C...UPVETO
C...Dummy routine, to be replaced by user, to veto event generation
C...on the parton level, after parton showers but before multiple
C...interactions, beam remnants and hadronization is added.
C...If resonances like W, Z, top, Higgs and SUSY particles are handed
C...undecayed from UPEVNT, or are generated by PYTHIA, they will also
C...be undecayed at this stage; if decayed their decay products will
C...have been allowed to shower.

C...All partons at the end of the shower phase are stored in the
C...HEPEVT commonblock. The interesting information is
C...NHEP = the number of such partons, in entries 1 <= i <= NHEP,
C...IDHEP(I) = the particle ID code according to PDG conventions,
C...PHEP(J,I) = the (p_x, p_y, p_z, E, m) of the particle.
C...All ISTHEP entries are 1, while the rest is zeroed.

C...The user decision is to be conveyed by the IVETO value.
C...IVETO = 0 : retain current event and generate in full;
C...      = 1 : abort generation of current event and move to next.

!C      KTCLUS: written by Mike Seymour, July 1992.
!C      Last modified November 2000.
!C      Please send comments or suggestions to Mike.Seymour@rl.ac.uk
!C
!C      This is a general-purpose kt clustering package.
!C      It can handle ee, ep and pp collisions.
!C      It is loosely based on the program of Siggi Bethke.
!C
!C      The time taken (on a 10MIP machine) is (0.2microsec)*N**3
!C      where N is the number of particles.
!C      Over 90 percent of this time is used in subroutine KTPMIN, which
!C      simply finds the minimum member of a one-dimensional array.
!C      It is well worth thinking about optimization: on the SPARCstation
!C      a factor of two increase was obtained simply by increasing the
!C      optimization level from its default value.
!C
!C      The approach is to separate the different stages of analysis.
!C      KTCLUS does all the clustering and records a merging history.
!C      It returns a simple list of the y values at which each merging
!C      occurred. Then the following routines can be called to give extra
!C      information on the most recently analysed event.
!C      KTCLUR is identical but includes an R parameter, see below.
!C      KTYCUT gives the number of jets at each given YCUT value.
!C      KTYSUB gives the number of sub-jets at each given YCUT value.
!C      KTBEAM gives same info as KTCLUS but only for merges with the beam
!C      KTJOIN gives same info as KTCLUS but for merges of sub-jets.
!C      KTRECO reconstructs the jet momenta at a given value of YCUT.
!C      It also gives information on which jets at scale YCUT belong to
!C      which macro-jets at scale YMAC, for studying sub-jet properties.
!C      KTINCL reconstructs the jet momenta according to the inclusive jet
!C      definition of Ellis and Soper.
!C      KTISUB, KTIJOI and KTIREC are like KTYSUB, KTJOIN and KTRECO,
!C      except that they only apply to one inclusive jet at a time,
!C      with the pt of that jet automatically used for ECUT.
!C      KTWICH gives a list of which particles ended up in which jets.
!C      KTWCHS gives the same thing, but only for subjets.
!C      Note that the numbering of jets used by these two routines is
!C      guaranteed to be the same as that used by KTRECO.
!C
!C      The collision type and analysis type are indicated by the first
!C      argument of KTCLUS. IMODE=<TYPE><ANGLE><MONO><RECOM> where
!C      TYPE:  1=>ee, 2=>ep with p in -z direction, 3=>pe, 4=>pp
!C      ANGLE: 1=>angular kt def., 2=>DeltaR, 3=>f(DeltaEta,DeltaPhi)
!C              where f()=2(cosh(eta)-cos(phi)) is the QCD emission metric
!C      MONO:  1=>derive relative pseudoparticle angles from jets
!C              2=>monotonic definitions of relative angles
!C      RECOM: 1=>E recombination scheme, 2=>pt scheme, 3=>pt**2 scheme
!C
!C      There are also abbreviated forms for the most common combinations:

```

```

!C      IMODE=1 => E scheme in e+e-                      (=1111)
!C      2 => E scheme in ep                             (=2111)
!C      3 => E scheme in pe                             (=3111)
!C      4 => E scheme in pp                             (=4111)
!C      5 => covariant E scheme in pp                   (=4211)
!C      6 => covariant pt-scheme in pp                  (=4212)
!C      7 => covariant monotonic pt**2-scheme in pp     (=4223)
!C
!C      KTRECO no longer needs to reconstruct the momenta according to the
!C      same recombination scheme in which they were clustered. Its first
!C      argument gives the scheme, taking the same values as RECOM above.
!C
!C      Note that unlike previous versions, all variables which hold y
!C      values have been named in a consistent way:
!C      Y() is the output scale at which jets were merged,
!C      YCUT is the input scale at which jets should be counted, and
!C      jet-momenta reconstructed etc,
!C      YMAC is the input macro-jet scale, used in determining whether
!C      or not each jet is a sub-jet.
!C      The original scheme defined in our papers is equivalent to always
!C      setting YMAC=1.
!C      Whenever a YCUT or YMAC variable is used, it is rounded down
!C      infinitesimally, so that for example, setting YCUT=Y(2) refers
!C      to the scale where the event is 2-jet, even if rounding errors
!C      have shifted its value slightly.
!C
!C      An R parameter can be used in hadron-hadron collisions by
!C      calling KTCLUR instead of KTCLUS. This is as suggested by
!C      Ellis and Soper, but implemented slightly differently,
!C      as in M.H. Seymour, LU TP 94/2 (submitted to Nucl. Phys. B.).
!C      R**2 multiplies the single Kt everywhere it is used.
!C      Calling KTCLUR with R=1 is identical to calling KTCLUS.
!C      R plays a similar role to the jet radius in a cone-type algorithm,
!C      but is scaled up by about 40% (ie R=0.7 in a cone algorithm is
!C      similar to this algorithm with R=1).
!C      Note that R.EQ.1 must be used for the e+e- and ep versions,
!C      and is strongly recommended for the hadron-hadron version.
!C      However, R values smaller than 1 have been found to be useful for
!C      certain applications, particularly the mass reconstruction of
!C      highly-boosted colour-singlets such as high-pt hadronic Ws,
!C      as in M.H. Seymour, LU TP 93/8 (to appear in Z. Phys. C.).
!C      Situations in which R<1 is useful are likely to also be those in
!C      which the inclusive reconstruction method is more useful.
!C
!C      Also included is a set of routines for doing Lorentz boosts:
!C      KTLBST finds the boost matrix to/from the cm frame of a 4-vector
!C      KTRROT finds the rotation matrix from one vector to another
!C      KTMMUL multiplies together two matrices
!C      KTMVUL multiplies a vector by a matrix
!C      KTINVT inverts a transformation matrix (nb NOT a general 4 by 4)
!C      KTFRAM boosts a list of vectors between two arbitrary frames
!C      KTBREI boosts a list of vectors between the lab and Breit frames
!C      KTHADR boosts a list of vectors between the lab and hadronic cmf
!C      The last two need the momenta in the +z direction of the lepton

```

```

!C      and hadron beams, and the 4-momentum of the outgoing lepton.
!C
!C      The main reference is:
!C      S. Catani, Yu.L. Dokshitzer, M.H. Seymour and B.R. Webber,
!C      Nucl.Phys.B406(1993)187.
!C      The ep version was proposed in:
!C      S. Catani, Yu.L. Dokshitzer and B.R. Webber,
!C      Phys.Lett.285B(1992)291.
!C      The inclusive reconstruction method was proposed in:
!C      S.D. Ellis and D.E. Soper,
!C      Phys.Rev.D48(1993)3160.

CKKW settings, data and (pseudo) weights

This module contains the definitions for the basic settings for CKKW matching.

The type `ckkw_pseudo_shower_weights_t` gives the (relative) weights for different clusterings of the final particles, as given in Eq. (2.7) of hep-ph/0503281v1. Each particle has a binary labelling (power of 2) (first particle = 1, second particle = 2, third particle = 4, ...). Each recombination therefore corresponds to an integer, that is not a power of 2. For multiple subsequent recombinations, no different weights for different sequences of clustering are stored. It is assumed that the weight of a multiply recombined state is a combination of the states with one fewer recombination and that these states' contributions are proportional to their weights. For a $2-n > n$ event, the weights array thus has the size $2^{(2+n)-1}$. The `weights_by_type` array gives the weights depending on the type of the particle, the first index is the same as for weights, the second index gives the type of the new mother particle:

- 0: uncolored (γ , Z , W , Higgs)
- 1: colored (quark)
- 2: gluon
- 3: squark
- 4: gluino

`alphaS` gives the value for α_s used in the generation of the matrix element. This is needed for the reweighting using the values for a running α_s at the scales of the clusterings.

Chapter 21

Multiple Interactions (MPI) Code

This is the code for the `WHIZARD` module for multiple interactions (MPI) in hadron collisions. It also provides the interleaved shower with together with the shower module.

21.1 Basic types

This file contains the module `multi_basic` which is included by all other modules of the MPI code. It's main purpose is serialization and deserialization, but it also contains some bitmodel parameters and some minor definitions common to all modules and types.

Serialization is implemented in three layers:

1. **I/O layer:** streamfile access and exact, retrievable and compiler independent representation of all intrinsic types
2. **Marking layer:** storing/restoring pointer association and better human readability
3. **Derived type layer:** abstract type as parent for all serializable derived types

The I/O Layer The I/O layer is implemented by `page_ring_t` and its type bound procedures. We chose not to use the standard formatted sequential I/O for several reasons:

- Sequential I/O is line orientated, but serialization is not.
- Formatted I/O of floating point numbers is inexact. There were problems in reading numbers like `1+epsilon(1)` or `huge(1)` including arithmetic exeptions and wrong results.
- Formatted reading is slow. This does matter, when you read files of $\mathcal{O}(100)$ MB.

`page_ring_t` is a ring buffer of default kind characters holding a region of the addressed file. All read and write procedures use the ring buffer, not the file. `page_ring` automatically reads more characters from the file when needed and writes and discards parts of the ring buffer when not any longer needed.

Marking layer Marking is done by `marking_t` and its type bound procedures. Files written by `marking_t` are regular XML files, so you can use your favorite XML editor to examine or edit serialized contents. The main purpose of this layer is to recover the type of polymorphic entities and to restore association of pointers, but it also assigns names to all contents, so it is much easier to read generated files.

Type recovery is done by a reference list. You must push a representative object to this reference list for each type that might get resolved before starting deserialization. `marker_t` will care for comparing these representatives to the contents of the files.

Association restoration is done by a heap list. It is technically equal to the reference list, but holds all targets that have been processed so far. Generation of this list is handled by `marking_t`, so you don't have to care for this aspect at all. Up to the present it is not possible to restore association, when a non-pointer target is serialized after its associated pointer is serialized. There is no trivial solution and this case does not appear here, so we will not take care of this.

Derived type layer Each instance that shall become serialized must extend `ser_class_t`. Essential for type recovery is the virtual type bound procedure `get_type`. Each non-virtual type shall override `get_type` and return the actual name of its type in lower-case letters. Each type which adds new, non-redundant components shall override `write_to_marker` and `read_from_marker`. These type-bound procedures define, what contents get serialized. While the marker cares about tagging the type and association of the instance, every instance still has to define what to serialize. The rule is to mark the begin of its contents, then its parents procedure, then mark all non-redundant components, then mark the end of its contents. Finally, each serializable type shall override `print_to_unit`. This procedure is called for an arbitrary human-readable output. It is quite similar to `write_to_ring`, but without strict format and ignoring machine-readability.

`ser_class_t` has strictly speaking two layers. `write_to_marker` and `read_from_marker` are only for internal usage. Serialization and deserialization are triggered by the TBPs `serialize` and `deserialize`. These procedures take care of initialization and finalization of the marker. A serializable type should override these procedures to push a representative of itself and any other references to the reference list of its marker before (de)serialization and to pop them from the list afterwards.

These are the `page_ring_t` procedures, here for read access only:

```

<Muli base: page ring: TBP>≡
procedure :: open_for_read_access => page_ring_open_for_read_access

<Muli base: procedures>+≡
subroutine page_ring_open_for_read_access &
  (this, file, eof_string, asynchronous)
class(page_ring_t), intent(inout) :: this
character(*), intent(in) :: file, eof_string
logical, intent(in), optional :: asynchronous
logical :: exist
this%eof_string = eof_string
inquire (file=file, exist=exist)
if (exist) then
  this%action = 2
else
  call msg_error ("page_ring_open: File " // file // " is opened " &
    // "for read access but does not exist.")
end if
if (present (asynchronous)) this%asynchronous = asynchronous
if (this%unit < 0) call generate_unit (this%unit, 100, 1000)
if (this%unit < 0) then
  call msg_error ("page_ring_open: No free unit found.")
end if
this%ring_size = 2
call this%set_position ([i_zero,i_one])
this%active_pages = [i_zero,-i_one]
if (allocated (this%ring)) deallocate (this%ring)
allocate (this%ring (i_zero:this%ring_size - i_one))
if (this%asynchronous) then
  open (this%unit, file=file, access="stream", &
    action="read", asynchronous="yes", status="old")
else
  open (this%unit, file=file, access="stream", action="read", &

```

```

        asynchronous="no", status="old")
    end if
    call this%read_page ()
end subroutine page_ring_open_for_read_access

```

<Muli base: page ring: TBP>+≡

```

    procedure :: read_page => page_ring_read_page

```

<Muli base: procedures>+≡

```

subroutine page_ring_read_page (this)
    class(page_ring_t), intent(inout) :: this
    integer(dik) :: iostat
    character(8) :: iomsg
    if (.not. this%eof_reached) then
        call this%activate_next_page ()

21.2 Transverse momenta

This file contains the module `muli_momentum`. Its purpose is to store the actual value of the evolution parameter p_t^2 in a convenient way. We use the normalized value $p_t^2/p_{t,\max}^2$ for generating the next value of the scale, also need the square root of both p_t^2 and $p_t^2/p_{t,\max}^2$ for other purposes. That's why I store all four combinations together with $p_{t,\max}$ in an array.

21.3 Multi parton interactions

This file contains the module `muli_interactions`. The allowed interactions and their cross sections are defined here. Additionally, some coordinate transformations which annihilate divergencies of the cross sections are defined. Since the phase space border is hyperbolic, this transformations are also hyperbolic. That's why all interactions are named `x_cart` for cartesian or `x_hyp` for hyperbolic to avoid confusion.

```

21.4 VEGAS and CUBA integration routines

This file contains the module `muli_cuba`, a wrapper for the CUBA integration library. Different algorithms and settings have been tried out for the integration, including VEGAS, and this wrapper has been mainly written for that purpose.

```

21.5 Trapezoidal integration routines

This file contains the module "muli_trapezium". The name is derived from the trapezoidal integration rule. The purpose of this module is to define a binary tree `muli_trapezium_tree_t` which holds a probability function in terms of trapezoidal segments. Its leaves of type `muli_trapezium_list_t` are connected to form a list, so you can either walk the root function back and forth or pick a certain segment in logarithmic time by walking down the tree. All nodes extend `muli_trapezium_t` which holds the actual values. Those are the values of the density function, the integral from this segment to the end of the integration area and a probability function calculated from these values. All values are taken at the upper "right" bound of the segment. Additionally the differences of these values to the values of the left neighbor is stored.

```

21.6 Fibonacci trees

This file contains the module `multi_fibonacci_tree`. A fibonacci tree is a self-balancing binary tree. "Balanced" means that the depth of the left successor may differ from the depth of the right successor in any node by maximally one. The maximally unbalanced tree is maximally unbalanced in every node. So the number of leaves of a maximally unbalanced fibonacci tree of depth n is precisely the n th fibonacci number.

We use this tree for the adaptive quadrature. In every iteration of the algorithm, we have to pick the segment with largest integration error, cut it into pieces and calculate the new integration error for the pieces. A binary tree is obviously a good choice for soring these segments. The problem is, that we always pick leaves from the same side of the tree. So the tree must decline at one side and grow at the other side. Sorting gets less efficient and finally most of the overall CPU time gets wasted for sorting. This tree outperforms a naive binary tree significantly in this particular job.

21.7 Adaptive Quadrature

This file contains the module `muli_aq` which is an acronym for adaptive quadrature. The abstract type `aq_class` is extended and the deferred procedure `evaluate` is defined. `muli_aq` calls `evaluate` to evaluate the integrand at any point in the given range. We have tried to use a procedure pointer instead of the deferred type-bound procedure, but no compiler was able to handle procedure pointers plus `cuba` was not able to handle parameters, to wit dimensions of the integrand that should not get integrated. So we switched to this odd way of using inheritance. Meanwhile these problems got solved and we could go for a more straightforward solution, but it works fine as it is.

`aq_class` uses `muli_trapezium` to approximate the integral. It still has to do the subdivision of segments and has to check whether the precision goal is reached.

Finally, the result is written to disc using the serialization framework defined in `muli_base`. Since QCD is not expected to change frequently, the only reason to regenerate this function is a change of the used PDF set. Then you can read the integral from disc each time you run a simulation with the same PDF set.

```

```

⟨Muli aq: procedures⟩

```
end module muli_aq
```

The variables `error_goal`, `err_tree` and `int_list` must be initialised before the main loop can be called. Additionally, the nodes and segments should be preprocessed by `first_run` before the main loop is called.

```

Usually, the tree is sorted by the sum of errors. Now it shall be sorted by the right position. When at least one branch of the tree is itself a tree, i.e. each branch has got at least two leaves, then process each branch and merge the results. Now we got two sorted lists. Which one's leftmost node has got the lowest value of `r_position`? That one shall be the beginning of the merged list `lin_list`. Everything is prepared for the algorithm: `lin_list` is the beginning of the sorted list, `last_node` is its end. `left_node` and `right_node` are the leftmost nodes of the remainders of `left_list` and `right_list`. The latter will get stripped from left to right, until one of them ends. Then, either `left_list` or `right_list` is completely merged into `lin_list`. The other one gets appended to `lin_list`. In the second part of the big if clause, the tree has got two leaves at most. Is it more than one? There, `fib_tree` is a single leave with an allocated "content" component of type `muli_trapezium_t`. If "content" is not type-compatible with `muli_trapezium_t`, then this whole conversion cannot succeed. We allocate a new node of type `muli_trapezium_list_t`. This list does not contain the content of `fib_tree`, it *is* a copy of the content, for `muli_trapezium_list_t` is an extension of `muli_trapezium_t`. In the next step, each branch of `fib_tree` is a single leave. We could call this subroutine for each branch, but we do copy and paste for each branch instead. Finally we append one list to the other, the lowest value of `r_position` comes first.

21.8 Integrands for Multiple Interactions

This file contains the module `multi_dsigma`. Its only type `multi_dsigma_t` provides an integrand to `aq_class`. The actual integrand is the normalized differential cross section of a QCD $2 \rightarrow 2$ process $1/\sigma_0 \times d^3\sigma/(dp_T^2 dx_1 dx_2)$. We need a root function of this integrand in terms of p_T , so we have to integrate out x_1 and x_2 and have to approximate the root function of the leftover variable p_T .

Integration of x_1 and x_2 is done by CUBA, the root function is approximated by `muli_aq`.

21.9 MC Integrations for QCD $2 \rightarrow 2$ processes

This file contains the module `muli_mcint` which is the Monte Carlo generator for QCD $2 \rightarrow 2$ interactions at given evolution parameter and given stratus. While `muli_t` takes care of generating the evolution parameter and the stratus, this module is about bookkeeping the strati and implementing a downstream importance sampling. The evolution parameter is a measure of transferred momentum and a “stratus” is a PDF category or, to be more precise, is whether the incoming partons are gluons or sea quarks or valence quarks.

The importance sampling then subdivides the phase space of variables $\{x_1, x_2, p_T\}$ into n^3 regions such that each region holds approximately n interactions. Thus, we can generate a phase space point very quickly just by randomly picking a region, randomly picking a point within this region and comparing its exact cross section with the mean cross section for this actual evolution parameter and the actual stratus times the area of the picked phase space region.

The mean values must be generated in the module `muli_dsigma` before and are given to the procedure `sample_inclusive_generate_hit`. Finally the generated subregions should be written to a file via `write_to_marker` and then reused for each later WHIZARD run.

The type `sample_inclusive_t` holds the 16 strati, while the type `sample_int_kind_t` represents a single stratus, `sample_3d_t` is the whole $\{x_1, x_2, p_T\}$ phase space for each stratus, `sample_2d_t` is the $\{x_1, x_2\}$ plane with a slice of p_T and `sample_region_t` finally is a phase space region.

21.11 The Multiple Interactions main module

This file contains the module `muli` which is the multiple parton interactions interface module to `WHIZARD`. `muli` is supposed to run together with initial state radiation. Both share a momentum evolution variable and compete for beam momentum, so the generation of this scale variable must be fully transparent to `WHIZARD`. That is why the corresponding procedures are here, while all other work like phase space integration, flavor generation and treatment of the beam remnant is put into `muli_dsigma`, `muli_mcint` and `muli_remnant`, respectively.

`qcd_2_2_t` is a container class for properties of QCD $2 \rightarrow 2$ interactions. It holds a very condensed internal representation and offers a convenient set of TBP to query all aspects without the burden of the generator internals.

`muli_t` then is an extension of `qcd_2_2_t` that adds generator internals like random number generator, integrated cross-sections, the actual Monte Carlo generator for flavor generation and beam remnants in `tao_rnd`, `dsigma`, `samples` and `beam`, respectively.

        kind = valid_processes (6, this%process_id)
    end function qcd_2_2_get_diagram_kind

```

This is one more hack. Before merging into the interleaved algorithm, muli has only cared for summed cross sections, but not in specific color flows. So two different diagrams with equal cross sections were summed up to diagram kind 1. Now muli also generates color flows, so we must divide diagram kind 1 into diagram color kind 0 and diagram color kind 1.

Chapter 22

User Plugin Support

Here we collect interface code that enables the user to inject his own code into the WHIZARD workflow. The code uses data types defined elsewhere, and is referenced in the `eval_trees` module.

These are the modules:

user_code_interface Generic support and specific additions.

sf_user Handle user-defined structure functions.

22.1 User Code Interface

```
<user_code_interface.f90>≡  
  <File header>  
  
  module user_code_interface  
  
    use iso_c_binding !NODEP!  
    <Use kinds>  
    <Use strings>  
    use diagnostics  
    use c_particles  
    use os_interface  
  
    <Standard module head>  
  
    <User Code: public>  
  
    <User Code: variables>  
  
    <User Code: interfaces>  
  
    contains  
  
    <User Code: procedures>  
  
  end module user_code_interface
```

22.1.1 User Code Management

This data structure globally holds the filehandle of the user-code library:

```
<User Code: public>≡  
  public :: has_user_lib  
  
<User Code: variables>≡  
  type(dlaccess_t), save :: user_lib_handle  
  logical, save :: has_user_lib = .false.  
  type(string_t), save :: user
```

Compile, link and load user code files. Dlopen all user-provided libraries, included the one just compiled (if any).

By default, we are looking for a library `user.so/dylib`. If this is not present, try `user.f90` and compile it. This can be overridden.

In detail: First, compile all sources explicitly specified on the command line. Then collect all libraries specified on the command line, including `user.so` if it was generated. If there is still no code, check for an existing `user.f90` and compile this. Link everything into a `user.la` libtool library. When done, dlopen all libraries that we have so far.

```
<User Code: public>+≡  
  public :: user_code_init
```

```

{User Code: procedures}≡
subroutine user_code_init (user_src, user_lib, user_target, rebuild, os_data)

22.1.2 Interfaces for user-defined functions

The following functions represent user-defined real observables. There may be one or two particles as argument, the result is a real value.

