28.3.9 Constant process data

The following methods return basic process data that stay constant after initialization.

The process and IDs.

```
<Processes: process: TBP>+≡
  procedure :: get_id => process_get_id
  procedure :: get_num_id => process_get_num_id
  procedure :: get_run_id => process_get_run_id
  procedure :: get_library_name => process_get_library_name

<Processes: procedures>+≡
  function process_get_id (process) result (id)
    class(process_t), intent(in) :: process
    type(string_t) :: id
    id = process%meta%id
  end function process_get_id

  function process_get_num_id (process) result (id)
    class(process_t), intent(in) :: process
    integer :: id
    id = process%meta%num_id
  end function process_get_num_id

  function process_get_run_id (process) result (id)
    class(process_t), intent(in) :: process
    type(string_t) :: id
    id = process%meta%run_id
  end function process_get_run_id

  function process_get_library_name (process) result (id)
    class(process_t), intent(in) :: process
    type(string_t) :: id
    id = process%meta%lib%get_name ()
  end function process_get_library_name
```

The number of incoming particles.

```
<Processes: process: TBP>+≡
  procedure :: get_n_in => process_get_n_in

<Processes: procedures>+≡
  function process_get_n_in (process) result (n)
    class(process_t), intent(in) :: process
    integer :: n
    n = process%config%n_in

```

28.3.10 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```

<Processes: process: TBP>+=
  procedure :: compute_amplitude => process_compute_amplitude

<Processes: procedures>+=
  function process_compute_amplitude &
    (process, i, j, p, f, h, c, fac_scale, ren_scale, alpha_qcd_forced) &

    mci => process%mci_entry(1)%mci
  end subroutine test_get_mci_ptr

```

Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

sf_chain is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

phs is an instance of the phase space for the elementary process.

The array **f** contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either **sf_chain** or **phs** are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component ('owned' by the object) or as a pointer.

```

<Processes: types>+≡
  type :: kinematics_t

        end do
    end subroutine kinematics_compute_other_channels

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

```

<Processes: kinematics: TBP>+≡
    procedure :: get_incoming_momenta => kinematics_get_incoming_momenta

<Processes: procedures>+≡
    subroutine kinematics_get_incoming_momenta (k, p)
        class(kinematics_t), intent(in) :: k
        type(vector4_t), dimension(:), intent(out) :: p
        type(interaction_t), pointer :: int
        integer :: i

  end subroutine kinematics_return_beam_momenta

```

Process component instance

The actual calculation of a sampling point is done from here.

The `config` pointer accesses the corresponding configuration in the `process` object.

The `active` flag indicates that we are currently computing this component, together with all other components that share the same MC parameter set. Inactive components are using a different MC parameter set and are not in use for this sampling point.

The `k_seed` subobject contains the kinematics (structure-function chain, phase space, etc.) that implements the ‘seed’ configuration of momenta. This version of the process kinematics is accessed by the MCI setup.

`p_seed` is the array of momenta that we compute from the MC input parameters, via the `k_seed` subobject. Depending on the process variant, these may or may not coincide with the momenta that enter the process terms associated to this component.

The `core_state` object can be used for storing intermediate results. Its precise type and contents depend on the process variant.

```

<Processes: types>+≡

```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

```

Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The `k_term` object is the instance of the kinematics setup (structure-function chain, phase space, etc.) that applies specifically to this term. In ordinary cases, it consists of straight pointers to the seed kinematics.

The `amp` array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The `int_hard` interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The `isolated` object holds the effective parton state for the elementary interaction. The amplitude entries are computed from `int_hard`.

The `connected` evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The `checked` flag is set once we have applied cuts on this term. The result of this is stored in the `passed` flag. Once the term has passed cuts, we calculate the various scale and weight expressions.

end subroutine term_instance_final

```

For initialization, we make use of defined assignment for the `interaction_t` type. This creates a deep copy.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (`rearrange`) as effective structure-function chain and interaction, respectively.

Finally, we set up the `subevt` component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

The `rearrange` parts are still commented out; they could become relevant for a NLO algorithm.

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain. (If we have an algorithm that uses rearrangement, it should evaluate `k_term` explicitly.)

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

```

Return data that might be useful for external processing. The factorization scale:

```

⟨Processes: term instance: TBP⟩+≡
  procedure :: get_fac_scale => term_instance_get_fac_scale

⟨Processes: procedures⟩+≡
  function term_instance_get_fac_scale (term) result (fac_scale)
    class(term_instance_t), intent(in) :: term
    real(default) :: fac_scale
    fac_scale = term%fac_scale
  end function term_instance_get_fac_scale

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

```

<Processes: types>+=
    type :: mci_work_t
        type(process_mci_entry_t), pointer :: config => null ()
        real(default), dimension(:), allocatable :: x
        class(mci_instance_t), pointer :: mci => null ()
        type(process_counter_t) :: counter
    contains
        <Processes: mci work: TBP>
    end type mci_work_t

```

First write configuration data, then the current values.

```

<Processes: mci work: TBP>=
    procedure :: write => mci_work_write

<Processes: procedures>+=
    subroutine mci_work_write (mci_work, unit, testflag)
        class(mci_work_t), intent(in) :: mci_work
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: testflag
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A,I0,A)") "Active MCI instance #", &
            mci_work%config%i_mci, " ="
        write (u, "(2x)", advance="no")
        do i = 1, mci_work%config%n_par
            write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
            if (i == mci_work%config%n_par_sf) &
                write (u, "(1x,'|')", advance="no")
        end do
        write (u, *)
        if (associated (mci_work%mci)) then
            call mci_work%mci%write (u, pacify = testflag)
            call mci_work%counter%write (u)
        end if
    end subroutine mci_work_write

```

The `mci` component may require finalization.

```

<Processes: mci work: TBP>+=
    procedure :: final => mci_work_final

```

```

<Processes: procedures>+≡
subroutine mci_work_final (mci_work)
  class(mci_work_t), intent(inout) :: mci_work
  if (associated (mci_work%mci)) then
    call mci_work%mci%final ()
    deallocate (mci_work%mci)
  end if
end subroutine mci_work_final

```

Initialize with the maximum length that we will need. Contents are not initialized.

The integrator inside the `mci_entry` object is responsible for allocating and initializing its own instance, which is referred to by a pointer in the `mci_work` object.

```

<Processes: mci work: TBP>+≡
  procedure :: init => mci_work_init

<Processes: procedures>+≡
subroutine mci_work_init (mci_work, mci_entry)

    counter = mci_work%counter
  end function mci_work_get_counter

```

The process instance

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `count` object records process evaluations, broken down according to status.

The `sqme` value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The `weight` value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the `sqme` value times Jacobian weights from the integration, or unity, respectively.

The `i_mci` index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The `sf_chain` subobject is a realization of the beam and structure-function configuration in the `process` object. It is not used for calculation directly but serves as the template for the sf-chain instances that are contained in the `component` objects.

The `component` subobjects determine the state of each component.

The `term` subobjects are workspace for evaluating kinematics, matrix elements, cuts etc.

The `mci_work` subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the `mci_work` array is selected by the `i_mci` index above.

```

<Processes: public>+≡
    public :: process_instance_t

<Processes: types>+≡
    type, extends (mci_sampler_t) :: process_instance_t
        type(process_t), pointer :: process => null ()
        integer :: evaluation_status = STAT_UNDEFINED
        real(default) :: sqme = 0

    contains
        <Processes: process instance: TBP>
    end type process_instance_t

```

The output routine contains a header with the most relevant information about the process, copied from `process_metadata_write`. We mark the active components by an asterisk.

The next section is the MC parameter input. The following sections are written only if the evaluation status is beyond setting the parameters, or if the `verbose` option is set.

```

Initialization connects the instance with a process. All initial information is transferred from the process object. The process object contains templates for the interaction subobjects (beam and term), but no evaluators. The initialization routine creates evaluators for the matrix element trace, other evaluators are left untouched.

The `instance` object must have the `target` attribute (also in any caller) since the initialization routine assigns various pointers to subobject of `instance`.

```

Subroutine of the initialization above: initialize the beam and structure-function chain template. We establish pointers to the configuration data, so `beam_config` must have a `target` attribute.

The resulting chain is not used directly for calculation. It will acquire instances which are stored in the process-component instance objects.

```

<Processes: process instance: TBP>+≡
    procedure :: setup_sf_chain => process_instance_setup_sf_chain

<Processes: procedures>+≡
    subroutine process_instance_setup_sf_chain (instance, config)
        class(process_instance_t), intent(inout) :: instance
        type(process_beam_config_t), intent(in), target :: config
        integer :: n_strfun
        n_strfun = config%n_strfun
        if (n_strfun /= 0) then
            call instance%sf_chain%init (config%data, config%sf)
        else
            call instance%sf_chain%init (config%data)
        end if
        if (config%sf_trace) then
            call instance%sf_chain%setup_tracing (config%sf_trace_file)
        end if
    end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

<Processes: process instance: TBP>+≡
    procedure :: setup_event_data => process_instance_setup_event_data

<Processes: procedures>+≡
    subroutine process_instance_setup_event_data (instance, model)
        class(process_instance_t), intent(inout), target :: instance

```

```

class(model_data_t), intent(in), optional, target :: model
class(model_data_t), pointer :: current_model
integer :: i, i_component
if (present (model)) then
    current_model => model
else
    current_model => instance%process%config%model
end if
do i = 1, size (instance%term)
    associate (term => instance%term(i))
        if (associated (term%config)) then
            i_component = term%config%i_component
            associate (component => instance%process%component(i_component))
                call term%setup_event_data (component%core, current_model)
            end associate
        end if
    end associate
end do
end subroutine process_instance_setup_event_data

```

Choose a MC parameter set and the corresponding integrator. The choice persists beyond calls of the `reset` method above. This method is automatically called here.

```

<Processes: process instance: TBP>+≡
    procedure :: choose_mci => process_instance_choose_mci

<Processes: procedures>+≡
    subroutine process_instance_choose_mci (instance, i_mci)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci
        instance%i_mci = i_mci
        call instance%reset ()
    end subroutine process_instance_choose_mci

```

Explicitly set a MC parameter set. Works only if we are in initial state. We assume that the length of the parameter set is correct.

After setting the parameters, activate the components and terms that correspond to the chosen MC parameter set.

```

<Processes: process instance: TBP>+≡
    procedure :: set_mcpair => process_instance_set_mcpair

<Processes: procedures>+≡
    subroutine process_instance_set_mcpair (instance, x)
        class(process_instance_t), intent(inout) :: instance
        real(default), dimension(:), intent(in) :: x
        if (instance%evaluation_status == STAT_INITIAL) then
            associate (mci_work => instance%mci_work(instance%i_mci))
                call mci_work%set (x)
            end associate
            call instance%activate ()
        end if
    end subroutine process_instance_set_mcpair

```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The sf-chain instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```

(Processes: process instance: TBP)+≡
  procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

(Processes: procedures)+≡
  subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%receive_beam_momenta ()
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_receive_beam_momenta

```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```

(Processes: process instance: TBP)+≡
  procedure :: set_beam_momenta => process_instance_set_beam_momenta

(Processes: procedures)+≡
  subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%set_beam_momenta (p)
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_set_beam_momenta

```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```

(Processes: process instance: TBP)+≡
  procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

(Processes: procedures)+≡
  subroutine process_instance_recover_beam_momenta (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    integer :: i
    if (.not. instance%process%beam_config%lab_is_cm_frame) then
      if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
        i = instance%term(i_term)%config%i_component
        call instance%component(i)%return_beam_momenta ()
      end if
    end if
  end subroutine process_instance_recover_beam_momenta

```

```
end subroutine process_instance_recover_beam_momenta
```

Explicitly choose MC integration channel. We assume here that the channel count is identical for all active components.

```
<Processes: process instance: TBP>+≡
  procedure :: select_channel => process_instance_select_channel

<Processes: procedures>+≡
  subroutine process_instance_select_channel (instance, channel)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    instance%selected_channel = channel
  end subroutine process_instance_select_channel
```

First step of process evaluation: set up seed kinematics. That is, for each active process component, compute a momentum array from the MC input parameters.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```
<Processes: process instance: TBP>+≡
  procedure :: compute_seed_kinematics => &
    process_instance_compute_seed_kinematics

<Processes: procedures>+≡
  subroutine process_instance_compute_seed_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: channel, skip_component, i
    logical :: success
    channel = instance%selected_channel
    if (channel == 0) then
      call msg_bug ("Compute seed kinematics: undefined integration channel")
    end if
    if (present (skip_term)) then
      skip_component = instance%term(skip_term)%config%i_component
    else
      skip_component = 0
    end if
    if (instance%evaluation_status >= STAT_ACTIVATED) then
      success = .true.
      do i = 1, size (instance%component)
        if (i == skip_component) cycle
        if (instance%component(i)%active) then
          call instance%component(i)%compute_seed_kinematics &
            (instance%mci_work(instance%i_mci), channel, success)
          if (.not. success) exit
        end if
      end do
      if (success) then
        instance%evaluation_status = STAT_SEED_KINEMATICS
      else
        instance%evaluation_status = STAT_FAILED_KINEMATICS
      end if
    end if
```

```

end if
associate (mci_work => instance%mci_work(instance%i_mci))
  if (mci_work%config%combined_integration) &
    call instance%nlo_controller%set_x_rad (mci_work%get_x_process ())
  end associate
end subroutine process_instance_compute_seed_kinematics

```

Inverse: recover missing parts of the kinematics from the momentum configuration, which we know for a single term and component. Given a channel, reconstruct the MC parameter set.

```

<Processes: process instance: TBP>+≡
  procedure :: recover_mcpair => process_instance_recover_mcpair
<Processes: procedures>+≡
  subroutine process_instance_recover_mcpair (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    integer :: channel
    integer :: i
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
      channel = instance%selected_channel
      if (channel == 0) then
        call msg_bug ("Recover MC parameters: undefined integration channel")
      end if
      i = instance%term(i_term)%config%i_component
      call instance%component(i)%recover_mcpair &
        (instance%mci_work(instance%i_mci), channel)
    end if
  end subroutine process_instance_recover_mcpair

```

Second step of process evaluation: compute all momenta, for all active components, from the seed kinematics.

```

<Processes: process instance: TBP>+≡
  procedure :: compute_hard_kinematics => &
    process_instance_compute_hard_kinematics
<Processes: procedures>+≡
  subroutine process_instance_compute_hard_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: i
    logical :: real_phsp
    if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
      do i = 1, size (instance%component)
        if (instance%component(i)%active) then
          select case (instance%component(i)%config%config%get_nlo_type())
            case (BORN, NLO_VIRTUAL, NLO_PDF)
              real_phsp = .false.
            case (NLO_REAL)
              real_phsp = .true.
          end select
          call instance%component(i)% &
            compute_hard_kinematics (instance%term, skip_term, real_phsp)
        end if
      end do
    end if
  end subroutine process_instance_compute_hard_kinematics

```

```

        end do
        instance%evaluation_status = STAT_HARD_KINEMATICS
    end if
end subroutine process_instance_compute_hard_kinematics

```

Inverse: recover seed kinematics. We know the beam momentum configuration and the outgoing momenta of the effective interaction, for one specific term.

```

⟨Processes: process instance: TBP⟩+≡
    procedure :: recover_seed_kinematics => &
        process_instance_recover_seed_kinematics

⟨Processes: procedures⟩+≡
    subroutine process_instance_recover_seed_kinematics (instance, i_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_term
        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
            associate (i_component => instance%term(i_term)%config%i_component)
                call instance%component(i_component)% &
                    recover_seed_kinematics (instance%term(i_term))
            end associate
        end if
    end subroutine process_instance_recover_seed_kinematics

```

Third step of process evaluation: compute the effective momentum configurations, for all active terms, from the hard kinematics.

```

⟨Processes: process instance: TBP⟩+≡
    procedure :: compute_eff_kinematics => &
        process_instance_compute_eff_kinematics

⟨Processes: procedures⟩+≡
    subroutine process_instance_compute_eff_kinematics (instance, skip_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in), optional :: skip_term
        integer :: i
        if (instance%evaluation_status >= STAT_HARD_KINEMATICS) then
            do i = 1, size (instance%term)
                if (present (skip_term)) then
                    if (i == skip_term) cycle
                end if
                if (instance%term(i)%active) then
                    call instance%term(i)% &
                        compute_eff_kinematics (instance%component)
                end if
            end do
            instance%evaluation_status = STAT_EFF_KINEMATICS
        end if
    end subroutine process_instance_compute_eff_kinematics

```

Inverse: recover the hard kinematics from effective kinematics for one term, then compute effective kinematics for the other terms.

```

⟨Processes: process instance: TBP⟩+≡
    procedure :: recover_hard_kinematics => &
        process_instance_recover_hard_kinematics

```

```

<Processes: procedures>+≡
subroutine process_instance_recover_hard_kinematics (instance, i_term)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_term
  integer :: i
  if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
    call instance%term(i_term)%recover_hard_kinematics (instance%component)
    do i = 1, size (instance%term)
      if (i /= i_term) then
        if (instance%term(i)%active) then
          call instance%term(i)% &
            compute_eff_kinematics (instance%component)
        end if
      end if
    end do
    instance%evaluation_status = STAT_EFF_KINEMATICS
  end if
end subroutine process_instance_recover_hard_kinematics

```

Fourth step of process evaluation: check cuts for all terms. Where successful, compute any scales and weights. Otherwise, deactivate the term. If any of the terms has passed, set the state to STAT_PASSED_CUTS.

The argument `scale_forced`, if present, will override the scale calculation in the term expressions.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate_expressions => &
    process_instance_evaluate_expressions

<Processes: procedures>+≡
subroutine process_instance_evaluate_expressions (instance, scale_forced)
  class(process_instance_t), intent(inout) :: instance
  real(default), intent(in), allocatable, optional :: scale_forced
  integer :: i
  if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
    do i = 1, size (instance%term)
      if (instance%term(i)%active) then
        call instance%term(i)%evaluate_expressions (scale_forced)
      end if
    end do
    if (any (instance%term%passed)) then
      instance%evaluation_status = STAT_PASSED_CUTS
    else
      instance%evaluation_status = STAT_FAILED_CUTS
    end if
  end if
end subroutine process_instance_evaluate_expressions

```

Fifth step of process evaluation: fill the parameters for the non-selected channels, that have not been used for seeding. We should do this after evaluating cuts, since we may save some expensive calculations if the phase space point fails the cuts.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just

computing the rest.

