For EPA, we can in principle compute kinematics and function value in a single step. In order to be able to reweight events, kinematics and structure function application are separated. This function works on a single beam, assuming that the input momentum has been set. We need three random numbers as input: one for x , and two for the polar and azimuthal angles. Alternatively, for the no-recoil case, we can skip p_T generation; in this case, we only need one.

For obtaining splitting kinematics, we rely on the assumption that all in-particles are mass-degenerate (or there is only one), so the generated x values are identical.

10.6.1 Physics

The EWA structure function for a Z or W inside a fermion (lepton or quark) depends on the vector-boson polarization. We distinguish transversal (\pm) and

longitudinal (0) polarization.

$$F_+(x) = \frac{1}{16\pi^2} \frac{(v-a)^2 + (v+a)^2 \bar{x}^2}{x} \left[\ln \left(\frac{p_{\perp,\max}^2 + \bar{x}M^2}{\bar{x}M^2} \right) - \frac{p_{\perp,\max}^2}{p_{\perp,\max}^2 + \bar{x}M^2} \right] \quad (10.56)$$

$$F_-(x) = \frac{1}{16\pi^2} \frac{(v+a)^2 + (v-a)^2 \bar{x}^2}{x} \left[\ln \left(\frac{p_{\perp,\max}^2 + \bar{x}M^2}{\bar{x}M^2} \right) - \frac{p_{\perp,\max}^2}{p_{\perp,\max}^2 + \bar{x}M^2} \right] \quad (10.57)$$

$$F_0(x) = \frac{v^2 + a^2}{8\pi^2} \frac{2\bar{x}}{x} \frac{p_{\perp,\max}^2}{p_{\perp,\max}^2 + \bar{x}M^2} \quad (10.58)$$

where $p_{\perp,\max}$ is the cutoff in transversal momentum, M is the vector-boson mass, v and a are the vector and axial-vector couplings, and $\bar{x} \equiv 1-x$. Note that the longitudinal structure function is finite for large cutoff, while the transversal structure function is logarithmically divergent.

The maximal transverse momentum is given by the kinematical limit, it is

$$p_{\perp,\max} = \bar{x}\sqrt{s}/2. \quad (10.59)$$

The vector and axial couplings for a fermion branching into a W are

$$v_W = \frac{g}{2\sqrt{2}}, \quad a_W = \frac{g}{2\sqrt{2}}. \quad (10.60)$$

For Z emission, this is replaced by

$$v_Z = \frac{g}{2\cos\theta_w} (t_3 - 2q\sin^2\theta_w), \quad a_Z = \frac{g}{2\cos\theta_w} t_3, \quad (10.61)$$

where $t_3 = \pm\frac{1}{2}$ is the fermion isospin, and q its charge.

For an initial antifermion, the signs of the axial couplings are inverted. Note that a common sign change of v and a is irrelevant.

The EWA depends on the parameters g , $\sin^2\theta_w$, M_W , and M_Z . These can all be taken from the SM input, and the prefactors are calculated from those and the incoming particle type.

Since these structure functions have a $1/x$ singularity (which is not really relevant in practice, however, since the vector boson mass is finite), we map this singularity allowing for nontrivial x bounds:

$$x = \exp(\bar{r} \ln x_0 + r \ln x_1) \quad (10.62)$$

such that

$$\int_{x_0}^{x_1} \frac{dx}{x} = (\ln x_1 - \ln x_0) \int_0^1 dr. \quad (10.63)$$

As a user parameter, we have the cutoff $p_{\perp,\max}$. The divergence $1/x$ also requires a x_0 cutoff; and for completeness we introduce a corresponding x_1 . Physically, the minimal sensible value of x is M^2/s , although the approximation loses its value already at higher x values.

10.6.2 The EWA data block

The EWA parameters are: $p_{T,\max}$, c_V , c_A , and m . Instead of m we can use the incoming particle PDG code as input; from this we can deduce the mass and charges. In the initialization phase it is not yet determined whether a W or a Z is radiated, hence we set the vector and axial-vector couplings equal to the common prefactors $g/2 = e/2/\sin\theta_W$.

In principle, for EWA it would make sense to allow the user to also set the upper bound for x , x_{\max} , but we fix it to one here.

10.6.3 The EWA object

The `ewa_t` data type is a $1 \rightarrow 2$ interaction. We should be able to handle several flavors in parallel, since EWA is not necessarily applied immediately after beam collision: Photons may be radiated from quarks. In that case, the partons are massless and q_{\min} applies instead, so we do not need to generate several kinematical configurations in parallel.

The particles are ordered as (incoming, radiated, W/Z), where the W/Z initiates the hard interaction.

For EPA, we generate an unpolarized photon and transfer initial polarization to the radiated parton. Color is transferred in the same way. I do not know whether the same can/should be done for EWA, as the structure functions depend on the W/Z polarization. If we are having Z bosons, both up- and down-type fermions can participate. Otherwise, with a W^+ an up-type fermion is transferred to a down-type fermion, and the other way round.

```

<SF ewa: types>+≡
  type, extends (sf_int_t) :: ewa_t
    type(ewa_data_t), pointer :: data => null ()
    real(default) :: x = 0
    real(default) :: q = 0
  contains
    <SF ewa: ewa: TBP>
  end type ewa_t

```

Type string: has to here, but there is no string variable on which EWA depends. Hence, a dummy routine.

```

10.6.5 EWA structure function

The EWA structure function allows for a straightforward mapping of the unit interval. So, to leading order, the structure function value is unity, but the x value is transformed. Higher orders affect the function value.

The structure function implementation applies the above mapping to the input (random) number r to generate the momentum fraction x and the function value f . For numerical stability reasons, we also output xb , which is $\bar{x} = 1 - x$. The mapping ensures that $f = 1$ at leading order, and the higher-order

corrections are well-behaved.

10.6.6 EWA application

For EWA, we can compute kinematics and function value in a single step. This function works on a single beam, assuming that the input momentum has been set. We need four random numbers as input: one for x , one for Q^2 , and two for the polar and azimuthal angles. Alternatively, we can skip p_T generation; in this case, we only need one.

For obtaining splitting kinematics, we rely on the assumption that all in-particles are mass-degenerate (or there is only one), so the generated x values are identical.

10.7.1 Physics

Beamstrahlung is applied before ISR. The CIRCE1 implementation has a single structure function for both beams (which makes sense since it has to be switched on or off for both beams simultaneously). Nevertheless it is factorized:

The functional form in the CIRCE1 parameterization is defined for electrons or photons

$$f(x) = \alpha x^\beta (1-x)^\gamma \quad (10.64)$$

for $x < 1 - \epsilon$ (resp. $x > \epsilon$ in the photon case). In the remaining interval, the standard form is zero, with a delta singularity at $x = 1$ (resp. $x = 0$). Equivalently, the delta part may be distributed uniformly among this interval.

This latter form is implemented in the `kirke` version of the `CIRCE1` subroutines, and is used here.

The parameter ϵ is hardcoded in `CIRCE1` (set equal to 10^{-6}). Therefore, it cannot be changed in the namelist.

```
<SF circe1: public parameters>≡
  real(kind=default), parameter, public :: KIREPS = 1E-6_default
```

The other parameters are the parameterization version and revision number, the accelerator type, and the \sqrt{s} value used by `CIRCE1`. The chattiness can also be set (?).

Since the energy is distributed in a narrow region around unity (for electrons) or zero (for photons), it is advantageous to map the interval first. The mapping is controlled by the powers `beta` and `gamma` which are taken from the `CIRCE1` internal data structure.

The \sqrt{s} value, if not explicitly set, is taken from the process data. Note that interpolating \sqrt{s} is not recommended; one should rather choose one of the distinct values known to `CIRCE1`.

10.7.2 The CIRCE1 data block

The `CIRCE1` parameters are: The incoming flavors, the flags whether the photon or the lepton is the parton in the hard interaction, the flags for the generation mode (generator/mapping/no mapping), the mapping parameters β and γ , \sqrt{s} and several steering parameters: `ver`, `rev`, `acc`, `chat`.

In generator mode, the x values are actually discarded and a random number generator is used instead.

```

10.7.3 The CIRCE1 object

This is a $2 \rightarrow 4$ interaction, where, depending on the parameters, any two of the four outgoing particles are connected to the hard interactions, the others are radiated. Knowing that all particles are colorless, we do not have to deal with color.

The flavors are sorted such that the first two particles are the incoming leptons, the next two are the radiated particles, and the last two are the partons initiating the hard interaction.

CIRCE1 does not support polarized beams explicitly. For simplicity, we nevertheless carry beam polarization through to the outgoing electrons and make the photons unpolarized.

```

10.7.4 Kinematics

Set kinematics. If *map* is unset, the *r* and *x* values coincide, and the Jacobian $f(r)$ is trivial.

If *map* is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

10.7.5 CIRCE1 structure function

Compute the CIRCE1 structure function: either using the generator or the structure function value. In the latter case, we may employ a mapping that depends on the β, γ parameters.

The generator mode is the default and by far more useful, since there is virtually no loss in accuracy or reweighting efficiency for a process with CIRCE1 and without. The formal problem with this approach is the indeterministic integration, which is presumably harmless since the corresponding integration dimensions factorize in the VEGAS approach.

If `no_map` is set, we switch off generator and mapping.

```

<Limits: public parameters>+=
    double precision, parameter, public :: CIRCE1_EPSILON = 1d-6

<CIRCE1: procedures>+=
    subroutine strfun (f, x, xb, r, circe1_data, no_map)
        real(default), intent(out) :: f
        real(default), dimension(2), intent(out) :: x, xb
        real(default), dimension(2), intent(in) :: r
        type(circe1_data_t), intent(in) :: circe1_data
        logical, intent(in) :: no_map
        real(kind=default), parameter :: eps = CIRCE1_EPSILON
        real(default), dimension(2) :: fi
        if (circe1_data%generate .and. .not. no_map) then
            call circe_generate &
                (x, circe1_data%rng, circe1_data%pdg_in < 0, circe1_data%photon)
            xb = 1 - x
            f = 1
        else if (circe1_data%map .and. .not. no_map) then
            call circe_map_p (fi, x, xb, r, eps, &
                circe1_data%beta, circe1_data%gamma, circe1_data%photon)
            f = product (fi) * strfun_circe1 (x, circe1_data%pdg_in)
        else
            x = r
            xb = 1 - r
            f = strfun_circe1 (x, circe1_data%pdg_in)
        end if
    end subroutine strfun

```

Call the CIRCE1 generator. The integration variables are not used in this case. Instead, we call a random-number generator.

The CIRCE1 generator calls need the generator as argument, but not the generator state. Thus, we temporarily assign a pointer to the state to a module variable which is accessed by the generator.

```

<CIRCE1: variables>=
    type(tao_random_state), pointer :: rng_tmp => null ()

```

```

<CIRCE1: procedures>+≡
  subroutine rn_sub (r)
    double precision, intent(out) :: r
    real(default) :: x
    call tao_random_number (rng_tmp, x)
    r = x
  end subroutine rn_sub

<CIRCE1: procedures>+≡

    else if (.not. anti(1) .and. anti(2)) then
      call gircee (xdum(1), xdum(2), rn_sub)
    else if (anti(1) .and. .not. anti(2)) then
      call gircee (xdum(2), xdum(1), rn_sub)
    else
      call msg_bug ("CIRCE1: impossible flavor assignment")
    end if
    x = xdum
    rng_tmp => null ()
  end subroutine circe_generate

```

Apply the appropriate mapping, exchanging x vs. $1 - x$ depending on the particle. This can be done for both beams simultaneously, since the parameterization factorizes.

The CIRCE1 structure function has the form of a β distribution

$$f(x) = \begin{cases} \alpha x^\beta (1-x)^\gamma & \text{for } 0 < x < x_0 \\ \alpha x_0^\beta (1-x_0)^\gamma & \text{for } x_0 < x < 1 \end{cases} \quad (10.65)$$

in the electron/positron case. In the photon case, this form holds for $1 - x$. Instead of mapping this function in one step, we consider the two factors separately, such that the mapping $y(x)$ satisfies either

$$\frac{dy}{dx} = \begin{cases} ax^\beta & \text{for } 0 < x < x_0 \\ ax_0^\beta & \text{for } x_0 < x < 1 \end{cases} \quad (10.66)$$

or

$$\frac{dy}{dx} = \begin{cases} a(1-x)^\gamma & \text{for } 0 < x < x_0 \\ a(1-x_0)^\gamma & \text{for } x_0 < x < 1 \end{cases} \quad (10.67)$$

where, typically, $\beta > 0$ and $\gamma < 0$.

Integrating this leads to

$$y = \begin{cases} a \frac{x^{1+\beta}}{a + \beta}, & x < x_0 \\ y_0 + a(x - x_0)x_0^\beta, & x > x_0 \end{cases} \quad (10.68)$$

resp.

$$y = \begin{cases} a \frac{1 - (1 - x)^{1+\gamma}}{1 + \gamma}, & x < x_0 \\ y_0 + ax_0^\gamma(x - x_0) & x > x_0 \end{cases} \quad (10.69)$$

We need the inverse mapping: The y value is taken from the random number set and has to be transformed into a x value which is fed into **CIRCE1**.

$$x = \begin{cases} \left((1 + \beta) \frac{y}{a} \right)^{\frac{1}{1+\beta}} & y < y_0 \\ x_0 + \frac{y - y_0}{ax_0^\beta} & y > y_0 \end{cases} \quad (10.70)$$

or

$$x = \begin{cases} 1 - \left(1 - (1 + \gamma) \frac{y}{a} \right)^{\frac{1}{1+\gamma}} & y < y_0 \\ x_0 + \frac{y - y_0}{a(1 - x_0)^\gamma} & y > y_0 \end{cases} \quad (10.71)$$

The boundary in y is given by

$$y_0 = a \frac{x_0^{1+\beta}}{1 + \beta} \quad \text{resp.} \quad y_0 = a \frac{1 - (1 - x_0)^{1+\gamma}}{1 + \gamma} \quad (10.72)$$

and the normalization is chosen such that $y(1) = 1$

$$a = \left(\frac{x_0^{1+\beta}}{1 + \beta} + (1 - x_0)x_0^\beta \right)^{-1} \quad (10.73)$$

or

$$a = \left(\frac{1 - (1 - x_0)^{1+\gamma}}{1 + \gamma} + (1 - x_0)^{1+\gamma} \right)^{-1} \quad (10.74)$$

$\langle \text{CIRCE1: procedures} \rangle + \equiv$

    if (x<x0) then
      dy_dx = a * (1-x)**power
    else
      dy_dx = a * (1-x0)**power
    end if
  else
    if (x<x0) then
      dy_dx = a * x**power
    else
      dy_dx = a * x0**power
    end if
  end if
end function circe_jacobian
```

The actual CIRCE call. The parameters are already mapped, so we can directly call the structure function.

<CIRCE1: procedures>+≡

```
function strfun_circe1 (x, pdg) result (f)
  real(default) :: f
  real(default), dimension(2), intent(in) :: x
  integer, dimension(2), intent(in) :: pdg
  if (all (x /= 0)) then
    f = kirke (dble (x(1)), dble (x(2)), pdg(1), pdg(2))
  else
    f = 0
  end if
end function strfun_circe1
```

10.7.6 CIRCE1 application

CIRCE is applied for the two beams at once. We can safely assume that no structure functions are applied before this, so the incoming particles are on-shell electrons/positrons. There will however be at some point the lumi-linker implementations, which are used as an alternative to the CIRCE1 structure function.

  end subroutine lumi_linker_data_allocate_sf_int

```

10.8.3 The Lumi Linker object

This is a $2 \rightarrow 4$ interaction, where, depending on the parameters, any two of the four outgoing particles are connected to the hard interactions, the others are radiated. Knowing that all particles are colorless, we do not have to deal with color.

The flavors are sorted such that the first two particles are the incoming leptons, the next two are the radiated particles, and the last two are the partons initiating the hard interaction. !!! JRR: WK please check I don't know actually whether this really fits into the setup done by WK.

```

<SF lumi linker: types>+≡
  !!! JRR: WK please check
  type, extends (sf_int_t) :: lumi_linker_t
    type(lumi_linker_data_t), pointer :: data => null ()
    real(default) :: x = 0
    real(default) :: q = 0
  contains
    <SF lumi linker: lumi linker: TBP>
  end type lumi_linker_t

```

Type string: At the moment a dummy routine.

```

<SF lumi linker: lumi linker: TBP>≡
  procedure :: type_string => lumi_linker_type_string

<SF lumi linker: procedures>+≡
  function lumi_linker_type_string (object) result (string)

    end if
  end subroutine lumi_linker_write

```

10.8.4 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

<SF lumi linker: lumi linker: TBP>+≡
  procedure :: complete_kinematics => lumi_linker_complete_kinematics

```

<SF lumi linker: procedures>+≡

```
subroutine lumi_linker_complete_kinematics (sf_int, x, f, r, map)
  !!! JRR: WK please check
  !!! This cannot be correct, as the lumi linker structure function has
  !!! twice the variables (2->4 instead of 1->2 splitting)
  class(lumi_linker_t), intent(inout) :: sf_int
  real(default), dimension(:), intent(out) :: x
  real(default), intent(out) :: f
  real(default), dimension(:), intent(in) :: r
  logical, intent(in) :: map
  real(default) :: xb1
  if (map) then
    call msg_fatal ("Lumi linker: map flag not supported")
  else
    x(1) = r(1)
    f = 1
  end if
  xb1 = 1 - x(1)
  call sf_int%split_momentum (x, xb1)
  select case (sf_int%status)
  case (SF_DONE_KINEMATICS)

10.9.1 Physics

CIRCE2 describes photon spectra Beamstrahlung is applied before ISR. The CIRCE2 implementation has a single structure function for both beams (which makes sense since it has to be switched on or off for both beams simultaneously).

10.9.2 The CIRCE2 data block

The CIRCE2 parameters are: file and collider specification, incoming (= outgoing) particles. The luminosity is returned by `cir2lm`.

```

10.9.3 The CIRCE2 object

For CIRCE2 spectra it does not make sense to describe the state matrix as a radiation interaction, even if photons originate from laser backscattering. Instead, it is a $2 \rightarrow 2$ interaction where the incoming particles are identical to the outgoing ones.

The current implementation of CIRCE2 does support polarization and classical correlations, but no entanglement, so the density matrix of the outgoing particles is diagonal. The incoming particles are unpolarized (user-defined polarization for beams is meaningless, since polarization is described by the data file). The outgoing particles are polarized or polarization-averaged, depending on user request.

When assigning matrix elements, we scan the previously initialized state matrix. For each entry, we extract helicity and call the structure function. In the unpolarized case, the helicity is undefined and replaced by value zero. In the polarized case, there are four entries. If the generator is used, only one entry is nonzero in each call. Which one, is determined by comparing with a previously (randomly, distributed by relative luminosity) selected pair of helicities.

10.9.4 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

10.9.5 CIRCE2 structure function

Compute the CIRCE2 structure function: either using the generator or the structure function value. In the latter case, we may employ a power mapping for the singular endpoint that uses some heuristics for the mapping parameters.

The generator mode is the default and by far more useful, since there is virtually no loss in accuracy or reweighting efficiency for a process with CIRCE2 and without. The formal problem with this approach is the indeterministic integration, which is presumably harmless since the corresponding integration dimensions factorize in the VEGAS approach.

In generator mode with polarized beams, for each event only one helicity is selected. (See `interaction_apply_circe2` below.) The selection is based on the relative luminosities. Hence, the function value (unity) is multiplied by the number of helicity states (four).

Similarly, in non-generator mode, the luminosity densities for the helicity states are individually normalized and must be multiplied by their luminosity fraction and multiplied by four.

If `no_map` is set, switch off generator and mapping modes.

```

<CIRCE2: procedures>≡
subroutine strfun (f, x, r, hel, data, no_map)
    real(default), intent(out) :: f
    real(default), dimension(2), intent(out) :: x
    real(default), dimension(2), intent(in) :: r
    real(default), dimension(2) :: fi
    integer, dimension(2), intent(in) :: hel
    double precision, dimension(2) :: xx
    type(circe2_data_t), intent(in) :: data
    logical, intent(in) :: no_map
    if (data%generate .and. .not. no_map) then
        rng_tmp => data%rng
        call cir2gn &
            (data%pdg(1), hel(1), data%pdg(2), hel(2), xx(1), xx(2), rn_sub)
        x = xx
        if (data%polarized) then
            f = 4
        else
            f = 1
        end if
    else
        if (no_map) then
            x = r
            fi = 1
        else
            call circe2_map (fi, x, r, data%map_mode, data%map_power)
        end if
        f = product (fi) &
            * cir2dn (data%pdg(1), hel(1), data%pdg(2), hel(2), &

```

```

                                dble (x(1)), dble (x(2)))
    if (data%polarized) then
        f = 4 * f * data%lumi_hel_frac (hel(1), hel(2))
    end if
end if
end subroutine strfun

```

The CIRCE2 calls need the generator as argument, but not the generator state. Thus, we temporarily assign a pointer to the state to a module variable which is accessed by the generator.

(CIRCE2: variables)≡
 type(tao_random_state), pointer :: rng_tmp => null ()

Here is the generator call in the form that CIRCE2 expects:

(CIRCE2: procedures)+≡
 subroutine rn_sub (r)
 double precision, intent(out) :: r
 real(default) :: x
 call tao_random_number (rng_tmp, x)
 r = x
end subroutine rn_sub

Map the random numbers to x values, using specified power mappings for both beams. This function applies to a single beam but is elemental, so it is applied to the beam pair simultaneously.

We define power mappings (modes) for $x = 0$ or, alternatively, for $x = 1$. Mode $x = -1$ means no mapping.

Near zero (photon case) a power 2...3 should be sufficient to cancel the singularity, while near one (electron) the very narrow smeared delta function requires a high power ~ 10 to be identified. Quite generically, if a low x value x_0 needs to be resolved by the mapping, a power of the order $-\frac{1}{2} \log x_0$ is appropriate.

(CIRCE2: procedures)+≡
 elemental subroutine circe2_map (f, x, r, mode, power)
 real(default), intent(out) :: f, x
 real(default), intent(in) :: r
 integer, intent(in) :: mode
 real(default), intent(in) :: power
 real(default) :: xbar, rbar
 select case (mode)
 case (0)
 if (r <= tiny(1._default)) then
 x = 0
 f = 0
 else
 x = r ** power
 f = power * x / r
 end if
 case (1)
 rbar = 1 - r
 if (rbar <= tiny(1._default)) then
 xbar = 0

```

        f = 0
    else
        xbar = rbar ** power
        f = power * xbar / rbar
    end if
    x = 1 - xbar
case default
    x = r
    f = 1
end select
end subroutine circe2_map

```

10.9.6 CIRCE2 application

This function works on both beams, assuming that the input momentum has been set. We apply the usual splitting formalism, specializing to collinear splitting, but throw away the radiated momenta.

        end do
    end do
    call msg_bug ("CIRCE2: helicity selection failed")
end subroutine circe2_select_hel

```

10.10 Energy-scan spectrum

This spectrum is actually a trick that allows us to plot the c.m. energy dependence of a cross section without scanning the input energy. We start with the observation that a spectrum $f(x)$, applied to one of the incoming beams only, results in a cross section

$$\sigma = \int dx f(x) \hat{\sigma}(xs). \quad (10.75)$$

We want to compute the distribution of $E = \sqrt{\hat{s}} = \sqrt{xs}$, i.e.,

$$\frac{d\sigma}{dE} = \frac{2\sqrt{x}}{\sqrt{s}} \frac{d\sigma}{dx} = \frac{2\sqrt{x}}{\sqrt{s}} f(x) \hat{\sigma}(xs), \quad (10.76)$$

so if we set

$$f(x) = \frac{\sqrt{s}}{2\sqrt{x}}, \quad (10.77)$$

we get the distribution

$$\frac{d\sigma}{dE} = \hat{\sigma}(\hat{s} = E^2). \quad (10.78)$$

If we want to start, in the first iteration, from a homogeneous energy scan, we should apply a mapping

$$x = y^2 \quad \text{with} \quad dx = 2\sqrt{x} dy, \quad (10.79)$$

which cancels out $f(x)$ apart from the numerator \sqrt{s} .

The input parameter for this spectrum applies to the energy directly. Note that the spectrum must not be applied to more than one beam, and that the total cross section is essentially meaningless (it is the area under the energy distribution).

A direct application of this procedure would, of course, result in boosted events since only one beam energy is scaled down. However, we can achieve the same effect without a boost if we scale both x values such that their product remains constant, i.e., instead of generating x and applying it for one beam, we apply \sqrt{x} for both beams.

    end subroutine escan_data_allocate_sf_int

```

10.10.2 The Energy-scan object

This is a spectrum, not a radiation. Depending on whether one or both beams are involved, we create an interaction with 1 (2) incoming and 1 (2) outgoing particles, flavor, color, and helicity being carried through. So, x and q are 2-dimensional and have to be restricted to one dimension if only one beam is affected.

```

<SF escan: types>+≡
  !!! JRR: WK please check: do we need a q variable for the energy scan?
  type, extends (sf_int_t) :: escan_t
    type(escan_data_t), pointer :: data => null ()

end subroutine escan_write

```

10.10.3 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

This is the structure function for a single beam, suitably mapped.

As stated above, the mapping cancels the denominator of the structure function, so the factor is a constant. The normalization is determined such that the integral (the 'cross section' returned by WHIZARD) is unity for a unit test matrix element.

So the default here is to apply the map.

```

<Escan: procedures>≡

10.11 Using beam event data

Instead of an analytic beam description, beam data may be provided in form of an event file. In its most simple form, the event file contains pairs of x values, relative to nominal beam energies. More advanced formats may include polarization, etc. The current implementation carries beam polarization through, if specified.

The code is very similar to the energy scan described above.

```

<sf_beam_events.f90>≡
  <File header>

  module sf_beam_events

    <Use kinds>
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!

    data%unit = 0
  end if
end subroutine beam_events_data_close

```

10.11.2 The beam events object

This is a spectrum, not a radiation. Depending on whether one or both beams are involved, we create an interaction with 1 (2) incoming and 1 (2) outgoing particles, flavor, color, and helicity being carried through. !!! JRR: WK please check I don't know actually whether this really fits into the setup done by WK.

```

<SF beam events: types>+≡
  !!! JRR: WK please check
  type, extends (sf_int_t) :: beam_events_t
    type (beam_events_data_t), pointer :: data => null ()
    real (default) :: x = 0
    real (default) :: q = 0
  contains
    <SF beam events: beam events: TBP>
  end type beam_events_t

```

Type string: show beam events file.

```

<SF beam events: beam events: TBP>≡
  procedure :: type_string => beam_events_type_string

<SF beam events: procedures>+≡
  function beam_events_type_string (object) result (string)
    !!! JRR: WK please check
    class (beam_events_t), intent (in) :: object
    type (string_t) :: string
    if (associated (object%data)) then
      string = "Beam events: " // object%data%file
    else
      string = "Beam events: [undefined]"
    end if
  end function beam_events_type_string

```

Output. Call the interaction routine after displaying the configuration.

```

<SF beam events: beam events: TBP>+≡
  procedure :: write => beam_events_write

<SF beam events: procedures>+≡
  subroutine beam_events_write (object, unit)
    !!! JRR: WK please check

10.11.4 Beam-event file structure function

This is actually not a structure function but a routine that reads a single line from the event file. If EOF is reached, we reread from the beginning and issue a warning (unless `warn_eof` is unset).

