Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

This is the function $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

Mimicking the behavior of a process object, we store the argument and result inside the sampler, so we can fetch results.

<MCI midpoint: test types>≡

type, extends (mci_sampler_t) :: test_sampler_1_t

real(default), dimension(:), allocatable :: x

real(default) :: val

contains

<MCI midpoint: test sampler 1: TBP>

end type test_sampler_1_t

Output: There is nothing stored inside, so just print an informative line.

<MCI midpoint: test sampler 1: TBP>≡

procedure :: write => test_sampler_1_write

<MCI midpoint: tests>≡

subroutine test_sampler_1_write (object, unit, testflag)

class(test_sampler_1_t), intent(in) :: object

integer, intent(in), optional :: unit

logical, intent(in), optional :: testflag

integer :: u

u = given_output_unit (unit)

write (u, "(1x,A)") "Test sampler: f(x) = 3 x^2"

end subroutine test_sampler_1_write

Evaluation: compute the function value. The output x parameter (only one channel) is identical to the input x , and the Jacobian is 1.

<MCI midpoint: test sampler 1: TBP>+≡

procedure :: evaluate => test_sampler_1_evaluate

```

<MCI midpoint: tests>+≡

19.5 VAMP interface

The standard method for integration is **VAMP**: the multi-channel version of the VEGAS algorithm. Each parameterization (channel) of the hypercube is binned in each dimension. The binning is equally equidistant, but an iteration of the integration procedure, the binning is updated for each dimension, according to the variance distribution of the integrand, summed over all other dimension. In the next iteration, the binning approximates (hopefully) follows the integrand more closely, and the accuracy of the result is increased. Furthermore, the relative weight of the individual channels is also updated after an iteration.

The bin distribution is denoted as the grid for a channel, which we can write to file and reuse later.

In our implementation we specify the generic **VAMP** algorithm more tightly: the number of bins is equal for all dimensions, the initial weights are all equal. The user controls whether to update bins and/or weights after each iteration. The integration is organized in passes, each one consisting of several iterations with a common number of calls to the integrand. The first passes are intended as warmup, so the results are displayed but otherwise discarded. In the final pass, the integration estimates for the individual iterations are averaged for the final result.

Update the MCI record (i.e., the integration passes) by reading from input stream. The stream should contain a `write` output from a previous run. We first check the MD5 sum of the configuration parameters. If that matches, we proceed directly to the stored integration passes. If successful, we may continue to read the file; the position will be after a blank line that must follow the MCI record.

Integrate. Perform a new integration pass (possibly reusing previous results), which may consist of several iterations.

Note: we record the integral once per iteration. The integral stored in the `mci` record itself is the last integral of the current iteration, no averaging done. The `results` record may average results.

Note: recording the efficiency is not supported yet.

Prepare an event generation pass. Should be called before a sequence of events is generated, then we should call the corresponding finalizer.

The pass-specific data of the previous integration pass are retained, but we reset the number of iterations and calls to zero. The latter now counts the number of events (calls to the sampling function, actually).

Generate weighted event. Note that the event weight (`vamp_weight`) is not just the MCI weight. `vamp_next_event` selects a channel based on the channel weights multiplied by the (previously recorded) maximum integrand value of the channel. The MCI weight is renormalized accordingly, to cancel this effect on the result.

19.5.5 Sampler as Workspace

In the full setup, the sampling function requires the process instance object as workspace. We implement this by (i) implementing the process instance as a type extension of the abstract `sampler_t` object used by the MCI implementation and (ii) providing such an object as an extra argument to the sampling function that VAMP can call. To minimize cross-package dependencies, we use an abstract type `vamp_workspace` that VAMP declares and extend this by including a pointer to the `sampler` and `instance` objects. In the body of the sampling function, we dereference this pointer and can then work with the contents.

```
<MCI vamp: types>+≡
  type, extends (vamp_data_t) :: mci_workspace_t
    class(mci_sampler_t), pointer :: sampler => null ()
    class(mci_vamp_instance_t), pointer :: instance => null ()
  end type mci_workspace_t
```

19.5.6 Integrator instance

The history entries should point to the corresponding history entry in the `pass_t` object. If there is none, we may allocate a local history, which is then just transient.

```

Prepare a new integration pass: write the pass-specific settings to the `instance` object. This should be called initially, together with the `create_grids` procedure, and whenever we start a new integration pass.

Set `reshape` if the number of calls is different than previously (unless it was zero, indicating the first pass).

We link VAMP histories to the allocated histories in the current pass object, so the recorded results are persistent. However, if there are no histories present there, we allocate them locally. In that case, the histories will disappear together with the MCI instance object.

            end if
        end associate
    end subroutine mci_vamp_instance_create_grids

```

Reset a grid set, so we can start a fresh integration pass. In effect, we delete results of previous integrations, but keep the grid shapes, weights, and variance arrays, so adaptation is still possible. The grids are prepared for a specific number of calls (per iteration) and sampling mode (stratified/importance).

The `vamp_discard_integrals` implementation will reshape the grids only if the argument `num_calls` is present.

```

Integration: sample the VAMP grids. The number of calls etc. are already stored inside the grids. We provide the random-number generator, the sampling function, and a link to the workspace object, which happens to contain a pointer to the sampler object. The sampler object thus becomes the workspace of the sampling function.

Note: in the current implementation, the random-number generator must be the TAO generator. This explicit dependence should be removed from the VAMP implementation.

```

19.5.7 Sampling function

The VAMP sampling function has a well-defined interface which we have to implement. The **data** argument allows us to pass pointers to the **sampler** and **instance** objects, so we can access configuration data and fill point-dependent contents within these objects.

The **weights** and **channel** argument must be present in the call.

Note: we would normally declare the **instance** pointer with the concrete type, or just use the **data** component directly. Unfortunately, gfortran 4.6 forgets the inherited base-type methods in that case.

Note: this is the place where we must look for external signals, i.e., interrupt from the OS. We would like to raise a VAMP exception which is then caught by **vamp_sample_grids** as the caller, so it dumps its current state and returns (with the signal still pending). WHIZARD will then terminate gracefully. Of course, VAMP should be able to resume from the dump.

In the current implementation, we handle the exception in place and terminate immediately. The incomplete current integration pass is lost.

```

<MCI vamp: procedures>+≡
    function vamp_sampling_function &
        (xi, data, weights, channel, grids) result (f)
    real(default) :: f
    real(default), dimension(:), intent(in) :: xi
    class(vamp_data_t), intent(in) :: data
    real(default), dimension(:), intent(in), optional :: weights
    integer, intent(in), optional :: channel
    type(vamp_grid), dimension(:), intent(in), optional :: grids
    type(exception) :: exc

```

```

class(mci_instance_t), pointer :: instance
logical :: verbose
character(*), parameter :: FN = "WHIZARD sampling function"
select type (data)
type is (mci_workspace_t)
    instance => data%instance
    select type (instance)
    class is (mci_vamp_instance_t)
        instance%calls = instance%calls + 1
        verbose = instance%mci%verbose
    end select
    call instance%evaluate (data%sampler, channel, xi)
    if (signal_is_pending ()) then
        call raise_exception (exc, EXC_FATAL, FN, "signal received")
        call handle_vamp_exception (exc, verbose)
        call terminate_now_if_signal ()
    end if
    call terminate_now_if_single_event ()
    f = instance%get_value ()
end select
end function vamp_sampling_function

```

This is supposed to be the mapping between integration channels. The VAMP event generating procedures technically require it, but it is meaningless in our setup where all transformations happen inside the sampler object. So, this implementation is trivial:

```

⟨MCI vamp: procedures⟩+=≡
pure function phi_trivial (xi, channel_dummy) result (x)
    real(default), dimension(:), intent(in) :: xi
    integer, intent(in) :: channel_dummy
    real(default), dimension(size(xi)) :: x
    x = xi
end function phi_trivial

```

19.5.8 Integrator instance: evaluation

Here, we compute the multi-channel reweighting factor for the current channel, that accounts for the Jacobians of the transformations from/to all other channels.

The computation of the VAMP probabilities may consume considerable time, therefore we enable parallel evaluation. (Collecting the contributions to `mci%g` is a reduction, which we should also implement via OpenMP.)

```

⟨MCI vamp: mci vamp instance: TBP⟩+=≡
procedure :: compute_weight => mci_vamp_instance_compute_weight

⟨MCI vamp: procedures⟩+=≡
subroutine mci_vamp_instance_compute_weight (mci, c)
    class(mci_vamp_instance_t), intent(inout) :: mci
    integer, intent(in) :: c
    integer :: i
    mci%selected_channel = c
    !$OMP PARALLEL PRIVATE(i) SHARED(mci)

```

```

!$OMP DO
do i = 1, mci%nci%nc_channel
  if (mci%w(i) /= 0) then
    mci%gi(i) = vamp_probability (mci%grids%grids(i), mci%x(:,i))
  else
    mci%gi(i) = 0
  end if
end do
!$OMP END DO
!$OMP END PARALLEL
mci%g = 0
if (mci%gi(c) /= 0) then
  do i = 1, mci%nci%nc_channel
    if (mci%w(i) /= 0 .and. mci%f(i) /= 0) then
      mci%g = mci%g + mci%w(i) * mci%gi(i) / mci%f(i)
    end if
  end do
end if
if (mci%g /= 0) then
  mci%nci_weight = mci%gi(c) / mci%g
else
  mci%nci_weight = 0
end if
end subroutine mci_vamp_instance_compute_weight

```

Record the integrand.

```

<MCI vamp: mci vamp instance: TBP>+≡
  procedure :: record_integrand => mci_vamp_instance_record_integrand

<MCI vamp: procedures>+≡
  subroutine mci_vamp_instance_record_integrand (mci, integrand)
    class(mci_vamp_instance_t), intent(inout) :: mci
    real(default), intent(in) :: integrand
    mci%integrand = integrand
  end subroutine mci_vamp_instance_record_integrand

```

Get the event weight. The default routine returns the same value that we would use for integration. This is correct if we select the integration channel according to the channel weight. `vamp_next_event` does differently, so we should rather rely on the weight that VAMP returns. This is the value stored in `vamp_weight`. We override the default TBP accordingly.

```

<MCI vamp: mci vamp instance: TBP>+≡
  procedure :: get_event_weight => mci_vamp_instance_get_event_weight
  procedure :: get_event_excess => mci_vamp_instance_get_event_excess

<MCI vamp: procedures>+≡

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is $11x^{10}$, also with integral 1.

Mode 4 includes ranges of zero and negative function value, the integral is negative. The results should be identical to the results of `mci_midpoint_4`, where the same function is evaluated. The function is $f(x) = (1 - 3x^2) \theta(x - 1/2)$ with integral $\int_0^1 f(x) dx = -3/8$, minimum $f(1) = -2$ and maximum $f(1/2) = 1/4$.

```

<MCI vamp: test types>≡
  type, extends (mci_sampler_t) :: test_sampler_1_t
    real(default), dimension(:), allocatable :: x
    real(default) :: val
    integer :: mode = 1
  contains
    <MCI vamp: test sampler 1: TBP>
  end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

Two-channel, two dimension test sampler

This sampler implements the function

$$f(x, y) = 4 \sin^2(\pi x) \sin^2(\pi y) + 2 \sin^2(\pi v) \quad (19.11)$$

where

$$x = u^v \quad u = xy \quad (19.12)$$

$$y = u^{(1-v)} \quad v = \frac{1}{2} \left(1 + \frac{\log(x/y)}{\log xy} \right) \quad (19.13)$$

Each term contributes 1 to the integral. The first term in the function is peaked along a cross aligned to the coordinates x and y , while the second term is peaked along the diagonal $x = y$.

The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = |\log u| \quad (19.14)$$

```

Two-channel, one dimension test sampler

This sampler implements the function

$$f(x, y) = a * 5x^4 + b * 5(1 - x)^4 \quad (19.15)$$

Each term contributes 1 to the integral, multiplied by a or b , respectively. The first term is peaked at $x = 1$, the second one at $x = 0$.

We implement the two mappings

$$x = u^{1/5} \quad \text{and} \quad x = 1 - v^{1/5}, \quad (19.16)$$

with Jacobians

$$\frac{\partial(x)}{\partial(u)} = u^{-4/5}/5 \quad \text{and} \quad v^{-4/5}/5, \quad (19.17)$$

respectively. The first mapping concentrates points near $x = 1$, the second one near $x = 0$.

One-dimensional integration

Construct an integrator and use it for a one-dimensional sampler.

Note: We would like to check the precise contents of the grid allocated during integration, but the output format for reals is very long (for good reasons), so the last digits in the grid content display are numerical noise. So, we just check the integration results.

Chapter 20

Parton shower and interface to PYTHIA6

This is the code for the WHIZARD QCD parton shower for final state radiation (FSR) and initial state radiation (ISR) as well as the interface to the PYTHIA module for showering and hadronization.

20.1 Basics of the shower

```
<shower_base.f90>≡  
  <File header>  
  
  module shower_base  
  
    <Use kinds with double>  
    <Use strings>  
    use io_units  
    use constants  
    use diagnostics  
    use format_utils, only: write_separator  
    use lorentz  
    use particles  
    use os_interface  
    use rng_base  
    use physics_defs  
    use sm_physics, only: running_as_lam  
    use particles  
    use variables  
    use model_data  
    use pdf  
  
    <Standard module head>  
  
    <Shower base: parameters>  
  
    <Shower base: public>
```

```

    <Shower base: types>

    <Shower base: interfaces>

contains

    <Shower base: procedures>

end module shower_base

```

20.1.1 Shower implementations

```

<Shower base: public>≡
    public :: PS_WHIZARD, PS_PYTHIA6, PS_PYTHIA8, PS_UNDEFINED

<Shower base: parameters>≡
    integer, parameter :: PS_WHIZARD = 1
    integer, parameter :: PS_PYTHIA6 = 2
    integer, parameter :: PS_PYTHIA8 = 3
    integer, parameter :: PS_UNDEFINED = 17

A dictionary
<Shower base: public>+≡
    public :: shower_method_of_string

<Shower base: procedures>≡
    elemental function shower_method_of_string (string) result (i)

```

```

    case default
        string = "UNDEFINED"
    end select
end function shower_method_to_string

```

20.1.2 Shower settings

These are the general shower settings, the settings and parameters for the matching are defined in the corresponding matching modules. The width and the cutoff of the Gaussian primordial k_t distribution, PARP(91) and PARP(93), in GeV, are called `isr_primordial_kt_width` and `isr_primordial_kt_cutoff` in WHIZARD. The parameter MSTJ(45) gives the maximum number of flavors in gluon decay to quarks, and is here called `max_n_flavors`.

The two parameters `isr_alpha_s_running` and `[[fsr_alpha_s_running` decide whether to use constant or running α_s in the form of the function $D_{\alpha_s}(t)$ for the FSR and ISR (MSTJ(44), MSTP(64)), respectively. The next parameter, `fixed_alpha_s` is the parameter PARU(111), which sets the value for constant α_s , and the flag whether to use P_t -ordered ISR is `isr_pt_ordered`.

```

```

Mass and mass squared selection functions. All masses are in GeV. Light quarks are assumed to be ordered, $m_1 < m_2 < m_3 \dots$, and they get current masses, not elementary ones. Mesons and baryons other than proton and neutron are needed as beam-remnants. Particles with PDG number zero are taken massless, as well as proper beam remnants and any other particles.

