentry%expr (n_expr))
        if (n_expr > 0) then
            i = 0
            pn_expr => parse_node_get_sub_ptr (pn)
            pn_extra => parse_node_get_next_ptr (pn_expr)
            do i = 1, n_expr
                sentry%expr(i)%ptr => pn_expr
                if (associated (pn_extra)) then
                    pn_expr => parse_node_get_sub_ptr (pn_extra, 2)
                    pn_extra => parse_node_get_next_ptr (pn_extra)
                end if
            end do
        end if
    end subroutine sentry_expr_compile

```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

```

    global%pn%cuts_lexpr => cmd%pn_lexpr
  end subroutine cmd_cuts_execute

```

General, Factorization and Renormalization Scales

Define a scale expression for either the renormalization or the factorization scale. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd scale: TBP⟩
  end type cmd_scale_t

```

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_fac_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd fac scale: TBP⟩
  end type cmd_fac_scale_t

```

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_ren_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd ren scale: TBP⟩
  end type cmd_ren_scale_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

⟨Commands: cmd scale: TBP⟩≡
  procedure :: write => cmd_scale_write

⟨Commands: procedures⟩+≡
  subroutine cmd_scale_write (cmd, unit, indent)
    class(cmd_scale_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent

```

```

integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)") "scale: [defined]"
end subroutine cmd_scale_write

```

<Commands: cmd fac scale: TBP>≡
 procedure :: write => cmd_fac_scale_write

<Commands: procedures>+≡
 subroutine cmd_fac_scale_write (cmd, unit, indent)
 class(cmd_fac_scale_t), intent(in) :: cmd
 integer, intent(in), optional :: unit, indent
 integer :: u
 u = given_output_unit (unit); if (u < 0) return
 call write_indent (u, indent)
 write (u, "(1x,A)") "factorization scale: [defined]"
end subroutine cmd_fac_scale_write

<Commands: cmd ren scale: TBP>≡
 procedure :: write => cmd_ren_scale_write

<Commands: procedures>+≡
 subroutine cmd_ren_scale_write (cmd, unit, indent)
 class(cmd_ren_scale_t), intent(in) :: cmd
 integer, intent(in), optional :: unit, indent
 integer :: u
 u = given_output_unit (unit); if (u < 0) return
 call write_indent (u, indent)
 write (u, "(1x,A)") "renormalization scale: [defined]"
end subroutine cmd_ren_scale_write

Compile. Simply store the parse (sub)tree.

<Commands: cmd scale: TBP>+≡
 procedure :: compile => cmd_scale_compile

<Commands: procedures>+≡
 subroutine cmd_scale_compile (cmd, global)
 class(cmd_scale_t), intent(inout) :: cmd

    type(rt_data_t), intent(inout), target :: global
    global%pn%weight_expr => cmd%pn_expr
  end subroutine cmd_weight_execute

```

Selection

Define a selection expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_selection_t
  private

```

```

    type(parse_node_t), pointer :: pn_expr => null ()
contains
  <Commands: cmd selection: TBP>≡
end type cmd_selection_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd selection: TBP>≡
  procedure :: write => cmd_selection_write

<Commands: procedures>+≡
  subroutine cmd_selection_write (cmd, unit, indent)
    class(cmd_selection_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "selection expression: [defined]"
  end subroutine cmd_selection_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd selection: TBP>+≡
  procedure :: compile => cmd_selection_compile

<Commands: procedures>+≡
  subroutine cmd_selection_compile (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_selection_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd selection: TBP>+≡
  procedure :: execute => cmd_selection_execute

<Commands: procedures>+≡
  subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_reweight_t

```

```

    private
    type(parse_node_t), pointer :: pn_expr => null ()
contains
  <Commands: cmd reweight: TBP>
end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd reweight: TBP>≡
  procedure :: write => cmd_reweight_write
<Commands: procedures>+≡
  subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: compile => cmd_reweight_compile
<Commands: procedures>+≡
  subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: execute => cmd_reweight_execute
<Commands: procedures>+≡
  subroutine cmd_reweight_execute (cmd, global)

    type(rt_data_t), intent(inout), target :: global
    global%pn%reweight_expr => cmd%pn_expr
  end subroutine cmd_reweight_execute