This is a rare occasion where a conditional jump is really appropriate: we want to catch EOF, but not other I/O errors.

```

<Beam events: procedures>+=
subroutine read_x (x, data)
    real(default), dimension(:), intent(out) :: x
    type(beam_events_data_t), intent(in) :: data
    read (unit=data%unit, fmt=*, end=1) x
    return
1  if (data%warn_eof) &
        call msg_warning ("Reading beam event file: EOF reached, rewinding.")
    rewind (data%unit)
    read (unit=data%unit, fmt=*) x
end subroutine read_x

```

10.11.5 Beam events application

Depending on the affected beams, we either apply the read x values to one beam or to both beams.

```

<SF beam events: beam events: TBP>+=
procedure :: apply => beam_events_apply

<SF beam events: procedures>+=
subroutine beam_events_apply (sf_int, scale) !, data)
    !!! JRR: WK please check

  function has_photon () result(flag)
    logical :: flag
  end function has_photon
end interface

```

10.12.3 The LHAPDF status

This type holds the initialization status of the LHAPDF system. Entry 1 is for proton PDFs, entry 2 for pion PDFs, entry 3 for photon PDFs.

```
<SF lhpdf: public>≡
    public :: lhpdf_status_t

<SF lhpdf: types>≡
    type :: lhpdf_status_t
    private
        logical, dimension(3) :: initialized = .false.
    end type lhpdf_status_t

<SF lhpdf: public>+≡
    public :: lhpdf_status_reset

<SF lhpdf: procedures>≡
    subroutine lhpdf_status_reset (lhpdf_status)
        type(lhpdf_status_t), intent(inout) :: lhpdf_status
        lhpdf_status%initialized = .false.
    end subroutine lhpdf_status_reset

<SF lhpdf: procedures>+≡
    function lhpdf_status_is_initialized (lhpdf_status, set) result (flag)
        logical :: flag
        type(lhpdf_status_t), intent(in) :: lhpdf_status
        integer, intent(in), optional :: set
        if (present (set)) then
            select case (set)
                case (1:3);    flag = lhpdf_status%initialized(set)
                case default;  flag = .false.
            end select
        else
            flag = any (lhpdf_status%initialized)
        end if
    end function lhpdf_status_is_initialized

<SF lhpdf: procedures>+≡
    subroutine lhpdf_status_set_initialized (lhpdf_status, set)
        type(lhpdf_status_t), intent(inout) :: lhpdf_status
        integer, intent(in) :: set
        lhpdf_status%initialized(set) = .true.
    end subroutine lhpdf_status_set_initialized
```

10.12.4 LHAPDF initialization

Before using LHAPDF, we have to initialize it with a particular data set and member. This applies not just if we use structure functions, but also if we just use an α_s formula. The integer `set` should be 1 for proton, 2 for pion, and 3 for photon, but this is just convention.

If the particular set has already been initialized, do nothing. This implies that whenever we want to change the setup for a particular set, we have to

reset the LHAPDF status. `lhpdf_initialize` has an obvious name clash with `lhpdf_init`, the reason it works for `pdf_builtin` is that these things are outsourced to a separate module (inc. `lhpdf_status` etc.).

```

<SF lhpdf: public>+≡
    public :: lhpdf_initialize

<SF lhpdf: procedures>+≡
    subroutine lhpdf_initialize (status, set, prefix, file, member, b_match)
        type(lhpdf_status_t), intent(inout) :: status
        integer, intent(in) :: set
        type(string_t), intent(inout) :: prefix
        type(string_t), intent(inout) :: file
        integer, intent(inout) :: member
        logical, intent(in), optional :: b_match
        if (lhpdf_status_is_initialized (status, set)) return
        if (prefix == "") prefix = LHAPDF_PDFSETS_PATH
        if (file == "") then
            select case (set)
            case (1); file = LHAPDF_DEFAULT_PROTON
            case (2); file = LHAPDF_DEFAULT_PION

10.12.6 The LHAPDF data block

The data block holds the incoming flavor (which has to be proton, pion, or photon), the corresponding pointer to the global access data (1, 2, or 3), the flag `invert` which is set for an antiproton, the bounds as returned by LHAPDF for the specified set, and a mask that determines which partons will be actually in use.

```

10.12.7 The LHAPDF object

The `lhpdf_t` data type is a $1 \rightarrow 2$ interaction which describes the splitting of an (anti)proton into a parton and a beam remnant. We stay in the strict forward-splitting limit, but allow some invariant mass for the beam remnant such that the outgoing parton is exactly massless. For a real event, we would replace this by a parton cascade, where the outgoing partons have virtuality as dictated by parton-shower kinematics, and transverse momentum is generated.

This is the LHAPDF object which holds input data together with the interaction. We also store the x momentum fraction and the scale, since kinematics and function value are requested at different times.

The PDF application is a $1 \rightarrow 2$ splitting process, where the particles are ordered as (hadron, remnant, parton).

Polarization is ignored completely. The beam particle is colorless, while partons and beam remnant carry color. The remnant gets a special flavor code.

```
<SF lhpdf: types>+≡
  type, extends (sf_int_t) :: lhpdf_t
    type(lhpdf_data_t), pointer :: data => null ()
    real(default) :: x = 0
    real(default) :: q = 0
    real(default) :: s = 0
  contains
    <SF lhpdf: lhpdf: TBP>
  end type lhpdf_t
```

Type string: display the chosen PDF set.

```
<SF lhpdf: lhpdf: TBP>+≡
  procedure :: type_string => lhpdf_type_string

<SF lhpdf: procedures>+≡
  function lhpdf_type_string (object) result (string)
    class(lhpdf_t), intent(in) :: object
    type(string_t) :: string
    if (associated (object%data)) then
      string = "LHAPDF: " // object%data%file
    else
      string = "LHAPDF: [undefined]"
    end if
  end function lhpdf_type_string
```

Output. Call the interaction routine after displaying the configuration.

```
<SF lhpdf: lhpdf: TBP>+≡
  procedure :: write => lhpdf_write

<SF lhpdf: procedures>+≡
  subroutine lhpdf_write (object, unit)
    class(lhpdf_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    if (associated (object%data)) then
      call object%data%write (u)
      if (object%status >= SF_DONE_KINEMATICS) then
```

```

        write (u, "(1x,A)") "SF parameters:"
        write (u, "(3x,A,ES17.10)") "x =", object%x
        if (object%status >= SF_FAILED_EVALUATION) then
            write (u, "(3x,A,ES17.10)") "Q =", object%q
        end if
    end if
    call object%base_write (u)
else
    write (u, "(1x,A)") "LHAPDF data: [undefined]"
end if
end subroutine lhapdf_write

```

Initialize. We know that `data` will be of concrete type `sf_test_data_t`, but we have to cast this explicitly.

For this implementation, we set the incoming and outgoing masses equal to the physical particle mass, but keep the radiated mass zero.

```

10.12.8 Structure function

For the PDFs, we separate kinematics from dynamics. We first generate appropriate x values, independent of flavor and scale. This allows us to determine the momenta that initiate the hard scattering. Only when the hard process has been computed, we can be sure about the scattering scale and compute the structure function values.

For the x values, we can only apply a simple mapping that eliminates the $1/x$ singularity, i.e., we generate x on a logarithmic scale. This produces a Jacobian factor that we store along with the generated x value. The boundaries are used as returned by the LHAPDF library for the chosen PDF set.

```

<LHAPDF: procedures>+≡
subroutine generate_x (x, f, r, lhpdf_data)
    real(default), intent(out) :: x, f
    real(default), intent(in) :: r
    type(lhpdf_data_t), intent(in) :: lhpdf_data
    real(default) :: lg
    x = r
    f = 1
!    lg = log (lhpdf_data% xmax / lhpdf_data% xmin)
!    x = lhpdf_data% xmin * exp (r * lg)
!    f = x * lg
end subroutine generate_x

```

The previous routine is called here, so we can compute the complete kinematics.

(There is no mapping involved [see above], otherwise we should take and respect a `no_map` flag.)

```

<LHAPDF: public>+≡
public :: interaction_set_kinematics_lhpdf

<LHAPDF: procedures>+≡
subroutine interaction_set_kinematics_lhpdf (int, x, f, s, r, lhpdf_data)
    type(interaction_t), intent(inout) :: int
    real(default), intent(out) :: x, f, s
    real(default), intent(in) :: r
    type(lhpdf_data_t), intent(in) :: lhpdf_data
    type(vector4_t) :: k
    type(splitting_data_t) :: sd

```

```

call generate_x (x, f, r, lhpdf_data)
k = interaction_get_momentum (int, 1)
s = k**2
sd = new_splitting_data (k, s, 0._default, 0._default)
call splitting_set_t_bounds (sd, x, 1 - x)
call splitting_set_collinear (sd)
call interaction_set_momenta &
    (int, split_momentum (k, sd), outgoing=.true.)
end subroutine interaction_set_kinematics_lhpdf

```

Once the scale is also known, we can actually call the library and set the values. If the scale is out of bounds, we reset it to the boundary. Account for the Jacobian.

We have to cast the LHAPDF arguments to/from double precision (possibly from/to quadruple precision), if necessary. Furthermore, some structure functions can yield negative results (sea quarks close to $x = 1$). We set these unphysical values to zero.

```

10.13.3 The PDF object

The PDF $1 \rightarrow 2$ interaction which describes the splitting of an (anti)proton into a parton and a beam remnant. We stay in the strict forward-splitting limit, but allow some invariant mass for the beam remnant such that the outgoing parton is exactly massless. For a real event, we would replace this by a parton cascade, where the outgoing partons have virtuality as dictated by parton-shower kinematics, and transverse momentum is generated.

The PDF application is a $1 \rightarrow 2$ splitting process, where the particles are ordered as (hadron, remnant, parton).

Polarization is ignored completely. The beam particle is colorless, while partons and beam remnant carry color. The remnant gets a special flavor code.

```

10.13.4 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set $x = r^2$ and consequently $f(r) = 2r$.

```

10.13.5 Structure function

Once the scale is also known, we can actually call the PDF and set the values. Contrary to LHAPDF, the wrapper already takes care of adjusting to the x and Q bounds. Account for the Jacobian.

```
<SF pdf builtin: pdf builtin: TBP>+≡
  procedure :: apply => pdf_builtin_apply

<SF pdf builtin: procedures>+≡
  subroutine pdf_builtin_apply (sf_int, scale)
    class(pdf_builtin_t), intent(inout) :: sf_int
    real(default), intent(in) :: scale
    real(default), dimension(-6:6) :: ff
    real(default) :: x, fph
    complex(default), dimension(:), allocatable :: fc
    associate (data => sf_int%data)
      sf_int%q = scale
      x = sf_int%x
      if (data%invert) then
        if (data%has_photon) then
          call pdf_evolve (data%id, x, scale, ff(6:-6:-1), fph)
        else
          call pdf_evolve (data%id, x, scale, ff(6:-6:-1))
        end if
      else
        if (data%has_photon) then
          call pdf_evolve (data%id, x, scale, ff, fph)
        else
          call pdf_evolve (data%id, x, scale, ff)
        end if
      end if
      if (data%has_photon) then

    sf_int%status = SF_EVALUATED
  end subroutine pdf_builtin_apply
```

10.13.6 Strong Coupling

Since the PDF codes provide a function for computing the running α_s value, we make this available as an implementation of the abstract `alpha_qcd_t` type, which is used for matrix element evaluation.

```
<SF pdf builtin: public>+≡
  public :: alpha_qcd_pdf_builtin_t
```

```

<SF pdf builtin: types>+≡
  type, extends (alpha_qcd_t) :: alpha_qcd_pdf_builtin_t
  type(string_t) :: pdfset_name
  integer :: pdfset_id = -1
  contains
  <SF pdf builtin: alpha qcd: TBP>
end type alpha_qcd_pdf_builtin_t

```

Output.

```

<SF pdf builtin: alpha qcd: TBP>≡
  procedure :: write => alpha_qcd_pdf_builtin_write

<SF pdf builtin: procedures>+≡
  subroutine alpha_qcd_pdf_builtin_write (object, unit)
    class(alpha_qcd_pdf_builtin_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(3x,A)") "QCD parameters (pdf_builtin):"
    write (u, "(5x,A,A)") "PDF set = ", char (object%pdfset_name)
    write (u, "(5x,A,I0)") "PDF ID = ", object%pdfset_id
  end subroutine alpha_qcd_pdf_builtin_write

```

Calculation: the numeric ID selects the correct PDF set, which must be properly initialized.

```

<SF pdf builtin: alpha qcd: TBP>+≡
  procedure :: get => alpha_qcd_pdf_builtin_get

<SF pdf builtin: procedures>+≡
  function alpha_qcd_pdf_builtin_get (alpha_qcd, scale) result (alpha)
    class(alpha_qcd_pdf_builtin_t), intent(in) :: alpha_qcd

10.14 User Plugin for Structure Functions

This variant gives access to user-defined structure functions or spectra.

10.14.1 The module

```

<sf_user.f90>≡
  <File header>

  module sf_user

    use iso_c_binding !NODEP!
    <Use kinds>
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!

```

```

use c_particles !NODEP!
use lorentz !NODEP!
use subevents
use user_code_interface
use models
use flavors
use helicities
use colors
use quantum_numbers
use state_matrices
use polarizations
use interactions
use sf_aux
use sf_base

```

⟨Standard module head⟩

⟨SF user: public⟩

⟨SF user: types⟩

contains

⟨SF user: procedures⟩

end module sf_user

10.14.2 The user structure function data block

The data block holds the procedure pointers that are used for retrieving static information, as well as the actual evaluation.

⟨SF user: public⟩≡

```
public :: user_data_t
```

⟨SF user: types⟩≡

```

type, extends(sf_data_t) :: user_data_t
  private
  type(string_t) :: name
  integer :: n_in
  integer :: n_out
  integer :: n_tot
  integer :: n_states
  integer :: n_col
  integer :: n_dim
  integer :: n_var
  integer, dimension(2) :: pdg_in
  type(model_t), pointer :: model => null ()
  procedure(user_int_info), nopass, pointer :: info => null ()
  procedure(user_int_mask), nopass, pointer :: mask => null ()
  procedure(user_int_state), nopass, pointer :: state => null ()
  procedure(user_int_kinematics), nopass, pointer :: kinematics => null ()
  procedure(user_int_evaluate), nopass, pointer :: evaluate => null ()
contains

```

```

    <SF user: user data: TBP>
end type user_data_t

```

Assign procedure pointers from a dynamically loaded library, given the specified name.

We have to distinguish three cases: (1) Both beams are affected, and the user spectrum implements both beams. There is a single data object. (2) Both beams are affected, and the user spectrum applies to single beams. Fill two different objects. (3) A single beam is affected.

```

10.14.3 The interaction

We fill the interaction by looking up the table of states using the interface functions.

For particles which have a known flavor (as indicated by the mask), we compute the mass squared, so we can use it for the invariant mass of the particle objects.

```

10.14.4 The user structure function

For maximal flexibility, user structure functions separate kinematics from dynamics just as the PDF interface does. (JRR: Ok, I guess this now done for all structure functions, right?) We create `c_prt_t` particle objects from the incoming momenta (all other quantum numbers are irrelevant) and call the user-supplied kinematics function to compute the outgoing momenta, along with other variables that will be needed for matrix element evaluation. If known, we use the mass squared computed above. !!! JRR: WK please check I don't know actually whether this really fits into the setup done by WK.

```

<SF user: types>+≡
  !!! JRR: WK please check
  type, extends (sf_int_t) :: user_t

```

Chapter 11

Phase space and hard matrix elements

These modules contain the internal representation and evaluation of phase space and the interface to (hard-)process evaluation.

mappings Generate invariant masses and decay angles from given random numbers (or the inverse operation). Each mapping pertains to a particular node in a phase-space tree. Different mappings account for uniform distributions, resonances, zero-mass behavior, and so on.

phs_trees Phase space parameterizations for scattering processes are defined recursively as if there was an initial particle decaying. This module sets up a representation in terms of abstract trees, where each node gets a unique binary number. Each tree is stored as an array of branches, where integers indicate the connections. This emulates pointers in a transparent way. Real pointers would also be possible, but seem to be less efficient for this particular case.

phs_forests The type defined by this module collects the decay trees corresponding to a given process and the applicable mappings. To set this up, a file is read which is either written by the user or by the **cascades** module functions. The module also contains the routines that evaluate phase space, i.e., generate momenta from random numbers and back.

cascades This module is a Feynman diagram generator with the particular purpose of finding the phase space parameterizations best suited for a given process. It uses a model file to set up the possible vertices, generates all possible diagrams, identifies resonances and singularities, and simplifies the list by merging equivalent diagrams and dropping irrelevant ones. This process can be controlled at several points by user-defined parameters. Note that it depends on the particular values of particle masses, so it cannot be done before reading the input file.

11.1 Process data block

We define a simple transparent type that contains universal constant process data. We will reference objects of this type for the phase-space setup, for interfacing with process libraries, for implementing matrix-element generation, and in the master process-handling module.

```
<process_constants.f90>≡  
  <File header>
```

```
  module process_constants
```

```
    <Use kinds>
```

```
    <Use strings>
```

```
    <Standard module head>
```

```
    <Process constants: public>
```

```
    <Process constants: types>
```

```
  end module process_constants
```

The data type is just a block of public objects, only elementary types, no type-bound procedures.

```
<Process constants: public>≡  
  public :: process_constants_t  
  
<Process constants: types>≡  
  type :: process_constants_t  
    type(string_t) :: id  
    type(string_t) :: model_name  
    character(32) :: md5sum = ""  
    logical :: openmp_supported = .false.  
    integer :: n_in = 0  
    integer :: n_out = 0  
    integer :: n_flv = 0  
    integer :: n_hel = 0  
    integer :: n_col = 0  
    integer :: n_cin = 0  
    integer :: n_cf = 0  
    integer, dimension(:,:), allocatable :: flv_state  
    integer, dimension(:,:), allocatable :: hel_state  
    integer, dimension(:,:), allocatable :: col_state  
    logical, dimension(:,:), allocatable :: ghost_flag  
    complex(default), dimension(:), allocatable :: color_factors  
    integer, dimension(:,:), allocatable :: cf_index  
  end type process_constants_t
```

11.2 Abstract phase-space module

In this module we define an abstract base type (and a trivial test implementation) for multi-channel phase-space parameterizations.

```
<phs_base.f90>≡  
<File header>  
  
module phs_base  
  
  <Use kinds>  
  <Use strings>  
  <Use file utils>  
  use constants !NODEP!  
  use diagnostics !NODEP!  
  use lorentz !NODEP!  
  use unit_tests  
  use os_interface  
  use md5  
  use variables  
  use models  
  use flavors  
  use process_constants  
  use sf_mappings  
  use sf_base  
  
  <Standard module head>  
  
  <PHS base: public>  
  
  <PHS base: types>  
  
  <PHS base: interfaces>  
  
  <PHS base: test types>  
  
  contains  
  
  <PHS base: procedures>  
  
  <PHS base: tests>  
  
end module phs_base
```

11.2.1 Phase-space channels

The kinematics configuration may generate multiple parameterizations of phase space. Some of those have specific properties, such as a resonance in the s channel.

This is the abstract type for the channel properties.

```
<PHS base: types>≡  
  type, abstract :: channel_prop_t  
  contains  
    procedure (channel_prop_to_string), deferred :: to_string
```

```
end type channel_prop_t
```

```
<PHS base: interfaces>≡
abstract interface
  function channel_prop_to_string (object) result (string)
    import
    class(channel_prop_t), intent(in) :: object
    type(string_t) :: string
  end function channel_prop_to_string
end interface
```

This type describes an equivalence. The current channel is equivalent to channel c. The equivalence involves a permutation **perm** of integration dimensions and, within each integration dimension, a mapping **mode**.

```
<PHS base: types>+≡
type :: phs_equivalence_t
  integer :: c = 0
  integer, dimension(:), allocatable :: perm
  integer, dimension(:), allocatable :: mode
contains
  <PHS base: phs equivalence: TBP>
end type phs_equivalence_t
```

The mapping modes are

```
<PHS base: types>+≡
integer, parameter, public :: &
  EQ_IDENTITY = 0, EQ_INVERT = 1, EQ_SYMMETRIC = 2, EQ_INVARIANT = 3
```

In particular, if a channel is equivalent to itself in the EQ_SYMMETRIC mode, the integrand can be assumed to be symmetric w.r.t. a reflection $x \rightarrow 1 - x$ of the corresponding integration variable.

These are the associated tags, for output:

```
<PHS base: types>+≡
character, dimension(0:3), parameter :: TAG = ["+", "-", ":", "x"]
```

Write an equivalence.

```
<PHS base: phs equivalence: TBP>≡
procedure :: write => phs_equivalence_write

<PHS base: procedures>≡
subroutine phs_equivalence_write (object, unit)
  class(phs_equivalence_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u, j
  u = output_unit (unit)
  write (u, "(5x,'=',1x,I0,1x)", advance = "no") object%c
  if (allocated (object%perm)) then
    write (u, "(A)", advance = "no") "("
    do j = 1, size (object%perm)
      if (j > 1) write (u, "(1x)", advance = "no")
      write (u, "(I0,A1)", advance = "no") &
```

```

        object%perm(j), TAG(object%mode(j))
    end do
    write (u, "(A)" " ")
else
    write (u, "(A)")
end if
end subroutine phs_equivalence_write

```

Initialize an equivalence. This allocates the `perm` and `mode` arrays with equal size.

```

<PHS base: phs equivalence: TBP>+=
    procedure :: init => phs_equivalence_init

<PHS base: procedures>+=
    subroutine phs_equivalence_init (eq, n_dim)
        class(phs_equivalence_t), intent(out) :: eq
        integer, intent(in) :: n_dim
        allocate (eq%perm (n_dim), source = 0)
        allocate (eq%mode (n_dim), source = EQ_IDENTITY)
    end subroutine phs_equivalence_init

```

The channel entry holds (optionally) specific properties.

`sf_channel` is the structure-function channel that corresponds to this phase-space channel. The structure-function channel may be set up with a specific mapping that depends on the phase-space channel properties. (The default setting is to leave the properties empty.)

```

<PHS base: public>=
    public :: phs_channel_t

<PHS base: types>+=
    type :: phs_channel_t
        class(channel_prop_t), allocatable :: prop
        integer :: sf_channel = 1
        type(phs_equivalence_t), dimension(:), allocatable :: eq
    contains
        <PHS base: phs channel: TBP>
    end type phs_channel_t

```

Output.

```

<PHS base: phs channel: TBP>=
    procedure :: write => phs_channel_write

<PHS base: procedures>+=
    subroutine phs_channel_write (object, unit)
        class(phs_channel_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, j
        u = output_unit (unit)
        write (u, "(1x,I0)", advance="no") object%sf_channel
        if (allocated (object%prop)) then
            write (u, "(1x,A)" char (object%prop%to_string ()))
        else
            write (u, *)

```

```

end if
if (allocated (object%eq)) then
  do j = 1, size (object%eq)
    call object%eq(j)%write (u)
  end do
end if
end subroutine phs_channel_write

```

11.2.2 Kinematics configuration

Here, we store the universal information that is specifically relevant for phase-space generation. It is a subset of the process data, supplemented by basic information on phase-space parameterization channels.

A concrete implementation will contain more data, that describe the phase space in detail.

MD5 sums: the phase space setup depends on the process, it depends on the model parameters (the masses, that is), and on the configuration parameters. (It doesn't depend on the QCD setup.)

```

<PHS base: public>+≡
  public :: phs_config_t
<PHS base: types>+≡
  type, abstract :: phs_config_t
  !
    private
    type(string_t) :: id
    integer :: n_in = 0
    integer :: n_out = 0
    integer :: n_tot = 0
    integer :: n_state = 0
    integer :: n_par = 0
    integer :: n_channel = 0
    real(default) :: sqrts = 0
    logical :: sqrts_fixed = .true.
    logical :: cm_frame = .true.
    logical :: azimuthal_dependence = .false.
    integer, dimension(:), allocatable :: dim_flat
    logical :: provides_equivalences = .false.
    logical :: provides_chains = .false.
    logical :: vis_channels = .false.
    integer, dimension(:), allocatable :: chain
    type(model_t), pointer :: model => null ()
    type(flavor_t), dimension(:,:), allocatable :: flv
    type(phs_channel_t), dimension(:), allocatable :: channel
    character(32) :: md5sum_process = ""
    character(32) :: md5sum_model_par = ""
    character(32) :: md5sum_phs_config = ""
  contains
    <PHS base: phs config: TBP>
  end type phs_config_t

```

Finalizer, deferred.

```

<PHS base: phs config: TBP>≡

```

```

    procedure (phs_config_final), deferred :: final
  <PHS base: interfaces>+=
    abstract interface
      subroutine phs_config_final (object)
        import
        class(phs_config_t), intent(inout) :: object
      end subroutine phs_config_final
    end interface

```

Output. We provide an implementation for the output of the base-type contents and an interface for the actual write method.

```

  <PHS base: phs config: TBP>+=
    procedure (phs_config_write), deferred :: write
    procedure :: base_write => phs_config_write

      call flavor_init (phs_config%flv(j,i), data%flv_state(j,i), &
        phs_config%model)
    end do
  end do
  phs_config%md5sum_process = data%md5sum
end subroutine phs_config_init

```

This procedure should complete the phase-space configuration. We need the `sqrts` value as overall scale, which is known only after the beams have been defined. The procedure should determine the number of channels, their properties (if any), and allocate and fill the `channel` array accordingly.

(PHS base: phs config: TBP)+≡

```

procedure (phs_config_configure), deferred :: configure

```

(PHS base: interfaces)+≡

```

abstract interface
  subroutine phs_config_configure (phs_config, sqrts, &

```

```

        sqrts_fixed, cm_frame, azimuthal_dependence, rebuild, ignore_mismatch)
import
class(phs_config_t), intent(inout) :: phs_config
real(default), intent(in) :: sqrts
logical, intent(in), optional :: sqrts_fixed
logical, intent(in), optional :: cm_frame
logical, intent(in), optional :: azimuthal_dependence
logical, intent(in), optional :: rebuild
logical, intent(in), optional :: ignore_mismatch
end subroutine phs_config_configure
end interface

```

Compute the MD5 sum. We abuse the `write` method. In type implementations, `write` should only display information that is relevant for the MD5 sum. The data include the process MD5 sum which is taken from the process constants, and the MD5 sum of the model parameters. This may change, so it is computed here.

```

<PHS base: phs_config: TBP>+≡
  procedure :: compute_md5sum => phs_config_compute_md5sum
<PHS base: procedures>+≡
  subroutine phs_config_compute_md5sum (phs_config)
    class(phs_config_t), intent(inout) :: phs_config
    integer :: u
    phs_config%md5sum_model_par = model_get_parameters_md5sum (phs_config%model)
    phs_config%md5sum_phs_config = ""
    u = free_unit ()
    open (u, status = "scratch", action = "readwrite")
    call phs_config%write (u)
    rewind (u)
    phs_config%md5sum_phs_config = md5sum (u)
    close (u)
  end subroutine phs_config_compute_md5sum

```

Print an informative message after phase-space configuration.

```

<PHS base: phs_config: TBP>+≡
  procedure (phs_startup_message), deferred :: startup_message
  procedure :: base_startup_message => phs_startup_message
<PHS base: procedures>+≡
  subroutine phs_startup_message (phs_config, unit)
    class(phs_config_t), intent(in) :: phs_config

      "Phase space:", &
      phs_config%n_channel, "channels,", &
      phs_config%n_par, "dimensions"
    call msg_message (unit = unit)
  end subroutine phs_startup_message

```

This procedure should assign structure-function channels to the phase-space channels. The assignment will depend on the phase-space channel properties

(which are known at this point) and on the available structure-function channels or mappings.

For the actual implementation, this procedure has to apply heuristics as to which structure-function mappings are appropriate for which phase-space structure. The mappings have to be prepared in advance. This requires extracting information (e.g., about resonance parameters) from the configured phase space.

```

<PHS base: phs config: TBP>+≡
  procedure (phs_config_match_channels), deferred :: match_channels

<PHS base: interfaces>+≡
  abstract interface
    subroutine phs_config_match_channels (phs_config, sf, sf_channel)
      import
      class(phs_config_t), intent(inout) :: phs_config

        phs%flux = conv * twopi4 / (2 * sqrt (lda))
      else
        phs%flux = 0
      end if
    end select
  end subroutine phs_compute_flux

```

Evaluate the phase-space point for a particular channel and compute momenta, Jacobian, and phase-space volume. Also compute the inverse mappings to completely fill the `r` and `f` arrays. This is, of course, deferred to the implementation.

```

(PHS base: phs: TBP)+≡
  procedure (phs_evaluate), deferred :: evaluate

(PHS base: interfaces)+≡
  abstract interface
    subroutine phs_evaluate (phs, c_in, r_in)
      import
      class(phs_t), intent(inout) :: phs
      integer, intent(in) :: c_in
      real(default), dimension(:), intent(in) :: r_in
    end subroutine phs_evaluate
  end interface

```

Inverse evaluation. If all momenta are known, we compute the inverse mappings to fill the **r** and **f** arrays.

```

<PHS base: phs: TBP>+≡
  procedure (phs_inverse), deferred :: inverse

<PHS base: interfaces>+≡
  abstract interface
    subroutine phs_inverse (phs)
      import
      class(phs_t), intent(inout) :: phs
    end subroutine phs_inverse
  end interface

```

11.2.5 Auxiliary stuff

The **pacify** subroutine, which is provided by the Lorentz module, has the purpose of setting numbers to zero which are (by comparing with a **tolerance** parameter) considered equivalent with zero. This is useful for numerical checks.