20.2.1 The basic type defintions

The type `parton_t` defines a parton for the shower. The `x` value of the parton is only needed for spacelike showers. The pointer `initial` is only needed for partons in initial showers, it points to the hadron the parton is coming from. An auxiliary value for the P_t -ordered ISR is `aux_pt`. Then, there are two auxiliary entries for the clustering of CKKW pseudo weights and CKKW matching, `ckkwlabel` and `ckkwscale`. In order to make shower settings available to all operations on the shower partons, we endow the `parton_t` type with a pointer to `shower_settings_t`.

```

The parameters of the shower module:

<Shower core: parameters>≡
 real(default), save :: alphasxpdfmax = 12._default

In this routine, y and y_{\min} are the jet measures, w and w_{\max} are weights, s is the kinematic energy squared of the interaction. The flag `isr_is_possible_and_allowed` checks whether the initial parton is set, lepton-hadron collisions are not implemented (yet).

As a workaround: as WHIZARD can treat partons as massless, there might be partons with $E < m$: if such a parton is found, quarks will be treated massless.

We combine the `particle_set` from the hard interaction with the partons of the shower. For simplicity, we do not maintain the mother-daughter-relations of the shower. Hadronic `beam_remnants` of the old `particle_set` are removed as they are provided, including proper flavor information, by the ISR shower.

!C      KTCLUS: written by Mike Seymour, July 1992.
!C      Last modified November 2000.
!C      Please send comments or suggestions to Mike.Seymour@rl.ac.uk
!C
!C      This is a general-purpose kt clustering package.
!C      It can handle ee, ep and pp collisions.
!C      It is loosely based on the program of Siggi Bethke.
!C
!C      The time taken (on a 10MIP machine) is (0.2microsec)*N**3
!C      where N is the number of particles.

```

```

!C      Over 90 percent of this time is used in subroutine KTPMIN, which
!C      simply finds the minimum member of a one-dimensional array.
!C      It is well worth thinking about optimization: on the SPARCstation
!C      a factor of two increase was obtained simply by increasing the
!C      optimization level from its default value.
!C
!C      The approach is to separate the different stages of analysis.
!C      KTCLUS does all the clustering and records a merging history.
!C      It returns a simple list of the y values at which each merging
!C      occurred. Then the following routines can be called to give extra
!C      information on the most recently analysed event.
!C      KTCLUR is identical but includes an R parameter, see below.
!C      KTYCUT gives the number of jets at each given YCUT value.
!C      KTYSUB gives the number of sub-jets at each given YCUT value.
!C      KTBEAM gives same info as KTCLUS but only for merges with the beam
!C      KTJOIN gives same info as KTCLUS but for merges of sub-jets.
!C      KTRECO reconstructs the jet momenta at a given value of YCUT.
!C      It also gives information on which jets at scale YCUT belong to
!C      which macro-jets at scale YMAC, for studying sub-jet properties.
!C      K TINCL reconstructs the jet momenta according to the inclusive jet
!C      definition of Ellis and Soper.
!C      KTISUB, KTIJOI and KTIREC are like KTYSUB, KTJOIN and KTRECO,
!C      except that they only apply to one inclusive jet at a time,
!C      with the pt of that jet automatically used for ECUT.
!C      KTWICH gives a list of which particles ended up in which jets.
!C      KTWCHS gives the same thing, but only for subjets.
!C      Note that the numbering of jets used by these two routines is
!C      guaranteed to be the same as that used by KTRECO.
!C
!C      The collision type and analysis type are indicated by the first
!C      argument of KTCLUS. IMODE=<TYPE><ANGLE><MONO><RECOM> where
!C      TYPE:  1=>ee, 2=>ep with p in -z direction, 3=>pe, 4=>pp
!C      ANGLE:  1=>angular kt def., 2=>DeltaR, 3=>f(DeltaEta,DeltaPhi)
!C              where f() $=2(\cosh(\eta)-\cos(\phi))$  is the QCD emission metric
!C      MONO:   1=>derive relative pseudoparticle angles from jets
!C              2=>monotonic definitions of relative angles
!C      RECOM:  1=>E recombination scheme, 2=>pt scheme, 3=>pt**2 scheme
!C
!C      There are also abbreviated forms for the most common combinations:
!C      IMODE=1 => E scheme in e+e-                (=1111)
!C              2 => E scheme in ep                 (=2111)
!C              3 => E scheme in pe                 (=3111)
!C              4 => E scheme in pp                 (=4111)
!C              5 => covariant E scheme in pp       (=4211)
!C              6 => covariant pt-scheme in pp      (=4212)
!C              7 => covariant monotonic pt**2-scheme in pp (=4223)
!C
!C      KTRECO no longer needs to reconstruct the momenta according to the
!C      same recombination scheme in which they were clustered. Its first
!C      argument gives the scheme, taking the same values as RECOM above.
!C
!C      Note that unlike previous versions, all variables which hold y
!C      values have been named in a consistent way:
!C      Y() is the output scale at which jets were merged,

```

```

!C      YCUT is the input scale at which jets should be counted, and
!C      jet-momenta reconstructed etc,
!C      YMAC is the input macro-jet scale, used in determining whether
!C      or not each jet is a sub-jet.
!C      The original scheme defined in our papers is equivalent to always
!C      setting YMAC=1.
!C      Whenever a YCUT or YMAC variable is used, it is rounded down
!C      infinitesimally, so that for example, setting YCUT=Y(2) refers
!C      to the scale where the event is 2-jet, even if rounding errors
!C      have shifted its value slightly.
!C
!C      An R parameter can be used in hadron-hadron collisions by
!C      calling KTCLUR instead of KTCLUS. This is as suggested by
!C      Ellis and Soper, but implemented slightly differently,
!C      as in M.H. Seymour, LU TP 94/2 (submitted to Nucl. Phys. B.).
!C      R**2 multiplies the single Kt everywhere it is used.
!C      Calling KTCLUR with R=1 is identical to calling KTCLUS.
!C      R plays a similar role to the jet radius in a cone-type algorithm,
!C      but is scaled up by about 40% (ie R=0.7 in a cone algorithm is
!C      similar to this algorithm with R=1).
!C      Note that R.EQ.1 must be used for the e+e- and ep versions,
!C      and is strongly recommended for the hadron-hadron version.
!C      However, R values smaller than 1 have been found to be useful for
!C      certain applications, particularly the mass reconstruction of
!C      highly-boosted colour-singlets such as high-pt hadronic Ws,
!C      as in M.H. Seymour, LU TP 93/8 (to appear in Z. Phys. C.).
!C      Situations in which R<1 is useful are likely to also be those in
!C      which the inclusive reconstruction method is more useful.
!C
!C      Also included is a set of routines for doing Lorentz boosts:
!C      KTLBST finds the boost matrix to/from the cm frame of a 4-vector
!C      KTRROT finds the rotation matrix from one vector to another
!C      KTMUL multiplies together two matrices
!C      KTMUL multiplies a vector by a matrix
!C      KTINVT inverts a transformation matrix (nb NOT a general 4 by 4)
!C      KTFRAM boosts a list of vectors between two arbitrary frames
!C      KTBREI boosts a list of vectors between the lab and Breit frames
!C      KTHADR boosts a list of vectors between the lab and hadronic cmf
!C      The last two need the momenta in the +z direction of the lepton
!C      and hadron beams, and the 4-momentum of the outgoing lepton.
!C
!C      The main reference is:
!C      S. Catani, Yu.L. Dokshitzer, M.H. Seymour and B.R. Webber,
!C      Nucl.Phys.B406(1993)187.
!C      The ep version was proposed in:
!C      S. Catani, Yu.L. Dokshitzer and B.R. Webber,
!C      Phys.Lett.285B(1992)291.
!C      The inclusive reconstruction method was proposed in:
!C      S.D. Ellis and D.E. Soper,
!C      Phys.Rev.D48(1993)3160.

Chapter 21

Multiple Interactions (MPI) Code

This is the code for the `WHIZARD` module for multiple interactions (MPI) in hadron collisions. It also provides the interleaved shower with together with the shower module.

21.1 Basic types

This file contains the module `muli_basic` which is included by all other modules of the MPI code. It's main purpose is serialization and deserialization, but it also contains some bitmodel parameters and some minor definitions common to all modules and types.

Serialization is implemented in three layers:

1. **I/O layer:** streamfile access and exact, retrievable and compiler independent representation of all intrinsic types
2. **Marking layer:** storing/restoring pointer association and better human readability
3. **Derived type layer:** abstract type as parent for all serializable derived types

The I/O Layer The I/O layer is implemented by `page_ring_t` and its type bound procedures. We chose not to use the standard formatted sequential I/O for several reasons:

- Sequential I/O is line orientated, but serialization is not.
- Formatted I/O of floating point numbers is inexact. There were problems in reading numbers like `1+epsilon(1)` or `huge(1)` including arithmetic exeptions and wrong results.
- Formatted reading is slow. This does matter, when you read files of $\mathcal{O}(100)$ MB.

`page_ring_t` is a ring buffer of default kind characters holding a region of the addressed file. All read and write procedures use the ring buffer, not the file. `page_ring` automatically reads more characters from the file when needed and writes and discards parts of the ring buffer when not any longer needed.

Marking layer Marking is done by `marking_t` and its type bound procedures. Files written by `marking_t` are regular XML files, so you can use your favorite XML editor to examine or edit serialized contents. The main purpose of this layer is to recover the type of polymorphic entities and to restore association of pointers, but it also assigns names to all contents, so it is much easier to read generated files.

Type recovery is done by a reference list. You must push a representative object to this reference list for each type that might get resolved before starting deserialization. `marker_t` will care for comparing these representatives to the contents of the files.

Association restoration is done by a heap list. It is technically equal to the reference list, but holds all targets that have been processed so far. Generation of this list is handled by `marking_t`, so you don't have to care for this aspect at all. Up to the present it is not possible to restore association, when a non-pointer target is serialized after its associated pointer is serialized. There is no trivial solution and this case does not appear here, so we will not take care of this.

Derived type layer Each instance that shall become serialized must extend `ser_class_t`. Essential for type recovery is the virtual type bound procedure `get_type`. Each non-virtual type shall override `get_type` and return the actual name of its type in lower-case letters. Each type which adds new, non-redundant components shall override `write_to_marker` and `read_from_marker`. These type-bound procedures define, what contents get serialized. While the marker cares about tagging the type and association of the instance, every instance still has to define what to serialize. The rule is to mark the begin of its contents, then its parents procedure, then mark all non-redundant components, then mark the end of its contents. Finally, each serializable type shall override `print_to_unit`. This procedure is called for an arbitrary human-readable output. It is quite similar to `write_to_ring`, but without strict format and ignoring machine-readability.

`ser_class_t` has strictly speaking two layers. `write_to_marker` and `read_from_marker` are only for internal usage. Serialization and deserialization are triggered by the TBPs `serialize` and `deserialize`. These procedures take care of initialization and finalization of the marker. A serializable type should override these procedures to push a representative of itself and any other references to the reference list of its marker before (de)serialization and to pop them from the list afterwards.

```
<multi_base.f90>≡
  <File header>
```

```
module multi_base
  use, intrinsic :: iso_fortran_env
  <Use kinds with double>
  use kinds, only: i64

21.2 Transverse momenta

This file contains the module `muli_momentum`. Its purpose is to store the actual value of the evolution parameter p_t^2 in a convenient way. We use the normalized value $p_t^2/p_{t,\max}^2$ for generating the next value of the scale, also need the square root of both p_t^2 and $p_t^2/p_{t,\max}^2$ for other purposes. That's why I store all four combinations together with $p_{t,\max}$ in an array.

21.3 Multi parton interactions

This file contains the module `muli_interactions`. The allowed interactions and their cross sections are defined here. Additionally, some coordinate transformations which annihilate divergencies of the cross sections are defined. Since the phase space border is hyperbolic, this transformations are also hyperbolic. That's why all interactions are named `x_cart` for cartesian or `x_hyp` for hyperbolic to avoid confusion.

```

21.4 VEGAS and CUBA integration routines

This file contains the module `muli_cuba`, a wrapper for the CUBA integration library. Different algorithms and settings have been tried out for the integration, including VEGAS, and this wrapper has been mainly written for that purpose.

```

21.5 Trapezoidal integration routines

This file contains the module "muli_trapezium". The name is derived from the trapezoidal integration rule. The purpose of this module is to define a binary tree `muli_trapezium_tree_t` which holds a probability function in terms of trapezoidal segments. Its leaves of type `muli_trapezium_list_t` are connected to form a list, so you can either walk the root function back and forth or pick a certain segment in logarithmic time by walking down the tree. All nodes extend `muli_trapezium_t` which holds the actual values. Those are the values of the density function, the integral from this segment to the end of the integration area and a probability function calculated from these values. All values are taken at the upper "right" bound of the segment. Additionally the differences of these values to the values of the left neighbor is stored.

```

```

This is the base type `muli_trapezium_t`. Its component values has a first index is in $\{0, \dots, \text{dim} - 1\}$, while the second index distinguishes between `r_value`, `d_value`, `r_integral`, `d_integral`, `r_probability`, `d_probability`.

21.6 Fibonacci trees

This file contains the module `muli_fibonacci_tree`. A fibonacci tree is a self-balancing binary tree. "Balanced" means that the depth of the left successor may differ from the depth of the right successor in any node by maximally one. The maximally unbalanced tree is maximally unbalanced in every node. So the number of leaves of a maximally unbalanced fibonacci tree of depth n is precisely the n th fibonacci number.

We use this tree for the adaptive quadrature. In every iteration of the algorithm, we have to pick the segment with largest integration error, cut it into pieces and calculate the new integration error for the pieces. A binary tree is obviously a good choice for sorting these segments. The problem is, that we always pick leaves from the same side of the tree. So the tree must decline at one side and grow at the other side. Sorting gets less efficient and finally most of the overall CPU time gets wasted for sorting. This tree outperforms a naive binary tree significantly in this particular job.

21.7 Adaptive Quadrature

This file contains the module `muli_aq` which is an acronym for adaptive quadrature. The abstract type `aq_class` is extended and the deferred procedure `evaluate` is defined. `muli_aq` calls `evaluate` to evaluate the integrand at any point in the given range. We have tried to use a procedure pointer instead of the deferred type-bound procedure, but no compiler was able to handle procedure pointers plus `cuba` was not able to handle parameters, to wit dimensions of the integrand that should not get integrated. So we switched to this odd way of using inheritance. Meanwhile these problems got solved and we could go for a more straightforward solution, but it works fine as it is.

`aq_class` uses `muli_trapezium` to approximate the integral. It still has to do the subdivision of segments and has to check whether the precision goal is reached.