```

(Processes: process instance: TBP)+≡
  procedure :: compute_other_channels => &
    process_instance_compute_other_channels

(Processes: procedures)+≡
  subroutine process_instance_compute_other_channels (instance, skip_term)

else
    ! failed kinematics, failed cuts: set sqme to zero
    instance%sqme = 0
end if
end if
end subroutine process_instance_evaluate_trace

```

Final step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

If **weight** is provided, we already know the kinematical event weight (the MCI weight which depends on the kinematics sampling algorithm, but not on the matrix element), so we do not need to take it from the MCI record.

(Processes: process instance: TBP)+≡

      instance%sqme = instance%sqme_collector%get_sqme_sum ()
  end subroutine process_instance_evaluate_sqme

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows

us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

```

<Processes: process instance: TBP>+≡
  procedure :: recover => process_instance_recover
<Processes: procedures>+≡
  subroutine process_instance_recover &
    (instance, channel, i_term, update_sqme, scale_forced)

```

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the x array, and the f Jacobian array are exposed by the `sampler_t` object.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate => process_instance_evaluate
<Processes: procedures>+≡
  subroutine process_instance_evaluate (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call sampler%evaluate_sqme (c, x_in)
    if (sampler%is_valid ()) call sampler%fetch (val, x, f)
    call sampler%record_call ()
  end subroutine process_instance_evaluate

```

The phase-space point is valid if the event has valid kinematics and has passed the cuts.

```

<Processes: process instance: TBP>+≡
  procedure :: is_valid => process_instance_is_valid

```

```

<Processes: procedures>+≡
  function process_instance_is_valid (sampler) result (valid)
    class(process_instance_t), intent(in) :: sampler
    logical :: valid
    valid = sampler%evaluation_status >= STAT_PASSED_CUTS
  end function process_instance_is_valid

```

The `rebuild` method should rebuild the kinematics section out of the `x_in` parameter set. The integrand value `val` should not be computed, but is provided as input.

```

<Processes: process instance: TBP>+≡
  procedure :: rebuild => process_instance_rebuild

<Processes: procedures>+≡
  subroutine process_instance_rebuild (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c

end function process_instance_get_counter

```

28.3.13 Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

NB: The `recover_beams` option should be used only when the particle set originates from an external event file, and the user has asked for it. It should be switched off when reading from raw event file.

```

(Processes: process instance: TBP)+≡
  procedure :: get_trace => process_instance_get_trace
  procedure :: set_trace => process_instance_set_trace

(Processes: procedures)+≡
  subroutine process_instance_get_trace (instance, pset, i_term)

Test process type

For the following tests, we define a simple implementation of the abstract `prc_core_t`, designed such as to complement the `prc_test_t` process definition type.

Note that it is not given that the actual process is defined as `prc_test_t` type. We enforce this by calling `prc_test_create_library`. The driver component in the process core will then become of type `prc_test_t`.

```

Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```
(Processes: execute tests)+≡

28.4 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

```

<process_stacks.f90>≡
  <File header>

  module process_stacks

    <Use strings>
    use io_units
    use format_utils, only: write_separator
    use diagnostics
    use os_interface
    use sm_qcd
    use model_data
    use rng_base
    use variables
    use observables
    use process_libraries
    use prc_test, only: prc_test_create_library
    use processes

    <Standard module head>

    <Process stacks: public>

```

```

    <Process stacks: types>

contains

    <Process stacks: procedures>

end module process_stacks

```

28.4.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```

<Process stacks: public>≡
    public :: process_entry_t

<Process stacks: types>≡
    type, extends (process_t) :: process_entry_t
        type(process_entry_t), pointer :: next => null ()
    end type process_entry_t

```

28.4.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

The process stack can be linked to another one. This allows us to work with stacks of local scope.

```

<Process stacks: public>+≡
    public :: process_stack_t

<Process stacks: types>+≡
    type :: process_stack_t
        integer :: n = 0
        type(process_entry_t), pointer :: first => null ()
        type(var_list_t), pointer :: var_list => null ()
        type(process_stack_t), pointer :: next => null ()
    contains
        <Process stacks: process stack: TBP>
    end type process_stack_t

```

Finalize partly: deallocate the process stack and variable list entries, but keep the variable list as an empty object. This way, the variable list links are kept.

```

<Process stacks: process stack: TBP>≡
    procedure :: clear => process_stack_clear

<Process stacks: procedures>≡
    subroutine process_stack_clear (stack)
        class(process_stack_t), intent(inout) :: stack
        type(process_entry_t), pointer :: process
        if (associated (stack%var_list)) then

```

```

        call stack%var_list%final ()
    end if
    do while (associated (stack%first))
        process => stack%first
        stack%first => process%next
        call process%final ()
        deallocate (process)
    end do
    stack%n = 0
end subroutine process_stack_clear

```

Finalizer. Clear and deallocate the variable list.

```

<Process stacks: process stack: TBP>+≡
    procedure :: final => process_stack_final

<Process stacks: procedures>+≡
    subroutine process_stack_final (object)
        class(process_stack_t), intent(inout) :: object
        call object%clear ()
        if (associated (object%var_list)) then
            deallocate (object%var_list)
        end if
    end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write => process_stack_write

<Process stacks: procedures>+≡
    recursive subroutine process_stack_write (object, unit, pacify)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: pacify
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)
        call write_separator (u, 2)
        select case (object%n)
        case (0)
            write (u, "(1x,A)") "Process stack: [empty]"
            call write_separator (u, 2)
        case default
            write (u, "(1x,A)") "Process stack:"
            process => object%first
            do while (associated (process))
                call process%write (.false., u, pacify = pacify)
                process => process%next
            end do
        end select
        if (associated (object%next)) then
            write (u, "(1x,A)") "[Processes from context environment:]"
            call object%next%write (u, pacify)
        end if
    end subroutine process_stack_write

```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write_var_list => process_stack_write_var_list

<Process stacks: procedures>+≡
    subroutine process_stack_write_var_list (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        if (associated (object%var_list)) then
            call var_list_write (object%var_list, unit)
        end if
    end subroutine process_stack_write_var_list

```

Short output.

```

<Process stacks: process stack: TBP>+≡
    procedure :: show => process_stack_show

<Process stacks: procedures>+≡
    recursive subroutine process_stack_show (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)
        select case (object%n)
            case (0)
            case default
                process => object%first
                do while (associated (process))
                    call process%show (u, verbose=.false.)
                    process => process%next
                end do
            end select
            if (associated (object%next)) call object%next%show ()
        end subroutine process_stack_show

```

28.4.3 Link

Link the current process stack to a global one.

```

<Process stacks: process stack: TBP>+≡
    procedure :: link => process_stack_link

<Process stacks: procedures>+≡
    subroutine process_stack_link (local_stack, global_stack)
        class(process_stack_t), intent(inout) :: local_stack
        type(process_stack_t), intent(in), target :: global_stack
        local_stack%next => global_stack
    end subroutine process_stack_link

```

Initialize the process variable list and link the main variable list to it.

```

(Process stacks: process stack: TBP)+≡
  procedure :: init_var_list => process_stack_init_var_list

(Process stacks: procedures)+≡
  subroutine process_stack_init_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(inout), optional :: var_list
    allocate (stack%var_list)
    if (present (var_list)) call var_list%link (stack%var_list)
  end subroutine process_stack_init_var_list

```

Link the process variable list to a global variable list.

```

(Process stacks: process stack: TBP)+≡
  procedure :: link_var_list => process_stack_link_var_list

(Process stacks: procedures)+≡
  subroutine process_stack_link_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in), target :: var_list
    call stack%var_list%link (var_list)
  end subroutine process_stack_link_var_list

```

28.4.4 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

(Process stacks: process stack: TBP)+≡
  procedure :: push => process_stack_push

(Process stacks: procedures)+≡
  subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    process%next => stack%first
    stack%first => process
    process => null ()
    stack%n = stack%n + 1
  end subroutine process_stack_push

```

Initialize process variables for a given process ID, without setting values.

```

(Process stacks: process stack: TBP)+≡
  procedure :: init_result_vars => process_stack_init_result_vars

(Process stacks: procedures)+≡
  subroutine process_stack_init_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    call var_list_init_num_id (stack%var_list, id)
    call var_list_init_process_results (stack%var_list, id)
  end subroutine process_stack_init_result_vars

```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```

(Process stacks: process stack: TBP)+≡
  procedure :: fill_result_vars => process_stack_fill_result_vars

(Process stacks: procedures)+≡
  subroutine process_stack_fill_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    type(process_t), pointer :: process
    process => stack%get_process_ptr (id)
    if (associated (process)) then
      call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
      if (process%has_integral ()) then
        call var_list_init_process_results (stack%var_list, id, &
          integral = process%get_integral (), &
          error = process%get_error ())
      end if
    else
      call msg_bug ("process_stack_fill_result_vars: unknown process ID")
    end if
  end subroutine process_stack_fill_result_vars

```

28.4.5 Data Access

Tell if a process exists.

```

(Process stacks: process stack: TBP)+≡
  procedure :: exists => process_stack_exists

(Process stacks: procedures)+≡
  function process_stack_exists (stack, id) result (flag)
    class(process_stack_t), intent(in) :: stack
    type(string_t), intent(in) :: id
    logical :: flag
    type(process_t), pointer :: process
    process => stack%get_process_ptr (id)
    flag = associated (process)
  end function process_stack_exists

```

Return a pointer to a process with specific ID. Look also at a linked stack, if necessary.

```

(Process stacks: process stack: TBP)+≡
  procedure :: get_process_ptr => process_stack_get_process_ptr

(Process stacks: procedures)+≡
  recursive function process_stack_get_process_ptr (stack, id) result (ptr)
    class(process_stack_t), intent(in) :: stack
    type(string_t), intent(in) :: id
    type(process_t), pointer :: ptr
    type(process_entry_t), pointer :: entry
    ptr => null ()

```

```

entry => stack%first
do while (associated (entry))
  if (entry%get_id () == id) then
    ptr => entry%process_t
    return
  end if
  entry => entry%next
end do
if (associated (stack%next)) ptr => stack%next%get_process_ptr (id)
end function process_stack_get_process_ptr

```

28.4.6 Unit tests

Test module, followed by the corresponding implementation module.

`<process_stacks_ut.f90>`≡

Chapter 29

Event Implementation

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

event_transforms Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

decays Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

showers Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

tau_decays (not implemented yet) Let τ leptons decay taking full spin correlations into account.

events Combine all pieces to generate full events.

eio_raw Raw I/O for complete events.

29.1 Abstract Event Transforms

```
(event_transforms.f90)≡  
  <File header>
```

```
  module event_transforms
```

```
    <Use kinds>  
    <Use strings>
```

```

use io_units
use format_utils, only: write_separator
use diagnostics
use model_data
use interactions
use particles
use subevents
use rng_base
use processes
use process_stacks

<Standard module head>

<Event transforms: public>

<Event transforms: types>

<Event transforms: interfaces>

contains

<Event transforms: procedures>

end module event_transforms

```

29.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified settings that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include `previous` and `next` pointers.

```

<Event transforms: public>≡
    public :: evt_t

<Event transforms: types>≡
    type, abstract :: evt_t
        type(process_t), pointer :: process => null ()
        type(process_instance_t), pointer :: process_instance => null ()
        class(model_data_t), pointer :: model => null ()
        class(rng_t), allocatable :: rng
        integer :: rejection_count = 0
        logical :: particle_set_exists = .false.
        type(particle_set_t) :: particle_set
        class(evt_t), pointer :: previous => null ()
        class(evt_t), pointer :: next => null ()
        real(default) :: weight = 0._default
        logical :: only_weighted_events = .false.

```

```

contains
  <Event transforms: evt: TBP>
end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡
  procedure :: final => evt_final
  procedure :: base_final => evt_final

<Event transforms: procedures>≡
  subroutine evt_final (evt)
    class(evt_t), intent(inout) :: evt
    if (allocated (evt%rng)) call evt%rng%final ()
    if (evt%particle_set_exists) &
      call evt%particle_set%final ()
  end subroutine evt_final

<Event transforms: evt: TBP>+≡
  procedure (evt_write), deferred :: write

<Event transforms: interfaces>≡
  abstract interface
    subroutine evt_write (evt, unit, verbose, more_verbose, testflag)
      import
      class(evt_t), intent(in) :: evt
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose, more_verbose, testflag
    end subroutine evt_write
  end interface

```

Output. We can print r.n.g. info.

```

<Event transforms: evt: TBP>+≡
  procedure :: base_write => evt_base_write

<Event transforms: procedures>+≡
  subroutine evt_base_write (evt, unit, testflag, show_set)
    class(evt_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag, show_set
    integer :: u
    logical :: show
    u = given_output_unit (unit)
    show = .true.; if (present (show_set)) show = show_set
    if (associated (evt%process)) then
      write (u, "(3x,A,A,A)") "Associated process: '", &
        char (evt%process%get_id ()), "'"
    end if
    if (allocated (evt%rng)) then
      call evt%rng%write (u, 1)
      write (u, "(3x,A,I0)") "Number of tries = ", evt%rejection_count
    end if
    if (show) then
      if (evt%particle_set_exists) then

```

```

        call write_separator (u)
        call evt%particle_set%write (u, testflag = testflag)
    end if
end if
end subroutine evt_base_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

```

<Event transforms: evt: TBP>+≡
    procedure :: connect => evt_connect
    procedure :: base_connect => evt_connect

<Event transforms: procedures>+≡
    subroutine evt_connect (evt, process_instance, model, process_stack)
        class(evt_t), intent(inout), target :: evt
        type(process_instance_t), intent(in), target :: process_instance
        class(model_data_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        evt%process => process_instance%process
        evt%process_instance => process_instance
        evt%model => model
        call evt%process%make_rng (evt%rng)
    end subroutine evt_connect

```

Reset internal state.

```

<Event transforms: evt: TBP>+≡
    procedure :: reset => evt_reset
    procedure :: base_reset => evt_reset

<Event transforms: procedures>+≡
    subroutine evt_reset (evt)
        class(evt_t), intent(inout) :: evt
        evt%rejection_count = 0
        evt%particle_set_exists = .false.
    end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

<Event transforms: evt: TBP>+≡
    procedure (evt_prepare_new_event), deferred :: prepare_new_event

<Event transforms: interfaces>+≡
    interface
        subroutine evt_prepare_new_event (evt, i_mci, i_term)
            import
            class(evt_t), intent(inout) :: evt
            integer, intent(in) :: i_mci, i_term
        end subroutine evt_prepare_new_event
    end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)
      import
      class(evt_t), intent(inout) :: evt
      real(default), intent(inout) :: probability
    end subroutine evt_generate_weighted
  end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted

(Event transforms: procedures)+≡
  subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set

(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
  end interface

```

```

        integer, intent(in) :: factorization_mode
        logical, intent(in) :: keep_correlations
        real(default), dimension(:), intent(in), optional :: r
    end subroutine evt_make_particle_set
end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

<Event transforms: evt: TBP>+≡
    procedure :: set_particle_set => evt_set_particle_set

<Event transforms: procedures>+≡
    subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
        class(evt_t), intent(inout) :: evt
        type(particle_set_t), intent(in) :: particle_set
        integer, intent(in) :: i_term, i_mci
        call evt%prepare_new_event (i_mci, i_term)
        evt%particle_set = particle_set
        evt%particle_set_exists = .true.
    end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. (We need two interactions, one with color summed over, and one with the probability distributed among flows.)

We use the two values from the random number generator for factorizing the state. For testing purposes, we can provide those numbers explicitly.

```

<Event transforms: evt: TBP>+≡
    procedure :: factorize_interactions => evt_factorize_interactions

<Event transforms: procedures>+≡
    subroutine evt_factorize_interactions &
        (evt, int_matrix, int_flows, factorization_mode, keep_correlations, r)
        class(evt_t), intent(inout) :: evt
        type(interaction_t), intent(in), target :: int_matrix, int_flows
        integer, intent(in) :: factorization_mode
        logical, intent(in) :: keep_correlations
        real(default), dimension(:), intent(in), optional :: r
        real(default), dimension(2) :: x
        if (present (r)) then
            if (size (r) == 2) then
                x = r
            else
                call msg_bug ("event factorization: size of r array must be 2")
            end if
        else
            call evt%rng%generate (x)
        end if
        call evt%particle_set%init (evt%particle_set_exists, &
            int_matrix, int_flows, factorization_mode, x, &
            keep_correlations, keep_virtual=.true.)
        evt%particle_set_exists = .true.
    end subroutine evt_factorize_interactions

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

```

<Event transforms: evt: TBP>+≡
  procedure :: tag_incoming => evt_tag_incoming

<Event transforms: procedures>+≡
  subroutine evt_tag_incoming (evt)
    class(evt_t), intent(inout) :: evt
    integer :: i_term, n_in
    integer, dimension(:), allocatable :: beam_index, in_index
    n_in = evt%process%get_n_in ()
    i_term = 1
    allocate (beam_index (n_in))
    call evt%process_instance%get_beam_index (i_term, beam_index)
    call evt%particle_set%reset_status (beam_index, PRT_BEAM)
    allocate (in_index (n_in))
    call evt%process_instance%get_in_index (i_term, in_index)
    call evt%particle_set%reset_status (in_index, PRT_INCOMING)
  end subroutine evt_tag_incoming

```

29.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

<Event transforms: public>+≡
  public :: evt_trivial_t

<Event transforms: types>+≡
  type, extends (evt_t) :: evt_trivial_t
    contains
    <Event transforms: evt trivial: TBP>
  end type evt_trivial_t

```

The finalizer is trivial. Some output:

```

<Event transforms: evt trivial: TBP>≡
  procedure :: write => evt_trivial_write

<Event transforms: procedures>+≡
  subroutine evt_trivial_write (evt, unit, verbose, more_verbose, testflag)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, more_verbose, testflag
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    write (u, "(1x,A)") "Event transform: trivial (hard process)"
  end subroutine evt_trivial_write

```

```

        call write_separator (u)
        call evt%base_write (u, testflag = testflag)
    end subroutine evt_trivial_write

```

Nothing to do here:

```

<Event transforms: evt trivial: TBP>+≡
    procedure :: prepare_new_event => evt_trivial_prepare_new_event

<Event transforms: procedures>+≡
    subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
        class(evt_trivial_t), intent(inout) :: evt
        integer, intent(in) :: i_mci, i_term
        call evt%reset ()
    end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

<Event transforms: evt trivial: TBP>+≡
    procedure :: generate_weighted => evt_trivial_generate_weighted

<Event transforms: procedures>+≡
    subroutine evt_trivial_generate_weighted (evt, probability)
        class(evt_trivial_t), intent(inout) :: evt
        real(default), intent(inout) :: probability
        probability = 1
    end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is.

```

<Event transforms: evt trivial: TBP>+≡
    procedure :: make_particle_set => evt_trivial_make_particle_set

<Event transforms: procedures>+≡
    subroutine evt_trivial_make_particle_set &
        (evt, factorization_mode, keep_correlations, r)
        class(evt_trivial_t), intent(inout) :: evt
        integer, intent(in) :: factorization_mode
        logical, intent(in) :: keep_correlations
        real(default), dimension(:), intent(in), optional :: r
        integer :: i_term
        type(interaction_t), pointer :: int_matrix, int_flows
        if (evt%process_instance%is_complete_event ()) then
            call evt%process_instance%select_i_term (i_term)
            int_matrix => evt%process_instance%get_matrix_int_ptr (i_term)
            int_flows => evt%process_instance%get_flows_int_ptr (i_term)
            call evt%factorize_interactions (int_matrix, int_flows, &
                factorization_mode, keep_correlations, r)
            call evt%tag_incoming ()
        else
            call msg_bug ("Event factorization: event is incomplete")
        end if
    end subroutine evt_trivial_make_particle_set

```

29.2.5 Hadronization Event Transform

This is the type for the hadronization event transform. It does not depend on the specific hadronization implementation of `hadrons_t`.