```

<PHS base: public>+≡
  public :: pacify

<PHS base: interfaces>+≡
  interface pacify
    module procedure pacify_phs
  end interface pacify

<PHS base: procedures>+≡
  subroutine pacify_phs (phs)
    class(phs_t), intent(inout) :: phs
    if (phs%p_defined) then
      call pacify (phs%p, 10 * epsilon (1._default) * phs%config%sqrts)
      call pacify (phs%lt_cm_to_lab, 10 * epsilon (1._default))
    end if
    if (phs%q_defined) then
      call pacify (phs%q, 10 * epsilon (1._default) * phs%config%sqrts)
    end if
  end subroutine pacify_phs

```

11.2.6 Unit tests

```

<PHS base: public>+≡
  public :: phs_base_test

<PHS base: tests>≡
  subroutine phs_base_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <PHS base: execute tests>
  end subroutine phs_base_test

```

Test process data

We provide a procedure that initializes a test case for the process constants. This set of process data contains just the minimal contents that we need for the phase space. The rest is left uninitialized.

```
<PHS base: public>+≡
    public :: init_test_process_data

<PHS base: tests>+≡
    subroutine init_test_process_data (id, data)
        type(process_constants_t), intent(out) :: data
        type(string_t), intent(in), optional :: id
        if (present (id)) then
            data%id = id
        else
            data%id = "testproc"
        end if
        data%model_name = "Test"
        data%n_in = 2
        data%n_out = 2
        data%n_flv = 1
        allocate (data%flv_state (data%n_in + data%n_out, data%n_flv))
        data%flv_state = 25
    end subroutine init_test_process_data
```

This is the variant for a decay process.

```
<PHS base: public>+≡
    public :: init_test_decay_data

<PHS base: tests>+≡
    subroutine init_test_decay_data (id, data)
        type(process_constants_t), intent(out) :: data
        type(string_t), intent(in), optional :: id
        if (present (id)) then
            data%id = id
        else
            data%id = "testproc"
        end if
        data%model_name = "Test"
        data%n_in = 1
        data%n_out = 2
        data%n_flv = 1
        allocate (data%flv_state (data%n_in + data%n_out, data%n_flv))
        data%flv_state(:,1) = [25, 6, -6]
    end subroutine init_test_decay_data
```

Test kinematics configuration

This is a trivial implementation of the `phs_config_t` configuration object.

```
<PHS base: public>+≡
    public :: phs_test_config_t
```

```

<PHS base: test types>≡
type, extends (phs_config_t) :: phs_test_config_t
  logical :: create_equivalences = .false.
contains
  procedure :: final => phs_test_config_final
  procedure :: write => phs_test_config_write
  procedure :: configure => phs_test_config_configure
  procedure :: startup_message => phs_test_config_startup_message
  procedure :: match_channels => phs_test_config_match_channels
  procedure, nopass :: allocate_instance => phs_test_config_allocate_instance
end type phs_test_config_t

```

The finalizer is empty.

```

<PHS base: tests>+≡
subroutine phs_test_config_final (object)
  class(phs_test_config_t), intent(inout) :: object
end subroutine phs_test_config_final

```

The `cm_frame` parameter is not tested here; we defer this to the `phs_single` implementation.

```

<PHS base: tests>+≡
subroutine phs_test_config_write (object, unit)
  class(phs_test_config_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u
  u = output_unit (unit)
  write (u, "(1x,A)") "Partonic phase-space configuration:"
  call object%base_write (unit)
end subroutine phs_test_config_write

subroutine phs_test_config_configure (phs_config, sqrts, &
  sqrts_fixed, cm_frame, azimuthal_dependence, rebuild, ignore_mismatch)

    end select
end if
end subroutine phs_test_config_match_channels

```

```

        end if
    end subroutine phs_test_config_match_channels

```

The instance type that matches `phs_test_config_t` is `phs_test_t`.

```

<PHS base: tests>+≡
    subroutine phs_test_config_allocate_instance (phs)
        class(phs_t), intent(inout), pointer :: phs
        allocate (phs_test_t :: phs)
    end subroutine phs_test_config_allocate_instance

```

Test kinematics implementation

This implementation of kinematics generates a simple two-particle configuration from the incoming momenta. The incoming momenta must be in the c.m. system, all masses equal.

There are two channels: one generates $\cos\theta$ and ϕ uniformly, in the other channel we map the r_1 parameter which belongs to $\cos\theta$.

We should store the mass parameter that we need.

```

<PHS base: public>+≡
    public :: phs_test_t

<PHS base: test types>+≡
    type, extends (phs_t) :: phs_test_t
        real(default) :: m = 0
    contains
        <PHS base: phs test: TBP>
    end type phs_test_t

```

Output. The specific data are displayed only if `verbose` is set.

```

<PHS base: phs test: TBP>≡
    procedure :: write => phs_test_write

<PHS base: tests>+≡

            phs%f(2) = 1 / (3 * phs%r(1,2) ** (2/3._default))
        else
            phs%f(2) = 0
        end if
        phs%volume = 1
        phs%r_defined = .true.
    end if
end subroutine phs_test_inverse

```

Uniform angular distribution

These procedures implement the uniform angular distribution, generated from two parameters x_1 and x_2 :

$$\cos \theta = 1 - 2x_1, \quad \phi = 2\pi x_2 \quad (11.1)$$

We generate a rotation (Lorentz transformation) which rotates the positive z axis into this point on the unit sphere. This rotation is applied to the \mathbf{p} momenta, which are assumed to be back-to-back, on-shell, and with the correct mass.

We do not compute a Jacobian (constant). The uniform distribution is assumed to be normalized.

```
<PHS base: public>+≡
  public :: compute_kinematics_solid_angle
<PHS base: tests>+≡
  subroutine compute_kinematics_solid_angle (p, q, x)
    type(vector4_t), dimension(2), intent(in) :: p
    type(vector4_t), dimension(2), intent(out) :: q
    real(default), dimension(2), intent(in) :: x
    real(default) :: ct, st, phi
    type(lorentz_transformation_t) :: rot
    integer :: i
    ct = 1 - 2*x(1)
    st = sqrt (1 - ct**2)
    phi = twopi * x(2)
    rot = rotation (phi, 3) * rotation (ct, st, 2)
    do i = 1, 2
      q(i) = rot * p(i)
    end do
  end subroutine compute_kinematics_solid_angle
```

This is the inverse transformation. We assume that the outgoing momenta are rotated versions of the incoming momenta, back-to-back. Thus, we determine the angles from $q(1)$ alone. p is unused.

```
<PHS base: public>+≡
  public :: inverse_kinematics_solid_angle
<PHS base: tests>+≡
  subroutine inverse_kinematics_solid_angle (p, q, x)
    type(vector4_t), dimension(:), intent(in) :: p
    type(vector4_t), dimension(2), intent(in) :: q
    real(default), dimension(2), intent(out) :: x
    real(default) :: ct, phi
    ct = polar_angle_ct (q(1))
    phi = azimuthal_angle (q(1))
    x(1) = (1 - ct) / 2
    x(2) = phi / twopi
  end subroutine inverse_kinematics_solid_angle
```

11.3 Single-particle phase space

This module implements the phase space for a single particle, i.e., the solid angle, in a straightforward parameterization with a single channel. The phase-space implementation may be used either for $1 \rightarrow 2$ decays or for $2 \rightarrow 2$ scattering processes, so the number of incoming particles is the only free parameter in the configuration. In the latter case, we should restrict its use to non-resonant s-channel processes, because there is no mapping of the scattering angle.

(We might extend this later to account for generic $2 \rightarrow 2$ situations, e.g., account for a Coulomb singularity or detect an s-channel resonance structure that requires matching structure-function mappings.)

This is derived from the `phs_test` implementation in the `phs_base` module above, even more simplified, but intended for actual use.

  end subroutine phs_single_write

```

The finalizer is empty.

```

<PHS single: phs single: TBP>+≡
  procedure :: final => phs_single_final

<PHS single: procedures>+≡
  subroutine phs_single_final (object)
    class(phs_single_t), intent(inout) :: object
  end subroutine phs_single_final

```

Initialization. We allocate arrays (`base_init`) and adjust the phase-space volume. The massless two-particle phase space volume is

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.55294034614 \times 10^{-5} \quad (11.2)$$

For a decay with nonvanishing masses (m_3, m_4), there is a correction factor

$$\Phi_2(m)/\Phi_2(0) = \frac{1}{\hat{s}} \lambda^{1/2}(\hat{s}, m_3^2, m_4^2). \quad (11.3)$$

For a scattering process with nonvanishing masses, the correction factor is

$$\Phi_2(m)/\Phi_2(0) = \frac{1}{\hat{s}^2} \lambda^{1/2}(\hat{s}, m_1^2, m_2^2) \lambda^{1/2}(\hat{s}, m_3^2, m_4^2). \quad (11.4)$$

If the energy is fixed, this is constant. Otherwise, we have to account for varying \hat{s} .

```

<PHS single: phs single: TBP>+≡
  procedure :: init => phs_single_init
<PHS single: procedures>+≡
  subroutine phs_single_init (phs, phs_config)
    class(phs_single_t), intent(out) :: phs
    class(phs_config_t), intent(in), target :: phs_config
    call phs%base_init (phs_config)
    phs%volume = 1 / (4 * twopi5)
    call phs%compute_factor ()
  end subroutine phs_single_init

```

Compute the correction factor for nonzero masses. We do this during initialization (when the incoming momenta \mathbf{p} are undefined), unless `sqrts` is variable. We do this again once for each phase-space point, but then we skip the calculation if `sqrts` is fixed.

```

11.4 Mappings

Mappings are objects that encode the transformation of the interval $(0,1)$ to a physical variable m^2 or $\cos\theta$ (and back), as it is used in the phase space parameterization. The mapping objects contain fixed parameters, the associated methods implement the mapping and inverse mapping operations, including the computation of the Jacobian (phase space factor).

```
<mappings.f90>≡  
  <File header>  
  
  module mappings  
  
    <Use kinds>  
    use kinds, only: TC !NODEP!  
    <Use strings>  
    use constants, only: pi !NODEP!  
    <Use file utils>  
    use diagnostics !NODEP!  
    use md5  
    use models  
    use flavors  
  
    <Standard module head>  
  
    <Mappings: public>  
  
    <Mappings: parameters>  
  
    <Mappings: types>  
  
    <Mappings: interfaces>  
  
    contains  
  
    <Mappings: procedures>  
  
  end module mappings
```

11.4.1 Default parameters

This type holds the default parameters, needed for setting the scale in cases where no mass parameter is available. The contents are public.

```
<Mappings: public>≡

```

11.4.2 The Mapping type

Each mapping has a type (e.g., s-channel, infrared), a binary code (redundant, but useful for debugging), and a reference particle. The flavor code of this par-

ticle is stored for bookkeeping reasons, what matters are the mass and width of this particle. Furthermore, depending on the type, various mapping parameters can be set and used.

The parameters **a1** to **a3** (for m^2 mappings) and **b1** to **b3** (for $\cos \theta$ mappings) are values that are stored once to speed up the calculation, if **variable_limits** is false. The exact meaning of these parameters depends on the mapping type. The limits are fixed if there is a fixed c.m. energy.

```

<Mappings: public>+≡
    public :: mapping_t

<Mappings: types>+≡
    type :: mapping_t
    private
        integer :: type = NO_MAPPING
        integer(TC) :: bincode
        type(flavor_t) :: flv
        real(default) :: mass = 0
        real(default) :: width = 0
        logical :: a_unknown = .true.
        real(default) :: a1 = 0
        real(default) :: a2 = 0
        real(default) :: a3 = 0
        logical :: b_unknown = .true.
        real(default) :: b1 = 0
        real(default) :: b2 = 0
        real(default) :: b3 = 0
        logical :: variable_limits = .true.
    end type mapping_t

```

The valid mapping types. The extra type STEP_MAPPING is used only internally.

```

<Mappings: parameters>≡
    <Mapping modes>

```

11.4.3 Screen output

      end select
    end if
  end if
end if
1 format (1x,A,3ES19.12)
end subroutine mapping_write

```

11.4.4 Define a mapping

The initialization routine sets the mapping type and the particle (binary code and flavor code) for which the mapping applies (e.g., a Z resonance in branch #3). We only need the absolute value of the flavor code.

(Mappings: public)+≡

public :: mapping_init

(Mappings: procedures)+≡

```

subroutine mapping_init (mapping, bincode, type, f, model)
  type(mapping_t), intent(inout) :: mapping
  integer(TC), intent(in) :: bincode
  type(string_t), intent(in) :: type
  integer, intent(in), optional :: f
  type(model_t), intent(in), optional, target :: model
  mapping%bincode = bincode
  select case (char (type))
  case ("s_channel"); mapping%type = S_CHANNEL
  case ("collinear"); mapping%type = COLLINEAR
  case ("infrared"); mapping%type = INFRARED

```

```

case ("radiation"); mapping%type = RADIATION
case ("t_channel"); mapping%type = T_CHANNEL
case ("u_channel"); mapping%type = U_CHANNEL
case ("step_exp"); mapping%type = STEP_MAPPING_E
case ("step_hyp"); mapping%type = STEP_MAPPING_H
end select
if (present (f) .and. present (model)) &
    call flavor_init (mapping%flv, abs (f), model)
end subroutine mapping_init

```

This sets the actual mass and width, using a parameter set. Since the auxiliary parameters will only be determined when the mapping is first called, they are marked as unknown.

```

<Mappings: public>+≡
    public :: mapping_set_parameters

<Mappings: procedures>+≡
    subroutine mapping_set_parameters (map, mapping_defaults, variable_limits)
        type(mapping_t), intent(inout) :: map
        type(mapping_defaults_t), intent(in) :: mapping_defaults
        logical, intent(in) :: variable_limits
        if (map%type /= NO_MAPPING) then
            map%mass = flavor_get_mass (map%flv)
            map%width = flavor_get_width (map%flv)
            map%variable_limits = variable_limits
            map%a_unknown = .true.
            map%b_unknown = .true.
            select case (map%type)
            case (S_CHANNEL)
                if (map%mass <= 0) then
                    call mapping_write (map)
                    call msg_fatal &
                        & (" S-channel resonance must have positive mass")
                else if (map%width <= 0) then
                    call mapping_write (map)
                    call msg_fatal &
                        & (" S-channel resonance must have positive width")
                end if
            case (RADIATION)
                map%width = max (map%width, mapping_defaults%energy_scale)
            case (INFRARED, COLLINEAR)
                map%mass = max (map%mass, mapping_defaults%invariant_mass_scale)
            case (T_CHANNEL, U_CHANNEL)
                map%mass = max (map%mass, mapping_defaults%momentum_transfer_scale)
            end select
        end if
    end subroutine mapping_set_parameters

```

For a step mapping the mass and width are set directly, instead of being determined from the flavor parameter (which is meaningless here). They correspond to the effective upper bound of phase space due to a resonance, as opposed to the absolute upper bound.

```

<Mappings: public>+≡

```

```

    public :: mapping_set_step_mapping_parameters

      equal = .false.
    end if
  end function mapping_equal

```

11.4.7 Mappings of the invariant mass

Inserting an x value between 0 and 1, we want to compute the corresponding invariant mass $m^2(x)$ and the jacobian, aka phase space factor $f(x)$. We also need the reverse operation.

In general, the phase space factor f is defined by

$$\frac{1}{s} \int_{m_{\min}^2}^{m_{\max}^2} dm^2 g(m^2) = \int_0^1 dx \frac{1}{s} \frac{dm^2}{dx} g(m^2(x)) = \int_0^1 dx f(x) g(x), \quad (11.5)$$

where thus

$$f(x) = \frac{1}{s} \frac{dm^2}{dx}. \quad (11.6)$$

With this mapping, a function of the form

$$g(m^2) = c \frac{dx(m^2)}{dm^2} \quad (11.7)$$

is mapped to a constant:

$$\frac{1}{s} \int_{m_{\min}^2}^{m_{\max}^2} dm^2 g(m^2) = \int_0^1 dx f(x) g(m^2(x)) = \int_0^1 dx \frac{c}{s}. \quad (11.8)$$

Here is the mapping routine. Input are the available energy squared s , the limits for m^2 , and the x value. Output are the m^2 value and the phase space factor f .

```

```

Trivial mapping

We simply map the boundaries of the interval (m_{\min}, m_{\max}) to $(0, 1)$:

$$m^2 = (1 - x)m_{\min}^2 + xm_{\max}^2; \quad (11.9)$$

the inverse is

$$x = \frac{m^2 - m_{\min}^2}{m_{\max}^2 - m_{\min}^2}. \quad (11.10)$$

Hence

$$f(x) = \frac{m_{\max}^2 - m_{\min}^2}{s}, \quad (11.11)$$

and we have, as required,

$$f(x) \frac{dx}{dm^2} = \frac{1}{s}. \quad (11.12)$$

We store the constant parameters the first time the mapping is called – or, if limits vary, recompute them each time.

<Constants for trivial msq mapping>≡

```

if (map%variable_limits .or. map%a_unknown) then
  map%a1 = 0
  map%a2 = msq_max - msq_min
  map%a3 = map%a2 / s
  map%a_unknown = .false.
end if

⟨Apply trivial msq mapping⟩≡
  msq = (1-x) * msq_min + x * msq_max
  f = map%a3

```

```

⟨Apply inverse trivial msq mapping⟩≡
  if (map%a2 /= 0) then
    x = (msq - msq_min) / map%a2
  else
    x = 0
  end if
  f = map%a3

```

Resonance or step mapping does not make much sense if the resonance mass is outside the kinematical bounds. If this is the case, revert to `NO_MAPPING`. This is possible even if the kinematical bounds vary from event to event.

```

⟨Modify mapping type if necessary⟩≡
  select case (type)
  case (S_CHANNEL, STEP_MAPPING_E, STEP_MAPPING_H)
    msq0 = map%mass**2
    if (msq0 < msq_min .or. msq0 > msq_max) type = NO_MAPPING
  end select

```

Breit-Wigner mapping

A Breit-Wigner resonance with mass M and width Γ is flattened by the following mapping:

This mapping does not make much sense if the resonance mass is too low. If this is the case, revert to `NO_MAPPING`. There is a tricky point with this if the mass is too high: `msq_max` is not a constant if structure functions are around. However, switching the type depending on the overall energy does not change the integral, it is just another branching point.

$$m^2 = M(M + t\Gamma), \quad (11.13)$$

where

$$t = \tan \left[(1-x) \arctan \frac{m_{\min}^2 - M^2}{M\Gamma} + x \arctan \frac{m_{\max}^2 - M^2}{M\Gamma} \right]. \quad (11.14)$$

The inverse:

$$x = \frac{\arctan \frac{m^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma}}{\arctan \frac{m_{\max}^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma}} \quad (11.15)$$

The phase-space factor of this transformation is

$$f(x) = \frac{M\Gamma}{s} \left(\arctan \frac{m_{\max}^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma} \right) (1 + t^2). \quad (11.16)$$

This maps any function proportional to

$$g(m^2) = \frac{M\Gamma}{(m^2 - M^2)^2 + M^2\Gamma^2} \quad (11.17)$$

to a constant times $1/s$.

```

⟨Constants for s-channel resonance mapping⟩≡
  if (map%variable_limits .or. map%a_unknown) then
    msq0 = map%mass ** 2
    map%a1 = atan ((msq_min - msq0) / (map%mass * map%width))
    map%a2 = atan ((msq_max - msq0) / (map%mass * map%width))
    map%a3 = (map%a2 - map%a1) * (map%mass * map%width) / s
    map%a_unknown = .false.
  end if

⟨Apply s-channel resonance mapping⟩≡

    tmp = tan (z)
    msq = map%mass * (map%mass + map%width * tmp)
    f = map%a3 * (1 + tmp**2)
  else
    msq = 0
    f = 0
  end if

⟨Apply inverse s-channel resonance mapping⟩≡
  tmp = (msq - msq0) / (map%mass * map%width)
  x = (atan (tmp) - map%a1) / (map%a2 - map%a1)
  f = map%a3 * (1 + tmp**2)

```

Mapping for massless splittings

This mapping accounts for approximately scale-invariant behavior where $\ln M^2$ is evenly distributed.

$$m^2 = m_{\min}^2 + M^2 (\exp(xL) - 1) \quad (11.18)$$

where

$$L = \ln \left(\frac{m_{\max}^2 - m_{\min}^2}{M^2} + 1 \right). \quad (11.19)$$

The inverse:

$$x = \frac{1}{L} \ln \left(\frac{m^2 - m_{\min}^2}{M^2} + 1 \right) \quad (11.20)$$

The constant M is a characteristic scale. Above this scale ($m^2 - m_{\min}^2 \gg M^2$), this mapping behaves like $x \propto \ln m^2$, while below the scale it reverts to a linear mapping.

The phase-space factor is

$$f(x) = \frac{M^2}{s} \exp(xL) L. \quad (11.21)$$

A function proportional to

$$g(m^2) = \frac{1}{(m^2 - m_{\min}^2) + M^2} \quad (11.22)$$

is mapped to a constant, i.e., a simple pole near m_{\min} with a regulator mass M .

This type of mapping is useful for massless collinear and infrared singularities, where the scale is stored as the mass parameter. In the radiation case (IR radiation off massive particle), the heavy particle width is the characteristic scale.

```

⟨Constants for s-channel pole mapping⟩≡
  if (map%variable_limits .or. map%a_unknown) then
    if (type == RADIATION) then
      msq0 = map%width**2
    else
      msq0 = map%mass**2
    end if
    map%a1 = msq0
    map%a2 = log ((msq_max - msq_min) / msq0 + 1)
    map%a3 = map%a2 / s
    map%a_unknown = .false.
  end if

⟨Apply s-channel pole mapping⟩≡
  msq1 = map%a1 * exp (x * map%a2)
  msq = msq1 - map%a1 + msq_min
  f = map%a3 * msq1

⟨Apply inverse s-channel pole mapping⟩≡
  msq1 = msq - msq_min + map%a1
  x = log (msq1 / map%a1) / map%a2
  f = map%a3 * msq1

```

Mapping for t-channel poles

This is also approximately scale-invariant, and we use the same type of mapping as before. However, we map $1/x$ singularities at both ends of the interval; again, the mapping becomes linear when the distance is less than M^2 :

$$m^2 = \begin{cases} m_{\min}^2 + M^2 (\exp(xL) - 1) & \text{for } 0 < x < \frac{1}{2} \\ m_{\max}^2 - M^2 (\exp((1-x)L) - 1) & \text{for } \frac{1}{2} \leq x < 1 \end{cases} \quad (11.23)$$

where

$$L = 2 \ln \left(\frac{m_{\max}^2 - m_{\min}^2}{2M^2} + 1 \right). \quad (11.24)$$

The inverse:

$$x = \begin{cases} \frac{1}{L} \ln \left(\frac{m^2 - m_{\min}^2}{M^2} + 1 \right) & \text{for } m^2 < (m_{\max}^2 - m_{\min}^2)/2 \\ 1 - \frac{1}{L} \ln \left(\frac{m_{\max}^2 - m^2}{M^2} + 1 \right) & \text{for } m^2 \geq (m_{\max}^2 - m_{\min}^2)/2 \end{cases} \quad (11.25)$$

The phase-space factor is

$$f(x) = \begin{cases} \frac{M^2}{s} \exp(xL) L. & \text{for } 0 < x < \frac{1}{2} \\ \frac{M^2}{s} \exp((1-x)L) L. & \text{for } \frac{1}{2} \leq x < 1 \end{cases} \quad (11.26)$$

A (continuous) function proportional to

$$g(m^2) = \begin{cases} 1/(m^2 - m_{\min}^2) + M^2 & \text{for } m^2 < (m_{\max}^2 - m_{\min}^2)/2 \\ 1/((m_{\max}^2 - m^2) + M^2) & \text{for } m^2 \geq (m_{\max}^2 - m_{\min}^2)/2 \end{cases} \quad (11.27)$$

is mapped to a constant by this mapping, i.e., poles near both ends of the interval.

```

⟨Constants for t-channel pole mapping⟩≡
  if (map%variable_limits .or. map%a_unknown) then
    msq0 = map%mass**2
    map%a1 = msq0

    x = log (msq1/map%a1) / map%a2
  else
    msq1 = msq_max - msq + map%a1
    x = 1 - log (msq1/map%a1) / map%a2
  end if
  f = map%a3 * msq1

```

11.4.8 Step mapping

Step mapping is useful when the allowed range for a squared-mass variable is large, but only a fraction at the lower end is populated because the particle in question is an (off-shell) decay product of a narrow resonance. I.e., if the resonance was forced to be on-shell, the upper end of the range would be the resonance mass, minus the effective (real or resonance) mass of the particle(s) in the sibling branch of the decay.

The edge of this phase space section has a width which is determined by the width of the parent, plus the width of the sibling branch. (The widths might be added in quadrature, but this precision is probably not important.)

Fermi function

A possible mapping is derived from the Fermi function which has precisely this behavior. The Fermi function is given by

$$f(x) = \frac{1}{1 + \exp \frac{x-\mu}{\gamma}} \quad (11.28)$$

where x is taken as the invariant mass squared, μ is the invariant mass squared of the edge, and γ is the effective width which is given by the widths of the

parent and the sibling branch. (Widths might be added in quadrature, but we do not require this level of precision.)

$$x = \frac{m^2 - m_{\min}^2}{\Delta m^2} \quad (11.29)$$

$$\mu = \frac{m_{\max, \text{eff}}^2 - m_{\min}^2}{\Delta m^2} \quad (11.30)$$

$$\gamma = \frac{2m_{\max, \text{eff}}\Gamma}{\Delta m^2} \quad (11.31)$$

with

$$\Delta m^2 = m_{\max}^2 - m_{\min}^2 \quad (11.32)$$

m^2 is thus given by

$$m^2(x) = xm_{\max}^2 + (1-x)m_{\min}^2 \quad (11.33)$$

For the mapping, we compute the integral $g(x)$ of the Fermi function, normalized such that $g(0) = 0$ and $g(1) = 1$. We introduce the abbreviations

$$\alpha = 1 - \gamma \ln \frac{1 + \beta e^{1/\gamma}}{1 + \beta} \quad (11.34)$$

$$\beta = e^{-\mu/\gamma} \quad (11.35)$$

and obtain

$$g(x) = \frac{1}{\alpha} \left(x - \gamma \ln \frac{1 + \beta e^{x/\gamma}}{1 + \beta} \right) \quad (11.36)$$

The actual mapping is the inverse function $h(y) = g^{-1}(y)$,

$$h(y) = -\gamma \ln \left(e^{-\alpha y/\gamma} (1 + \beta) - \beta \right) \quad (11.37)$$

The Jacobian is

$$\frac{dh}{dy} = \alpha \left(1 - e^{\alpha y/\gamma} \frac{\beta}{1 + \beta} \right)^{-1} \quad (11.38)$$

which is equal to $1/(dg/dx)$, namely

$$\frac{dg}{dx} = \frac{1}{\alpha} \frac{1}{1 + \beta e^{x/\gamma}} \quad (11.39)$$

The final result is

$$\int_{m_{\min}^2}^{m_{\max}^2} dm^2 F(m^2) = \Delta m^2 \int_0^1 dx F(m^2(x)) \quad (11.40)$$

$$= \Delta m^2 \int_0^1 dy F(m^2(h(y))) \frac{dh}{dy} \quad (11.41)$$

Here is the implementation. We fill **a1**, **a2**, **a3** with α, β, γ , respectively.

```

⟨Constants for exponential step mapping⟩≡
  if (map%variable_limits .or. map%a_unknown) then
    map%a3 = max (2 * map%mass * map%width / (msq_max - msq_min), 0.01_default)
    map%a2 = exp (- (map%mass**2 - msq_min) / (msq_max - msq_min) &
                  / map%a3)

  msq = z * msq_max + (1 - z) * msq_min
  f = map%a1 / (1 - map%a2 / tmp) * (msq_max - msq_min) / s

⟨Apply inverse exponential step mapping⟩≡
  z = (msq - msq_min) / (msq_max - msq_min)
  tmp = 1 + map%a2 * exp (z / map%a3)
  x = (z - map%a3 * log (tmp / (1 + map%a2))) &
    / map%a1
  f = map%a1 * tmp * (msq_max - msq_min) / s

```

Hyperbolic mapping

The Fermi function has the drawback that it decreases exponentially. It might be preferable to take a function with a power-law decrease, such that the high-mass region is not completely depopulated.