```

Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

<Commands: types>+≡

```

```

type, extends (command_t) :: cmd_alt_setup_t
  private
  type(parse_node_p), dimension(:), allocatable :: setup
contains
  <Commands: cmd alt setup: TBP>
end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

<Commands: cmd alt setup: TBP>≡
  procedure :: write => cmd_alt_setup_write

<Commands: procedures>+≡
  subroutine cmd_alt_setup_write (cmd, unit, indent)
    class(cmd_alt_setup_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
  end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

<Commands: cmd alt setup: TBP>+≡
  procedure :: compile => cmd_alt_setup_compile

<Commands: procedures>+≡
  subroutine cmd_alt_setup_compile (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_list, pn_setup
    integer :: i
    pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
    if (associated (pn_list)) then
      allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
      i = 1
      pn_setup => parse_node_get_sub_ptr (pn_list)
      do while (associated (pn_setup))
        cmd%setup(i)%ptr => pn_setup
        i = i + 1
        pn_setup => parse_node_get_next_ptr (pn_setup)
      end do
    else
      allocate (cmd%setup (0))
    end if
  end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

<Commands: cmd alt setup: TBP>+≡
  procedure :: execute => cmd_alt_setup_execute

<Commands: procedures>+≡
  subroutine cmd_alt_setup_execute (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global

```

```

        integer :: u, i
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)", advance="no") "integrate ("
        do i = 1, cmd%n_proc
            if (i > 1) write (u, "(A,1x)", advance="no") ", "
            write (u, "(A)", advance="no") char (cmd%process_id(i))
        end do
        write (u, "(A)") ")"
    end subroutine cmd_integrate_write

```

Compile.

```

<Commands: cmd integrate: TBP>+≡
    procedure :: compile => cmd_integrate_compile

<Commands: procedures>+≡
    subroutine cmd_integrate_compile (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_proclist, pn_proc
        integer :: i
        pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
        cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
        call cmd%compile_options (global)
        cmd%n_proc = parse_node_get_n_sub (pn_proclist)
        allocate (cmd%process_id (cmd%n_proc))
        pn_proc => parse_node_get_sub_ptr (pn_proclist)
        do i = 1, cmd%n_proc

```

```

        cmd%process_id(i) = parse_node_get_string (pn_proc)
        call global%process_stack%init_result_vars (cmd%process_id(i))
        pn_proc => parse_node_get_next_ptr (pn_proc)
    end do
end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

<Commands: cmd integrate: TBP>+≡
    procedure :: execute => cmd_integrate_execute

<Commands: procedures>+≡
    subroutine cmd_integrate_execute (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        integer :: i

```

Plots

Declare a plot. No mandatory arguments, just options.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_plot_t
    private
    type(string_t) :: id
    contains
    <Commands: cmd plot: TBP>
end type cmd_plot_t

```

Output. Just print the ID.

```

<Commands: cmd plot: TBP>≡
    procedure :: write => cmd_plot_write

<Commands: procedures>+≡
    subroutine cmd_plot_write (cmd, unit, indent)
        class(cmd_plot_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A)") "plot: ", char (cmd%id)
    end subroutine cmd_plot_write

```

Compile. Record the plot ID and initialize lower, upper bound and bin width.

```

<Commands: cmd plot: TBP>+≡
    procedure :: compile => cmd_plot_compile

```

```

<Commands: procedures>+≡
  subroutine cmd_plot_compile (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_tag
    pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%init (pn_tag, global)
  end subroutine cmd_plot_compile

```

This init routine is separated because it is reused below for graph initialization.

```

<Commands: cmd plot: TBP>+≡
  procedure :: init => cmd_plot_init

<Commands: procedures>+≡
  subroutine cmd_plot_init (plot, pn_tag, global)
    class(cmd_plot_t), intent(inout) :: plot
    type(parse_node_t), intent(in), pointer :: pn_tag
    type(rt_data_t), intent(inout), target :: global
    call plot%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
      case ("analysis_id")
        plot%id = parse_node_get_string (pn_tag)
      case default
        call msg_bug ("plot: name expression not implemented (yet)")
    end select
  end subroutine cmd_plot_init