```

<User Code: public>+≡
    public :: user_obs_int_unary
    public :: user_obs_int_binary
    public :: user_obs_real_unary
    public :: user_obs_real_binary

<User Code: interfaces>≡
    abstract interface
        function user_obs_int_unary (prt1) result (ival) bind(C)
            use iso_c_binding !NODEP!

```

```

        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1
        integer(c_int) :: ival
    end function user_obs_int_unary
end interface

abstract interface
    function user_obs_int_binary (prt1, prt2) result (ival) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        integer(c_int) :: ival
    end function user_obs_int_binary
end interface

abstract interface
    function user_obs_real_unary (prt1) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1
        real(c_double) :: rval
    end function user_obs_real_unary
end interface

abstract interface
    function user_obs_real_binary (prt1, prt2) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        real(c_double) :: rval
    end function user_obs_real_binary
end interface

```

The following function takes an array of C-compatible particles and return a single value. The particle array represents a subevent. For C interoperability, we have to use an assumed-size array, hence the array size has to be transferred explicitly.

The cut function returns an `int`, which we should interpret as a logical value (nonzero=true).

```

<User Code: public>+≡
    public :: user_cut_fun

<User Code: interfaces>+≡
    abstract interface
        function user_cut_fun (prt, n_prt) result (iflag) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt
            integer(c_int), intent(in) :: n_prt
            integer(c_int) :: iflag
        end function user_cut_fun
    end interface

```

The event-shape function returns a real value.

```

<User Code: public>+≡
    public :: user_event_shape_fun

<User Code: interfaces>+≡
    abstract interface
        function user_event_shape_fun (prt, n_prt) result (rval) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt
            integer(c_int), intent(in) :: n_prt
            real(c_double) :: rval
        end function user_event_shape_fun
    end interface

```

22.1.3 Interfaces for user-defined interactions

The following procedure interfaces pertain to user-defined interactions, e.g., spectra or structure functions.

This subroutine retrieves the basic information for setting up the interaction and event generation. All parameters are `intent(inout)`, so we can provide default values. `n_in` and `n_out` are the number of incoming and outgoing particles, respectively. `n_states` is the total number of distinct states that should be generated (counting all states of the incoming particles). `n_col` is the maximal number of color entries a particle can have. `n_dim` is the number of input parameters, i.e., integration dimensions, that the structure function call requires for computing kinematics and matrix elements. `n_var` is the number of variables (e.g., momentum fractions) that the structure function call has to transfer from the kinematics to the dynamics evaluation.

```

<User Code: public>+≡
    public :: user_int_info

<User Code: interfaces>+≡
    abstract interface
        subroutine user_int_info (n_in, n_out, n_states, n_col, n_dim, n_var) &
            bind(C)
            use iso_c_binding !NODEP!
            integer(c_int), intent(inout) :: n_in, n_out, n_states, n_col
            integer(c_int), intent(inout) :: n_dim, n_var
        end subroutine user_int_info
    end interface

```

This subroutine retrieves the settings for the quantum number mask of a given particle index in the interaction. A nonzero value indicates that the corresponding quantum number is to be ignored. The lock index is the index of a particle that the current particle is related to. The relation applies if quantum numbers of one of the locked particles are summed over. (This is intended for helicity.)

```

<User Code: public>+≡
    public :: user_int_mask

```

```

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_mask (i_prt, m_flv, m_hel, m_col, i_lock) bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(in) :: i_prt
      integer(c_int), intent(inout) :: m_flv, m_hel, m_col, i_lock
    end subroutine user_int_mask
  end interface

```

This subroutine retrieves the quantum numbers for the particle index `i_prt` in state `i_state`. The `flv` value is a PDG code. The `hel` value is an integer helicity (twice the helicity for fermions). The `col` array is an array which has at most `n_col` entries (see above). All parameters are `intent(inout)` since default values exist. In particular, if a mask entry is set by the previous procedure, the corresponding quantum number is ignored anyway.

```

<User Code: public>+≡
  public :: user_int_state

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_state (i_state, i_prt, flv, hel, col) bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(in) :: i_state, i_prt
      integer(c_int), intent(inout) :: flv, hel
      integer(c_int), dimension(*), intent(inout) :: col
    end subroutine user_int_state
  end interface

```

This subroutine takes an array of particle objects with array length `n_in` and an array of input parameters between 0 and 1 with array length `n_dim`. It returns an array of particle objects with array length `n_out`. In addition, it returns an array of internal variables (e.g., momentum fractions, Jacobian) with array length `n_var` that is used by the following subroutine for evaluating the dynamics, i.e., the matrix elements.

```

<User Code: public>+≡
  public :: user_int_kinematics

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_kinematics (prt_in, rval, prt_out, xval) bind(C)
      use iso_c_binding !NODEP!
      use c_particles !NODEP!
      type(c_prt_t), dimension(*), intent(in) :: prt_in
      real(c_double), dimension(*), intent(in) :: rval
      type(c_prt_t), dimension(*), intent(inout) :: prt_out
      real(c_double), dimension(*), intent(out) :: xval
    end subroutine user_int_kinematics
  end interface

```

This subroutine takes the array of variables (e.g., momentum fractions) with length `n_var` which has been generated by the previous subroutine and a real variable, the energy scale of the event. It returns an array of matrix-element

values, one entry for each quantum state `n_states`. The ordering of matrix elements must correspond to the ordering of states.

```

<User Code: public>+≡
    public :: user_int_evaluate

<User Code: interfaces>+≡
    abstract interface
        subroutine user_int_evaluate (xval, scale, fval) bind(C)
            use iso_c_binding !NODEP!
            real(c_double), dimension(*), intent(in) :: xval
            real(c_double), intent(in) :: scale
            real(c_double), dimension(*), intent(out) :: fval
        end subroutine user_int_evaluate
    end interface

```

22.2 User Plugin for Structure Functions

This variant gives access to user-defined structure functions or spectra.

22.2.1 The module

```

<sf_user.f90>≡
    <File header>

    module sf_user

        use, intrinsic :: iso_c_binding !NODEP!
        <Use kinds>
        <Use strings>
        use io_units
        use format_defs, only: FMT_17
        use diagnostics
        use c_particles
        use lorentz
        use subevents
        use user_code_interface
        use pdg_arrays
        use model_data
        use flavors
        use helicities
        use colors
        use quantum_numbers
        use state_matrices
        use polarizations
        use interactions
        use sf_aux
        use sf_base

        <Standard module head>

        <SF user: public>

```

```

<SF user: types>

contains

<SF user: procedures>

end module sf_user

```

22.2.2 The user structure function data block

The data block holds the procedure pointers that are used for retrieving static information, as well as the actual evaluation.

```

<SF user: public>≡
    public :: user_data_t

<SF user: types>≡
    type, extends(sf_data_t) :: user_data_t
        private
        type(string_t) :: name
        integer :: n_in
        integer :: n_out
        integer :: n_tot
        integer :: n_states
        integer :: n_col
        integer :: n_dim
        integer :: n_var
        integer, dimension(2) :: pdg_in
        class(model_data_t), pointer :: model => null ()
        procedure(user_int_info), nopass, pointer :: info => null ()
        procedure(user_int_mask), nopass, pointer :: mask => null ()
        procedure(user_int_state), nopass, pointer :: state => null ()
        procedure(user_int_kinematics), nopass, pointer :: kinematics => null ()
        procedure(user_int_evaluate), nopass, pointer :: evaluate => null ()
    contains
        <SF user: user data: TBP>
    end type user_data_t

```

Assign procedure pointers from a dynamically loaded library, given the specified name.

We have to distinguish three cases: (1) Both beams are affected, and the user spectrum implements both beams. There is a single data object. (2) Both beams are affected, and the user spectrum applies to single beams. Fill two different objects. (3) A single beam is affected.

```

<SF User: public>≡
    public :: sf_user_data_init

```

22.2.3 The interaction

We fill the interaction by looking up the table of states using the interface functions.

For particles which have a known flavor (as indicated by the mask), we compute the mass squared, so we can use it for the invariant mass of the particle objects.

```

```

22.2.4 The user structure function

For maximal flexibility, user structure functions separate kinematics from dynamics just as the PDF interface does. (JRR: Ok, I guess this now done for all structure functions, right?) We create `c_prt_t` particle objects from the incoming momenta (all other quantum numbers are irrelevant) and call the user-supplied kinematics function to compute the outgoing momenta, along with other variables that will be needed for matrix element evaluation. If known, we use the mass squared computed above. !!! JRR: WK please check (#529) I don't know actually whether this really fits into the setup done by WK.

```

<SF user: types>+≡
    !!! JRR: WK please check (#529)
    type, extends (sf_int_t) :: user_t
        type(user_data_t), pointer :: data => null ()

else
  write (u, "(1x,A)") "User structure function data: [undefined]"
end if
end subroutine user_write

```

22.2.5 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

<SF user: user: TBP>+≡
  procedure :: complete_kinematics => user_complete_kinematics
<SF user: procedures>+≡
  subroutine user_complete_kinematics (sf_int, x, f, r, rb, map)

Chapter 23

BLHA Interface

The code in this chapter implements support for the BLHA record that communicates data for NLO processes.

These are the modules:

blha_config

blha_interface

blha_driver

23.1 Module definition

These modules implement the communication with one loop matrix element providers according to the Binoth LesHouches Accord Interface. The actual matrix element(s) are loaded as a dynamic library.

This module defines the common OLP-interfaces defined through the Binoth Les-Houches accord.

```
<blha_olp_interfaces.f90>≡  
  <File header>  
  
  module blha_olp_interfaces  
  
    use, intrinsic :: iso_c_binding !NODEP!

Compute the Born matrix element. This will always occur in connection to a subtraction term, so scales and couplings have already been set, and the momenta are in the BLHA format. Hence, the interface is simpler than in the other routines.

The BLHA-interface conventions require the quantity $S_{ij} = \langle M_{i,+} | T_i T_j | M_{i,-} \rangle$ to be produced, where i is the position of the splitting gluon. However, $\tilde{M} = \langle M_{i,-} | M_{i,+} \rangle$ is needed. This can be obtained using color conservation, $\sum_j T_j |M\rangle = 0$, so that

$$\sum_{j \neq i} S_{ij} = -\langle M_{i,+} | T_i^2 | M_{i,-} \rangle = -C_A \langle M_{i,+} | M_{i,-} \rangle = -C_A \tilde{M}^*$$

According to BLHA conventions, the real part of S_{ij} is located at positions $2i + 2nj$ in the output array, where n denotes the number of external particles and the enumeration of particles starts at zero. The subsequent position, i.e. $2i + 2nj + 1$ is designated to the imaginary part of S_{ij} . Note that, since the first array position is 1, the implemented position association deviates from the above one in the addition of 1.

Chapter 25

FKS Subtraction Scheme

The code in this chapter implements the FKS subtraction scheme for use with WHIZARD.

These are the modules:

fks_regions Given a process definition, identify singular regions in the associated phase space.

virtual Handle the virtual correction matrix element.

real_subtraction Handle the real-subtraction matrix element.

nlo_data Manage the subtraction objects.

phs_fks Phase-space parameterization with modifications for the FKS scheme.

This chapter deals with next-to-leading order contributions to cross sections. Basically, there are three major issues to be addressed: The creation of the $N+1$ -particle flavor structure, the construction of the $N+1$ -particle phase space and the actual calculation of the real- and virtual-subtracted matrix elements. The first is dealt with using the **auto_components** class, and it will be shown that the second and third issue are connected in FKS subtraction.

25.1 Brief outline of FKS subtraction

In the current state, this discussion is only concerned with lepton collisions. For hadron collisions, renormalization of parton distributions has to be taken into account. Further, for QCD corrections, initial-state radiation is necessarily present. However, most quantities have so far been only constructed for final-state emissions

The aim is to calculate the next-to-leading order cross section according to

$$d\sigma_{\text{NLO}} = \mathcal{B} + \mathcal{V} + \mathcal{R}d\Phi_{\text{rad}}.$$

Analytically, the divergences, in terms of poles in the complex quantity $\varepsilon = 2 - d/2$, cancel. However, this is in general only valid in an arbitrary, complex number of dimensions. This is, roughly, the content of the KLN-theorem. WHIZARD, as any other numerical program, is confined to four dimensions. We will assume

that the KLN-theorem is valid and that there exist subtraction terms \mathcal{C} such that

$$d\sigma_{\text{NLO}} = \mathcal{B} + \underbrace{\mathcal{V} + \mathcal{C}}_{\text{finite}} + \underbrace{\mathcal{R} - \mathcal{C}}_{\text{finite}},$$

i.e. the subtraction terms correspond to the divergent limits of the real and virtual matrix element.

Because \mathcal{C} subtracts the divergences of \mathcal{R} as well as those of \mathcal{V} , it suffices to consider one of them, so we focus on \mathcal{R} . For this purpose, \mathcal{R} is rewritten,

$$\mathcal{R} = \frac{1}{\xi^2} \frac{1}{1-y} (\xi^2(1-y)\mathcal{R}) = \frac{1}{\xi^2} \frac{1}{1-y} \tilde{\mathcal{R}},$$

with $\xi = (2k_{\text{rad}}^0)/\sqrt{s}$ and $y = \cos\theta$, where k_{rad}^0 denotes the energy of the radiated parton and θ is the angle between emitter and radiated parton. $\tilde{\mathcal{R}}$ is finite, therefore the whole singularity structure is contained in the prefactor $\xi^{-2}(1-y)^{-1}$. Combined with the d-dimensional phase space element,

$$\frac{d^{d-1}k}{2k^0(2\pi)^{d-1}} = \frac{s^{1-\varepsilon}}{(4\pi)^{d-1}} \xi^{1-2\varepsilon} (1-y)^{-\varepsilon} d\xi dy d\Omega^{d-2},$$

this yields

$$d\Phi_{\text{rad}}\mathcal{R} = dy(1-y)^{-1-\varepsilon} d\xi \xi^{-1-2\varepsilon} \tilde{R}.$$

This can further be rewritten in terms of plus-distributions,

$$\begin{aligned} \xi^{-1-2\varepsilon} &= -\frac{1}{2\varepsilon} \delta(\xi) + \left(\frac{1}{\xi}\right)_+ - 2\varepsilon \left(\frac{\log \xi}{\xi}\right)_+ + \mathcal{O}(\varepsilon^2), \\ (1-y)^{-1-\varepsilon} &= -\frac{2^{-\varepsilon}}{\varepsilon} \delta(1-y) + \left(\frac{1}{1-y}\right)_+ - \varepsilon \left(\frac{1}{1-y}\right)_+ \log(1-y) + \mathcal{O}(\varepsilon^2), \end{aligned}$$

(imagine that all this is written inside of integrals, which are spared for ease of notation) such that

$$\begin{aligned} d\Phi_{\text{rad}}\mathcal{R} &= -\frac{1}{2\varepsilon} dy(1-y)^{-1-\varepsilon} \tilde{R}(0, y) - d\xi \left[\frac{2^{-\varepsilon}}{\varepsilon} \left(\frac{1}{\xi}\right)_+ - 2 \left(\frac{\log \xi}{\xi}\right)_+ \right] \tilde{R}(\xi, 1) \\ &\quad + dy d\xi \left(\frac{1}{\xi}\right)_+ \left(\frac{1}{1-y}\right)_+ \tilde{R}(\xi, y) + \mathcal{O}(\varepsilon). \end{aligned}$$

The summand in the second line is of order $\mathcal{O}(1)$ and is the only one to reproduce $\mathcal{R}\xi, y$. It thus constitutes the sum of the real matrix element and the corresponding counterterms. The first summand consequently consists of the subtraction terms to the virtual matrix elements. Above formula thus allows to calculate all quantities to render the matrix elements finite.

4	[-11,11,2,-2,2,-2]	5	(5,6)

Table 25.1: List of singular regions. The particles are represented by their PDG codes. The third column contains the emitter for the specific singular region. For the process involving an additional gluon, the gluon can either be emitted from one of the quarks or from the first gluon. Each emitter yields the same list of fundamental tuples, five in total. The last singular region corresponds to the process where the gluon splits up into two quarks. Here, there is only one fundamental tuple, corresponding to a singular configuration of the momenta of the additional quarks.

25.2 Identifying singular regions

In the FKS subtraction scheme, the phase space is decomposed into disjoint singular regions, such that

$$\sum_i \mathcal{S}_i + \sum_{ij} \mathcal{S}_{ij} = 1. \quad (25.1)$$

The quantities \mathcal{S}_i and \mathcal{S}_{ij} are functions of phase space corresponding to a pair of particles indices which can make up a divergent phase space region. We call such an index pair a fundamental tuple. For example, the process $e^+ e^- \rightarrow u \bar{u} g$ has two singular regions, (3, 5) and (4, 5), indicating that the gluon can be soft or collinear with respect to either the quark or the anti-quark. Therefore, the functions \mathcal{S}_{ij} have to be chosen in such a way that their contribution makes up most of (25.1) in phase-space configurations where (final-state) particle j is collinear to particle i or/and particle j is soft. The functions \mathcal{S}_i is the corresponding quantity for initial-state divergences.

As a singular region we understand the collection of real flavor structures associated with an emitter and a list of all possible fundamental tuples. As an example, consider the process $e^+ e^- \rightarrow u \bar{u} g$. At next-to-leading order, processes with an additionally radiated particle have to be considered. In this case, these are $e^+ e^- \rightarrow u \bar{u}, g g$, and $e^+ e^- \rightarrow u \bar{u} u \bar{u}$ (or the same process with any other quark). Table 25.2 sums up all possible singular regions for this problem.

Thus, during the preparation of a NLO-calculation, the possible singular regions have to be identified. `fkf_regions.f90` deals with this issue.

alr	ftuple	emitter	flst_alr
1	(3, 5)	5	[-11,11,-2,21,2,21]
2	(4, 5)	5	[-11,11,2,21,-2,21]
3	(3, 6)	5	[-11,11,-2,21,2,21]
4	(4, 6)	5	[-11,11,2,21,-2,21]
5	(5, 6)	5	[-11,11,2,-2,21,21]
6	(5, 6)	5	[-11,11,2,-2,2,-2]

```

Class for working with the flavor specification arrays.

```

<fks regions: public>+≡
    public :: flv_structure_t

<fks regions: types>+≡
    type :: flv_structure_t
        integer, dimension(:), allocatable :: flst
        integer :: nlegs
        logical, dimension(:), allocatable :: massive
        logical, dimension(:), allocatable :: colored
    contains
    <fks regions: flv structure: TBP>
    end type flv_structure_t

```

Returns `true` if the two particles at position `i` and `j` in the flavor array can originate from the same splitting. For this purpose, the function first checks

whether the splitting is allowed at all. If this is the case, the emitter is removed from the flavor array. If the resulting array is equivalent to the Born flavor structure `flv_born`, the pair is accepted as a valid splitting.

```

(fks regions: flv structure: TBP)≡
  procedure :: valid_pair => flv_structure_valid_pair

(fks regions: procedures)+≡
  function flv_structure_valid_pair &
    (flv_real,i,j, flv_born, model) result (valid)
    class(flv_structure_t), intent(in) :: flv_real
    integer, intent(in) :: i,j
    type(flv_structure_t), intent(in) :: flv_born
    type(model_data_t), intent(in) :: model
    logical :: valid
    integer :: k, n_orig
    type(flv_structure_t) :: flv_test
    integer, dimension(:), allocatable :: flv_orig, flv_orig2
    valid = .false.

```

First check whether the splitting is possible. The array `flv_orig` contains all particles which share a vertex with the particles at position `i` and `j`. If its size is equal to zero, no splitting is possible and the subroutine is exited.

```

(fks regions: procedures)+≡
  call model%match_vertex &
    (flv_real%flst(i), flv_real%flst(j), flv_orig)
  n_orig = size (flv_orig)
  if (n_orig == 0) then
    return
  else

```

For a quark emitting a gluon, `flv_orig` contains the PDG code of the anti-quark. To be on the safe side, a second array is created, which contains both the positively and negatively signed PDG codes. Then, the original tuple (i, j) is removed from the real flavor structure and the particles in `flv_orig2` are inserted. If the resulting Born configuration is equal to the underlying Born configuration, up to a permutation of final-state particles, the tuple (i, j) is accepted as valid.