Here, we start with the actual mapping which we take as

$$h(y) = \frac{b}{a-y} - \frac{b}{a} + \mu y \quad (11.42)$$

with the abbreviation

$$a = \frac{1}{2} \left(1 + \sqrt{1 + \frac{4b}{1-\mu}} \right) \quad (11.43)$$

This is a hyperbola in the xy plane. The derivative is

$$\frac{dh}{dy} = \frac{b}{(a-y)^2} + \mu \quad (11.44)$$

The constants correspond to

$$\mu = \frac{m_{\text{max,eff}}^2 - m_{\text{min}}^2}{\Delta m^2} \quad (11.45)$$

$$b = \frac{1}{\mu} \left(\frac{2m_{\text{max,eff}}\Gamma}{\Delta m^2} \right)^2 \quad (11.46)$$

The inverse function is the solution of a quadratic equation,

$$g(x) = \frac{1}{2} \left[\left(a + \frac{x}{\mu} + \frac{b}{a\mu} \right) - \sqrt{\left(a - \frac{x}{\mu} \right)^2 + 2\frac{b}{a\mu} \left(a + \frac{x}{\mu} \right) + \left(\frac{b}{a\mu} \right)^2} \right] \quad (11.47)$$

The constants $a_{1,2,3}$ are identified with a, b, μ .

```

⟨Constants for hyperbolic step mapping⟩≡

  tmp = map%a2 / (map%a1 * map%a3)
  x = ((map%a1 + z / map%a3 + tmp) &
        - sqrt((map%a1 - z / map%a3)**2 + 2 * tmp * (map%a1 + z / map%a3) &
              + tmp**2)) / 2
  f = (map%a2 / (map%a1 - x)**2 + map%a3) * (msq_max - msq_min) / s

```

11.4.9 Mappings of the polar angle

The other type of singularity, a simple pole just outside the integration region, can occur in the integration over $\cos\theta$. This applies to exchange of massless (or light) particles.

Double poles (Coulomb scattering) are also possible, but only in certain cases. These are also handled by the single-pole mapping.

The mapping is analogous to the previous m^2 pole mapping, but with a different normalization and notation of variables:

$$\frac{1}{2} \int_{-1}^1 d\cos\theta g(\theta) = \int_0^1 dx \frac{d\cos\theta}{dx} g(\theta(x)) = \int_0^1 dx f(x) g(x), \quad (11.48)$$

where thus

$$f(x) = \frac{1}{2} \frac{d\cos\theta}{dx}. \quad (11.49)$$

With this mapping, a function of the form

$$g(\theta) = c \frac{dx(\cos\theta)}{d\cos\theta} \quad (11.50)$$

is mapped to a constant:

$$\int_{-1}^1 d\cos\theta g(\theta) = \int_0^1 dx f(x) g(\theta(x)) = \int_0^1 dx c. \quad (11.51)$$

```

Trivial mapping

This is just the mapping of the interval $(-1, 1)$ to $(0, 1)$:

$$\cos \theta = -1 + 2x \quad (11.52)$$

and

$$f(x) = 1 \quad (11.53)$$

with the inverse

$$x = \frac{1 + \cos \theta}{2} \quad (11.54)$$

```

<Apply trivial ct mapping>≡
    tmp = 2 * (1-x)
    ct = 1 - tmp
    st = sqrt (tmp * (2-tmp))
    f = 1

<Apply inverse trivial ct mapping>≡
    x = (ct + 1) / 2
    f = 1

```

Pole mapping

As above for m^2 , we simultaneously map poles at both ends of the $\cos \theta$ interval. The formulae are completely analogous:

$$\cos \theta = \begin{cases} \frac{M^2}{s} [\exp(xL) - 1] - 1 & \text{for } x < \frac{1}{2} \\ -\frac{M^2}{s} [\exp((1-x)L) - 1] + 1 & \text{for } x \geq \frac{1}{2} \end{cases} \quad (11.55)$$

where

$$L = 2 \ln \frac{M^2 + s}{M^2}. \quad (11.56)$$

Inverse:

$$x = \begin{cases} \frac{1}{2L} \ln \frac{1 + \cos \theta + M^2/s}{M^2/s} & \text{for } \cos \theta < 0 \\ 1 - \frac{1}{2L} \ln \frac{1 - \cos \theta + M^2/s}{M^2/s} & \text{for } \cos \theta \geq 0 \end{cases} \quad (11.57)$$

The phase-space factor:

$$f(x) = \begin{cases} \frac{M^2}{s} \exp(xL) L & \text{for } x < \frac{1}{2} \\ \frac{M^2}{s} \exp((1-x)L) L & \text{for } x \geq \frac{1}{2} \end{cases} \quad (11.58)$$

```

<Constants for ct pole mapping>≡
  if (map%variable_limits .or. map%b_unknown) then
    map%b1 = map%mass**2 / s
    map%b2 = log ((map%b1 + 1) / map%b1)
    map%b3 = 0
    map%b_unknown = .false.
  end if

<Apply ct pole mapping>≡
  if (x < .5_default) then
    ct1 = map%b1 * exp (2 * x * map%b2)

  else
    ct1 = map%b1 * exp (2 * (1-x) * map%b2)
    ct = -(ct1 - map%b1) + 1
  end if
  if (ct >= -1 .and. ct <= 1) then
    st = sqrt (1 - ct**2)
    f = ct1 * map%b2
  else
    ct = 1; st = 0; f = 0
  end if

<Apply inverse ct pole mapping>≡
  if (ct < 0) then
    ct1 = ct + map%b1 + 1
    x = log (ct1 / map%b1) / (2 * map%b2)
  else
    ct1 = -ct + map%b1 + 1
    x = 1 - log (ct1 / map%b1) / (2 * map%b2)
  end if
  f = ct1 * map%b2

```

11.5 Phase-space trees

The phase space evaluation is organized in terms of trees, where each branch corresponds to three integrations: m^2 , $\cos\theta$, and ϕ . The complete tree thus makes up a specific parameterization of the multidimensional phase-space integral. For the multi-channel integration, the phase-space tree is a single channel.

The trees imply mappings of formal Feynman tree graphs into arrays of integer numbers: Each branch, corresponding to a particular line in the graph, is assigned an integer code c (with kind value $\text{TC} = \text{tree code}$).

In this integer, each bit determines whether a particular external momentum flows through the line. The external branches therefore have codes 1, 2, 4, 8, ... An internal branch has those bits ORed corresponding to the momenta flowing through it. For example, a branch with momentum $p_1 + p_4$ has code $2^0 + 2^3 = 1 + 8 = 9$.

There is a two-fold ambiguity: Momentum conservation implies that the branch with code

$$c_0 = \sum_{i=1}^{n(\text{ext})} 2^{i-1} \quad (11.59)$$

i.e. the branch with momentum $p_1 + p_2 + \dots p_n$ has momentum zero, which is equivalent to tree code 0 by definition. Correspondingly,

$$c \quad \text{and} \quad c_0 - c = c \text{ XOR } c_0 \quad (11.60)$$

are equivalent. E.g., if there are five externals with codes $c = 1, 2, 4, 8, 16$, then $c = 9$ and $\bar{c} = 31 - 9 = 22$ are equivalent.

This ambiguity may be used to assign a direction to the line: If all momenta are understood as outgoing, $c = 9$ in the example above means $p_1 + p_4$, but $c = 22$ means $p_2 + p_3 + p_5 = -(p_1 + p_4)$.

Here we make use of the ambiguity in a slightly different way. First, the initial particles are singled out as those externals with the highest bits, the IN-bits. (Here: 8 and 16 for a $2 \rightarrow 3$ scattering process, 16 only for a $1 \rightarrow 4$ decay.) Then we invert those codes where all IN-bits are set. For a decay process this maps each tree of an equivalence class onto a unique representative (that one with the smallest integer codes). For a scattering process we proceed further:

The ambiguity remains in all branches where only one IN-bit is set, including the initial particles. If there are only externals with this property, we have an s -channel graph which we leave as it is. In all other cases, an internal with only one IN-bit is a t -channel line, which for phase space integration should be associated with one of the initial momenta as a reference axis. We take that one whose bit is set in the current tree code. (E.g., for branch $c = 9$ we use the initial particle $c = 8$ as reference axis, whereas for the same branch we would take $c = 16$ if it had been assigned $\bar{c} = 31 - 9 = 22$ as tree code.) Thus, different ways of coding the same t -channel graph imply different phase space parameterizations.

s -channel graphs have a unique parameterization. The same sets of parameterizations are used for t -channel graphs, except for the reference frames of their angular parts. We map each t -channel graph onto an s -channel graph as follows:

Working in ascending order, for each t -channel line (whose code has exactly one IN-bit set) the attached initial line is flipped upstream, while the outgoing

line is flipped downstream. (This works only if t -channel graphs are always parameterized beginning at their outer vertices, which we require as a restriction.) After all possible flips have been applied, we have an s -channel graph. We only have to remember the initial particle a vertex was originally attached to.

11.5.2 The phase-space tree type

Definition

In the concrete implementation, each branch c may have two *daughters* c_1 and c_2 such that $c_1 + c_2 = c$, a *sibling* c_s and a *mother* c_m such that $c + c_s = c_m$, and a *friend* which is kept during flips, such that it can indicate a fixed reference frame. Absent entries are set $c = 0$.

First, declare the branch type. There is some need to have this public. Give initializations for all components, so no `init` routine is necessary. The branch has some information about the associated coordinates and about connections.

```

<PHS trees: types>+≡
type :: phs_branch_t
  private
  logical :: set = .false.
  logical :: inverted_decay = .false.
  logical :: inverted_axis = .false.
  integer(TC) :: mother = 0
  integer(TC) :: sibling = 0
  integer(TC) :: friend = 0
  integer(TC) :: origin = 0
  integer(TC), dimension(2) :: daughter = 0
  integer :: firstborn = 0

```

```

        logical :: has_children = .false.
        logical :: has_friend = .false.
    end type phs_branch_t

```

The tree type: No initialization, this is done by `phs_tree_init`. In addition to the branch array which

The branches are collected in an array which holds all possible branches, of which only a few are set. After flips have been applied, the branch $c_M = \sum_{i=1}^{n(\text{fin})} 2^{i-1}$ must be there, indicating the mother of all decay products. In addition, we should check for consistency at the beginning.

`n_branches` is the number of those actually set. `n externals` defines the number of significant bit, and `mask` is a code where all bits are set. Analogous: `n_in` and `mask_in` for the incoming particles.

The mapping array contains the mappings associated to the branches (corresponding indices). The array `mass_sum` contains the sum of the real masses of the external final-state particles associated to the branch. During phase-space evaluation, this determines the boundaries.

```

<PHS trees: public>+≡
    public :: phs_tree_t

<PHS trees: types>+≡
    type :: phs_tree_t
        private
        integer :: n_branches, n externals, n_in, n_msq, n_angles
        integer(TC) :: n_branches_tot, n_branches_out
        integer(TC) :: mask, mask_in, mask_out
        type(phs_branch_t), dimension(:), allocatable :: branch
        type(mapping_t), dimension(:), allocatable :: mapping
        real(default), dimension(:), allocatable :: mass_sum
        real(default), dimension(:), allocatable :: effective_mass
        real(default), dimension(:), allocatable :: effective_width
    end type phs_tree_t

```

The maximum number of external particles that can be represented is related to the bit size of the integer that stores binary codes. With the default integer of 32 bit on common machines, this is more than enough space. If TC is actually the default integer kind, there is no need to keep it separate, but doing so marks this as a special type of integer. So, just state that the maximum number is 32:

```

<Limits: public parameters>+≡
    integer, parameter, public :: MAX_EXTERNAL = 32

```

Constructor and destructor

Allocate memory for a phase-space tree with given number of externals and incoming. The number of allocated branches can easily become large, but appears manageable for realistic cases, e.g., for `n_in=2` and `n_out=8` we get $2^{10} - 1 = 1023$.

```

<PHS trees: public>+≡
    public :: phs_tree_init
    public :: phs_tree_final

```

Here we set the masks for incoming and for all externals.

```

<PHS trees: procedures>+≡
  elemental subroutine phs_tree_init (tree, n_in, n_out, n_masses, n_angles)
    type(phs_tree_t), intent(inout) :: tree
    integer, intent(in) :: n_in, n_out, n_masses, n_angles
    integer(TC) :: i
    tree%n_externals = n_in + n_out
    tree%n_branches_tot = 2**(n_in+n_out) - 1
    tree%n_branches_out = 2**n_out - 1

```

11.5.3 PHS tree setup

Transformation into an array of branch codes and back

Assume that the tree/array has been created before with the appropriate length and is empty.

```

<PHS trees: public>+≡
    public :: phs_tree_from_array

<PHS trees: procedures>+≡
    subroutine phs_tree_from_array (tree, a)
        type(phs_tree_t), intent(inout) :: tree
        integer(TC), dimension(:), intent(in) :: a
        integer :: i
        integer(TC) :: k
        <Set branches from array a>
        <Set external branches if necessary>
        <Check number of branches>
        <Determine the connections>
    contains
        <Subroutine: set relatives>
    end subroutine phs_tree_from_array

```

First, set all branches specified by the user. If all IN-bits are set, we invert the branch code.

```

<Set branches from array a>≡
    do i=1, size(a)
        k = a(i)
        if (iand(k, tree%mask_in) == tree%mask_in) k = ieor(tree%mask, k)
        tree%branch(k)%set = .true.
        tree%n_branches = tree%n_branches+1
    end do

```

The external branches are understood, so set them now if not yet done. In all cases ensure that the representative with one bit set is used, except for decays where the in-particle is represented by all OUT-bits set instead.

```

<Set external branches if necessary>≡
do i=0, tree%n_externals-1
  k = ibset(0,i)
  if (iand(k, tree%mask_in) == tree%mask_in) k = ieor(tree%mask, k)
  if (tree%branch(ieor(tree%mask, k))%set) then
    tree%branch(ieor(tree%mask, k))%set = .false.
    tree%branch(k)%set = .true.
  else if (.not.tree%branch(k)%set) then
    tree%branch(k)%set = .true.
    tree%n_branches = tree%n_branches+1
  end if
end do

```

Now the number of branches set can be checked. Here we assume that the tree is binary. For three externals there are three branches in total, and for each additional external branch we get another internal one.

```

<Check number of branches>≡
if (tree%n_branches /= tree%n_externals*2-3) then
  call phs_tree_write (tree)
  call msg_bug &
    & (" Wrong number of branches set in phase space tree")
end if

```

For all branches that are set, except for the externals, we try to find the daughter branches:

```

<Determine the connections>≡
do k=1, size (tree%branch)
  if (tree%branch(k)%set .and. tc_decay_level (k) /= 1) then
    call branch_set_relatives(k)
  end if
end do

```

To this end, we scan all codes less than the current code, whether we can find two branches which are set and which together give the current code. After that, the tree may still not be connected, but at least we know if a branch does not have daughters: This indicates some inconsistency.

The algorithm ensures that, at this stage, the first daughter has a smaller code value than the second one.

```

<Subroutine: set relatives>≡
subroutine branch_set_relatives (k)
  integer(TC), intent(in) :: k
  integer(TC) :: m,n
  do m=1, k-1
    if(iand(k,m)==m) then
      n = ieor(k,m)
      if ( tree%branch(m)%set .and. tree%branch(n)%set ) then
        tree%branch(k)%daughter(1) = m; tree%branch(k)%daughter(2) = n
        tree%branch(m)%mother      = k; tree%branch(n)%mother      = k
        tree%branch(m)%sibling      = n; tree%branch(n)%sibling      = m
        tree%branch(k)%has_children = .true.
      return
    end if
  end do
end subroutine

```

```

        end if
    end if
end do
call phs_tree_write (tree)
call msg_bug &
    & (" Missing daughter branch(es) in phase space tree")
end subroutine branch_set_relatives

```

The inverse: this is trivial, fortunately.

Flip t -channel into s -channel

Flipping the tree is done upwards, beginning from the decay products. First we select a t -channel branch k : one which is set, which does have an IN-bit, and which is not an external particle.

Next, we determine the adjacent in-particle (called the 'friend' f here, since it will provide the reference axis for the angular integration). In addition, we look for the 'mother' and 'sibling' of this particle. If the latter field is empty, we select the (unique) other out-particle which has no mother, calling the internal subroutine `find_orphan`.

The flip is done as follows: We assume that the first daughter d is an s -channel line, which is true if the daughters are sorted. This will stay the first daughter. The second one is a t -channel line; it is exchanged with the 'sibling' s . The new line which replaces the branch k is just the sum of s and d . In addition, we have to rearrange the relatives of s and d , as well of f .

Finally, we flip 'sibling' and 'friend' and set the new s -channel branch n which replaces the t -channel branch k . After this is complete, we are ready to execute another flip.

[Although the friend is not needed for the final flip, since it would be an initial particle anyway, we need to know whether we have t - or u -channel.]

```

After the tree has been flipped, one may need to determine what has become of a particular t -channel branch. This function gives the bincode of the flipped tree. If the original bincode does not contain IN-bits, we leave it as it is.

(PHS trees: procedures)+≡

```

function tc_flipped (tree, kt) result (ks)
    type(phs_tree_t), intent(in) :: tree
    integer(TC), intent(in) :: kt
    integer(TC) :: ks
    if (iand (kt, tree%mask_in) == 0) then
        ks = kt
    else
        ks = tree%branch(iand (kt, tree%mask_out))%mother
    end if
end function tc_flipped

```

Scan a tree and make sure that the first daughter has always a smaller code than the second one. Furthermore, delete any `friend` entry in the root branch – this branching has the incoming particle direction as axis anyway. Keep track of reordering by updating `inverted_axis`, `inverted_decay` and `firstborn`.

      call mapping_set_parameters &
        (tree%mapping(k), mapping_defaults, variable_limits)
    end do
  end subroutine phs_tree_set_mapping_parameters

```

Return the mapping for the sum of all outgoing particles. This should either be no mapping or a global s-channel mapping.

```

<PHS trees: public>+≡
  public :: phs_tree_assign_s_mapping

<PHS trees: procedures>+≡
  subroutine phs_tree_assign_s_mapping (tree, mapping)
    type(phs_tree_t), intent(in) :: tree
    type(mapping_t), intent(out) :: mapping
    mapping = tree%mapping(tree%mask_out)
  end subroutine phs_tree_assign_s_mapping

```

Kinematics

Fill the mass sum array, starting from the external particles and working down to the tree root. For each bincode k we scan the bits in k ; if only one is set, we take the physical mass of the corresponding external particle; if more than one is set, we sum up the two masses (which we know have already been set).

```

<PHS trees: public>+≡
  public :: phs_tree_set_mass_sum

<PHS trees: procedures>+≡
  subroutine phs_tree_set_mass_sum (tree, flv)
    type(phs_tree_t), intent(inout) :: tree
    type(flavor_t), dimension(:), intent(in) :: flv
    integer(TC) :: k
    integer :: i

    do k = 1, tree%n_branches_out
      do i = 0, size(flav) - 1
        if (btest(k,i)) then
          if (ibclr(k,i) == 0) then
            tree%mass_sum(k) = flavor_get_mass (flv(i+1))
          else
            tree%mass_sum(k) = &
              tree%mass_sum(ibclr(k,i)) + tree%mass_sum(ibset(0,i))
          end if
        end if
      end do
    end do
  end subroutine phs_tree_set_mass_sum

```

```

        end do
    end do
end subroutine phs_tree_set_mass_sum

```

Set the effective masses and widths. For each non-resonant branch in a tree, the effective mass is equal to the sum of the effective masses of the children (and analogous for the width). External particles have their real mass and width zero. For resonant branches, we insert mass and width from the corresponding mapping.

This routine has `phs_tree_set_mass_sum` and `phs_tree_set_mapping_parameters` as prerequisites.

(PHS trees: public)+≡

```

public :: phs_tree_set_effective_masses

```

(PHS trees: procedures)+≡

```

subroutine phs_tree_set_effective_masses (tree)

        end if
    end subroutine set_masses_x
end subroutine phs_tree_set_effective_masses

```

Define step mappings, recursively, for the decay products of all intermediate resonances. Step mappings account for the fact that a branch may originate from a resonance, which almost replaces the upper limit on the possible invariant mass. The step mapping implements a smooth cutoff that interpolates between the resonance and the real kinematic limit. The mapping width determines the sharpness of the cutoff.

Step mappings are inserted only for branches that are not mapped otherwise.

At each branch, we record the mass that is effectively available for phase space, by taking the previous limit and subtracting the effective mass of the sibling branch. Widths are added, not subtracted.

If we encounter a resonance decay, we discard the previous limit and replace it by the mass and width of the resonance, also subtracting the sibling branch.

Initially, the limit is zero, so it becomes negative at any branch. Only if there is a resonance, the limit becomes positive. Whenever the limit is positive, and the current branch decays, we activate a step mapping for the current branch.

As a result, step mappings are implemented for all internal lines that originate from an intermediate resonance decay.

The flag `variable_limits` applies to the ultimate limit from the available energy, not to the intermediate resonances whose masses are always fixed.

This routine requires `phs_tree_set_effective_masses`

```

Structural comparison

This function allows to check whether one tree is the permutation of another one. The permutation is applied to the second tree in the argument list. We do not make up a temporary permuted tree, but compare the two trees directly. The branches are scanned recursively, where for each daughter we check the friend and the mapping as well. Once a discrepancy is found, the recursion is exited immediately.

11.5.4 Phase-space evaluation

Phase-space volume

We compute the phase-space volume recursively, following the same path as for computing other kinematical variables. However, the volume depends just on $\sqrt{\hat{s}}$, not on the momentum configuration.

Note: counting branches, we may replace this by a simple formula.

```

<PHS trees: public>+≡
    public :: phs_tree_compute_volume

<PHS trees: procedures>+≡
    subroutine phs_tree_compute_volume (tree, sqrts, volume)

        end if
        if (initial) then
            volume = v1 * v2 / (4 * twopi5)
        else
            volume = v1 * v2 * sqrts**2 / (4 * twopi2)
        end if
    end subroutine compute_volume_x
end subroutine phs_tree_compute_volume

```

Determine momenta

This is done in two steps: First the masses are determined. This step may fail, in which case `ok` is set to `false`. If successful, we generate angles and the actual momenta. The array `decay_p` serves for transferring the individual three-momenta of the daughter particles in their mother rest frame from the mass generation to the momentum generation step.

```

<PHS trees: public>+≡
    public :: phs_tree_compute_momenta_from_x

<PHS trees: procedures>+≡
    subroutine phs_tree_compute_momenta_from_x &
        (tree, prt, factor, volume, sqrts, x, ok)
        type(phs_tree_t), intent(inout) :: tree
        type(phs_prt_t), dimension(:), intent(inout) :: prt
        real(default), intent(out) :: factor, volume
        real(default), intent(in) :: sqrts
        real(default), dimension(:), intent(in) :: x
        logical, intent(out) :: ok
        real(default), dimension(tree%mask_out) :: decay_p
        integer :: n1, n2
        n1 = tree%n_msq
        n2 = n1 + tree%n_angles
        call phs_tree_set_msq &
            (tree, prt, factor, volume, decay_p, sqrts, x(1:n1), ok)
        if (ok) call phs_tree_set_angles &
            (tree, prt, factor, decay_p, sqrts, x(n1+1:n2))
    end subroutine phs_tree_compute_momenta_from_x

```

Mass generation is done recursively. The `ok` flag causes the filled tree to be discarded if set to `false`. This happens if a three-momentum turns out to be imaginary, indicating impossible kinematics. The index `ix` tells us how far we have used up the input array `x`.

```

<PHS trees: procedures>+≡

```

The heart of phase space generation: Now we have the invariant masses, let us generate angles. At each branch, we take a Lorentz transformation and augment it by a boost to the current particle rest frame, and by rotations ϕ and θ around the z and y axis, respectively. This transformation is passed down to the daughter particles, if present.

end subroutine phs_tree_get_msq

```

This subroutine is the most time-critical part of the whole program. Therefore, we do not exactly parallel the angle generation routine above but make sure that things get evaluated only if they are really needed, at the expense of readability. Particularly important is to have as few multiplications of Lorentz transformations as possible.

    end subroutine phs_tree_setup_prt_combinations

```

11.6 The phase-space forest

Simply stated, a phase-space forest is a collection of phase-space trees. More precisely, a `phs_forest` object contains all parameterizations of phase space that `WHIZARD` will use for a single hard process, prepared in the form of `phs_tree` objects. This is suitable for evaluation by the `VAMP` integration package: each parameterization (tree) is a valid channel in the multi-channel adaptive integration, and each variable in a tree corresponds to an integration dimension, defined by an appropriate mapping of the $(0, 1)$ interval to the allowed range of the integration variable.

The trees are grouped in groves. The trees (integration channels) within a grove share a common weight, assuming that they are related by some approximate symmetry.

Trees/channels that are related by an exact symmetry are connected by an array of equivalences; each equivalence object holds the data that relate one channel to another.

The phase-space setup, i.e., the detailed structure of trees and forest, are read from a file. Therefore, this module also contains the syntax definition and the parser needed for interpreting this file.

```

11.6.1 Phase-space setup parameters

This transparent container holds the parameters that the algorithm needs for phase-space setup, with reasonable defaults.

The threshold mass (for considering a particle as effectively massless) is specified separately for s- and t-channel. The default is to treat W and Z bosons as massive in the s-channel, but as massless in the t-channel. The b -quark is treated always massless, the t -quark always massive.

```
⟨PHS forests: public⟩≡
```

```
public :: phs_parameters_t
```

```
⟨PHS forests: types⟩≡
```

```
type :: phs_parameters_t
  real(default) :: sqrts = 0
  real(default) :: m_threshold_s = 50._default
  real(default) :: m_threshold_t = 100._default
  integer :: off_shell = 1
  integer :: t_channel = 2
  logical :: keep_nonresonant = .true.
end type phs_parameters_t
```

Write phase-space parameters to file.

```
⟨PHS forests: public⟩+≡
```

```

    else
      write (u, "(1x,A)", advance="no") "-"
    end if
  end do
  write (u, *)
  if (associated (eq%next)) call equivalence_write_rec (eq%next, u)
end subroutine equivalence_write_rec
end subroutine equivalence_list_write

```

11.6.3 Groves

A grove is a group of trees (phase-space channels) that share a common weight in the integration. Within a grove, channels can be declared equivalent, so they also share their integration grids (up to symmetries). The grove contains a list of equivalences. The `tree_count_offset` is the total number of trees of the preceding groves; when the trees are counted per forest (integration channels), the offset has to be added to all tree indices.

```

<PHS forests: types>+=
  type :: phs_grove_t
  private
  integer :: tree_count_offset
  type(phs_tree_t), dimension(:), allocatable :: tree
  type(equivalence_list_t) :: equivalence_list
end type phs_grove_t

```

Call `phs_tree_init` which is also elemental:

```

<PHS forests: procedures>+=
  elemental subroutine phs_grove_init &
    (grove, n_trees, n_in, n_out, n_masses, n_angles)
  type(phs_grove_t), intent(inout) :: grove
  integer, intent(in) :: n_trees, n_in, n_out, n_masses, n_angles
  grove%tree_count_offset = 0
  allocate (grove%tree (n_trees))
  call phs_tree_init (grove%tree, n_in, n_out, n_masses, n_angles)

```

```
end subroutine phs_grove_init
```

The trees do not have pointer components, thus no call to `phs_tree_final`:

```
(PHS forests: procedures)+≡
  elemental subroutine phs_grove_final (grove)
    type(phs_grove_t), intent(inout) :: grove
    deallocate (grove%tree)
    call equivalence_list_final (grove%equivalence_list)
  end subroutine phs_grove_final
```

Deep copy.

```
(PHS forests: interfaces)+≡
  interface assignment(=)
    module procedure phs_grove_assign0
    module procedure phs_grove_assign1
  end interface

(PHS forests: procedures)+≡
  subroutine phs_grove_assign0 (grove_out, grove_in)
    type(phs_grove_t), intent(out) :: grove_out
    type(phs_grove_t), intent(in) :: grove_in
    grove_out%tree_count_offset = grove_in%tree_count_offset
    if (allocated (grove_in%tree)) then
      allocate (grove_out%tree (size (grove_in%tree)))
      grove_out%tree = grove_in%tree
    end if
    grove_out%equivalence_list = grove_in%equivalence_list
  end subroutine phs_grove_assign0

  subroutine phs_grove_assign1 (grove_out, grove_in)
    type(phs_grove_t), dimension(:), intent(out) :: grove_out
    type(phs_grove_t), dimension(:), intent(in) :: grove_in
    integer :: i
    do i = 1, size (grove_in)
      call phs_grove_assign0 (grove_out(i), grove_in(i))
    end do
  end subroutine phs_grove_assign1
```

Get the global (s-channel) mappings. Implemented as a subroutine which returns an array (slice).