```

Command execution. This declares the plot and allocates it in the analysis store.

```

<Commands: cmd plot: TBP>+≡
  procedure :: execute => cmd_plot_execute

<Commands: procedures>+≡
  subroutine cmd_plot_execute (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call drawing_options_init_plot (drawing_options)
    call set_drawing_options (drawing_options, var_list)

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_graph_t
    private
    type(string_t) :: id
    integer :: n_elements = 0
    type(cmd_plot_t), dimension(:), allocatable :: el
    type(string_t), dimension(:), allocatable :: element_id
  contains
    <Commands: cmd graph: TBP>
  end type cmd_graph_t
```

Output. Just print the ID.

```
<Commands: cmd graph: TBP>≡
  procedure :: write => cmd_graph_write

<Commands: procedures>+≡
  subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)") "graph: ", char (cmd%id), &
      " (" , cmd%n_elements, " entries)"
  end subroutine cmd_graph_write
```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```
<Commands: cmd graph: TBP>+≡
  procedure :: compile => cmd_graph_compile

<Commands: procedures>+≡
  subroutine cmd_graph_compile (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
    integer :: i

    pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      cmd%id = parse_node_get_string (pn_tag)
```

```

case default
  call msg_bug ("graph: name expression not implemented (yet)")
end select
pn_def => parse_node_get_next_ptr (pn_term, 2)
cmd%n_elements = parse_node_get_n_sub (pn_def)
allocate (cmd%element_id (cmd%n_elements))
allocate (cmd%el (cmd%n_elements))
pn_term => parse_node_get_sub_ptr (pn_def)
pn_tag => parse_node_get_sub_ptr (pn_term)
cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
call cmd%el(1)%init (pn_tag, global)
cmd%element_id(1) = parse_node_get_string (pn_tag)
pn_app => parse_node_get_next_ptr (pn_term)
do i = 2, cmd%n_elements
  pn_term => parse_node_get_sub_ptr (pn_app, 2)
  pn_tag => parse_node_get_sub_ptr (pn_term)
  cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
  call cmd%el(i)%init (pn_tag, global)
  cmd%element_id(i) = parse_node_get_string (pn_tag)
  pn_app => parse_node_get_next_ptr (pn_app)
end do

end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

<Commands: cmd graph: TBP>+≡

```

procedure :: execute => cmd_graph_execute

```

<Commands: procedures>+≡

```

subroutine cmd_graph_execute (cmd, global)
  class(cmd_graph_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  type(graph_options_t) :: graph_options
  type(drawing_options_t) :: drawing_options
  integer :: i, type

  var_list => cmd%local%get_var_list_ptr ()
  call graph_options_init (graph_options)
  call set_graph_options (graph_options, var_list)
  call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

  do i = 1, cmd%n_elements
    if (associated (cmd%el(i)%options)) then
      call cmd%el(i)%options%execute (cmd%el(i)%local)
    end if
    type = analysis_store_get_object_type (cmd%element_id(i))
  end do

```

```

select case (type)
case (AN_HISTOGRAM)
    call drawing_options_init_histogram (drawing_options)
case (AN_PLOT)
    call drawing_options_init_plot (drawing_options)
end select
call set_drawing_options (drawing_options, var_list)
if (associated (cmd%el(i)%options)) then
    call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
end if
call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
end do
end subroutine cmd_graph_execute

```

Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
type :: analysis_id_t
type(string_t) :: tag
type(parse_node_t), pointer :: pn_sexpr => null ()
end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_analysis_t
private
type(parse_node_t), pointer :: pn_lexpr => null ()
contains
⟨Commands: cmd analysis: TBP⟩
end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

⟨Commands: cmd analysis: TBP⟩≡
procedure :: write => cmd_analysis_write

⟨Commands: procedures⟩+≡
subroutine cmd_analysis_write (cmd, unit, indent)
class(cmd_analysis_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)") "analysis: [defined]"
end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd analysis: TBP⟩+≡
procedure :: compile => cmd_analysis_compile

```

```

<Commands: procedures>+≡
  subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd analysis: TBP>+≡
  procedure :: execute => cmd_analysis_execute