```

<Hadrons: public>+≡
  public :: evt_hadrons_t

<Hadrons: types>+≡
  type, extends (evt_t) :: evt_hadrons_t
    class(hadrons_t), allocatable :: hadrons
    type(shower_settings_t) :: settings
    type(model_t), pointer :: model_hadrons => null()
    type(qcd_t), pointer :: qcd_t => null()
  contains
    <Hadrons: evt hadrons: TBP>
  end type evt_hadrons_t

```

Initialize the parameters. The `model_hadrons` is supposed to be the SM variant that contains all hadrons that may be generated in the shower.

```

<Hadrons: evt hadrons: TBP>≡
  procedure :: init => evt_hadrons_init

<Hadrons: procedures>+≡

```

Here we take the particle set from the previous event transform and apply the hadronization. The result is stored in the `evt%hadrons` object. We always return a probability of unity as we don't have the analytic weight of the hadronization. Invalid events have to be discarded by the caller which is why we mark the particle set as invalid.

```

29.4.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

<Decays: types>≡
    type, abstract :: any_config_t
        private
        contains
        <Decays: any config: TBP>
    end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
    procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
    interface
        subroutine any_config_final (object)
            import
            class(any_config_t), intent(inout) :: object
        end subroutine any_config_final
    end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
    procedure (any_config_write), deferred :: write

```

```

<Decays: interfaces>+≡
  interface
    subroutine any_config_write (object, unit, indent, verbose)
      import
      class(any_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
    end subroutine any_config_write
  end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_config_t
  private
    class(any_config_t), allocatable :: c
  end type particle_config_t

```

29.4.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above. This also works around a compiler bug in gfortran.

```

<Decays: types>+≡
  type, abstract :: any_t
  private
  contains
    <Decays: any: TBP>
  end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final
<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
      class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write
<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
      import

```

```

        class(any_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
    end subroutine any_write
end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
    type :: particle_out_t
    private
    class(any_t), allocatable :: c
end type particle_out_t

```

29.4.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+≡
    type :: decay_term_config_t
    private
    type(particle_config_t), dimension(:), allocatable :: prt
    contains
    <Decays: decay term config: TBP>
end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>≡
    procedure :: final => decay_term_config_final

<Decays: procedures>≡
    recursive subroutine decay_term_config_final (object)
    class(decay_term_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%prt)) then
        do i = 1, size (object%prt)
            if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
        end do
    end if
end subroutine decay_term_config_final

```

Output, with optional indentation

```

<Decays: decay term config: TBP>+≡
    procedure :: write => decay_term_config_write

<Decays: procedures>+≡
    recursive subroutine decay_term_config_write (object, unit, indent, verbose)
    class(decay_term_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: i, j, u, ind

```

```

logical :: verb
u = given_output_unit (unit)
ind = 0; if (present (indent)) ind = indent
verb = .true.; if (present (verbose)) verb = verbose
call write_indent (u, ind)
write (u, "(1x,A)", advance="no") "Final state:"

end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

For the unstable particles, we have to check whether their masses match between the production and the decay. Fortunately, both versions are available for comparison.

29.4.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```

<Decays: types>+≡
    type, abstract :: decay_gen_t
    private
    type(decay_term_t), dimension(:), allocatable :: term
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_mci = 0

```

```

        integer :: selected_term = 0
contains
  <Decays: decay gen: TBP>
end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

<Decays: public>+≡
  public :: decay_root_t

<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_root_t
  private
    type(decay_root_config_t), pointer :: config => null ()
contains
  <Decays: decay root: TBP>
end type decay_root_t

```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```

<Decays: decay gen: TBP>≡
  procedure :: base_final => decay_gen_final

<Decays: procedures>+≡
  recursive subroutine decay_gen_final (object)
    class(decay_gen_t), intent(inout) :: object

    else
      call msg_bug ("Decays: no term selected for parent process")
    end if
  end subroutine decay_root_generate

```

29.4.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

The flavor component should be identical to the flavor component of the parent particle (`unstable` object).

```

<Decays: types>+≡
  type, extends (decay_root_config_t) :: decay_config_t
  private
  type(flavor_t) :: flv
  real(default) :: weight = 0
  real(default) :: integral = 0
  real(default) :: abs_error = 0
  real(default) :: rel_error = 0
  type(selector_t) :: mci_selector
  contains
  <Decays: decay config: TBP>
  end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
  procedure :: write => decay_config_write

```

<Decays: procedures>+≡

```

recursive subroutine decay_config_write (object, unit, indent, verbose)
  class(decay_config_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent
  logical, intent(in), optional :: verbose
  integer :: u, ind
  u = given_output_unit (unit)
  ind = 0; if (present (indent)) ind = indent
  call write_indent (u, ind)
  write (u, "(1x,A)") "Decay:"

```

29.4.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_t
  private
  type(decay_config_t), pointer :: config => null ()
  class(rng_t), allocatable :: rng
  contains
  <Decays: decay: TBP>
end type decay_t

```

The finalizer is recursive.

```

<Decays: decay: TBP>≡
  procedure :: final => decay_final

```

```

<Decays: procedures>+≡
recursive subroutine decay_final (object)
  class(decay_t), intent(inout) :: object
  integer :: i
  call object%base_final ()
  do i = 1, object%config%process%get_n_mci ()
    call object%process_instance%final_simulation (i)
  end do
  call object%process_instance%final ()
  deallocate (object%process_instance)
end subroutine decay_final

```

Output.

```

<Decays: decay: TBP>+≡
  procedure :: write => decay_write

<Decays: procedures>+≡
recursive subroutine decay_write (object, unit, indent, recursive)
  class(decay_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent, recursive
  integer :: u, ind
  u = given_output_unit (unit)
  ind = 0; if (present (indent)) ind = indent
  call object%config%write (unit, indent, verbose = .false.)
  if (allocated (object%rng)) then
    call object%rng%write (u, ind + 1)
  end if
  call write_indent (u, ind)
  if (object%selected_mci > 0) then
    write (u, "(3x,A,I0)") "Selected MCI      = ", object%selected_mci
  else
    write (u, "(3x,A)") "Selected MCI      = [undefined]"
  end if
  call write_indent (u, ind)
  if (object%selected_term > 0) then
    write (u, "(3x,A,I0)") "Selected term   = ", object%selected_term
    call object%term(object%selected_term)%write (u, ind + 1)
  else
    write (u, "(3x,A)") "Selected term   = [undefined]"
  end if
end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
  procedure :: init => decay_init

<Decays: procedures>+≡
recursive subroutine decay_init (decay, config)
  class(decay_t), intent(out) :: decay
  type(decay_config_t), intent(in), target :: config
  integer :: i

```

```

call decay%base_init (config%term_config)
decay%config => config
allocate (decay%process_instance)
call decay%process_instance%init (decay%config%process)
call decay%process_instance%setup_event_data (decay%config%model)
do i = 1, decay%config%process%get_n_mci ()
    call decay%process_instance%init_simulation (i)
end do
call decay%config%process%make_rng (decay%rng)
call decay%make_term_rng (decay%config%process)
end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
    procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
    recursive subroutine decay_link_interactions (decay, i_prt, trace)
        class(decay_t), intent(inout) :: decay
        integer, intent(in) :: i_prt
        type(interaction_t), intent(in), target :: trace
        type(interaction_t), pointer :: beam_int
        integer :: n_in, n_vir
        beam_int => decay%process_instance%get_beam_int_ptr ()
        n_in = trace%get_n_in ()
        n_vir = trace%get_n_vir ()
        call beam_int%set_source_link (1, trace, &
            n_in + n_vir + i_prt)
        call decay%link_term_interactions ()
    end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
    procedure :: select_chain => decay_select_chain

<Decays: procedures>+≡
    recursive subroutine decay_select_chain (decay)
        class(decay_t), intent(inout) :: decay
        real(default) :: x
        integer :: i
        call decay%rng%generate (x)
        decay%selected_mci = decay%config%mc_selector%select (x)
        call decay%process_instance%choose_mci (decay%selected_mci)
        call decay%process_instance%select_i_term (decay%selected_term)
        do i = 1, size (decay%term)
            call decay%term(i)%select_chain ()
        end do
    end subroutine decay_select_chain

```

```
end subroutine decay_select_chain
```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```
<Decays: decay: TBP>+≡
  procedure :: generate => decay_generate

<Decays: procedures>+≡
  recursive subroutine decay_generate (decay)
    class(decay_t), intent(inout) :: decay
    type(isolated_state_t), pointer :: isolated_state
    integer :: i
    call decay%process_instance%receive_beam_momenta ()
    call decay%config%process%generate_unweighted_event &
      (decay%process_instance, decay%selected_mci)
    if (signal_is_pending ()) return
    call decay%process_instance%evaluate_event_data ()
    isolated_state => &
      decay%process_instance%get_isolated_state_ptr (decay%selected_term)
    call isolated_state%normalize_matrix_by_trace ()
    do i = 1, size (decay%term)
      call decay%term(i)%generate ()
      if (signal_is_pending ()) return
    end do
  end subroutine decay_generate
```

29.4.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```
<Decays: types>+≡
  type, extends (any_config_t) :: stable_config_t
  private
  type(flavor_t), dimension(:), allocatable :: flv
  contains
  <Decays: stable config: TBP>
  end type stable_config_t
```

The finalizer is empty:

```
<Decays: stable config: TBP>≡
  procedure :: final => stable_config_final

<Decays: procedures>+≡
  subroutine stable_config_final (object)
    class(stable_config_t), intent(inout) :: object
  end subroutine stable_config_final
```

Output.

```

<Decays: stable config: TBP>+≡
  procedure :: write => stable_config_write

<Decays: procedures>+≡
  recursive subroutine stable_config_write (object, unit, indent, verbose)
    class(stable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"
    write (u, "(1x,A)", advance = "no") char (object%flv(1)%get_name ())
    do i = 2, size (object%flv)
      write (u, "(:',',A)", advance = "no") &
        char (object%flv(i)%get_name ())
    end do
    write (u, *)
  end subroutine stable_config_write

```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```

<Decays: stable config: TBP>+≡
  procedure :: init => stable_config_init

<Decays: procedures>+≡
  subroutine stable_config_init (config, flv)
    class(stable_config_t), intent(out) :: config
    type(flavor_t), dimension(:), intent(in) :: flv
    integer, dimension (size (flv)) :: pdg
    logical, dimension (size (flv)) :: mask
    integer :: i
    pdg = flv%get_pdg ()
    mask(1) = .true.
    forall (i = 2 : size (pdg))
      mask(i) = all (pdg(i) /= pdg(1:i-1))
    end forall
    allocate (config%flv (count (mask)))
    config%flv = pack (flv, mask)
  end subroutine stable_config_init

```

Here is the corresponding object instance. Except for the pointer to the configuration, there is no content.

```

<Decays: types>+≡
  type, extends (any_t) :: stable_t
    private
    type(stable_config_t), pointer :: config => null ()
  contains
    <Decays: stable: TBP>
  end type stable_t

```

The finalizer does nothing.

```

<Decays: stable: TBP>≡
    procedure :: final => stable_final

<Decays: procedures>+≡
    subroutine stable_final (object)
        class(stable_t), intent(inout) :: object
    end subroutine stable_final

```

We can delegate output to the configuration object.

```

<Decays: stable: TBP>+≡
    procedure :: write => stable_write

<Decays: procedures>+≡
    subroutine stable_write (object, unit, indent)
        class(stable_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        call object%config%write (unit, indent)
    end subroutine stable_write

```

Initializer: just assign the configuration.

```

<Decays: stable: TBP>+≡
    procedure :: init => stable_init

<Decays: procedures>+≡
    subroutine stable_init (stable, config)
        class(stable_t), intent(out) :: stable
        type(stable_config_t), intent(in), target :: config
        stable%config => config
    end subroutine stable_init

```

29.4.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: public>+≡
    public :: unstable_config_t

<Decays: types>+≡
    type, extends (any_config_t) :: unstable_config_t
    private
    type(flavor_t) :: flv
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: selector
    type(decay_config_t), dimension(:), allocatable :: decay_config
contains

```

```

    <Decays: unstable config: TBP>
end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
    procedure :: final => unstable_config_final

<Decays: procedures>+≡
    recursive subroutine unstable_config_final (object)
        class(unstable_config_t), intent(inout) :: object
        integer :: i
        if (allocated (object%decay_config)) then
            do i = 1, size (object%decay_config)
                call object%decay_config(i)%final ()
            end do
        end if
    end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
    procedure :: write => unstable_config_write

<Decays: procedures>+≡
    recursive subroutine unstable_config_write (object, unit, indent, verbose)
        class(unstable_config_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        logical, intent(in), optional :: verbose
        integer :: u, i, ind
        logical :: verb
        u = given_output_unit (unit)
        ind = 0; if (present (indent)) ind = indent
        verb = .true.; if (present (verbose)) verb = verbose
        call write_indent (u, ind)
        write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
            char (object%flv%get_name ())
        call write_indent (u, ind)
        write (u, 1) "total width =", object%integral
        call write_indent (u, ind)
        write (u, 1) "error (abs) =", object%abs_error
        call write_indent (u, ind)
        write (u, 1) "error (rel) =", object%rel_error
1    format (5x,A,ES19.12)
        if (verb .and. allocated (object%decay_config)) then
            do i = 1, size (object%decay_config)
                call object%decay_config(i)%write (u, ind + 1)
            end do
        end if
    end subroutine unstable_config_write

```

Initializer. For the unstable particle, the flavor is unique.

```

<Decays: unstable config: TBP>+≡
    procedure :: init => unstable_config_init

```

```

<Decays: procedures>+≡
  subroutine unstable_config_init (unstable, flv, set_decays, model)
    class(unstable_config_t), intent(out) :: unstable
    type(flavor_t), intent(in) :: flv
    logical, intent(in), optional :: set_decays
    class(model_data_t), intent(in), optional, target :: model
    type(string_t), dimension(:), allocatable :: decay
    unstable%flv = flv
    if (present (set_decays)) then
      call unstable%flv%get_decays (decay)
      call unstable%init_decays (decay, model)
    end if
  end subroutine unstable_config_init

```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```

<Decays: unstable config: TBP>+≡
  procedure :: init_decays => unstable_config_init_decays

<Decays: procedures>+≡
  recursive subroutine unstable_config_init_decays &
    (unstable, decay_id, model, process_stack)
    class(unstable_config_t), intent(inout) :: unstable
    type(string_t), dimension(:), intent(in) :: decay_id
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    integer :: i
    allocate (unstable%decay_config (size (decay_id)))
    do i = 1, size (decay_id)
      associate (decay => unstable%decay_config(i))
        if (present (process_stack)) then
          call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
            model, process_stack)
        else
          call decay%init (model, decay_id(i))
        end if
        call decay%set_flv (unstable%flv)
      end associate
    end do
  end subroutine unstable_config_init_decays

```

Explicitly connect a specific decay with a process. This is used only in unit tests.

```

<Decays: unstable config: TBP>+≡
  procedure :: connect_decay => unstable_config_connect_decay

<Decays: procedures>+≡
  subroutine unstable_config_connect_decay (unstable, i, process, model)
    class(unstable_config_t), intent(inout) :: unstable
    integer, intent(in) :: i
    type(process_t), intent(in), target :: process

```

```

class(model_data_t), intent(in), target :: model
associate (decay => unstable%decay_config(i))
    call decay%connect (process, model)
end associate
end subroutine unstable_config_connect_decay

```

Compute the total width and branching ratios, initializing the decay selector.

```

<Decays: unstable config: TBP>+≡
    procedure :: compute => unstable_config_compute

<Decays: procedures>+≡
    recursive subroutine unstable_config_compute (unstable)
        class(unstable_config_t), intent(inout) :: unstable
        integer :: i
        do i = 1, size (unstable%decay_config)
            call unstable%decay_config(i)%compute ()
        end do
        unstable%integral = sum (unstable%decay_config%integral)
        if (unstable%integral <= 0) then
            call unstable%write ()
            call msg_fatal ("Decay configuration: computed total width is zero")
        end if
        unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
        unstable%rel_error = unstable%abs_error / unstable%integral
        call unstable%selector%init (unstable%decay_config%integral)
        do i = 1, size (unstable%decay_config)
            unstable%decay_config(i)%weight &
                = unstable%selector%get_weight (i)
        end do
    end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: public>+≡
    public :: unstable_t

<Decays: types>+≡
    type, extends (any_t) :: unstable_t
        private
        type(unstable_config_t), pointer :: config => null ()
        class(rng_t), allocatable :: rng
        integer :: selected_decay = 0
        type(decay_t), dimension(:), allocatable :: decay
    contains
        <Decays: unstable: TBP>
    end type unstable_t

```

Recursive finalizer.

```

<Decays: unstable: TBP>≡
    procedure :: final => unstable_final

    end subroutine unstable_link_interactions

```

Import the random-number generator state.

```

<Decays: unstable: TBP>+≡
    procedure :: import_rng => unstable_import_rng

<Decays: procedures>+≡
    subroutine unstable_import_rng (unstable, rng)
        class(unstable_t), intent(inout) :: unstable
        class(rng_t), intent(inout), allocatable :: rng
        call move_alloc (from = rng, to = unstable%rng)
    end subroutine unstable_import_rng

```

Generate a decay chain. First select a decay mode, then call the `select_chain` method of the selected mode.

```

<Decays: unstable: TBP>+≡
    procedure :: select_chain => unstable_select_chain

<Decays: procedures>+≡
    recursive subroutine unstable_select_chain (unstable)
        class(unstable_t), intent(inout) :: unstable
        real(default) :: x
        call unstable%rng%generate (x)
        unstable%selected_decay = unstable%config%selector%select (x)
        call unstable%decay(unstable%selected_decay)%select_chain ()
    end subroutine unstable_select_chain

```

Generate a decay event.

```

<Decays: unstable: TBP>+≡
    procedure :: generate => unstable_generate

```

```

⟨Decays: procedures⟩+≡
  recursive subroutine unstable_generate (unstable)
    class(unstable_t), intent(inout) :: unstable
    call unstable%decay(unstable%selected_decay)%generate ()
  end subroutine unstable_generate

```

29.4.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

⟨Decays: types⟩+≡
  type, extends (connected_state_t) :: decay_chain_entry_t
  private
    integer :: index = 0
    type(decay_config_t), pointer :: config => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
    type(decay_chain_entry_t), pointer :: previous => null ()
  end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

                end select
            end do
        end do
    end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations is under construction. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid. This procedure directly takes the (MLM) matching into account.

29.6 Fixed Order NLO Events

This section deals with the generation of weighted event samples which take into account next-to-leading order corrections. An approach generating unweighted events is not possible here, because negative weights might occur due to subtraction. Note that the events produced this way are not physical in the sense that they will not keep NLO-accuracy when interfaced to a parton shower. They are rather useful for theoretical consistency checks and a fast estimate of NLO effects.

We generate NLO events in the following way: First, the integration is carried out using the complete divergence-subtracted NLO matrix element. In the subsequent simulation, N -particle kinematics are generated using $\mathcal{B} + \mathcal{V} + \mathcal{C}$ as weight. After that, the program loops over all singular regions and for each of them generates an event with $N + 1$ -particle kinematics. The weight for those events corresponds to the real matrix element \mathcal{R}^α evaluated at the α -region's emitter's phase space point, multiplied with S_α . This procedure is implemented using the `evt_nlo` transform.