Finally, the result is written to disc using the serialization framework defined in `muli_base`. Since QCD is not expected to change frequently, the only reason to regenerate this function is a change of the used PDF set. Then you can read the integral from disc each time you run a simulation with the same PDF set.

```

<muli_aq.f90>=

```

```

<File header>

module multi_aq

  <Use kinds>
    use constants
    use diagnostics
    use multi_base
    use multi_cuba
    use multi_trapezium
    use multi_fibonacci_tree

  <Multi aq: public>

  <Multi aq: types>

  <Multi aq: interfaces>

  contains

  <Multi aq: procedures>

end module multi_aq

```

The variables `error_goal`, `err_tree` and `int_list` must be initialised before the main loop can be called. Additionally, the nodes and segments should be preprocessed by `first_run` before the main loop is called.

```

Usually, the tree is sorted by the sum of errors. Now it shall be sorted by the right position. When at least one branch of the tree is itself a tree, i.e. each branch has got at least two leaves, then process each branch and merge the results. Now we got two sorted lists. Which one's leftmost node has got the lowest value of `r_position`? That one shall be the beginning of the merged list `lin_list`. Everything is prepared for the algorithm: `lin_list` is the beginning of the sorted list, `last_node` is its end. `left_node` and `right_node` are the leftmost nodes of the remainders of `left_list` and `right_list`. The latter will get stripped from left to right, until one of them ends. Then, either `left_list` or `right_list` is completely merged into `lin_list`. The other one gets appended to `lin_list`. In the second part of the big if clause, the tree has got two leaves at most. Is it more than one? There, `fib_tree` is a single leave with an allocated "content" component of type `muli_trapezium_t`. If "content" is not type-compatible with `muli_trapezium_t`, then this whole conversion cannot succeed. We allocate a new node of type `muli_trapezium_list_t`. This list does not contain the content of `fib_tree`, it *is* a copy of the content, for `muli_trapezium_list_t` is an extension of `muli_trapezium_t`. In the next step, each branch of `fib_tree` is a single leave. We could call this subroutine for each branch, but we do copy and paste for each branch instead. Finally we append one list to the other, the lowest value of `r_position` comes first.

21.8 Integrands for Multiple Interactions

This file contains the module `multi_dsigma`. Its only type `multi_dsigma_t` provides an integrand to `aq_class`. The actual integrand is the normalized differential cross section of a QCD $2 \rightarrow 2$ process $1/\sigma_0 \times d^3\sigma/(dp_T^2 dx_1 dx_2)$. We need a root function of this integrand in terms of p_T , so we have to integrate out x_1 and x_2 and have to approximate the root function of the leftover variable p_T .

Integration of x_1 and x_2 is done by CUBA, the root function is approximated by multi_aq.

```

21.9 MC Integrations for QCD $2 \rightarrow 2$ processes

This file contains the module `muli_mcint` which is the Monte Carlo generator for QCD $2 \rightarrow 2$ interactions at given evolution parameter and given stratus. While `muli_t` takes care of generating the evolution parameter and the stratus, this module is about bookkeeping the strati and implementing a downstream importance sampling. The evolution parameter is a measure of transferred momentum and a “stratus” is a PDF category or, to be more precise, is whether the incoming partons are gluons or sea quarks or valence quarks.

The importance sampling then subdivides the phase space of variables $\{x_1, x_2, p_T\}$ into n^3 regions such that each region holds approximately n interactions. Thus, we can generate a phase space point very quickly just by randomly picking a region, randomly picking a point within this region and comparing its exact cross section with the mean cross section for this actual evolution parameter and the actual stratus times the area of the picked phase space region.

The mean values must be generated in the module `muli_dsigma` before and are given to the procedure `sample_inclusive_generate_hit`. Finally the generated subregions should be written to a file via `write_to_marker` and then reused for each later WHIZARD run.

The type `sample_inclusive_t` holds the 16 strati, while the type `sample_int_kind_t` represents a single stratus, `sample_3d_t` is the whole $\{x_1, x_2, p_T\}$ phase space for each stratus, `sample_2d_t` is the $\{x_1, x_2\}$ plane with a slice of p_T and `sample_region_t` finally is a phase space region.

21.10 Proton remnants

This file contains the module `muli_remnant`. All bookkeeping of the proton remnants and twin quarks is done here. Furthermore, reweighting of the PDFs

to derive remnant PDFs is done here.

```

21.11 The Multiple Interactions main module

This file contains the module `muli` which is the multiple parton interactions interface module to `WHIZARD`. `muli` is supposed to run together with initial state radiation. Both share a momentum evolution variable and compete for beam momentum, so the generation of this scale variable must be fully transparent to `WHIZARD`. That is why the corresponding procedures are here, while all other work like phase space integration, flavor generation and treatment of the beam remnant is put into `muli_dsigma`, `muli_mcint` and `muli_remnant`, respectively.

`qcd_2_2_t` is a container class for properties of QCD $2 \rightarrow 2$ interactions. It holds a very condensed internal representation and offers a convenient set of TBP to query all aspects without the burden of the generator internals.

`muli_t` then is an extension of `qcd_2_2_t` that adds generator internals like random number generator, integrated cross-sections, the actual Monte Carlo generator for flavor generation and beam remnants in `tao_rnd`, `dsigma`, `samples` and `beam`, respectively.

```

This is one more hack. Before merging into the interleaved algorithm, muli has only cared for summed cross sections, but not in specific color flows. So two different diagrams with equal cross sections were summed up to diagram kind 1. Now muli also generates color flows, so we must divide diagram kind 1 into diagram color kind 0 and diagram color kind 1.

Chapter 22

User Plugin Support

Here we collect interface code that enables the user to inject his own code into the WHIZARD workflow. The code uses data types defined elsewhere, and is referenced in the `eval_trees` module.

These are the modules:

user_code_interface Generic support and specific additions.

sf_user Handle user-defined structure functions.

22.1 User Code Interface

```
<user_code_interface.f90>≡  
  <File header>  
  
  module user_code_interface  
  
    use iso_c_binding !NODEP!  
    <Use kinds>  
    <Use strings>  
    use diagnostics  
    use c_particles  
    use os_interface  
  
    <Standard module head>  
  
    <User Code: public>  
  
    <User Code: variables>  
  
    <User Code: interfaces>  
  
    contains  
  
    <User Code: procedures>  
  
  end module user_code_interface
```

22.1.1 User Code Management

This data structure globally holds the filehandle of the user-code library:

```
<User Code: public>≡  
  public :: has_user_lib  
  
<User Code: variables>≡  
  type(dlaccess_t), save :: user_lib_handle  
  logical, save :: has_user_lib = .false.  
  type(string_t), save :: user
```

Compile, link and load user code files. Dlopen all user-provided libraries, included the one just compiled (if any).

By default, we are looking for a library `user.so/dylib`. If this is not present, try `user.f90` and compile it. This can be overridden.

In detail: First, compile all sources explicitly specified on the command line. Then collect all libraries specified on the command line, including `user.so` if it was generated. If there is still no code, check for an existing `user.f90` and compile this. Link everything into a `user.la` libtool library. When done, dlopen all libraries that we have so far.

```
<User Code: public>+≡  
  public :: user_code_init
```

{User Code: procedures}≡

```
subroutine user_code_init (user_src, user_lib, user_target, rebuild, os_data)
  type(string_t), dimension(:), intent(in) :: user_src, user_lib
  type(string_t), intent(in) :: user_target
  logical, intent(in) :: rebuild
  type(os_data_t), intent(in) :: os_data
  type(string_t) :: user_src_file, user_obj_files, user_lib_file
  logical :: exist
  type(c_funptr) :: fptr

          // "' called without user library (missing -u flag?)")
      end if
    end if
  end function user_code_find_proc
```

22.1.2 Interfaces for user-defined functions

The following functions represent user-defined real observables. There may be one or two particles as argument, the result is a real value.

```
<User Code: public>+≡
  public :: user_obs_int_unary
  public :: user_obs_int_binary
  public :: user_obs_real_unary
  public :: user_obs_real_binary

<User Code: interfaces>≡
  abstract interface
    function user_obs_int_unary (prt1) result (ival) bind(C)
      use iso_c_binding !NODEP!
```

```

        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1
        integer(c_int) :: ival
    end function user_obs_int_unary
end interface

abstract interface
    function user_obs_int_binary (prt1, prt2) result (ival) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        integer(c_int) :: ival
    end function user_obs_int_binary
end interface

abstract interface
    function user_obs_real_unary (prt1) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1
        real(c_double) :: rval
    end function user_obs_real_unary
end interface

abstract interface
    function user_obs_real_binary (prt1, prt2) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        real(c_double) :: rval
    end function user_obs_real_binary
end interface

```

The following function takes an array of C-compatible particles and return a single value. The particle array represents a subevent. For C interoperability, we have to use an assumed-size array, hence the array size has to be transferred explicitly.

The cut function returns an `int`, which we should interpret as a logical value (nonzero=true).

```

<User Code: public>+≡
    public :: user_cut_fun

<User Code: interfaces>+≡
    abstract interface
        function user_cut_fun (prt, n_prt) result (iflag) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt
            integer(c_int), intent(in) :: n_prt
            integer(c_int) :: iflag
        end function user_cut_fun
    end interface

```

The event-shape function returns a real value.

```

<User Code: public>+≡
    public :: user_event_shape_fun

<User Code: interfaces>+≡
    abstract interface
        function user_event_shape_fun (prt, n_prt) result (rval) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt
            integer(c_int), intent(in) :: n_prt
            real(c_double) :: rval
        end function user_event_shape_fun
    end interface

```

22.1.3 Interfaces for user-defined interactions

The following procedure interfaces pertain to user-defined interactions, e.g., spectra or structure functions.

This subroutine retrieves the basic information for setting up the interaction and event generation. All parameters are `intent(inout)`, so we can provide default values. `n_in` and `n_out` are the number of incoming and outgoing particles, respectively. `n_states` is the total number of distinct states that should be generated (counting all states of the incoming particles). `n_col` is the maximal number of color entries a particle can have. `n_dim` is the number of input parameters, i.e., integration dimensions, that the structure function call requires for computing kinematics and matrix elements. `n_var` is the number of variables (e.g., momentum fractions) that the structure function call has to transfer from the kinematics to the dynamics evaluation.

```

<User Code: public>+≡
    public :: user_int_info

<User Code: interfaces>+≡
    abstract interface
        subroutine user_int_info (n_in, n_out, n_states, n_col, n_dim, n_var) &
            bind(C)
            use iso_c_binding !NODEP!
            integer(c_int), intent(inout) :: n_in, n_out, n_states, n_col
            integer(c_int), intent(inout) :: n_dim, n_var
        end subroutine user_int_info
    end interface

```

This subroutine retrieves the settings for the quantum number mask of a given particle index in the interaction. A nonzero value indicates that the corresponding quantum number is to be ignored. The lock index is the index of a particle that the current particle is related to. The relation applies if quantum numbers of one of the locked particles are summed over. (This is intended for helicity.)

```

<User Code: public>+≡
    public :: user_int_mask

```

```

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_mask (i_prt, m_flv, m_hel, m_col, i_lock) bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(in) :: i_prt
      integer(c_int), intent(inout) :: m_flv, m_hel, m_col, i_lock
    end subroutine user_int_mask
  end interface

```

This subroutine retrieves the quantum numbers for the particle index `i_prt` in state `i_state`. The `flv` value is a PDG code. The `hel` value is an integer helicity (twice the helicity for fermions). The `col` array is an array which has at most `n_col` entries (see above). All parameters are `intent(inout)` since default values exist. In particular, if a mask entry is set by the previous procedure, the corresponding quantum number is ignored anyway.

```

<User Code: public>+≡
  public :: user_int_state

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_state (i_state, i_prt, flv, hel, col) bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(in) :: i_state, i_prt
      integer(c_int), intent(inout) :: flv, hel
      integer(c_int), dimension(*), intent(inout) :: col
    end subroutine user_int_state
  end interface

```

This subroutine takes an array of particle objects with array length `n_in` and an array of input parameters between 0 and 1 with array length `n_dim`. It returns an array of particle objects with array length `n_out`. In addition, it returns an array of internal variables (e.g., momentum fractions, Jacobian) with array length `n_var` that is used by the following subroutine for evaluating the dynamics, i.e., the matrix elements.

```

<User Code: public>+≡
  public :: user_int_kinematics

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_kinematics (prt_in, rval, prt_out, xval) bind(C)
      use iso_c_binding !NODEP!
      use c_particles !NODEP!
      type(c_prt_t), dimension(*), intent(in) :: prt_in
      real(c_double), dimension(*), intent(in) :: rval
      type(c_prt_t), dimension(*), intent(inout) :: prt_out
      real(c_double), dimension(*), intent(out) :: xval
    end subroutine user_int_kinematics
  end interface

```

This subroutine takes the array of variables (e.g., momentum fractions) with length `n_var` which has been generated by the previous subroutine and a real variable, the energy scale of the event. It returns an array of matrix-element

values, one entry for each quantum state `n_states`. The ordering of matrix elements must correspond to the ordering of states.

```

<User Code: public>+≡
    public :: user_int_evaluate

<User Code: interfaces>+≡
    abstract interface
        subroutine user_int_evaluate (xval, scale, fval) bind(C)
            use iso_c_binding !NODEP!
            real(c_double), dimension(*), intent(in) :: xval
            real(c_double), intent(in) :: scale
            real(c_double), dimension(*), intent(out) :: fval
        end subroutine user_int_evaluate
    end interface

```

22.2 User Plugin for Structure Functions

This variant gives access to user-defined structure functions or spectra.

22.2.1 The module

```

<sf_user.f90>≡
    <File header>

    module sf_user

        use, intrinsic :: iso_c_binding !NODEP!
        <Use kinds>
        <Use strings>

```

22.2.2 The user structure function data block

The data block holds the procedure pointers that are used for retrieving static information, as well as the actual evaluation.

```

<SF user: public>≡
    public :: user_data_t

<SF user: types>≡
    type, extends(sf_data_t) :: user_data_t
        private
        type(string_t) :: name
        integer :: n_in
        integer :: n_out
        integer :: n_tot
        integer :: n_states
        integer :: n_col
        integer :: n_dim
        integer :: n_var
        integer, dimension(2) :: pdg_in
        class(model_data_t), pointer :: model => null ()
        procedure(user_int_info), nopass, pointer :: info => null ()
        procedure(user_int_mask), nopass, pointer :: mask => null ()
        procedure(user_int_state), nopass, pointer :: state => null ()
        procedure(user_int_kinematics), nopass, pointer :: kinematics => null ()
        procedure(user_int_evaluate), nopass, pointer :: evaluate => null ()
    contains
        <SF user: user data: TBP>
    end type user_data_t

```

Assign procedure pointers from a dynamically loaded library, given the specified name.

We have to distinguish three cases: (1) Both beams are affected, and the user spectrum implements both beams. There is a single data object. (2) Both beams are affected, and the user spectrum applies to single beams. Fill two different objects. (3) A single beam is affected.

```

<SF User: public>≡

```

22.2.3 The interaction

We fill the interaction by looking up the table of states using the interface functions.

For particles which have a known flavor (as indicated by the mask), we compute the mass squared, so we can use it for the invariant mass of the particle objects.

```

<SF user: user: TBP>≡
    procedure :: init => user_init

```

<SF user: procedures>+≡

```

```

22.2.4 The user structure function

For maximal flexibility, user structure functions separate kinematics from dynamics just as the PDF interface does. (JRR: Ok, I guess this now done for all structure functions, right?) We create `c_prt_t` particle objects from the incoming momenta (all other quantum numbers are irrelevant) and call the user-supplied kinematics function to compute the outgoing momenta, along with other variables that will be needed for matrix element evaluation. If known, we use the mass squared computed above. !!! JRR: WK please check (#529) I don't know actually whether this really fits into the setup done by WK.

```

<SF user: types>+≡
    !!! JRR: WK please check (#529)
    type, extends (sf_int_t) :: user_t
        type(user_data_t), pointer :: data => null ()

  write (u, "(1x,A)") "User structure function data: [undefined]"
end if
end subroutine user_write

```

22.2.5 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

<SF user: user: TBP>+≡
  procedure :: complete_kinematics => user_complete_kinematics

Chapter 23

BLHA Interface

The code in this chapter implements support for the BLHA record that communicates data for NLO processes.

These are the modules:

blha_config

blha_interface

blha_driver

23.1 Module definition

These modules implement the communication with one loop matrix element providers according to the Binoth LesHouches Accord Interface. The actual matrix element(s) are loaded as a dynamic library.