<Commands: procedures>+≡
  subroutine cmd_analysis_execute (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%analysis_lexpr => cmd%pn_lexpr
  end subroutine cmd_analysis_execute

```

Write histograms and plots

The data type encapsulating the command:

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_write_analysis_t
  private
    type(analysis_id_t), dimension(:), allocatable :: id
    type(string_t), dimension(:), allocatable :: tag
  contains
    <Commands: cmd write analysis: TBP>
  end type cmd_write_analysis_t

```

Output. Just the keyword.

```

<Commands: cmd write analysis: TBP>≡
  procedure :: write => cmd_write_analysis_write

<Commands: procedures>+≡
  subroutine cmd_write_analysis_write (cmd, unit, indent)
    class(cmd_write_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "write_analysis"
  end subroutine cmd_write_analysis_write

```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: compile => cmd_write_analysis_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_write_analysis_compile (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
  integer :: n, i
  pn_clause => parse_node_get_sub_ptr (cmd%pn)
  pn_args => parse_node_get_sub_ptr (pn_clause, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
  call cmd%compile_options (global)
  if (associated (pn_args)) then
    n = parse_node_get_n_sub (pn_args)
    allocate (cmd%id (n))
    do i = 1, n
      pn_id => parse_node_get_sub_ptr (pn_args, i)
      if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
        cmd%id(i)%tag = parse_node_get_string (pn_id)
      else
        cmd%id(i)%pn_sexpr => pn_id
      end if
    end do
  else
    allocate (cmd%id (0))
  end if
end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

⟨Commands: parameters⟩+≡
character(*), parameter, public :: &
  DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
  FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(5), parameter, public :: &
  FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "lo", "la" ]
character(len=3), dimension(16), parameter, public :: &
  FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
    "f95", "log", "ltp", "mpx", "olc", "olp", "pdf", "phs", "sin", "tex" ]

```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```

⟨Commands: cmd write analysis: TBP⟩+≡
  procedure :: execute => cmd_write_analysis_execute

⟨Commands: procedures⟩+≡
subroutine cmd_write_analysis_execute (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  var_list => cmd%local%get_var_list_ptr ()
  call write_analysis_wrap (var_list, global%out_files, &
    cmd%id, tag = cmd%tag)
end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

(Commands: procedures)+≡

```

subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
  type(var_list_t), intent(inout), target :: var_list
  type(file_list_t), intent(inout), target :: out_files

      end if
    end if
  end subroutine cmd_printf_execute

```

Record data

The expression syntax already contains a `record` keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_record_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  ⟨Commands: cmd record: TBP⟩
  end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

⟨Commands: cmd record: TBP⟩≡
  procedure :: write => cmd_record_write

⟨Commands: procedures⟩+≡
  subroutine cmd_record_write (cmd, unit, indent)
    class(cmd_record_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u

```

```

    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "record"
end subroutine cmd_record_write

```

Compile. This is a hack which transforms the `record` command into a `record` expression, which we handle in the `expressions` module.

```

⟨Commands: cmd record: TBP⟩+≡
    procedure :: compile => cmd_record_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_record_compile (cmd, global)
        class(cmd_record_t), intent(inout) :: cmd

```

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

```

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

Note: for the integer/real range array, the obvious implementation as a polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are apparently broken.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_scan_t
    private
    type(string_t) :: name
    integer :: n_values = 0
    type(parse_node_p), dimension(:), allocatable :: scan_cmd
    !!! !!! gfortran 4.7.x memory corruption
    !!! class(range_t), dimension(:), allocatable :: range
    type(range_int_t), dimension(:), allocatable :: range_int
    type(range_real_t), dimension(:), allocatable :: range_real
contains
    <Commands: cmd scan: TBP>
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

<Commands: cmd scan: TBP>≡

```

```

    procedure :: final => cmd_scan_final
  <Commands: procedures>+≡
    recursive subroutine cmd_scan_final (cmd)
      class(cmd_scan_t), intent(inout) :: cmd

      integer :: u
      u = given_output_unit (unit); if (u < 0) return
      call write_indent (u, indent)
      write (u, "(1x,A,1x,A,1x,'(',I0,')')") "scan:", char (cmd%name), &
        cmd%n_values
    end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

    deallocate (local)
end if
end do
end subroutine cmd_scan_execute

```

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of `else if` constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_if_t
private
type(parse_node_t), pointer :: pn_if_lexpr => null ()
type(command_list_t), pointer :: if_body => null ()
type(cmd_if_t), dimension(:), pointer :: elsif_cmd => null ()
type(command_list_t), pointer :: else_body => null ()
contains
<Commands: cmd if: TBP>
end type cmd_if_t

```

Finalizer. There are no local options, therefore we can simply override the default finalizer.