```

The event transform has a variable which counts the number of times it has already been called for one generation point. If `i_evaluation` is zero, this means that `evt_nlo_generate` is called for the first time, so that the generation of an N -particle event is required. In all other cases, emission events are generated. Note that for the first event, the computed weights are added to `probability`, which at this point is equal to $\mathcal{B} + \mathcal{V}$, whereas for all other runs `probability` is replaced.

29.7.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The **safety_factor** reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The **sigma** and **n** values, if nontrivial, allow for reweighting the events according to the requested **norm_mode**.

Various **parse_node_t** objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the **event_expr_t** objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

```

<Events: types>≡
    type :: event_config_t
        logical :: unweighted = .false.

```

29.7.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event_base` module. The core manages the main (dressed) particle set pointer and the current values for weights and sqme. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the

particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the **ref** value is the number in the file, while the **prc** value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of **alt** values is copied from an array of alternative event records. These values should represent calculated values.

The **sqme** and **weight** values mirror corresponding values in the **expr** sub-object. The idea is that when generating or reading events, the event record is filled first, then the **expr** object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the **expr** subobject. In particular, evaluating the event-selection expression sets the **passed** flag. Furthermore, the **expr** subobject collects data that can be used in the analysis and should be written to file, including copies of **sqme** and **weight**.

```

29.7.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```

<Events: event: TBP>+≡
  procedure :: basic_init => event_init

<Events: procedures>+≡

    event%config%sigma = sigma
  end subroutine event_set_sigma

  elemental subroutine event_set_n (event, n)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: n
    event%config%n = n
  end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
  procedure :: import_transform => event_import_transform

<Events: procedures>+≡
  subroutine event_import_transform (event, evt)
    class(event_t), intent(inout) :: event
    class(evt_t), intent(inout), pointer :: evt
    event%transform_last%next => evt
    evt%previous => event%transform_last
    event%transform_last => evt
    evt => null ()
  end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding

unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

<Events: procedures>+≡
  subroutine event_connect (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(string_t) :: id
    integer :: num_id
    class(evt_t), pointer :: evt
    event%process => process_instance%process
    event%instance => process_instance
    id = event%process%get_id ()
    if (id /= "") call event%expr%set_process_id (id)
    num_id = event%process%get_num_id ()
    if (num_id /= 0) call event%expr%set_process_num_id (num_id)
    call event%expr%setup_vars (event%process%get_sqrts ())
    call event%expr%link_var_list (event%process%get_var_list_ptr ())
    call event%process%make_rng (event%rng)
    evt => event%transform_first
    do while (associated (evt))
      call evt%connect (process_instance, model, process_stack)
      evt => evt%next
    end do
  end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
  procedure :: set_selection => event_set_selection
  procedure :: set_reweight => event_set_reweight
  procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡
  subroutine event_set_selection (event, ef_selection)
    class(event_t), intent(inout) :: event

    allocate (event%config%ef_analysis, source = ef_analysis)

```

```
end subroutine event_set_analysis
```

Create evaluation trees from the parse trees. The **target** attribute is required because the expressions contain pointers to event subobjects.

```
<Events: event: TBP>+≡
  procedure :: setup_expressions => event_setup_expressions
<Events: procedures>+≡
  subroutine event_setup_expressions (event)
    class(event_t), intent(inout), target :: event
    call event%expr%setup_selection (event%config%ef_selection)
    call event%expr%setup_analysis (event%config%ef_analysis)
    call event%expr%setup_reweight (event%config%ef_reweight)
  end subroutine event_setup_expressions
```

29.7.4 Evaluation

To fill the **particle_set**, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```
<Events: event: TBP>+≡
  procedure :: evaluate_transforms => event_evaluate_transforms
<Events: procedures>+≡
  subroutine event_evaluate_transforms (event, r)
    class(event_t), intent(inout) :: event
    real(default), dimension(:), intent(in), optional :: r
    class(evt_t), pointer :: evt
    integer :: i_term
    call event%discard_particle_set ()
    call event%check ()
    if (event%instance%is_complete_event ()) then
      call event%instance%select_i_term (i_term)
      event%selected_i_term = i_term
      evt => event%transform_first
      do while (associated (evt))
        call evt%prepare_new_event &
          (event%selected_i_mci, event%selected_i_term)
        evt => evt%next
      end do
      evt => event%transform_first
      do while (associated (evt))
```

```

!
      if (evt%only_weighted_events) then
        call evt%generate_weighted (event%weight_prc)
        call evt%generate_weighted (event%sqme_prc)
      else
        call evt%generate_unweighted ()
      end if
      if (signal_is_pending ()) return
      call evt%make_particle_set (event%config%factorization_mode, &
        event%config%keep_correlations)

      .and. event%weight_ref_is_known () &
      .and. event%weight_prc_is_known ()
    if (event%get_n_alt () /= 0) then
      event%is_complete = event%is_complete &
        .and. event%sqme_alt_is_known () &
        .and. event%weight_alt_is_known ()
    end if
  end subroutine event_check
```

29.7.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we accept the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```
<Events: event: TBP>+≡
  procedure :: generate => event_generate

<Events: procedures>+≡
  subroutine event_generate (event, i_mci, r, i_nlo)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci
    real(default), dimension(:), intent(in), optional :: r
    integer, intent(in), optional :: i_nlo
    logical :: generate_new = .true.
    if (present (i_nlo)) generate_new = (i_nlo == 1)
    if (generate_new) call event%reset ()
    event%selected_i_mci = i_mci
    if (event%config%unweighted) then
      call event%process%generate_unweighted_event (event%instance, i_mci)
      if (signal_is_pending ()) return
      call event%instance%evaluate_event_data ()
      call event%instance%normalize_weight ()
    else
```

```

        if (event%nlo_event) &
            call event%process%deactivate_real_component ()
        if (generate_new) call event%process%generate_weighted_event (event%instance, i_mci)

        if (associated (event%instance)) then
            event%selected_i_mci = i_mci
            event%selected_i_term = i_term
            event%selected_channel = channel
        else
            call msg_bug ("Event: select term: process instance undefined")
        end if
    end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. The event reader may either read in the transformed event separately,

or apply all event transforms to the hard particle set to (re)generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
  procedure :: set_hard_particle_set => event_set_hard_particle_set

<Events: procedures>+≡
  subroutine event_set_hard_particle_set (event, particle_set)
    class(event_t), intent(inout) :: event
    type(particle_set_t), intent(in) :: particle_set
    class(evt_t), pointer :: evt
    evt => event%transform_first
    call evt%set_particle_set (particle_set, &
      event%selected_i_mci, event%selected_i_term)
    call event%link_particle_set (evt%particle_set)
    evt => evt%next
    do while (associated (evt))
      call evt%reset ()
      evt => evt%next
    end do
  end subroutine event_set_hard_particle_set

```

Set the α_s value that should be used in a recalculation. This should be called only if we explicitly want to override the QCD setting of the process core.

```

<Events: event: TBP>+≡
  procedure :: set_alpha_qcd_forced => event_set_alpha_qcd_forced

<Events: procedures>+≡
  subroutine event_set_alpha_qcd_forced (event, alpha_qcd)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: alpha_qcd
    if (allocated (event%alpha_qcd_forced)) then
      event%alpha_qcd_forced = alpha_qcd
    else
      allocate (event%alpha_qcd_forced, source = alpha_qcd)
    end if
  end subroutine event_set_alpha_qcd_forced

```

Analogously, for the common scale. This forces also renormalization and factorization scale.

```

<Events: event: TBP>+≡
  procedure :: set_scale_forced => event_set_scale_forced

<Events: procedures>+≡
  subroutine event_set_scale_forced (event, scale)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: scale
    if (allocated (event%scale_forced)) then
      event%scale_forced = scale
    else
      allocate (event%scale_forced, source = scale)
    end if
  end subroutine event_set_scale_forced

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

<Events: event: TBP>+≡
  procedure :: recalculate => event_recalculate

<Events: procedures>+≡
  subroutine event_recalculate &
    (event, update_sqme, weight_factor, recover_beams)
    class(event_t), intent(inout) :: event

29.8 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the `events` module which provides the concrete implementation of `event_base`. The other I/O formats access only the methods that are defined in `event_base`.

```

<eio_raw.f90>≡
  <File header>

  module eio_raw

    <Use kinds>
    <Use strings>
    use io_units
    use diagnostics
    use model_data
    use particles
    use event_base
    use eio_data
    use eio_base
    use events

    <Standard module head>

    <EIO raw: public>

    <EIO raw: parameters>

    <EIO raw: types>

    contains

    <EIO raw: procedures>

  end module eio_raw

```

29.8.1 File Format Version

This is the current default file version.

```

<EIO raw: parameters>≡
  integer, parameter :: CURRENT_FILE_VERSION = 2

```

The user may change this number; this should force some compatibility mode for reading and writing. In any case, the file version stored in a event file that we read has to match the expected file version.

History of version numbers:

1. Format for WHIZARD 2.2.0 to 2.2.3. No version number stored in the raw file.
2. Format from 2.2.4 on. File contains version number. The file contains the transformed particle set (if applicable) after the hard-process particle set.

29.8.2 Type

Note the file version number. The default may be reset during initialization, which should enforce some compatibility mode.

```

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

The `passed` flag is not written. This allow us to apply different selection criteria upon rereading.

29.9 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit

internally. We need procedures for opening, closing, and printing files.

```

<user_files.f90>≡
  <File header>

  module user_files

    <Use strings>
    use io_units
    use diagnostics
    use ifiles
    use analysis

    <Standard module head>

    <User files: public>

    <User files: types>

    <User files: interfaces>

    contains

    <User files: procedures>

  end module user_files

```

29.9.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```

<User files: types>≡
  type :: file_t
  private
  type(string_t) :: name
  integer :: unit = -1
  logical :: reading = .false.
  logical :: writing = .false.
  type(file_t), pointer :: prev => null ()
  type(file_t), pointer :: next => null ()
  end type file_t

```

The initializer opens the file.

```

<User files: procedures>≡
  subroutine file_init (file, name, action, status, position)
    type(file_t), intent(out) :: file
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    file%unit = free_unit ()
    file%name = name
    open (unit = file%unit, file = char (file%name), &
          action = action, status = status, position = position)
    select case (action)

```

```

    case ("read")
        file%reading = .true.
    case ("write")
        file%writing = .true.
    case ("readwrite")
        file%reading = .true.
        file%writing = .true.
    end select
end subroutine file_init

```

The finalizer closes it.

```

<User files: procedures>+≡
subroutine file_final (file)
    type(file_t), intent(inout) :: file
    close (unit = file%unit)
    file%unit = -1
end subroutine file_final

```

Check if a file is open with correct status.

```

<User files: procedures>+≡
function file_is_open (file, action) result (flag)
    logical :: flag
    type(file_t), intent(in) :: file
    character(*), intent(in) :: action
    select case (action)
    case ("read")
        flag = file%reading
    case ("write")
        flag = file%writing
    case ("readwrite")
        flag = file%reading .and. file%writing
    case default
        call msg_bug ("Checking file '" // char (file%name) &
            // "': illegal action specifier")
    end select
end function file_is_open

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the `advancing` option.

```

<User files: procedures>+≡
subroutine file_write_string (file, string, advancing)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: string
    logical, intent(in), optional :: advancing
    if (file%writing) then
        if (present (string)) then
            if (present (advancing)) then
                if (advancing) then
                    write (file%unit, "(A)") char (string)
                else
                    write (file%unit, "(A)", advance="no") char (string)
                end if
            end if
        end if
    end if

```

```

        else
            write (file%unit, "(A)") char (string)
        end if
    else
        write (file%unit, *)
    end if
else
    call msg_error ("Writing to file: File '" // char (file%name) &
        // "' is not open for writing.")
end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
subroutine file_write_ifile (file, ifile)
    type(file_t), intent(in) :: file
    type(ifile_t), intent(in) :: ifile
    type(line_p) :: line
    call line_init (line, ifile)
    do while (line_is_associated (line))
        call file_write_string (file, line_get_string_advance (line))
    end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
subroutine file_write_analysis (file, tag)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: tag
    if (file%writing) then
        if (present (tag)) then
            call analysis_write (tag, unit = file%unit)
        else
            call analysis_write (unit = file%unit)
        end if
    else
        call msg_error ("Writing analysis to file: File '" // char (file%name) &
            // "' is not open for writing.")
    end if
end subroutine file_write_analysis

```

29.9.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
    public :: file_list_t

<User files: types>+≡
    type :: file_list_t
        type(file_t), pointer :: first => null ()
        type(file_t), pointer :: last => null ()

```

```
end type file_list_t
```

There is no initialization routine, but a finalizer which deletes all:

```
<User files: public>+≡
public :: file_list_final

<User files: procedures>+≡
subroutine file_list_final (file_list)
  type(file_list_t), intent(inout) :: file_list
  type(file_t), pointer :: current
  do while (associated (file_list%first))
    current => file_list%first
    file_list%first => current%next
    call file_final (current)
    deallocate (current)
  end do
  file_list%last => null ()
end subroutine file_list_final
```

Find an entry in the list. Return null pointer on failure.

```
<User files: procedures>+≡
function file_list_get_file_ptr (file_list, name) result (current)
  type(file_t), pointer :: current
  type(file_list_t), intent(in) :: file_list
  type(string_t), intent(in) :: name
  current => file_list%first
  do while (associated (current))
    if (current%name == name) return
    current => current%next
  end do
end function file_list_get_file_ptr
```

Check if a file is open, public version:

```
<User files: public>+≡
public :: file_list_is_open

<User files: procedures>+≡
function file_list_is_open (file_list, name, action) result (flag)
  logical :: flag
  type(file_list_t), intent(in) :: file_list
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action
  type(file_t), pointer :: current
  current => file_list_get_file_ptr (file_list, name)
  if (associated (current)) then
    flag = file_is_open (current, action)
  else
    flag = .false.
  end if
end function file_list_is_open
```

Append a new file entry, i.e., open this file. Error if it is already open.

```
<User files: public>+≡
    public :: file_list_open

<User files: procedures>+≡
    subroutine file_list_open (file_list, name, action, status, position)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action, status, position
        type(file_t), pointer :: current
        if (.not. associated (file_list_get_file_ptr (file_list, name))) then
            allocate (current)
            call msg_message ("Opening file '" // char (name) // "' for output")
            call file_init (current, name, action, status, position)
            if (associated (file_list%last)) then
                file_list%last%next => current
                current%prev => file_list%last
            else
                file_list%first => current
            end if
            file_list%last => current
        else
            call msg_error ("Opening file: File '" // char (name) &
                // "' is already open.")
        end if
    end subroutine file_list_open
```

Delete a file entry, i.e., close this file. Error if it is not open.

```
<User files: public>+≡
    public :: file_list_close

<User files: procedures>+≡
    subroutine file_list_close (file_list, name)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then

  end module rt_data
```

29.10.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn, is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

29.10.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()
    type(parse_node_t), pointer :: fac_scale_expr => null ()
    type(parse_node_t), pointer :: ren_scale_expr => null ()
    type(parse_node_t), pointer :: weight_expr => null ()
    type(parse_node_t), pointer :: selection_lexpr => null ()
    type(parse_node_t), pointer :: reweight_expr => null ()
    type(parse_node_t), pointer :: analysis_lexpr => null ()
    type(parse_node_p), dimension(:), allocatable :: alt_setup
  contains
    <RT data: rt parse nodes: TBP>
  end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

```

```

<RT data: procedures>≡
subroutine rt_parse_nodes_clear (rt_pn, name)
  class(rt_parse_nodes_t), intent(inout) :: rt_pn
  type(string_t), intent(in) :: name
  select case (char (name))
  case ("cuts")
    rt_pn%cuts_lexpr => null ()
  case ("scale")
    rt_pn%scale_expr => null ()
  case ("factorization_scale")
    rt_pn%fac_scale_expr => null ()
  case ("renormalization_scale")
    rt_pn%ren_scale_expr => null ()
  case ("weight")
    rt_pn%weight_expr => null ()
  case ("selection")
    rt_pn%selection_lexpr => null ()
  case ("reweight")
    rt_pn%reweight_expr => null ()
  case ("analysis")
    rt_pn%analysis_lexpr => null ()
  end select
end subroutine rt_parse_nodes_clear

```

Output for the parse nodes.

```

<RT data: rt parse nodes: TBP>+≡
  procedure :: write => rt_parse_nodes_write

<RT data: procedures>+≡

    end subroutine rt_data_clear_beams

```

29.10.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

```
<RT data: rt data: TBP>+≡

29.10.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init

<RT data: procedures>+≡
subroutine rt_data_local_init (local, global, env)
  class(rt_data_t), intent(inout), target :: local
  type(rt_data_t), intent(in), target :: global
  integer, intent(in), optional :: env
  local%context => global
  call local%process_stack%link (global%process_stack)
  call local%process_stack%init_var_list (local%var_list)

```

```

call local%process_stack%link_var_list (global%var_list)
call var_list_append_string &
    (local%var_list, var_str ("$_model_name"), var_str (""), &
    intrinsic=.true.)
call local%init_pointer_variables ()
local%fallback_model => global%fallback_model
local%radiation_model => global%radiation_model
local%os_data = global%os_data
local%logfile = global%logfile
call local%model_list%link (global%model_list)
local%model => global%model
if (associated (local%model)) then
    call local%model%link_var_list (local%var_list)
end if
end subroutine rt_data_local_init

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
    procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: procedures>+≡
    subroutine rt_data_init_pointer_variables (local)
        class(rt_data_t), intent(inout), target :: local
        logical, target, save :: known = .true.
        call var_list_append_string_ptr &
            (local%var_list, var_str ("$_fc"), local%os_data%fc, known, &
            intrinsic=.true.)
        call var_list_append_string_ptr &
            (local%var_list, var_str ("$_fcflags"), local%os_data%fcflags, known, &
            intrinsic=.true.)
    end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+≡
    procedure :: activate => rt_data_activate

<RT data: procedures>+≡
    subroutine rt_data_activate (local)
        class(rt_data_t), intent(inout), target :: local
        class(rt_data_t), pointer :: global
        global => local%context
        if (associated (global)) then

```

```

local%lexer => global%lexer
call global%copy_globals (local)
local%os_data = global%os_data
local%logfile = global%logfile
if (associated (global%prclib)) then
    local%prclib => &
        local%prclib_stack%get_library_ptr (global%prclib%get_name ())
end if
call local%import_values ()
call local%process_stack%link (global%process_stack)
local%it_list = global%it_list
local%beam_structure = global%beam_structure
local%pn = global%pn
if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
if (allocated (global%sample_fmt)) then
    allocate (local%sample_fmt (size (global%sample_fmt)), &
        source = global%sample_fmt)
end if
local%out_files => global%out_files
local%model => global%model
local%model_is_copy = .false.
else if (.not. associated (local%model)) then
    local%model => local%preload_model
    local%model_is_copy = .false.
end if
if (associated (local%model)) then
    call local%model%link_var_list (local%var_list)
    call local%var_list%set_string (var_str ("%model_name"), &
        local%model%get_name (), is_known = .true.)
else
    call local%var_list%set_string (var_str ("%model_name"), &
        var_str (""), is_known = .false.)
end if
end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
    procedure :: deactivate => rt_data_deactivate

<RT data: procedures>+≡
    subroutine rt_data_deactivate (local, global, keep_local)
        class(rt_data_t), intent(inout), target :: local
        class(rt_data_t), intent(inout), optional, target :: global
        logical, intent(in), optional :: keep_local
        type(string_t) :: global_model, local_model
        logical :: same_model, delete
    end subroutine