```
(PHS forests: procedures)+≡
  subroutine phs_grove_assign_s_mappings (grove, mapping)
    type(phs_grove_t), intent(in) :: grove
    type(mapping_t), dimension(:), intent(out) :: mapping
    integer :: i
    if (size (mapping) == size (grove%tree)) then
      do i = 1, size (mapping)
        call phs_tree_assign_s_mapping (grove%tree(i), mapping(i))
      end do
    else
      call msg_bug ("phs_grove_assign_s_mappings: array size mismatch")
    end if
  end subroutine
```

```
end subroutine phs_grove_assign_s_mappings
```

11.6.4 The forest type

This is a collection of trees and associated particles. In a given tree, each branch code corresponds to a particle in the `prt` array. Furthermore, we have an array of mass sums which is independent of the decay tree and of the particular event. The mappings directly correspond to the decay trees, and the decay groves collect the trees in classes. The permutation list consists of all permutations of outgoing particles that map the decay forest onto itself.

The particle codes `flv` (one for each external particle) are needed for determining masses and such. The trees and associated information are collected in the `grove` array, together with a lookup table that associates tree indices to groves. Finally, the `prt` array serves as workspace for phase-space evaluation.

The `prt_combination` is a list of index pairs, namely the particle momenta pairs that need to be combined in order to provide all momentum combinations that the phase-space trees need to know.

```
<PHS forests: public>+≡
  public :: phs_forest_t

<PHS forests: types>+≡
  type :: phs_forest_t
    private
    integer :: n_in, n_out, n_tot
    integer :: n_masses, n_angles, n_dimensions
    integer :: n_trees, n_equivalences
    type(flavor_t), dimension(:), allocatable :: flv
    type(phs_grove_t), dimension(:), allocatable :: grove
    integer, dimension(:), allocatable :: grove_lookup
    type(phs_prt_t), dimension(:), allocatable :: prt_in
    type(phs_prt_t), dimension(:), allocatable :: prt_out
    type(phs_prt_t), dimension(:), allocatable :: prt
    integer(TC), dimension(:,:), allocatable :: prt_combination
    type(mapping_t), dimension(:), allocatable :: s_mapping
  contains
    <PHS forests: phs forest: TBP>
  end type phs_forest_t
```

The initialization merely allocates memory. We have to know how many trees there are in each grove, so we can initialize everything. The number of groves is the size of the `n_tree` array.

In the `grove_lookup` table we store the grove index that belongs to each absolute tree index. The difference between the absolute index and the relative (to the grove) index is stored, for each grove, as `tree_count_offset`.

The particle array is allocated according to the total number of branches each tree has, but not filled.

```
<PHS forests: public>+≡
  public :: phs_forest_init
```

(PHS forests: procedures)+≡

```

subroutine phs_forest_init (forest, n_tree, n_in, n_out)
  type(phs_forest_t), intent(inout) :: forest
  integer, dimension(:), intent(in) :: n_tree
  integer, intent(in) :: n_in, n_out
  integer :: g, count, k_root
  forest%n_in = n_in
  forest%n_out = n_out
  forest%n_tot = n_in + n_out
  forest%n_masses = max (n_out - 2, 0)
  forest%n_angles = max (2*n_out - 2, 0)
  forest%n_dimensions = forest%n_masses + forest%n_angles
  forest%n_trees = sum (n_tree)
  forest%n_equivalences = 0
  allocate (forest%grove (size (n_tree)))
  call phs_grove_init &
    (forest%grove, n_tree, n_in, n_out, forest%n_masses, forest%n_angles)
  allocate (forest%grove_lookup (forest%n_trees))
  count = 0
  do g = 1, size (forest%grove)
    forest%grove(g)%tree_count_offset = count
    forest%grove_lookup (count+1:count+n_tree(g)) = g
    count = count + n_tree(g)
  end do
  allocate (forest%prt_in (n_in))
  allocate (forest%prt_out (n_out))
  k_root = 2**forest%n_tot - 1
  allocate (forest%prt (k_root))
  allocate (forest%prt_combination (2, k_root))
  allocate (forest%s_mapping (forest%n_trees))
end subroutine phs_forest_init

```

Assign the global (s-channel) mappings.

(PHS forests: public)+≡

```

public :: phs_forest_set_s_mappings

```

(PHS forests: procedures)+≡

```

subroutine phs_forest_set_s_mappings (forest)
  type(phs_forest_t), intent(inout) :: forest
  integer :: g, i0, i1, n
  do g = 1, size (forest%grove)
    call phs_forest_get_grove_bounds (forest, g, i0, i1, n)
    call phs_grove_assign_s_mappings &
      (forest%grove(g), forest%s_mapping(i0:i1))
  end do
end subroutine phs_forest_set_s_mappings

```

The grove finalizer is called because it contains the equivalence list:

(PHS forests: public)+≡

```

public :: phs_forest_final

```

(PHS forests: procedures)+≡

```

subroutine phs_forest_final (forest)
  type(phs_forest_t), intent(inout) :: forest

```

```

    if (allocated (forest%grove)) then

11.6.7 Read the phase space setup from file

The phase space setup is stored in a file. The file may be generated by the `cascades` module below, or by other means. This file has to be read and parsed to create the PHS forest as the internal phase-space representation.

Create lexer and syntax:

```

<PHS forests: procedures>+≡
subroutine define_phs_forest_syntax (ifile)
    type(ifile_t) :: ifile
    call ifile_append (ifile, "SEQ phase_space_list = process_phase_space*")
    call ifile_append (ifile, "SEQ process_phase_space = " &
        // "process_def process_header phase_space")
    call ifile_append (ifile, "SEQ process_def = process process_list")
    call ifile_append (ifile, "KEY process")
    call ifile_append (ifile, "LIS process_list = process_tag*")
    call ifile_append (ifile, "IDE process_tag")
    call ifile_append (ifile, "SEQ process_header = " &
        // "md5sum_process = md5sum " &
        // "md5sum_model_par = md5sum " &
        // "md5sum_phs_config = md5sum " &
        // "sqrts = real " &
        // "m_threshold_s = real " &
        // "m_threshold_t = real " &
        // "off_shell = integer " &
        // "t_channel = integer " &
        // "keep_nonresonant = logical")
    call ifile_append (ifile, "KEY '='")
    call ifile_append (ifile, "KEY md5sum_process")
    call ifile_append (ifile, "KEY md5sum_model_par")
    call ifile_append (ifile, "KEY md5sum_phs_config")
    call ifile_append (ifile, "KEY sqrts")
    call ifile_append (ifile, "KEY m_threshold_s")
    call ifile_append (ifile, "KEY m_threshold_t")
    call ifile_append (ifile, "KEY off_shell")
    call ifile_append (ifile, "KEY t_channel")
    call ifile_append (ifile, "KEY keep_nonresonant")
    call ifile_append (ifile, "QUO md5sum = '""' ... '""'")
    call ifile_append (ifile, "REA real")
    call ifile_append (ifile, "INT integer")
    call ifile_append (ifile, "IDE logical")
    call ifile_append (ifile, "SEQ phase_space = grove_def+")

```

```

call ifile_append (ifile, "SEQ grove_def = grove tree_def+")
call ifile_append (ifile, "KEY grove")
call ifile_append (ifile, "SEQ tree_def = tree bincodes mapping*")
call ifile_append (ifile, "KEY tree")
call ifile_append (ifile, "SEQ bincodes = bincodes+")
call ifile_append (ifile, "INT bincodes")
call ifile_append (ifile, "SEQ mapping = map bincodes channel pdg")
call ifile_append (ifile, "KEY map")
call ifile_append (ifile, "ALT channel = s_channel | t_channel | u_channel | collinear | infrared")
call ifile_append (ifile, "KEY s_channel")
!!! JRR: WK please check: why commented out?
! call ifile_append (ifile, "KEY t_channel")
call ifile_append (ifile, "KEY u_channel")
call ifile_append (ifile, "KEY collinear")
call ifile_append (ifile, "KEY infrared")
call ifile_append (ifile, "KEY radiation")
call ifile_append (ifile, "INT pdg")
end subroutine define_phs_forest_syntax

```

The model-file syntax and lexer are fixed, therefore stored as module variables:

```

<PHS forests: variables>≡

    subroutine syntax_phs_forest_write (unit)
        integer, intent(in), optional :: unit
        call syntax_write (syntax_phs_forest, unit)
    end subroutine syntax_phs_forest_write

```

The concrete parser and interpreter. Generate an input stream for the external `unit`, read the parse tree (with given `syntax` and `lexer`) from this stream, and transfer the contents of the parse tree to the PHS forest.

We look for the matching `process` tag, count groves and trees for initializing the `forest`, and fill the trees.

If the optional parameters are set, compare the parameters stored in the file to those. Set `match` true if everything agrees.

```

(PHS forests: public)+≡
    public :: phs_forest_read

(PHS forests: interfaces)+≡
    interface phs_forest_read
        module procedure phs_forest_read_file

    end do
  end subroutine phs_tree_set

```

11.6.8 Preparation

The trees that we read from file do not carry flavor information. This is set separately:

The flavor list must be unique for a unique set of masses; if a given particle can have different flavor, the mass must be degenerate, so we can choose one of the possible flavor combinations.

```

<PHS forests: public>+≡
  public :: phs_forest_set_flavors

<PHS forests: procedures>+≡
  subroutine phs_forest_set_flavors (forest, flv)
    type(phs_forest_t), intent(inout) :: forest
    type(flavor_t), dimension(:), intent(in) :: flv
    allocate (forest%flv (size (flv)))
    forest%flv = flv
  end subroutine phs_forest_set_flavors

```

Once the parameter set is fixed, the masses and the widths of the particles are known and the `mass_sum` arrays as well as the mapping parameters can be computed. Note that order is important: we first compute the mass sums, then the ordinary mappings. The resonances obtained here determine the effective masses, which in turn are used to implement step mappings for resonance decay products that are not mapped otherwise.

```

<PHS forests: public>+≡
  public :: phs_forest_set_parameters

<PHS forests: procedures>+≡
  subroutine phs_forest_set_parameters &
    (forest, mapping_defaults, variable_limits)
    type(phs_forest_t), intent(inout) :: forest
    type(mapping_defaults_t), intent(in) :: mapping_defaults

        call phs_tree_set_mass_sum &
          (forest%grove(g)%tree(t), forest%flv(forest%n_in+1:))
        call phs_tree_set_mapping_parameters (forest%grove(g)%tree(t), &
          mapping_defaults, variable_limits)
        call phs_tree_set_effective_masses (forest%grove(g)%tree(t))
        if (mapping_defaults%step_mapping) then

```

```

        call phs_tree_set_step_mappings (forest%grove(g)%tree(t), &
            mapping_defaults%step_mapping_exp, variable_limits)
    end if
end do
end do
end subroutine phs_forest_set_parameters

```

Generate the particle combination table. Scan all trees and merge their individual combination tables. At the end, valid entries are non-zero, and they indicate the indices of a pair of particles to be combined to a new particle. If a particle is accessible by more than one tree (this is usual), only keep the first possibility.

```

11.6.10 Find equivalences among phase-space trees

Scan phase space for equivalences. We generate the complete set of unique permutations for the given list of outgoing particles, and use this for scanning equivalences within each grove. We scan all pairs of trees, using all permutations. This implies that trivial equivalences are included, and equivalences between different trees are recorded twice. This is intentional.

(PHS forests: procedures)+≡

```
subroutine phs_grove_set_equivalences (grove, perm_array)

11.7 Finding phase space parameterizations

If the phase space configuration is not found in the appropriate file, we should generate one.

The idea is to construct all Feynman diagrams subject to certain constraints which eliminate everything that is probably irrelevant for the integration. These Feynman diagrams (cascades) are grouped in groves by finding equivalence classes related by symmetry and ordered with respect to their importance (resonances). Finally, the result (or part of it) is written to file and used for the integration.

This module may eventually disappear and be replaced by CAML code. In particular, we need here a set of Feynman rules (vertices with particle codes, but not the factors). Thus, the module works for the Standard Model only.

Note that this module is stand-alone, it communicates to the main program only via the generated ASCII phase-space configuration file.

```

<cascades.f90>≡
  <File header>

  module cascades

    <Use kinds>
    use kinds, only: TC, i8, i32 !NODEP!
    <Use strings>
    use limits, only: CASCADE_SET_FILL_RATIO, MAX_WARN_RESONANCE !NODEP!
    <Use file utils>
    use diagnostics !NODEP!

    <Cascades: interfaces>

    contains

    <Cascades: procedures>

    <Cascades: tests>

end module cascades

```

11.7.1 The mapping modes

The valid mapping modes, to be used below. We will make use of the convention that mappings of internal particles have a positive value. Only for positive values, the flavor code is propagated when combining cascades.

```

<Mapping modes>≡
    integer, parameter :: &
        & EXTERNAL_PRT = -1, &
        & NO_MAPPING = 0, S_CHANNEL = 1, T_CHANNEL = 2, U_CHANNEL = 3, &
        & RADIATION = 4, COLLINEAR = 5, INFRARED = 6, &
        & STEP_MAPPING_E = 11, STEP_MAPPING_H = 12

    <Cascades: parameters>≡
    <Mapping modes>

```

11.7.2 The cascade type

A cascade is essentially the same as a decay tree (both definitions may be merged in a later version). It contains a linked tree of nodes, each of which representing an internal particle. In contrast to decay trees, each node has a definite particle code. These nodes need not be modified, therefore we can use pointers and do not have to copy them. Thus, physically each cascades has only a single node, the mother particle. However, to be able to compare trees quickly, we store in addition an array of binary codes which is always sorted in ascending order. This is accompanied by a corresponding list of particle codes. The index is the location of the corresponding cascade in the cascade set, this may be used to access the daughters directly.

The real mass is the particle mass belonging to the particle code. The minimal mass is the sum of the real masses of all its daughters; this is the kinematical cutoff. The effective mass may be zero if the particle mass is below a certain threshold; it may be the real mass if the particle is resonant; or it may be some other value.

The logical `t_channel` is set if this a t -channel line, while `initial` is true only for an initial particle. Note that both initial particles are also `t_channel` by definition, and that they are distinguished by the direction of the tree: One of them decays and is the root of the tree, while the other one is one of the leaves.

The cascade is a list of nodes (particles) which are linked via the `daughter` entries. The node is the mother particle of the decay cascade. Much of the information in the nodes is repeated in arrays, to be accessible more easily. The arrays will be kept sorted by binary codes.

The counter `n_off_shell` is increased for each internal line that is neither resonant nor log-enhanced. It is set to zero if the current line is resonant, since this implies on-shell particle production and subsequent decay.

The counter `n_t_channel` is non-negative once an initial particle is included in the tree: then, it counts the number of t -channel lines.

The `multiplicity` is the number of branchings to follow until all daughters are on-shell. A resonant or non-decaying particle has multiplicity one. Merging nodes, the multiplicities add unless the mother is a resonance. An initial or final node has multiplicity zero.

The arrays correspond to the subnode tree `tree` of the current cascade. PDG codes are stored only for those positions which are resonant, with the exception of the last entry, i.e., the current node. Other positions, in particular external legs, are assigned undefined PDG code.

A cascade is uniquely identified by its tree, the tree of PDG codes, and the tree of mappings. The tree of resonances is kept only to mask the PDG tree as described above.

$\langle \text{Cascades: types} \rangle \equiv$

```

type :: cascade_t

    end if
end subroutine cascade_write

```

11.7.3 Creating new cascades

This initializes a single-particle cascade (external, final state). The PDG entry in the tree is set undefined because the cascade is not resonant. However, the flavor entry is set, so the cascade flavor is identified nevertheless.

```
(Cascades: procedures)+≡
  subroutine cascade_init_outgoing (cascade, flv, pos, m_thr)
    type(cascade_t), intent(out) :: cascade
    type(flavor_t), intent(in) :: flv
    integer, intent(in) :: pos
    real(default), intent(in) :: m_thr
    call cascade_init (cascade, 1)
    cascade%bincode = ibset (0_TC, pos-1)
    cascade%flv = flv
    cascade%pdg = abs (flavor_get_pdg (cascade%flv))
    cascade%is_vector = flavor_get_spin_type (flv) == VECTOR
    cascade%m_min = flavor_get_mass (flv)
    cascade%m_rea = cascade%m_min
    if (cascade%m_rea >= m_thr) then
      cascade%m_eff = cascade%m_rea
    end if
    cascade%on_shell = .true.
    cascade%multiplicity = 1
    cascade%tree(1) = cascade%bincode
    cascade%tree_pdg(1) = cascade%pdg
    cascade%tree_mapping(1) = EXTERNAL_PRT
    cascade%tree_resonant(1) = .false.
  end subroutine cascade_init_outgoing
```

The same for an incoming line:

```
(Cascades: procedures)+≡
  subroutine cascade_init_incoming (cascade, flv, pos, m_thr)
    type(cascade_t), intent(out) :: cascade
    type(flavor_t), intent(in) :: flv
    integer, intent(in) :: pos
    real(default), intent(in) :: m_thr
    call cascade_init (cascade, 1)
    cascade%incoming = .true.
    cascade%bincode = ibset (0_TC, pos-1)
    cascade%flv = flavor_anti (flv)
    cascade%pdg = abs (flavor_get_pdg (flv))
    cascade%is_vector = flavor_get_spin_type (flv) == VECTOR
    cascade%m_min = flavor_get_mass (flv)
    cascade%m_rea = cascade%m_min
    if (cascade%m_rea >= m_thr) then
      cascade%m_eff = cascade%m_rea
    end if
    cascade%on_shell = .true.
    cascade%n_t_channel = 0
    cascade%n_off_shell = 0
    cascade%tree(1) = cascade%bincode
    cascade%tree_pdg(1) = cascade%pdg
    cascade%tree_mapping(1) = EXTERNAL_PRT
  end subroutine cascade_init_incoming
```

```

        cascade%tree_resonant(1) = .false.
    end subroutine cascade_init_incoming

```

11.7.4 Tools

This function returns true if the two cascades share no common external particle. This is a requirement for joining them.

```

<Cascades: interfaces>≡
    interface operator(.disjunct.)
        module procedure cascade_disjunct
    end interface

<Cascades: procedures>+=
    function cascade_disjunct (cascade1, cascade2) result (flag)
        logical :: flag
        type(cascade_t), intent(in) :: cascade1, cascade2
        flag = iand (cascade1%bincode, cascade2%bincode) == 0
    end function cascade_disjunct

```

Compute a hash code for the resonance pattern of a cascade. We count the number of times each particle appears as a resonance.

We pack the PDG codes of the resonances in two arrays (s-channel and t-channel), sort them both, concatenate the results, transfer to i8 integers, and compute the hash code from this byte stream.

```

<Cascades: procedures>+=
    subroutine cascade_assign_resonance_hash (cascade)
        type(cascade_t), intent(inout) :: cascade
        integer(i8), dimension(1) :: mold
        cascade%res_hash = hash (transfer &
            (concat (sort (pack (cascade%tree_pdg, &
                cascade%tree_resonant))), &
                sort (pack (cascade%tree_pdg, &
                    cascade%tree_mapping == T_CHANNEL .or. &
                    cascade%tree_mapping == U_CHANNEL))), &
            mold))
    end subroutine cascade_assign_resonance_hash

```

11.7.5 Hash entries for cascades

We will set up a hash array which contains keys of and pointers to cascades. We hold a list of cascade (pointers) within each bucket. This is not for collision resolution, but for keeping similar, but unequal cascades together.

```

<Cascades: types>+=
    type :: cascade_p
        type(cascade_t), pointer :: cascade => null ()
        type(cascade_p), pointer :: next => null ()
    end type cascade_p

```

Here is the bucket or hash entry type:

```
(Cascades: types)+≡
type :: hash_entry_t
integer(i32) :: hashval = 0
integer(i8), dimension(:), allocatable :: key
type(cascade_p), pointer :: first => null ()
type(cascade_p), pointer :: last => null ()
end type hash_entry_t
```

Finalize: just deallocate the list; the contents are just pointers.

```
(Cascades: procedures)+≡
subroutine hash_entry_final (hash_entry)
type(hash_entry_t), intent(inout) :: hash_entry
type(cascade_p), pointer :: current
do while (associated (hash_entry%first))
current => hash_entry%first
hash_entry%first => current%next
deallocate (current)
end do
end subroutine hash_entry_final
```

Output: concise format for debugging, just list cascade indices.

```
(Cascades: procedures)+≡
subroutine hash_entry_write (hash_entry, unit)
type(hash_entry_t), intent(in) :: hash_entry
integer, intent(in), optional :: unit
type(cascade_p), pointer :: current
integer :: u, i
u = output_unit (unit); if (u < 0) return
write (u, "(1x,A)", advance="no") "Entry:"
do i = 1, size (hash_entry%key)
write (u, "(1x,I0)", advance="no") hash_entry%key(i)
end do
write (u, "(1x,A)", advance="no") "->"
current => hash_entry%first
do while (associated (current))
write (u, "(1x,I7)", advance="no") current%cascade%index
current => current%next
end do
write (u, *)
end subroutine hash_entry_write
```

This function adds a cascade pointer to the bucket. If ok is present, check first if it is already there and return failure if yes. If cascade_ptr is also present, set it to the current cascade if successful. If not, set it to the cascade that is already there.

```
(Cascades: procedures)+≡
subroutine hash_entry_add_cascade_ptr (hash_entry, cascade, ok, cascade_ptr)
type(hash_entry_t), intent(inout) :: hash_entry
type(cascade_t), intent(in), target :: cascade
logical, intent(out), optional :: ok
type(cascade_t), optional, pointer :: cascade_ptr
```

```

type(cascade_p), pointer :: current
if (present (ok)) then
  call hash_entry_check_cascade (hash_entry, cascade, ok, cascade_ptr)
  if (.not. ok) return
end if
allocate (current)
current%cascade => cascade
if (associated (hash_entry%last)) then
  hash_entry%last%next => current
else
  hash_entry%first => current
end if
hash_entry%last => current
end subroutine hash_entry_add_cascade_ptr

```

This function checks whether a cascade is already in the bucket. For incomplete cascades, we look for an exact match. It should suffice to verify the tree, the PDG codes, and the mapping modes. This is the information that is written to the phase space file.

For complete cascades, we ignore the PDG code at positions with mappings infrared, collinear, or t/u-channel. Thus a cascade which is distinguished only by PDG code at such places, is flagged existent. If the convention is followed that light particles come before heavier ones (in the model definition), this ensures that the lightest particle is kept in the appropriate place, corresponding to the strongest peak.

For external cascades (incoming/outgoing) we take the PDG code into account even though it is zeroed in the PDG-code tree.

(Cascades: procedures)+≡

```

subroutine hash_entry_check_cascade (hash_entry, cascade, ok, cascade_ptr)
  type(hash_entry_t), intent(in), target :: hash_entry
  type(cascade_t), intent(in), target :: cascade
  logical, intent(out) :: ok
  type(cascade_t), optional, pointer :: cascade_ptr
  type(cascade_p), pointer :: current
  integer, dimension(:), allocatable :: tree_pdg
  ok = .true.
  allocate (tree_pdg (size (cascade%tree_pdg)))
  if (cascade%complete) then
    where (cascade%tree_mapping == INFRARED .or. &
           cascade%tree_mapping == COLLINEAR .or. &
           cascade%tree_mapping == T_CHANNEL .or. &
           cascade%tree_mapping == U_CHANNEL)
      tree_pdg = 0
    elsewhere
      tree_pdg = cascade%tree_pdg
    end where
  else
    tree_pdg = cascade%tree_pdg
  end if
  current => hash_entry%first
  do while (associated (current))
    if (current%cascade%depth == cascade%depth) then
      if (all (current%cascade%tree == cascade%tree)) then

```

```

        if (all (current%cascade%tree_mapping == cascade%tree_mapping)) &
            then
                if (all (current%cascade%tree_pdg .match. tree_pdg)) then
                    if (present (cascade_ptr)) cascade_ptr => current%cascade
                    ok = .false.; return
                end if
            end if
        end if
    end if
    current => current%next
end do
if (present (cascade_ptr)) cascade_ptr => cascade
end subroutine hash_entry_check_cascade

```

For PDG codes, we specify that the undefined code matches any code. This is already defined for flavor objects, but here we need it for the codes themselves.

```

<Cascades: interfaces>+≡
    interface operator(.match.)
        module procedure pdg_match
    end interface

<Cascades: procedures>+≡
    elemental function pdg_match (pdg1, pdg2) result (flag)
        logical :: flag
        integer(TC), intent(in) :: pdg1, pdg2
        select case (pdg1)
        case (0)
            flag = .true.
        case default
            select case (pdg2)
            case (0)
                flag = .true.
            case default
                flag = pdg1 == pdg2
            end select
        end select
    end function pdg_match

```

11.7.6 The cascade set

The cascade set will later be transformed into the decay forest. It is set up as a linked list. In addition to the usual **first** and **last** pointers, there is a **first_t** pointer which points to the first t-channel cascade (after all s-channel cascades), and a **first_k** pointer which points to the first final cascade (with a keystone).

As an auxiliary device, the object contains a hash array with associated parameters where an additional pointer is stored for each cascade. The keys are made from the relevant cascade data. This hash is used for fast detection (and thus avoidance) of double entries in the cascade list.

```

<Cascades: public>≡
    public :: cascade_set_t

```

```

<Cascades: types>+≡
type :: cascade_set_t
private
type(model_t), pointer :: model
integer :: n_in, n_out, n_tot
type(flavor_t), dimension(:,:), allocatable :: flv
integer :: depth_out, depth_tot
real(default) :: sqrts = 0
real(default) :: m_threshold_s = 0
real(default) :: m_threshold_t = 0
integer :: off_shell = 0
integer :: t_channel = 0
logical :: keep_nonresonant
integer :: n_groves = 0
! The cascade list
type(cascade_t), pointer :: first => null ()
type(cascade_t), pointer :: last => null ()
type(cascade_t), pointer :: first_t => null ()
type(cascade_t), pointer :: first_k => null ()
! The hashtable
integer :: n_entries = 0
real :: fill_ratio = 0
integer :: n_entries_max = 0
integer(i32) :: mask = 0
logical :: fatal_beam_decay = .true.
type(hash_entry_t), dimension(:), allocatable :: entry
end type cascade_set_t

```

Return true if there are cascades which are active and complete, so the phase space file would be nonempty.

```

<Cascades: public>+≡
public :: cascade_set_is_valid

<Cascades: procedures>+≡
function cascade_set_is_valid (cascade_set) result (flag)
logical :: flag
type(cascade_set_t), intent(in) :: cascade_set
type(cascade_t), pointer :: cascade
flag = .false.
cascade => cascade_set%first_k
do while (associated (cascade))
    if (cascade%active .and. cascade%complete) then
        flag = .true.
        return
    end if
    cascade => cascade%next
end do
end function cascade_set_is_valid

```

The initializer sets up the hash table with some initial size guessed by looking at the number of external particles. We choose 256 for 3 external particles and a factor of 4 for each additional particle, limited at $2^{30}=1\text{G}$.

```

<Limits: public parameters>+≡

```

```

real, parameter, public :: CASCADE_SET_FILL_RATIO = 0.1

```

11.7.7 Adding cascades

Add a deep copy of a cascade to the set. The copy has all content of the original, but the pointers are nullified. We do not care whether insertion was successful or not. The pointer argument, if present, is assigned to the input cascade, or to the hash entry if it is already present.

The procedure is recursive: any daughter or mother entries are also deep-copied and added to the cascade set before the current copy is added.

```

<Cascades: procedures>+≡
recursive subroutine cascade_set_add_copy &
  (cascade_set, cascade_in, cascade_ptr)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in) :: cascade_in
  type(cascade_t), optional, pointer :: cascade_ptr
  type(cascade_t), pointer :: cascade
  logical :: ok
  allocate (cascade)
  cascade = cascade_in
  if (associated (cascade_in%daughter1)) call cascade_set_add_copy &
    (cascade_set, cascade_in%daughter1, cascade%daughter1)
  if (associated (cascade_in%daughter2)) call cascade_set_add_copy &
    (cascade_set, cascade_in%daughter2, cascade%daughter2)
  if (associated (cascade_in%mother)) call cascade_set_add_copy &
    (cascade_set, cascade_in%mother, cascade%mother)
  cascade%next => null ()
  call cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
end subroutine cascade_set_add_copy

```

Add a cascade to the set. This does not deep-copy. We first try to insert it in the hash array. If successful, add it to the list. Failure indicates that it is already present, and we drop it.