```

<Commands: cmd if: TBP>≡
procedure :: final => cmd_if_final

<Commands: procedures>+≡
recursive subroutine cmd_if_final (cmd)
class(cmd_if_t), intent(inout) :: cmd
integer :: i
if (associated (cmd%if_body)) then
    call command_list_final (cmd%if_body)
    deallocate (cmd%if_body)
end if
if (associated (cmd%elsif_cmd)) then
    do i = 1, size (cmd%elsif_cmd)
        call cmd_if_final (cmd%elsif_cmd(i))
    end do
    deallocate (cmd%elsif_cmd)
end if
if (associated (cmd%else_body)) then
    call command_list_final (cmd%else_body)
    deallocate (cmd%else_body)
end if

```

```

end if
end subroutine cmd_if_final

```

Output. Recursively write the command lists.

```

<Commands: cmd if: TBP>+≡

call parse_tree_init (cmd%parse_tree, syntax_cmd_list, lexer)
call stream_final (stream)
call lexer_final (lexer)
close (u)
allocate (cmd%command_list)
call cmd%command_list%compile (parse_tree_get_root_ptr (cmd%parse_tree), &
    global)
end subroutine cmd_include_compile

```

Execute file contents in the global context.

```

<Commands: cmd include: TBP>+=
    procedure :: execute => cmd_include_execute

<Commands: procedures>+=
    subroutine cmd_include_execute (cmd, global)
        class(cmd_include_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%command_list)) then
            call msg_message &
                ("Including Sindarin from '" // char (cmd%file) // "'")
            call cmd%command_list%execute (global)
            call msg_message &
                ("End of included '" // char (cmd%file) // "'")
        end if
    end subroutine cmd_include_execute

```

Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```

<Commands: types>+=
    type, extends (command_t) :: cmd_quit_t
        private
        logical :: has_code = .false.
        type(parse_node_t), pointer :: pn_code_expr => null ()
    contains
        <Commands: cmd quit: TBP>
    end type cmd_quit_t

```

Output.

```

<Commands: cmd quit: TBP>=
    procedure :: write => cmd_quit_write

```

```

<Commands: procedures>+≡
subroutine cmd_quit_write (cmd, unit, indent)
  class(cmd_quit_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,L1)") "quit: has_code = ", cmd%has_code
end subroutine cmd_quit_write

```

Compile: allocate a quit object which serves as a placeholder.

```

<Commands: cmd quit: TBP>+≡
  procedure :: compile => cmd_quit_compile

<Commands: procedures>+≡
subroutine cmd_quit_compile (cmd, global)
  class(cmd_quit_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_arg
  pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
  if (associated (pn_arg)) then
    cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
    cmd%has_code = .true.
  end if
end subroutine cmd_quit_compile

```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```

<Commands: cmd quit: TBP>+≡
  procedure :: execute => cmd_quit_execute

<Commands: procedures>+≡
subroutine cmd_quit_execute (cmd, global)
  class(cmd_quit_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  logical :: is_known
  var_list => global%get_var_list_ptr ()
  if (cmd%has_code) then
    global%quit_code = eval_int (cmd%pn_code_expr, var_list, &
      is_known=is_known)
    if (.not. is_known) then
      call msg_error ("Undefined return code of quit/exit command")
    end if
  end if
  global%quit = .true.
end subroutine cmd_quit_execute

```

30.1.6 The command list

The command list holds a list of commands and relevant global data.

```
<Commands: public>+≡
    public :: command_list_t

<Commands: types>+≡
    type :: command_list_t
        ! not private anymore as required by the whizard-c-interface
        class(command_t), pointer :: first => null ()
        class(command_t), pointer :: last => null ()
    contains
        <Commands: command list: TBP>
    end type command_list_t
```

Output.