```

```

delete = .true.; if (present (keep_local)) delete = .not. keep_local
if (present (global)) then
  if (associated (global%model) .and. associated (local%model)) then
    global_model = global%model%get_name ()
    local_model = local%model%get_name ()
    same_model = global_model == local_model
  else
    same_model = .false.
  end if
  if (delete) then
    call local%process_stack%clear ()
    call local%unselect_model ()
    call local%unset_values ()
  else if (associated (local%model)) then
    call local%ensure_model_copy ()
  end if
  if (.not. same_model .and. global_model /= "") then
    call msg_message ("Restoring model '" // char (global_model) // "'")
  end if
  if (associated (global%model)) then
    call global%model%link_var_list (global%var_list)
  end if
  call global%restore_globals (local)
else
  call local%unselect_model ()
end if
end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
  procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
  subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
    local%prclib_stack = global%prclib_stack
  end subroutine rt_data_copy_globals

```

This restores global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡
  procedure :: restore_globals => rt_data_restore_globals

<RT data: procedures>+≡
  subroutine rt_data_restore_globals (global, local)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(in) :: local
    global%prclib_stack = local%prclib_stack
  end subroutine rt_data_restore_globals

```

29.10.8 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```
<RT data: rt data: TBP>+≡
  procedure :: final => rt_data_global_final

<RT data: procedures>+≡
  subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
    !   call global%delete_model_copy ()
    call global%model_list%final ()
    call global%var_list%final (follow_link=.false.)
    if (associated (global%out_files)) then
      call file_list_final (global%out_files)
      deallocate (global%out_files)
    end if
  end subroutine rt_data_global_final
```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```
<RT data: rt data: TBP>+≡
  procedure :: local_final => rt_data_local_final

<RT data: procedures>+≡
  subroutine rt_data_local_final (local)
    class(rt_data_t), intent(inout) :: local
    call local%process_stack%clear ()
    !   call local%delete_model_copy ()
    call local%model_list%final ()
    call local%var_list%final (follow_link=.false.)
  end subroutine rt_data_local_final
```

29.10.9 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```
<RT data: rt data: TBP>+≡
  procedure :: read_model => rt_data_read_model

<RT data: procedures>+≡
  subroutine rt_data_read_model (global, name, model)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(model_t), pointer, intent(out) :: model
```

```

    type(string_t) :: filename
    filename = name // ".mdl"
    call global%model_list%read_model &
        (name, filename, global%os_data, model)
end subroutine rt_data_read_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
    procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: procedures>+≡
    subroutine rt_data_init_fallback_model (global, name, filename)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name, filename
        call global%model_list%read_model &
            (name, filename, global%os_data, global%fallback_model)
    end subroutine rt_data_init_fallback_model

```

Initialize the radiation model. This model is used by a radiation-generator algorithm which is part of the NLO machinery. It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
    procedure :: init_radiation_model => rt_data_init_radiation_model

<RT data: procedures>+≡
    subroutine rt_data_init_radiation_model (global, name, filename)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name, filename
        call global%model_list%read_model &
            (name, filename, global%os_data, global%radiation_model)
    end subroutine rt_data_init_radiation_model

```

Activate a model: assign the current-model pointer and set the model name in the variable list. If necessary, read the model from file. Link the global variable list to the model variable list.

```

<RT data: rt data: TBP>+≡
    procedure :: select_model => rt_data_select_model

<RT data: procedures>+≡
    subroutine rt_data_select_model (global, name)
        class(rt_data_t), intent(inout), target :: global
        type(string_t), intent(in) :: name
        logical :: same_model
        if (associated (global%model)) then
            same_model = global%model%get_name () == name
        else
            same_model = .false.
        end if
        if (.not. same_model) then
            ! call global%delete_model_copy ()
            global%model => global%model_list%get_model_ptr (name)

```

```

        if (.not. associated (global%model)) then
            call global%read_model (name, global%model)
            global%model_is_copy = .false.
        else if (associated (global%context)) then
            global%model_is_copy = &
                global%model_list%model_exists (name, follow_link=.false.)
        else
            global%model_is_copy = .false.
        end if
    end if
    if (associated (global%model)) then
        call global%model%link_var_list (global%var_list)
        call global%var_list%set_string (var_str ("$model_name"), &

Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```

<RT data: test auxiliary>≡

29.11 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

This module provides no new types, just procedures.

```
<dispatch.f90>≡  
  <File header>  
  
  module dispatch  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use diagnostics  
    use os_interface  
    use rt_data  
  
    <Standard module head>  
  
    <Dispatch: public>  
  
    <Dispatch: types>  
  
    <Dispatch: interfaces>  
  
    <Dispatch: variables>  
  
    contains  
  
    <Dispatch: procedures>  
  
  end module dispatch
```

29.11.1 Interfaces

```
<Dispatch: interfaces>≡  
  interface  
    subroutine GetXminM (set, mem, xmin)  
      integer, intent(in) :: set, mem  
      double precision, intent(out) :: xmin  
    end subroutine GetXminM  
  end interface  
  
<Dispatch: interfaces>+≡  
  interface  
    subroutine GetXmaxM (set, mem, xmax)  
      integer, intent(in) :: set, mem  
      double precision, intent(out) :: xmax  
    end subroutine GetXmaxM  
  end interface
```

```

<Dispatch: interfaces>+≡
interface
  subroutine GetQ2minM (set, mem, q2min)
    integer, intent(in) :: set, mem
    double precision, intent(out) :: q2min
  end subroutine GetQ2minM
end interface

```

```

<Dispatch: interfaces>+≡
interface
  subroutine GetQ2maxM (set, mem, q2max)
    integer, intent(in) :: set, mem
    double precision, intent(out) :: q2max
  end subroutine GetQ2maxM
end interface

```

29.11.2 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable.

Note: `core_def` has `intent(inout)` because gfortran 4.7.1 crashes for `intent(out)`.

```

<Dispatch: public>≡
public :: dispatch_core_def

<Dispatch: procedures>≡
subroutine dispatch_core_def (core_def, prt_in, prt_out, &

```

29.11.3 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```

<Dispatch: public>+≡
    public :: dispatch_core

<Dispatch: procedures>+≡
    subroutine dispatch_core (core, core_def, model, &
        helicity_selection, qcd, use_color_factors)
    use sm_qcd

```

```

use model_data
use prc_core_def
use prc_core
use prc_template_me
use prc_test
use prc_omega
use prc_gosam
use prc_openloops
use processes, only: test_t

class(prc_core_t), allocatable, intent(inout) :: core
class(prc_core_def_t), intent(in) :: core_def
class(model_data_t), intent(in), target, optional :: model
type(helicity_selection_t), intent(in), optional :: helicity_selection
type(qcd_t), intent(in), optional :: qcd
logical, intent(in), optional :: use_color_factors

select type (core_def)
type is (prc_test_def_t)
    allocate (test_t :: core)
type is (template_me_def_t)
    allocate (prc_template_me_t :: core)
    select type (core)
    type is (prc_template_me_t)
        call core%set_parameters (model)
    end select
class is (omega_def_t)
    if (.not. allocated (core)) allocate (prc_omega_t :: core)
    select type (core)
    type is (prc_omega_t)
        call core%set_parameters (model, &
            helicity_selection, qcd, use_color_factors)
    end select
type is (gosam_def_t)
    if (.not. allocated (core)) allocate (prc_gosam_t :: core)
    select type (core)
    type is (prc_gosam_t)
        call core%set_parameters (qcd, use_color_factors)
    end select
type is (openloops_def_t)
    if (.not. allocated (core)) allocate (prc_openloops_t :: core)
    select type (core)
    type is (prc_openloops_t)
        call core%set_parameters (qcd, use_color_factors)
    end select
class default
    call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

29.11.4 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

```
<Dispatch: public>+≡
  public :: dispatch_core_update
  public :: dispatch_core_restore

<Dispatch: procedures>+≡
  subroutine dispatch_core_update (core, model, helicity_selection, qcd, &
    saved_core)
    use sm_qcd
    use model_data
    use prc_core
    use prc_omega
    use prc_gosam
    use processes, only: test_t

    class(prc_core_t), allocatable, intent(inout) :: core
    class(model_data_t), intent(in), optional, target :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    class(prc_core_t), allocatable, intent(inout), optional :: saved_core

    if (present (saved_core)) then
      allocate (saved_core, source = core)
    end if
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
      call core%set_parameters (model, helicity_selection, qcd)
      call core%activate_parameters ()
    type is (prc_gosam_t)
      call msg_message ("dispatch core restore: Gosam implementation not present yet!")
    class default
      call msg_bug ("Process core update: unexpected process definition type")
    end select
  end subroutine dispatch_core_update

  subroutine dispatch_core_restore (core, saved_core)
    use prc_core
    use prc_omega
    use processes, only: test_t

    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_t), allocatable, intent(inout) :: saved_core

    call move_alloc (from = saved_core, to = core)
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
```

```

        call core%activate_parameters ()
    class default
        call msg_bug ("Process core restore: unexpected process definition type")
    end select
end subroutine dispatch_core_restore

```

29.11.5 Integrator allocation

Allocate an integrator according to the variable `$integration_method`.

```

<Dispatch: public>+≡
    public :: dispatch_mci

    end subroutine dispatch_fks

```

29.11.8 Random-number generator

Allocate a random-number generator factory according to the variable `$rng_method`, using the current seed in the global record. We take only the lower 15 bits of the seed, so the actual value fits into a positive 16-bit signed integer.

Since we want to guarantee that all random-number generators in a run are independent, we increment the global seed by one after creating the rng factory. If the user wants to have identical sequences, he can always set the seed manually, before it is used.

(Dispatch: public)+≡

```
public :: dispatch_rng_factory
```

(Dispatch: procedures)+≡

```
subroutine dispatch_rng_factory (rng_factory, global, local_input)
  use kinds, only: i16
  use rng_base
  use rng_tao
  class(rng_factory_t), allocatable, intent(inout) :: rng_factory
  type(rt_data_t), intent(inout), target :: global
  type(rt_data_t), intent(in), target, optional :: local_input
  type(rt_data_t), pointer :: local
  type(string_t) :: rng_method
  integer :: seed
  character(30) :: buffer
  integer(i16) :: s
  if (present (local_input)) then
    local => local_input
  else
    local => global
  end if
  rng_method = &
    local%var_list%get_sval (var_str ("rng_method"))
  seed = &
    local%var_list%get_ival (var_str ("seed"))
  s = int (mod (seed, 32768), i16)
  select case (char (rng_method))
  case ("tao")
    allocate (rng_tao_factory_t :: rng_factory)
    call msg_message ("RNG: Initializing TAO random-number generator")
  case default
    if (associated (dispatch_rng_factory_extra)) then
      call dispatch_rng_factory_extra (rng_factory, global, local_input)
    end if
    if (.not. allocated (rng_factory)) then
      call msg_fatal ("Random-number generator '" &
        // char (rng_method) // "' not implemented")
    end if
  end select
  end if
  write (buffer, "(I0)") s
  call msg_message ("RNG: Setting seed for random-number generator to " &
    // trim (buffer))
  call rng_factory%init (s)
  call global%set_int (var_str ("seed"), seed + 1, &
    is_known = .true.)
```

```
end subroutine dispatch_rng_factory
```

This is a hook that allows us to inject further handlers for RNG factory objects, in particular a test RNG.

```
<Dispatch: public>+≡
  public :: dispatch_rng_factory_extra

<Dispatch: variables>≡
  procedure (dispatch_rng_factory), pointer :: &
    dispatch_rng_factory_extra => null ()
```

29.11.9 Structure function configuration data

This data type is a container for transferring structure-function specific data from the `dispatch_sf_data` to the `dispatch_sf_channels` subroutine.

```
<Dispatch: public>+≡
  public :: sf_prop_t

<Dispatch: types>≡
  type :: sf_prop_t
    real(default), dimension(2) :: isr_eps = 1
  end type sf_prop_t
```

Allocate a structure-function configuration object according to the `sf_method` string.

The `sf_prop` object can be used to transfer structure-function specific data up and to the `dispatch_sf_channels` subroutine below, so they can be used for particular mappings.

The `global` object is intent(inout) because the RNG generator seed may change during initialization.

The `pdg_in` array is the array of incoming flavors, corresponding to the upstream structure function or the beam array. This will be checked for the structure function in question and replaced by the outgoing flavors. The `pdg_prc` array is the array of incoming flavors (beam index, component index) for the hard process.

```
<Dispatch: public>+≡
  public :: dispatch_sf_data

<Dispatch: procedures>+≡
  subroutine dispatch_sf_data (data, sf_method, i_beam, sf_prop, global, &
    pdg_in, pdg_prc, polarized)
    use constants, only: PI
    use physics_defs, only: PHOTON
    use unit_tests, only: vanishes

```

This is a hook that allows us to inject further handlers for structure-function objects, in particular a test structure function.

```

<Dispatch: public>+≡
    public :: dispatch_sf_data_extra

<Dispatch: variables>+≡
    procedure (dispatch_sf_data), pointer :: &
        dispatch_sf_data_extra => null ()

```

This is an auxiliary procedure, used by the beam-structure expansion: tell for a given structure function name, whether it corresponds to a pair spectrum ($n = 2$), a single-particle structure function ($n = 1$), or nothing ($n = 0$). Though `energy_scan` can in principle also be a pair spectrum, it always has only one parameter.

```

<Dispatch: procedures>+≡
    function strfun_mode (name) result (n)
        type(string_t), intent(in) :: name
        integer :: n
        select case (char (name))

```

```

case ("none")
  n = 0
case ("sf_test_0", "sf_test_1")
  n = 1
case ("pdf_builtin","pdf_builtin_photon", &
      "lhapdf","lhapdf_photon")
  n = 1
case ("isr","epa","ewa")
  n = 1
case ("circe1", "circe2")
  n = 2
case ("gaussian")
  n = 2
case ("beam_events")
  n = 2
case ("energy_scan")
  n = 2
case default
  call msg_bug ("Structure function '" // char (name) &
               // "' not supported yet")
end select
end function strfun_mode

```

Dispatch a whole structure-function chain, given beam data and beam structure data.

This could be done generically, but we should look at the specific combination of structure functions in order to select appropriate mappings.

The `beam_structure` argument gets copied because we want to expand it to canonical form (one valid structure-function entry per record) before proceeding further.

The `pdg_prc` argument is the array of incoming flavors. The first index is the beam index, the second one the process component index. Each element is itself a PDG array, nontrivial if there is a flavor sum for the incoming state of this component.

The dispatcher is divided in two parts. The first part configures the structure function data themselves. After this, we can configure the phase space for the elementary process.

<Dispatch: public>+≡

```
public :: dispatch_sf_config
```

<Dispatch: procedures>+≡

```

        beam_structure%polarized ())
    call sf_config(i)%init (beam_structure%get_i_entry (i), sf_data)
    deallocate (sf_data)
end do
end subroutine dispatch_sf_config

```

The second part configures channel mappings, using some conditions from the phase space configuration. If there are no structure functions, we enable a default setup with a single (dummy) structure-function channel. Otherwise, we look at the channel collection that we got from the phase-space configuration step. Each entry should be translated into an independent structure-function channel, where typically there is one default entry, which could be mapped using a standard s-channel mapping if the structure function setup recommends this, and other entries with s-channel resonances. The latter need to be translated into global mappings from the structure-function chain.

```

29.11.11 QCD coupling

Allocate the `alpha` (running coupling) component of the `qcd` block with a concrete implementation, depending on the variable settings in the `global` record.

If a fixed α_s is requested, we do not allocate the `qcd%alpha` object. In this case, the matrix element code will just take the model parameter as-is, which implies fixed α_s . If the object is allocated, the α_s value is computed and updated for each matrix-element call.

```

```

29.12 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

```
<process_configurations.f90>≡  
  <File header>  
  
  module process_configurations  
  
    <Use strings>  
    use diagnostics  
    use models  
    use prc_core_def  
    use particle_specifiers  
    use process_libraries  
    use rt_data  
  
    use dispatch, only: dispatch_core_def  
  
    <Standard module head>  
  
    <Process configurations: public>  
  
    <Process configurations: types>  
  
    contains  
  
    <Process configurations: procedures>  
  
  end module process_configurations
```

29.12.1 Data Type

```
<Process configurations: public>≡  
  public :: process_configuration_t  
  
<Process configurations: types>≡  
  type :: process_configuration_t  
    type(process_def_entry_t), pointer :: entry => null ()  
    type(string_t) :: id  
    integer :: num_id = 0  
    contains  
    <Process configurations: process configuration: TBP>  
  end type process_configuration_t
```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

```
<Process configurations: process configuration: TBP>≡  
  procedure :: init => process_configuration_init
```

```

(Process configurations: procedures)≡
  subroutine process_configuration_init &
    (config, prc_name, n_in, n_components, global)
    class(process_configuration_t), intent(out) :: config
    type(string_t), intent(in) :: prc_name
    integer, intent(in) :: n_in
    integer, intent(in) :: n_components
    type(rt_data_t), intent(in) :: global
    type(model_t), pointer :: model
    model => global%model
    config%id = prc_name
    allocate (config%entry)
    if (global%var_list%is_known (var_str ("process_num_id"))) then
      config%num_id = &
        global%var_list%get_ival (var_str ("process_num_id"))
      call config%entry%init (prc_name, &
        model = model, n_in = n_in, n_components = n_components, &
        num_id = config%num_id, nlo_process = global%nlo_calculation)
    else
      call config%entry%init (prc_name, &
        model = model, n_in = n_in, n_components = n_components, &
        nlo_process = global%nlo_calculation)
    end if
  end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

```

(Process configurations: process configuration: TBP)+≡
  procedure :: setup_component => process_configuration_setup_component

    end module process_configurations_util

```

API: driver for the unit tests below.

```

<Process configurations: public test>≡
    public :: process_configurations_test

<Process configurations: test driver>≡
    subroutine process_configurations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Process configurations: execute tests>
    end subroutine process_configurations_test

```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

This is re-exported by the UT module.

```

<Process configurations: public test auxiliary>≡
    public :: prepare_test_library

<Process configurations: test auxiliary>≡
    subroutine prepare_test_library (global, libname, mode, procname)
        type(rt_data_t), intent(inout), target :: global

    end if
  end subroutine compilation_item_success

```

29.13.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
  public :: compile_library

<Compilations: procedures>+≡
  subroutine compile_library (libname, global)
    type(string_t), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
    type(compilation_item_t) :: comp
    logical :: force, recompile
    force = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    recompile = &
      global%var_list%get_lval (var_str ("?recompile_library"))
    if (associated (global%model)) then
      call comp%init (libname, global%prclib_stack, global%var_list)
      call comp%compile (global%model, global%os_data, force, recompile)
      if (signal_is_pending ()) return
      call comp%load (global%os_data)
      if (signal_is_pending ()) return
    else

```

```

        call msg_fatal ("Process library compilation: " &
            // " model is undefined.")
    end if
    call comp%success ()
end subroutine compile_library

```

29.13.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```

<Compilations: public>+≡
    public :: compilation_t

<Compilations: types>+≡
    type :: compilation_t
        private
        type(string_t) :: exe_name
        type(string_t), dimension(:), allocatable :: lib_name
    contains
        <Compilations: compilation: TBP>
    end type compilation_t

```

Output.

```

<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write

29.13.6 Test static build

The tests for building a static executable are separate, since they should be skipped if the WHIZARD build itself has static libraries disabled.