```

(fks regions: procedures)+≡
  allocate (flv_orig2 (2*n_orig))
  flv_orig2 (1:n_orig) = flv_orig
  flv_orig2 (n_orig+1:2*n_orig) = -flv_orig
  do k = 1, 2*n_orig
    flv_test = flv_real%insert_particle (i,j,flv_orig2(k))
    valid = flv_born == flv_test
    if (valid) return
  end do
end if
end function flv_structure_valid_pair

```

This function checks whether two flavor arrays are the same up to a permutation of the final-state particles

```

```

This subroutine starts with a specification of N - and $N + 1$ -particle configurations, `flst_born` and `flst_real`, saved in `reg_data`. From these, it creates a list of fundamental tuples, a list of emitters and a list containing the $N + 1$ -particle configuration, rearranged in such a way that the emitter-radiation pair is last (`flst_alr`). For the $e^+ e^- \rightarrow u \bar{u} g$ - example, the generated objects are shown in table 25.2. Note that at this point, `flst_alr` is arranged in such a way that the emitter can only be equal to $n_{legs} - 1$ for final-state radiation or 0, 1, or 2 for initial-state radiation. Further, it occurs that regions can be equivalent. For example in table 25.2 the regions corresponding to `alr = 1` and `alr = 3` as well as `alr = 2` and `alr = 4` describe the same physics and are therefore equivalent.

The virtual-subtracted matrix element is given by the equation

$$\mathcal{V} = \frac{\alpha_s}{2\pi} \left(\mathcal{Q}\mathcal{B} + \sum \mathcal{I}_{ij} \mathcal{B}_{ij} + \mathcal{V}_{fin} \right), \quad (25.2)$$

where the quantity \mathcal{Q} is given by

$$\begin{aligned} \mathcal{Q} = \sum_{i=1}^n \left[\gamma'_{fi} - \log \frac{s}{Q^2} \left(\gamma_{fi} - 2C_{fi} \log \frac{2E_i}{\sqrt{s}} \right) \right. \\ \left. + 2C_{fi} \log^2 \frac{2E_i}{\sqrt{s}} - 2\gamma_{fi} \frac{2E_i}{\sqrt{s}} \right] \\ - \log \frac{\mu_F^2}{Q^2} (\gamma_{f+} + \gamma_{f-}). \end{aligned} \quad (25.3)$$

The expressions for \mathcal{I}_{ij} can be found in equations (25.4), (25.5), (25.6), depending on whether the particles involved in the radiation process are massive or massless.

The following code implements the \mathcal{I}_{ij} -function appearing in eq. blub. They are defined as follows:

Massless-Massless Case

$$\begin{aligned}\mathcal{I}_{ij} = & \frac{1}{2} \log^2 \frac{s}{Q^2} + \log \frac{s}{Q^2} \log \frac{k_i k_j}{2E_i E_j} - \text{Li}_2 \left(\frac{k_i k_j}{2E_i E_j} \right) \\ & + \frac{1}{2} \log^2 \frac{k_i k_j}{2E_i E_j} - \log \left(1 - \frac{k_i k_j}{2E_i E_j} \right) \log \frac{k_i k_j}{2E_i E_j}.\end{aligned}\quad (25.4)$$

Massive-Massive Case

$$\mathcal{I}_{ij} = -\frac{1}{2} I_0(k_i, k_j) \log \frac{Q^2}{s} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (25.5)$$

with

$$I_0(k_i, k_j) = \frac{1}{\beta} \log \frac{1+\beta}{1-\beta}, \quad \beta = \sqrt{1 - \frac{k_i^2 k_j^2}{(k_i \cdot k_j)^2}}$$

and a rather involved expression for I_ϵ :

$$\begin{aligned}I_\epsilon(k_i, k_j) = & (K(z_j) - K(z_i)) \frac{1 - \vec{\beta}_i \cdot \vec{\beta}_j}{\sqrt{a(1-b)}}, \\ \vec{\beta}_i = & \frac{\vec{k}_i}{k_i^0}, \\ a = & \beta_i^2 + \beta_j^2 - 2\vec{\beta}_i \cdot \vec{\beta}_j, \\ x_i = & \frac{\beta_i^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a}, \\ x_j = & \frac{\beta_j^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a} = 1 - x_i, \\ b = & \frac{\beta_i^2 \beta_j^2 - (\vec{\beta}_i \cdot \vec{\beta}_j)^2}{a}, \\ c = & \sqrt{\frac{b}{4a}}, \\ z_+ = & \frac{1 + \sqrt{1-b}}{\sqrt{b}}, \\ z_- = & \frac{1 - \sqrt{1-b}}{\sqrt{b}}, \\ z_i = & \frac{\sqrt{x_i^2 + 4c^2} - x_i}{2c}, \\ z_j = & \frac{\sqrt{x_j^2 + 4c^2} + x_j}{2c}, \\ K(z) = & -\frac{1}{2} \log^2 \frac{(z - z_-)(z_+ - z)}{(z_+ + z)(z_- + z)} - 2\text{Li}_2 \left(\frac{2z_-(z_+ - z)}{(z_+ - z_-)(z_- + z)} \right) \\ & - 2\text{Li}_2 \left(-\frac{2z_+(z_- + z)}{(z_+ - z_-)(z_+ - z)} \right)\end{aligned}$$

Massive-Massless Case

$$\mathcal{I}_{ij} = \frac{1}{2} \left[\log^2 \frac{Q}{s} - \frac{\pi^2}{6} \right] - \frac{1}{2} I_0(k_i, k_j) \log \frac{Q^2}{s} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (25.6)$$

with

$$I_0(p, k) = \log \frac{(\hat{p} \cdot \hat{k})^2}{\hat{k}^2},$$

$$I_\epsilon(p, k) = -2 \left[\frac{1}{4} \log^2 \frac{1-\beta}{1+\beta} + \log \frac{\hat{p} \cdot \hat{k}}{1+\beta} \log \frac{\hat{p} \cdot \hat{k}}{1-\beta} + Li_2 \left(1 - \frac{\hat{p} \cdot \hat{k}}{1+\beta} \right) + Li_2 \left(1 - \frac{\hat{p} \cdot \hat{k}}{1-\beta} \right) \right]$$

using

$$\hat{p} = \frac{p}{p^0}, \quad \hat{k} = \frac{k}{k^0}, \quad \beta = \frac{|\vec{k}|}{k_0}.$$

Soft subtraction terms

In the soft limit, the real matrix element behaves as

$$\mathcal{R}_{\text{soft}} = 4\pi\alpha_s \left[\sum_{i \neq j} \mathcal{B}_{ij} \frac{k_i \cdot k_j}{(k_i \cdot k)(k_j \cdot k)} - \mathcal{B} \sum_i \frac{k_i^2}{(k_i \cdot k)^2} C_i \right],$$

where k denotes the momentum of the emitted parton. The quantity \mathcal{B}_{ij} is called the color-correlated Born matrix element defined as

$$\mathcal{B}_{ij} = \frac{1}{2s} \sum_{\substack{\text{colors} \\ \text{spins}}} \mathcal{M}_{\{c_k\}} \left(\mathcal{M}_{\{c_k\}}^\dagger \right)_{\substack{c_i \rightarrow c'_i \\ c_j \rightarrow c'_j}} T_{c_i, c'_i}^a T_{c_j, c'_j}^a.$$

```

⟨real subtraction: types⟩≡
  type :: soft_subtraction_t

        sub_soft%reg_data = reg_data
        sub_soft%nlegs_born = nlegs_born
        sub_soft%nlegs_real = nlegs_real
        allocate (sub_soft%value (reg_data%n_regions))
        allocate (sub_soft%momentum_matrix &
                  (nlegs_born, nlegs_born))
    end subroutine soft_subtraction_init

```

The treatment of the momentum k follows the discussion about the soft limit of the partition functions (ref????). The parton momentum is pulled out, $k = E\hat{k}$. In fact, we will substitute \hat{k} for k throughout the code, because the energy will factor out of the equation when the soft \mathcal{S} -function is multiplied. The soft momentum is a unit vector, because $k^2 = (k^0)^2 - (\hat{k})^2 = 0$.

```

<real subtraction: procedures>+≡
    function create_softvec_fsr (p_born, y, phi, emitter) result (p_soft)
        type(vector4_t), intent(in), dimension(:) :: p_born
        real(default), intent(in) :: y, phi
        integer, intent(in) :: emitter
        type(vector4_t) :: p_soft
        type(vector3_t) :: dir
        type(lorentz_transformation_t) :: rot

```

The soft momentum is constructed by first creating a unit vector parallel to the emitter's Born momentum. This unit vector is then rotated about the corresponding angles y and ϕ .

```

<real subtraction: procedures>+≡
    p_soft%p(0) = 1._default
    p_soft%p(1:3) = p_born(emitter)%p(1:3) / space_part_norm (p_born(emitter))
    dir = create_orthogonal (space_part (p_born(emitter)))
    rot = rotation (y, sqrt(1-y**2), dir)
    p_soft = rot*p_soft
    if (.not. vanishes (phi)) then
        dir = space_part (p_born(emitter)) / &
              space_part_norm (p_born(emitter))
        rot = rotation (cos(phi), sin(phi), dir)
        p_soft = rot*p_soft
    end if

```

```
end function create_softvec_fsr
```

Computation of $\mathcal{R}_{\text{soft}}$:

```
⟨real subtraction: soft sub: TBP⟩+=
  procedure :: compute => soft_subtraction_compute

⟨real subtraction: procedures⟩+=
  subroutine soft_subtraction_compute (sub_soft, p_born, &
    born_ij, y, y_soft, phi, alpha_s_born, alr, emitter)
    class(sub_soft), intent(inout) :: sub_soft
    type(vector4_t), intent(in), dimension(:) :: p_born
    real(default), intent(in), dimension(:, :) :: born_ij
    real(default), intent(in) :: y, y_soft, phi
    real(default), intent(in) :: alpha_s_born
    integer, intent(in) :: alr, emitter
    type(vector4_t) :: p_soft
    real(default) :: s_alpha_soft
    real(default) :: q02
    real(default) :: kb
    integer :: i, j

    p_soft = create_softvec_fsr (p_born, y_soft, phi, emitter)
    s_alpha_soft = sub_soft%reg_data%get_svalue_soft &
      (p_born, p_soft, alr, emitter)
    call sub_soft%compute_momentum_matrix (p_born, p_soft)
    sub_soft%value(alr) = 4*pi*alpha_s_born * s_alpha_soft
    kb = 0._default
    do i = 1, size (p_born)
      do j = 1, size (p_born)
        kb = kb + sub_soft%momentum_matrix (i,j) * &
          born_ij (i,j)
      end do
    end do
    sub_soft%value(alr) = sub_soft%value(alr)*kb
    q02 = 4* vector4_get_component (p_born(1), 0) * &
      vector4_get_component (p_born(2), 0)
    sub_soft%value(alr) = 4/q02 * (1-y) * sub_soft%value(alr)
  end subroutine soft_subtraction_compute
```

We have to multiply this with $\xi^2(1-y)$. Further, when applying the soft \mathcal{S} -function, the energy of the radiated particle is factored out. Thus we have $\xi^2/E_{em}^2(1-y) = 4/q_0^2(1-y)$.

⟨nlo controller: soft subtraction computation⟩=

      sub_soft%momentum_matrix(i,j) = sub_soft%momentum_matrix(j,i)
    end if
  end do
end do
end subroutine soft_subtraction_compute_momentum_matrix

```

25.5.1 Collinear and soft-collinear subtraction terms

This data type deals with the calculation of the collinear and soft-collinear contribution to the cross section.

```

⟨real subtraction: types⟩+≡
type :: coll_subtraction_t
  real(default), dimension(:), allocatable :: value
  real(default), dimension(:), allocatable :: value_soft
  integer :: n_alr
  real(default), dimension(0:3,0:3) :: b_munu
  real(default) , dimension(0:3,0:3) :: k_perp_matrix
contains
  ⟨real subtraction: coll sub: TBP⟩
end type coll_subtraction_t

```

```

⟨real subtraction: coll sub: TBP⟩≡
  procedure :: init => coll_subtraction_init

```

```

⟨real subtraction: procedures⟩+≡
  subroutine coll_subtraction_init (coll_sub, n_alr)
    class(coll_subtraction_t), intent(inout) :: coll_sub
    integer, intent(in) :: n_alr
    coll_sub%n_alr = n_alr
    allocate (coll_sub%value (n_alr))
    allocate (coll_sub%value_soft (n_alr))
  end subroutine coll_subtraction_init

```

To compute the collinear limit of \mathcal{R} , we follow the original FKS-paper. Here, the real amplitude is supposed to factorize in the collinear limit. considering a splitting $g \rightarrow g(i)g(j)$,

$$\mathcal{A}^{(n)}(h_i, h_j, \{h_l\}) \xrightarrow{i||j} g_s \sum_{d_e} \sum_{h_e} C(d_e, b, c) S_{gg}^{h_e h_i h_j}(z) \mathcal{A}_{d_e}^{(n-1)}(h_e, \{h_l\})$$

Explain quantities. Evaluating this expression leads to

$$|\mathcal{A}^{(n)}(h_i, h_j, \{h_l\})|^2 \xrightarrow{i||j} |\mathcal{N}^{(n)}(h_i, h_j, \{h_l\})|^2 + \mathcal{R}(h_i, h_j, \{h_l\})|^2,$$

where \mathcal{R} contains all contributions with spin-correlated amplitudes, i.e. terms like $\mathcal{A}_{d_e}^{(n-1)}(+, \{h_l\}) \left(\mathcal{A}_{d_e}^{(n-1)}(-, \{h_l\}) \right)^*$. Explicitly,

$$\sum_{h_i, h_j, \{h_l\}} \sum_{\{d_l\}} |\mathcal{N}^{(n)}(h_i, h_j, \{h_l\})|^2 = \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{gg}(z) |\mathcal{A}^{(n-1)}|^2,$$

and

$$\begin{aligned} \sum_{h_i, h_j, \{h_l\}} \sum_{\{d_l\}} \mathcal{R}(h_i, h_j, \{h_l\}) &= 32\pi\alpha_s C_A z(1-z) \\ &\times \underbrace{Re \left\{ \frac{\langle ij \rangle}{[ij]} \sum_{\{h_l\}} \sum_{d_e, \{d_l\}} \mathcal{A}_{d_e}^{(n-1)}(+, \{h_l\}) \left(\mathcal{A}_{d_e}^{(n-1)}(-, \{h_l\}) \right)^* \right\}}_{-\tilde{\mathcal{M}}^{(n-1)}/(2k_i \cdot k_j)}. \end{aligned}$$

This yields

$$\mathcal{M}^{(n)} \xrightarrow{i||j} \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{gg}(z) \mathcal{M}^{(n-1)} - \frac{16\pi\alpha_s}{k_i \cdot k_j} C_A z(1-z) \tilde{\mathcal{M}}^{(n-1)}. \quad (25.7)$$

The equivalent expression for a $g \rightarrow qq$ -splitting is given by

$$\mathcal{M}^{(n)} \xrightarrow{i||j} \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{qg}(z) \mathcal{M}^{(n-1)} + \frac{16\pi\alpha_s}{k_i \cdot k_j} T_F z(1-z) \tilde{\mathcal{M}}^{(n-1)}. \quad (25.8)$$

```

<real subtraction: coll sub: TBP>+≡
  procedure :: compute => coll_subtraction_compute

<real subtraction: procedures>+≡
  subroutine coll_subtraction_compute &
    (coll_sub, sregion, p_born, sqme_born, sqme_born_sc, &
     xi, alpha_s, alr, soft_in)
    class(coll_subtraction_t), intent(inout) :: coll_sub
    type(singular_region_t), intent(in) :: sregion
    type(vector4_t), intent(in), dimension(:) :: p_born

    real(default), intent(in) :: sqme_born_sc
    real(default), intent(in) :: xi, alpha_s
    integer, intent(in) :: alr

```

The function obtains a flag to indicate whether the limit to be computed is also soft. Moreover, this consideration explains the structure of the code. In the soft limit, we find $z \rightarrow 0$ as well as $\xi \rightarrow 0$. However, the quantity z/ξ is finite, because

$$\frac{z}{\xi} = \frac{p_{rad}^0}{\bar{p}_{em}^0} \frac{q^0}{2p_{em}^0} = \frac{q^0}{2\bar{p}_{em}^0}.$$

Thus, all expressions are written in terms of this well-behaved quantity. Recalling that there is a prefactor of $(\xi^2 z)^{-1}$, it is necessary to expand with z once.

25.5.3 The real contribution to the cross section

In each singular region α , the real contribution to σ is given by the second summand of eqn. ??,

$$\sigma_{\text{real}}^\alpha = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 dy \int_0^{\xi_{\text{max}}} d\xi \left(\frac{1}{\xi} \right)_+ \left(\frac{1}{1-y} \right)_+ \underbrace{\frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1-y)\xi^2 \mathcal{R}^\alpha(\Phi_{n+1})]}_{g^\alpha(\xi, y)} . \quad (25.9)$$

Writing out the plus-distribution and introducing $\tilde{\xi} = \xi/\xi_{\text{max}}$ to set the upper integration limit to 1, this turns out to be equal to

$$\begin{aligned} \sigma_{\text{real}}^\alpha = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 \frac{dy}{1-y} \left\{ \int_0^1 d\tilde{\xi} \left[\frac{g^\alpha(\tilde{\xi}\xi_{\text{max}}, y)}{\tilde{\xi}} - \underbrace{\frac{g^\alpha(0, y)}{\tilde{\xi}}}_{\text{soft}} - \underbrace{\frac{g^\alpha(\tilde{\xi}\xi_{\text{max}}, 1)}{\tilde{\xi}}}_{\text{coll.}} + \underbrace{\frac{g^\alpha(0, 1)}{\tilde{\xi}}}_{\text{coll.+soft}} \right] \right. \\ \left. + [\log \xi_{\text{max}}(y)g^\alpha(0, y) - \log \xi_{\text{max}}(1)g^\alpha(0, 1)] \right\} . \end{aligned} \quad (25.10)$$

This formula is implemented in `compute_sqme_real_fin`

```
<real subtraction: real subtraction: TBP>+≡
  procedure :: compute => real_subtraction_compute

<real subtraction: procedures>+≡
  function real_subtraction_compute (rsub, emitter, alpha_s) result (sqme)
    class(real_subtraction_t), intent(inout) :: rsub
    integer, intent(in) :: emitter
    real(default) :: alpha_s
    real(default) :: sqme
    integer :: alr

    sqme = 0._default
    !!! Loop over all singular regions
    do alr = 1, size (rsub%reg_data%regions)
      if (emitter == rsub%reg_data%regions(alr)%emitter) then
        call rsub%set_alr (alr)
        sqme = sqme + rsub%evaluate_region (emitter, alpha_s)
      end if
    end do
    if (rsub%subtraction_active) sqme = sqme*rsub%get_phs_factor ()
  end function real_subtraction_compute
```

This subroutine computes the finite part of the real matrix element in an individual singular region. First, the radiation variables are fetched and \mathcal{R} is multiplied by the appropriate S_α -factors, region multiplicities and double-FSR factors. Then, it computes the soft, collinear, soft-collinear and remnant matrix elements and supplies the corresponding factor $1/\xi/(1-y)$ as well as the corresponding jacobians.

25.7 The FKS phase space

To handle the FKS phase space and adapt it to multi-channel integration, some extensions have to be made for pre-existing types. The `phs_tree`-type has an attribute containing the tree-code of the emitting branch.

```
<PHS trees: phs tree: TBP>≡
  procedure :: get_emitter => phs_tree_get_emitter

The fks phase space type contains the wood phase space and separately the in- and outcoming momenta for the real process and the corresponding Born momenta. Additionally, there are the variables ξ, ξ_{max}, y and ϕ which are used to create the real phase space, as well as the jacobian and its corresponding soft and collinear limit. Lastly, the array `ch_to_em` connects each channel with an emitter.

Evaluate selected channel. First, the subroutine calls the evaluation procedure of the underlying Born phase space, using $n_r - 3$ random numbers. Then, the remaining three random numbers are used to create ξ , y and ϕ , from which the real momenta are calculated from the Born momenta.

25.7.1 Creation of the real phase space - FSR

At this point, the Born phase space has been generated, as well as the three random variables ξ , y and ϕ . The question is how the real phase space is generated for a final-state emission configuration. We work with two different sets of momenta, the Born configuration $\{\bar{k}_\oplus, \bar{k}_\ominus, \bar{k}_1, \dots, \bar{k}_n\}$ and the real configuration $\{k_\oplus, k_\ominus, k_1, \dots, k_n, k_{n+1}\}$. We define the momentum of the emitter to be on the n -th position and the momentum of the radiated particle to be at position $n+1$. The magnitude of the spatial component of \mathbf{k} is denoted by \underline{k} .

For final-state emissions, it is $\bar{k}_\oplus = k_\oplus$ and $\bar{k}_\ominus = k_\ominus$. Thus, the center-of-mass systems coincide and it is

$$q = \sum_{i=1}^n \bar{k}_i = \sum_{i=1}^{n+1} k_i, \quad (25.11)$$

with $\vec{q} = 0$ and $q^2 = (q^0)^2$.

We want to construct the real phase space from the Born phase space using three random numbers. They are defined as follows:

- $\xi = \frac{2k_{n+1}^0}{\sqrt{s}} \in [0, \xi_{max}]$, where k_{n+1} denotes the four-momentum of the radiated particle.
- $y = \cos \theta = \frac{\vec{k}_n \cdot \vec{k}_{n+1}}{\underline{k}_n \underline{k}_{n+1}}$ is the splitting angle.
- The angle between the two splitting particles in the transversal plane, $\phi \in [0, 2\pi]$.

Further, $k_{rec} = \sum_{i=1}^{n-1} k_i$ denotes the sum of all recoiling momenta.

Construction of the recoiling momenta. The reshuffling of momenta must not change the invariant mass of the recoiling system, which means $k_{\text{rec}}^2 = k_{\text{rec}}^{-2}$. Therefore, the momenta are related by a boost, $\bar{k}_i = \Lambda k_i$. The boost parameter is

$$\beta = \frac{q^2 - (k_{\text{rec}}^0 + \underline{k}_{\text{rec}})^2}{q^2 + (k_{\text{rec}}^0 + \underline{k}_{\text{rec}})^2}$$

The momentum of the radiated particle is computed according to

$$\underline{k}_n = \frac{q^2 - M_{\text{rec}}^2 - 2q^0 \underline{k}_{n+1}}{2(q^0 - \underline{k}_{n+1}(1-y))}, \quad (25.12)$$

with $k = k_n + k_{n+1}$ and $M_{\text{rec}}^2 = k_{\text{rec}}^2 = (q - k)^2$. Because of $\bar{\mathbf{k}}_n \parallel \mathbf{k}_n + \mathbf{k}_{n+1}$

we find $M_{\text{rec}}^2 = (q - \bar{k}_n)^2$. Equation ?? follows from the fact that $(\mathbf{k} - \mathbf{k}_n)^2 = \mathbf{k}_{n+1}^2$, which is equivalent to $\mathbf{k}_n \cdot \mathbf{k} = \frac{1}{2} (\underline{k}_n^2 + \underline{k}^2 - \underline{k}_{n+1}^2)$. \mathbf{k}_n and \mathbf{k}_{n+1} are obtained by first setting up vectors parallel to $\bar{\mathbf{k}}_n$,

$$\mathbf{k}'_n = \underline{k}_n \frac{\bar{\mathbf{k}}_n}{\bar{k}_n}, \quad \mathbf{k}'_{n+1} = \underline{k}_{n+1} \frac{\bar{\mathbf{k}}_n}{\bar{k}_n},$$

and then rotating these vectors by an amount of $\cos \psi_n = \frac{\mathbf{k}_n \cdot \mathbf{k}}{\bar{k}_n \bar{k}}$. The emitted particle cannot have more momentum than the emitter has in the Born phase space. Thus, there is an upper bound for ξ , determined by the condition $k_{n+1}^0 = \bar{k}_n$, which is equal to

$$\xi_{\text{max}} = \frac{2}{\bar{k}_n} q^0.$$

Chapter 26

Model Handling and Features

These modules deal with process definitions and physics models.

These modules use the `model_data` methods to automatically generate process definitions.

auto_components Generic process-definition generator. We can specify a basic process or initial particle(s) and some rules to extend this process, given a model definition with particle names and vertex structures.

radiation_generator Applies the generic generator to the specific problem of generating NLO corrections in a restricted setup.

Model construction:

eval_trees Implementation of the generic `expr_t` type for the concrete evaluation of expressions that access user variables.

This module is actually part of the Sindarin language implementation, and should be moved elsewhere. Currently, the `models` module relies on it.

models Extends the `model_data_t` structure by user-variable objects for easy access, and provides the means to read a model definition from file.

slha_interface Read/write a SUSY model in the standardized SLHA format. The format defines fields and parameters, but no vertices.

26.1 Automatic generation of process components

This module provides the functionality for automatically generating radiation corrections or decays, provided as lists of PDG codes.

```
<auto_components.f90>≡  
  <File header>  
  
  module auto_components  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use unit_tests  
    use diagnostics  
    use model_data  
    use pdg_arrays  
    use model_testbed  
  
    <Standard module head>  
  
    <Auto components: public>  
  
    <Auto components: types>  
  
    <Auto components: interfaces>  
  
    contains  
  
    <Auto components: procedures>  
  
    <Auto components: tests>  
  
  end module auto_components
```

26.1.1 Constraints: Abstract types

An abstract type that denotes a constraint on the automatically generated states. The concrete objects are applied as visitor objects at certain hooks during the splitting algorithm.

```
<Auto components: types>≡  
  type, abstract :: split_constraint_t  
    contains  
    <Auto components: split constraint: TBP>  
  end type split_constraint_t
```

By default, all checks return true.

```
<Auto components: split constraint: TBP>≡  
  procedure :: check_before_split => split_constraint_check_before_split  
  procedure :: check_before_insert => split_constraint_check_before_insert  
  procedure :: check_before_record => split_constraint_check_before_record
```

```

<Auto components: procedures>≡
  subroutine split_constraint_check_before_split (c, table, pl, k, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: k
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_split

  subroutine split_constraint_check_before_insert (c, table, pa, pl, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_array_t), intent(in) :: pa
    type(pdg_list_t), intent(inout) :: pl
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_insert

  subroutine split_constraint_check_before_record (c, table, pl, n_loop, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_record

```

A transparent wrapper, so we can collect constraints of different type.

```

<Auto components: types>+≡
  type :: split_constraint_wrap_t
    class(split_constraint_t), allocatable :: c
  end type split_constraint_wrap_t

```

A collection of constraints.

```

<Auto components: public>≡
  public :: split_constraints_t

<Auto components: types>+≡
  type :: split_constraints_t
    class(split_constraint_wrap_t), dimension(:), allocatable :: cc
    contains
    <Auto components: split constraints: TBP>
  end type split_constraints_t

```

Initialize the constraints set with a specific number of elements.