```
<Commands: command list: TBP>≡
    procedure :: write => command_list_write

<Commands: procedures>+≡
    recursive subroutine command_list_write (cmd_list, unit, indent)
        class(command_list_t), intent(in) :: cmd_list
        integer, intent(in), optional :: unit, indent
        class(command_t), pointer :: cmd
        cmd => cmd_list%first
        do while (associated (cmd))
            call cmd%write (unit, indent)
            cmd => cmd%next
        end do
    end subroutine command_list_write
```

Append a new command to the list and free the original pointer.

```
<Commands: command list: TBP>+≡
    procedure :: append => command_list_append

<Commands: procedures>+≡
    subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
        if (associated (cmd_list%last)) then
            cmd_list%last%next => command
        else
            cmd_list%first => command
        end if
        cmd_list%last => command
        command => null ()
    end subroutine command_list_append
```

Finalize.

```
<Commands: command list: TBP>+≡
    procedure :: final => command_list_final
```

```

<Commands: procedures>+≡
recursive subroutine command_list_final (cmd_list)
  class(command_list_t), intent(inout) :: cmd_list
  class(command_t), pointer :: command
  do while (associated (cmd_list%first))
    command => cmd_list%first
    cmd_list%first => cmd_list%first%next
    call command%final ()
    deallocate (command)
  end do
  cmd_list%last => null ()
end subroutine command_list_final

```

30.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```

<Commands: command list: TBP>+≡
  procedure :: compile => command_list_compile

<Commands: procedures>+≡
recursive subroutine command_list_compile (cmd_list, pn, global)
  class(command_list_t), intent(inout), target :: cmd_list
  type(parse_node_t), intent(in), target :: pn
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_cmd
  class(command_t), pointer :: command
  integer :: i
  pn_cmd => parse_node_get_sub_ptr (pn)
  do i = 1, parse_node_get_n_sub (pn)
    call dispatch_command (command, pn_cmd)
    call command%compile (global)
    call cmd_list%append (command)
    call terminate_now_if_signal ()
    pn_cmd => parse_node_get_next_ptr (pn_cmd)
  end do
end subroutine command_list_compile

```

30.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```

<Commands: command list: TBP>+≡
  procedure :: execute => command_list_execute

<Commands: procedures>+≡
recursive subroutine command_list_execute (cmd_list, global)
  class(command_list_t), intent(in) :: cmd_list
  type(rt_data_t), intent(inout), target :: global

```

```

class(command_t), pointer :: command
command => cmd_list%first
COMMAND_COND: do while (associated (command))
    call command%execute_options (global)
    call command%execute (global)
    call command%reset_options (global)
    call terminate_now_if_signal ()
    if (global%quit) exit COMMAND_COND
    command => command%next
end do COMMAND_COND
end subroutine command_list_execute

```

30.1.9 Command list syntax

```

<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡

<Standard module head>

<WHIZARD: public>

<WHIZARD: types>

save

contains

<WHIZARD: procedures>

end module whizard

```

30.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```

<WHIZARD: public>≡
    public :: whizard_options_t

<WHIZARD: types>≡
    type :: whizard_options_t
        type(string_t) :: preload_model
        type(string_t) :: default_lib
        type(string_t) :: preload_libraries
        logical :: rebuild_library = .false.
        logical :: recompile_library = .false.
        logical :: rebuild_user
        logical :: rebuild_phs = .false.
        logical :: rebuild_grids = .false.
        logical :: rebuild_events = .false.
    end type whizard_options_t

```

30.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global`

object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

<WHIZARD: types>+≡
  type, extends (parse_tree_t) :: pt_entry_t
    type(pt_entry_t), pointer :: previous => null ()
  end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the `last` pointer.

```

<WHIZARD: types>+≡
  type :: pt_stack_t
    type(pt_entry_t), pointer :: last => null ()
    contains
      <WHIZARD: pt_stack: TBP>
  end type pt_stack_t