```

<Compilations: public test>+≡
    public :: compilations_static_test

<Compilations: test driver>+≡
    subroutine compilations_static_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Compilations: static tests>
    end subroutine compilations_static_test

```

External Matrix Element

Compile an external test matrix element (omega type) and incorporate this in a new static WHIZARD executable.

```

<Compilations: static tests>≡
    call test (compilations_static_1, "compilations_static_1", &
        "static executable: compilation", &
        u, results)

<Compilations: test declarations>+≡
    public :: compilations_static_1

<Compilations: tests>+≡
    subroutine compilations_static_1 (u)
        integer, intent(in) :: u
        type(string_t) :: libname, procname, exename
        type(rt_data_t), target :: global
        type(compilation_item_t) :: item

end module integrations

29.14.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

⟨Integrations: public⟩≡

public :: integration_t

⟨Integrations: types⟩≡

```
type :: integration_t
  private
  type(string_t) :: process_id
  type(string_t) :: run_id
  type(process_t), pointer :: process => null ()
  type(var_list_t), pointer :: model_vars => null ()
  type(qcd_t) :: qcd
  logical :: rebuild_phs = .false.
  logical :: ignore_phs_mismatch = .false.
  logical :: phs_only = .false.
  logical :: process_has_me = .true.
  integer :: n_calls_test = 0
  logical :: vis_history = .true.
  type(string_t) :: history_filename
  type(string_t) :: log_filename
  logical :: combined_integration = .false.
contains
  ⟨Integrations: integration: TBP⟩
end type integration_t
```

29.14.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied.

⟨Integrations: integration: TBP⟩≡

procedure :: create_process => integration_create_process

⟨Integrations: procedures⟩≡

```
subroutine integration_create_process (intg, process_id, global)
  class(integration_t), intent(out) :: intg
  type(rt_data_t), intent(inout), optional, target :: global
  type(string_t), intent(in) :: process_id
  type(process_entry_t), pointer :: process_entry
  intg%process_id = process_id
```

```

if (present (global)) then
  allocate (process_entry)
  intg%process => process_entry%process_t
  call global%process_stack%push (process_entry)
else
  allocate (process_t :: intg%process)
end if
intg%model_vars => null ()
end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the `local` stack directly. The `intent(inout)` attribute for the `local` data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

(Integrations: integration: TBP)+≡

```

procedure :: init_process => integration_init_process

```

(Integrations: procedures)+≡

```

subroutine integration_init_process (intg, local)
  class(integration_t), intent(inout) :: intg
  type(rt_data_t), intent(inout), target :: local
  type(string_t) :: model_name
  type(model_t), pointer :: model
  class(model_data_t), pointer :: model_instance
  class(rng_factory_t), allocatable :: rng_factory
  if (.not. local%prclib%contains (intg%process_id)) then
    call msg_fatal ("Process '" // char (intg%process_id) // "' not found" &
      // " in library '" // char (local%prclib%get_name ()) // "'")
    return
  end if
  intg%run_id = &
    local%var_list%get_sval (var_str ("run_id"))

29.14.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

<Integrations: integration: TBP>+≡
    procedure :: evaluate => integration_evaluate

<Integrations: procedures>+≡
    subroutine integration_evaluate &
        (intg, process_instance, i_mci, pass, it_list, pacify)
        class(integration_t), intent(inout) :: intg
        type(process_instance_t), intent(inout), target :: process_instance
        integer, intent(in) :: i_mci
        integer, intent(in) :: pass
        type(iterations_list_t), intent(in) :: it_list
        logical, intent(in), optional :: pacify
        integer :: n_calls, n_it
        logical :: adapt_grids, adapt_weights, final

        n_it = it_list%get_n_it (pass)
        n_calls = it_list%get_n_calls (pass)
        adapt_grids = it_list%adapt_grids (pass)
        adapt_weights = it_list%adapt_weights (pass)
        final = pass == it_list%get_n_pass ()

        call intg%process%integrate (process_instance, &
            i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
            final, pacify)

    end subroutine integration_evaluate

```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct

passes, one for adaptation and one for integration.

```

<Integrations: integration: TBP>+≡
  procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: procedures>+≡
  subroutine integration_make_iterations_list (intg, it_list)

Return the process pointer (needed by simulate):

```

<Integrations: integration: TBP>+≡
    procedure :: get_process_ptr => integration_get_process_ptr

<Integrations: procedures>+≡
    function integration_get_process_ptr (intg) result (ptr)
        class(integration_t), intent(in) :: intg
        type(process_t), pointer :: ptr
        ptr => intg%process
    end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the `global` environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the `process` object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

```

<Integrations: public>+≡
    public :: integrate_process

<Integrations: procedures>+≡

Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (29.1)$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (29.2)$$

f is the flux of the incoming particles with mass $m = 125 \text{ GeV}$ and energy $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (29.3)$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (29.4)$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (29.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function $f(x) = x$ for both beams. Together with the $1/x_1x_2$ factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the m_s mass which we set to zero here.

```

29.15 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
(event_streams.f90)≡  
  <File header>  
  
  module event_streams  
  
    <Use strings>  
    use io_units  
    use diagnostics  
    use events  
    use eio_data  
    use eio_base  
    use rt_data  
  
    use dispatch, only: dispatch_eio  
  
    <Standard module head>  
  
    <Event streams: public>  
  
    <Event streams: types>  
  
    contains  
  
    <Event streams: procedures>  
  
  end module event_streams
```

29.15.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡  
  type :: event_stream_entry_t  
    class(eio_t), allocatable :: eio  
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```
<Event streams: public>≡  
  public :: event_stream_array_t  
  
<Event streams: types>+≡  
  type :: event_stream_array_t  
    type(event_stream_entry_t), dimension(:), allocatable :: entry  
    integer :: i_in = 0  
    contains  
    <Event streams: event stream array: TBP>  
  end type event_stream_array_t
```

Output.

```

<Event streams: event stream array: TBP>≡
  procedure :: write => event_stream_array_write

<Event streams: procedures>≡
  subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event stream array:"
    if (allocated (object%entry)) then
      select case (size (object%entry))
      case (0)
        write (u, "(3x,A)") "[empty]"
      case default
        do i = 1, size (object%entry)
          if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
          call object%entry(i)%eio%write (u)
        end do
      end select
    else
      write (u, "(3x,A)") "[undefined]"
    end if
  end subroutine event_stream_array_write

```

Finalize all streams.

```

<Event streams: event stream array: TBP>+≡
  procedure :: final => event_stream_array_final

<Event streams: procedures>+≡
  subroutine event_stream_array_final (es_array)
    class(event_stream_array_t), intent(inout) :: es_array
    integer :: i
    do i = 1, size (es_array%entry)
      call es_array%entry(i)%eio%final ()
    end do
  end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

```

<Event streams: event stream array: TBP>+≡
  procedure :: init => event_stream_array_init

    object%has_integral = .true.
  end if
end subroutine mci_set_init
```

29.16.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

(Simulations: types)+≡

```
type :: core_safe_t
  class(prc_core_t), allocatable :: core
end type core_safe_t
```

29.16.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

(Simulations: procedures)+≡

```
subroutine prepare_process &
  (process, process_id, integrate, local, global)
  type(process_t), pointer, intent(out) :: process
  type(string_t), intent(in) :: process_id
  logical, intent(in) :: integrate
  type(rt_data_t), intent(inout), target :: local
```

```

type(rt_data_t), intent(inout), optional, target :: global
if (present (global)) then
    process => global%process_stack%get_process_ptr (process_id)
else
    process => local%process_stack%get_process_ptr (process_id)
end if
if (.not. associated (process)) then
    if (integrate) then
        call msg_message ("Simulate: process '" &
            // char (process_id) // "' needs integration")
    else
        call msg_message ("Simulate: process '" &
            // char (process_id) // "' needs initialization")
    end if
    if (present (global)) then
        call integrate_process (process_id, local, global, &
            init_only = .not. integrate)
    else
        call integrate_process (process_id, local, local_stack=.true., &
            init_only = .not. integrate)
    end if
    if (signal_is_pending ()) return
    process => global%process_stack%get_process_ptr (process_id)
    if (associated (process)) then
        if (integrate) then
            call msg_message ("Simulate: integration done")
            call global%process_stack%fill_result_vars (process_id)
        else
            call msg_message ("Simulate: process initialization done")
        end if
    else
        call msg_fatal ("Simulate: process '" &
            // char (process_id) // "' could not be initialized: aborting")
    end if
end if
end subroutine prepare_process

```

29.16.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

For the purpose of NLO events, `entry_t` contains a pointer list to other simulation-entries. This is due to the fact that we have to associate an event for each component of the fixed order simulation, i.e. one N -particle event and N_α $N + 1$ -particle events. However, all entries share the same event transforms.

```

<Simulations: types>+≡
  type, extends (event_t) :: entry_t
  private
  type(string_t) :: process_id
  type(string_t) :: library
  type(string_t) :: run_id
  logical :: has_integral = .false.
  real(default) :: integral = 0
  real(default) :: error = 0
  real(default) :: process_weight = 0
  logical :: valid = .false.
  type(counter_t) :: counter
  integer :: n_in = 0
  integer :: n_mci = 0
  type(mci_set_t), dimension(:), allocatable :: mci_set
  type(selector_t) :: mci_selector
  type(core_safe_t), dimension(:), allocatable :: core_safe
  class(model_data_t), pointer :: model => null ()
  type(qcd_t) :: qcd
  type(entry_t), pointer :: first => null ()
  type(entry_t), pointer :: next => null ()
  contains
  <Simulations: entry: TBP>
end type entry_t

```

Output. Write just the configuration, the event is written by a separate routine.

The `verbose` option is unused, it is required by the interface of the base-object method.

```

<Simulations: entry: TBP>≡
  procedure :: write_config => entry_write_config

<Simulations: procedures>+≡
  subroutine entry_write_config (object, unit)
    class(entry_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(3x,A,A,A)") "Process   = ", char (object%process_id), ""
    write (u, "(3x,A,A,A)") "Library   = ", char (object%library), ""

end if
entry2%model => entry1%model
entry2%qcd = entry1%qcd
!   entry2%first => entry1%first
end subroutine entry_copy_entry

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the `process_instance` pointer. Assign data by looking at the process object and at the environment.

If `n_alt` is set, we prepare for additional alternate sqme and weight entries.

If the process object is not found initially: if `integrate` is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If `generate` is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the `instance` and `process` pointers of the base type by the `connect` method, so we can reference them later.

<Simulations: entry: TBP>+≡

29.16.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
  type, extends (entry_t) :: alt_entry_t
    contains
    <Simulations: alt entry: TBP>
  end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

Write the current event record. If an explicit index is given, write that event record.

We implement writing to unit (event contents / debugging format) and writing to an eio event stream (storage). We include a `testflag` in order to suppress numerical noise in the testsuite.

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the luminosity setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the luminosity, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

```

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

NB: When reading from file, event transforms can't be applied because the process instance will not be complete. This should be fixed.

```

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate

everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

<Simulations: simulation: TBP>+≡

  else
    call msg_fatal ("Simulation: write event: no process selected")
  end if
end subroutine simulation_write_event_eio
```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration channel, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

(Simulations: simulation: TBP)+≡

```
generic :: read_event => read_event_eio

Chapter 30

More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in init/final hooks that we can set at runtime.)

30.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
(expr_tests_ut.f90)≡
  <File header>
  module expr_tests_ut

      use unit_tests
      use expr_tests_util

  <Standard module head>

  <Expr tests: public test>

Chapter 31

Top Level

The top level consists of

commands Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

whizard This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

main The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

whizard_c_interface Alternative top-level procedures, for use in the context of a C-compatible caller program.

31.1 Commands

This module defines the command language of the main input file.

```

end module commands

```

31.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```

<Commands: types>≡
    type, abstract :: command_t
        type(parse_node_t), pointer :: pn => null ()
        class(command_t), pointer :: next => null ()

end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_write), deferred :: write

⟨Commands: interfaces⟩≡
  abstract interface
    subroutine command_write (cmd, unit, indent)
      import
      class(command_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
    end subroutine command_write
  end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_compile), deferred :: compile

⟨Commands: interfaces⟩+≡
  abstract interface
    subroutine command_compile (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_compile
  end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_execute), deferred :: execute

⟨Commands: interfaces⟩+≡
  abstract interface
    subroutine command_execute (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_execute
  end interface

```

31.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```
<Commands: command: TBP>+≡
  procedure :: write_options => command_write_options

<Commands: procedures>+≡
  recursive subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options
```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```
<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
  recursive subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call cmd%options%compile (cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
      call cmd%local%deactivate ()
    else
      cmd%local => global
    end if
  end subroutine command_compile_options
```

Execute options. First prepare the local environment, then execute the command list.

```
<Commands: command: TBP>+≡
  procedure :: execute_options => cmd_execute_options

<Commands: procedures>+≡
  recursive subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call cmd%local%activate ()
      call cmd%options%execute (cmd%local)
```

```

        end if
    end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

⟨Commands: command: TBP⟩+≡
    procedure :: reset_options => cmd_reset_options

⟨Commands: procedures⟩+≡
    subroutine cmd_reset_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call cmd%local%deactivate (global)
        end if
    end subroutine cmd_reset_options

```

31.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_model_t
    private
        type(string_t) :: name
    contains
        ⟨Commands: cmd model: TBP⟩
    end type cmd_model_t

```

Output

```

⟨Commands: cmd model: TBP⟩≡
    procedure :: write => cmd_model_write

⟨Commands: procedures⟩+≡
    subroutine cmd_model_write (cmd, unit, indent)
        class(cmd_model_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,1x,'"',A,'\"') "model =", char (cmd%name)
    end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

```

⟨Commands: cmd model: TBP⟩+≡
    procedure :: compile => cmd_model_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_model_compile (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_name
  type(model_t), pointer :: model
  pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
  cmd%name = parse_node_get_string (pn_name)
  model => null ()
  if (associated (global%model)) then
    if (global%model%get_name () == cmd%name) model => global%model
  end if
  if (.not. associated (model)) then
    if (global%model_list%model_exists (cmd%name)) then
      model => global%model_list%get_model_ptr (cmd%name)
    else
      call global%read_model (cmd%name, model)
    end if
  end if
  global%model => model
  if (associated (global%model)) then
    call global%model%link_var_list (global%var_list)
  end if
end subroutine cmd_model_compile

```

Execute: Insert a pointer into the global data record and reassign the variable list.

```

⟨Commands: cmd model: TBP⟩+≡
  procedure :: execute => cmd_model_execute

⟨Commands: procedures⟩+≡
subroutine cmd_model_execute (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  call global%select_model (cmd%name)
  if (.not. associated (global%model)) &
    call msg_fatal ("Switching to model '" &
      // char (cmd%name) // "' : model not found")
end subroutine cmd_model_execute

```

Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_library_t
  private
  type(string_t) :: name
contains
  ⟨Commands: cmd library: TBP⟩
end type cmd_library_t

```

Output.

```

<Commands: cmd library: TBP>≡
  procedure :: write => cmd_library_write

<Commands: procedures>+≡
  subroutine cmd_library_write (cmd, unit, indent)
    class(cmd_library_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit)
    call write_indent (u, indent)
    write (u, "(1x,A,1x,'"',A,'\"')") "library =", char (cmd%name)
  end subroutine cmd_library_write

```

Compile. Get the library name.

```

<Commands: cmd library: TBP>+≡
  procedure :: compile => cmd_library_compile

<Commands: procedures>+≡
  subroutine cmd_library_compile (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_name
    pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
    cmd%name = parse_node_get_string (pn_name)
  end subroutine cmd_library_compile

```

Execute: Initialize a new library and push it on the library stack (if it does not yet exist). Insert a pointer to the library into the global data record. Then, try to load the library unless the rebuild flag is set.

```

<Commands: cmd library: TBP>+≡
  procedure :: execute => cmd_library_execute

<Commands: procedures>+≡
  subroutine cmd_library_execute (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(prclib_entry_t), pointer :: lib_entry
    type(process_library_t), pointer :: lib
    logical :: rebuild_library
    lib => global%prclib_stack%get_library_ptr (cmd%name)
    rebuild_library = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    if (.not. (associated (lib))) then
      allocate (lib_entry)
      call lib_entry%init (cmd%name)
      lib => lib_entry%process_library_t
      call global%add_prclib (lib_entry)
    else
      call global%update_prclib (lib)
    end if
    if (associated (lib) .and. .not. rebuild_library) then
      call lib%update_status (global%os_data)
    end if
  end subroutine cmd_library_execute

```

```

    end if
end subroutine cmd_library_execute

```

Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_process_t
    private
    type(string_t) :: id
    integer :: n_in = 0
    type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
    type(parse_node_t), pointer :: pn_out => null ()
    contains
    ⟨Commands: cmd process: TBP⟩
  end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

⟨Commands: cmd process: TBP⟩≡
  procedure :: write => cmd_process_write

⟨Commands: procedures⟩+≡
  subroutine cmd_process_write (cmd, unit, indent)
    class(cmd_process_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)") "process: ", char (cmd%id), " (", &
      size (cmd%pn_pdg_in), " -> X)"
    call cmd%write_options (u, indent)
  end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

⟨Commands: cmd process: TBP⟩+≡
  procedure :: compile => cmd_process_compile

```

```

<Commands: procedures>+≡
subroutine cmd_process_compile (cmd, global)
  class(cmd_process_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_id, pn_in, pn_codes
  integer :: i
  pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
  pn_in => parse_node_get_next_ptr (pn_id, 2)
  cmd%pn_out => parse_node_get_next_ptr (pn_in, 2)
  cmd%pn_opt => parse_node_get_next_ptr (cmd%pn_out)
  call cmd%compile_options (global)
  cmd%id = parse_node_get_string (pn_id)
  cmd%n_in = parse_node_get_n_sub (pn_in)
  pn_codes => parse_node_get_sub_ptr (pn_in)
  allocate (cmd%pn_pdg_in (cmd%n_in))
  do i = 1, cmd%n_in
    cmd%pn_pdg_in(i)%ptr => pn_codes
    pn_codes => parse_node_get_next_ptr (pn_codes)
  end do
end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

```

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_slha_t
private
type(string_t) :: file
logical :: write_mode = .false.
contains
<Commands: cmd slha: TBP>

```

```
end type cmd_slha_t
```

Output.

```
<Commands: cmd slha: TBP>≡
  procedure :: write => cmd_slha_write

<Commands: procedures>+≡
  subroutine cmd_slha_write (cmd, unit, indent)
    class(cmd_slha_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "slha: file name = ", char (cmd%file)
    write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
  end subroutine cmd_slha_write
```

Compile. Read the filename and store it.