```

<Auto components: split constraints: TBP>≡
  procedure :: init => split_constraints_init

<Auto components: procedures>+≡
  subroutine split_constraints_init (constraints, n)
    class(split_constraints_t), intent(out) :: constraints
    integer, intent(in) :: n

```

```

        allocate (constraints%cc (n))
    end subroutine split_constraints_init

```

Set a constraint.

```

<Auto components: split constraints: TBP>+≡
    procedure :: set => split_constraints_set

<Auto components: procedures>+≡
    subroutine split_constraints_set (constraints, i, c)
        class(split_constraints_t), intent(inout) :: constraints
        integer, intent(in) :: i
        class(split_constraint_t), intent(in) :: c
        allocate (constraints%cc(i)%c, source = c)
    end subroutine split_constraints_set

```

Apply checks.

```

    check_before_split is applied to the particle list that we want to split.
    check_before_insert is applied to the particle list pl that is to replace the
    particle pa that is split. This check may transform the particle list.
    check_before_record is applied to the complete new particle list that re-
    sults from splitting before it is recorded.

<Auto components: split constraints: TBP>+≡
    procedure :: check_before_split => split_constraints_check_before_split
    procedure :: check_before_insert => split_constraints_check_before_insert
    procedure :: check_before_record => split_constraints_check_before_record

        (constraints, table, pa, pl, passed)
        class(split_constraints_t), intent(in) :: constraints
        class(ps_table_t), intent(in) :: table
        type(pdg_array_t), intent(in) :: pa
        type(pdg_list_t), intent(inout) :: pl
        logical, intent(out) :: passed
        integer :: i
        passed = .true.
        do i = 1, size (constraints%cc)
            call constraints%cc(i)%c%check_before_insert (table, pa, pl, passed)

```

```

        if (.not. passed) return
    end do
end subroutine split_constraints_check_before_insert

subroutine split_constraints_check_before_record &
    (constraints, table, pl, n_loop, passed)
    class(split_constraints_t), intent(in) :: constraints
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    integer :: i
    passed = .true.
    do i = 1, size (constraints%cc)
        call constraints%cc(i)%check_before_record (table, pl, n_loop, passed)
        if (.not. passed) return
    end do
end subroutine split_constraints_check_before_record

```

26.1.2 Specific constraints

Number of particles

Specific constraint: The number of particles plus the number of loops, if any, must remain less than the given limit. Note that the number of loops is defined only when we are recording the entry.

```

<Auto components: types>+≡
    type, extends (split_constraint_t) :: constraint_n_tot
    private
    integer :: n_max = 0
    contains
    procedure :: check_before_split => constraint_n_tot_check_before_split
    procedure :: check_before_record => constraint_n_tot_check_before_record
end type constraint_n_tot

<Auto components: public>+≡
    public :: constrain_n_tot

<Auto components: procedures>+≡
    function constrain_n_tot (n_max) result (c)
    integer, intent(in) :: n_max
    type(constraint_n_tot) :: c
    c%n_max = n_max
end function constrain_n_tot

subroutine constraint_n_tot_check_before_split (c, table, pl, k, passed)
    class(constraint_n_tot), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: k
    logical, intent(out) :: passed
    passed = pl%get_size () < c%n_max
end subroutine constraint_n_tot_check_before_split

```

```

subroutine constraint_n_tot_check_before_record (c, table, pl, n_loop, passed)
  class(constraint_n_tot), intent(in) :: c
  class(ps_table_t), intent(in) :: table
  type(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n_loop
  logical, intent(out) :: passed
  passed = pl%get_size () + n_loop <= c%n_max
end subroutine constraint_n_tot_check_before_record

```

Number of loops

Specific constraint: The number of loops is limited, independent of the total number of particles.

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_n_loop
  private
  integer :: n_loop_max = 0
  contains
  procedure :: check_before_record => constraint_n_loop_check_before_record
end type constraint_n_loop

<Auto components: public>+≡
  public :: constrain_n_loop

<Auto components: procedures>+≡
  function constrain_n_loop (n_loop_max) result (c)
    integer, intent(in) :: n_loop_max
    type(constraint_n_loop) :: c
    c%n_loop_max = n_loop_max
  end function constrain_n_loop

  subroutine constraint_n_loop_check_before_record &
    (c, table, pl, n_loop, passed)
    class(constraint_n_loop), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    passed = n_loop <= c%n_loop_max
  end subroutine constraint_n_loop_check_before_record

```

Particles allowed in splitting

Specific constraint: The entries in the particle list ready for insertion are matched to a given list of particle patterns. If a match occurs, the entry is replaced by the corresponding pattern. If there is no match, the check fails.

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_insert
  private
  type(pdg_list_t) :: pl_match

```

```

contains
  procedure :: check_before_insert => constraint_insert_check_before_insert
end type constraint_insert

<Auto components: public>+≡
  public :: constrain_insert

<Auto components: procedures>+≡
  function constrain_insert (pl_match) result (c)
    type(pdg_list_t), intent(in) :: pl_match
    type(constraint_insert) :: c
    c%pl_match = pl_match
  end function constrain_insert

  subroutine constraint_insert_check_before_insert (c, table, pa, pl, passed)
    class(constraint_insert), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_array_t), intent(in) :: pa
    type(pdg_list_t), intent(inout) :: pl
    logical, intent(out) :: passed
    call pl%match_replace (c%pl_match, passed)
  end subroutine constraint_insert_check_before_insert

```

Particles required in final state

Specific constraint: The entries in the recorded state must be a superset of the entries in the given list (for instance, the lowest-order state).

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_require
  private
  type(pdg_list_t) :: pl
  contains
  procedure :: check_before_record => constraint_require_check_before_record
end type constraint_require

```

We check the current state by matching all particle entries against the stored particle list, and crossing out the particles in the latter list when a match is found. The constraint passed if all entries have been crossed out.

For an `if_table` in particular, we check the final state only.

```

<Auto components: public>+≡
  public :: constrain_require

<Auto components: procedures>+≡
  function constrain_require (pl) result (c)
    type(pdg_list_t), intent(in) :: pl
    type(constraint_require) :: c
    c%pl = pl
  end function constrain_require

  subroutine constraint_require_check_before_record &
    (c, table, pl, n_loop, passed)
    class(constraint_require), intent(in) :: c

```

```

class(ps_table_t), intent(in) :: table
type(pdg_list_t), intent(in) :: pl
integer, intent(in) :: n_loop
logical, intent(out) :: passed
logical, dimension(:), allocatable :: mask
integer :: i, k, n_in
select type (table)
type is (if_table_t)
    n_in = 2
class default
    n_in = 0
end select
allocate (mask (c%pl%get_size ()), source = .true.)
do i = n_in + 1, pl%get_size ( )
    k = c%pl%find_match (pl%get (i), mask)
    if (k /= 0) mask(k) = .false.
end do
passed = .not. any (mask)
end subroutine constraint_require_check_before_record

```

Radiation

Specific constraint: We have radiation pattern if the original particle matches an entry in the list of particles that should replace it. The constraint prohibits this situation.

```

<Auto components: public>+≡
public :: constrain_radiation

```

```

<Auto components: types>+≡
type, extends (split_constraint_t) :: constraint_radiation
private
contains
    procedure :: check_before_insert => &
        constraint_radiation_check_before_insert
end type constraint_radiation

```

```

<Auto components: procedures>+≡
function constrain_radiation ( ) result (c)
    type(constraint_radiation) :: c
end function constrain_radiation

```

```

subroutine constraint_radiation_check_before_insert (c, table, pa, pl, passed)
    class(constraint_radiation), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_array_t), intent(in) :: pa
    type(pdg_list_t), intent(inout) :: pl
    logical, intent(out) :: passed
    passed = .not. (pl .match. pa)
end subroutine constraint_radiation_check_before_insert

```

Mass sum

Specific constraint: The sum of masses within the particle list must be smaller than a given limit. For in/out state combinations, we check initial and final state separately.

If we specify `margin` in the initialization, the sum must be strictly less than the limit minus the given margin (which may be zero). If not, equality is allowed.

```
(Auto components: public)+≡
    public :: constrain_mass_sum

(Auto components: types)+≡
    type, extends (split_constraint_t) :: constraint_mass_sum
    private
        real(default) :: mass_limit = 0
        logical :: strictly_less = .false.
        real(default) :: margin = 0
    contains
        procedure :: check_before_record => constraint_mass_sum_check_before_record
    end type constraint_mass_sum

(Auto components: procedures)+≡
    function constrain_mass_sum (mass_limit, margin) result (c)
        real(default), intent(in) :: mass_limit
        real(default), intent(in), optional :: margin
        type(constraint_mass_sum) :: c
        c%mass_limit = mass_limit
        if (present (margin)) then
            c%strictly_less = .true.
            c%margin = margin
        end if
    end function constrain_mass_sum

    subroutine constraint_mass_sum_check_before_record &
        (c, table, pl, n_loop, passed)
        class(constraint_mass_sum), intent(in) :: c
        class(ps_table_t), intent(in) :: table
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: n_loop
        logical, intent(out) :: passed
        real(default) :: limit
        if (c%strictly_less) then
            limit = c%mass_limit - c%margin
            select type (table)
            type is (if_table_t)
                passed = mass_sum (pl, 1, 2, table%model) < limit &
                    .and. mass_sum (pl, 3, pl%get_size (), table%model) < limit
            class default
                passed = mass_sum (pl, 1, pl%get_size (), table%model) < limit
            end select
        else
            limit = c%mass_limit
            select type (table)
            type is (if_table_t)

                if (.not. (c%pl .match. pl%get (i))) return
            end do
        end select
        passed = .true.
    end subroutine constraint_in_state_check_before_record

```

26.1.3 Tables of states

Automatically generate a list of possible process components for a given initial set (a single massive particle or a preset list of states).

The set of process components are generated by recursive splitting, applying constraints on the fly that control and limit the process. The generated states are accumulated in a table that we can read out after completion.

```

⟨Auto components: types⟩+≡
  type, extends (pdg_list_t) :: ps_entry_t
    integer :: n_loop = 0
    integer :: n_rad = 0
    type(ps_entry_t), pointer :: previous => null ()
    type(ps_entry_t), pointer :: next => null ()
  end type ps_entry_t

```

This is the wrapper type for the decay tree for the list of final states and the final array. First, an abstract base type:

```

⟨Auto components: public⟩+≡
  public :: ps_table_t

⟨Auto components: types⟩+≡
  type, abstract :: ps_table_t
    private
      class(model_data_t), pointer :: model => null ()
      logical :: loops = .false.
      type(ps_entry_t), pointer :: first => null ()
      type(ps_entry_t), pointer :: last => null ()
    contains
      ⟨Auto components: ps table: TBP⟩
  end type ps_table_t

```

The extensions: one for decay, one for generic final states. The decay-state table stores the initial particle. The final-state table is indifferent, and the initial/final state table treats the first two particles in its list as incoming antiparticles.

```

⟨Auto components: public⟩+≡
  public :: ds_table_t
  public :: if_table_t

⟨Auto components: types⟩+≡
  type, extends (ps_table_t) :: ds_table_t
    private
      integer :: pdg_in = 0
    contains
      ⟨Auto components: ds table: TBP⟩
  end type ds_table_t

  type, extends (ps_table_t) :: fs_table_t
    contains
      ⟨Auto components: fs table: TBP⟩
  end type fs_table_t

  type, extends (fs_table_t) :: if_table_t
    contains

```

```

    <Auto components: if table: TBP>
end type if_table_t

```

Finalizer: we must deallocate the embedded list.

```

<Auto components: ps table: TBP>≡
    procedure :: final => ps_table_final

<Auto components: procedures>+≡
    subroutine ps_table_final (object)

        call table%init (model, pl, constraints)
        table%pdg_in = pdg_in
        call pl_in%init (1)
        call pl_in%set (1, [pdg_in])
        call table%split (pl_in, 0, constraints)
    end subroutine ds_table_make

```

Split all entries in a growing table, starting from a table that may already contain states. Add and record split states on the fly.

```

<Auto components: fs table: TBP>+≡
    procedure :: radiate => fs_table_radiate

```

```

<Auto components: procedures>+≡
subroutine fs_table_radiate (table, constraints)
  class(fs_table_t), intent(inout) :: table
  type(split_constraints_t) :: constraints
  type(ps_entry_t), pointer :: current
  integer :: i, s
  logical :: passed
  current => table%first
  do while (associated (current))
    call table%split (current, 0, constraints, record = .true.)
    current => current%next
  end do
end subroutine fs_table_radiate

```

26.1.5 Splitting algorithm

Recursive splitting. First of all, we record the current `pdg_list` in the table, subject to `constraints`, if requested. We also record copies of the list marked as loop corrections.

When we record a particle list, we sort it first.

If there is room for splitting, We take a PDG array list and the index of an element, and split this element in all possible ways. The split entry is inserted into the list, which we split further.

The recursion terminates whenever the split array would have a length greater than n_{\max} .

```

<Auto components: ps table: TBP>+≡
  procedure :: split => ps_table_split

<Auto components: procedures>+≡
recursive subroutine ps_table_split (table, pl, n_rad, constraints, &
  record)
  class(ps_table_t), intent(inout) :: table
  class(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n_rad
  type(split_constraints_t), intent(in) :: constraints
  logical, intent(in), optional :: record
  integer :: n_loop, i
  logical :: passed
  type(vertex_iterator_t) :: vit
  integer, dimension(:), allocatable :: pdg1
  integer, dimension(:), allocatable :: pdg2
  if (present (record)) then
    if (record) then
      n_loop = 0
      INCR_LOOPS: do
        call table%record_sorted (pl, n_loop, n_rad, constraints, passed)
        if (.not. passed) exit INCR_LOOPS
        if (.not. table%loops) exit INCR_LOOPS
        n_loop = n_loop + 1
      end do INCR_LOOPS
    end if
  end if
end if

```

```

do i = 1, pl%get_size ()
  call constraints%check_before_split (table, pl, i, passed)
  if (passed) then
    pdg1 = pl%get (i)
    call vit%init (table%model, pdg1)
    SCAN_VERTICES: do
      call vit%get_next_match (pdg2)
      if (allocated (pdg2)) then
        call table%insert (pl, n_rad, i, pdg2, constraints)
      else
        exit SCAN_VERTICES
      end if
    end do SCAN_VERTICES
  end if
end do
end subroutine ps_table_split

```

The worker part: insert the list of particles found by vertex matching in place of entry *i* in the PDG list. Then split/record further.

The *n_in* parameter tells the replacement routine to insert the new particles after entry *n_in*. Otherwise, they follow index *i*.

(Auto components: ps table: TBP)+≡

```

procedure :: insert => ps_table_insert

```

(Auto components: procedures)+≡

```

recursive subroutine ps_table_insert &
  (table, pl, n_rad, i, pdg, constraints, n_in)
  class(ps_table_t), intent(inout) :: table
  class(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n_rad, i
  integer, dimension(:), intent(in) :: pdg
  type(split_constraints_t), intent(in) :: constraints
  integer, intent(in), optional :: n_in
  type(pdg_list_t) :: pl_insert
  logical :: passed
  integer :: k, s
  s = size (pdg)
  call pl_insert%init (s)
  do k = 1, s
    call pl_insert%set (k, pdg(k))
  end do
  call constraints%check_before_insert (table, pl%get (i), pl_insert, passed)
  if (passed) then
    call table%split (pl%replace (i, pl_insert, n_in), n_rad + s - 1, &
      constraints, record = .true.)
  end if
end subroutine ps_table_insert

```

Special case: If we are splitting an initial particle, there is slightly more to do. We loop over the particles from the vertex match and replace the initial particle by each of them in turn. The remaining particles must be appended after the second initial particle, so they will end up in the out state. This is done by providing the *n_in* argument to the base method as an optional argument.

Note that we must call the base-method procedure explicitly, so the `table` argument keeps its dynamic type as `if_table` inside this procedure.

```

<Auto components: if table: TBP>+≡
  procedure :: insert => if_table_insert

<Auto components: procedures>+≡
  recursive subroutine if_table_insert &
    (table, pl, n_rad, i, pdg, constraints, n_in)
    class(if_table_t), intent(inout) :: table
    class(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_rad, i
    integer, dimension(:), intent(in) :: pdg
    type(split_constraints_t), intent(in) :: constraints
    integer, intent(in), optional :: n_in
    integer, dimension(:), allocatable :: pdg_work
    integer :: p
    if (i > 2) then
      call ps_table_insert (table, pl, n_rad, i, pdg, constraints)
    else
      allocate (pdg_work (size (pdg)))
      do p = 1, size (pdg)
        pdg_work(1) = pdg(p)
        pdg_work(2:p) = pdg(1:p-1)
        pdg_work(p+1:) = pdg(p+1:)
        call ps_table_insert (table, &
          pl, n_rad, i, pdg_work, constraints, n_in = 2)
      end do
    end if
  end subroutine if_table_insert

```

Sort before recording. In the case of the `if_table`, we do not sort the first `n_in` particle entries. Instead, we check whether they are allowed in the `pl_beam` PDG list, if that is provided.

```

end subroutine if_table_record_sorted

```

Record an entry: insert into the list. Check the ordering and insert it at the correct place, unless it is already there.

We record an array only if its mass sum is less than the total available energy. This restriction is removed by setting `constrained` to false.

```

26.1.6 Tools

Compute the mass sum for a PDG list object, counting the entries with indices between (including) `n1` and `n2`. Rely on the requirement that if an entry is a PDG array, this array must be degenerate in mass.

(Auto components: procedures)+≡

```

function mass_sum (pl, n1, n2, model) result (m)
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n1, n2
    class(model_data_t), intent(in), target :: model
    integer, dimension(:), allocatable :: pdg
    real(default) :: m
    type(field_data_t), pointer :: prt
    integer :: i
    m = 0
    do i = n1, n2
        pdg = pl%get (i)
        prt => model%get_field_ptr (pdg(1))
        m = m + prt%get_mass ()
    end do
end function mass_sum

```

Invert a PDG array, replacing particles by antiparticles. This depends on the model.

(Auto components: procedures)+≡

```

function invert_pdg_array (pa, model) result (pa_inv)
    type(pdg_array_t), intent(in) :: pa
    class(model_data_t), intent(in), target :: model
    type(pdg_array_t) :: pa_inv
    type(field_data_t), pointer :: prt
    integer :: i, pdg
    pa_inv = pa
    do i = 1, pa_inv%get_length ()
        pdg = pa_inv%get (i)
        prt => model%get_field_ptr (pdg)
        if (prt%has_antiparticle ()) call pa_inv%set (i, -pdg)
    end do
end function invert_pdg_array

```

26.1.7 Access results

Return the number of generated decays.

```
<Auto components: ps table: TBP>+≡
  procedure :: get_length => ps_table_get_length

<Auto components: procedures>+≡
  function ps_table_get_length (ps_table) result (n)
    class(ps_table_t), intent(in) :: ps_table
    integer :: n
    type(ps_entry_t), pointer :: entry
    n = 0
    entry => ps_table%first
    do while (associated (entry))
      n = n + 1
      entry => entry%next
    end do
  end function ps_table_get_length
```

Return an allocated array of decay products (PDG codes). If requested, return also the loop and radiation order count.

```
<Auto components: ps table: TBP>+≡
  procedure :: get_pdg_out => ps_table_get_pdg_out

<Auto components: procedures>+≡
  subroutine ps_table_get_pdg_out (ps_table, i, pa_out, n_loop, n_rad)

26.3 Sindarin Expression Implementation

This module defines expressions of all kinds, represented in a tree structure, for repeated evaluation. This provides an implementation of the `expr_base` abstract type.

We have two flavors of expressions: one with particles and one without particles. The latter version is used for defining cut/selection criteria and for online analysis.

```

end module eval_trees

26.3.1 Tree nodes

The evaluation tree consists of branch nodes (unary and binary) and of leaf nodes, originating from a common root. The node object should be polymorphic. For the time being, polymorphism is emulated here. This means that we have to maintain all possibilities that the node may hold, including associated procedures as pointers.

The following parameter values characterize the node. Unary and binary operators have sub-nodes. The other are leaf nodes. Possible leafs are literal constants or named-parameter references.

<Eval trees: types>≡

```
integer, parameter :: EN_UNKNOWN = 0, EN_UNARY = 1, EN_BINARY = 2
integer, parameter :: EN_CONSTANT = 3, EN_VARIABLE = 4
integer, parameter :: EN_CONDITIONAL = 5, EN_BLOCK = 6
integer, parameter :: EN_RECORD_CMD = 7
integer, parameter :: EN_OBS1_INT = 11, EN_OBS2_INT = 12
integer, parameter :: EN_OBS1_REAL = 21, EN_OBS2_REAL = 22
integer, parameter :: EN_UOBS1_INT = 31, EN_UOBS2_INT = 32
integer, parameter :: EN_UOBS1_REAL = 41, EN_UOBS2_REAL = 42
integer, parameter :: EN_PRT_FUN_UNARY = 101, EN_PRT_FUN_BINARY = 102
integer, parameter :: EN_EVAL_FUN_UNARY = 111, EN_EVAL_FUN_BINARY = 112
integer, parameter :: EN_LOG_FUN_UNARY = 121, EN_LOG_FUN_BINARY = 122
integer, parameter :: EN_INT_FUN_UNARY = 131, EN_INT_FUN_BINARY = 132
integer, parameter :: EN_REAL_FUN_UNARY = 141, EN_REAL_FUN_BINARY = 142
integer, parameter :: EN_FORMAT_STR = 161
```

case (V_STR); allocate (node%sval)
end select
allocate (node%value_is_known)
node%value_is_known = .false.
end subroutine eval_node_allocate_value

```

Initialize a block node which contains, in addition to the expression to be evaluated, a variable definition. The result type is not yet assigned, because we can compile the enclosed expression only after the var list is set up.

Note that the node always allocates a new variable list and appends it to the current one. Thus, if the variable redefines an existing one, it only shadows it but does not reset it. Any side-effects are therefore absent and need not be undone outside the block.

If the flag `new` is set, a variable is (re)declared. This must not be done for intrinsic variables. Vice versa, if the variable is not existent, the `new` flag is required.

(Eval trees: procedures)+≡

```

  end select
end if
end subroutine eval_node_init_block

```

Complete block initialization by assigning the expression to evaluate to `arg0`.

(Eval trees: procedures)+≡

```

subroutine eval_node_set_expr (node, arg, result_type)
  type(eval_node_t), intent(inout) :: node
  type(eval_node_t), intent(in), target :: arg
  integer, intent(in), optional :: result_type
  if (present (result_type)) then
    node%result_type = result_type
  else
    node%result_type = arg%result_type
  end if
  call eval_node_allocate_value (node)
  node%arg0 => arg

```

```
end subroutine eval_node_set_expr
```

Initialize a conditional. There are three branches: the condition (evaluates to logical) and the two alternatives (evaluate both to the same arbitrary type).

(Eval trees: procedures)+≡

```
subroutine eval_node_init_conditional (node, result_type, cond, arg1, arg2)
  type(eval_node_t), intent(out) :: node
  integer, intent(in) :: result_type
  type(eval_node_t), intent(in), target :: cond, arg1, arg2
  node%type = EN_CONDITIONAL
  node%tag = "cond"
  node%result_type = result_type
  call eval_node_allocate_value (node)
  node%arg0 => cond
  node%arg1 => arg1
  node%arg2 => arg2
end subroutine eval_node_init_conditional
```

Initialize a recording command (which evaluates to a logical constant). The first branch is the ID of the analysis object to be filled, the optional branches 1 to 4 are the values to be recorded.