This module defines the common OLP-interfaces defined through the Binoth Les-Houches accord.

```
<blha_olp_interfaces.f90>≡

Chapter 24

GoSam Interface

The code in this chapter makes amplitudes accessible to **WHIZARD** that are generated and computed by the GoSam package.

These are the modules:

loop_archive Provide some useful extra functionality.

prc_gosam The actual interface, following the **WHIZARD** conventions for matrix-element generator methods.

24.1 Gosam Interface

```
<prc_gosam.f90>≡

```

The BLHA-interface conventions require the quantity $S_{ij} = \langle M_{i,+} | T_i T_j | M_{i,-} \rangle$ to be produced, where i is the position of the splitting gluon. However, $\tilde{M} =$

$\langle M_{i,-} | M_{i,+} \rangle$ is needed. This can be obtained using color conservation, $\sum_j T_j |M\rangle = 0$, so that

$$\sum_{j \neq i} S_{ij} = -\langle M_{i,+} | T_i^2 | M_{i,-} \rangle = -C_A \langle M_{i,+} | M_{i,-} \rangle = -C_A \tilde{M}^*$$

According to BLHA conventions, the real part of S_{ij} is located at positions $2i + 2nj$ in the output array, where n denotes the number of external particles and the enumeration of particles starts at zero. The subsequent position, i.e. $2i + 2nj + 1$ is designated to the imaginary part of S_{ij} . Note that, since the first array position is 1, the implemented position association deviates from the above one in the addition of 1.

Chapter 26

FKS Subtraction Scheme

The code in this chapter implements the FKS subtraction scheme for use with WHIZARD.

These are the modules:

fks_regions Given a process definition, identify singular regions in the associated phase space.

virtual Handle the virtual correction matrix element.

real_subtraction Handle the real-subtraction matrix element.

nlo_data Manage the subtraction objects.

phs_fks Phase-space parameterization with modifications for the FKS scheme.

This chapter deals with next-to-leading order contributions to cross sections. Basically, there are three major issues to be addressed: The creation of the $N+1$ -particle flavor structure, the construction of the $N+1$ -particle phase space and the actual calculation of the real- and virtual-subtracted matrix elements. The first is dealt with using the **auto_components** class, and it will be shown that the second and third issue are connected in FKS subtraction.

26.1 Brief outline of FKS subtraction

In the current state, this discussion is only concerned with lepton collisions. For hadron collisions, renormalization of parton distributions has to be taken into account. Further, for QCD corrections, initial-state radiation is necessarily present. However, most quantities have so far been only constructed for final-state emissions

The aim is to calculate the next-to-leading order cross section according to

$$d\sigma_{\text{NLO}} = \mathcal{B} + \mathcal{V} + \mathcal{R}d\Phi_{\text{rad}}.$$

Analytically, the divergences, in terms of poles in the complex quantity $\varepsilon = 2 - d/2$, cancel. However, this is in general only valid in an arbitrary, complex number of dimensions. This is, roughly, the content of the KLN-theorem. WHIZARD, as any other numerical program, is confined to four dimensions. We will assume

that the KLN-theorem is valid and that there exist subtraction terms \mathcal{C} such that

$$d\sigma_{\text{NLO}} = \mathcal{B} + \underbrace{\mathcal{V} + \mathcal{C}}_{\text{finite}} + \underbrace{\mathcal{R} - \mathcal{C}}_{\text{finite}},$$

i.e. the subtraction terms correspond to the divergent limits of the real and virtual matrix element.

Because \mathcal{C} subtracts the divergences of \mathcal{R} as well as those of \mathcal{V} , it suffices to consider one of them, so we focus on \mathcal{R} . For this purpose, \mathcal{R} is rewritten,

$$\mathcal{R} = \frac{1}{\xi^2} \frac{1}{1-y} (\xi^2(1-y)\mathcal{R}) = \frac{1}{\xi^2} \frac{1}{1-y} \tilde{\mathcal{R}},$$

with $\xi = (2k_{\text{rad}}^0)/\sqrt{s}$ and $y = \cos\theta$, where k_{rad}^0 denotes the energy of the radiated parton and θ is the angle between emitter and radiated parton. $\tilde{\mathcal{R}}$ is finite, therefore the whole singularity structure is contained in the prefactor $\xi^{-2}(1-y)^{-1}$. Combined with the d-dimensional phase space element,

$$\frac{d^{d-1}k}{2k^0(2\pi)^{d-1}} = \frac{s^{1-\varepsilon}}{(4\pi)^{d-1}} \xi^{1-2\varepsilon} (1-y)^{-\varepsilon} d\xi dy d\Omega^{d-2},$$

this yields

$$d\Phi_{\text{rad}}\mathcal{R} = dy(1-y)^{-1-\varepsilon} d\xi \xi^{-1-2\varepsilon} \tilde{R}.$$

This can further be rewritten in terms of plus-distributions,

$$\begin{aligned} \xi^{-1-2\varepsilon} &= -\frac{1}{2\varepsilon} \delta(\xi) + \left(\frac{1}{\xi}\right)_+ - 2\varepsilon \left(\frac{\log \xi}{\xi}\right)_+ + \mathcal{O}(\varepsilon^2), \\ (1-y)^{-1-\varepsilon} &= -\frac{2^{-\varepsilon}}{\varepsilon} \delta(1-y) + \left(\frac{1}{1-y}\right)_+ - \varepsilon \left(\frac{1}{1-y}\right)_+ \log(1-y) + \mathcal{O}(\varepsilon^2), \end{aligned}$$

(imagine that all this is written inside of integrals, which are spared for ease of notation) such that

$$\begin{aligned} d\Phi_{\text{rad}}\mathcal{R} &= -\frac{1}{2\varepsilon} dy(1-y)^{-1-\varepsilon} \tilde{R}(0, y) - d\xi \left[\frac{2^{-\varepsilon}}{\varepsilon} \left(\frac{1}{\xi}\right)_+ - 2 \left(\frac{\log \xi}{\xi}\right)_+ \right] \tilde{R}(\xi, 1) \\ &\quad + dy d\xi \left(\frac{1}{\xi}\right)_+ \left(\frac{1}{1-y}\right)_+ \tilde{R}(\xi, y) + \mathcal{O}(\varepsilon). \end{aligned}$$

The summand in the second line is of order $\mathcal{O}(1)$ and is the only one to reproduce $\mathcal{R}\xi, y$. It thus constitutes the sum of the real matrix element and the corresponding counterterms. The first summand consequently consists of the subtraction terms to the virtual matrix elements. Above formula thus allows to calculate all quantities to render the matrix elements finite.

alr	flst_alr	emi	ftuple_list

4	[-11,11,2,-2,2,-2]	5	(5,6)

Table 26.1: List of singular regions. The particles are represented by their PDG codes. The third column contains the emitter for the specific singular region. For the process involving an additional gluon, the gluon can either be emitted from one of the quarks or from the first gluon. Each emitter yields the same list of fundamental tuples, five in total. The last singular region corresponds to the process where the gluon splits up into two quarks. Here, there is only one fundamental tuple, corresponding to a singular configuration of the momenta of the additional quarks.

26.2 Identifying singular regions

In the FKS subtraction scheme, the phase space is decomposed into disjoint singular regions, such that

$$\sum_i \mathcal{S}_i + \sum_{ij} \mathcal{S}_{ij} = 1. \quad (26.1)$$

The quantities \mathcal{S}_i and \mathcal{S}_{ij} are functions of phase space corresponding to a pair of particles indices which can make up a divergent phase space region. We call such an index pair a fundamental tuple. For example, the process $e^+ e^- \rightarrow u \bar{u} g$ has two singular regions, (3, 5) and (4, 5), indicating that the gluon can be soft or collinear with respect to either the quark or the anti-quark. Therefore, the functions \mathcal{S}_{ij} have to be chosen in such a way that their contribution makes up most of (26.1) in phase-space configurations where (final-state) particle j is collinear to particle i or/and particle j is soft. The functions \mathcal{S}_i is the corresponding quantity for initial-state divergences.

As a singular region we understand the collection of real flavor structures associated with an emitter and a list of all possible fundamental tuples. As an example, consider the process $e^+ e^- \rightarrow u \bar{u} g$. At next-to-leading order, processes with an additionally radiated particle have to be considered. In this case, these are $e^+ e^- \rightarrow u \bar{u}, g g$, and $e^+ e^- \rightarrow u \bar{u} u \bar{u}$ (or the same process with any other quark). Table 26.2 sums up all possible singular regions for this problem.

Thus, during the preparation of a NLO-calculation, the possible singular regions have to be identified. `fkf_regions.f90` deals with this issue.

```

Returns `true` if the two particles at position `i` and `j` in the flavor array can originate from the same splitting. For this purpose, the function first checks whether the splitting is allowed at all. If this is the case, the emitter is removed from the flavor array. If the resulting array is equivalent to the Born flavor structure `flv_born`, the pair is accepted as a valid splitting. We first check whether the splitting is possible. The array `flv_orig` contains all particles which share a vertex with the particles at position `i` and `j`. If its size is equal to zero, no splitting is possible and the subroutine is exited. Otherwise, we loop over all possible underlying Born flavor structures and check if any of them equals the actual underlying Born flavor structure. For a quark emitting a gluon, `flv_orig` contains the PDG code of the anti-quark. To be on the safe side, a second array is created, which contains both the positively and negatively signed PDG codes. Then, the original tuple (i, j) is removed from the real flavor structure and the particles in `flv_orig2` are inserted. If the resulting Born configuration is equal to the underlying Born configuration, up to a permutation of final-state particles, the tuple (i, j) is accepted as valid.

A singular region is a partition of phase space which is associated with an individual emitter and, if relevant, resonance. It is associated with an α_r - and resonance-index, with a real flavor structure and its underlying Born flavor structure. To compute the FKS weights, it is relevant to know all the other particle indices which can result in a divergent phase space configuration, which are collected in the `ftuples`-array.

Some singular regions might behave physically identical. E.g. a real flavor structure associated with three-jet production is $[11, -11, 0, 2 - 2, 0]$. Here, there are two possible `ftuples` which contribute to the same $u \rightarrow ug$ splitting, namely $(3, 4)$ and $(4, 6)$. The resulting singular regions will be identical. To avoid this, one singular region is associated with the multiplicity factor `mult`. When computing the subtraction terms for each singular region, the result is then simply multiplied by this factor.

The `double_fsr`-flag indicates whether the singular region should also be supplied by a symmetry factor, explained below.

In case of a $g \rightarrow gg$ or $g \rightarrow qq$ splitting, the factor

$$\frac{2E_{\text{em}}}{E_{\text{em}} + E_{\text{rad}}}$$

is multiplied to the real matrix element. This way, the symmetry of the splitting is used and only one singular region has to be taken into account. However, the factor ensures that there is only a soft singularity if the radiated parton becomes soft.

```

This subroutine starts with a specification of N - and $N + 1$ -particle configurations, `flst_born` and `flst_real`, saved in `reg_data`. From these, it creates a list of fundamental tuples, a list of emitters and a list containing the $N + 1$ -particle configuration, rearranged in such a way that the emitter-radiation pair is last (`flst_alr`). For the $e^+ e^- \rightarrow u \bar{u} g$ - example, the generated objects are shown in table 26.2. Note that at this point, `flst_alr` is arranged in such a way that the emitter can only be equal to $n_{legs} - 1$ for final-state radiation or 0, 1, or 2 for initial-state radiation. Further, it occurs that regions can be equivalent. For example in table 26.2 the regions corresponding to `alr = 1` and `alr = 3` as well as `alr = 2` and `alr = 4` describe the same physics and are therefore equivalent.

In the soft limit, our treatment of the divergences requires a modification of the mapping functions. Recall that there, the ratios of the d -functions must approach either 1 or 0. This means

$$\frac{d_{lm}}{d_{0m}} = \frac{(2k_l \cdot k_m) [E_l E_m / (E_l + E_m)^2]}{E_m^2 (1 - y^2)} =_{k_m \equiv E_m \hat{k}} \frac{E_l E_m^2}{(E_l + E_m)^2} \frac{2k_l \cdot \hat{k}}{E_m^2 (1 - y^2)} \xrightarrow{E_m \rightarrow 0} \frac{2}{k_l \cdot \hat{k}} (1 - y^2) E_l,$$

where we have written the gluon momentum in terms of the soft momentum \hat{k} .

In the same limit

$$\frac{d_{lm}}{d_{nm}} = \frac{k_l \cdot \hat{k}}{k_n \cdot \hat{k}} \frac{E_n}{E_l}.$$

From these equations we can deduce the soft limit of d :

$$\begin{aligned}
d_0^{\text{soft}} &= 1 - y^2, \\
d_1^{\text{soft}} &= 2(1 - y), \\
d_2^{\text{soft}} &= 2(1 + y), \\
d_i^{\text{soft}} &= \frac{2k_i \cdot \hat{k}}{E_i}.
\end{aligned}$$

The $d_{ij,k}$ -functions for the resonance mapping are basically the same as in the default case, but the kinematical values here must be evaluated in the resonance frame of reference. The energy of parton i in a given resonance frame with momentum p_{res} is

$$E_i = \frac{p_i^0 \cdot p_{res}}{m_{res}}.$$

However, since the expressions only depend on ratios of four-momenta, we leave out the denominator because it will cancel out anyway.

The virtual-subtracted matrix element is given by the equation

$$\mathcal{V} = \frac{\alpha_s}{2\pi} \left(\mathcal{Q}\mathcal{B} + \sum \mathcal{I}_{ij}\mathcal{B}_{ij} + \mathcal{V}_{fin} \right), \quad (26.2)$$

where the quantity \mathcal{Q} is given by

$$\begin{aligned} \mathcal{Q} = \sum_{i=3}^n & \left[\gamma'_{fi} - \log \frac{s}{Q^2} \left(\gamma_{fi} - 2C_{fi} \log \frac{2E_i}{\sqrt{s}} \right) \right. \\ & \left. + 2C_{fi} \log^2 \frac{2E_i}{\sqrt{s}} - 2\gamma_{fi} \frac{2E_i}{\sqrt{s}} \right] \\ & - \log \frac{\mu_F^2}{Q^2} (\gamma_{f+} + \gamma_{f-}). \end{aligned} \quad (26.3)$$

Note that the summation only runs over final-state particles. The expressions for \mathcal{I}_{ij} can be found in equations (26.4), (26.5), (26.6), depending on whether the particles involved in the radiation process are massive or massless.

The following code implements the \mathcal{I}_{ij} -function appearing in eq. blub. They are defined as follows:

Massless-Massless Case

$$\begin{aligned}
\mathcal{I}_{ij} = & \frac{1}{2} \log^2 \frac{s}{Q^2} + \log \frac{s}{Q^2} \log \frac{k_i k_j}{2E_i E_j} - \text{Li}_2 \left(\frac{k_i k_j}{2E_i E_j} \right) \\
& + \frac{1}{2} \log^2 \frac{k_i k_j}{2E_i E_j} - \log \left(1 - \frac{k_i k_j}{2E_i E_j} \right) \log \frac{k_i k_j}{2E_i E_j}.
\end{aligned} \tag{26.4}$$

Massive-Massive Case

$$\mathcal{I}_{ij} = -\frac{1}{2} I_0(k_i, k_j) \log \frac{Q^2}{s} - \frac{1}{2} I_\epsilon(k_i, k_j) \tag{26.5}$$

with

$$I_0(k_i, k_j) = \frac{1}{\beta} \log \frac{1 + \beta}{1 - \beta}, \quad \beta = \sqrt{1 - \frac{k_i^2 k_j^2}{(k_i \cdot k_j)^2}}$$

and a rather involved expression for I_ϵ :

$$\begin{aligned}
I_\epsilon(k_i, k_j) &= (K(z_j) - K(z_i)) \frac{1 - \vec{\beta}_i \cdot \vec{\beta}_j}{\sqrt{a(1-b)}}, \\
\vec{\beta}_i &= \frac{\vec{k}_i}{k_i^0}, \\
a &= \beta_i^2 + \beta_j^2 - 2\vec{\beta}_i \cdot \vec{\beta}_j, \\
x_i &= \frac{\beta_i^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a}, \\
x_j &= \frac{\beta_j^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a} = 1 - x_i, \\
b &= \frac{\beta_i^2 \beta_j^2 - (\vec{\beta}_i \cdot \vec{\beta}_j)^2}{a}, \\
c &= \sqrt{\frac{b}{4a}}, \\
z_+ &= \frac{1 + \sqrt{1-b}}{\sqrt{b}}, \\
z_- &= \frac{1 - \sqrt{1-b}}{\sqrt{b}}, \\
z_i &= \frac{\sqrt{x_i^2 + 4c^2} - x_i}{2c}, \\
z_j &= \frac{\sqrt{x_j^2 + 4c^2} + x_j}{2c}, \\
K(z) &= -\frac{1}{2} \log^2 \frac{(z - z_-)(z_+ - z)}{(z_+ + z)(z_- + z)} - 2Li_2 \left(\frac{2z_-(z_+ - z)}{(z_+ - z_-)(z_- + z)} \right) \\
&\quad - 2Li_2 \left(-\frac{2z_+(z_- + z)}{(z_+ - z_-)(z_+ - z)} \right)
\end{aligned}$$

Massive-Massless Case

$$\mathcal{I}_{ij} = \frac{1}{2} \left[\log^2 \frac{Q}{s} - \frac{\pi^2}{6} \right] - \frac{1}{2} I_0(k_i, k_j) \log \frac{Q^2}{s} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (26.6)$$

with

$$\begin{aligned}
I_0(p, k) &= \log \frac{(\hat{p} \cdot \hat{k})^2}{\hat{k}^2}, \\
I_\epsilon(p, k) &= -2 \left[\frac{1}{4} \log^2 \frac{1-\beta}{1+\beta} + \log \frac{\hat{p} \cdot \hat{k}}{1+\beta} \log \frac{\hat{p} \cdot \hat{k}}{1-\beta} + Li_2 \left(1 - \frac{\hat{p} \cdot \hat{k}}{1+\beta} \right) + Li_2 \left(1 - \frac{\hat{p} \cdot \hat{k}}{1-\beta} \right) \right]
\end{aligned}$$

using

$$\hat{p} = \frac{p}{p^0}, \quad \hat{k} = \frac{k}{k^0}, \quad \beta = \frac{|\vec{k}|}{k_0}.$$