The hash key is built solely from the tree array, so neither particle codes nor resonances count, just topology.

Technically, hash and list receive only pointers, so the cascade can be considered as being in either of both. We treat it as part of the list.

```

<Cascades: procedures>+≡
subroutine cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
  type(cascade_set_t), intent(inout), target :: cascade_set

```

```

type(cascade_t), intent(in), target :: cascade
logical, intent(out) :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i8), dimension(1) :: mold
call cascade_set_hash_insert &
    (cascade_set, transfer (cascade%tree, mold), cascade, ok, cascade_ptr)
if (ok) call cascade_set_list_add (cascade_set, cascade)
end subroutine cascade_set_add

```

Add a new cascade to the list:

```

<Cascades: procedures>+=
subroutine cascade_set_list_add (cascade_set, cascade)
type(cascade_set_t), intent(inout) :: cascade_set
type(cascade_t), intent(in), target :: cascade
if (associated (cascade_set%last)) then
    cascade_set%last%next => cascade
else
    cascade_set%first => cascade
end if
cascade_set%last => cascade
end subroutine cascade_set_list_add

```

Add a cascade entry to the hash array:

```

<Cascades: procedures>+=
subroutine cascade_set_hash_insert &
    (cascade_set, key, cascade, ok, cascade_ptr)
type(cascade_set_t), intent(inout), target :: cascade_set
integer(i8), dimension(:), intent(in) :: key
type(cascade_t), intent(in), target :: cascade
logical, intent(out) :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i32) :: h
if (cascade_set%n_entries >= cascade_set%n_entries_max) &
    call cascade_set_hash_expand (cascade_set)
h = hash (key)
call cascade_set_hash_insert_rec &
    (cascade_set, h, h, key, cascade, ok, cascade_ptr)
end subroutine cascade_set_hash_insert

```

Double the hashtable size when necessary:

```

<Cascades: procedures>+=
subroutine cascade_set_hash_expand (cascade_set)
type(cascade_set_t), intent(inout), target :: cascade_set
type(hash_entry_t), dimension(:), allocatable, target :: table_tmp
type(cascade_p), pointer :: current
integer :: i, s
allocate (table_tmp (0:cascade_set%mask))
table_tmp = cascade_set%entry
deallocate (cascade_set%entry)
s = 2 * size (table_tmp)
cascade_set%n_entries = 0
cascade_set%n_entries_max = s * cascade_set%fill_ratio

```

```

cascade_set%mask = s - 1
allocate (cascade_set%entry (0:cascade_set%mask))
do i = 0, ubound (table_tmp, 1)
  current => table_tmp(i)%first
  do while (associated (current))
    call cascade_set_hash_insert_rec &
      (cascade_set, table_tmp(i)%hashval, table_tmp(i)%hashval, &
        table_tmp(i)%key, current%cascade)
    current => current%next
  end do
end do
end subroutine cascade_set_hash_expand

```

Insert the cascade at the bucket determined by the hash value. If the bucket is filled, check first for a collision (unequal keys). In that case, choose the following bucket and repeat. Otherwise, add the cascade to the bucket.

If the bucket is empty, record the hash value, allocate and store the key, and then add the cascade to the bucket.

If ok is present, before insertion we check whether the cascade is already stored, and return failure if yes.

(Cascades: procedures)+≡

```

recursive subroutine cascade_set_hash_insert_rec &
  (cascade_set, h, hashval, key, cascade, ok, cascade_ptr)
  type(cascade_set_t), intent(inout) :: cascade_set
  integer(i32), intent(in) :: h, hashval
  integer(i8), dimension(:), intent(in) :: key
  type(cascade_t), intent(in), target :: cascade
  logical, intent(out), optional :: ok
  type(cascade_t), optional, pointer :: cascade_ptr
  integer(i32) :: i
  i = iand (h, cascade_set%mask)
  if (allocated (cascade_set%entry(i)%key)) then
    if (size (cascade_set%entry(i)%key) /= size (key)) then
      call cascade_set_hash_insert_rec &
        (cascade_set, h + 1, hashval, key, cascade, ok, cascade_ptr)
    else if (any (cascade_set%entry(i)%key /= key)) then
      call cascade_set_hash_insert_rec &
        (cascade_set, h + 1, hashval, key, cascade, ok, cascade_ptr)
    else
      call hash_entry_add_cascade_ptr &
        (cascade_set%entry(i), cascade, ok, cascade_ptr)
    end if
  else
    cascade_set%entry(i)%hashval = hashval
    allocate (cascade_set%entry(i)%key (size (key)))
    cascade_set%entry(i)%key = key
    call hash_entry_add_cascade_ptr &
      (cascade_set%entry(i), cascade, ok, cascade_ptr)
    cascade_set%n_entries = cascade_set%n_entries + 1
  end if
end subroutine cascade_set_hash_insert_rec

```

11.7.8 External particles

We want to initialize the cascade set with the outgoing particles. In case of multiple processes, initial cascades are prepared for all of them. The hash array check ensures that no particle appears more than once at the same place.

```

<Cascades: interfaces>+=
  interface cascade_set_add_outgoing
    module procedure cascade_set_add_outgoing1
    module procedure cascade_set_add_outgoing2
  end interface

<Cascades: procedures>+=
  subroutine cascade_set_add_outgoing2 (cascade_set, flv)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(flavor_t), dimension(:,:), intent(in) :: flv
    integer :: pos, prc, n_out, n_prc
    type(cascade_t), pointer :: cascade
    logical :: ok
    n_out = size (flv, dim=1)
    n_prc = size (flv, dim=2)
    do prc = 1, n_prc
      do pos = 1, n_out
        allocate (cascade)
        call cascade_init_outgoing &
          (cascade, flv(pos,prc), pos, cascade_set%m_threshold_s)
        call cascade_set_add (cascade_set, cascade, ok)
        if (.not. ok) then
          deallocate (cascade)
        end if
      end do
    end do
  end subroutine cascade_set_add_outgoing2

  subroutine cascade_set_add_outgoing1 (cascade_set, flv)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(flavor_t), dimension(:), intent(in) :: flv
    integer :: pos, n_out
    type(cascade_t), pointer :: cascade
    logical :: ok
    n_out = size (flv, dim=1)
    do pos = 1, n_out
      allocate (cascade)
      call cascade_init_outgoing &
        (cascade, flv(pos), pos, cascade_set%m_threshold_s)
      call cascade_set_add (cascade_set, cascade, ok)
      if (.not. ok) then
        deallocate (cascade)
      end if
    end do
  end subroutine cascade_set_add_outgoing1

```

The incoming particles are added one at a time. Nevertheless, we may have several processes which are looped over. At the first opportunity, we set the

pointer `first_t` in the cascade set which should point to the first t-channel cascade.

Return the indices of the first and last cascade generated.

(Cascades: interfaces)+≡

```

```

11.7.9 Cascade combination I: flavor assignment

We have two disjunct cascades, now use the vertex table to determine the possible flavors of the combination cascade. For each possibility, try to generate a new cascade. The total cascade depth has to be one less than the limit, because this is reached by setting the keystone.

```

<Cascades: procedures>+=
subroutine cascade_match_pair (cascade_set, cascade1, cascade2, s_channel)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in), target :: cascade1, cascade2
  logical, intent(in) :: s_channel
  integer, dimension(:), allocatable :: pdg3
  integer :: i, depth_max
  type(flavor_t) :: flv
  if (s_channel) then
    depth_max = cascade_set%depth_out
  else
    depth_max = cascade_set%depth_tot
  end if
  if (cascade1%depth + cascade2%depth < depth_max) then
    call model_match_vertex (cascade_set%model, &
      flavor_get_pdg (cascade1%flv), &
      flavor_get_pdg (cascade2%flv), &
      pdg3)
    do i = 1, size (pdg3)
      call flavor_init (flv, pdg3(i), cascade_set%model)
      if (s_channel) then
        call cascade_combine_s (cascade_set, cascade1, cascade2, flv)
      else
        call cascade_combine_t (cascade_set, cascade1, cascade2, flv)
      end if
    end do
    deallocate (pdg3)
  end if
end subroutine cascade_match_pair

```

The triplet version takes a third cascade, and we check whether this triplet has a matching vertex in the database. If yes, we make a keystone cascade.

```

<Cascades: procedures>+=
subroutine cascade_match_triplet &
  (cascade_set, cascade1, cascade2, cascade3, s_channel)
  type(cascade_set_t), intent(inout), target :: cascade_set

```

```

type(cascade_t), intent(in), target :: cascade1, cascade2, cascade3
logical, intent(in) :: s_channel
integer :: depth_max
depth_max = cascade_set%depth_tot
if (cascade1%depth + cascade2%depth + cascade3%depth == depth_max) then
  if (model_check_vertex (cascade_set%model, &
    flavor_get_pdg (cascade1%flv), &
    flavor_get_pdg (cascade2%flv), &
    flavor_get_pdg (cascade3%flv))) then
    call cascade_combine_keystone &
      (cascade_set, cascade1, cascade2, cascade3, s_channel)
  end if
end if
end subroutine cascade_match_triplet

```

11.7.10 Cascade combination II: kinematics setup and check

Having three matching flavors, we start constructing the combination cascade. We look at the mass hierarchies and determine whether the cascade is to be kept. In passing we set mapping modes, resonance properties and such.

If successful, the cascade is finalized. For a resonant cascade, we prepare in addition a copy without the resonance.

```

Here we complete a decay cascade. The third input is the single-particle cascade for the initial particle. There is no resonance or mapping assignment. The only condition for keeping the cascade is the mass sum of the final state, which must be less than the available energy.

Two modifications are necessary for scattering cascades: a pure s-channel diagram (cascade1 is the incoming particle) do not have a logarithmic mapping at top-level. And in a t-channel diagram, the last line exchanged is mapped t-channel, not u-channel. In both cases we register a new cascade with the modified mapping.

11.7.11 Cascade combination III: node connections and tree fusion

Here we assign global tree properties. If the allowed number of off-shell lines is exceeded, discard the new cascade. Otherwise, assign the trees, sort them, and assign connections. Finally, append the cascade to the list. This may fail (because in the hash array there is already an equivalent cascade). On failure, discard the cascade.

(Cascades: procedures) +=

```

            deallocate (cascade4)
        end if
    end if
end subroutine cascade_keystone

```

Sort a tree (array of binary codes) and particle code array simultaneously, by ascending binary codes. A convenient method is to use the `maxloc` function iteratively, to find and remove the largest entry in the tree array one by one.

(*Cascades: procedures*) +=

```

subroutine tree_sort (tree, pdg, mapping, resonant)
    integer(TC), dimension(:), intent(inout) :: tree
    integer, dimension(:), intent(inout) :: pdg, mapping
    logical, dimension(:), intent(inout) :: resonant
    integer(TC), dimension(size(tree)) :: tree_tmp
    integer, dimension(size(pdg)) :: pdg_tmp, mapping_tmp
    logical, dimension(size(resonant)) :: resonant_tmp
    integer, dimension(1) :: pos
    integer :: i
    tree_tmp = tree
    pdg_tmp = pdg
    mapping_tmp = mapping
    resonant_tmp = resonant
    do i = size(tree), 1, -1
        pos = maxloc (tree_tmp)
        tree(i) = tree_tmp (pos(1))
        pdg(i) = pdg_tmp (pos(1))
        mapping(i) = mapping_tmp (pos(1))
        resonant(i) = resonant_tmp (pos(1))
        tree_tmp(pos(1)) = 0
    end do
end subroutine tree_sort

```

11.7.12 Cascade set generation

These procedures loop over cascades and build up the cascade set. After each iteration of the innermost loop, we set a breakpoint.

s-channel: We use a nested scan to combine all cascades with all other cascades.

```
(Cascades: procedures) +=  
  subroutine cascade_set_generate_s (cascade_set)  
    type(cascade_set_t), intent(inout), target :: cascade_set  
    type(cascade_t), pointer :: cascade1, cascade2  
    cascade1 => cascade_set%first  
    LOOP1: do while (associated (cascade1))  
      cascade2 => cascade_set%first  
      LOOP2: do while (associated (cascade2))  
        if (cascade2%index >= cascade1%index) exit LOOP2  
        if (cascade1 .disjunct. cascade2) then  
          call cascade_match_pair (cascade_set, cascade1, cascade2, .true.)  
        end if  
        call terminate_now_if_signal ()  
        cascade2 => cascade2%next  
      end do LOOP2  
      cascade1 => cascade1%next  
    end do LOOP1  
  end subroutine cascade_set_generate_s
```

The t-channel cascades are directed and have a seed (one of the incoming particles) and a target (the other one). We loop over all possible seeds and targets. Inside this, we loop over all t-channel cascades (*cascade1*) and s-channel cascades (*cascade2*) and try to combine them.

```
(Cascades: procedures) +=  
  subroutine cascade_set_generate_t (cascade_set, pos_seed, pos_target)  
    type(cascade_set_t), intent(inout), target :: cascade_set  
    integer, intent(in) :: pos_seed, pos_target  
    type(cascade_t), pointer :: cascade_seed, cascade_target  
    type(cascade_t), pointer :: cascade1, cascade2  
    integer(TC) :: bc_seed, bc_target  
    bc_seed = ibset (0_TC, pos_seed-1)  
    bc_target = ibset (0_TC, pos_target-1)  
    cascade_seed => cascade_set%first_t  
    LOOP_SEED: do while (associated (cascade_seed))  
      if (cascade_seed%bincode == bc_seed) then  
        cascade_target => cascade_set%first_t  
        LOOP_TARGET: do while (associated (cascade_target))  
          if (cascade_target%bincode == bc_target) then  
            cascade1 => cascade_set%first_t  
            LOOP_T: do while (associated (cascade1))  
              if ((cascade1 .disjunct. cascade_target) &

    cascade_seed => cascade_seed%next
end do LOOP_SEED
end subroutine cascade_set_generate_scattering

```

11.7.13 Groves

Before assigning groves, assign hashcodes to the resonance patterns, so they can easily be compared.

(Cascades: procedures)+≡

```
subroutine cascade_set_assign_resonance_hash (cascade_set)
  type(cascade_set_t), intent(inout) :: cascade_set
  type(cascade_t), pointer :: cascade
  cascade => cascade_set%first_k
  do while (associated (cascade))
    call cascade_assign_resonance_hash (cascade)
    cascade => cascade%next
  end do
end subroutine cascade_set_assign_resonance_hash
```

After all cascades are recorded, we group the complete cascades in groves. A grove consists of cascades with identical multiplicity, number of resonances, log-enhanced, t-channel lines, and resonance flavors.

(Cascades: procedures)+≡

```
subroutine cascade_set_assign_groves (cascade_set)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), pointer :: cascade1, cascade2
  integer :: multiplicity
  integer :: n_resonances, n_log_enhanced, n_t_channel, n_off_shell
  integer :: res_hash
  integer :: grove
  grove = 0
  cascade1 => cascade_set%first_k
  do while (associated (cascade1))
    if (cascade1%active .and. cascade1%complete &
        .and. cascade1%grove == 0) then
      grove = grove + 1
      cascade1%grove = grove
      multiplicity = cascade1%multiplicity
      n_resonances = cascade1%n_resonances
      n_log_enhanced = cascade1%n_log_enhanced
      n_off_shell = cascade1%n_off_shell
      n_t_channel = cascade1%n_t_channel
      res_hash = cascade1%res_hash
      cascade2 => cascade1%next
      do while (associated (cascade2))
        if (cascade2%grove == 0) then
          if (cascade2%multiplicity == multiplicity &
              .and. cascade2%n_resonances == n_resonances &
              .and. cascade2%n_log_enhanced == n_log_enhanced &
              .and. cascade2%n_off_shell == n_off_shell &
              .and. cascade2%n_t_channel == n_t_channel &
              .and. cascade2%res_hash == res_hash) then
            cascade2%grove = grove
          end if
        end if
      end do
      call terminate_now_if_signal ()
      cascade2 => cascade2%next
    end if
  end do
```

```

        end do
    end if
    call terminate_now_if_signal ()
    cascade1 => cascade1%next
end do
cascade_set%n_groves = grove
end subroutine cascade_set_assign_groves

```

11.7.14 Generate the phase space file

Generate a complete phase space configuration.

For each flavor assignment: First, all s-channel graphs that can be built up from the outgoing particles. Then we distinguish (1) decay, where we complete the s-channel graphs by connecting to the input line, and (2) scattering, where we now generate t-channel graphs by introducing an incoming particle, and complete this by connecting to the other incoming particle.

After all cascade sets have been generated, merge them into a common set. This eliminates redundancies between flavor assignments.

```

<Cascades: public>+=
    public :: cascade_set_generate

<Cascades: procedures>+=
    subroutine cascade_set_generate &
        (cascade_set, model, n_in, n_out, flv, phs_par, fatal_beam_decay)
        type(cascade_set_t), intent(out) :: cascade_set
        type(model_t), intent(in), target :: model
        integer, intent(in) :: n_in, n_out
        type(flavor_t), dimension(:,:), intent(in) :: flv
        type(phs_parameters_t), intent(in) :: phs_par
        logical, intent(in) :: fatal_beam_decay
        type(cascade_set_t), dimension(:), allocatable :: cset
        type(cascade_t), pointer :: cascade
        integer :: i
        if (phase_space_vanishes (phs_par%sqrts, n_in, flv)) return
        call cascade_set_init (cascade_set, model, n_in, n_out, phs_par, &
            fatal_beam_decay, flv)
        allocate (cset (size (flv, 2)))
        do i = 1, size (cset)
            call cascade_set_generate_single (cset(i), &
                model, n_in, n_out, flv(:,i), phs_par, fatal_beam_decay)
            cascade => cset(i)%first_k
            do while (associated (cascade))
                if (cascade%active .and. cascade%complete) then
                    call cascade_set_add_copy (cascade_set, cascade)
                end if
                cascade => cascade%next
            end do
            call cascade_set_final (cset(i))
        end do
        cascade_set%first_k => cascade_set%first
        call cascade_set_assign_resonance_hash (cascade_set)
        call cascade_set_assign_groves (cascade_set)
    end subroutine cascade_set_generate

```

```
end subroutine cascade_set_generate
```

This generates phase space for a single channel, without assigning groves.

(Cascades: procedures)+≡

```

11.8 WOOD phase space

This is the module that interfaces the `phs_forests` phase-space treatment and the `cascades` module for generating phase-space channels. As an extension of the `phs_base` abstract type, the phase-space configuration and instance implement the standard API.

(Currently, this is the only generic phase-space implementation of `WHIZARD`. For trivial two-particle phase space, there is `phs_wood` as an alternative.)

11.8.3 Phase-space configuration

We read the phase-space configuration from the stored I/O unit. If this is not set, we assume that we have to generate a phase space configuration. When done, we open a scratch file and write the configuration.

If `rebuild` is set, we should trash any existing phase space file and build a new one. Otherwise, we try to use an old one, which we check for existence and integrity. If `ignore_mismatch` is set, we reuse an existing file even if it does not match the current setup.

```

<PHS wood: phs_wood_config: TBP>+≡
    procedure :: configure => phs_wood_config_configure

```

        call msg_fatal ()
    end if
end subroutine phs_wood_config_configure

```

The MD5 sum of the forest is computed in addition to the MD5 sum of the configuration. The reason is that the forest may depend on a user-provided external file. On the other hand, this MD5 sum encodes all information that is relevant for further processing. Therefore, the `get_md5sum` method returns this result, once it is available.

```

<PHS wood: phs wood config: TBP>+≡
    procedure :: compute_md5sum_forest => phs_wood_config_compute_md5sum_forest

<PHS wood: procedures>+≡
    subroutine phs_wood_config_compute_md5sum_forest (phs_config)

        phs%forest = phs_config%forest
    end select
  end subroutine phs_wood_init

```

11.8.5 Evaluation

We compute the outgoing momenta from the incoming momenta and the input parameter set `r_in` in channel `r_in`. We also compute the `r` parameters and Jacobians `f` for all other channels.

We do *not* need to apply a transformation from/to the c.m. frame, because in `phs_base` the momenta are already boosted to the c.m. frame before assigning them in the `phs` object, and inversely boosted when extracting them.

Note: We should postpone computation of the complete `r` and `f` arrays until after cut evaluation. This was done in the previous WHIZARD version, to save computing time for events which fail cut evaluation.

```

<PHS wood: phs wood: TBP>+=

Chapter 12

Random Number Generation

The integration and event generation modules need a random-number generator. Here, we provide an abstract interface for a random-number generator and a concrete implementation.

Module `rng_base`: Abstract type for interfacing or implementing a r.n.g.

Module `rng_tao`: Implementation as an interface to the TAO random number generator which the VAMP package provides.

Module `selectors`: Select from a range of integers based on a set of weights and a random-number generator.

12.1 Generic Random-Number Generator

For all generator implementations, we define a `rng` type which represents the state of a random-number generator with the associated methods that produce a random number. Furthermore, we define a `rng_factory` type. An object of this type is capable of allocating a sequence of `rng` objects. These generator states should be, if possible, statistically independent, so they can be used in parallel in different places of the event-generation chain.

```
<rng_base.f90>≡  
  <File header>
```

```
module rng_base
```

```
  use kinds !NODEP!
```

```
  <Use file utils>
```

```
  use unit_tests
```

```
  <Standard module head>
```

```
  <RNG base: public>
```

```
  <RNG base: types>
```

⟨RNG base: interfaces⟩

⟨RNG base: test types⟩

contains

⟨RNG base: procedures⟩

⟨RNG base: tests⟩

end module rng_base

12.1.1 Generator type

The `rng` object is actually the state of the random-number generator. The methods `initialize/reset` and `call` the generator for this state.

⟨RNG base: public⟩≡

public :: rng_t

⟨RNG base: types⟩≡

type, abstract :: rng_t

contains

⟨RNG base: rng: TBP⟩

end type rng_t

The `init` method initializes the generator and sets a seed. We should implement the interface such that a single integer is sufficient for a seed.

The seed may be omitted. The behavior without seed is not defined, however.

⟨RNG base: rng: TBP⟩≡

procedure (rng_init), deferred :: init

⟨RNG base: interfaces⟩≡

abstract interface

subroutine rng_init (rng, seed)

import

class(rng_t), intent(out) :: rng

integer, intent(in), optional :: seed

end subroutine rng_init

end interface

The `final` method deallocates memory where necessary and allows for another call of `init` to reset the generator.

⟨RNG base: rng: TBP⟩+≡

procedure (rng_final), deferred :: final

⟨RNG base: interfaces⟩+≡

abstract interface

subroutine rng_final (rng)

import

class(rng_t), intent(inout) :: rng

end subroutine rng_final

end interface

Output. We should, at least, identify the generator.

```

<RNG base: rng: TBP>+≡
  procedure (rng_write), deferred :: write
<RNG base: interfaces>+≡
  abstract interface
    subroutine rng_write (rng, unit, indent)
      import
      class(rng_t), intent(in) :: rng
      integer, intent(in), optional :: unit, indent
    end subroutine rng_write
  end interface

```

These routines generate a single and an array of default-precision random numbers, respectively.

```

<RNG base: rng: TBP>+≡
  generic :: generate => generate_single, generate_array
  procedure (rng_generate_single), deferred :: generate_single
  procedure (rng_generate_array), deferred :: generate_array
<RNG base: interfaces>+≡
  abstract interface
    subroutine rng_generate_single (rng, x)
      import
      class(rng_t), intent(inout) :: rng
      real(default), intent(out) :: x
    end subroutine rng_generate_single
  end interface

  abstract interface
    subroutine rng_generate_array (rng, x)
      import
      class(rng_t), intent(inout) :: rng
      real(default), dimension(:), intent(out) :: x
    end subroutine rng_generate_array
  end interface

```

12.1.2 RNG Factory

A factory object has a `make` method that allocates and initializes a new generator of appropriate type. It uses a 16-bit integer for initialization. For a real-life implementation, the factory should return a sequence of statistically independent generators, and for different seeds, the sequences should also be independent.

```

<RNG base: public>+≡
  public :: rng_factory_t
<RNG base: types>+≡
  type, abstract :: rng_factory_t
    contains
    <RNG base: rng factory: TBP>
  end type rng_factory_t

```

Output. Should be short, just report the seed and current state of the factory.

```

<RNG base: rng factory: TBP>≡
  procedure (rng_factory_write), deferred :: write

<RNG base: interfaces>+≡
  abstract interface
    subroutine rng_factory_write (object, unit)
      import
      class(rng_factory_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine rng_factory_write
  end interface

```

Initialize. It should be possible to do this repeatedly, resetting the state. The default seed should be 0.

```

<RNG base: rng factory: TBP>+≡
  procedure (rng_factory_init), deferred :: init

<RNG base: interfaces>+≡
  abstract interface
    subroutine rng_factory_init (factory, seed)
      import
      class(rng_factory_t), intent(out) :: factory
      integer(i16), intent(in), optional :: seed
    end subroutine rng_factory_init
  end interface

```

Spawn a new generator.

```

<RNG base: rng factory: TBP>+≡
  procedure (rng_factory_make), deferred :: make

<RNG base: interfaces>+≡
  abstract interface
    subroutine rng_factory_make (factory, rng)
      import
      class(rng_factory_t), intent(inout) :: factory
      class(rng_t), intent(out), allocatable :: rng
    end subroutine rng_factory_make
  end interface

```

12.1.3 Auxiliary stuff

Auxiliary for output:

```

<RNG base: procedures>≡
  subroutine write_indent (unit, indent)
    integer, intent(in) :: unit
    integer, intent(in), optional :: indent
    if (present (indent)) then
      write (unit, "(1x,A)", advance="no") repeat (" ", indent)
    end if
  end subroutine write_indent

```

12.1.4 Unit tests

```
<RNG base: public>+≡
  public :: rng_base_test

<RNG base: tests>≡
  subroutine rng_base_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <RNG base: execute tests>
  end subroutine rng_base_test
```

Test generator

The test 'mock' random generator generates a repeating series with the numbers 0.1, 0.3, 0.5, 0.7, 0.9. It has an integer stored as state. The integer must be one of 1, 3, 5, 7, 9.

```
<RNG base: public>+≡
  public :: rng_test_t

<RNG base: test types>≡
  type, extends (rng_t) :: rng_test_t
    integer :: state = 1
  contains
    procedure :: write => rng_test_write
    procedure :: init => rng_test_init
    procedure :: final => rng_test_final
    procedure :: generate_single => rng_test_generate_single
    procedure :: generate_array => rng_test_generate_array
  end type rng_test_t
```

Output. The state is a single number, so print it.

```
<RNG base: tests>+≡
  subroutine rng_test_write (rng, unit, indent)
    class(rng_test_t), intent(in) :: rng
    integer, intent(in), optional :: unit, indent
    integer :: u, ind
    u = output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(A,IO,A)") "Random-number generator: &
      &test (state = ", rng%state, ")"
  end subroutine rng_test_write
```

The default seed is 1.

```
<RNG base: tests>+≡
  subroutine rng_test_init (rng, seed)
    class(rng_test_t), intent(out) :: rng
    integer, intent(in), optional :: seed
    if (present (seed)) rng%state = seed
  end subroutine rng_test_init
```

Nothing to finalize:

```
<RNG base: tests>+≡  
  subroutine rng_test_final (rng)  
    class(rng_test_t), intent(inout) :: rng  
  end subroutine rng_test_final
```

Generate a single number and advance the state.

```
<RNG base: tests>+≡  
  subroutine rng_test_generate_single (rng, x)  
    class(rng_test_t), intent(inout) :: rng  
    real(default), intent(out) :: x  
    x = rng%state / 10._default  
    rng%state = mod (rng%state + 2, 10)  
  end subroutine rng_test_generate_single
```

The array generator calls the single-item generator multiple times.

```
<RNG base: tests>+≡  
  subroutine rng_test_generate_array (rng, x)  
    class(rng_test_t), intent(inout) :: rng  
    real(default), dimension(:), intent(out) :: x  
    integer :: i  
    do i = 1, size (x)  
      call rng%generate (x(i))  
    end do  
  end subroutine rng_test_generate_array
```

Test Factory

This factory makes `rng_test_t` generators, initialized with integers 1, 3, 5, 7, 9 if given the input 0, 1, 2, 3, 4. The generators within one sequence are all identical, however.

```
<RNG base: public>+≡  
  public :: rng_test_factory_t  
  
<RNG base: test types>+≡  
  type, extends (rng_factory_t) :: rng_test_factory_t  
    integer :: seed = 1  
  contains  
    <RNG base: rng test factory: TBP>  
  end type rng_test_factory_t
```

Output.

```
<RNG base: rng test factory: TBP>≡  
  procedure :: write => rng_test_factory_write  
  
<RNG base: tests>+≡  
  subroutine rng_test_factory_write (object, unit)  
    class(rng_test_factory_t), intent(in) :: object  
    integer, intent(in), optional :: unit  
    integer :: u  
    u = output_unit (unit)
```

```

        write (u, "(1x,A,I0,A)") "RNG factory: test (" , object%seed, ")"
    end subroutine rng_test_factory_write

```

Initialize, translating the given seed.

```

<RNG base: rng test factory: TBP>+≡
    procedure :: init => rng_test_factory_init

<RNG base: tests>+≡
    subroutine rng_test_factory_init (factory, seed)
        class(rng_test_factory_t), intent(out) :: factory
        integer(i16), intent(in), optional :: seed
        if (present (seed)) factory%seed = mod (seed * 2 + 1, 10)
    end subroutine rng_test_factory_init

```

call rng%final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: rng_base_2"

end subroutine rng_base_2

```

12.2 TAO Random-Number Generator

This module provides an implementation for the generic random-number generator. Actually, we interface the TAO random-number generator which is available via the VAMP package.