If the event-weight pointer is null, we record values with unit weight. Otherwise, we use the value pointed to as event weight.

There can be up to four arguments which represent x , y , Δy , Δx . Therefore, this is the only node type that may fill four sub-nodes.

(Eval trees: procedures)+≡

```
subroutine eval_node_init_record_cmd &
  (node, event_weight, id, arg1, arg2, arg3, arg4)
  type(eval_node_t), intent(out) :: node
  real(default), pointer :: event_weight
  type(eval_node_t), intent(in), target :: id
  type(eval_node_t), intent(in), optional, target :: arg1, arg2, arg3, arg4
  call eval_node_init_log (node, .true.)
  node%type = EN_RECORD_CMD
  node%rval => event_weight
  node%tag = "record_cmd"
  node%arg0 => id
  if (present (arg1)) then
    node%arg1 => arg1
    if (present (arg2)) then
      node%arg2 => arg2
      if (present (arg3)) then
        node%arg3 => arg3
        if (present (arg4)) then
          node%arg4 => arg4
        end if
      end if
    end if
  end if
end if
end if
end if
end if
end subroutine eval_node_init_record_cmd
```

Initialize a node for operations on subevents. The particle lists (one or two) are inserted as `arg1` and `arg2`. We allocated particle pointers as temporaries for iterating over particle lists. The procedure pointer which holds the function to evaluate for the subevents (e.g., combine, select) is also initialized.

(Eval trees: procedures)+≡

```

subroutine eval_node_init_prt_fun_unary (node, arg1, name, proc)
  type(eval_node_t), intent(out) :: node
  type(eval_node_t), intent(in), target :: arg1
  type(string_t), intent(in) :: name

  node%result_type = V_STR
  call eval_node_allocate_value (node)
  node%arg0 => fmt
  node%arg1 => arg
  allocate (node%ival)
  node%ival = n_args
end subroutine eval_node_init_format_string

```

If particle functions depend upon a condition (or an expression is evaluated), the observables that can be evaluated for the given particles have to be thrown on the local variable stack. This is done here. Each observable is initialized with the particle pointers which have been allocated for the node.

The integer variable that is referred to by the `Index` pseudo-observable is always known when it is referred to.

```

<Eval trees: procedures>+≡
subroutine eval_node_set_observables (node, var_list)
  type(eval_node_t), intent(inout) :: node
  type(var_list_t), intent(in), target :: var_list
  logical, save, target :: known = .true.
  allocate (node%var_list)
  call node%var_list%link (var_list)
  allocate (node%index, source = 0)
  call var_list_append_int_ptr &
    (node%var_list, var_str ("Index"), node%index, known, intrinsic=.true.)
  if (.not. associated (node%prt2)) then
    call var_list_set_observables_unary &
      (node%var_list, node%prt1)
  else
    call var_list_set_observables_binary &
      (node%var_list, node%prt1, node%prt2)
  end if
end subroutine eval_node_set_observables

```

Output

26.3.2 Operation types

For the operations associated to evaluation tree nodes, we define abstract interfaces for all cases.

Particles/subevents are transferred by-reference, to avoid unnecessary copying. Therefore, subroutines instead of functions. (Furthermore, the function version of `unary_prt` triggers an obscure bug in nagfor 5.2(649) [invalid C code].)

(Eval trees: interfaces)≡

```

abstract interface
  logical function unary_log (arg)
    import eval_node_t
    type(eval_node_t), intent(in) :: arg
  end function unary_log

```

```

end interface
abstract interface

26.3.3 Specific operators

Our expression syntax contains all Fortran functions that make sense. These functions have to be provided in a form that they can be used in procedures pointers, and have the abstract interfaces above. For some intrinsic functions, we could use specific versions provided by Fortran directly. However, this has two drawbacks: (i) We should work with the values instead of the eval-nodes as argument, which complicates the interface; (ii) more importantly, the **default** real type need not be equivalent to double precision. This would, at least, introduce system dependencies. Finally, for operators there are no specific versions.

Therefore, we write wrappers for all possible functions, at the expense of some overhead.

Binary numerical functions

```

<Eval trees: procedures>+≡
integer function add_ii (en1, en2) result (y)

    lval = .not. en0%lval
    if (lval) exit
end do
end function no_p

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

<Eval trees: procedures>+≡

```

        int (subvt_get_length (en1%pval), kind=c_int))
end subroutine user_event_shape_a

```

Binary particle-list functions

This joins two subevents, stored in the evaluation nodes `en1` and `en2`. If `en0` is also present, it amounts to a logical test returning true or false for every pair of particles. A particle of the second list gets a mask entry only if it passes the test for all particles of the first list.

```

<Eval trees: procedures>+≡
subroutine join_pp (subvt, en1, en2, en0)
    type(subvt_t), intent(inout) :: subvt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:), allocatable :: mask2
    integer :: i, j, n1, n2
    n1 = subvt_get_length (en1%pval)
    n2 = subvt_get_length (en2%pval)
    allocate (mask2 (n2))
    mask2 = .true.
    if (present (en0)) then
        do i = 1, n1
            en0%index = i
            en0%prt1 = subvt_get_prt (en1%pval, i)
            do j = 1, n2
                en0%prt2 = subvt_get_prt (en2%pval, j)
                call eval_node_evaluate (en0)
                mask2(j) = mask2(j) .and. en0%lval
            end do
        end do
    end if
end subroutine join_pp

```

```

        end do
    end do
end if
    call subevt_join (subevt, en1%pval, en2%pval, mask2)
end subroutine join_pp

```

Combine two subevents, i.e., make a list of composite particles built from all possible particle pairs from the two lists. If `en0` is present, create a mask which is true only for those pairs that pass the test.

(Eval trees: procedures)+≡

```

subroutine combine_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:,:), allocatable :: mask12
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    if (present (en0)) then
        allocate (mask12 (n1, n2))
        do i = 1, n1
            en0%index = i
            en0%prt1 = subevt_get_prt (en1%pval, i)
            do j = 1, n2
                en0%prt2 = subevt_get_prt (en2%pval, j)
                call eval_node_evaluate (en0)
                mask12(i,j) = en0%lval
            end do
        end do
        call subevt_combine (subevt, en1%pval, en2%pval, mask12)
    else
        call subevt_combine (subevt, en1%pval, en2%pval)
    end if
end subroutine combine_pp

```

Combine all particles of the first argument. If `en0` is present, create a mask which is true only for those particles that pass the test w.r.t. all particles in the second argument. If `en0` is absent, the second argument is ignored.

(Eval trees: procedures)+≡

```

subroutine collect_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:), allocatable :: mask1
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    allocate (mask1 (n1))
    mask1 = .true.
    if (present (en0)) then
        do i = 1, n1
            en0%index = i
            en0%prt1 = subevt_get_prt (en1%pval, i)

```

```

        do j = 1, n2
            en0%prt2 = subevt_get_prt (en2%pval, j)
            call eval_node_evaluate (en0)
            mask1(i) = mask1(i) .and. en0%lval
        end do
    end do
end if
call subevt_collect (subevt, en1%pval, mask1)
end subroutine collect_pp

```

Select all particles of the first argument. If **en0** is present, create a mask which is true only for those particles that pass the test w.r.t. all particles in the second argument. If **en0** is absent, the second argument is ignored, and the first argument is transferred unchanged. (This case is not very useful, of course.)

(Eval trees: procedures)+≡

```

subroutine select_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:), allocatable :: mask1
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    allocate (mask1 (n1))
    mask1 = .true.
    if (present (en0)) then
        do i = 1, n1
            en0%index = i
            en0%prt1 = subevt_get_prt (en1%pval, i)
            do j = 1, n2
                en0%prt2 = subevt_get_prt (en2%pval, j)
                call eval_node_evaluate (en0)
                mask1(i) = mask1(i) .and. en0%lval
            end do
        end do
    end if
    call subevt_select (subevt, en1%pval, mask1)
end subroutine select_pp

```

Sort the first subevent according to the result of evaluating **en0**. From the second subevent, only the first element is taken as reference. If **en0** is absent, we sort by default method (PDG code, particles before antiparticles).

(Eval trees: procedures)+≡

```

  end do
end do LOOP1
end subroutine eval_pp

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

(Eval trees: procedures)+≡

```

function user_obs_int_pp (en0, prt1, prt2) result (ival)
  integer :: ival
  type(eval_node_t), intent(inout) :: en0
  type(prt_t), intent(in) :: prt1, prt2
  type(string_t) :: name
  procedure(user_obs_int_binary), pointer :: user_obs

else
    call eval_node_write_rec (en0)
    call msg_fatal ("User observable name is undefined")
end if
end function user_obs_real_pp

```

The following function returns an integer value, namely the number of valid particle-pairs from both lists for which the condition is true. Invalid pairs (with common src entry) are ignored. If there is no condition, it returns the number of valid particle pairs.

A function would be more natural. Making it a subroutine avoids another compiler bug (internal error in nagfor 5.2 (649)). (See the interface `binary_num`.)

<Eval trees: procedures>+≡

```

subroutine count_pp (ival, en1, en2, en0)
    integer, intent(out) :: ival
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    integer :: i, j, n1, n2, count
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    if (present (en0)) then
        count = 0

                end if
            end do
        end do
    end if
    ival = count

```

```
end subroutine count_pp
```

This function makes up a subevent from the second argument which consists only of particles which match the PDG code array (first argument).

<Eval trees: procedures>+≡

```
subroutine select_pdg_ca (subevt, en1, en2, en0)
  type(subevt_t), intent(inout) :: subevt
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0
  if (present (en0)) then
    call subevt_select_pdg_code (subevt, en1%aval, en2%pval, en0%ival)
  else
    call subevt_select_pdg_code (subevt, en1%aval, en2%pval)
  end if
end subroutine select_pdg_ca
```

Binary string functions

Currently, the only string operation is concatenation.

<Eval trees: procedures>+≡

```
subroutine concat_ss (string, en1, en2)
  type(string_t), intent(out) :: string
  type(eval_node_t), intent(in) :: en1, en2
  string = en1%sval // en2%sval
end subroutine concat_ss
```

26.3.4 Compiling the parse tree

The evaluation tree is built recursively by following a parse tree. Debug option:

<Eval trees: variables>≡

```
logical, parameter :: debug = .false.
```

Evaluate an expression. The requested type is given as an optional argument; default is numeric (integer or real).

<Eval trees: procedures>+≡

```
recursive subroutine eval_node_compile_genexpr &
  (en, pn, var_list, result_type)
  type(eval_node_t), pointer :: en
  type(parse_node_t), intent(in) :: pn
  type(var_list_t), intent(in), target :: var_list
  integer, intent(in), optional :: result_type
  if (debug) then
    print *, "read genexpr"; call parse_node_write (pn)
  end if
  if (present (result_type)) then
    select case (result_type)
    case (V_INT, V_REAL, V_CMPLX)
      call eval_node_compile_expr (en, pn, var_list)
    case (V_LOG)
```

```

        call eval_node_compile_lexpr (en, pn, var_list)
    case (V_SEV)
        call eval_node_compile_pexpr (en, pn, var_list)
    case (V_PDG)
        call eval_node_compile_cexpr (en, pn, var_list)

    end select
else
    call eval_node_compile_expr (en, pn, var_list)
end if
if (debug) then
    call eval_node_write (en)
    print *, "done genexpr"
end if
end subroutine eval_node_compile_genexpr

```

Numeric expressions

This procedure compiles a numerical expression. This is a single term or a sum or difference of terms. We have to account for all combinations of integer and real arguments. If both are constant, we immediately do the calculation and allocate a constant node.

(Eval trees: procedures)+≡

```

recursive subroutine eval_node_compile_expr (en, pn, var_list)

```

Real, complex and integer values are numeric literals with an optional unit attached. In case of an integer, the unit actually makes it a real value in disguise. The signed version of real values is not possible in generic expressions; it is a special case for numeric constants in model files (see below). We do not introduce signed versions of complex values.

```

Compile a variable, with or without a specified type. Take the list of variables, look for the name and make a node with a pointer to the value. If no type is provided, the variable is numeric, and the stored value determines whether it is real or integer.

We explicitly demand that the variable is defined, so we do not accidentally point to variables that are declared only later in the script but have come into existence in a previous compilation pass.

Variables may actually be anonymous, these are expressions in disguise. In that case, the expression replaces the variable name in the parse tree, and we allocate an ordinary expression node in the eval tree.

Variables of type V_PDG (pdg-code array) are not treated here. They are handled by `eval_node_compile_cvariable`.

Retrieve the result of an integration. If the requested process has been integrated, the results are available as special variables. (The variables cannot be accessed in the usual way since they contain brackets in their names.)

Since this compilation step may occur before the processes have been loaded, we have to initialize the required variables before they are used.

```

This user observable behaves like a variable. We link the node to the generic user-observable entry in the variable list. The syntax element has an argument which provides the name of the user variable, this is stored as an eval-node alongside with the variable. When the variable value is used, the user-supplied external function is called and provides the (real) result value.

Variable definition

A block expression contains a variable definition (first argument) and an expression where the definition can be used (second argument). The `result_type` decides which type of expression is expected for the second argument. For numeric variables, if there is a mismatch between real and integer type, insert an

extra node for type conversion.

Conditionals

A conditional has the structure if lexpr then expr else expr. So we first evaluate the logical expression, then depending on the result the first or second expression. Note that the second expression is mandatory.

The **result_type**, if present, defines the requested type of the **then** and **else** clauses. Default is numeric (int/real). If there is a mismatch between real and integer result types, insert conversion nodes.

Comparisons

Up to the loop, this is easy. There is always at least one comparison. This is evaluated, and the result is the logical node **en**. If it is constant, we keep its second sub-node as **en2**. (Thus, at the very end **en2** has to be deleted if **en** is (still) constant.)

If there is another comparison, we first check if the first comparison was constant. In that case, there are two possibilities: (i) it was true. Then, its right-hand side is compared with the new right-hand side, and the result replaces the previous one which is deleted. (ii) it was false. In this case, the result of the whole comparison is false, and we can exit the loop without evaluating anything else.

Now assume that the first comparison results in a valid branch, its second sub-node kept as **en2**. We first need a copy of this, which becomes the new left-hand side. If **en2** is constant, we make an identical constant node **en1**. Otherwise, we make **en1** an appropriate pointer node. Next, the first branch is saved as **en0** and we evaluate the comparison between **en1** and the a right-hand side. If this turns out to be constant, there are again two possibilities: (i) true, then we revert to the previous result. (ii) false, then the wh

```

This takes two extra arguments: **en1**, the left-hand-side of the comparison, is already allocated and evaluated. **en2** (the right-hand side) and **en** (the result) are allocated by the routine. **pn** is the parse node which contains the operator and the right-hand side as subnodes.

If the result of the comparison is constant, **en1** is deleted but **en2** is kept, because it may be used in a subsequent comparison. **en** then becomes a constant. If the result is variable, **en** becomes a branch node which refers to **en1** and **en2**.

```

A particle-list value is a PDG-code array, a particle identifier, a variable, a (grouped) pexpr, a block pexpr, a conditional, or a particle-list function.

The `cexpr` node is responsible for transforming a constant PDG-code array into a subevent. It takes the code array as its first argument, the event subevent as its second argument, and the requested particle type (incoming/outgoing) as its zero-th argument. The result is the list of particles in the event that match the code array.

Particle functions

This combines the treatment of 'join', 'combine', 'collect', 'cluster', 'select', and 'extract' which all have the same syntax. The one or two argument nodes are allocated. If there is a condition, the condition node is also allocated as a logical expression, for which the variable list is augmented by the appropriate (unary/binary) observables.

(Eval trees: procedures) +≡

There is currently one string function, `sprintf`. For `sprintf`, the first argument (no brackets) is the format string, the optional arguments in brackets are the expressions or variables to be formatted.

26.3.5 Auxiliary functions for the compiler

Issue an error that the current node could not be compiled because of type mismatch:

```

<Eval trees: procedures>+≡
subroutine eval_type_error (pn, string, t)
    type(parse_node_t), intent(in) :: pn
    character(*), intent(in) :: string
    integer, intent(in) :: t
    type(string_t) :: type
    select case (t)
    case (V_NONE); type = "(none)"
    case (V_LOG); type = "'logical'"
    case (V_INT); type = "'integer'"
    case (V_REAL); type = "'real'"
    case (V_CMPLX); type = "'complex'"
    case default; type = "(unknown)"
    end select
    call parse_node_write (pn)
    call msg_fatal (" The " // string // &
        " operation is not defined for the given argument type " // &
        char (type))
end subroutine eval_type_error

```

If two numerics are combined, the result is integer if both arguments are integer, if one is integer and the other real or both are real, than its argument is real, otherwise complex.

```

<Eval trees: procedures>+≡
function numeric_result_type (t1, t2) result (t)
    integer, intent(in) :: t1, t2
    integer :: t
    if (t1 == V_INT .and. t2 == V_INT) then
        t = V_INT
    else if (t1 == V_INT .and. t2 == V_REAL) then
        t = V_REAL
    else if (t1 == V_REAL .and. t2 == V_INT) then
        t = V_REAL
    end if
end function numeric_result_type

```

```

else if (t1 == V_REAL .and. t2 == V_REAL) then
    t = V_REAL
else
    t = V_CMPLX
end if
end function numeric_result_type

```

26.3.6 Evaluation

Evaluation is done recursively. For leaf nodes nothing is to be done.

Evaluating particle-list functions: First, we evaluate the particle lists. If a condition is present, we assign the particle pointers of the condition node to the allocated particle entries in the parent node, keeping in mind that the observables in the variable stack used for the evaluation of the condition also contain pointers to these entries. Then, the assigned procedure is evaluated, which sets the subevent in the parent node. If required, the procedure evaluates the condition node once for each (pair of) particles to determine the result.

(Eval trees: procedures)+≡

26.3.7 Evaluation syntax

We have two different flavors of the syntax: with and without particles.

```

<Eval trees: variables>+≡
    type(syntax_t), target, save :: syntax_expr
    type(syntax_t), target, save :: syntax_pexpr

```

These are for testing only and may be removed:

```

<Eval trees: public>≡
    public :: syntax_expr_init
    public :: syntax_pexpr_init

<Eval trees: procedures>+≡
    subroutine syntax_expr_init ()
        type(ifile_t) :: ifile
        call define_expr_syntax (ifile, particles=.false., analysis=.false.)
        call syntax_init (syntax_expr, ifile)
        call ifile_final (ifile)
    end subroutine syntax_expr_init

    subroutine syntax_pexpr_init ()
        type(ifile_t) :: ifile
        call define_expr_syntax (ifile, particles=.true., analysis=.false.)
        call syntax_init (syntax_pexpr, ifile)
        call ifile_final (ifile)
    end subroutine syntax_pexpr_init

<Eval trees: public>+≡
    public :: syntax_expr_final
    public :: syntax_pexpr_final

<Eval trees: procedures>+≡
    subroutine syntax_expr_final ()
        call syntax_final (syntax_expr)
    end subroutine syntax_expr_final

    subroutine syntax_pexpr_final ()
        call syntax_final (syntax_pexpr)
    end subroutine syntax_pexpr_final

```

```

end subroutine syntax_pexpr_final

<Eval trees: public>+≡
public :: syntax_pexpr_write

<Eval trees: procedures>+≡
subroutine syntax_pexpr_write (unit)
  integer, intent(in), optional :: unit
  call syntax_write (syntax_pexpr, unit)
end subroutine syntax_pexpr_write

<Eval trees: public>+≡

    type(eval_tree_t), intent(in) :: eval_tree
    type(parse_node_t), intent(in) :: parse_node
    call parse_node_write_rec (parse_node)
    call eval_tree_write (eval_tree)
    call msg_error ("Evaluation yields an undefined result, inserting default")
end subroutine eval_tree_unknown

```

26.3.11 Factory Type

Since `eval_tree_t` is an implementation of `expr_t`, we also need a matching factory type and build method.

```

<Eval trees: public>+≡
    public :: eval_tree_factory_t

<Eval trees: types>+≡
    type, extends (expr_factory_t) :: eval_tree_factory_t
    private
        type(parse_node_t), pointer :: pn => null ()
    contains
    <Eval trees: eval tree factory: TBP>
    end type eval_tree_factory_t

```

Output: delegate to the output of the embedded parse node.

```

<Eval trees: eval tree factory: TBP>≡
    procedure :: write => eval_tree_factory_write

<Eval trees: procedures>+≡
    subroutine eval_tree_factory_write (expr_factory, unit)
        class(eval_tree_factory_t), intent(in) :: expr_factory
        integer, intent(in), optional :: unit
        if (associated (expr_factory%pn)) then
            call parse_node_write_rec (expr_factory%pn, unit)
        end if
    end subroutine eval_tree_factory_write

```

Initializer: take a parse node and hide it thus from the environment.

```

<Eval trees: eval tree factory: TBP>+≡
    procedure :: init => eval_tree_factory_init

```

```

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_init (expr_factory, pn)
    class(eval_tree_factory_t), intent(out) :: expr_factory
    type(parse_node_t), intent(in), pointer :: pn
    expr_factory%pn => pn
  end subroutine eval_tree_factory_init

```

Factory method: allocate expression with correct eval tree type. If the stored parse node is not associate, don't allocate.

```

<Eval trees: eval tree factory: TBP>+≡
  procedure :: build => eval_tree_factory_build

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_build (expr_factory, expr)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    class(expr_t), intent(out), allocatable :: expr
    if (associated (expr_factory%pn)) then
      allocate (eval_tree_t :: expr)
      select type (expr)

26.4 Physics Models

A model object represents a physics model. It contains a table of particle data, a list of parameters, and a vertex table. The list of parameters is a variable list which includes the real parameters (which are pointers to the particle data table) and PDG array variables for the particles themselves. The vertex list is used for phase-space generation, not for calculating the matrix element.

The actual numeric model data are in the base type `model_data_t`, as part of the `qft` section. We implement the `model_t` as an extension of this, for convenient direct access to the base-type methods via inheritance. (Alternatively, we could delegate these calls explicitly.) The extension contains administrative additions, such as the methods for recalculating derived data and keeping the parameter set consistent. It thus acts as a proxy of the actual model-data object towards the WHIZARD package. There are further proxy objects, such as the `parameter_t` array which provides the interface to the actual numeric parameters.

Model definitions are read from model files. Therefore, this module contains a parser for model files. The parameter definitions (derived parameters) are Sindarin expressions.

The models, as read from file, are stored in a model library which is a simple list of model definitions. For setting up a process object we should make a copy (an instance) of a model, which gets the current parameter values from the global variable list.

26.4.1 Module

`<models.f90>`≡

end module models

```

26.4.2 Physics Parameters

A parameter has a name, a value. Derived parameters also have a definition in terms of other parameters, which is stored as an `eval_tree`. External parameters are set by an external program.

This parameter object should be considered as a proxy object. The parameter name and value are stored in a corresponding `modelpar_data_t` object which is located in a `model_data_t` object. The latter is a component of the `model_t` handler. Methods of `parameter_t` can be delegated to the `par_data_t` component.

The `pn` component is a pointer to the parameter definition inside the model parse tree. It allows us to recreate the `eval_tree` when making copies (instances) of the parameter object.