```

The treatment of the momentum k follows the discussion about the soft limit of the partition functions (ref????). The parton momentum is pulled out, $k = E\hat{k}$. In fact, we will substitute \hat{k} for k throughout the code, because the energy will factor out of the equation when the soft \mathcal{S} -function is multiplied. The soft momentum is a unit vector, because $k^2 = (k^0)^2 - (\hat{k}^0)^2 \hat{k}^2 = 0$.

The soft momentum is constructed by first creating a unit vector parallel to the emitter's Born momentum. This unit vector is then rotated about the corresponding angles y and ϕ .

The soft vector for the real mismatch is basically the same as for usual FSR, except for the scaling with the total gluon energy. Moreover, the resulting vector is rotated into the frame where the 3-axis points along the direction of the emitter. This is necessary because in the collinear limit, the approximation

$$k_i = \frac{k_i^0}{\bar{k}_j^0} \bar{k}_j = \frac{\xi \sqrt{s}}{2\bar{k}_j^0} \bar{k}_j$$

is used. The collinear limit is not included in the soft mismatch yet, but we keep the rotation for future usage here already (the performance loss is negligible).

```

Computation of the soft limit of R_α . Note that what we are actually integrating (in the case of final-state radiation) is the quantity $f(0, y)/\xi$, where

$$f(\xi, y) = \frac{J(\xi, y, \phi)}{\xi} \xi^2 R_\alpha.$$

J/ξ is computed by the phase space generator. The additional factor of ξ^{-1} is supplied in the `evaluate_region_fsr`-routine. Thus, we are left with a factor of ξ^2 . A look on the expression for the soft limit of R_α below reveals that we are factoring out the gluon energy E_i in the denominator. Therefore, we have a factor $\xi^2/E_i^2 = q^2/4$.

Note that the same routine is used also for the computation of the soft mismatch. There, the gluon energy is not factored out from the soft vector, so that we are left with the ξ^2 -factor, which will eventually be cancelled out again. So, we just multiply with 1. Both cases are distinguished by the flag `xi2_expanded`.

Main routine to compute the soft mismatch. Loops over all singular regions.
There, it first creates the soft vector, then the necessary soft real matrix element.
These inputs are then used to get the numerical value of the soft mismatch.

    integer, intent(in) :: n_alr, n_in
    coll_sub%n_in = n_in
    coll_sub%n_alr = n_alr
    allocate (coll_sub%value (n_alr))
    allocate (coll_sub%value_soft (n_alr))
  end subroutine coll_subtraction_init
```

To compute the collinear limit of \mathcal{R} , we follow the original FKS-paper. Here, the real amplitude is supposed to factorize in the collinear limit. considering a splitting $g \rightarrow g(i)g(j)$,

$$\mathcal{A}^{(n)}(h_i, h_j, \{h_l\}) \xrightarrow{i||j} g_s \sum_{d_e} \sum_{h_e} C(d_e, b, c) S_{gg}^{h_e h_i h_j}(z) \mathcal{A}_{d_e}^{(n-1)}(h_e, \{h_l\})$$

Explain quantities. Evaluating this expression leads to

$$|\mathcal{A}^{(n)}(h_i, h_j, \{h_l\})|^2 \xrightarrow{i||j} |\mathcal{N}^{(n)}(h_i, h_j, \{h_l\})|^2 + \mathcal{R}(h_i, h_j, \{h_l\})^2,$$

where \mathcal{R} contains all contributions with spin-correlated amplitudes, i.e. terms like $\mathcal{A}_{d_e}^{(n-1)}(+, \{h_l\}) \left(\mathcal{A}_{d_e}^{(n-1)}(-, \{h_l\}) \right)^*$. Explicitly,

$$\sum_{h_i, h_j, \{h_l\}} \sum_{\{d_l\}} |\mathcal{N}^{(n)}(h_i, h_j, \{h_l\})|^2 = \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{gg}(z) |\mathcal{A}^{(n-1)}|^2,$$

and

$$\sum_{h_i, h_j, \{h_l\}} \sum_{\{d_l\}} \mathcal{R}(h_i, h_j, \{h_l\}) = 32\pi\alpha_s C_A z(1-z) \times \underbrace{\text{Re} \left\{ \frac{\langle ij \rangle}{[ij]} \sum_{\{h_l\}} \sum_{d_e, \{d_l\}} \mathcal{A}_{d_e}^{(n-1)}(+, \{h_l\}) \left(\mathcal{A}_{d_e}^{(n-1)}(-, \{h_l\}) \right)^* \right\}}_{-\tilde{\mathcal{M}}^{(n-1)}/(2k_i \cdot k_j)}.$$

This yields

$$\mathcal{M}^{(n)} \xrightarrow{i||j} \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{gg}(z) \mathcal{M}^{(n-1)} - \frac{16\pi\alpha_s}{k_i \cdot k_j} C_A z(1-z) \tilde{\mathcal{M}}^{(n-1)}. \quad (26.7)$$

The equivalent expression for a $g \rightarrow qq$ -splitting is given by

$$\mathcal{M}^{(n)} \xrightarrow{i||j} \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{qq}(z) \mathcal{M}^{(n-1)} + \frac{16\pi\alpha_s}{k_i \cdot k_j} T_F z(1-z) \tilde{\mathcal{M}}^{(n-1)}. \quad (26.8)$$

The function obtains a flag to indicate whether the limit to be computed is also soft. Moreover, this consideration explains the structure of the code. In the soft limit, we find $z \rightarrow 0$ as well as $\xi \rightarrow 0$. However, the quantity z/ξ is finite, because

$$\frac{z}{\xi} = \frac{p_{rad}^0}{\bar{p}_{em}^0} \frac{q^0}{2p_{em}^0} = \frac{q^0}{2\bar{p}_{em}^0}.$$

Thus, all expressions are written in terms of this well-behaved quantity. Recalling that there is a prefactor of $(\xi^2 z)^{-1}$, it is necessary to expand with z once.

26.5.4 The real contribution to the cross section

In each singular region α , the real contribution to σ is given by the second summand of eqn. ??,

$$\sigma_{\text{real}}^\alpha = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 dy \int_0^{\xi_{\text{max}}} d\xi \left(\frac{1}{\xi} \right)_+ \left(\frac{1}{1-y} \right)_+ \underbrace{\frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1-y)\xi^2 \mathcal{R}^\alpha(\Phi_{n+1})]}_{g^\alpha(\xi, y)} \quad (26.9)$$

Writing out the plus-distribution and introducing $\tilde{\xi} = \xi/\xi_{\text{max}}$ to set the upper integration limit to 1, this turns out to be equal to

$$\begin{aligned} \sigma_{\text{real}}^\alpha = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 \frac{dy}{1-y} \left\{ \int_0^1 d\tilde{\xi} \left[\frac{g^\alpha(\tilde{\xi}\xi_{\text{max}}, y)}{\tilde{\xi}} - \underbrace{\frac{g^\alpha(0, y)}{\tilde{\xi}}}_{\text{soft}} - \underbrace{\frac{g^\alpha(\tilde{\xi}\xi_{\text{max}}, 1)}{\tilde{\xi}}}_{\text{coll.}} + \underbrace{\frac{g^\alpha(0, 1)}{\tilde{\xi}}}_{\text{coll.+soft}} \right] \right. \\ \left. + [\log \xi_{\text{max}}(y)g^\alpha(0, y) - \log \xi_{\text{max}}(1)g^\alpha(0, 1)] \right\}. \end{aligned} \quad (26.10)$$

This formula is implemented in `compute_sqme_real_fin`

```
<real subtraction: real subtraction: TBP>+≡
  procedure :: compute => real_subtraction_compute

end function real_subtraction_evaluate_emitter_region

```

This subroutine computes the finite part of the real matrix element in an individual singular region. First, the radiation variables are fetched and \mathcal{R} is multiplied by the appropriate S_α -factors, region multiplicities and double-FSR factors. Then, it computes the soft, collinear, soft-collinear and remnant matrix elements and supplies the corresponding factor $1/\xi/(1-y)$ as well as the corresponding jacobians.

```

The same as above, but for the collinear subtraction terms. They are proportional to the Born matrix element so they enter the subroutine with pdfs evaluated for the Born flavor structure. Therefore, we additionally have to take the flavor of the underlying Born particle when dividing out the Born contribution.

This routine computes the bounds of the Dalitz region for massive emitters, see below. It is also used by `Powheg`, so the routine is public. The input parameter `m2` corresponds to the squared mass of the emitter and `p` is the four-momentum of the emitter.

```

26.7 The FKS phase space

To handle the FKS phase space and adapt it to multi-channel integration, some extensions have to be made for pre-existing types. The `phs_tree`-type has an attribute containing the tree-code of the emitting branch.

```
<PHS trees: phs tree: TBP>≡
  procedure :: get_emitter => phs_tree_get_emitter
<PHS trees: procedures>+≡
  function phs_tree_get_emitter (tree) result (emitter)
    class(phs_tree_t), intent(in) :: tree
    integer :: emitter
    emitter = tree%emitter
  end function phs_tree_get_emitter
```

```

26.7.1 Creation of the real phase space - FSR

At this point, the Born phase space has been generated, as well as the three random variables ξ , y and ϕ . The question is how the real phase space is generated for a final-state emission configuration. We work with two different sets of momenta, the Born configuration $\{\bar{k}_{\oplus}, \bar{k}_{\ominus}, \bar{k}_1, \dots, \bar{k}_n\}$ and the real configuration $\{k_{\oplus}, k_{\ominus}, k_1, \dots, k_n, k_{n+1}\}$. We define the momentum of the emitter to be on the n -th position and the momentum of the radiated particle to be at position $n+1$. The magnitude of the spatial component of k is denoted by \underline{k} .

For final-state emissions, it is $\bar{k}_\oplus = k_\oplus$ and $\bar{k}_\ominus = k_\ominus$. Thus, the center-of-mass systems coincide and it is

$$q = \sum_{i=1}^n \bar{k}_i = \sum_{i=1}^{n+1} k_i, \quad (26.12)$$

with $\vec{q} = 0$ and $q^2 = (q^0)^2$.

We want to construct the real phase space from the Born phase space using three random numbers. They are defined as follows:

- $\xi = \frac{2k_{n+1}^0}{\sqrt{s}} \in [0, \xi_{max}]$, where k_{n+1} denotes the four-momentum of the radiated particle.
- $y = \cos \theta = \frac{\vec{k}_n \cdot \vec{k}_{n+1}}{k_n k_{n+1}}$ is the splitting angle.
- The angle between the two splitting particles in the transversal plane, $\phi \in [0, 2\pi]$.

Further, $k_{rec} = \sum_{i=1}^{n-1} k_i$ denotes the sum of all recoiling momenta.

```

Construction of the recoiling momenta. The reshuffling of momenta must not change the invariant mass of the recoiling system, which means $k_{\text{rec}}^2 = k_{\text{rec}}^{-2}$. Therefore, the momenta are related by a boost, $\bar{k}_i = \Lambda k_i$. The boost parameter is

$$\beta = \frac{q^2 - (k_{\text{rec}}^0 + k_{\text{rec}})^2}{q^2 + (k_{\text{rec}}^0 + k_{\text{rec}})^2}$$

The momentum of the radiated particle is computed according to

$$\underline{k}_n = \frac{q^2 - M_{\text{rec}}^2 - 2q^0 \underline{k}_{n+1}}{2(q^0 - \underline{k}_{n+1}(1 - y))}, \quad (26.13)$$

with $k = k_n + k_{n+1}$ and $M_{\text{rec}}^2 = k_{\text{rec}}^2 = (q - k)^2$. Because of $\bar{\mathbf{k}}_n \parallel \mathbf{k}_n + \mathbf{k}_{n+1}$ we find $M_{\text{rec}}^2 = (q - \bar{\mathbf{k}}_n)^2$. Equation ?? follows from the fact that $(\mathbf{k} - \mathbf{k}_n)^2 =$

\mathbf{k}_{n+1}^2 , which is equivalent to $\mathbf{k}_n \cdot \mathbf{k} = \frac{1}{2}(\underline{k}_n^2 + \underline{k}^2 - \underline{k}_{n+1}^2)$.
 \mathbf{k}_n and \mathbf{k}_{n+1} are obtained by first setting up vectors parallel to $\bar{\mathbf{k}}_n$,

$$\mathbf{k}'_n = \underline{k}_n \frac{\bar{\mathbf{k}}_n}{\underline{k}_n}, \quad \mathbf{k}'_{n+1} = \underline{k}_{n+1} \frac{\bar{\mathbf{k}}_n}{\underline{k}_n},$$

and then rotating these vectors by an amount of $\cos \psi_n = \frac{\mathbf{k}_n \cdot \mathbf{k}}{\underline{k}_n \underline{k}}$. The emitted particle cannot have more momentum than the emitter has in the Born phase space. Thus, there is an upper bound for ξ , determined by the condition $k_{n+1}^0 = \underline{k}_n$, which is equal to

$$\xi_{\max} = \frac{2}{\underline{k}_n} q^0.$$

```

  end function get_xi_max_fsr_massless

```

The computation of ξ_{\max} for massive emitters is described in arXiv:1202.0465. Let's recapitulate it here.