```

⟨rng_tao.f90⟩≡
  ⟨File header⟩

module rng_tao

  use kinds !NODEP!
  ⟨Use file utils⟩
  use unit_tests
  use tao_random_numbers !NODEP!

  use rng_base

  ⟨Standard module head⟩

  ⟨RNG tao: public⟩

  ⟨RNG tao: types⟩

contains

  ⟨RNG tao: procedures⟩

  ⟨RNG tao: tests⟩

end module rng_tao

```

12.2.1 Generator type

The rng object is actually the state of the random-number generator. The methods initialize/reset and call the generator for this state.

We keep the seed, in case we want to recover it later, and count the number of calls since seeding.

```

<RNG tao: public>≡
  public :: rng_tao_t

<RNG tao: types>≡
  type, extends (rng_t) :: rng_tao_t
    integer :: seed = 0
    integer :: n_calls = 0
    type(tao_random_state) :: state
  contains
    <RNG tao: rng tao: TBP>
  end type rng_tao_t

```

Output: Display seed and number of calls.

```

<RNG tao: rng tao: TBP>≡
  procedure :: write => rng_tao_write

<RNG tao: procedures>≡
  subroutine rng_tao_write (rng, unit, indent)
    class(rng_tao_t), intent(in) :: rng
    integer, intent(in), optional :: unit, indent
    integer :: u, ind
    u = output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(A)") "TA0 random-number generator:"
    call write_indent (u, ind)
    write (u, "(2x,A,I0)") "seed = ", rng%seed
    call write_indent (u, ind)
    write (u, "(2x,A,I0)") "calls = ", rng%n_calls
  end subroutine rng_tao_write

```

The `init` method initializes the generator and sets a seed. We should implement the interface such that a single integer is sufficient for a seed.

The seed may be omitted. The default seed is 0.

```

<RNG tao: rng tao: TBP>+≡
  procedure :: init => rng_tao_init

<RNG tao: procedures>+≡
  subroutine rng_tao_init (rng, seed)
    class(rng_tao_t), intent(out) :: rng
    integer, intent(in), optional :: seed
    if (present (seed)) rng%seed = seed
    call tao_random_create (rng%state, rng%seed)
  end subroutine rng_tao_init

```

The `final` method deallocates memory where necessary and allows for another call of `init` to reset the generator.

```

<RNG tao: rng tao: TBP>+≡
  procedure :: final => rng_tao_final

```

```

(RNG tao: procedures)+≡
  subroutine rng_tao_final (rng)
    class(rng_tao_t), intent(inout) :: rng
    call tao_random_destroy (rng%state)
  end subroutine rng_tao_final

```

These routines generate a single and an array of default-precision random numbers, respectively.

We have to convert from explicit double to abstract default precision. Under normal conditions, both are equivalent, however. Unless, someone decides to do single precision, there is always an interface for `tao_random_numbers`.

```

(RNG tao: rng tao: TBP)+≡
  procedure :: generate_single => rng_tao_generate_single
  procedure :: generate_array => rng_tao_generate_array

(RNG tao: procedures)+≡
  subroutine rng_tao_generate_single (rng, x)
    class(rng_tao_t), intent(inout) :: rng
    real(default), intent(out) :: x
    real(default) :: r
    call tao_random_number (rng%state, r)
    x = r
    rng%n_calls = rng%n_calls + 1
  end subroutine rng_tao_generate_single

  subroutine rng_tao_generate_array (rng, x)
    class(rng_tao_t), intent(inout) :: rng
    real(default), dimension(:), intent(out) :: x
    real(default) :: r
    integer :: i
    do i = 1, size (x)
      call tao_random_number (rng%state, r)
      x(i) = r
    end do
    rng%n_calls = rng%n_calls + size (x)
  end subroutine rng_tao_generate_array

```

Factory

This factory makes `rng_tao_t` generators, initialized with the seeds

$$s_i = s_0 * 2^{16} + i \quad (12.1)$$

where s_0 is the seed (a 16-bit integer) given to the factory object, and i is the index in the generated sequence of generators, starting with zero.

```

(RNG tao: public)+≡
  public :: rng_tao_factory_t

(RNG tao: types)+≡
  type, extends (rng_factory_t) :: rng_tao_factory_t
    integer(i16) :: s = 0
    integer(i16) :: i = 0

```

```

contains
  <RNG tao: rng tao factory: TBP>
end type rng_tao_factory_t

```

Output.

```

<RNG tao: rng tao factory: TBP>≡
  procedure :: write => rng_tao_factory_write

<RNG tao: procedures>+≡
  subroutine rng_tao_factory_write (object, unit)
    class(rng_tao_factory_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(1x,A,2(IO,A))") &
      "RNG factory: tao (" , object%s, ", ", object%i, ")"
  end subroutine rng_tao_factory_write

```

Initialize, translating the given seed.

```

<RNG tao: rng tao factory: TBP>+≡
  procedure :: init => rng_tao_factory_init

<RNG tao: procedures>+≡
  subroutine rng_tao_factory_init (factory, seed)
    class(rng_tao_factory_t), intent(out) :: factory
    integer(i16), intent(in), optional :: seed
    if (present (seed)) factory%s = seed
  end subroutine rng_tao_factory_init

```

```

<RNG tao: rng tao factory: TBP>+≡
  procedure :: make => rng_tao_factory_make

<RNG tao: procedures>+≡
  subroutine rng_tao_factory_make (factory, rng)
    class(rng_tao_factory_t), intent(inout) :: factory
    class(rng_t), intent(out), allocatable :: rng
    allocate (rng_tao_t :: rng)
    select type (rng)
    type is (rng_tao_t)
      call rng%init (factory%s * 65536 + factory%i)
      factory%i = int (factory%i + 1, kind = i16)
    end select
  end subroutine rng_tao_factory_make

```

12.2.2 Auxiliary stuff

Auxiliary for output:

```

<RNG tao: procedures>+≡
  subroutine write_indent (unit, indent)
    integer, intent(in) :: unit
    integer, intent(in), optional :: indent
    if (present (indent)) then

```

```

        write (unit, "(1x,A)", advance="no") repeat (" ", indent)
    end if
end subroutine write_indent

```

12.2.3 Unit tests

```

<RNG tao: public>+≡
    public :: rng_tao_test

<RNG tao: tests>≡
    subroutine rng_tao_test (u, results)
        integer, intent(in) :: u

```

Chapter 13

Multi-Channel Integration

In this chapter we provide a generic module for handling multi-channel phase space and concrete implementations.

Module mci_base: The abstract types and their methods. It provides a test integrator that is referenced in later unit tests.

Module mci_midpoint: A simple integrator that uses the midpoint rule to sample the integrand uniformly over the unit hypercube. There is only one integration channel, so this can be matched only to single-channel phase space.

Module mci_vamp: Interface for the VAMP package.

13.1 Generic Integrator

This module provides a multi-channel integrator (MCI) base type, a corresponding configuration type, and methods for integration and event generation.

```
<mci_base.f90>≡  
<File header>  
  
module mci_base  
  
    use kinds !NODEP!  
<Use strings>  
<Use file utils>  
    use diagnostics !NODEP!  
    use unit_tests  
    use cputime  
  
    use phs_base  
    use rng_base  
  
<Standard module head>  
  
<MCI base: public>  
  
<MCI base: types>
```

⟨MCI base: interfaces⟩

⟨MCI base: test types⟩

contains

⟨MCI base: procedures⟩

⟨MCI base: tests⟩

end module mci_base

13.1.1 MCI: integrator

The MCI object contains the methods for integration and event generation. For the actual work and data storage, it spawns an MCI instance object.

The base object contains the number of integration dimensions and the number of channels as configuration data. Further configuration data are stored in the concrete extensions.

The MCI sum contains all relevant information about the integrand. It can be used for comparing the current configuration against a previous one. If they match, we can skip an actual integration. (Implemented only for the VAMP version.)

There is a random-number generator (its state with associated methods) available as **rng**. It may or may not be used for integration. It will be used for event generation.

⟨MCI base: public⟩≡

public :: mci_t

⟨MCI base: types⟩≡

```
type, abstract :: mci_t
  integer :: n_dim = 0
  integer :: n_channel = 0
  integer :: n_chain = 0
  integer, dimension(:), allocatable :: chain
  character(32) :: md5sum = ""
  logical :: integral_known = .false.
  logical :: error_known = .false.
  logical :: efficiency_known = .false.
  real(default) :: integral = 0
  real(default) :: error = 0
  real(default) :: efficiency = 0
  logical :: use_timer = .false.
  type(timer_t) :: timer
  class(rng_t), allocatable :: rng
contains
⟨MCI base: mci: TBP⟩
end type mci_t
```

Finalizer: the random-number generator may need one.

⟨MCI base: mci: TBP⟩≡

```

procedure :: base_final => mci_final
procedure (mci_final), deferred :: final

<MCI base: procedures>+=
subroutine mci_final (object)
  class(mci_t), intent(inout) :: object
  if (allocated (object%rng)) call object%rng%final ()
end subroutine mci_final

```

Output: basic and extended output.

```

<MCI base: mci: TBP>+=
procedure :: base_write => mci_write
procedure (mci_write), deferred :: write

<MCI base: procedures>+=
subroutine mci_write (object, unit)
  class(mci_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u, i, j
  u = output_unit (unit)
  if (object%use_timer) then
    write (u, "(2x)", advance="no")

  if (object%n_chain > 0) then
    write (u, "(3x,A,I0)") "Number of chains" = ", object%n_chain
    write (u, "(3x,A)") "Chains:"
    do i = 1, object%n_chain
      write (u, "(5x,I0,':')", advance = "no") i
      do j = 1, object%n_channel
        if (object%chain(j) == i) &
          write (u, "(1x,I0)", advance = "no") j
        end do
      write (u, "(A)")
    end do
  end if
end subroutine mci_write

```

Print an informative message when starting integration.

```

<MCI base: mci: TBP>+=
procedure (mci_startup_message), deferred :: startup_message
procedure :: base_startup_message => mci_startup_message

```

```

<MCI base: procedures>+=
  subroutine mci_startup_message (mci, unit, n_calls)
    class(mci_t), intent(in) :: mci
    integer, intent(in), optional :: unit, n_calls
    if (mci%n_chain > 0) then
      write (msg_buffer, "(A,3(1x,I0,1x,A))") &
        "Integrator:", mci%n_chain, "chains,", &
        mci%n_channel, "channels,", &
        mci%n_dim, "dimensions"
    else
      write (msg_buffer, "(A,3(1x,I0,1x,A))") &
        "Integrator:", &
        mci%n_channel, "channels,", &
        mci%n_dim, "dimensions"
    end if
    call msg_message (unit = unit)
  end subroutine mci_startup_message

```

There is no Initializer for the abstract type, but a generic setter for the number of channels and dimensions. We make two aliases available, to be able to override it.

```

<MCI base: mci: TBP>+=
  procedure :: set_dimensions => mci_set_dimensions
  procedure :: base_set_dimensions => mci_set_dimensions

<MCI base: procedures>+=
  subroutine mci_set_dimensions (mci, n_dim, n_channel)
    class(mci_t), intent(inout) :: mci
    integer, intent(in) :: n_dim
    integer, intent(in) :: n_channel
    mci%n_dim = n_dim
    mci%n_channel = n_channel
  end subroutine mci_set_dimensions

```

Declare particular dimensions as flat. This information can be used to simplify integration. When generating events, the flat dimensions should be sampled with uniform and uncorrelated distribution. It depends on the integrator what to do with that information.

```

<MCI base: mci: TBP>+=
  procedure (mci_declare_flat_dimensions), deferred :: declare_flat_dimensions

<MCI base: interfaces>=
  abstract interface
    subroutine mci_declare_flat_dimensions (mci, dim_flat)
      import
      class(mci_t), intent(inout) :: mci
      integer, dimension(:), intent(in) :: dim_flat
    end subroutine mci_declare_flat_dimensions
  end interface

```

Declare particular channels as equivalent, possibly allowing for permutations or reflections of dimensions. We use the information stored in the `phs_channel_t` object array that the phase-space module provides.

(We do not test this here, deferring the unit test to the `mci_vamp` implementation where we actually use this feature.)

```

<MCI base: mci: TBP>+≡
  procedure (mci_declare_equivalences), deferred :: declare_equivalences

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_declare_equivalences (mci, channel, dim_offset)
      import
      class(mci_t), intent(inout) :: mci
      type(phys_channel_t), dimension(:), intent(in) :: channel
      integer, intent(in) :: dim_offset
    end subroutine mci_declare_equivalences
  end interface

```

Declare particular channels as chained together. The implementation may use this array for keeping their weights equal to each other, etc.

The chain array is an array sized by the number of channels. For each channel, there is an integer entry that indicates the corresponding chains. The total number of chains is the maximum value of this entry.

```

<MCI base: mci: TBP>+≡
  procedure :: declare_chains => mci_declare_chains

<MCI base: procedures>+≡
  subroutine mci_declare_chains (mci, chain)
    class(mci_t), intent(inout) :: mci
    integer, dimension(:), intent(in) :: chain
    allocate (mci%chain (size (chain)))
    mci%n_chain = maxval (chain)
    mci%chain = chain
  end subroutine mci_declare_chains

```

Set the MD5 sum, independent of initialization.

```

<MCI base: mci: TBP>+≡
  procedure :: set_md5sum => mci_set_md5sum

<MCI base: procedures>+≡
  subroutine mci_set_md5sum (mci, md5sum)
    class(mci_t), intent(inout) :: mci
    character(32), intent(in) :: md5sum
    mci%md5sum = md5sum
  end subroutine mci_set_md5sum

```

Initialize a new integration pass. This is not necessarily meaningful, so we provide an empty base method. The `mci_vamp` implementation overrides this.

```

<MCI base: mci: TBP>+≡
  procedure :: add_pass => mci_add_pass

<MCI base: procedures>+≡
  subroutine mci_add_pass (mci, adapt_grids, adapt_weights, final)
    class(mci_t), intent(inout) :: mci
    logical, intent(in), optional :: adapt_grids
    logical, intent(in), optional :: adapt_weights

```

```

    logical, intent(in), optional :: final
end subroutine mci_add_pass

```

Allocate an instance with matching type. This must be deferred.

```

<MCI base: mci: TBP>+≡
    procedure (mci_allocate_instance), deferred :: allocate_instance

<MCI base: interfaces>+≡
    abstract interface
        subroutine mci_allocate_instance (mci, mci_instance)
            import
            class(mci_t), intent(in) :: mci
            class(mci_instance_t), intent(out), pointer :: mci_instance
        end subroutine mci_allocate_instance
    end interface

```

Import a random-number generator. We transfer the allocation of an existing generator state into the object. The generator state may already be initialized, or we can reset it by its `init` method.

```

<MCI base: mci: TBP>+≡
    procedure :: import_rng => mci_import_rng

<MCI base: procedures>+≡
    subroutine mci_import_rng (mci, rng)
        class(mci_t), intent(inout) :: mci
        class(rng_t), intent(inout), allocatable :: rng
        call move_alloc (rng, mci%rng)
    end subroutine mci_import_rng

```

Activate or deactivate the timer.

```

<MCI base: mci: TBP>+≡
    procedure :: set_timer => mci_set_timer

<MCI base: procedures>+≡
    subroutine mci_set_timer (mci, active)
        class(mci_t), intent(inout) :: mci
        logical, intent(in) :: active
        mci%use_timer = active
    end subroutine mci_set_timer

```

Start and stop signal for the timer, if active. The elapsed time can then be retrieved from the MCI record.

```

<MCI base: mci: TBP>+≡
    procedure :: start_timer => mci_start_timer
    procedure :: stop_timer => mci_stop_timer

<MCI base: procedures>+≡
    subroutine mci_start_timer (mci)
        class(mci_t), intent(inout) :: mci
        if (mci%use_timer) call mci%timer%start ()
    end subroutine mci_start_timer

    subroutine mci_stop_timer (mci)

```

```

class(mci_t), intent(inout) :: mci
if (mci%use_timer) call mci%timer%stop ()
end subroutine mci_stop_timer

```

Sampler test. Evaluate the sampler a given number of times. Results are discarded, so we don't need the MCI instance which would record them.

The evaluation channel is iterated, and the x parameters are randomly chosen.

```

⟨MCI base: mci: TBP⟩+≡
  procedure :: sampler_test => mci_sampler_test

⟨MCI base: procedures⟩+≡
  subroutine mci_sampler_test (mci, sampler, n_calls)
    class(mci_t), intent(inout) :: mci
    class(mci_sampler_t), intent(inout), target :: sampler
    integer, intent(in) :: n_calls
    real(default), dimension(:), allocatable :: x_in, f
    real(default), dimension(:,:), allocatable :: x_out
    real(default) :: val
    integer :: i, c
    allocate (x_in (mci%n_dim))
    allocate (f (mci%n_channel))
    allocate (x_out (mci%n_dim, mci%n_channel))
    do i = 1, n_calls
      c = mod (i, mci%n_channel) + 1
      call mci%rng%generate_array (x_in)
      call sampler%evaluate (c, x_in, val, x_out, f)
    end do
  end subroutine mci_sampler_test

```

Integrate: this depends on the implementation.

```

⟨MCI base: mci: TBP⟩+≡
  procedure (mci_integrate), deferred :: integrate

⟨MCI base: interfaces⟩+≡
  abstract interface
    subroutine mci_integrate (mci, instance, &
      sampler, n_it, n_calls, results, grove_weight)
      import
      class(mci_t), intent(inout) :: mci
      class(mci_instance_t), intent(inout) :: instance
      class(mci_sampler_t), intent(inout) :: sampler
      integer, intent(in) :: n_it
      integer, intent(in) :: n_calls
      real(default), dimension(:,:), intent(in), optional :: &
        grove_weight
      class(mci_results_t), intent(inout), optional :: results
    end subroutine mci_integrate
  end interface

```

Event generation. Depending on the implementation, event generation may or may not require a previous integration pass.

Instead of a black-box `simulate` method, we require an initializer, a finalizer, and procedures for generating a single event. This allows us to interface simulation event by event from the outside, and it facilitates the further processing of an event after successful generation. For integration, this is not necessary.

The initializer has `intent(inout)` for the `mci` passed object. The reason is that the initializer can read integration results and grids from file, where the results can modify the `mci` record.

```

(MCI base: mci: TBP)+≡
  procedure (mci_prepare_simulation), deferred :: prepare_simulation

(MCI base: interfaces)+≡
  abstract interface
    subroutine mci_prepare_simulation (mci)
      import
      class(mci_t), intent(inout) :: mci
    end subroutine mci_prepare_simulation
  end interface

```

The generated event will reside in in the `instance` object (overall results and weight) and in the `sampler` object (detailed data). In the real application, we can subsequently call methods of the `sampler` in order to further process the generated event.

The `target` attributes are required by the VAMP implementation, which uses pointers to refer to the instance and sampler objects from within the integration function.

```

(MCI base: mci: TBP)+≡
  procedure (mci_generate), deferred :: generate_weighted_event
  procedure (mci_generate), deferred :: generate_unweighted_event

(MCI base: interfaces)+≡
  abstract interface
    subroutine mci_generate (mci, instance, sampler)
      import
      class(mci_t), intent(inout) :: mci
      class(mci_instance_t), intent(inout), target :: instance
      class(mci_sampler_t), intent(inout), target :: sampler
    end subroutine mci_generate
  end interface

```

This is analogous, but we rebuild the event from the information stored in `state` instead of generating it.

```

(MCI base: mci: TBP)+≡
  procedure (mci_rebuild), deferred :: rebuild_event

(MCI base: interfaces)+≡
  abstract interface
    subroutine mci_rebuild (mci, instance, sampler, state)
      import
      class(mci_t), intent(inout) :: mci
      class(mci_instance_t), intent(inout) :: instance
      class(mci_sampler_t), intent(inout) :: sampler
      class(mci_state_t), intent(in) :: state
    end subroutine mci_rebuild

```

```
end interface
```

Return the value of the integral, error, efficiency, and time per call.

```
<MCI base: mci: TBP>+=
  procedure :: get_integral => mci_get_integral
  procedure :: get_error => mci_get_error
  procedure :: get_efficiency => mci_get_efficiency
  procedure :: get_time => mci_get_time

<MCI base: procedures>+=
function mci_get_integral (mci) result (integral)
  class(mci_t), intent(in) :: mci
  real(default) :: integral
  if (mci%integral_known) then
    integral = mci%integral
  else
    !!! JRR: WK please check
    ! error?
    integral = 0
  end if
end function mci_get_integral

function mci_get_error (mci) result (error)
  class(mci_t), intent(in) :: mci
  real(default) :: error
  if (mci%error_known) then
    error = mci%error
  else
    ! error?
    error = 0
  end if
end function mci_get_error

function mci_get_efficiency (mci) result (efficiency)
  class(mci_t), intent(in) :: mci
  real(default) :: efficiency
  if (mci%efficiency_known) then
    efficiency = mci%efficiency
  else
    ! error?
    efficiency = 0
  end if
end function mci_get_efficiency

function mci_get_time (mci) result (time)
  class(mci_t), intent(in) :: mci
  real(default) :: time
  if (mci%use_timer) then
    time = mci%timer
  else
    ! error?
    time = 0
  end if
end function mci_get_time
```

Return the MD5 sum of the configuration. This may be overridden in an extension, to return a different MD5 sum.

```

<MCI base: mci: TBP>+≡
  procedure :: get_md5sum => mci_get_md5sum

<MCI base: procedures>+≡
  function mci_get_md5sum (mci) result (md5sum)
    class(mci_t), intent(in) :: mci
    character(32) :: md5sum
    md5sum = mci%md5sum
  end function mci_get_md5sum

```

13.1.2 MCI instance

The base type contains an array of channel weights. The value `mci_weight` is the combined MCI weight that corresponds to a particular sampling point.

For convenience, we also store the `x` and Jacobian values for this sampling point.

```

<MCI base: public>+≡
  public :: mci_instance_t

<MCI base: types>+≡
  type, abstract :: mci_instance_t
    real(default), dimension(:), allocatable :: w
    real(default), dimension(:), allocatable :: f
    real(default), dimension(:, :), allocatable :: x
    integer :: selected_channel = 0
    real(default) :: mci_weight = 0
    real(default) :: integrand = 0
  contains
    <MCI base: mci instance: TBP>
  end type mci_instance_t

```

Output: deferred

```

<MCI base: mci instance: TBP>≡
  procedure (mci_instance_write), deferred :: write

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_instance_write (object, unit)
      import
      class(mci_instance_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine mci_instance_write
  end interface

```

A finalizer, just in case.

```

<MCI base: mci instance: TBP>+≡
  procedure (mci_instance_final), deferred :: final

```

```

<MCI base: interfaces>+=
  abstract interface
    subroutine mci_instance_final (object)
      import
      class(mci_instance_t), intent(inout) :: object
    end subroutine mci_instance_final
  end interface

```

Init: basic initializer for the arrays, otherwise deferred. Assigning the `mci` object is also deferred, because it depends on the concrete type.

The weights are initialized with an uniform normalized value.

```

<MCI base: mci instance: TBP>+=
  procedure (mci_instance_base_init), deferred :: init
  procedure :: base_init => mci_instance_base_init

<MCI base: procedures>+=
  subroutine mci_instance_base_init (mci_instance, mci)
    class(mci_instance_t), intent(out) :: mci_instance
    class(mci_t), intent(in), target :: mci
    allocate (mci_instance%w (mci%n_channel))
    allocate (mci_instance%f (mci%n_channel))
    allocate (mci_instance%x (mci%n_dim, mci%n_channel))
    if (size (mci_instance%w) /= 0) then
      mci_instance%w = 1._default / size (mci_instance%w)
    end if
    mci_instance%f = 0
    mci_instance%x = 0
  end subroutine mci_instance_base_init

```

Compute the overall weight factor for a configuration of x values and Jacobians f . The x values come in `n_channel` rows with `n_dim` entries each. The f factors constitute an array with `n_channel` entries.

We assume that the x and f arrays are already stored inside the MC instance. The result is also stored there.

```

<MCI base: mci instance: TBP>+=
  procedure (mci_instance_compute_weight), deferred :: compute_weight

<MCI base: interfaces>+=
  abstract interface
    subroutine mci_instance_compute_weight (mci, c)
      import
      class(mci_instance_t), intent(inout) :: mci
      integer, intent(in) :: c
    end subroutine mci_instance_compute_weight
  end interface

```

Record the integrand as returned by the sampler. Depending on the implementation, this may merely copy the value, or do more complicated things.

We may need the MCI weight for the actual computations, so this should be called after the previous routine.

```

<MCI base: mci instance: TBP>+=
  procedure (mci_instance_record_integrand), deferred :: record_integrand

```

```

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_instance_record_integrand (mci, integrand)
      import
      class(mci_instance_t), intent(inout) :: mci
      real(default), intent(in) :: integrand
    end subroutine mci_instance_record_integrand
  end interface

```

Sample a point directly: evaluate the sampler, then compute the weight and the weighted integrand. Finally, record the integrand within the MCI instance.

If a signal (interrupt) was raised recently, we abort the calculation before entering the sampler. Thus, a previous calculation will have completed and any data are already recorded, but any new point can be discarded. If the `abort` flag is present, we may delay the interrupt, so we can do some cleanup.

```

<MCI base: mci instance: TBP>+≡
  procedure :: evaluate => mci_instance_evaluate

<MCI base: procedures>+≡
  subroutine mci_instance_evaluate (mci, sampler, c, x)
    class(mci_instance_t), intent(inout) :: mci
    class(mci_sampler_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x
    real(default) :: val
    call sampler%evaluate (c, x, val, mci%x, mci%f)
    call mci%compute_weight (c)
    call mci%record_integrand (val)
  end subroutine mci_instance_evaluate

```

Initiate and terminate simulation. In contrast to integration, we implement these as methods of the process instance, since the `mci` configuration object is unchanged.

The safety factor reduces the acceptance probability for unweighted event. The implementation of this feature depends on the concrete type.

```

<MCI base: mci instance: TBP>+≡
  procedure (mci_instance_init_simulation), deferred :: init_simulation
  procedure (mci_instance_final_simulation), deferred :: final_simulation

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_instance_init_simulation (instance, safety_factor)
      import
      class(mci_instance_t), intent(inout) :: instance
      real(default), intent(in), optional :: safety_factor
    end subroutine mci_instance_init_simulation
  end interface

  abstract interface
    subroutine mci_instance_final_simulation (instance)
      import
      class(mci_instance_t), intent(inout) :: instance
    end subroutine mci_instance_final_simulation

```

```
end interface
```

Assuming that the sampler is in a completely defined state, just extract the data that `evaluate` would compute. Also record the integrand.

```
<MCI base: mci instance: TBP>+≡
  procedure :: fetch => mci_instance_fetch

<MCI base: procedures>+≡
  subroutine mci_instance_fetch (mci, sampler, c)
    class(mci_instance_t), intent(inout) :: mci
    class(mci_sampler_t), intent(in) :: sampler
    integer, intent(in) :: c
    real(default) :: val
    call sampler%fetch (val, mci%x, mci%f)
    call mci%compute_weight (c)
    call mci%record_integrand (val)
  end subroutine mci_instance_fetch
```

The value, i.e., the weighted integrand, is the integrand (which should be taken as-is from the sampler) multiplied by the MCI weight.