```

The finalizer is called at the very end.

```

<WHIZARD: pt_stack: TBP>≡
  procedure :: final => pt_stack_final

<WHIZARD: procedures>≡
  subroutine pt_stack_final (pt_stack)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(pt_entry_t), pointer :: current
    do while (associated (pt_stack%last))
      current => pt_stack%last
      pt_stack%last => current%previous
      call parse_tree_final (current%parse_tree_t)
      deallocate (current)
    end do
  end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt_stack: TBP>+≡
  procedure :: push => pt_stack_push

<WHIZARD: procedures>+≡
  subroutine pt_stack_push (pt_stack, parse_tree)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(parse_tree_t), intent(out), pointer :: parse_tree
    type(pt_entry_t), pointer :: current
    allocate (current)
    parse_tree => current%parse_tree_t
    current%previous => pt_stack%last
    pt_stack%last => current
  end subroutine pt_stack_push

```

30.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a `WHIZARD` instance. The object holds various default settings and the current state of the generator,

the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+=
  public :: whizard_t

<WHIZARD: types>+=
  type :: whizard_t
    type(whizard_options_t) :: options
    type(rt_data_t) :: global
    type(pt_stack_t) :: pt_stack
  contains
    <WHIZARD: whizard: TBP>
  end type whizard_t

```

30.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>=
  procedure :: init => whizard_init

<WHIZARD: procedures>+=
  subroutine whizard_init (whizard, options, paths, logfile)
    class(whizard_t), intent(out), target :: whizard
    type(whizard_options_t), intent(in) :: options
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
    call init_syntax_tables ()
    whizard%options = options
    call whizard%global%global_init (paths, logfile)
    call whizard%init_rebuild_flags ()
    call whizard%preload_model ()
    call whizard%preload_library ()
    call whizard%global%init_fallback_model &
      (var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))
    call whizard%global%init_radiation_model &
      (var_str ("SM_rad"), var_str ("SM_rad.mdl"))
  end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+=
  procedure :: final => whizard_final

```

```

<WHIZARD: procedures>+≡
  subroutine whizard_final (whizard)
    class(whizard_t), intent(inout), target :: whizard
    call whizard%global%final ()
    call whizard%pt_stack%final ()
    !!! JRR: WK please check (#529)
    !   call user_code_final ()
    call final_syntax_tables ()
  end subroutine whizard_final

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: procedures>+≡
  subroutine whizard_init_rebuild_flags (whizard)
    class(whizard_t), intent(inout), target :: whizard
    associate (var_list => whizard%global%var_list, options => whizard%options)
      call var_list_append_log &

    end if
end do SCAN_LIBS
end subroutine whizard_preload_library

```

30.2.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution.

Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

```

<WHIZARD: public>+≡
    public :: init_syntax_tables
    public :: final_syntax_tables

<WHIZARD: procedures>+≡
    subroutine init_syntax_tables ()
        call syntax_model_file_init ()
        call syntax_phs_forest_init ()
        call syntax_pexpr_init ()
        call syntax_slha_init ()
        call syntax_blha_contract_init ()
        call syntax_cmd_list_init ()
    end subroutine init_syntax_tables

    subroutine final_syntax_tables ()
        call syntax_model_file_final ()
        call syntax_phs_forest_final ()
        call syntax_pexpr_final ()
        call syntax_slha_final ()
        call syntax_blha_contract_final ()
        call syntax_cmd_list_final ()
    end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
    public :: write_syntax_tables

<WHIZARD: procedures>+≡
    subroutine write_syntax_tables ()
        integer :: unit
        character(*), parameter :: file_model = "whizard.model_file.syntax"

    end do COMMAND_LOOP
    print *
    call lexer_final (lexer)
end subroutine whizard_shell

```

30.2.8 Self-tests

For those self-tests, we need some auxiliary routines that provide an environment. The environment depends on things that are not available at the level of the module that we want to test.

Testbed for event I/O

This subroutine prepares a test process with a single event. All objects are allocated via anonymous pointers, because we want to recover the pointers and delete the objects in a separate procedure.

```

<WHIZARD: procedures>+≡
subroutine prepare_eio_test (event, unweighted, n_alt)
    use variables
    use model_data
    use event_base
    class(generic_event_t), intent(inout), pointer :: event
    logical, intent(in), optional :: unweighted
    integer, intent(in), optional :: n_alt
    type(model_data_t), pointer :: model
    type(var_list_t) :: var_list
    type(process_t), pointer :: process
    type(process_instance_t), pointer :: process_instance

    allocate (model)
    call model%init_test ()

    allocate (process)
    allocate (process_instance)

    call prepare_test_process (process, process_instance, model)
    call process_instance%setup_event_data ()

    call model%final ()
    deallocate (model)

    allocate (event_t :: event)
    select type (event)
    type is (event_t)
        if (present (unweighted)) then
            call var_list_append_log (var_list, &
                var_str ("?unweighted"), unweighted, &
                intrinsic = .true.)
        else
            call var_list_append_log (var_list, &
                var_str ("?unweighted"), .true., &