We consider the Dalitz-domain created by k_{n+1}^0 , k_n^0 and k_{rec}^0 and introduce the parameterization

$$k_n^0 = \bar{k}_n^0 - z k_{n+1}^0$$

Then, for each value of z , there exists a maximum value of \underline{k}_{n+1} from which ξ_{\max} can be extracted via $\xi_{\max} = 2k_{n+1}^0/q$. It is determined by the condition

$$\underline{k}_{n+1} \pm \underline{k}_n \pm \underline{k}_{\text{rec}} = 0.$$

This can be manipulated to yield

$$(\underline{k}_{n+1}^2 + \underline{k}_n^2 - \underline{k}_{\text{rec}}^2)^2 = 4\underline{k}_{n+1}^2 \underline{k}_n^2.$$

Here we can use $\underline{k}_n^2 = (k_n^0)^2 - m^2$ and $\underline{k}_{\text{rec}}^2 = (q - k_n^0 - k_{n+1}^0)^2 - M_{\text{rec}}^2$, as well as the above parameterization of k_n^0 , to obtain

$$4\underline{k}_{n+1}^2 (2\underline{k}_{n+1} q z (1 - z) + q^2 z^2 - 2q \bar{k}_{\text{rec}}^0 z + M_{\text{rec}}^2) = 0.$$

Solving for k_{n+1}^0 gives

$$k_{n+1}^0 = \frac{2q \bar{k}_{\text{rec}}^0 z - q^2 z^2 - M_{\text{rec}}^2}{2q z (1 - z)}. \quad (26.14)$$

It is still open how to compute z . For this, consider that the right-hand-side of equation (26.14) vanishes for

$$z_{1,2} = \left(\bar{k}_{\text{rec}}^0 \pm \sqrt{(\bar{k}_{\text{rec}}^0)^2 - M_{\text{rec}}^2} \right) / q,$$

which corresponds to the borders of the Dalitz-region where the gluon momentum vanishes. Thus we define

$$z = z_2 - \frac{1}{2}(z_2 - z_1)(1 + y).$$

The real phase space for an initial-state emission involved in a decay process is generated by first setting the gluon momentum like in the scattering case by using its angular coordinates y and ϕ and then adjusting the gluon energy with ξ . The emitter momentum is kept identical to the Born case, i.e. $p_{\text{in}} = \bar{p}_{\text{in}}$, so that after the emission it has momentum $p_{\text{virt}} = p_{\text{in}} - p_g$ and invariant mass $m^2 = p_{\text{virt}}^2$. Note that the final state momenta have to remain on-shell, so that $p_1^2 = \bar{p}_1^2 = m_1^2$ and $p_2^2 = \bar{p}_2^2 = m_2^2$. Let Λ be the boost from into the rest frame of the emitter after emission, i.e. $\Lambda p_{\text{virt}} = (m, 0, 0, 0)$. In this reference frame, the spatial components of the final-state momenta sum up to zero, and their magnitude is

$$p = \frac{\sqrt{\lambda(m^2, m_1^2, m_2^2)}}{2m},$$

a fact already used in the evaluation of the phase space trees of `phs_forest`. Obviously, from this, the final-state energies can be deferred via $E_i^2 = m_i^2 - p^2$. In the next step, the $p_{1,2}$ are set up as vectors $(E, 0, 0, \pm p)$ along the z-axis and then rotated about the same azimuthal and polar angles as in the Born system. Finally, the momenta are boosted out of the rest frame by multiplying with Λ .

26.8 Subtraction of initial-state divergences

We must calculate two terms, G_{\oplus} and G_{\ominus} for each possible initial-state emitter. Following the notation of 0709.2092, this is separated into $G = \tilde{\mathcal{L}}\mathcal{G}$, such that $\tilde{\mathcal{L}}$ contains the PDF-values at the scales, explicitly

$$\tilde{\mathcal{L}} = \begin{cases} \mathcal{L}(\bar{x}_{\oplus}/z, \bar{x}_{\ominus}) & \text{for } \alpha \in \text{ISR}_{\oplus} \\ \mathcal{L}(\bar{x}_{\oplus}, \bar{x}_{\ominus}/z) & \text{for } \alpha \in \text{ISR}_{\ominus} \end{cases}$$

For each flavor combination f_{\oplus} and f_{\ominus} of initial-state particles, the relevant terms are given by

$$\mathcal{G}_{\oplus}^{f_{\oplus}f_{\ominus}}(z) = \frac{\alpha_s}{2\pi} \sum_{f'_{\oplus}} \left\{ (1-z)P^{f_{\oplus}f'_{\oplus}}(z, 0) \left[\left(\frac{1}{1-z} \right)_+ \log \frac{s}{2\mu_F^2} + 2 \left(\frac{\log(1-z)}{1-z} \right)_+ \right] - \left[\frac{\partial P^{f_{\oplus}f'_{\oplus}}(z, \epsilon)}{\partial \epsilon} \right]_{\epsilon=0} - K^{f_{\oplus}f'_{\oplus}} \right\} \mathcal{B}^{f_{\oplus}f_{\ominus}}(z)$$

where $P(z, \epsilon)$ are the Altarelli-Parisi splitting functions

$$\begin{aligned} P_{qq}(z, \epsilon) &= C_F \left[\frac{1+z^2}{1-z} - \epsilon(1-z) \right], \\ P_{qg}(z, \epsilon) &= C_F \left[\frac{1+(1-z)^2}{z} - \epsilon z \right], \\ P_{gq}(z, \epsilon) &= T_F \left[1 - \frac{2z(1-z)}{1-\epsilon} \right], \\ P_{gg}(z, \epsilon) &= 2C_A \left[\frac{z}{1-z} + \frac{1-z}{z} + z(1-z) \right]. \end{aligned}$$

In the code we deal with $\hat{P}^{f_{\oplus}f_{\ominus}}(z) = (1-z)P^{f_{\oplus}f_{\ominus}}(z, 0)$ because this quantity behaves nicely in the limit $z \rightarrow 1$. The factor $K^{f_{\oplus}f_{\ominus}}$ depends on the renormalization scheme and vanishes for \overline{MS} .

The second thing to consider is the fact that the integration over z is carried out over the interval $[\bar{x}_{\oplus}, 1]$ or $[\bar{x}_{\ominus}, 1]$, respectively, but the plus-distribution can only be evaluated over $[0, 1]$. We thus use the identities

$$\begin{aligned} \int_{\bar{x}_{\oplus}}^1 dz \left(\frac{1}{1-z} \right)_+ f(z) &= \log(1-\bar{x}_{\oplus})f(1) + \int_{\bar{x}_{\oplus}}^1 dz \frac{f(z) - f(1)}{1-z}, \\ \int_{\bar{x}_{\oplus}}^1 dz \left(\frac{\log(1-z)}{1-z} \right)_+ f(z) &= \frac{1}{2} \log^2(1-\bar{x}_{\oplus})f(1) + \int_{\bar{x}_{\oplus}}^1 dz \frac{\log(1-z)[f(z) - f(1)]}{1-z}. \end{aligned}$$

Chapter 27

Model Handling and Features

These modules deal with process definitions and physics models.

These modules use the `model_data` methods to automatically generate process definitions.

auto_components Generic process-definition generator. We can specify a basic process or initial particle(s) and some rules to extend this process, given a model definition with particle names and vertex structures.

radiation_generator Applies the generic generator to the specific problem of generating NLO corrections in a restricted setup.

Model construction:

eval_trees Implementation of the generic `expr_t` type for the concrete evaluation of expressions that access user variables.

This module is actually part of the Sindarin language implementation, and should be moved elsewhere. Currently, the `models` module relies on it.

models Extends the `model_data_t` structure by user-variable objects for easy access, and provides the means to read a model definition from file.

slha_interface Read/write a SUSY model in the standardized SLHA format. The format defines fields and parameters, but no vertices.

27.1 Automatic generation of process components

This module provides the functionality for automatically generating radiation corrections or decays, provided as lists of PDG codes.

```
<auto_components.f90>≡  
  <File header>  
  
  module auto_components

    contains  
  
    <Auto components: procedures>  
  
  end module auto_components
```

27.1.1 Constraints: Abstract types

An abstract type that denotes a constraint on the automatically generated states. The concrete objects are applied as visitor objects at certain hooks during the splitting algorithm.

```
<Auto components: types>≡  
  type, abstract :: split_constraint_t  
    contains  
    <Auto components: split constraint: TBP>  
  end type split_constraint_t
```

By default, all checks return true.

```
<Auto components: split constraint: TBP>≡  
  procedure :: check_before_split => split_constraint_check_before_split  
  procedure :: check_before_insert => split_constraint_check_before_insert  
  procedure :: check_before_record => split_constraint_check_before_record  
  
<Auto components: procedures>≡  
  subroutine split_constraint_check_before_split (c, table, pl, k, passed)
```

```

class(split_constraint_t), intent(in) :: c
class(ps_table_t), intent(in) :: table
type(pdg_list_t), intent(in) :: pl
integer, intent(in) :: k
logical, intent(out) :: passed
passed = .true.
end subroutine split_constraint_check_before_split

subroutine split_constraint_check_before_insert (c, table, pa, pl, passed)
class(split_constraint_t), intent(in) :: c
class(ps_table_t), intent(in) :: table
type(pdg_array_t), intent(in) :: pa
type(pdg_list_t), intent(inout) :: pl
logical, intent(out) :: passed
passed = .true.
end subroutine split_constraint_check_before_insert

subroutine split_constraint_check_before_record (c, table, pl, n_loop, passed)
class(split_constraint_t), intent(in) :: c
class(ps_table_t), intent(in) :: table
type(pdg_list_t), intent(in) :: pl
integer, intent(in) :: n_loop
logical, intent(out) :: passed
passed = .true.
end subroutine split_constraint_check_before_record

```

A transparent wrapper, so we can collect constraints of different type.

```

<Auto components: types>+≡
type :: split_constraint_wrap_t
class(split_constraint_t), allocatable :: c
end type split_constraint_wrap_t

```

A collection of constraints.

```

<Auto components: public>≡
public :: split_constraints_t

<Auto components: types>+≡
type :: split_constraints_t
class(split_constraint_wrap_t), dimension(:), allocatable :: cc
contains
<Auto components: split constraints: TBP>
end type split_constraints_t

```

Initialize the constraints set with a specific number of elements.

```

<Auto components: split constraints: TBP>≡
procedure :: init => split_constraints_init

<Auto components: procedures>+≡
subroutine split_constraints_init (constraints, n)
class(split_constraints_t), intent(out) :: constraints
integer, intent(in) :: n
allocate (constraints%cc (n))
end subroutine split_constraints_init

```

Set a constraint.

```

<Auto components: split constraints: TBP>+≡
  procedure :: set => split_constraints_set

<Auto components: procedures>+≡
  subroutine split_constraints_set (constraints, i, c)
    class(split_constraints_t), intent(inout) :: constraints
    integer, intent(in) :: i
    class(split_constraint_t), intent(in) :: c
    allocate (constraints%cc(i)%c, source = c)
  end subroutine split_constraints_set

```

Apply checks.

`check_before_split` is applied to the particle list that we want to split.

`check_before_insert` is applied to the particle list `pl` that is to replace the particle `pa` that is split. This check may transform the particle list.

`check_before_record` is applied to the complete new particle list that results from splitting before it is recorded.

```

<Auto components: split constraints: TBP>+≡
  procedure :: check_before_split => split_constraints_check_before_split
  procedure :: check_before_insert => split_constraints_check_before_insert
  procedure :: check_before_record => split_constraints_check_before_record

<Auto components: procedures>+≡
  subroutine split_constraints_check_before_split &
    (constraints, table, pl, k, passed)

      if (.not. passed) return
    end do
  end subroutine split_constraints_check_before_split

  subroutine split_constraints_check_before_insert &
    (constraints, table, pa, pl, passed)
    class(split_constraints_t), intent(in) :: constraints
    class(ps_table_t), intent(in) :: table
    type(pdg_array_t), intent(in) :: pa
    type(pdg_list_t), intent(inout) :: pl
    logical, intent(out) :: passed
    integer :: i
    passed = .true.
    do i = 1, size (constraints%cc)
      call constraints%cc(i)%c%check_before_insert (table, pa, pl, passed)
      if (.not. passed) return
    end do
  end subroutine split_constraints_check_before_insert

```

```

subroutine split_constraints_check_before_record &
  (constraints, table, pl, n_loop, passed)
  class(split_constraints_t), intent(in) :: constraints
  class(ps_table_t), intent(in) :: table
  type(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n_loop
  logical, intent(out) :: passed
  integer :: i
  passed = .true.
  do i = 1, size (constraints%cc)
    call constraints%cc(i)%check_before_record (table, pl, n_loop, passed)
    if (.not. passed) return
  end do
end subroutine split_constraints_check_before_record

```

27.1.2 Specific constraints

Number of particles

Specific constraint: The number of particles plus the number of loops, if any, must remain less than the given limit. Note that the number of loops is defined only when we are recording the entry.

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_n_tot
  private
  integer :: n_max = 0
  contains
    procedure :: check_before_split => constraint_n_tot_check_before_split
    procedure :: check_before_record => constraint_n_tot_check_before_record
  end type constraint_n_tot

<Auto components: public>+≡
  public :: constrain_n_tot

<Auto components: procedures>+≡
  function constrain_n_tot (n_max) result (c)
    integer, intent(in) :: n_max
    type(constraint_n_tot) :: c
    c%n_max = n_max
  end function constrain_n_tot

  subroutine constraint_n_tot_check_before_split (c, table, pl, k, passed)
    class(constraint_n_tot), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: k
    logical, intent(out) :: passed
    passed = pl%get_size () < c%n_max
  end subroutine constraint_n_tot_check_before_split

  subroutine constraint_n_tot_check_before_record (c, table, pl, n_loop, passed)
    class(constraint_n_tot), intent(in) :: c
    class(ps_table_t), intent(in) :: table

```

```

    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    passed = pl%get_size () + n_loop <= c%n_max
end subroutine constraint_n_tot_check_before_record

```

Number of loops

Specific constraint: The number of loops is limited, independent of the total number of particles.

```

<Auto components: types>+≡
    type, extends (split_constraint_t) :: constrain_n_loop
    private
    integer :: n_loop_max = 0

    logical, intent(out) :: passed
    passed = n_loop <= c%n_loop_max
end subroutine constraint_n_loop_check_before_record

```

Particles allowed in splitting

Specific constraint: The entries in the particle list ready for insertion are matched to a given list of particle patterns. If a match occurs, the entry is replaced by the corresponding pattern. If there is no match, the check fails.

```

<Auto components: types>+≡
    type, extends (split_constraint_t) :: constraint_insert
    private
    type(pdg_list_t) :: pl_match
    contains
    procedure :: check_before_insert => constraint_insert_check_before_insert
end type constraint_insert

```

```

<Auto components: public>+≡
    public :: constrain_insert

<Auto components: procedures>+≡
    function constrain_insert (pl_match) result (c)
        type(pdg_list_t), intent(in) :: pl_match
        type(constraint_insert) :: c
        c%pl_match = pl_match
    end function constrain_insert

    subroutine constraint_insert_check_before_insert (c, table, pa, pl, passed)
        class(constraint_insert), intent(in) :: c
        class(ps_table_t), intent(in) :: table
        type(pdg_array_t), intent(in) :: pa
        type(pdg_list_t), intent(inout) :: pl
        logical, intent(out) :: passed
        call pl%match_replace (c%pl_match, passed)
    end subroutine constraint_insert_check_before_insert

```

Particles required in final state

Specific constraint: The entries in the recorded state must be a superset of the entries in the given list (for instance, the lowest-order state).