```

<Models: parameters>≡
    integer, parameter :: PAR_NONE = 0
    integer, parameter :: PAR_INDEPENDENT = 1, PAR_DERIVED = 2
    integer, parameter :: PAR_EXTERNAL = 3

<Models: types>≡
    type :: parameter_t
    private
        integer :: type = PAR_NONE
        class(modelpar_data_t), pointer :: data => null ()
        type(parse_node_t), pointer :: pn => null ()
        class(expr_t), allocatable :: expr
    contains
        <Models: parameter: TBP>
    end type parameter_t

```

Initialization depends on parameter type. Independent parameters are initialized by a constant value or a constant numerical expression (which may contain a unit). Derived parameters are initialized by an arbitrary numerical expression, which makes use of the current variable list. The expression is evaluated by the function `parameter_reset`.

This implementation supports only real parameters and real values.

```

<Models: parameter: TBP>≡
  procedure :: init_independent_value => parameter_init_independent_value
  procedure :: init_independent => parameter_init_independent
  procedure :: init_derived => parameter_init_derived
  procedure :: init_external => parameter_init_external

<Models: procedures>≡

        end if
    end subroutine parameter_show

```

26.4.3 Model Object

A model object holds all information about parameters, particles, and vertices. For models that require an external program for parameter calculation, there is the pointer to a function that does this calculation, given the set of independent and derived parameters.

As explained above, the type inherits from `model_data_t`, which is the actual storage for the model data.

When reading a model, we create a parse tree. Parameter definitions are available via parse nodes. Since we may need those later when making model instances, we keep the whole parse tree in the model definition (but not in the instances).

```

<Models: public>≡
    public :: model_t

```

```

<Models: types>+=
  type, extends (model_data_t) :: model_t
    private
      character(32) :: md5sum = ""
      type(parameter_t), dimension(:), allocatable :: par
      integer :: max_par_name_length = 0
      integer :: max_field_name_length = 0
      type(var_list_t) :: var_list
      type(string_t) :: dlname
      procedure(model_init_external_parameters), nopass, pointer :: &
        init_external_parameters => null ()
      type(dlaccess_t) :: dlaccess
      type(parse_tree_t) :: parse_tree
    contains
      <Models: model: TBP>
    end type model_t

```

This is the interface for a procedure that initializes the calculation of external parameters, given the array of all parameters.

```

<Models: interfaces>=
  abstract interface
    subroutine model_init_external_parameters (par) bind (C)
      import
      real(c_default_float), dimension(*), intent(inout) :: par
    end subroutine model_init_external_parameters
  end interface

```

Initialization: Specify the number of parameters, particles, vertices and allocate memory. If an associated DL library is specified, load this library.

```

<Models: model: TBP>=
  generic :: init => model_init
  procedure, private :: model_init

<Models: procedures>+=
  subroutine model_init &
    (model, name, libname, os_data, n_par, n_prt, n_vtx)

Make a copy of a parameter. We assume that the `model_data_t` parameter arrays have already been copied, so names and values are available in the current model, and can be used as targets. The eval tree should not be copied, since it should refer to the new variable list. The safe solution is to make use of the above initializers, which also take care of the building a new variable list.

    end subroutine model_list_link

```

(Private, used below:) Append an existing model, for which we have allocated a pointer entry, to the model list. The original pointer becomes disassociated, and the model should now be considered as part of the list. We assume that this model is not yet part of the list.

If we provide a `model` argument, this returns a pointer to the new entry.

```

⟨Models: model list: TBP⟩+≡
  procedure, private :: import => model_list_import

⟨Models: procedures⟩+≡
  subroutine model_list_import (model_list, current, model)
    class(model_list_t), intent(inout) :: model_list
    type(model_entry_t), pointer, intent(inout) :: current
    type(model_t), optional, pointer, intent(out) :: model
    if (associated (current)) then
      if (associated (model_list%first)) then
        model_list%last%next => current
      else
        model_list%first => current
      end if
      model_list%last => current
      if (present (model)) model => current%model_t
      current => null ()
    end if
  end subroutine model_list_import

```

(Private, currently test only:) Add a new model with given `name` to the list, if it does not yet exist. If successful, return a pointer to the new model.

```

⟨Models: model list: TBP⟩+≡
  procedure, private :: add => model_list_add

⟨Models: procedures⟩+≡
  subroutine model_list_add (model_list, &
    name, os_data, n_par, n_prt, n_vtx, model)
    class(model_list_t), intent(inout) :: model_list
    type(string_t), intent(in) :: name
    type(os_data_t), intent(in) :: os_data

        n_par, n_prt, n_vtx)
      call model_list%import (current, model)
    end if
  end subroutine model_list_add

```

Read a new model from file and add to the list, if it does not yet exist. Finalize the model by allocating the vertex table. Return a pointer to the new model. If unsuccessful, return the original pointer.

The model is always inserted in the last link of a chain of model lists. This way, we avoid loading models twice from different contexts. When a model is modified, we should first allocate a local copy.

```

26.4.7 Model instances

A model instance is a copy of a model object. The parameters are true copies. The particle data and the variable list pointers should point to the copy, so modifying the parameters has only a local effect. Hence, we build them up explicitly. The vertex array is also rebuilt, it contains particle pointers. Finally, the vertex hash table can be copied directly since it contains no pointers.

The `multiplicity` entry depends on the association of the `mass_data` entry and therefore has to be set at the end.

The instance must carry the `target` attribute.

Parameters: the `copy_parameter` method essentially copies the parameter decorations (parse node, expression etc.). The current parameter values are part of the `model_data_t` base type and are copied afterwards via its `copy_from` method.

```

⟨Models: model: TBP⟩+≡
    procedure :: init_instance => model_copy

⟨Models: procedures⟩+≡
    subroutine model_copy (model, orig)
        class(model_t), intent(out), target :: model
        type(model_t), intent(in) :: orig
        integer :: n_par, n_prt, n_vtx
        integer :: i
        n_par = size (orig%par)
        n_prt = orig%get_n_field ()
        n_vtx = orig%get_n_vtx ()
        call model%basic_init (orig%get_name (), n_par, n_prt, n_vtx)

26.5.1 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a

data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

<SLHA: parameters>≡

```
integer, parameter :: MODE_SKIP = 0, MODE_DATA = 1, MODE_INFO = 2
```

<SLHA: procedures>≡

```
subroutine slha_preprocess (stream, ifile)
  type(stream_t), intent(inout), target :: stream
  type(ifile_t), intent(out) :: ifile
  type(string_t) :: buffer, line, item
  integer :: iostat
  integer :: mode
  mode = MODE
  SCAN_FILE: do
    call stream_get_record (stream, buffer, iostat)
    select case (iostat)
    case (0)
      call split (buffer, line, "#")
      if (len_trim (line) == 0) cycle SCAN_FILE
      select case (char (extract (line, 1, 1)))
      case ("B", "b")
        mode = check_block_handling (line)
        call ifile_append (ifile, line // "$")
      case ("D", "d")
        mode = MODE_DATA
        call ifile_append (ifile, line // "$")
      case (" ")
        select case (mode)
        case (MODE_DATA)
          call ifile_append (ifile, "DATA" // line // "$")
        case (MODE_INFO)
          line = adjustl (line)
          call split (line, item, " ")
          call ifile_append (ifile, "INFO" // " " // item // " " &

    end subroutine define_slha_syntax

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed

somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

```

<SLHA: public>+=
    public :: lexer_init_slha

        call model%set_field_mass (pdg, mass)
      else
        call msg_error ("SLHA: Block MASS: Missing mass value")
      end if
    else
      call msg_error ("SLHA: Block MASS: Missing PDG code")
    end if
    pn_data => parse_node_get_next_ptr (pn_data)
  end do
end subroutine slha_handle_MASS
```

Widths

Set widths. For each DECAY block, extract the header, read the PDG code and width, and try to set the appropriate particle width in the current model.

(SLHA: procedures)+≡

```
subroutine slha_handle_decays (parse_tree, model)
  type(parse_tree_t), intent(in) :: parse_tree
  type(model_t), intent(inout), target :: model
  type(parse_node_t), pointer :: pn_decay, pn_decay_spec, pn_code, pn_width
  integer :: pdg
  real(default) :: width
  pn_decay => slha_get_first_decay_ptr (parse_tree)
  do while (associated (pn_decay))
    pn_decay_spec => parse_node_get_sub_ptr (pn_decay, 2)
```

```

        pn_code => parse_node_get_sub_ptr (pn_decay_spec)
        pdg = get_integer_parameter (pn_code)
        pn_width => parse_node_get_next_ptr (pn_code)
        width = get_real_parameter (pn_width)
        call model%set_field_width (pdg, width)
        pn_decay => slha_get_next_decay_ptr (pn_decay)
    end do
end subroutine slha_handle_decays

```

Mixing matrices

Read mixing matrices. We can treat all matrices by a single procedure if we just know the block name, variable prefix, and matrix dimension. The matrix dimension must be less than 10. For the pseudoscalar Higgses in NMSSM-type models we need off-diagonal matrices, so we generalize the definition.

(SLHA: procedures)+≡

```

subroutine slha_handle_matrix_block &
    (parse_tree, block_name, var_prefix, dim1, dim2, model)
    type(parse_tree_t), intent(in) :: parse_tree
    character(*), intent(in) :: block_name, var_prefix
    integer, intent(in) :: dim1, dim2
    type(model_t), intent(inout), target :: model
    type(parse_node_t), pointer :: pn_block
    type(var_list_t), pointer :: var_list
    integer :: i, j
    character(len=len(var_prefix)+2) :: var_name
    var_list => model%get_var_list_ptr ()
    pn_block => slha_get_block_ptr &
        (parse_tree, var_str (block_name), required=.false.)
    if (.not. (associated (pn_block))) return
    do i = 1, dim1
        do j = 1, dim2
            write (var_name, "(A,I1,I1)") var_prefix, i, j
            call set_matrix_element (pn_block, i, j, var_str (var_name), var_list)
        end do
    end do
end subroutine slha_handle_matrix_block

```

Higgs data

Read the block ALPHA which holds just the Higgs mixing angle.

(SLHA: procedures)+≡

```

subroutine slha_handle_ALPHA (parse_tree, model)
    type(parse_tree_t), intent(in) :: parse_tree
    type(model_t), intent(inout), target :: model

end subroutine slha_handle_NMSSMRUN

```

26.5.5 Parser

Read a SLHA file from stream, including preprocessing, and make up a parse tree.

<SLHA: procedures>+≡

```

subroutine slha_parse_stream (stream, parse_tree)
    type(stream_t), intent(inout), target :: stream

```

```

type(parse_tree_t), intent(out) :: parse_tree
type(ifile_t) :: ifile
type(lexer_t) :: lexer
type(stream_t), target :: stream_tmp
call slha_preprocess (stream, ifile)
call stream_init (stream_tmp, ifile)
call lexer_init_slha (lexer)
call lexer_assign_stream (lexer, stream_tmp)
call parse_tree_init (parse_tree, syntax_slha, lexer)
call lexer_final (lexer)
call stream_final (stream_tmp)
call ifile_final (ifile)
end subroutine slha_parse_stream

```

Read a SLHA file chosen by name. Check first the current directory, then the directory where SUSY input files should be located.

<SLHA: procedures>+≡

```

subroutine slha_parse_file (file, os_data, parse_tree)
type(string_t), intent(in) :: file
type(os_data_t), intent(in) :: os_data
type(parse_tree_t), intent(out) :: parse_tree
logical :: exist
type(string_t) :: filename
type(stream_t), target :: stream
call msg_message ("Reading SLHA input file '" // char (file) // "'")
filename = file
inquire (file=char(filename), exist=exist)
if (.not. exist) then
filename = os_data%whizard_susypath // "/" // file
inquire (file=char(filename), exist=exist)
if (.not. exist) then
call msg_fatal ("SLHA input file '" // char (file) // "' not found")
return
end if
end if
call stream_init (stream, char (filename))
call slha_parse_stream (stream, parse_tree)
call stream_final (stream)
end subroutine slha_parse_file

```

26.5.6 API

Read the SLHA file, parse it, and interpret the parse tree. The model parameters retrieved from the file will be inserted into the appropriate model, which is loaded and modified in the background. The pointer to this model is returned as the last argument.

<SLHA: public>+≡

```

public :: slha_read_file

```

<SLHA: procedures>+≡

```

subroutine slha_read_file &
(file, os_data, model, input, spectrum, decays)

Chapter 27

Integration and Process Objects

This is the central part of the WHIZARD package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

subvt_expr This enables process observables as (abstract) expressions, to be evaluated for each process call.

parton_states A `parton_state_t` object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

processes Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: `prc_core` for matrix-element evaluation, `prc_core_def` for the associated configuration and driver, `sf_base` for beams and structure-functions, `phs_base` for phase space, and `mci_base` for integration and event generation.

process_stacks Process stacks collect process objects.

27.1 Process observables

We define an abstract `subvt_expr_t` object as an extension of the `subvt_t` type. The object contains a local variable list, variable instances (as targets for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the `subvt`.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression `selection` which determines whether the object passes user-defined cuts.

The intention is that we fill the `subvt_t` base object and compute the variables once we have evaluated a kinematical phase space point (or a complete

event). We then evaluate the expressions and can use the results in further calculations.

The `process_expr_t` extension contains furthermore scale and weight expressions. The `event_expr_t` extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

Note that there are unit tests, but they are deferred to the `expr_tests` module.

```

<subevt_expr.f90>≡

        end if
    end subroutine subvt_expr_final

```

27.1.2 Initialization

Initialization: define local variables and establish pointers.

The common variables are `sqrts` (the nominal beam energy, fixed), `sqrts_hat` (the actual energy), `n_in`, `n_out`, and `n_tot` for the subevt. With the exception of `sqrts`, all are implemented as pointers to subobjects.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure (subevt_expr_setup_vars), deferred :: setup_vars
  procedure :: base_setup_vars => subevt_expr_setup_vars
<Subevt expr: procedures>+≡
  subroutine subevt_expr_setup_vars (expr, sqrts)

      call expr%selection%setup_lexpr (expr%var_list)
      expr%has_selection = .true.
    end if
  end subroutine subvt_expr_setup_selection

```

27.1.3 Evaluation

Reset to initial state, i.e., mark the subvt as invalid.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: reset => subvt_expr_reset
  procedure :: base_reset => subvt_expr_reset

<Subvt expr: procedures>+≡
  subroutine subvt_expr_reset (expr)
    class(subvt_expr_t), intent(inout) :: expr
    expr%subvt_filled = .false.
  end subroutine subvt_expr_reset

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: base_evaluate => subvt_expr_evaluate

<Subvt expr: procedures>+≡
  subroutine subvt_expr_evaluate (expr, passed)
    class(subvt_expr_t), intent(inout) :: expr
    logical, intent(out) :: passed
    if (expr%has_selection) then
      call expr%selection%evaluate ()
      if (expr%selection%is_known ()) then
        passed = expr%selection%get_log ()
      else
        call msg_error ("Evaluate selection expression: result undefined")
      end if
    end if
  end subroutine subvt_expr_evaluate

```

```

        passed = .false.
    end if
else
    passed = .true.
end if
end subroutine subevt_expr_evaluate

```

27.1.4 Implementation for partonic events

This implementation contains the expressions that we can evaluate for the partonic process during integration.

```

⟨Subevt expr: public⟩≡
    public :: parton_expr_t

⟨Subevt expr: types⟩+≡
    type, extends (subevt_expr_t) :: parton_expr_t
        integer, dimension(:), allocatable :: i_beam

```

```

        expr%has_weight = .true.
    end if
end subroutine parton_expr_setup_weight

```

Filling the partonic state consists of two parts. The first routine prepares the subevt without assigning momenta. It takes the particles from an `interaction_t`. It needs the indices and flavors for the beam, incoming, and outgoing particles.

We can assume that the particle content of the subevt does not change. Therefore, we set the event variables `n_in`, `n_out`, `n_tot` already in this initialization step.

```

<Subevt expr: parton_expr: TBP>+≡

27.1.5 Implementation for full events

This implementation contains the expressions that we can evaluate for the full event. It also contains data that pertain to the event, suitable for communication with external event formats. These data simultaneously serve as pointer targets for the variable lists hidden in the expressions (eval trees).

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

```

⟨Subvt expr: public⟩+≡
  public :: event_expr_t

27.2 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states, depending on the the beam setup allows. The result is used for integration.

The `matrix` evaluator is the counterpart of `trace` which is kept exclusive in all observable quantum numbers. The `flows` evaluator is furthermore exclusive in colors, but neglecting all color interference. The `matrix` and `flows` evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. However, this causes memory corruption in gfortran 4.6.3. The extra `has_XXX` flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the `processes` module below.

```

end module parton_states

```

27.2.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

⟨Parton states: types⟩≡
  type, abstract :: parton_state_t
    logical :: has_trace = .false.
    logical :: has_matrix = .false.
    logical :: has_flows = .false.
    type(evaluator_t) :: trace
    type(evaluator_t) :: matrix
    type(evaluator_t) :: flows
  contains
    ⟨Parton states: parton state: TBP⟩
  end type parton_state_t

```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both implemented as a pointer.

The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```

(Parton states: public)≡
  public :: isolated_state_t

(Parton states: types)+≡
  type, extends (parton_state_t) :: isolated_state_t
    logical :: sf_chain_is_allocated = .false.
    type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()
    logical :: int_is_allocated = .false.
    type(interaction_t), pointer :: int_eff => null ()
  contains
    (Parton states: isolated state: TBP)
  end type isolated_state_t

```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

```

(Parton states: types)+≡
  public :: connected_state_t

(Parton states: types)+≡
  type, extends (parton_state_t) :: connected_state_t
    type(state_flv_content_t) :: state_flv
    logical :: has_flows_sf = .false.

        end if
      end select
    end subroutine parton_state_final

```

27.2.2 Common Initialization

Initialize the isolated parton state. In this version, the effective structure-function chain `sf_chain_eff` and the effective interaction `int_eff` both are trivial pointers to the seed structure-function chain and to the hard interaction, respectively.

```

  (Parton states: isolated state: TBP)≡
    procedure :: init => isolated_state_init_pointers
  (Parton states: procedures)+≡
    subroutine isolated_state_init_pointers (state, sf_chain, int)
      class(isolated_state_t), intent(out) :: state
      type(sf_chain_instance_t), intent(in), target :: sf_chain
      type(interaction_t), intent(in), target :: int
      state%sf_chain_eff => sf_chain
      state%int_eff => int
    end subroutine isolated_state_init_pointers

```

27.2.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask_in`.

There are two options: explicitly computing the color factor table (`use_cf` false; `nc` defined), or taking the color factor table from the hard matrix element data.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_square_trace => isolated_state_setup_square_trace

(Parton states: procedures)+≡
  subroutine isolated_state_setup_square_trace (state, core, qn_mask_in, &
    col)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), dimension(:), intent(in) :: qn_mask_in
    integer, dimension(:), intent(in) :: col
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    associate (data => core%data)
      allocate (qn_mask (data%n_in + data%n_out))
      qn_mask(:data%n_in) = &
        quantum_numbers_mask (.false., .true., .false.) &
        .or. qn_mask_in
      qn_mask(data%n_in+1:) = &
        quantum_numbers_mask (.true., .true., .true.)
    if (core%use_color_factors) then
      call state%trace%init_square (state%int_eff, qn_mask, &
        col_flow_index = data%cf_index, &
        col_factor = data%color_factors, &
        col_index_hi = col, &
        nc = core%nc)
    else
      call state%trace%init_square (state%int_eff, qn_mask, nc = core%nc)
    end if
    end associate
    state%has_trace = .true.
  end subroutine isolated_state_setup_square_trace

```

Setup the evaluator for the transition matrix, exclusive in helicities where this is requested.

For all unstable final-state particles we keep polarization according to the applicable decay options. If the process is a decay itself, this applies also to the initial state.

For all polarized final-state particles, we keep polarization including off-diagonal entries. We drop helicity completely for unpolarized final-state particles.

For the initial state, if the particle has not been handled yet, we apply the provided `qn_mask_in` which communicates the beam properties.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_square_matrix => isolated_state_setup_square_matrix

```

```

(Parton states: procedures)+≡
subroutine isolated_state_setup_square_matrix &
  (state, core, model, qn_mask_in, col)
  class(isolated_state_t), intent(inout), target :: state
  class(prc_core_t), intent(in) :: core
  class(model_data_t), intent(in), target :: model
  type(quantum_numbers_mask_t), dimension(:), intent(in) :: qn_mask_in
  integer, dimension(:), intent(in) :: col
  type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
  type(flavor_t), dimension(:), allocatable :: flv
  integer :: i
  logical :: helmask, helmask_hd
  associate (data => core%data)
    allocate (qn_mask (data%n_in + data%n_out))
    allocate (flv (data%n_flv))
    do i = 1, data%n_in + data%n_out
      call flv%init (data%flv_state(i,:), model)
      if ((data%n_in == 1 .or. i > data%n_in) &
        .and. any (.not. flv%is_stable ())) then
        helmask = all (flv%decays_isotropically ())
        helmask_hd = all (flv%decays_diagonal ())
        qn_mask(i) = quantum_numbers_mask (.false., .true., helmask, &
          mask_hd = helmask_hd)
      else if (i > data%n_in) then
        helmask = all (.not. flv%is_polarized ())
        qn_mask(i) = quantum_numbers_mask (.false., .true., helmask)
      else
        qn_mask(i) = quantum_numbers_mask (.false., .true., .false.) &
          .or. qn_mask_in(i)
      end if
    end do
  end do
  if (core%use_color_factors) then
    call state%matrix%init_square (state%int_eff, qn_mask, &
      col_flow_index = data%cf_index, &
      col_factor = data%color_factors, &
      col_index_hi = col, &
      nc = core%nc)
  else
    call state%matrix%init_square (state%int_eff, &
      qn_mask, &
      nc = core%nc)
  end if
end associate
state%has_matrix = .true.
end subroutine isolated_state_setup_square_matrix

```

This procedure initializes the evaluator that computes the contributions to color flows, neglecting color interference. The incoming-particle mask can be used to sum over incoming flavor.

Helicity handling: see above.

      expand_color_flows = .true.)
  end associate
  state%has_flows = .true.
end subroutine isolated_state_setup_square_flows

```

27.2.4 Evaluator initialization: connected state

Setup a trace evaluator as a product of two evaluators (incoming state, effective interaction). In the result, all quantum numbers are summed over.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`.

The `resonant` flag applies if we want to construct a decay chain. The resonance property can propagate to the final event output.