```
<Commands: cmd slha: TBP>+≡
  procedure :: compile => cmd_slha_compile

<Commands: procedures>+≡
  subroutine cmd_slha_compile (cmd, global)
    class(cmd_slha_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global

```

Clear values

This command clears the current values of variables or other objects, where this makes sense. It parallels the `show` command. The objects are cleared, but not deleted.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_clear_t
    private
      type(string_t), dimension(:), allocatable :: name
    contains
      <Commands: cmd clear: TBP>
    end type cmd_clear_t
```

Output: list the names of the objects to be cleared.

```
<Commands: cmd clear: TBP>≡
  procedure :: write => cmd_clear_write

<Commands: procedures>+≡
  subroutine cmd_clear_write (cmd, unit, indent)
    class(cmd_clear_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u, i
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)", advance="no") "clear: "
    if (allocated (cmd%name)) then
      do i = 1, size (cmd%name)
        write (u, "(1x,A)", advance="no") char (cmd%name(i))

```

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

⟨Commands: types⟩+=
  type, extends (command_t) :: cmd_expect_t
    private
      type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
      ⟨Commands: cmd expect: TBP⟩
    end type cmd_expect_t

```

Simply tell the status.

```

⟨Commands: cmd expect: TBP⟩=
  procedure :: write => cmd_expect_write

⟨Commands: procedures⟩+=
  subroutine cmd_expect_write (cmd, unit, indent)
    class(cmd_expect_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    if (associated (cmd%pn_lexpr)) then
      write (u, "(1x,A)") "expect: [expression associated]"
    else
      write (u, "(1x,A)") "expect: [undefined]"
    end if
  end subroutine cmd_expect_write

```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

```

⟨Commands: cmd expect: TBP⟩+=
  procedure :: compile => cmd_expect_compile

⟨Commands: procedures⟩+=
  subroutine cmd_expect_compile (cmd, global)
    class(cmd_expect_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_arg
    pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_arg)
    cmd%pn_lexpr => parse_node_get_sub_ptr (pn_arg)
    call cmd%compile_options (global)
  end subroutine cmd_expect_compile

```

```
end subroutine cmd_expect_compile
```

Execute. Evaluate both arguments, print them and their difference (if numerical), and whether they agree. Record the result.

```
⟨Commands: cmd expect: TBP⟩+≡
  procedure :: execute => cmd_expect_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_expect_execute (cmd, global)
    class(cmd_expect_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    logical :: success, is_known

      call msg_error ("expect: undefined result")
      success = .false.
    end if
    call expect_record (success)
  end subroutine cmd_expect_execute
```

Beams

The beam command includes both beam and structure-function definition.

```
⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_beams_t
  private
  integer :: n_in = 0
  type(parse_node_p), dimension(:), allocatable :: pn_pdg
  integer :: n_sf_record = 0
  integer, dimension(:), allocatable :: n_entry
  type(parse_node_p), dimension(:, :), allocatable :: pn_sf_entry
  contains
  ⟨Commands: cmd beams: TBP⟩
end type cmd_beams_t
```

Output. The particle expressions are not resolved.

```

Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

⟨Commands: types⟩+≡
    type :: sentry_expr_t
        type(parse_node_p), dimension(:), allocatable :: expr
        contains
        ⟨Commands: sentry expr: TBP⟩
    end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

⟨Commands: sentry expr: TBP⟩≡
    procedure :: compile => sentry_expr_compile

⟨Commands: procedures⟩+≡
    subroutine sentry_expr_compile (sentry, pn)
        class(sentry_expr_t), intent(out) :: sentry
        type(parse_node_t), intent(in), target :: pn
        type(parse_node_t), pointer :: pn_expr, pn_extra
        integer :: n_expr, i
        n_expr = parse_node_get_n_sub (pn)
        allocate (sentry%expr (n_expr))
        if (n_expr > 0) then

    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%weight_expr => cmd%pn_expr
  end subroutine cmd_weight_execute

```

Selection

Define a selection expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_selection_t
  private

```

```

        type(parse_node_t), pointer :: pn_expr => null ()
contains
  <Commands: cmd selection: TBP>≡
end type cmd_selection_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd selection: TBP>≡
  procedure :: write => cmd_selection_write

<Commands: procedures>+≡
  subroutine cmd_selection_write (cmd, unit, indent)
    class(cmd_selection_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "selection expression: [defined]"
  end subroutine cmd_selection_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd selection: TBP>+≡
  procedure :: compile => cmd_selection_compile

<Commands: procedures>+≡
  subroutine cmd_selection_compile (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_selection_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd selection: TBP>+≡
  procedure :: execute => cmd_selection_execute

<Commands: procedures>+≡
  subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_reweight_t

```

```

    private
    type(parse_node_t), pointer :: pn_expr => null ()
contains
  <Commands: cmd reweight: TBP>
end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd reweight: TBP>≡
  procedure :: write => cmd_reweight_write
<Commands: procedures>+≡
  subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: compile => cmd_reweight_compile
<Commands: procedures>+≡
  subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: execute => cmd_reweight_execute
<Commands: procedures>+≡
  subroutine cmd_reweight_execute (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%reweight_expr => cmd%pn_expr
  end subroutine cmd_reweight_execute

```

Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

<Commands: types>+≡

```

```

type, extends (command_t) :: cmd_alt_setup_t
  private
  type(parse_node_p), dimension(:), allocatable :: setup
contains
  <Commands: cmd alt setup: TBP>
end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

<Commands: cmd alt setup: TBP>≡
  procedure :: write => cmd_alt_setup_write

<Commands: procedures>+≡
  subroutine cmd_alt_setup_write (cmd, unit, indent)
    class(cmd_alt_setup_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
  end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

<Commands: cmd alt setup: TBP>+≡
  procedure :: compile => cmd_alt_setup_compile

<Commands: procedures>+≡
  subroutine cmd_alt_setup_compile (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_list, pn_setup
    integer :: i
    pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
    if (associated (pn_list)) then
      allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
      i = 1
      pn_setup => parse_node_get_sub_ptr (pn_list)
      do while (associated (pn_setup))
        cmd%setup(i)%ptr => pn_setup
        i = i + 1
        pn_setup => parse_node_get_next_ptr (pn_setup)
      end do
    else
      allocate (cmd%setup (0))
    end if
  end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

<Commands: cmd alt setup: TBP>+≡
  procedure :: execute => cmd_alt_setup_execute

<Commands: procedures>+≡
  subroutine cmd_alt_setup_execute (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global

```

```

        if (allocated (global%pn%alt_setup)) deallocate (global%pn%alt_setup)
        allocate (global%pn%alt_setup (size (cmd%setup)), source = cmd%setup)
    end subroutine cmd_alt_setup_execute

```

Integration

Integrate several processes, consecutively with identical parameters.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_integrate_t
    private
        integer :: n_proc = 0
        type(string_t), dimension(:), allocatable :: process_id
    contains
        <Commands: cmd integrate: TBP>
    end type cmd_integrate_t

```

Output: we know the process IDs.

```

<Commands: cmd integrate: TBP>≡
    procedure :: write => cmd_integrate_write

<Commands: procedures>+≡
    subroutine cmd_integrate_write (cmd, unit, indent)

        integer, intent(in), optional :: unit, indent
        integer :: u, i
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)", advance="no") "integrate ("
        do i = 1, cmd%n_proc
            if (i > 1) write (u, "(A,1x)", advance="no") ", "
            write (u, "(A)", advance="no") char (cmd%process_id(i))
        end do
        write (u, "(A)") ")"
    end subroutine cmd_integrate_write

```

Compile.

```

<Commands: cmd integrate: TBP>+≡
    procedure :: compile => cmd_integrate_compile

<Commands: procedures>+≡
    subroutine cmd_integrate_compile (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_proclist, pn_proc
        integer :: i
        pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
        cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
        call cmd%compile_options (global)
        cmd%n_proc = parse_node_get_n_sub (pn_proclist)
        allocate (cmd%process_id (cmd%n_proc))
        pn_proc => parse_node_get_sub_ptr (pn_proclist)
        do i = 1, cmd%n_proc

```

```

        cmd%process_id(i) = parse_node_get_string (pn_proc)
        call global%process_stack%init_result_vars (cmd%process_id(i))
        pn_proc => parse_node_get_next_ptr (pn_proc)
    end do
end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

<Commands: cmd integrate: TBP>+≡
    procedure :: execute => cmd_integrate_execute

<Commands: procedures>+≡
    subroutine cmd_integrate_execute (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        integer :: i
        do i = 1, cmd%n_proc
            call integrate_process (cmd%process_id(i), cmd%local, global)
            call global%process_stack%fill_result_vars (cmd%process_id(i))
            if (signal_is_pending ()) return
        end do
    end subroutine cmd_integrate_execute

```

Observables

Declare an observable. After the declaration, it can be used to record data, and at the end one can retrieve average and error.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_observable_t
        private
        type(string_t) :: id
        contains
        <Commands: cmd observable: TBP>
    end type cmd_observable_t

```

Output. We know the ID.

```

<Commands: cmd observable: TBP>≡
    procedure :: write => cmd_observable_write

<Commands: procedures>+≡
    subroutine cmd_observable_write (cmd, unit, indent)
        class(cmd_observable_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
    end subroutine cmd_observable_write

```

```

integer :: u

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_graph_t
  private
  type(string_t) :: id
  integer :: n_elements = 0
  type(cmd_plot_t), dimension(:), allocatable :: el
  type(string_t), dimension(:), allocatable :: element_id
  contains
  <Commands: cmd graph: TBP>
end type cmd_graph_t
```

Output. Just print the ID.

```
<Commands: cmd graph: TBP>≡
  procedure :: write => cmd_graph_write

<Commands: procedures>+≡
  subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)") "graph: ", char (cmd%id), &
      " (", cmd%n_elements, " entries)"
  end subroutine cmd_graph_write
```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```
<Commands: cmd graph: TBP>+≡
  procedure :: compile => cmd_graph_compile

<Commands: procedures>+≡
  subroutine cmd_graph_compile (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
    integer :: i

    pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      cmd%id = parse_node_get_string (pn_tag)
```

```

case default
  call msg_bug ("graph: name expression not implemented (yet)")
end select
pn_def => parse_node_get_next_ptr (pn_term, 2)
cmd%n_elements = parse_node_get_n_sub (pn_def)
allocate (cmd%element_id (cmd%n_elements))
allocate (cmd%el (cmd%n_elements))
pn_term => parse_node_get_sub_ptr (pn_def)
pn_tag => parse_node_get_sub_ptr (pn_term)
cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
call cmd%el(1)%init (pn_tag, global)
cmd%element_id(1) = parse_node_get_string (pn_tag)
pn_app => parse_node_get_next_ptr (pn_term)
do i = 2, cmd%n_elements
  pn_term => parse_node_get_sub_ptr (pn_app, 2)
  pn_tag => parse_node_get_sub_ptr (pn_term)
  cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
  call cmd%el(i)%init (pn_tag, global)
  cmd%element_id(i) = parse_node_get_string (pn_tag)
  pn_app => parse_node_get_next_ptr (pn_app)
end do

end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

<Commands: cmd graph: TBP>+≡

```

procedure :: execute => cmd_graph_execute

```

<Commands: procedures>+≡

```

subroutine cmd_graph_execute (cmd, global)
  class(cmd_graph_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  type(graph_options_t) :: graph_options
  type(drawing_options_t) :: drawing_options
  integer :: i, type

  var_list => cmd%local%get_var_list_ptr ()
  call graph_options_init (graph_options)
  call set_graph_options (graph_options, var_list)
  call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

  do i = 1, cmd%n_elements
    if (associated (cmd%el(i)%options)) then
      call cmd%el(i)%options%execute (cmd%el(i)%local)
    end if
    type = analysis_store_get_object_type (cmd%element_id(i))
  end do

```

```

select case (type)
case (AN_HISTOGRAM)
    call drawing_options_init_histogram (drawing_options)
case (AN_PLOT)
    call drawing_options_init_plot (drawing_options)
end select
call set_drawing_options (drawing_options, var_list)
if (associated (cmd%el(i)%options)) then
    call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
end if
call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
end do
end subroutine cmd_graph_execute

```

Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
type :: analysis_id_t
type(string_t) :: tag
type(parse_node_t), pointer :: pn_sexpr => null ()
end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_analysis_t
private
type(parse_node_t), pointer :: pn_lexpr => null ()
contains
⟨Commands: cmd analysis: TBP⟩
end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

⟨Commands: cmd analysis: TBP⟩≡
procedure :: write => cmd_analysis_write

⟨Commands: procedures⟩+≡
subroutine cmd_analysis_write (cmd, unit, indent)
class(cmd_analysis_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)") "analysis: [defined]"
end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd analysis: TBP⟩+≡
procedure :: compile => cmd_analysis_compile

```

```

<Commands: procedures>+≡
  subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd analysis: TBP>+≡
  procedure :: execute => cmd_analysis_execute

<Commands: procedures>+≡
  subroutine cmd_analysis_execute (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%analysis_lexpr => cmd%pn_lexpr
  end subroutine cmd_analysis_execute

```

Write histograms and plots

The data type encapsulating the command:

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_write_analysis_t
  private

```

The output format for real data values:

```

⟨Commands: parameters⟩+≡
character(*), parameter, public :: &
  DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
  FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(5), parameter, public :: &
  FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "lo", "la" ]
character(len=3), dimension(16), parameter, public :: &
  FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
    "f95", "log", "ltp", "mpx", "olc", "olp", "pdf", "phs", "sin", "tex" ]

```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```

⟨Commands: cmd write analysis: TBP⟩+≡
  procedure :: execute => cmd_write_analysis_execute

⟨Commands: procedures⟩+≡
subroutine cmd_write_analysis_execute (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  var_list => cmd%local%get_var_list_ptr ()
  call write_analysis_wrap (var_list, global%out_files, &
    cmd%id, tag = cmd%tag)
end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

(Commands: procedures)+≡

```

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

```

Polarized particles

These commands mark particles as (un)polarized, to be applied in subsequent simulation passes. Since this is technically the same as the `stable` command, we take a shortcut and make this an extension, just overriding methods.

```

⟨Commands: types⟩+≡
  type, extends (cmd_stable_t) :: cmd_polarized_t
  contains
    ⟨Commands: cmd polarized: TBP⟩
  end type cmd_polarized_t

  type, extends (cmd_stable_t) :: cmd_unpolarized_t
  contains
    ⟨Commands: cmd unpolarized: TBP⟩
  end type cmd_unpolarized_t

```

Output: we know only the number of particles.

```

⟨Commands: cmd polarized: TBP⟩≡
  procedure :: write => cmd_polarized_write

⟨Commands: cmd unpolarized: TBP⟩≡
  procedure :: write => cmd_unpolarized_write

⟨Commands: procedures⟩+≡

```

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

```

Parameters: number of iterations

Specify number of iterations and number of calls for one integration pass.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_iterations_t
  private
  integer :: n_pass = 0
  type(parse_node_p), dimension(:), allocatable :: pn_expr_n_it
  type(parse_node_p), dimension(:), allocatable :: pn_expr_n_calls
  type(parse_node_p), dimension(:), allocatable :: pn_sexpr_adapt
  contains
  <Commands: cmd iterations: TBP>
end type cmd_iterations_t
```

Output. Display the number of passes, which is known after compilation.

```
<Commands: cmd iterations: TBP>≡
  procedure :: write => cmd_iterations_write

<Commands: procedures>+≡
  subroutine cmd_iterations_write (cmd, unit, indent)

```

Range expressions

We need a special type for storing and evaluating range expressions.

```
(Commands: parameters)+≡  
  integer, parameter :: STEP_NONE = 0  
  integer, parameter :: STEP_ADD = 1  
  integer, parameter :: STEP_SUB = 2  
  integer, parameter :: STEP_MUL = 3  
  integer, parameter :: STEP_DIV = 4  
  integer, parameter :: STEP_COMP_ADD = 11  
  integer, parameter :: STEP_COMP_MUL = 13
```

There is an abstract base type and two implementations: scan over integers and scan over reals.

```
(Commands: types)+≡  
  type, abstract :: range_t  
    type(parse_node_t), pointer :: pn_expr => null ()  
    type(parse_node_t), pointer :: pn_term => null ()  
    type(parse_node_t), pointer :: pn_factor => null ()  
    type(parse_node_t), pointer :: pn_value => null ()  
    type(parse_node_t), pointer :: pn_literal => null ()  
    type(parse_node_t), pointer :: pn_beg => null ()  
    type(parse_node_t), pointer :: pn_end => null ()  
    type(parse_node_t), pointer :: pn_step => null ()  
    type(eval_tree_t) :: expr_beg  
    type(eval_tree_t) :: expr_end  
    type(eval_tree_t) :: expr_step  
    integer :: step_mode = 0  
    integer :: n_step = 0  
  contains  
    (Commands: range: TBP)  
  end type range_t
```

These are the implementations:

```
(Commands: types)+≡  
  type, extends (range_t) :: range_int_t  
    integer :: i_beg = 0  
    integer :: i_end = 0  
    integer :: i_step = 0  
  contains  
    (Commands: range int: TBP)  
  end type range_int_t  
  
  type, extends (range_t) :: range_real_t  
    real(default) :: r_beg = 0  
    real(default) :: r_end = 0  
    real(default) :: r_step = 0  
    real(default) :: lr_beg = 0  
    real(default) :: lr_end = 0  
    real(default) :: lr_step = 0  
  contains  
    (Commands: range real: TBP)  
  end type range_real_t
```

Finalize the allocated dummy node. The other nodes are just pointers.

```

<Commands: range: TBP>≡
    procedure :: final => range_final

<Commands: procedures>+≡
    subroutine range_final (object)
        class(range_t), intent(inout) :: object
        if (associated (object%pn_expr)) then
            call parse_node_final (object%pn_expr, recursive = .false.)
            call parse_node_final (object%pn_term, recursive = .false.)
            call parse_node_final (object%pn_factor, recursive = .false.)
            call parse_node_final (object%pn_value, recursive = .false.)
            call parse_node_final (object%pn_literal, recursive = .false.)
            deallocate (object%pn_expr)
            deallocate (object%pn_term)
            deallocate (object%pn_factor)
            deallocate (object%pn_value)
            deallocate (object%pn_literal)
        end if
    end subroutine range_final

```

Output.

```

end select
end subroutine range_init

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

<Commands: range: TBP>+≡

Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

Note: for the integer/real range array, the obvious implementation as a polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are apparently broken.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_scan_t
  private
  type(string_t) :: name
  integer :: n_values = 0
  type(parse_node_p), dimension(:), allocatable :: scan_cmd
  !!! !!! gfortran 4.7.x memory corruption
  !!! class(range_t), dimension(:), allocatable :: range
  type(range_int_t), dimension(:), allocatable :: range_int
  type(range_real_t), dimension(:), allocatable :: range_real
contains
  <Commands: cmd scan: TBP>
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

<Commands: cmd scan: TBP>≡

```

```

    procedure :: final => cmd_scan_final
  <Commands: procedures>+≡
    recursive subroutine cmd_scan_final (cmd)
      class(cmd_scan_t), intent(inout) :: cmd
      type(parse_node_t), pointer :: pn_var_single, pn_decl_single
      type(string_t) :: key
      integer :: i
      if (allocated (cmd%scan_cmd)) then

          call cmd%range_real(i)%final ()
        end do
      end if
    end subroutine cmd_scan_final

```

Output.