```

<Auto components: types>+≡
    type, extends (split_constraint_t) :: constraint_require
    private
    type(pdg_list_t) :: pl
    contains
    procedure :: check_before_record => constraint_require_check_before_record
end type constraint_require

```

We check the current state by matching all particle entries against the stored particle list, and crossing out the particles in the latter list when a match is found. The constraint passed if all entries have been crossed out.

For an `if_table` in particular, we check the final state only.

```

<Auto components: public>+≡
    public :: constrain_require

<Auto components: procedures>+≡
    function constrain_require (pl) result (c)
        type(pdg_list_t), intent(in) :: pl
        type(constraint_require) :: c
        c%pl = pl
    end function constrain_require

    subroutine constraint_require_check_before_record &
        (c, table, pl, n_loop, passed)
        class(constraint_require), intent(in) :: c
        class(ps_table_t), intent(in) :: table
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: n_loop
        logical, intent(out) :: passed
        logical, dimension(:), allocatable :: mask

```

```

integer :: i, k, n_in
select type (table)
type is (if_table_t)
  if (table%proc_type > 0) then
    select case (table%proc_type)
    case (PROC_DECAY)
      n_in = 1
    case (PROC_SCATTER)
      n_in = 2
    end select
  else
    call msg_fatal ("Neither a decay nor a scattering process")
  end if
class default
  n_in = 0
end select
allocate (mask (c%pl%get_size ()), source = .true.)
do i = n_in + 1, pl%get_size ()
  k = c%pl%find_match (pl%get (i), mask)
  if (k /= 0) mask(k) = .false.
end do
passed = .not. any (mask)
end subroutine constraint_require_check_before_record

```

Radiation

Specific constraint: We have radiation pattern if the original particle matches an entry in the list of particles that should replace it. The constraint prohibits this situation.

```

<Auto components: public>+≡
  public :: constrain_radiation

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_radiation
  private
  contains
    procedure :: check_before_insert => &
      constraint_radiation_check_before_insert
  end type constraint_radiation

<Auto components: procedures>+≡
  function constrain_radiation () result (c)
    type(constraint_radiation) :: c
  end function constrain_radiation

subroutine constraint_radiation_check_before_insert (c, table, pa, pl, passed)
  class(constraint_radiation), intent(in) :: c
  class(ps_table_t), intent(in) :: table
  type(pdg_array_t), intent(in) :: pa
  type(pdg_list_t), intent(inout) :: pl
  logical, intent(out) :: passed
  passed = .not. (pl .match. pa)

```

```
end subroutine constraint_radiation_check_before_insert
```

Mass sum

Specific constraint: The sum of masses within the particle list must be smaller than a given limit. For in/out state combinations, we check initial and final state separately.

If we specify `margin` in the initialization, the sum must be strictly less than the limit minus the given margin (which may be zero). If not, equality is allowed.

```
<Auto components: public>+≡
public :: constrain_mass_sum

<Auto components: types>+≡
type, extends (split_constraint_t) :: constraint_mass_sum
private
real(default) :: mass_limit = 0
logical :: strictly_less = .false.
real(default) :: margin = 0
contains
procedure :: check_before_record => constraint_mass_sum_check_before_record
end type constraint_mass_sum

        (c, table, pl, n_loop, passed)
        class(constraint_in_state), intent(in) :: c
        class(ps_table_t), intent(in) :: table
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: n_loop
        logical, intent(out) :: passed
        integer :: i
        select type (table)
        type is (if_table_t)
            passed = .false.
            do i = 1, 2
                if (.not. (c%pl .match. pl%get (i))) return
            end do
        end select
        passed = .true.
    end subroutine constraint_in_state_check_before_record

```

27.1.3 Tables of states

Automatically generate a list of possible process components for a given initial set (a single massive particle or a preset list of states).

The set of process components are generated by recursive splitting, applying constraints on the fly that control and limit the process. The generated states are accumulated in a table that we can read out after completion.

```

⟨Auto components: types⟩+≡
  type, extends (pdg_list_t) :: ps_entry_t
    integer :: n_loop = 0
    integer :: n_rad = 0
    type(ps_entry_t), pointer :: previous => null ()
    type(ps_entry_t), pointer :: next => null ()
  end type ps_entry_t

```

```

⟨Auto components: parameters⟩≡
  integer, parameter :: PROC_UNDEFINED = 0
  integer, parameter :: PROC_DECAY = 1
  integer, parameter :: PROC_SCATTER = 2

```

This is the wrapper type for the decay tree for the list of final states and the final array. First, an abstract base type:

```

⟨Auto components: public⟩+≡
  public :: ps_table_t

⟨Auto components: types⟩+≡
  type, abstract :: ps_table_t
    private
    class(model_data_t), pointer :: model => null ()
    logical :: loops = .false.
    type(ps_entry_t), pointer :: first => null ()
    type(ps_entry_t), pointer :: last => null ()
    integer :: proc_type
    contains
    ⟨Auto components: ps table: TBP⟩
  end type ps_table_t

```

The extensions: one for decay, one for generic final states. The decay-state table stores the initial particle. The final-state table is indifferent, and the initial/final state table treats the first two particles in its list as incoming antiparticles.

```

⟨Auto components: public⟩+≡
  public :: ds_table_t
  public :: fs_table_t
  public :: if_table_t

⟨Auto components: types⟩+≡
  type, extends (ps_table_t) :: ds_table_t
    private
    integer :: pdg_in = 0
    contains
    ⟨Auto components: ds table: TBP⟩
  end type ds_table_t

```

```

type, extends (ps_table_t) :: fs_table_t
contains
  <Auto components: fs table: TBP>
end type fs_table_t

type, extends (fs_table_t) :: if_table_t
contains
  <Auto components: if table: TBP>

      current => current%next
    end do
  end subroutine fs_table_radiate

```

27.1.5 Splitting algorithm

Recursive splitting. First of all, we record the current `pdg_list` in the table, subject to `constraints`, if requested. We also record copies of the list marked as loop corrections.

When we record a particle list, we sort it first.

If there is room for splitting, We take a PDG array list and the index of an element, and split this element in all possible ways. The split entry is inserted into the list, which we split further.

The recursion terminates whenever the split array would have a length greater than n_{\max} .

```

<Auto components: ps table: TBP>+≡
  procedure :: split => ps_table_split

<Auto components: procedures>+≡
  recursive subroutine ps_table_split (table, pl, n_rad, constraints, &
    record)
    class(ps_table_t), intent(inout) :: table
    class(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_rad
    type(split_constraints_t), intent(in) :: constraints
    logical, intent(in), optional :: record
    integer :: n_loop, i
    logical :: passed
    type(vertex_iterator_t) :: vit
    integer, dimension(:), allocatable :: pdg1
    integer, dimension(:), allocatable :: pdg2
    if (present (record)) then
      if (record) then
        n_loop = 0
        INCR_LOOPS: do
          call table%record_sorted (pl, n_loop, n_rad, constraints, passed)
          if (.not. passed) exit INCR_LOOPS
          if (.not. table%loops) exit INCR_LOOPS
          n_loop = n_loop + 1
        end do INCR_LOOPS
      end if
    end if
    do i = 1, pl%get_size ()
      call constraints%check_before_split (table, pl, i, passed)
      if (passed) then
        pdg1 = pl%get (i)
        call vit%init (table%model, pdg1)
        SCAN_VERTICES: do
          call vit%get_next_match (pdg2)
          if (allocated (pdg2)) then
            call table%insert (pl, n_rad, i, pdg2, constraints)
          else
            exit SCAN_VERTICES
          end if
        end do SCAN_VERTICES
      end if
    end do
  end subroutine ps_table_split

```

The worker part: insert the list of particles found by vertex matching in place of entry i in the PDG list. Then split/record further.

The `n_in` parameter tells the replacement routine to insert the new particles

after entry `n_in`. Otherwise, they follow index `i`.

```

<Auto components: ps table: TBP>+=
  procedure :: insert => ps_table_insert

<Auto components: procedures>+=
  recursive subroutine ps_table_insert &
    (table, pl, n_rad, i, pdg, constraints, n_in)
    class(ps_table_t), intent(inout) :: table
    class(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_rad, i
    integer, dimension(:), intent(in) :: pdg
    type(split_constraints_t), intent(in) :: constraints
    integer, intent(in), optional :: n_in
    type(pdg_list_t) :: pl_insert
    logical :: passed
    integer :: k, s
    s = size (pdg)
    call pl_insert%init (s)
    do k = 1, s
      call pl_insert%set (k, pdg(k))
    end do
    call constraints%check_before_insert (table, pl%get (i), pl_insert, passed)
    if (passed) then
      call table%split (pl%replace (i, pl_insert, n_in), n_rad + s - 1, &
        constraints, record = .true.)
    end if
  end subroutine ps_table_insert

```

Special case: If we are splitting an initial particle, there is slightly more to do. We loop over the particles from the vertex match and replace the initial particle by each of them in turn. The remaining particles must be appended after the second initial particle, so they will end up in the out state. This is done by providing the `n_in` argument to the base method as an optional argument.

Note that we must call the base-method procedure explicitly, so the `table` argument keeps its dynamic type as `if_table` inside this procedure.

```

<Auto components: if table: TBP>+=
  procedure :: insert => if_table_insert

<Auto components: procedures>+=
  recursive subroutine if_table_insert &
    (table, pl, n_rad, i, pdg, constraints, n_in)
    class(if_table_t), intent(inout) :: table
    class(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_rad, i
    integer, dimension(:), intent(in) :: pdg
    type(split_constraints_t), intent(in) :: constraints
    integer, intent(in), optional :: n_in
    integer, dimension(:), allocatable :: pdg_work
    integer :: p
    if (i > 2) then
      call ps_table_insert (table, pl, n_rad, i, pdg, constraints)
    else
      allocate (pdg_work (size (pdg)))
      do p = 1, size (pdg)

```

```

    pdg_work(1) = pdg(p)
    pdg_work(2:p) = pdg(1:p-1)
    pdg_work(p+1:) = pdg(p+1:)
    select case (table%proc_type)
    case (PROC_DECAY)
        call ps_table_insert (table, &
            pl, n_rad, i, pdg_work, constraints, n_in = 1)
    case (PROC_SCATTER)
        call ps_table_insert (table, &
            pl, n_rad, i, pdg_work, constraints, n_in = 2)
    end select
end do
end if
end subroutine if_table_insert

```

Sort before recording. In the case of the `if_table`, we do not sort the first `n_in` particle entries. Instead, we check whether they are allowed in the `pl_beam` PDG list, if that is provided.

```

<Auto components: ps table: TBP>+≡
    procedure :: record_sorted => ps_table_record_sorted

<Auto components: if table: TBP>+≡
    procedure :: record_sorted => if_table_record_sorted

27.1.6 Tools

Compute the mass sum for a PDG list object, counting the entries with indices between (including) `n1` and `n2`. Rely on the requirement that if an entry is a PDG array, this array must be degenerate in mass.

```
<Auto components: procedures>+≡
function mass_sum (pl, n1, n2, model) result (m)
  type(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n1, n2
  class(model_data_t), intent(in), target :: model
  integer, dimension(:), allocatable :: pdg
  real(default) :: m
  type(field_data_t), pointer :: prt
  integer :: i
  m = 0
  do i = n1, n2
    pdg = pl%get (i)
    prt => model%get_field_ptr (pdg(1))
    m = m + prt%get_mass ()
  end do
end function mass_sum
```

Invert a PDG array, replacing particles by antiparticles. This depends on the model.

```
<Auto components: procedures>+≡
function invert_pdg_array (pa, model) result (pa_inv)
  type(pdg_array_t), intent(in) :: pa
  class(model_data_t), intent(in), target :: model
  type(pdg_array_t) :: pa_inv
  type(field_data_t), pointer :: prt
  integer :: i, pdg
  pa_inv = pa
  do i = 1, pa_inv%get_length ()
    pdg = pa_inv%get (i)
    prt => model%get_field_ptr (pdg)
    if (prt%has_antiparticle ()) call pa_inv%set (i, -pdg)
  end do
end function invert_pdg_array
```

27.1.7 Access results

Return the number of generated decays.

```
<Auto components: ps table: TBP>+≡
procedure :: get_length => ps_table_get_length

<Auto components: procedures>+≡
function ps_table_get_length (ps_table) result (n)
  class(ps_table_t), intent(in) :: ps_table
  integer :: n
```

```

type(ps_entry_t), pointer :: entry
n = 0
entry => ps_table%first
do while (associated (entry))
    n = n + 1
    entry => entry%next
end do
end function ps_table_get_length

```

<Auto components: ps table: TBP>+≡

```

procedure :: get_emitters => ps_table_get_emitters

```

<Auto components: procedures>+≡

```

function ps_table_get_emitters (table, constraints) result (emitters)

27.3 Sindarin Expression Implementation

This module defines expressions of all kinds, represented in a tree structure, for repeated evaluation. This provides an implementation of the `expr_base` abstract type.

We have two flavors of expressions: one with particles and one without particles. The latter version is used for defining cut/selection criteria and for online analysis.

```

```

27.3.1 Tree nodes

The evaluation tree consists of branch nodes (unary and binary) and of leaf nodes, originating from a common root. The node object should be polymorphic. For the time being, polymorphism is emulated here. This means that we have to maintain all possibilities that the node may hold, including associated procedures as pointers.

The following parameter values characterize the node. Unary and binary operators have sub-nodes. The other are leaf nodes. Possible leafs are literal constants or named-parameter references.

(Eval trees: types)≡

```
integer, parameter :: EN_UNKNOWN = 0, EN_UNARY = 1, EN_BINARY = 2
integer, parameter :: EN_CONSTANT = 3, EN_VARIABLE = 4
integer, parameter :: EN_CONDITIONAL = 5, EN_BLOCK = 6
integer, parameter :: EN_RECORD_CMD = 7
integer, parameter :: EN_OBS1_INT = 11, EN_OBS2_INT = 12
integer, parameter :: EN_OBS1_REAL = 21, EN_OBS2_REAL = 22
integer, parameter :: EN_UOBS1_INT = 31, EN_UOBS2_INT = 32
integer, parameter :: EN_UOBS1_REAL = 41, EN_UOBS2_REAL = 42
integer, parameter :: EN_PRT_FUN_UNARY = 101, EN_PRT_FUN_BINARY = 102
integer, parameter :: EN_EVAL_FUN_UNARY = 111, EN_EVAL_FUN_BINARY = 112
integer, parameter :: EN_LOG_FUN_UNARY = 121, EN_LOG_FUN_BINARY = 122
integer, parameter :: EN_INT_FUN_UNARY = 131, EN_INT_FUN_BINARY = 132
integer, parameter :: EN_REAL_FUN_UNARY = 141, EN_REAL_FUN_BINARY = 142
integer, parameter :: EN_FORMAT_STR = 161
```

This is exported only for use within unit tests.

    case (V_STR); allocate (node%sval)
  end select
  allocate (node%value_is_known)
  node%value_is_known = .false.
end subroutine eval_node_allocate_value

```

Initialize a block node which contains, in addition to the expression to be evaluated, a variable definition. The result type is not yet assigned, because we can compile the enclosed expression only after the var list is set up.

Note that the node always allocates a new variable list and appends it to the current one. Thus, if the variable redefines an existing one, it only shadows it but does not reset it. Any side-effects are therefore absent and need not be undone outside the block.

If the flag **new** is set, a variable is (re)declared. This must not be done for intrinsic variables. Vice versa, if the variable is not existent, the **new** flag is required.

(Eval trees: procedures)+≡

```

subroutine eval_node_init_block (node, name, type, var_def, var_list)
  type(eval_node_t), intent(out), target :: node
  type(string_t), intent(in) :: name
  integer, intent(in) :: type

node%arg0 => arg
end subroutine eval_node_set_expr

```

Initialize a conditional. There are three branches: the condition (evaluates to logical) and the two alternatives (evaluate both to the same arbitrary type).