(Parton states: connected state: TBP)≡

```

  procedure :: setup_connected_trace => connected_state_setup_connected_trace

```

(Parton states: procedures)+≡

```

  subroutine connected_state_setup_connected_trace &
    (state, isolated, int, resonant)
    class(connected_state_t), intent(inout), target :: state
    type(isolated_state_t), intent(in), target :: isolated
    type(interaction_t), intent(in), optional, target :: int
    logical, intent(in), optional :: resonant

```

```

type(quantum_numbers_mask_t) :: mask
type(interaction_t), pointer :: src_int
mask = quantum_numbers_mask (.true., .true., .true.)
if (present (int)) then
    src_int => int
else
    src_int => isolated%sf_chain_eff%get_out_int_ptr ()
end if
call state%trace%init_product (src_int, isolated%trace, &
    qn_mask_conn = mask, &
    qn_mask_rest = mask, &
    connections_are_resonant = resonant)
state%has_trace = .true.
end subroutine connected_state_setup_connected_trace

```

Setup a matrix evaluator as a product of two evaluators (incoming state, effective interaction). In the intermediate state, color and helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

```

(Parton states: connected state: TBP)+≡
    procedure :: setup_connected_matrix => connected_state_setup_connected_matrix
(Parton states: procedures)+≡
    subroutine connected_state_setup_connected_matrix &
        (state, isolated, int, resonant, qn_filter_conn)
    class(connected_state_t), intent(inout), target :: state
    type(isolated_state_t), intent(in), target :: isolated
    type(interaction_t), intent(in), optional, target :: int
    logical, intent(in), optional :: resonant
    type(quantum_numbers_t), intent(in), optional :: qn_filter_conn
    type(quantum_numbers_mask_t) :: mask
    type(interaction_t), pointer :: src_int
    mask = quantum_numbers_mask (.false., .true., .true.)
    if (present (int)) then
        src_int => int
    else
        src_int => isolated%sf_chain_eff%get_out_int_ptr ()
    end if
    call state%matrix%init_product &
        (src_int, isolated%matrix, mask, &
        qn_filter_conn = qn_filter_conn, &
        connections_are_resonant = resonant)
    state%has_matrix = .true.
end subroutine connected_state_setup_connected_matrix

```

Setup a matrix evaluator as a product of two evaluators (incoming state, effective interaction). In the intermediate state, only helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`, after creating an intermediate interaction that includes a correlated color state. We assume that for a caller-provided `int`, this is not necessary.

```

(Parton states: connected state: TBP)+≡

```

```

    procedure :: setup_connected_flows => connected_state_setup_connected_flows
  (Parton states: procedures)+≡

    end function connected_state_get_state_flv

```

27.2.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

```

(Parton states: connected state: TBP)+≡
  procedure :: setup_subevt => connected_state_setup_subevt

(Parton states: procedures)+≡
  subroutine connected_state_setup_subevt (state, sf_chain, f_beam, f_in, f_out)

  end function parton_state_get_n_out

```

27.3 Complete Elementary Processes

This module combines hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the **computed** state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the **observed** state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible subsequent decay processes on the parton level, which are full-fledged process objects themselves.

27.3.1 The Process Object

A process object is the workspace for creating process instances for event generation. After initialization, its contents are filled by integration passes which shape the integration grids and compute cross sections. Processes are set up initially from user-level configuration data. After calculating integrals and thus developing integration grid data, the program may use a process object or a copy of it for the purpose of generating events.

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The **type** determines whether we are considering a decay or a scattering process.

The **meta** object describes the process and its environment. All contents become fixed when the object is initialized.

The **config** object holds physical and technical configuration data that have been obtained during process initialization, and which are common to all process components.

The individual process components are configured in the **component** objects. These objects contain more configuration parameters and workspace, as needed for the specific process variant.

The **term** objects describe parton configurations which are technically used as phase-space points. Each process component may split into several terms with distinct kinematics and particle content. Furthermore, each term may project on a different physical state, e.g., by particle recombination. The **term** object provides the framework for this projection, for applying cuts, weight, and thus completing the process calculation.

The **beam_config** object describes the incoming particles, either the decay mother or the scattering beams. It also contains the structure-function information.

The **mci_entry** objects configure a MC input parameter set and integrator, each. The number of parameters depends on the process component and on the beam and structure-function setup.

```

This procedure is an important debugging and inspection tool; it is not used during normal operation. The process object is written to a file (identified by unit, which may also be standard output). Optional flags determine whether we show everything or just the interesting parts.

end subroutine process_setup_terms

```

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a

scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam_data_t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by extending the code in the `beams` module.

```

```

We complete the kinematics configuration after the beam setup, but before we configure the chain of structure functions. The reason is that we need the total energy `sqrts` for the kinematics, but the structure-function setup requires the number of channels, which depends on the kinematics configuration. For instance, the kinematics module may return the need for parameterizing an s-channel resonance.

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

        class(process_t), intent(inout) :: process

```

```

class(expr_factory_t), intent(in) :: ef_weight
allocate (process%config%ef_weight, source = ef_weight)
end subroutine process_set_weight

```

MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

```

<Processes: process: TBP>+≡
  procedure :: compute_md5sum => process_compute_md5sum

<Processes: procedures>+≡
  subroutine process_compute_md5sum (process)
    class(process_t), intent(inout) :: process
    integer :: i
    call process%config%compute_md5sum ()

      associate (component => process%component(i))
        if (component%active) then
          call component%compute_md5sum ()
        end if
      end associate
    end do
    call process%beam_config%compute_md5sum ()
    do i = 1, process%config%n_mci
      call process%mci_entry(i)%compute_md5sum &
        (process%config, process%component, process%beam_config)
    end do
  end subroutine process_compute_md5sum

```

Integration and event generation

The sampler test should just evaluate the squared matrix element `n_calls` times, discarding the results, and return. This can be done before integration, e.g., for timing estimates.

```

<Processes: process: TBP>+≡
  procedure :: sampler_test => process_sampler_test

<Processes: procedures>+≡
  subroutine process_sampler_test (process, instance, i_mci, n_calls)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout), target :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_calls
    call process%mci_entry(i_mci)%sampler_test (instance, n_calls)
  end subroutine process_sampler_test

```

```
end subroutine process_sampler_test
```

Integrate the process, using a previously initialized process instance. We select one of the available MCI integrators by its index `i_mci` and thus integrate over (structure functions and) phase space for the associated (group of) process component(s).

The finalizer should be called after all integration passes have been completed. It will, for instance, write a summary of the integration results.

`integrate_dummy` does a “dummy” integration in the sense that nothing is done but just empty integration results appended.

```
(Processes: process: TBP)+≡
```

```
procedure :: integrate => process_integrate
procedure :: final_integration => process_final_integration
procedure :: integrate_dummy => process_integrate_dummy
```

```
(Processes: procedures)+≡
```

```

        call process%mci_entry(i_mci)%generate_unweighted_event (instance)
    end subroutine process_generate_unweighted_event

```

This replaces the event generation methods for the situation that the process instance object has been filled by other means (i.e., reading and/or recalculating its contents). We just have to fill in missing MCI data, especially the event weight.

```

    md5sum = process%config%md5sum
  end function process_get_md5sum_cfg

```

27.3.2 Metadata

This information describes the process and its environment. It is fixed upon initialization.

The `id` string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The `num_id` is meaningful if nonzero. It is used for communication with external programs or file standards which do not support string IDs.

The `run_id` string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The `var_list` is a snapshot of the variable list, taken at the point where the process was initialized.

The `lib` pointer accesses the process library where the process definition and the process driver are located.

The `lib_index` is the index of entry in the process library that corresponds to the current process.

The `component_id` array identifies the individual process components.

The `component_description` is an array of human-readable strings that characterize the process components, for instance `a, b => c, d`.

The `active` mask array marks those components which are active. The others are skipped.

27.3.3 Generic Configuration Data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the variable list.

The number **n_in** is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number **n_components** is the number of components that constitute the current process.

The number **n_terms** is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number **n_mci** is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The **model** pointer identifies the physics model and its parameters. This is a pointer to an external object.

The **rng_factory** component spawns independent random-number generators for use in integration, event generation, and event postprocessing.

Various **parse_node_t** objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the **effective_state** subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The **md5sum** is taken and used to verify the process configuration when re-reading data from file.

  call write_separator (u)
  write (u, "(3x,A,A,A)") "MD5 sum (config) = '", config%md5sum, "'"
end if
end subroutine process_config_data_write

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

The model that we import here should be an instance of the global model. If we create the instance outside, we can make it an extension of the basic `model_data_t`. This will allow us to synchronize the variable list with the model. Using a pointer instead of an allocatable, we can guarantee the `target` attribute.

The RNG factory object is imported by moving the allocation.

```

<Processes: process config data: TBP>+≡
  procedure :: init => process_config_data_init

<Processes: procedures>+≡
  subroutine process_config_data_init &
    (config, meta, os_data, qcd, rng_factory, model)
    class(process_config_data_t), intent(out) :: config

```

```

type(process_metadata_t), intent(in) :: meta
type(os_data_t), intent(in) :: os_data
type(qcd_t), intent(in) :: qcd
class(rng_factory_t), intent(inout), allocatable :: rng_factory
class(model_data_t), intent(inout), pointer :: model
config%n_in = meta%lib%get_n_in (meta%id)
config%n_components = size (meta%component_id)
config%os_data = os_data
config%qcd = qcd
call move_alloc (from = rng_factory, to = config%rng_factory)
config%model_name = model%get_name ()
config%model => model
model => null ()
end subroutine process_config_data_init

```

Since the captured model is a separate object allocated via a pointer, we need a finalizer.

```

<Processes: process config data: TBP>+=
  procedure :: final => process_config_data_final

<Processes: procedures>+=
  subroutine process_config_data_final (config)
    class(process_config_data_t), intent(inout) :: config
    if (associated (config%model)) then
      call config%model%final ()
      deallocate (config%model)
    end if
  end subroutine process_config_data_final

```

Compute the MD5 sum of the configuration data. This encodes, in particular, the model and the expressions for cut, scales, weight, etc. It should not contain the IDs and number of components, etc., since the MD5 sum should be useful for integrating individual components.

This is done only once. If the MD5 sum is nonempty, the calculation is skipped.

```

<Processes: process config data: TBP>+=
  procedure :: compute_md5sum => process_config_data_compute_md5sum

<Processes: procedures>+=
  subroutine process_config_data_compute_md5sum (config)
    class(process_config_data_t), intent(inout) :: config
    integer :: u
    if (config%md5sum == "") then
      u = free_unit ()
      open (u, status = "scratch", action = "readwrite")
      call config%write (u, counters = .false., os_data = .false., &
        rng_factory = .false., model = .true., expressions = .true.)
      rewind (u)
      config%md5sum = md5sum (u)
      close (u)
    end if
  end subroutine process_config_data_compute_md5sum

```

27.3.4 Beam configuration

The object `data` holds all details about the initial beam configuration. The allocatable array `sf` holds the structure-function configuration blocks. There are `n_strfun` entries in the structure-function chain (not counting the initial beam object). We maintain `n_channel` independent parameterizations of this chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is `n_sfpar`.

The flag `azimuthal_dependence` tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag `lab_is_cm_frame` is obvious.

```

<Processes: process part types>+=
  type :: process_beam_config_t
    private
    type (beam_data_t) :: data
    integer :: n_strfun = 0
    integer :: n_channel = 1
    integer :: n_sfpar = 0
    type (sf_config_t), dimension(:), allocatable :: sf
    type (sf_channel_t), dimension(:), allocatable :: sf_channel
    logical :: azimuthal_dependence = .false.
    logical :: lab_is_cm_frame = .true.
    character(32) :: md5sum = ""
    logical :: sf_trace = .false.
    type (string_t) :: sf_trace_file
  contains
    <Processes: process beam config: TBP>
  end type process_beam_config_t

```

Here we write beam data only if they are actually used.

```

<Processes: process beam config: TBP>=
  procedure :: write => process_beam_config_write

Process call statistics

This object can record process calls, categorized by evaluation status. It is a part of the `mci_entry` component below.

```

<Processes: types>≡
    type :: process_counter_t
        integer :: total = 0
        integer :: failed_kinematics = 0
        integer :: failed_cuts = 0
        integer :: passed = 0
        integer :: evaluated = 0
        integer :: complete = 0
    contains
        <Processes: process counter: TBP>
    end type process_counter_t

```

Here are the corresponding numeric codes:

```

<Processes: parameters>≡
    integer, parameter :: STAT_UNDEFINED = 0
    integer, parameter :: STAT_INITIAL = 1
    integer, parameter :: STAT_ACTIVATED = 2
    integer, parameter :: STAT_BEAM_MOMENTA = 3
    integer, parameter :: STAT_FAILED_KINEMATICS = 4
    integer, parameter :: STAT_SEED_KINEMATICS = 5

```

```

integer, parameter :: STAT_HARD_KINEMATICS = 6
integer, parameter :: STAT_EFF_KINEMATICS = 7
integer, parameter :: STAT_FAILED_CUTS = 8
integer, parameter :: STAT_PASSED_CUTS = 9
integer, parameter :: STAT_EVALUATED_TRACE = 10
integer, parameter :: STAT_EVENT_COMPLETE = 11

integer, parameter, public :: COMP_DEFAULT = 0
integer, parameter, public :: COMP_MASTER = 1
integer, parameter, public :: COMP_VIRT = 2
integer, parameter, public :: COMP_REAL = 3
integer, parameter, public :: COMP_SUB = 4

```

Output.

```

<Processes: process counter: TBP>≡
  procedure :: write => process_counter_write

<Processes: procedures>+≡
  subroutine process_counter_write (object, unit)
    class(process_counter_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    if (object%total > 0) then
      write (u, "(1x,A)") "Call statistics (current run):"
      write (u, "(3x,A,I0)") "total          = ", object%total

      write (u, "(3x,A,I0)") "evaluated   = ", object%evaluated
    else
      write (u, "(1x,A)") "Call statistics (current run): [no calls]"
    end if
  end subroutine process_counter_write

```

Reset. Just enforce default initialization.

```

<Processes: process counter: TBP>+≡
  procedure :: reset => process_counter_reset

<Processes: procedures>+≡
  subroutine process_counter_reset (counter)
    class(process_counter_t), intent(out) :: counter
  end subroutine process_counter_reset

```

We record an event according to the lowest status code greater or equal to the actual status. This is actually done by the process instance; the process object just copies the instance counter.

```

<Processes: process counter: TBP>+≡
  procedure :: record => process_counter_record

<Processes: procedures>+≡
  subroutine process_counter_record (counter, status)
    class(process_counter_t), intent(inout) :: counter
    integer, intent(in) :: status

```

```

if (status <= STAT_FAILED_KINEMATICS) then
  counter%failed_kinematics = counter%failed_kinematics + 1
else if (status <= STAT_FAILED_CUTS) then
  counter%failed_cuts = counter%failed_cuts + 1
else if (status <= STAT_PASSED_CUTS) then
  counter%passed = counter%passed + 1
else
  counter%evaluated = counter%evaluated + 1
end if
counter%total = counter%total + 1
end subroutine process_counter_record

```

27.3.5 Multi-channel integration

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly the values that apply to the current pass. Previous values are archived in the `results` object.

The `counter` receives the counter statistics from the associated process instance, for diagnostics.

The `results` object records results, broken down in passes and iterations.

(Processes: process part types)+≡

    end if
  end subroutine process_mci_entry_write_chain_weights

```

Initialize. From the existing configuration, we obtain the number of channels and the number of parameters, separately for the structure-function chain and for the associated process component. We assume that the phase-space object has already been configured.

The allocation of the MCI integrator with the appropriate concrete type is the duty of the process core.

We assume that there is only one component associated with a MCI entry. This restriction should be relaxed.

    end if
  end subroutine process_mci_entry_compute_md5sum
```

Test the MCI sampler by calling it a given number of time, discarding the results. The instance should be initialized.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

```
(Processes: process mci entry: TBP)+≡
  procedure :: sampler_test => process_mci_entry_sampler_test
(PProcesses: procedures)+≡
  subroutine process_mci_entry_sampler_test (mci_entry, instance, n_calls)
    class(process_mci_entry_t), intent(inout) :: mci_entry
    type(process_instance_t), intent(inout), target :: instance
    integer, intent(in) :: n_calls
    call instance%choose_mci (mci_entry%i_mci)
    call instance%reset_counter ()
    call mci_entry%pci%sampler_test (instance, n_calls)
    mci_entry%counter = instance%get_counter ()
  end subroutine process_mci_entry_sampler_test
```

Integrate. The instance should be initialized.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

```

Generate an event. The instance should be initialized, otherwise event generation is directed by the mci integrator subobject. The integrator instance is contained in a mci_work subobject of the process instance, which simultaneously serves as the sampler object. (We avoid the anti-aliasing rules if we assume that the sampling itself does not involve the integrator instance contained in the process instance.)

Regarding weighted events, we only take events which are valid, which means that they have valid kinematics and have passed cuts. Therefore, we have a rejection loop. For unweighted events, the unweighting routine should already take care of this.

```

27.3.6 Process Components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components can have different types. In short, `process_component_t` is a wrapper for the actual process variants.

If the `active` flag is false, we should skip this component. This happens if the associated process has vanishing matrix element.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

  <Processes: process part types>+≡
    type :: process_component_t
      private
      type(process_component_def_t), pointer :: config => null ()
      integer :: index = 0

```

27.3.7 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`. In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`.

This is the total number of independent entries in the density matrix. For each combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

(Processes: process part types) +≡

```

type :: process_term_t
  integer :: i_term_global = 0
  integer :: i_component = 0
  integer :: i_term = 0
  integer :: n_allowed = 0
  integer :: n_allowed_sub_born = 0
  type(process_constants_t) :: data
  real(default) :: alpha_s = 0
  integer, dimension(:), allocatable :: flv, hel, col
  logical :: rearrange = .false.
  type(interaction_t) :: int
  type(interaction_t), pointer :: int_eff => null ()
contains

```

```

    <Processes: process term: TBP>
end type process_term_t

```

For the output, we skip the process constants and the tables of allowed quantum numbers. Those can also be read off from the interaction object.

```

<Processes: process term: TBP>≡
    procedure :: write => process_term_write

<Processes: procedures>+≡
    subroutine process_term_write (term, unit)
        class(process_term_t), intent(in) :: term
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)

        end if
    end subroutine process_term_write

```

Write an account of all quantum number states and their current status.

```

<Processes: process term: TBP>+≡
    procedure :: write_state_summary => process_term_write_state_summary

<Processes: procedures>+≡
    subroutine process_term_write_state_summary (term, core, unit)
        class(process_term_t), intent(in) :: term
        class(prc_core_t), intent(in) :: core
        integer, intent(in), optional :: unit
        integer :: u, i, f, h, c
        type(state_iterator_t) :: it
        character :: sgn
        u = given_output_unit (unit)
        write (u, "(1x,A,I0)") "Term #", term%i_term_global
        call it%init (term%int%get_state_matrix_ptr ())
        do while (it%is_valid ())
            i = it%get_me_index ()
            f = term%flv(i)
            h = term%hel(i)
            c = term%col(i)
            if (core%is_allowed (term%i_term, f, h, c)) then

```

```

        sgn = "+"
    else
        sgn = " "
    end if
    write (u, "(1x,A1,1x,I0,2x)", advance="no") sgn, i
    call quantum_numbers_write (it%get_quantum_numbers (), u)
    write (u, *)
    call it%advance ()
end do
end subroutine process_term_write_state_summary

```

Finalizer: the `int` and potentially `int_eff` components have a finalizer that we must call.

```

<Processes: process term: TBP>+=
    procedure :: final => process_term_final

<Processes: procedures>+=
    subroutine process_term_final (term)
        class(process_term_t), intent(inout) :: term
        call term%int%final ()
        if (term%rearrange) then
            call term%int_eff%final ()
            deallocate (term%int_eff)
        end if
    end subroutine process_term_final

```

Initialize the term. We copy the process constants from the `core` object and set up the `int` hard interaction accordingly.

The `alpha_s` value is useful for writing external event records. This is the constant value which may be overridden by a event-specific running value. If the model does not contain the strong coupling, the value is zero.

The `rearrange` part is commented out; this or something equivalent could become relevant for NLO algorithms.

```

<Processes: process term: TBP>+=
    procedure :: init => process_term_init

<Processes: procedures>+=
    subroutine process_term_init &
        (term, i_term_global, i_component, i_term, core, model)
        class(process_term_t), intent(inout), target :: term
        integer, intent(in) :: i_term_global
        integer, intent(in) :: i_component
        integer, intent(in) :: i_term
        class(prc_core_t), intent(in) :: core

        term%i_term_global = i_term_global
        term%i_component = i_component
        term%i_term = i_term
        call core%get_constants (term%data, i_term)
!    var_list => model%get_var_list_ptr ()
!    if (var_list%contains (var_str ("alphas"))) then

```

```

!      term%alpha_s = var_list%get_rval (var_list, var_str ("alphas"))
!    else
!      term%alpha_s = -1
!    end if
alpha_s_ptr => model%get_par_data_ptr (var_str ("alphas"))
if (associated (alpha_s_ptr)) then
  term%alpha_s = alpha_s_ptr%get_real ()
else
  term%alpha_s = -1
end if

  call term%setup_interaction (core, model)
!  if (term%rearrange) then
!    call term%setup_effective_interaction (core, term%int, term%int_eff)
!  end if
end subroutine process_term_init

```

We fetch the process constants which determine the quantum numbers and use those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

    prc_constants = term%data
end subroutine process_term_fetch_process_constants

```

27.3.8 Default Iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

⟨Processes: process: TBP⟩+≡
    procedure :: get_n_pass_default => process_get_n_pass_default
    procedure :: adapt_grids_default => process_adapt_grids_default
    procedure :: adapt_weights_default => process_adapt_weights_default

```

```

(Processes: procedures)+=
function process_get_n_pass_default (process) result (n_pass)
  class(process_t), intent(in) :: process
  integer :: n_pass
  integer :: n_eff
  type(process_component_def_t), pointer :: config
  config => process%component(1)%config
  n_eff = config%get_n_tot () - 2
  select case (n_eff)
  case (1)
    n_pass = 1
  case default
    n_pass = 2
  end select
end function process_get_n_pass_default

function process_adapt_grids_default (process, pass) result (flag)

27.3.9 Constant process data

The following methods return basic process data that stay constant after initialization.

The process and IDs.

```

<Processes: process: TBP>+≡
    procedure :: get_id => process_get_id
    procedure :: get_num_id => process_get_num_id
    procedure :: get_run_id => process_get_run_id
    procedure :: get_library_name => process_get_library_name

<Processes: procedures>+≡
    function process_get_id (process) result (id)
        class(process_t), intent(in) :: process
        type(string_t) :: id
        id = process%meta%id
    end function process_get_id

    function process_get_num_id (process) result (id)
        class(process_t), intent(in) :: process
        integer :: id
        id = process%meta%num_id
    end function process_get_num_id

    function process_get_run_id (process) result (id)
        class(process_t), intent(in) :: process
        type(string_t) :: id
        id = process%meta%run_id
    end function process_get_run_id

    function process_get_library_name (process) result (id)
        class(process_t), intent(in) :: process
        type(string_t) :: id
        id = process%meta%lib%get_name ()
    end function process_get_library_name

```

The number of incoming particles.

```

<Processes: process: TBP>+≡
    procedure :: get_n_in => process_get_n_in

```

```

<Processes: procedures>+≡
  function process_get_n_in (process) result (n)
    class(process_t), intent(in) :: process
    integer :: n
    n = process%config%n_in
  end function process_get_n_in

```

The number of MCI data sets.

```

<Processes: process: TBP>+≡
  procedure :: get_n_mci => process_get_n_mci

<Processes: procedures>+≡
  function process_get_n_mci (process) result (n)
    class(process_t), intent(in) :: process
    integer :: n
    n = process%config%n_mci
  end function process_get_n_mci

```

The number of process components, total.

```

<Processes: process: TBP>+≡
  procedure :: get_n_components => process_get_n_components

<Processes: procedures>+≡

    end if
  end subroutine process_make_rng

```

27.3.10 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```

<Processes: process: TBP>+≡
  procedure :: compute_amplitude => process_compute_amplitude

```

```

<Processes: procedures>+≡
function process_compute_amplitude &
    (process, i, j, p, f, h, c, fac_scale, ren_scale, alpha_qcd_forced) &

27.3.11 Process instances

Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

`sf_chain` is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

`phs` is an instance of the phase space for the elementary process.