```

  <Commands: cmd scan: TBP>+≡
    procedure :: write => cmd_scan_write
  <Commands: procedures>+≡
    subroutine cmd_scan_write (cmd, unit, indent)
      class(cmd_scan_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = given_output_unit (unit); if (u < 0) return
      call write_indent (u, indent)
      write (u, "(1x,A,1x,A,1x,'(',I0,')')") "scan:", char (cmd%name), &
        cmd%n_values
    end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of `else if` constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_if_t
private
type(parse_node_t), pointer :: pn_if_lexpr => null ()
type(command_list_t), pointer :: if_body => null ()
type(cmd_if_t), dimension(:), pointer :: elsif_cmd => null ()
type(command_list_t), pointer :: else_body => null ()
contains
<Commands: cmd if: TBP>
end type cmd_if_t

```

Finalizer. There are no local options, therefore we can simply override the default finalizer.

```

<Commands: cmd if: TBP>≡
procedure :: final => cmd_if_final

        command => null ()
    end subroutine command_list_append
```

Finalize.

```
<Commands: command list: TBP>+≡
    procedure :: final => command_list_final
```

```

<Commands: procedures>+≡
recursive subroutine command_list_final (cmd_list)
  class(command_list_t), intent(inout) :: cmd_list
  class(command_t), pointer :: command
  do while (associated (cmd_list%first))
    command => cmd_list%first
    cmd_list%first => cmd_list%first%next
    call command%final ()
    deallocate (command)
  end do
  cmd_list%last => null ()
end subroutine command_list_final

```

31.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```

<Commands: command list: TBP>+≡
  procedure :: compile => command_list_compile

<Commands: procedures>+≡
recursive subroutine command_list_compile (cmd_list, pn, global)
  class(command_list_t), intent(inout), target :: cmd_list
  type(parse_node_t), intent(in), target :: pn
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_cmd
  class(command_t), pointer :: command
  integer :: i
  pn_cmd => parse_node_get_sub_ptr (pn)
  do i = 1, parse_node_get_n_sub (pn)
    call dispatch_command (command, pn_cmd)
    call command%compile (global)
    call cmd_list%append (command)
    call terminate_now_if_signal ()
    pn_cmd => parse_node_get_next_ptr (pn_cmd)
  end do
end subroutine command_list_compile

```

31.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```

<Commands: command list: TBP>+≡
  procedure :: execute => command_list_execute

<Commands: procedures>+≡
recursive subroutine command_list_execute (cmd_list, global)
  class(command_list_t), intent(in) :: cmd_list
  type(rt_data_t), intent(inout), target :: global

```

```

class(command_t), pointer :: command
command => cmd_list%first
COMMAND_COND: do while (associated (command))
    call command%execute_options (global)
    call command%execute (global)
    call command%reset_options (global)
    call terminate_now_if_signal ()
    if (global%quit) exit COMMAND_COND
    command => command%next
end do COMMAND_COND
end subroutine command_list_execute

```

31.1.9 Command list syntax

```

<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡
    public :: syntax_cmd_list_init

<Commands: procedures>+≡
    subroutine syntax_cmd_list_init ()
        type(ifile_t) :: ifile
        call define_cmd_list_syntax (ifile)
        call syntax_init (syntax_cmd_list, ifile)
        call ifile_final (ifile)
    end subroutine syntax_cmd_list_init

```

31.2 Toplevel module WHIZARD

```
<whizard.f90>≡  
  <File header>  
  
  module whizard  
  
    use io_units  
    <Use strings>  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF, BACKSLASH  
    use diagnostics  
    use os_interface  
    use ifiles  
    use lexers  
    use parser  
    use variables  
    use eval_trees  
    use models  
    use phs_forests  
    use prclib_stacks  
    use slha_interface  
    use blha_config  
    use rt_data  
    use commands  
  
    <Standard module head>  
  
    <WHIZARD: public>  
  
    <WHIZARD: types>  
  
    save  
  
    contains  
  
    <WHIZARD: procedures>  
  
  end module whizard
```

31.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```
<WHIZARD: public>≡  
  public :: whizard_options_t  
  
<WHIZARD: types>≡  
  type :: whizard_options_t  
    type(string_t) :: preload_model  
    type(string_t) :: default_lib  
    type(string_t) :: preload_libraries  
    logical :: rebuild_library = .false.
```

```

        logical :: recompile_library = .false.
        logical :: rebuild_user
        logical :: rebuild_phs = .false.
        logical :: rebuild_grids = .false.
        logical :: rebuild_events = .false.
    end type whizard_options_t

```

31.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

<WHIZARD: types> +=
    type, extends (parse_tree_t) :: pt_entry_t
        type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the `last` pointer.

```

<WHIZARD: types> +=
    type :: pt_stack_t
        type(pt_entry_t), pointer :: last => null ()
        contains
        <WHIZARD: pt_stack: TBP>
    end type pt_stack_t

```

The finalizer is called at the very end.

```

<WHIZARD: pt_stack: TBP> =
    procedure :: final => pt_stack_final

<WHIZARD: procedures> =
    subroutine pt_stack_final (pt_stack)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(pt_entry_t), pointer :: current
        do while (associated (pt_stack%last))
            current => pt_stack%last
            pt_stack%last => current%previous
            call parse_tree_final (current%parse_tree_t)
            deallocate (current)
        end do
    end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt_stack: TBP> +=
    procedure :: push => pt_stack_push

<WHIZARD: procedures> +=
    subroutine pt_stack_push (pt_stack, parse_tree)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(parse_tree_t), intent(out), pointer :: parse_tree
        type(pt_entry_t), pointer :: current

```

```

allocate (current)
parse_tree => current%parse_tree_t
current%previous => pt_stack%last
pt_stack%last => current
end subroutine pt_stack_push

```

31.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a `WHIZARD` instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+≡
public :: whizard_t

<WHIZARD: types>+≡
type :: whizard_t
type(whizard_options_t) :: options
type(rt_data_t) :: global
type(pt_stack_t) :: pt_stack
contains
<WHIZARD: whizard: TBP>
end type whizard_t

```

31.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>≡
procedure :: init => whizard_init

<WHIZARD: procedures>+≡
subroutine whizard_init (whizard, options, paths, logfile)
class(whizard_t), intent(out), target :: whizard
type(whizard_options_t), intent(in) :: options
type(paths_t), intent(in), optional :: paths
type(string_t), intent(in), optional :: logfile
call init_syntax_tables ()
whizard%options = options
call whizard%global%global_init (paths, logfile)
call whizard%init_rebuild_flags ()
call whizard%preload_model ()
call whizard%preload_library ()
call whizard%global%init_fallback_model &
(var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))

```

```

        call whizard%global%init_radiation_model &
            (var_str ("SM_rad"), var_str ("SM_rad.mdl"))
    end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+=
    procedure :: final => whizard_final

<WHIZARD: procedures>+=
    subroutine whizard_final (whizard)
        class(whizard_t), intent(inout), target :: whizard
        call whizard%global%final ()
        call whizard%pt_stack%final ()
        !!! JRR: WK please check (#529)
        !    call user_code_final ()
        call final_syntax_tables ()
    end subroutine whizard_final

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+=
    procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: procedures>+=
    subroutine whizard_init_rebuild_flags (whizard)
        class(whizard_t), intent(inout), target :: whizard
        associate (var_list => whizard%global%var_list, options => whizard%options)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_library"), options%rebuild_library, &
                    intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?recompile_library"), &
                    options%recompile_library, &
                    intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_phase_space"), options%rebuild_phs, &
                    intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_grids"), options%rebuild_grids, &
                    intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?powheg_rebuild_grids"), options%rebuild_grids, &
                    intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_events"), options%rebuild_events, &
                    intrinsic=.true.)
        end associate
    end subroutine whizard_init_rebuild_flags

```

This procedure preloads a model, if a model name is given.

```

<WHIZARD: whizard: TBP>+=
    procedure :: preload_model => whizard_preload_model

```

```

{WHIZARD: procedures}+=

  call split (libs, library_name, " ")
  if (library_name /= "") then
    allocate (lib_entry)
    call lib_entry%init (library_name)
    call whizard%global%add_prclib (lib_entry)
  end if
end do

```

```

        call msg_message ("Preloaded library: " // char (library_name))
    end if
end do SCAN_LIBS
end subroutine whizard_preload_library

```

31.2.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

```

<WHIZARD: public>+≡
    public :: init_syntax_tables
    public :: final_syntax_tables

<WHIZARD: procedures>+≡
    subroutine init_syntax_tables ()
        call syntax_model_file_init ()
        call syntax_phs_forest_init ()
        call syntax_pexpr_init ()
        call syntax_slha_init ()
        call syntax_blha_contract_init ()
        call syntax_cmd_list_init ()
    end subroutine init_syntax_tables

    subroutine final_syntax_tables ()
        call syntax_model_file_final ()
        call syntax_phs_forest_final ()
        call syntax_pexpr_final ()
        call syntax_slha_final ()
        call syntax_blha_contract_final ()
        call syntax_cmd_list_final ()
    end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
    public :: write_syntax_tables

<WHIZARD: procedures>+≡
    subroutine write_syntax_tables ()
        integer :: unit
        character(*), parameter :: file_model = "whizard.model_file.syntax"
        character(*), parameter :: file_phs = "whizard.phase_space_file.syntax"
        character(*), parameter :: file_pexpr = "whizard.prt_expressions.syntax"
        character(*), parameter :: file_slha = "whizard.slha.syntax"
        character(*), parameter :: file_sindarin = "whizard.sindarin.syntax"
        unit = free_unit ()
    end subroutine write_syntax_tables

```

```

print *, "Writing file '" // file_model // "'"
open (unit=unit, file=file_model, status="replace", action="write")
write (unit, "(A)")  VERSION_STRING
write (unit, "(A)")  "Syntax definition file: " // file_model
call syntax_model_file_write (unit)
close (unit)

write (unit, "(A)")  VERSION_STRING
write (unit, "(A)")  "Syntax definition file: " // file_sindarin
call syntax_cmd_list_write (unit)
close (unit)
end subroutine write_syntax_tables

```

31.2.6 Execute command lists

Process commands given on the command line, stored as an ifile. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: process_ifile => whizard_process_ifile

<WHIZARD: procedures>+≡
    subroutine whizard_process_ifile (whizard, ifile, quit, quit_code)
        class(whizard_t), intent(inout), target :: whizard
        type(ifile_t), intent(in) :: ifile
        logical, intent(out) :: quit
        integer, intent(out) :: quit_code
        type(lexer_t), target :: lexer
        type(stream_t), target :: stream
        call msg_message ("Reading commands given on the command line")
        call lexer_init_cmd_list (lexer)
        call stream_init (stream, ifile)
        call whizard%process_stream (stream, lexer, quit, quit_code)
        call stream_final (stream)
        call lexer_final (lexer)
    end subroutine whizard_process_ifile

```

```
end subroutine whizard_process_ifile
```

Process standard input as a command list. The whole input is read, compiled and executed as a whole.

```
<WHIZARD: whizard: TBP>+=
  procedure :: process_stdin => whizard_process_stdin
<WHIZARD: procedures>+=
  subroutine whizard_process_stdin (whizard, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    call msg_message ("Reading commands from standard input")
    call lexer_init_cmd_list (lexer)
    call stream_init (stream, 5)
    call whizard%process_stream (stream, lexer, quit, quit_code)
    call stream_final (stream)
    call lexer_final (lexer)
  end subroutine whizard_process_stdin
```

Process a file as a command list.

```
<WHIZARD: whizard: TBP>+=
  procedure :: process_file => whizard_process_file
<WHIZARD: procedures>+=
  subroutine whizard_process_file (whizard, file, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t), intent(in) :: file
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    logical :: exist

end if
end function get_option_value

end module cmdline_options

```

31.4 Driver program

The main program handles command options, initializes the environment, and runs WHIZARD in a particular mode (interactive, file, standard input).

This is also used in the C interface:

```
<Main: cmdline arg len declaration>≡  
    integer, parameter :: CMDLINE_ARG_LEN = 1000
```

The actual main program:

```
<main.f90>≡  
<File header>  
  
program main  
  
    <Use strings>  
    use unit_tests  
    use system_dependencies  
    use diagnostics  
    use ifiles  
    use os_interface  
    use whizard  
  
    use cmdline_options  
  
    implicit none  
  
    <Main: cmdline arg len declaration>  
  
    ! Main program variable declarations  
    character(CMDLINE_ARG_LEN) :: arg  
    character(2) :: option  
    type(string_t) :: long_option, value  
    integer :: i, j, arg_len, arg_status, area  
    logical :: look_for_options  
    logical :: interactive  
    logical :: banner  
    type(string_t) :: files, this, model, default_lib, library, libraries  
    type(string_t) :: logfile  
    logical :: user_code_enable = .false.  
    integer :: n_user_src = 0, n_user_lib = 0  
    type(string_t) :: user_src, user_lib, user_target  
    type(paths_t) :: paths  
    logical :: rebuild_library, rebuild_user

```

31.5.1 Self-tests

For those self-tests, we need some auxiliary routines that provide an environment. The environment depends on things that are not available at the level of the module that we want to test.

Testbed for event I/O

This subroutine prepares a test process with a single event. All objects are allocated via anonymous pointers, because we want to recover the pointers and delete the objects in a separate procedure.

```
<Main: tests>≡
subroutine prepare_eio_test (event, unweighted, n_alt)
  use variables
  use model_data
  use processes
  use processes_ut, only: prepare_test_process
  use event_base
  use events

  class(generic_event_t), intent(inout), pointer :: event
  logical, intent(in), optional :: unweighted
  integer, intent(in), optional :: n_alt
  type(model_data_t), pointer :: model
  type(var_list_t) :: var_list
  type(process_t), pointer :: process
  type(process_instance_t), pointer :: process_instance

  allocate (model)
  call model%init_test ()

  allocate (process)
  allocate (process_instance)

  call prepare_test_process (process, process_instance, model)
  call process_instance%setup_event_data ()

  call model%final ()
  deallocate (model)

  allocate (event_t :: event)
  select type (event)
  type is (event_t)
    if (present (unweighted)) then
      call var_list_append_log (var_list, &
        var_str ("?unweighted"), unweighted, &
        intrinsic = .true.)
    else
      call var_list_append_log (var_list, &
        var_str ("?unweighted"), .true., &
        intrinsic = .true.)
    end if
  call var_list_append_string (var_list, &
    var_str ("sample_normalization"), &
```

```

        var_str ("auto"), intrinsic = .true.)
    call event%basic_init (var_list, n_alt)
    call event%connect (process_instance, process%get_model_ptr ())
    call var_list%final ()
end select

end subroutine prepare_eio_test

```

Recover those pointers, finalize the objects and deallocate.

<Main: tests>+≡

```

subroutine cleanup_eio_test (event)
    use model_data
    use processes
    use event_base
    use events

    class(generic_event_t), intent(inout), pointer :: event
    type(process_t), pointer :: process
    type(process_instance_t), pointer :: process_instance

    select type (event)
    type is (event_t)
        process => event%get_process_ptr ()
        process_instance => event%get_process_instance_ptr ()
        call cleanup_test_process (process, process_instance)
        deallocate (process_instance)
        deallocate (process)
        call event%final ()
    end select
    deallocate (event)

end subroutine cleanup_eio_test

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

<Main: use tests>≡

```

    use eio_base_ut, only: eio_prepare_test
    use eio_base_ut, only: eio_cleanup_test

```

<Main: prepare testbed>≡

```

    eio_prepare_test => prepare_eio_test
    eio_cleanup_test => cleanup_eio_test

```

Any Model

This procedure reads any model from file and, optionally, assigns a var-list pointer.

<Main: tests>+≡

```

subroutine prepare_whizard_model (model, name, vars)
    <Use strings>
    use os_interface
    use model_data
    use var_base

```

```

use models
class(model_data_t), intent(inout), pointer :: model
type(string_t), intent(in) :: name
class(vars_t), pointer, intent(out), optional :: vars
type(os_data_t) :: os_data
call syntax_model_file_init ()
call os_data_init (os_data)
allocate (model_t :: model)
select type (model)
type is (model_t)
    call model%read (name // ".mdl", os_data)
    if (present (vars)) then
        vars => model%get_var_list_ptr ()
    end if
end select
end subroutine prepare_whizard_model

```

Cleanup after use. Includes deletion of the model-file syntax.

```

<Main: tests>+≡
subroutine cleanup_whizard_model (model)
    use model_data
    use models
    class(model_data_t), intent(inout), pointer :: model
    call model%final ()
    deallocate (model)
    call syntax_model_file_final ()
end subroutine cleanup_whizard_model

```

Assign those procedures to appropriate pointers (module variables) in the `model_testbed` module, so they can be called as if they were module procedures.

```

<Main: prepare testbed>+≡
prepare_model => prepare_whizard_model
cleanup_model => cleanup_whizard_model

```

Fallback model: hadrons

Some event format tests require the hadronic SM implementation, which has to be read from file. We provide the functionality here, so the tests do not depend on model I/O.

```

<Main: tests>+≡
subroutine prepare_fallback_model (model)
    use model_data
    class(model_data_t), intent(inout), pointer :: model
    call prepare_whizard_model (model, var_str ("SM_hadrons"))
end subroutine prepare_fallback_model

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

<Main: use tests>+≡
use eio_base_ut, only: eio_prepare_fallback_model
use eio_base_ut, only: eio_cleanup_fallback_model

```

```

⟨Main: prepare testbed⟩+≡
    eio_prepare_fallback_model => prepare_fallback_model
    eio_cleanup_fallback_model => cleanup_model

```

Access to the test random-number generator

This generator is not normally available for the dispatcher. We assign an additional dispatch routine to the hook in the `dispatch` module which will be checked before the default rule.

```

⟨Main: use tests⟩+≡
    use dispatch, only: dispatch_rng_factory_extra
    use dispatch_ut, only: dispatch_rng_factory_test

⟨Main: prepare testbed⟩+≡
    dispatch_rng_factory_extra => dispatch_rng_factory_test

```

Access to the test structure functions

These are not normally available for the dispatcher. We assign an additional dispatch routine to the hook in the `dispatch` module which will be checked before the default rule.

```

⟨Main: use tests⟩+≡
    use dispatch, only: dispatch_sf_data_extra
    use dispatch_ut, only: dispatch_sf_data_test

⟨Main: prepare testbed⟩+≡
    dispatch_sf_data_extra => dispatch_sf_data_test

```

Procedure for Checking

This is for developers only, but needs a well-defined interface.

```

⟨Main: tests⟩+≡
    subroutine whizard_check (check, results)
        use io_units
        use model_testbed

    ⟨Main: use tests⟩

        type(string_t), intent(in) :: check
        type(test_results_t), intent(inout) :: results
        type(os_data_t) :: os_data
        integer :: u

        call os_data_init (os_data)
        u = free_unit ()
        open (u, file="whizard_check." // char (check) // ".log", &
            action="write", status="replace")
        call msg_message (repeat ('=', 76), 0)
        call msg_message ("Running self-test: " // char (check), 0)
        call msg_message (repeat ('-', 76), 0)
    ⟨Main: prepare testbed⟩
        select case (char (check))
    ⟨Main: test cases⟩

```

```

    case ("all")
        <Main: all tests>
    case default
        call msg_fatal ("Self-test ' " // char (check) // "' not implemented.")
    end select
    close (u)
end subroutine whizard_check

```