(Eval trees: procedures)+≡

```

subroutine eval_node_init_conditional (node, result_type, cond, arg1, arg2)
  type(eval_node_t), intent(out) :: node
  integer, intent(in) :: result_type
  type(eval_node_t), intent(in), target :: cond, arg1, arg2
  node%type = EN_CONDITIONAL
  node%tag = "cond"
  node%result_type = result_type
  call eval_node_allocate_value (node)
  node%arg0 => cond
  node%arg1 => arg1
  node%arg2 => arg2
end subroutine eval_node_init_conditional

```

Initialize a recording command (which evaluates to a logical constant). The first branch is the ID of the analysis object to be filled, the optional branches 1 to 4 are the values to be recorded.

If the event-weight pointer is null, we record values with unit weight. Otherwise, we use the value pointed to as event weight.

There can be up to four arguments which represent $x, y, \Delta y, \Delta x$. Therefore, this is the only node type that may fill four sub-nodes.

(Eval trees: procedures)+≡

```

subroutine eval_node_init_record_cmd &
  (node, event_weight, id, arg1, arg2, arg3, arg4)
  type(eval_node_t), intent(out) :: node
  real(default), pointer :: event_weight
  type(eval_node_t), intent(in), target :: id
  type(eval_node_t), intent(in), optional, target :: arg1, arg2, arg3, arg4
  call eval_node_init_log (node, .true.)
  node%type = EN_RECORD_CMD
  node%rval => event_weight
  node%tag = "record_cmd"
  node%arg0 => id
  if (present (arg1)) then
    node%arg1 => arg1
    if (present (arg2)) then
      node%arg2 => arg2
      if (present (arg3)) then
        node%arg3 => arg3
        if (present (arg4)) then
          node%arg4 => arg4
        end if
      end if
    end if
  end if

```

```

        end if
    end if
end subroutine eval_node_init_record_cmd

```

Initialize a node for operations on subevents. The particle lists (one or two) are inserted as `arg1` and `arg2`. We allocated particle pointers as temporaries for iterating over particle lists. The procedure pointer which holds the function to evaluate for the subevents (e.g., combine, select) is also initialized.

(Eval trees: procedures)+≡

```

subroutine eval_node_init_prt_fun_unary (node, arg1, name, proc)
    type(eval_node_t), intent(out) :: node
    type(eval_node_t), intent(in), target :: arg1

call eval_node_allocate_value (node)
node%arg0 => fmt
node%arg1 => arg
allocate (node%ival)
node%ival = n_args
end subroutine eval_node_init_format_string

```

If particle functions depend upon a condition (or an expression is evaluated), the observables that can be evaluated for the given particles have to be thrown on the local variable stack. This is done here. Each observable is initialized with the particle pointers which have been allocated for the node.

The integer variable that is referred to by the `Index` pseudo-observable is always known when it is referred to.

(Eval trees: procedures)+≡

```

subroutine eval_node_set_observables (node, var_list)
type(eval_node_t), intent(inout) :: node
type(var_list_t), intent(in), target :: var_list
logical, save, target :: known = .true.
allocate (node%var_list)
call node%var_list%link (var_list)
allocate (node%index, source = 0)
call var_list_append_int_ptr &
    (node%var_list, var_str ("Index"), node%index, known, intrinsic=.true.)
if (.not. associated (node%prt2)) then
    call var_list_set_observables_unary &

27.3.2 Operation types

For the operations associated to evaluation tree nodes, we define abstract interfaces for all cases.

Particles/subevents are transferred by-reference, to avoid unnecessary copying. Therefore, subroutines instead of functions. (Furthermore, the function version of `unary_prt` triggers an obscure bug in nagfor 5.2(649) [invalid C code].)

(Eval trees: interfaces)≡

```

abstract interface
  logical function unary_log (arg)

27.3.3 Specific operators

Our expression syntax contains all Fortran functions that make sense. These functions have to be provided in a form that they can be used in procedures pointers, and have the abstract interfaces above. For some intrinsic functions, we could use specific versions provided by Fortran directly. However, this has two drawbacks: (i) We should work with the values instead of the eval-nodes as argument, which complicates the interface; (ii) more importantly, the **default** real type need not be equivalent to double precision. This would, at least, introduce system dependencies. Finally, for operators there are no specific versions.

Therefore, we write wrappers for all possible functions, at the expense of some overhead.

Binary numerical functions

```

        lval = .not. en0%lval
        if (lval) exit
    end do
end function no_p

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

<Eval trees: procedures>+≡

```

function user_obs_int_p (en0, prt1) result (ival)

                  int (subevt_get_length (en1%pval), kind=c_int)) &
    /= 0
end function user_cut_p

```

The following function returns an integer value, namely the number of particles for which the condition is true. If there is no condition, it returns simply the length of the subevent.

A function would be more natural. Making it a subroutine avoids another compiler bug (internal error in nagfor 5.2 (649)). (See the interface `unary_evi`.)

(Eval trees: procedures)+≡

```

subroutine count_a (ival, en1, en0)
  integer, intent(out) :: ival
  type(eval_node_t), intent(in) :: en1
  type(eval_node_t), intent(inout), optional :: en0

```

```

integer :: i, n, count
n = subevt_get_length (en1%pval)
if (present (en0)) then
  count = 0
  do i = 1, n
    en0%index = i
    en0%prt1 = subevt_get_prt (en1%pval, i)
    call eval_node_evaluate (en0)
    if (en0%lval) count = count + 1
  end do
  ival = count
else
  ival = n
end if
end subroutine count_a

```

This evaluates a user-defined event-shape observable for the current subevent.

<Eval trees: procedures>+≡

```

subroutine user_event_shape_a (rval, en1, en0)
  real(default), intent(out) :: rval
  type(eval_node_t), intent(in) :: en1
  type(eval_node_t), intent(inout), optional :: en0
  type(string_t) :: name
  procedure(user_event_shape_fun), pointer :: user_event_shape
  if (.not. present (en0)) call msg_bug &
    ("user_event_shape called without procedure name")
  call eval_node_evaluate (en0)
  select case (en0%result_type)
  case (V_STR); name = en0%sval

  call c_f_procpointer (user_code_find_proc (name), user_event_shape)
  rval = user_event_shape (c_prt (en1%pval), &
    int (subevt_get_length (en1%pval), kind=c_int))
end subroutine user_event_shape_a

```

Binary particle-list functions

This joins two subevents, stored in the evaluation nodes `en1` and `en2`. If `en0` is also present, it amounts to a logical test returning true or false for every pair of particles. A particle of the second list gets a mask entry only if it passes the test for all particles of the first list.

<Eval trees: procedures>+≡

```

subroutine join_pp (subevt, en1, en2, en0)
  type(subevt_t), intent(inout) :: subevt
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0
  logical, dimension(:), allocatable :: mask2
  integer :: i, j, n1, n2
  n1 = subevt_get_length (en1%pval)

```

```

n2 = subevt_get_length (en2%pval)
allocate (mask2 (n2))
mask2 = .true.
if (present (en0)) then
  do i = 1, n1
    en0%index = i
    en0%prt1 = subevt_get_prt (en1%pval, i)
    do j = 1, n2
      en0%prt2 = subevt_get_prt (en2%pval, j)
      call eval_node_evaluate (en0)
      mask2(j) = mask2(j) .and. en0%lval
    end do
  end do
end if
call subevt_join (subevt, en1%pval, en2%pval, mask2)
end subroutine join_pp

```

Combine two subevents, i.e., make a list of composite particles built from all possible particle pairs from the two lists. If `en0` is present, create a mask which is true only for those pairs that pass the test.

<Eval trees: procedures>+≡

```

subroutine combine_pp (subevt, en1, en2, en0)
  type(subevt_t), intent(inout) :: subevt
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0
  logical, dimension(:,,:), allocatable :: mask12
  integer :: i, j, n1, n2
  n1 = subevt_get_length (en1%pval)
  n2 = subevt_get_length (en2%pval)
  if (present (en0)) then
    allocate (mask12 (n1, n2))
    do i = 1, n1
      en0%index = i
      en0%prt1 = subevt_get_prt (en1%pval, i)
      do j = 1, n2
        en0%prt2 = subevt_get_prt (en2%pval, j)
        call eval_node_evaluate (en0)
        mask12(i,j) = en0%lval
      end do
    end do

    en0%prt2 = subevt_get_prt (en2%pval, j)
    call eval_node_evaluate (en0)
    mask1(i) = mask1(i) .and. en0%lval
  end do
end do
end if
call subevt_collect (subevt, en1%pval, mask1)
end subroutine collect_pp

```

Select all particles of the first argument. If `en0` is present, create a mask which is true only for those particles that pass the test w.r.t. all particles in the second argument. If `en0` is absent, the second argument is ignored, and the first argument is transferred unchanged. (This case is not very useful, of course.)

(Eval trees: procedures)+≡

```

subroutine select_pp (subevt, en1, en2, en0)
  type(subevt_t), intent(inout) :: subevt
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0

      end if
    end do
  end do LOOP1
end subroutine eval_pp

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

```

<Eval trees: procedures>+≡
function user_obs_int_pp (en0, prt1, prt2) result (ival)
  integer :: ival
  type(eval_node_t), intent(inout) :: en0
  type(prt_t), intent(in) :: prt1, prt2
  type(string_t) :: name
  procedure(user_obs_int_binary), pointer :: user_obs
  call eval_node_evaluate (en0)
  if (en0%value_is_known) then
    select case (en0%result_type)
    case (V_STR); name = en0% sval
    case default
      call msg_bug ("user_obs: procedure name must be a string")
      name = ""
    end select

    call msg_fatal ("User observable name is undefined")
  end if
end function user_obs_real_pp

```

The following function returns an integer value, namely the number of valid particle-pairs from both lists for which the condition is true. Invalid pairs (with common `src` entry) are ignored. If there is no condition, it returns the number of valid particle pairs.

A function would be more natural. Making it a subroutine avoids another compiler bug (internal error in nagfor 5.2 (649)). (See the interface `binary_num`.)

(Eval trees: procedures)+≡

```

subroutine count_pp (ival, en1, en2, en0)
  integer, intent(out) :: ival
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0
  integer :: i, j, n1, n2, count

  end if
end subroutine select_pdg_ca

```

Binary string functions

Currently, the only string operation is concatenation.

<Eval trees: procedures>+≡

```

subroutine concat_ss (string, en1, en2)
  type(string_t), intent(out) :: string
  type(eval_node_t), intent(in) :: en1, en2
  string = en1%sval // en2%sval
end subroutine concat_ss

```

27.3.4 Compiling the parse tree

The evaluation tree is built recursively by following a parse tree. Evaluate an expression. The requested type is given as an optional argument; default is numeric (integer or real).

<Eval trees: procedures>+≡

```

recursive subroutine eval_node_compile_genexpr &
  (en, pn, var_list, result_type)
  type(eval_node_t), pointer :: en
  type(parse_node_t), intent(in) :: pn
  type(var_list_t), intent(in), target :: var_list
  integer, intent(in), optional :: result_type
  if (debug_active (D_MODEL_F)) then
    print *, "read genexpr"; call parse_node_write (pn)
  end if
end subroutine eval_node_compile_genexpr

```

```

end if
if (present (result_type)) then
  select case (result_type)
    case (V_INT, V_REAL, V_CMPLX)
      call eval_node_compile_expr (en, pn, var_list)

  end select
else
  call eval_node_compile_expr (en, pn, var_list)
end if
if (debug_active (D_MODEL_F)) then
  call eval_node_write (en)
  print *, "done genexpr"
end if
end subroutine eval_node_compile_genexpr

```

Numeric expressions

This procedure compiles a numerical expression. This is a single term or a sum or difference of terms. We have to account for all combinations of integer and real arguments. If both are constant, we immediately do the calculation and allocate a constant node.

<Eval trees: procedures>+≡

```

```

Real, complex and integer values are numeric literals with an optional unit attached. In case of an integer, the unit actually makes it a real value in disguise. The signed version of real values is not possible in generic expressions; it is a special case for numeric constants in model files (see below). We do not introduce signed versions of complex values.

```

Compile a variable, with or without a specified type. Take the list of variables, look for the name and make a node with a pointer to the value. If no type is provided, the variable is numeric, and the stored value determines whether it is real or integer.

We explicitly demand that the variable is defined, so we do not accidentally point to variables that are declared only later in the script but have come into existence in a previous compilation pass.

Variables may actually be anonymous, these are expressions in disguise. In that case, the expression replaces the variable name in the parse tree, and we allocate an ordinary expression node in the eval tree.

Variables of type V_PDG (pdg-code array) are not treated here. They are handled by `eval_node_compile_cvariable`.

Retrieve the result of an integration. If the requested process has been integrated, the results are available as special variables. (The variables cannot be accessed in the usual way since they contain brackets in their names.)

Since this compilation step may occur before the processes have been loaded, we have to initialize the required variables before they are used.

```

This user observable behaves like a variable. We link the node to the generic user-observable entry in the variable list. The syntax element has an argument which provides the name of the user variable, this is stored as an eval-node alongside with the variable. When the variable value is used, the user-supplied external function is called and provides the (real) result value.

Variable definition

A block expression contains a variable definition (first argument) and an expression where the definition can be used (second argument). The `result_type` decides which type of expression is expected for the second argument. For numeric variables, if there is a mismatch between real and integer type, insert an extra node for type conversion.

Conditionals

A conditional has the structure if lexpr then expr else expr. So we first evaluate the logical expression, then depending on the result the first or second expression. Note that the second expression is mandatory.

The `result_type`, if present, defines the requested type of the `then` and `else` clauses. Default is numeric (int/real). If there is a mismatch between real and integer result types, insert conversion nodes.

(Eval trees: procedures) +=

```

Comparisons

Up to the loop, this is easy. There is always at least one comparison. This is evaluated, and the result is the logical node `en`. If it is constant, we keep its second sub-node as `en2`. (Thus, at the very end `en2` has to be deleted if `en` is (still) constant.)

If there is another comparison, we first check if the first comparison was constant. In that case, there are two possibilities: (i) it was true. Then, its right-hand side is compared with the new right-hand side, and the result replaces the previous one which is deleted. (ii) it was false. In this case, the result of the whole comparison is false, and we can exit the loop without evaluating anything else.

Now assume that the first comparison results in a valid branch, its second sub-node kept as `en2`. We first need a copy of this, which becomes the new left-hand side. If `en2` is constant, we make an identical constant node `en1`. Otherwise, we make `en1` an appropriate pointer node. Next, the first branch is saved as `en0` and we evaluate the comparison between `en1` and the a right-hand side. If this turns out to be constant, there are again two possibilities: (i) true, then we revert to the previous result. (ii) false, then the wh

        call eval_node_write (en)
        print *, "done compared_expr"
    end if
end subroutine eval_node_compile_compared_expr

```

This takes two extra arguments: **en1**, the left-hand-side of the comparison, is already allocated and evaluated. **en2** (the right-hand side) and **en** (the result) are allocated by the routine. **pn** is the parse node which contains the operator and the right-hand side as subnodes.

If the result of the comparison is constant, **en1** is deleted but **en2** is kept, because it may be used in a subsequent comparison. **en** then becomes a constant. If the result is variable, **en** becomes a branch node which refers to **en1** and **en2**.

```

A particle-list value is a PDG-code array, a particle identifier, a variable, a (grouped) pexpr, a block pexpr, a conditional, or a particle-list function.

The `cexpr` node is responsible for transforming a constant PDG-code array into a subevent. It takes the code array as its first argument, the event subevent as its second argument, and the requested particle type (incoming/outgoing) as its zero-th argument. The result is the list of particles in the event that match the code array.