The array `f` contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either `sf_chain` or `phs` are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component ('owned' by the object) or as a pointer.

```

<Processes: types>+≡
  type :: kinematics_t
    integer :: n_in = 0
    integer :: n_channel = 0
    integer :: selected_channel = 0
    type(sf_chain_instance_t), pointer :: sf_chain => null ()
    class(phs_t), pointer :: phs => null ()
    real(default), dimension(:), pointer :: f => null ()
    real(default) :: phs_factor
    logical :: sf_chain_allocated = .false.
    logical :: phs_allocated = .false.
    logical :: f_allocated = .false.
    integer :: nlo_type
    integer :: emitter
  contains
    <Processes: kinematics: TBP>
  end type kinematics_t

```

Output. Show only those components which are marked as owned.

```

        k%phs_factor = 0
        success = .false.
      end if
    end select
  end subroutine kinematics_compute_selected_channel

```

Complete kinematics by filling the non-selected phase-space parameter arrays.

```

(Processes: kinematics: TBP)+≡
  procedure :: compute_other_channels => kinematics_compute_other_channels

(Processes: procedures)+≡
  subroutine kinematics_compute_other_channels (k, mci_work, phs_channel)

```

```

class(kinematics_t), intent(inout) :: k
type(mci_work_t), intent(in) :: mci_work
integer, intent(in) :: phs_channel
integer :: c, c_sf
call k%phs%evaluate_other_channels (phs_channel)
do c = 1, k%n_channel
    c_sf = k%phs%config%get_sf_channel (c)
    k%f(c) = k%sf_chain%get_f (c_sf) * k%phs%get_f (c)
end do
end subroutine kinematics_compute_other_channels

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

```

<Processes: kinematics: TBP>+≡
    procedure :: get_incoming_momenta => kinematics_get_incoming_momenta

<Processes: procedures>+≡
    subroutine kinematics_get_incoming_momenta (k, p)
        class(kinematics_t), intent(in) :: k
        type(vector4_t), dimension(:), intent(out) :: p
        type(interaction_t), pointer :: int
        integer :: i
        int => k%sf_chain%get_out_int_ptr ()
        do i = 1, k%n_in
            p(i) = int%get_momentum (k%sf_chain%get_out_i (i))
        end do
    end subroutine kinematics_get_incoming_momenta

```

This inverts the remainder of the above `compute` method. We know the momenta and recover the rest, as far as needed. If we select a channel, we can complete the inversion and reconstruct the MC parameter set.

```

    class(kinematics_t), intent(in) :: k
    call k%sf_chain%return_beam_momenta ()
  end subroutine kinematics_return_beam_momenta
```

Process component instance

The actual calculation of a sampling point is done from here.

The `config` pointer accesses the corresponding configuration in the `process` object.

The `active` flag indicates that we are currently computing this component, together with all other components that share the same MC parameter set. Inactive components are using a different MC parameter set and are not in use for this sampling point.

The `k_seed` subobject contains the kinematics (structure-function chain, phase space, etc.) that implements the ‘seed’ configuration of momenta. This version of the process kinematics is accessed by the MCI setup.

`p_seed` is the array of momenta that we compute from the MC input parameters, via the `k_seed` subobject. Depending on the process variant, these may or may not coincide with the momenta that enter the process terms associated to this component.

The `core_state` object can be used for storing intermediate results. Its precise type and contents depend on the process variant.

```
<Processes: types>+≡
  type :: component_instance_t
    type(process_component_t), pointer :: config => null ()
    logical :: active = .false.
    type(kinematics_t) :: k_seed
    type(vector4_t), dimension(:), allocatable :: p_seed
    logical :: sqme_known = .false.
    real(default) :: sqme = 0
    class(prc_core_state_t), allocatable :: core_state
    type(nlo_controller_t), pointer :: nlo_controller => null ()
    integer :: nlo_type = BORN
  contains
    <Processes: component instance: TBP>
  end type component_instance_t
```

In the header, fetch the component index from the configuration record. `process_component_t` configuration block.

We write the `sf_chain` subobject only upon request, since its instances appear elsewhere.

```
<Processes: component instance: TBP>≡
```

```

Compute the momenta in the hard interactions, one for each term that constitutes this process component. In simple cases this amounts to just copying momenta. In more advanced cases, we may generate distinct sets of momenta from the seed kinematics.

The interactions in the term instances are accessed individually. We may choose to calculate all terms at once together with the seed kinematics, use `component%core_state` for storage, and just fill the interactions here.

```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The `k_term` object is the instance of the kinematics setup (structure-function chain, phase space, etc.) that applies specifically to this term. In ordinary cases, it consists of straight pointers to the seed kinematics.

The `amp` array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The `int_hard` interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The `isolated` object holds the effective parton state for the elementary interaction. The amplitude entries are computed from `int_hard`.

The `connected` evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The `checked` flag is set once we have applied cuts on this term. The result of this is stored in the `passed` flag. Once the term has passed cuts, we calculate the various scale and weight expressions.

For initialization, we make use of defined assignment for the `interaction_t` type. This creates a deep copy.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (`rearrange`) as effective structure-function chain and interaction, respectively.

Finally, we set up the `subevt` component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

The `rearrange` parts are still commented out; they could become relevant for a NLO algorithm.

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain. (If we have an algorithm that uses rearrangement, it should evaluate `k_term` explicitly.)

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

    real(default), intent(in) :: fac_scale
    term%fac_scale = fac_scale
  end subroutine term_instance_set_fac_scale

```

Return data that might be useful for external processing. The factorization scale:

```

<Processes: term instance: TBP>+≡
  procedure :: get_fac_scale => term_instance_get_fac_scale

<Processes: procedures>+≡
  function term_instance_get_fac_scale (term) result (fac_scale)
    class(term_instance_t), intent(in) :: term
    real(default) :: fac_scale
    fac_scale = term%fac_scale
  end function term_instance_get_fac_scale

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

  end function term_instance_get_alpha_s

```

MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

```
<Processes: types>+≡
  type :: mci_work_t
    type(process_mci_entry_t), pointer :: config => null ()
    real(default), dimension(:), allocatable :: x
    class(mci_instance_t), pointer :: mci => null ()
    type(process_counter_t) :: counter
  contains
    <Processes: mci work: TBP>
  end type mci_work_t
```

First write configuration data, then the current values.

```
<Processes: mci work: TBP>≡
  procedure :: write => mci_work_write

<Processes: procedures>+≡
  subroutine mci_work_write (mci_work, unit, testflag)
    class(mci_work_t), intent(in) :: mci_work
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A,I0,A)") "Active MCI instance #", &
      mci_work%config%i_mci, " ="
    write (u, "(2x)", advance="no")
    do i = 1, mci_work%config%n_par
      write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
      if (i == mci_work%config%n_par_sf) &
        write (u, "(1x,'|')", advance="no")
    end do
    write (u, *)
    if (associated (mci_work%mci)) then
      call mci_work%mci%write (u, pacify = testflag)
      call mci_work%counter%write (u)
    end if
  end subroutine mci_work_write
```

The `mci` component may require finalization.

```
<Processes: mci work: TBP>+≡
  procedure :: final => mci_work_final

<Processes: procedures>+≡
  subroutine mci_work_final (mci_work)
    class(mci_work_t), intent(inout) :: mci_work
    if (associated (mci_work%mci)) then
      call mci_work%mci%final ()
      deallocate (mci_work%mci)
    end if
  end subroutine mci_work_final
```

Initialize with the maximum length that we will need. Contents are not initialized.

The integrator inside the `mci_entry` object is responsible for allocating and initializing its own instance, which is referred to by a pointer in the `mci_work` object.

```

<Processes: mci work: TBP>+≡
  procedure :: init => mci_work_init

<Processes: procedures>+≡
  subroutine mci_work_init (mci_work, mci_entry)

    counter = mci_work%counter
  end function mci_work_get_counter

```

The process instance

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `count` object records process evaluations, broken down according to status.

The `sqme` value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The `weight` value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the `sqme` value times Jacobian weights from the integration, or unity, respectively.

The `i_mci` index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The `sf_chain` subobject is a realization of the beam and structure-function configuration in the `process` object. It is not used for calculation directly

but serves as the template for the sf-chain instances that are contained in the `component` objects.

The `component` subobjects determine the state of each component.

The `term` subobjects are workspace for evaluating kinematics, matrix elements, cuts etc.

The `mci_work` subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the `mci_work` array is selected by the `i_mci` index above.

```

<Processes: public>+=
  public :: process_instance_t

<Processes: types>+=
  type, extends (mci_sampler_t) :: process_instance_t
    type(process_t), pointer :: process => null ()

Initialization connects the instance with a process. All initial information is transferred from the process object. The process object contains templates for the interaction subobjects (beam and term), but no evaluators. The initialization routine creates evaluators for the matrix element trace, other evaluators are left untouched.

The **instance** object must have the **target** attribute (also in any caller) since the initialization routine assigns various pointers to subobject of **instance**.

```

Subroutine of the initialization above: initialize the beam and structure-function chain template. We establish pointers to the configuration data, so `beam_config` must have a `target` attribute.

The resulting chain is not used directly for calculation. It will acquire instances which are stored in the process-component instance objects.

```

<Processes: process instance: TBP>+≡
  procedure :: setup_sf_chain => process_instance_setup_sf_chain

<Processes: procedures>+≡
  subroutine process_instance_setup_sf_chain (instance, config)
    class(process_instance_t), intent(inout) :: instance
    type(process_beam_config_t), intent(in), target :: config
    integer :: n_strfun
    n_strfun = config%n_strfun
    if (n_strfun /= 0) then
      call instance%sf_chain%init (config%data, config%sf)
    else
      call instance%sf_chain%init (config%data)
    end if
    if (config%sf_trace) then
      call instance%sf_chain%setup_tracing (config%sf_trace_file)
    end if
  end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

<Processes: process instance: TBP>+≡
  procedure :: setup_event_data => process_instance_setup_event_data

<Processes: procedures>+≡
  subroutine process_instance_setup_event_data (instance, model)
    class(process_instance_t), intent(inout), target :: instance
    class(model_data_t), intent(in), optional, target :: model
    class(model_data_t), pointer :: current_model

```

```

        associate (component => instance%process%component(i_component))
        call term%setup_event_data (component%core, current_model)
        end associate
    end if
end associate
end do
end subroutine process_instance_setup_event_data

```

Choose a MC parameter set and the corresponding integrator. The choice persists beyond calls of the `reset` method above. This method is automatically called here.

```

<Processes: process instance: TBP>+≡
    procedure :: choose_mci => process_instance_choose_mci

<Processes: procedures>+≡
    subroutine process_instance_choose_mci (instance, i_mci)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci
        instance%i_mci = i_mci
        call instance%reset ()
    end subroutine process_instance_choose_mci

```

Explicitly set a MC parameter set. Works only if we are in initial state. We assume that the length of the parameter set is correct.

After setting the parameters, activate the components and terms that correspond to the chosen MC parameter set.

```

<Processes: process instance: TBP>+≡
    procedure :: set_mcpair => process_instance_set_mcpair

<Processes: procedures>+≡
    subroutine process_instance_set_mcpair (instance, x)
        class(process_instance_t), intent(inout) :: instance
        real(default), dimension(:), intent(in) :: x
        if (instance%evaluation_status == STAT_INITIAL) then
            associate (mci_work => instance%mci_work(instance%i_mci))
                call mci_work%set (x)
            end associate
            call instance%activate ()
        end if
    end subroutine process_instance_set_mcpair

```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The sf-chain instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```

<Processes: process instance: TBP>+≡
    procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

```

```

<Processes: procedures>+≡
  subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%receive_beam_momenta ()
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_receive_beam_momenta

```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```

<Processes: process instance: TBP>+≡
  procedure :: set_beam_momenta => process_instance_set_beam_momenta

<Processes: procedures>+≡
  subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%set_beam_momenta (p)
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_set_beam_momenta

```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```

<Processes: process instance: TBP>+≡
  procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

<Processes: procedures>+≡
  subroutine process_instance_recover_beam_momenta (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    integer :: i
    if (.not. instance%process%beam_config%lab_is_cm_frame) then
      if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
        i = instance%term(i_term)%config%i_component
        call instance%component(i)%return_beam_momenta ()
      end if
    end if
  end subroutine process_instance_recover_beam_momenta

```

Explicitly choose MC integration channel. We assume here that the channel count is identical for all active components.

```

<Processes: process instance: TBP>+≡
  procedure :: select_channel => process_instance_select_channel

<Processes: procedures>+≡
  subroutine process_instance_select_channel (instance, channel)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel

```

```

instance%selected_channel = channel
end subroutine process_instance_select_channel

```

First step of process evaluation: set up seed kinematics. That is, for each active process component, compute a momentum array from the MC input parameters.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Processes: process instance: TBP>+≡
  procedure :: compute_seed_kinematics => &
    process_instance_compute_seed_kinematics

<Processes: procedures>+≡
  subroutine process_instance_compute_seed_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: channel, skip_component, i
    logical :: success
    channel = instance%selected_channel
    if (channel == 0) then
      call msg_bug ("Compute seed kinematics: undefined integration channel")
    end if
    if (present (skip_term)) then
      skip_component = instance%term(skip_term)%config%i_component
    else
      skip_component = 0
    end if
    if (instance%evaluation_status >= STAT_ACTIVATED) then
      success = .true.
      do i = 1, size (instance%component)

        if (instance%component(i)%active) then
          call instance%component(i)%compute_seed_kinematics &
            (instance%mc_work(instance%i_mci), channel, success)
          if (.not. success) exit
        end if
      end do
      if (success) then
        instance%evaluation_status = STAT_SEED_KINEMATICS
      else
        instance%evaluation_status = STAT_FAILED_KINEMATICS
      end if
    end if
  end subroutine process_instance_compute_seed_kinematics

```

Inverse: recover missing parts of the kinematics from the momentum configuration, which we know for a single term and component. Given a channel, reconstruct the MC parameter set.

```

<Processes: process instance: TBP>+≡
  procedure :: recover_mcpair => process_instance_recover_mcpair

<Processes: procedures>+≡
  subroutine process_instance_recover_mcpair (instance, i_term)

```

```

class(process_instance_t), intent(inout) :: instance
integer, intent(in) :: i_term
integer :: channel
integer :: i
if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
  channel = instance%selected_channel
  if (channel == 0) then
    call msg_bug ("Recover MC parameters: undefined integration channel")
  end if
  i = instance%term(i_term)%config%i_component
  call instance%component(i)%recover_mcpair &
    (instance%mc_work(instance%i_mci), channel)
end if
end subroutine process_instance_recover_mcpair

```

Second step of process evaluation: compute all momenta, for all active components, from the seed kinematics.

```

<Processes: process instance: TBP>+≡
  procedure :: compute_hard_kinematics => &
    process_instance_compute_hard_kinematics

<Processes: procedures>+≡

        end associate
    end if
end subroutine process_instance_recover_seed_kinematics

```

Third step of process evaluation: compute the effective momentum configurations, for all active terms, from the hard kinematics.

```

<Processes: process instance: TBP>+≡
    procedure :: compute_eff_kinematics => &
        process_instance_compute_eff_kinematics

<Processes: procedures>+≡
    subroutine process_instance_compute_eff_kinematics (instance, skip_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in), optional :: skip_term
        integer :: i
        if (instance%evaluation_status >= STAT_HARD_KINEMATICS) then
            do i = 1, size (instance%term)
                if (present (skip_term)) then
                    if (i == skip_term) cycle
                end if
                if (instance%term(i)%active) then
                    call instance%term(i)% &
                        compute_eff_kinematics (instance%component)
                end if
            end do
            instance%evaluation_status = STAT_EFF_KINEMATICS
        end if
    end subroutine process_instance_compute_eff_kinematics

```

Inverse: recover the hard kinematics from effective kinematics for one term, then compute effective kinematics for the other terms.

```

<Processes: process instance: TBP>+≡
    procedure :: recover_hard_kinematics => &
        process_instance_recover_hard_kinematics

<Processes: procedures>+≡
    subroutine process_instance_recover_hard_kinematics (instance, i_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_term
        integer :: i
        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
            call instance%term(i_term)%recover_hard_kinematics (instance%component)
            do i = 1, size (instance%term)
                if (i /= i_term) then
                    if (instance%term(i)%active) then
                        call instance%term(i)% &
                            compute_eff_kinematics (instance%component)
                    end if
                end if
            end do
        end if
    end subroutine process_instance_recover_hard_kinematics

```

```

        instance%evaluation_status = STAT_EFF_KINEMATICS
    end if
end subroutine process_instance_recover_hard_kinematics

```

Fourth step of process evaluation: check cuts for all terms. Where successful, compute any scales and weights. Otherwise, deactivate the term. If any of the terms has passed, set the state to STAT_PASSED_CUTS.

The argument `scale_forced`, if present, will override the scale calculation in the term expressions.

```

<Processes: process instance: TBP>+≡
    procedure :: evaluate_expressions => &
        process_instance_evaluate_expressions

<Processes: procedures>+≡
    subroutine process_instance_evaluate_expressions (instance, scale_forced)
        class(process_instance_t), intent(inout) :: instance
        real(default), intent(in), allocatable, optional :: scale_forced
        integer :: i
        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
            do i = 1, size (instance%term)
                if (instance%term(i)%active) then
                    call instance%term(i)%evaluate_expressions (scale_forced)
                end if
            end do
            if (any (instance%term%passed)) then
                instance%evaluation_status = STAT_PASSED_CUTS
            else
                instance%evaluation_status = STAT_FAILED_CUTS
            end if
        end if
    end subroutine process_instance_evaluate_expressions

```

Fifth step of process evaluation: fill the parameters for the non-selected ,channels, that have not been used for seeding. We should do this after evaluating cuts, since we may save some expensive calculations if the phase space point fails the cuts.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Processes: process instance: TBP>+≡
    procedure :: compute_other_channels => &
        process_instance_compute_other_channels

<Processes: procedures>+≡
    subroutine process_instance_compute_other_channels (instance, skip_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in), optional :: skip_term
        integer :: channel, skip_component, i
        channel = instance%selected_channel
        if (channel == 0) then
            call msg_bug ("Compute other channels: undefined integration channel")
        end if
        if (present (skip_term)) then

```

```

        skip_component = instance%term(skip_term)%config%i_component
    else
        skip_component = 0
    end if
    if (instance%evaluation_status >= STAT_PASSED_CUTS) then
        do i = 1, size (instance%component)
            if (i == skip_component) cycle
            if (instance%component(i)%active) then
                call instance%component(i)%compute_other_channels &
                    (instance%nci_work(instance%i_nci), channel)
            end if
        end do
    end if
end subroutine process_instance_compute_other_channels

```

Sixth step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

```

<Processes: process instance: TBP>+≡
    procedure :: evaluate_trace => process_instance_evaluate_trace

<Processes: procedures>+≡
    subroutine process_instance_evaluate_trace (instance)
        class(process_instance_t), intent(inout) :: instance
        integer :: i, i_real
        instance%sqme = 0
        i_real = 0
        if (instance%evaluation_status >= STAT_PASSED_CUTS) then
            do i = 1, size (instance%term)
                associate (term => instance%term(i))
                    if (term%active .and. term%passed) then
                        select case (term%nlo_type)
                            case (NLO_REAL)
                                if (.not. associated (instance%sqme_collector)) then
                                    call instance%evaluate_trace_real (term, i)
                                else
                                    i_real = i
                                end if
                            case (BORN, NLO_VIRTUAL)
                                call term%evaluate_interaction (instance%component)
                                call term%evaluate_trace ()
                            end select
                        end if
                    end associate
                end do
            do i = 1, size (instance%component)
                associate (component => instance%component(i))
                    if (component%active) then
                        select case (component%config%config%get_nlo_type())
                            case (BORN, NLO_VIRTUAL)
                                call component%evaluate_sqme (instance%term)

    if (associated (instance%sqme_collector)) &
      instance%sqme = instance%sqme_collector%get_sqme_sum ()
  end subroutine process_instance_evaluate_sqme

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

```

<Processes: process instance: TBP>+=
  procedure :: recover => process_instance_recover

<Processes: procedures>+=
  subroutine process_instance_recover &
    (instance, channel, i_term, update_sqme, scale_forced)

  end subroutine process_instance_final_simulation

```

27.3.12 Accessing the process instance

Once the seed kinematics is complete, we can retrieve the MC input parameters for all channels, not just the seed channel.

Note: We choose the first active component. This makes sense only if the seed kinematics is identical for all active components.

```

<Processes: process instance: TBP>+≡
  procedure :: get_mcpair => process_instance_get_mcpair

<Processes: procedures>+≡
  subroutine process_instance_get_mcpair (instance, channel, x)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    real(default), dimension(:), intent(out) :: x
    integer :: i
    if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
      do i = 1, size (instance%component)
        if (instance%component(i)%active) then
          call instance%component(i)%k_seed%get_mcpair (channel, x)
          return
        end if
      end do
    end if
  end subroutine process_instance_get_mcpair

```

```

        end do
        call msg_bug ("Process instance: get_mcpair: no active channels")
    else
        call msg_bug ("Process instance: get_mcpair: no seed kinematics")
    end if
end subroutine process_instance_get_mcpair

```

Return true if the `sqme` value is known. This also implies that the event is kinematically valid and has passed all cuts.

```

<Processes: process instance: TBP>+≡
    procedure :: has_evaluated_trace => process_instance_has_evaluated_trace

<Processes: procedures>+≡
    function process_instance_has_evaluated_trace (instance) result (flag)
        class(process_instance_t), intent(in) :: instance
        logical :: flag
        flag = instance%evaluation_status >= STAT_EVALUATED_TRACE
    end function process_instance_has_evaluated_trace

```

Return true if the event is complete. In particular, the event must be kinematically valid, passed all cuts, and the event data have been computed.

```

<Processes: process instance: TBP>+≡
    procedure :: is_complete_event => process_instance_is_complete_event

<Processes: procedures>+≡
    function process_instance_is_complete_event (instance) result (flag)

```

27.3.13 Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-

number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

NB: The `recover_beams` option should be used only when the particle set originates from an external event file, and the user has asked for it. It should be switched off when reading from raw event file.

```

(Processes: process instance: TBP)+≡
  procedure :: get_trace => process_instance_get_trace
  procedure :: set_trace => process_instance_set_trace

(Processes: procedures)+≡
  subroutine process_instance_get_trace (instance, pset, i_term)
    class(process_instance_t), intent(in), target :: instance
    type(particle_set_t), intent(out) :: pset
    integer, intent(in) :: i_term
    type(interaction_t), pointer :: int
    logical :: ok
    int => instance%get_trace_int_ptr (i_term)
    call pset%init (ok, int, int, FM_IGNORE_HELICITY, &
      [0._default, 0._default], .false., .true.)
  end subroutine process_instance_get_trace

  subroutine process_instance_set_trace &
    (instance, pset, i_term, recover_beams, check_match)
    class(process_instance_t), intent(inout), target :: instance
    type(particle_set_t), intent(in) :: pset

The **pacify** subroutine has the purpose of setting numbers to zero which are (by comparing with a **tolerance** parameter) considered equivalent with zero. We do this in some unit tests. Here, we apply this to the phase space subobject of the process instance.

<Processes: public>+≡

```

    public :: pacify

```

<Processes: interfaces>≡

```

interface pacify
    module procedure pacify_process_instance
end interface pacify

```

<Processes: procedures>+≡

```

subroutine pacify_process_instance (instance)
    type(process_instance_t), intent(inout) :: instance
    integer :: i
    do i = 1, size (instance%component)

```

```

        call pacify (instance%component(i)%k_seed%phs)
    end do
end subroutine pacify_process_instance

<Processes: public>+≡
    public :: setup_nlo_component_cores

<Processes: procedures>+≡
    subroutine setup_nlo_component_cores (process)
        type(process_t), intent(inout), target :: process
        integer :: i_born, i_sub