```

```

        intrinsic = .true.)
    end if
    call var_list_append_string (var_list, &
        var_str ("sample_normalization"), &
        var_str ("auto"), intrinsic = .true.)
    call event%basic_init (var_list, n_alt)
    call event%connect (process_instance, process%get_model_ptr ())
    call var_list%final ()
end select
end subroutine prepare_eio_test

```

Recover those pointers, finalize the objects and deallocate.

```

<WHIZARD: procedures>+≡
subroutine cleanup_eio_test (event)
    use model_data
    use event_base
    class(generic_event_t), intent(inout), pointer :: event
    type(process_t), pointer :: process
    type(process_instance_t), pointer :: process_instance
    select type (event)
    type is (event_t)
        process => event%get_process_ptr ()
        process_instance => event%get_process_instance_ptr ()
        call cleanup_test_process (process, process_instance)
        deallocate (process_instance)
        deallocate (process)
        call event%final ()
    end select
    deallocate (event)
end subroutine cleanup_eio_test

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

<WHIZARD: prepare testbed>≡
    eio_prepare_test => prepare_eio_test
    eio_cleanup_test => cleanup_eio_test

```

Any Model

This procedure reads any model from file and, optionally, assigns a var-list pointer.

```

<WHIZARD: procedures>+≡
subroutine prepare_whizard_model (model, name, vars)
<Use strings>
    use os_interface
    use model_data
    use var_base
    use models
    class(model_data_t), intent(inout), pointer :: model
    type(string_t), intent(in) :: name
    class(vars_t), pointer, intent(out), optional :: vars
    type(os_data_t) :: os_data

```

```

call syntax_model_file_init ()
call os_data_init (os_data)
allocate (model_t :: model)
select type (model)
type is (model_t)
  call model%read (name // ".mdl", os_data)
  if (present (vars)) then
    vars => model%get_var_list_ptr ()
  end if
end select
end subroutine prepare_whizard_model

```

Cleanup after use. Includes deletion of the model-file syntax.

```

<WHIZARD: procedures>+≡
subroutine cleanup_whizard_model (model)
  use model_data
  use models
  class(model_data_t), intent(inout), pointer :: model
  call model%final ()
  deallocate (model)
  call syntax_model_file_final ()
end subroutine cleanup_whizard_model

```

Assign those procedures to appropriate pointers (module variables) in the `model_testbed` module, so they can be called as if they were module procedures.

```

<WHIZARD: prepare testbed>+≡
prepare_model => prepare_whizard_model
cleanup_model => cleanup_whizard_model

```

Fallback model: hadrons

Some event format tests require the hadronic SM implementation, which has to be read from file. We provide the functionality here, so the tests do not depend on model I/O.

```

<WHIZARD: procedures>+≡
subroutine prepare_fallback_model (model)
  use model_data
  class(model_data_t), intent(inout), pointer :: model
  call prepare_whizard_model (model, var_str ("SM_hadrons"))
end subroutine prepare_fallback_model

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

<WHIZARD: prepare testbed>+≡
eio_prepare_fallback_model => prepare_fallback_model
eio_cleanup_fallback_model => cleanup_model

```

30.3 Driver program

The main program handles command options, initializes the environment, and runs WHIZARD in a particular mode (interactive, file, standard input).

This is also used in the C interface:

```
<Main: cmdline arg len declaration>≡  
integer, parameter :: CMDLINE_ARG_LEN = 1000
```

The actual main program:

```
<main.f90>≡  
<File header>  
  
program main  
  
<Use strings>  
use unit_tests  
use system_dependencies  
use diagnostics  
use ifiles  
use os_interface  
use whizard  
  
implicit none  
  
<Main: cmdline arg len declaration>  
  
! Main program variable declarations