```
<MCI base: mci instance: TBP>+≡
  procedure :: get_value => mci_instance_get_value

<MCI base: procedures>+≡
  function mci_instance_get_value (mci) result (value)
    class(mci_instance_t), intent(in) :: mci
    real(default) :: value
    value = mci%integrand * mci%weight
  end function mci_instance_get_value
```

This is an extra routine. By default, the event weight is equal to the value returned by the previous routine. However, if we select a channel for event generation not just based on the channel weights, the event weight has to account for this bias, so the event weight that applies to event generation is different. In that case, we should override the default routine.

```
<MCI base: mci instance: TBP>+≡
  procedure :: get_event_weight => mci_instance_get_value
```

Excess weight can occur during unweighted event generation, if the assumed maximum value of the integrand is too small. This excess should be normalized in the same way as the event weight above (which for unweighted events becomes unity).

```
<MCI base: mci instance: TBP>+≡
  procedure (mci_instance_get_event_excess), deferred :: get_event_excess

<MCI base: interfaces>+≡
  abstract interface
    function mci_instance_get_event_excess (mci) result (excess)
      import
      class(mci_instance_t), intent(in) :: mci
      real(default) :: excess
    end function mci_instance_get_event_excess
  end interface
```

13.1.3 MCI state

This object can hold the relevant information that allows us to reconstruct the MCI instance without re-evaluating the sampler completely.

We store the `x_in` MC input parameter set, which coincides with the section of the complete `x` array that belongs to a particular channel. We also store the MC function value. When we want to reconstruct the state, we can use the input array to recover the complete `x` and `f` arrays (i.e., the kinematics), but do not need to recompute the MC function value (the dynamics).

The `mci_state_t` may be extended, to allow storing/recalling more information. In that case, we would override the type-bound procedures. However, the base type is also a concrete type and self-contained.

```

<MCI base: public>+≡
  public :: mci_state_t

<MCI base: types>+≡
  type :: mci_state_t
    integer :: selected_channel = 0
    real(default), dimension(:), allocatable :: x_in
    real(default) :: val
  contains
    <MCI base: mci state: TBP>
  end type mci_state_t

```

Output:

```

<MCI base: mci state: TBP>≡
  procedure :: write => mci_state_write

<MCI base: procedures>+≡
  subroutine mci_state_write (object, unit)
    class(mci_state_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(1x,A)") "MCI state:"
    write (u, "(3x,A,I0)") "Channel   = ", object%selected_channel
    write (u, "(3x,A,999(1x,F12.10))") "x (in)   = ", object%x_in
    write (u, "(3x,A,ES19.12)") "Integrand = ", object%val
  end subroutine mci_state_write

```

To store the object, we take the relevant section of the `x` array. The channel used for storing data is taken from the `instance` object, but it could be arbitrary in principle.

```

<MCI base: mci instance: TBP>+≡
  procedure :: store => mci_instance_store

<MCI base: procedures>+≡
  subroutine mci_instance_store (mci, state)
    class(mci_instance_t), intent(in) :: mci
    class(mci_state_t), intent(out) :: state
    state%selected_channel = mci%selected_channel
    allocate (state%x_in (size (mci%x, 1)))
    state%x_in = mci%x(:,mci%selected_channel)
  end subroutine mci_instance_store

```

```

    state%val = mci%integrand
end subroutine mci_instance_store

```

Recalling the state, we must consult the sampler in order to fully reconstruct the x and f arrays. The integrand value is known, and we also give it to the sampler, bypassing evaluation.

The final steps are equivalent to the `evaluate` method above.

```

⟨MCI base: mci instance: TBP⟩+≡
  procedure :: recall => mci_instance_recall

⟨MCI base: procedures⟩+≡
  subroutine mci_instance_recall (mci, sampler, state)
    class(mci_instance_t), intent(inout) :: mci
    class(mci_sampler_t), intent(inout) :: sampler
    class(mci_state_t), intent(in) :: state
    if (size (state%x_in) == size (mci%x, 1) &
        .and. state%selected_channel <= size (mci%x, 2)) then
      call sampler%rebuild (state%selected_channel, &
        state%x_in, state%val, mci%x, mci%f)
      call mci%compute_weight (state%selected_channel)
      call mci%record_integrand (state%val)
    else
      call msg_fatal ("Recalling event: mismatch in channel or dimension")
    end if
  end subroutine mci_instance_recall

```

13.1.4 MCI sampler

A sampler is an object that implements a multi-channel parameterization of the unit hypercube. Specifically, it is able to compute, given a channel and a set of x MC parameter values, a the complete set of x values and associated Jacobian factors f for all channels.

Furthermore, the sampler should return a single real value, the integrand, for the given point in the hypercube.

It must implement a method `evaluate` for performing the above computations.

```

⟨MCI base: public⟩+≡
  public :: mci_sampler_t

⟨MCI base: types⟩+≡
  type, abstract :: mci_sampler_t
    contains
    ⟨MCI base: mci sampler: TBP⟩
  end type mci_sampler_t

```

Output, deferred to the implementation.

```

⟨MCI base: mci sampler: TBP⟩≡
  procedure (mci_sampler_write), deferred :: write

```

```

<MCI base: interfaces>+=
  abstract interface
    subroutine mci_sampler_write (object, unit)
      import
      class(mci_sampler_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine mci_sampler_write
  end interface

```

The evaluation routine. Input is the channel index `c` and the one-dimensional parameter array `x_in`. Output are the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

```

<MCI base: mci_sampler: TBP>+=
  procedure (mci_sampler_evaluate), deferred :: evaluate

<MCI base: interfaces>+=
  abstract interface
    subroutine mci_sampler_evaluate (sampler, c, x_in, val, x, f)
      import
      class(mci_sampler_t), intent(inout) :: sampler
      integer, intent(in) :: c
      real(default), dimension(:), intent(in) :: x_in
      real(default), intent(out) :: val
      real(default), dimension(:, :), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_evaluate
  end interface

```

The shortcut. Again, the channel index `c` and the parameter array `x_in` are input. However, we also provide the integrand value `val`, and we just require that the complete parameter array `x` and Jacobian array `f` are recovered.

```

<MCI base: mci_sampler: TBP>+=
  procedure (mci_sampler_rebuild), deferred :: rebuild

<MCI base: interfaces>+=
  abstract interface
    subroutine mci_sampler_rebuild (sampler, c, x_in, val, x, f)
      import
      class(mci_sampler_t), intent(inout) :: sampler
      integer, intent(in) :: c
      real(default), dimension(:), intent(in) :: x_in
      real(default), intent(in) :: val
      real(default), dimension(:, :), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_rebuild
  end interface

```

This routine should extract the important data from a sampler that has been filled by other means. We fetch the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

```

<MCI base: mci_sampler: TBP>+=
  procedure (mci_sampler_fetch), deferred :: fetch

```

```

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_sampler_fetch (sampler, val, x, f)
      import
      class(mci_sampler_t), intent(in) :: sampler
      real(default), intent(out) :: val
      real(default), dimension(:,:), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_fetch
  end interface

```

13.1.5 Results record

This is an abstract type which allows us to implement callback: each integration results can optionally be recorded to an instance of this object. The actual object may store a new result, average results, etc. It may also display a result on-line or otherwise, whenever the `record` method is called.

```

<MCI base: public>+≡
  public :: mci_results_t

<MCI base: types>+≡
  type, abstract :: mci_results_t
    contains
    <MCI base: mci results: TBP>
  end type mci_results_t

```

The output routine is deferred. We provide an extra `verbose` flag, which could serve any purpose.

```

<MCI base: mci results: TBP>≡
  procedure (mci_results_write), deferred :: write

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_results_write (object, unit, verbose)
      import
      class(mci_results_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose
    end subroutine mci_results_write
  end interface

```

This is the `record` method, which can be called directly from the integrator.

```

<MCI base: mci results: TBP>+≡
  procedure (mci_results_record), deferred :: record

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_results_record (object, n_it, &
      n_calls, integral, error, efficiency, grove_weight)
      import
      class(mci_results_t), intent(inout) :: object
      integer, intent(in) :: n_it

```

```

        integer, intent(in) :: n_calls
        real(default), intent(in) :: integral
        real(default), intent(in) :: error
        real(default), intent(in) :: efficiency
        real(default), dimension(:,:), intent(in), optional :: &
            grove_weight
    end subroutine mci_results_record
end interface

```

13.1.6 Unit tests

```

<MCI base: public>+≡
    public :: mci_base_test

<MCI base: tests>≡
    subroutine mci_base_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <MCI base: execute tests>
    end subroutine mci_base_test

```

Test implementation of the configuration type

The concrete type contains the number of requested calls and the integral result, to be determined.

The `max_factor` entry is set for the actual test integration, where the integrand is not unity but some other constant value. This value should be set here, such that the actual maximum of the integrand is known when vetoing unweighted events.

```

<MCI base: public>+≡
    public :: mci_test_t

<MCI base: test types>≡
    type, extends (mci_t) :: mci_test_t
        integer :: divisions = 0
        integer :: tries = 0
        real(default) :: max_factor = 1
    contains
        procedure :: final => mci_test_final
        procedure :: write => mci_test_write
        procedure :: startup_message => mci_test_startup_message
        procedure :: declare_flat_dimensions => mci_test_ignore_flat_dimensions
        procedure :: declare_equivalences => mci_test_ignore_equivalences
        procedure :: set_divisions => mci_test_set_divisions
        procedure :: set_max_factor => mci_test_set_max_factor
        procedure :: allocate_instance => mci_test_allocate_instance
        procedure :: integrate => mci_test_integrate
        procedure :: prepare_simulation => mci_test_ignore_prepare_simulation
        procedure :: generate_weighted_event => mci_test_generate_weighted_event
        procedure :: generate_unweighted_event => &
            mci_test_generate_unweighted_event
        procedure :: rebuild_event => mci_test_rebuild_event

```

```
end type mci_test_t
```

Finalizer: base version is sufficient

```
<MCI base: tests>+≡
subroutine mci_test_final (object)
  class(mci_test_t), intent(inout) :: object
  call object%base_final ()
end subroutine mci_test_final
```

Output: trivial

```
<MCI base: tests>+≡
subroutine mci_test_write (object, unit)
  class(mci_test_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u
  u = output_unit (unit)
  write (u, "(1x,A)") "Test integrator:"
  call object%base_write (u)
  if (object%divisions /= 0) then
    write (u, "(3x,A,I0)") "Number of divisions = ", object%divisions
  end if
  if (allocated (object%rng)) call object%rng%write (u)
end subroutine mci_test_write
```

Short version.

```
<MCI base: tests>+≡
subroutine mci_test_startup_message (mci, unit, n_calls)
  class(mci_test_t), intent(in) :: mci
  integer, intent(in), optional :: unit, n_calls
  call mci%base_startup_message (unit = unit, n_calls = n_calls)
  write (msg_buffer, "(A,1x,I0,1x,A)") &
    "Integrator: Test:", mci%divisions, "divisions"
  call msg_message (unit = unit)
end subroutine mci_test_startup_message
```

This is a no-op for the test integrator.

```
<MCI base: tests>+≡
subroutine mci_test_ignore_flat_dimensions (mci, dim_flat)
  class(mci_test_t), intent(inout) :: mci
  integer, dimension(:), intent(in) :: dim_flat
end subroutine mci_test_ignore_flat_dimensions
```

Ditto.

```
<MCI base: tests>+≡
subroutine mci_test_ignore_equivalences (mci, channel, dim_offset)
  class(mci_test_t), intent(inout) :: mci
  type(phs_channel_t), dimension(:), intent(in) :: channel
  integer, intent(in) :: dim_offset
end subroutine mci_test_ignore_equivalences
```

Set the number of divisions to a nonzero value.

```
<MCI base: tests>+≡
subroutine mci_test_set_divisions (object, divisions)
  class(mci_test_t), intent(inout) :: object
  integer, intent(in) :: divisions
  object%divisions = divisions
end subroutine mci_test_set_divisions
```

Set the maximum factor (default is 1).

```
<MCI base: tests>+≡
subroutine mci_test_set_max_factor (object, max_factor)
  class(mci_test_t), intent(inout) :: object
  real(default), intent(in) :: max_factor
  object%max_factor = max_factor
end subroutine mci_test_set_max_factor
```

Allocate instance with matching type.

```
<MCI base: tests>+≡
subroutine mci_test_allocate_instance (mci, mci_instance)
  class(mci_test_t), intent(in) :: mci
  class(mci_instance_t), intent(out), pointer :: mci_instance
  allocate (mci_test_instance_t :: mci_instance)
end subroutine mci_test_allocate_instance
```

Integrate: sample at the midpoints of uniform bits and add the results. We implement this for one and for two dimensions. In the latter case, we scan over two channels and multiply with the channel weights.

The arguments `n_it` and `n_calls` are ignored in this implementations.

The test integrator does not set error or efficiency, so those will remain undefined.

```
<MCI base: tests>+≡
subroutine mci_test_integrate (mci, instance, sampler, &
  n_it, n_calls, results, grove_weight)
  class(mci_test_t), intent(inout) :: mci

    class(mci_state_t), intent(in) :: state
    select type (instance)
    type is (mci_test_instance_t)
        call instance%recall (sampler, state)
    end select
end subroutine mci_test_rebuild_event

```

Instance of the test MCI type

This instance type simulates the VAMP approach. We implement the VAMP multi-channel formula, but keep the channel-specific probability functions g_i smooth and fixed. We also keep the weights fixed.

The setup is as follows: we have n mappings of the unit hypercube

$$x = x(x^{(k)}) \quad \text{where } x = (x_1, \dots). \quad (13.1)$$

The Jacobian factors are the determinants

$$f^{(k)}(x^{(k)}) = \left| \frac{\partial x}{\partial x^{(k)}} \right| \quad (13.2)$$

We introduce arbitrary probability functions

$$g^{(k)}(x^{(k)}) \quad \text{with} \quad \int dx^{(k)} g^{(k)}(x^{(k)}) = 1 \quad (13.3)$$

and weights

$$w_k \quad \text{with} \quad \sum_k w_k = 1 \quad (13.4)$$

and construct the joint probability function

$$g(x) = \sum_k w_k \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \quad (13.5)$$

which also satisfies

$$\int g(x) dx = 1. \quad (13.6)$$

The algorithm implements a resolution of unity as follows

$$\begin{aligned} 1 &= \int dx = \int \frac{g(x)}{g(x)} dx \\ &= \sum_k w_k \int \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \frac{dx}{g(x)} \\ &= \sum_k w_k \int g^{(k)}(x^{(k)}) \frac{dx^{(k)}}{g(x(x^{(k)}))} \end{aligned} \quad (13.7)$$

where each of the integrals in the sum is evaluated using the channel-specific variables $x^{(k)}$.

We provide two examples: (1) trivial with one channel, one dimension, and all functions unity and (2) two channels and two dimensions with

$$\begin{aligned} x(x^{(1)}) &= (x_1^{(1)}, x_2^{(1)}) \\ x(x^{(2)}) &= (x_1^{(2)2}, x_2^{(2)}) \end{aligned} \quad (13.8)$$

hence

$$f^{(1)} \equiv 1, \quad f^{(2)}(x^{(2)}) = 2x_1^{(2)} \quad (13.9)$$

The probability functions are

$$g^{(1)} \equiv 1, \quad g^{(2)}(x^{(2)}) = 2x_2^{(2)} \quad (13.10)$$

In the concrete implementation of the integrator instance we store values for the channel probabilities g_i and the accumulated probability g .

We also store the result (product of integrand and MCI weight), the expected maximum for the result in each channel.

Test sampler

The test sampler implements a fixed configuration, either trivial (one-channel, one-dimension), or slightly nontrivial (two-channel, two-dimension). In the second channel, the first parameter is mapped according to $x_1 = x_1^{(2)2}$, so we have $f^{(2)}(x^{(2)}) = 2x_1^{(2)}$.

For display purposes, we store the return values inside the object. This is not strictly necessary.

```

13.2 Simple midpoint integration

This is a most simple implementation of an integrator. The algorithm is the straightforward multi-dimensional midpoint rule, i.e., the integration hypercube is binned uniformly, the integrand is evaluated at the midpoints of each bin, and the result is the average. The binning is equivalent for all integration dimensions.

This rule is accurate to the order h^2 , where h is the bin width. Given that $h = N^{-1/d}$, where d is the integration dimension and N is the total number of sampling points, we get a relative error of order $N^{-2/d}$. This is superior to MC integration if $d < 4$, and equivalent if $d = 4$. It is not worse than higher-order formulas (such as Gauss integration) if the integrand is not smooth, e.g., if it contains cuts.

The integrator is specifically single-channel. However, we do not limit the dimension.

```

    <MCI midpoint: tests>

    end module mci_midpoint

```

13.2.1 Integrator

The object contains the methods for integration and event generation. For the actual work and data storage, it spawns an instance object.

After an integration pass, we update the `max` parameter to indicate the maximum absolute value of the integrand that the integrator encountered. This is required for event generation.

```

Integrate. The number of dimensions is arbitrary. We make sure that the number of calls is evenly distributed among the dimensions. The actual number of calls will typically be smaller than the requested number, but never smaller than 1.

The sampling over a variable number of dimensions implies a variable number of nested loops. We implement this by a recursive subroutine, one loop in each recursion level.

The number of iterations `n_it` is ignored. Also, the error is set to zero in the current implementation.

With this integrator, we allow the calculation to abort immediately when forced by a signal. There is no state that we can save, hence we do not catch an interrupt.

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

This is the function $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

Mimicking the behavior of a process object, we store the argument and result inside the sampler, so we can `fetch` results.

```

  <MCI midpoint: test types>≡
    type, extends (mci_sampler_t) :: test_sampler_1_t
      real(default), dimension(:), allocatable :: x
      real(default) :: val
    contains

```

```

    <MCI midpoint: test sampler 1: TBP>
end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

<MCI midpoint: test sampler 1: TBP>≡

13.3 VAMP interface

The standard method for integration is **VAMP**: the multi-channel version of the VEGAS algorithm. Each parameterization (channel) of the hypercube is binned in each dimension. The binning is equally equidistant, but an iteration of the integration procedure, the binning is updated for each dimension, according to the variance distribution of the integrand, summed over all other dimension. In the next iteration, the binning approximates (hopefully) follows the integrand more closely, and the accuracy of the result is increased. Furthermore, the relative weight of the individual channels is also updated after an iteration.

The bin distribution is denoted as the grid for a channel, which we can write to file and reuse later.

In our implementation we specify the generic **VAMP** algorithm more tightly: the number of bins is equal for all dimensions, the initial weights are all equal. The user controls whether to update bins and/or weights after each iteration. The integration is organized in passes, each one consisting of several iterations with a common number of calls to the integrand. The first passes are intended as warmup, so the results are displayed but otherwise discarded. In the final pass, the integration estimates for the individual iterations are averaged for the final result.

Update the MCI record (i.e., the integration passes) by reading from input stream. The stream should contain a `write` output from a previous run. We first check the MD5 sum of the configuration parameters. If that matches, we proceed directly to the stored integration passes. If successful, we may continue to read the file; the position will be after a blank line that must follow the MCI record.

Integrate. Perform a new integration pass (possibly reusing previous results), which may consist of several iterations.

Note: we record the integral once per iteration. The integral stored in the mci record itself is the last integral of the current iteration, no averaging done. The results record may average results.

Note: recording the efficiency is not supported yet.

Generate weighted event. Note that the event weight (`vamp_weight`) is not just the MCI weight. `vamp_next_event` selects a channel based on the channel weights multiplied by the (previously recorded) maximum integrand value of the channel. The MCI weight is renormalized accordingly, to cancel this effect on the result.

13.3.5 Sampler as Workspace

In the full setup, the sampling function requires the process instance object as workspace. We implement this by (i) implementing the process instance as a type extension of the abstract `sampler_t` object used by the MCI implementation and (ii) providing such an object as an extra argument to the sampling function that VAMP can call. To minimize cross-package dependencies, we use an abstract type `vamp_workspace` that VAMP declares and extend this by including a pointer to the `sampler` and `instance` objects. In the body of the sampling function, we dereference this pointer and can then work with the contents.

```

<MCI vamp: types>+≡
  type, extends (vamp_data_t) :: mci_workspace_t
    class(mci_sampler_t), pointer :: sampler => null ()
    class(mci_vamp_instance_t), pointer :: instance => null ()
  end type mci_workspace_t

```

13.3.6 Integrator instance

The history entries should point to the corresponding history entry in the `pass_t` object. If there is none, we may allocate a local history, which is then just transient.

```

Prepare a new integration pass: write the pass-specific settings to the `instance` object. This should be called initially, together with the `create_grids` procedure, and whenever we start a new integration pass.

Set `reshape` if the number of calls is different than previously (unless it was zero, indicating the first pass).

We link VAMP histories to the allocated histories in the current pass object, so the recorded results are persistent. However, if there are no histories present there, we allocate them locally. In that case, the histories will disappear together with the MCI instance object.

Integration: sample the VAMP grids. The number of calls etc. are already stored inside the grids. We provide the random-number generator, the sampling function, and a link to the workspace object, which happens to contain a pointer to the sampler object. The sampler object thus becomes the workspace of the sampling function.

Note: in the current implementation, the random-number generator must be the TAO generator. This explicit dependence should be removed from the VAMP implementation.

```

```

13.3.7 Sampling function

The VAMP sampling function has a well-defined interface which we have to implement. The `data` argument allows us to pass pointers to the `sampler` and `instance` objects, so we can access configuration data and fill point-dependent contents within these objects.

The `weights` and `channel` argument must be present in the call.

Note: we would normally declare the `instance` pointer with the concrete type, or just use the `data` component directly. Unfortunately, gfortran 4.6 forgets the inherited base-type methods in that case.

Note: this is the place where we must look for external signals, i.e., interrupt from the OS. We would like to raise a VAMP exception which is then caught by `vamp_sample_grids` as the caller, so it dumps its current state and returns (with the signal still pending). WHIZARD will then terminate gracefully. Of course, VAMP should be able to resume from the dump.

In the current implementation, we handle the exception in place and terminate immediately. The incomplete current integration pass is lost.

```

(MCI vamp: procedures)+≡
function vamp_sampling_function (xi, data, weights, channel, grids) result (f)
  real(default) :: f
  real(default), dimension(:), intent(in) :: xi
  class(vamp_data_t), intent(in) :: data
  real(default), dimension(:), intent(in), optional :: weights
  integer, intent(in), optional :: channel
  type(vamp_grid), dimension(:), intent(in), optional :: grids
  type(exception) :: exc
  class(mci_instance_t), pointer :: instance
  character(*), parameter :: FN = "WHIZARD sampling function"
  select type (data)
  type is (mci_workspace_t)
    instance => data%instance
    select type (instance)
    class is (mci_vamp_instance_t)
      instance%calls = instance%calls + 1
    end select
    call instance%evaluate (data%sampler, channel, xi)
    if (signal_is_pending ()) then
      call raise_exception (exc, EXC_FATAL, FN, "signal received")
      call handle_vamp_exception (exc)
      call terminate_now_if_signal ()
    end if
    f = instance%get_value ()
  end select
end function vamp_sampling_function

```

This is supposed to be the mapping between integration channels. The VAMP event generating procedures technically require it, but it is meaningless in our setup where all transformations happen inside the sampler object. So, this implementation is trivial:

```

(MCI vamp: procedures)+≡
function phi_trivial (xi, channel_dummy) result (x)
  real(default), dimension(:), intent(in) :: xi
  integer, intent(in) :: channel_dummy
  real(default), dimension(size(xi)) :: x
  x = xi
end function phi_trivial

```

13.3.8 Integrator instance: evaluation

Here, we compute the multi-channel reweighting factor for the current channel, that accounts for the Jacobians of the transformations from/to all other channels.

The computation of the VAMP probabilities may consume considerable time, therefore we enable parallel evaluation. (Collecting the contributions to `mci%g` is a reduction, which we should also implement via OpenMP.)

Note: inactive channels not implemented yet.

```
(MCI vamp: mci vamp instance: TBP)+≡
  procedure :: compute_weight => mci_vamp_instance_compute_weight

(MCI vamp: procedures)+≡
  subroutine mci_vamp_instance_compute_weight (mci, c)
    class(mci_vamp_instance_t), intent(inout) :: mci
    integer, intent(in) :: c
    integer :: i
    mci%selected_channel = c
    !$OMP PARALLEL PRIVATE(i) SHARED(mci)
    !$OMP DO
    do i = 1, mci%nc
      mci%gi(i) = vamp_probability (mci%grids%grids(i), mci%x(:,i))
    end do
    !$OMP END DO
    !$OMP END PARALLEL
    mci%g = 0
    do i = 1, mci%nc
      mci%g = mci%g + mci%w(i) * mci%gi(i) / mci%f(i)
    end do
    if (mci%g /= 0) then
      mci%weight = mci%gi(c) / mci%g
    else
      mci%weight = 0
    end if
  end subroutine mci_vamp_instance_compute_weight
```

Record the integrand.

```
(MCI vamp: mci vamp instance: TBP)+≡
  procedure :: record_integrand => mci_vamp_instance_record_integrand

(MCI vamp: procedures)+≡
  subroutine mci_vamp_instance_record_integrand (mci, integrand)
    class(mci_vamp_instance_t), intent(inout) :: mci
    real(default), intent(in) :: integrand
    mci%integrand = integrand
  end subroutine mci_vamp_instance_record_integrand
```

Get the event weight. The default routine returns the same value that we would use for integration. This is correct if we select the integration channel according to the channel weight. `vamp_next_event` does differently, so we should rather rely on the weight that VAMP returns. This is the value stored in `vamp_weight`. We override the default TBP accordingly.

```
(MCI vamp: mci vamp instance: TBP)+≡
```

```

procedure :: get_event_weight => mci_vamp_instance_get_event_weight
procedure :: get_event_excess => mci_vamp_instance_get_event_excess
<MCI vamp: procedures>+=
function mci_vamp_instance_get_event_weight (mci) result (value)
  class(mci_vamp_instance_t), intent(in) :: mci
  real(default) :: value
  if (mci%vamp_weight_set) then
    value = mci%vamp_weight
  else
    call msg_bug ("VAMP: attempt to read undefined event weight")
  end if
end function mci_vamp_instance_get_event_weight

function mci_vamp_instance_get_event_excess (mci) result (value)
  class(mci_vamp_instance_t), intent(in) :: mci
  real(default) :: value
  if (mci%vamp_weight_set) then
    value = mci%vamp_excess
  else
    call msg_bug ("VAMP: attempt to read undefined event excess weight")
  end if
end function mci_vamp_instance_get_event_excess

```

13.3.9 VAMP exceptions

A VAMP routine may have raised an exception. Turn this into a WHIZARD error message.

An external signal could raise a fatal exception, but this should be delayed and handled by the correct termination routine.

```

<MCI vamp: procedures>+=
subroutine handle_vamp_exception (exc)
  type(exception), intent(in) :: exc
  if (exc%level > EXC_NONE) then
    write (msg_buffer, "(A,':',1x,A)") trim (exc%origin), trim (exc%message)
    select case (exc%level)
      case (EXC_INFO); call msg_message ()
      case (EXC_WARN); call msg_warning ()
      case (EXC_ERROR); call msg_error ()
      case (EXC_FATAL)
        if (signal_is_pending ()) then
          call msg_message ()
        else
          call msg_fatal ()
        end if
      end select
    end if
  end subroutine handle_vamp_exception

```

13.3.10 Unit tests

```

<MCI vamp: public>+=

```

```

public :: mci_vamp_test
<MCI vamp: tests>+≡
  subroutine mci_vamp_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <MCI vamp: execute tests>
  end subroutine mci_vamp_test

```

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is $11x^{10}$, also with integral 1.

```

<MCI vamp: test types>≡
  type, extends (mci_sampler_t) :: test_sampler_1_t
    real(default), dimension(:), allocatable :: x
    real(default) :: val
    integer :: mode = 1
  contains
    <MCI vamp: test sampler 1: TBP>
  end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

<MCI vamp: test sampler 1: TBP>≡
  procedure :: write => test_sampler_1_write

<MCI vamp: tests>+≡
  subroutine test_sampler_1_write (object, unit)
    class(test_sampler_1_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    select case (object%mode)
    case (1)
      write (u, "(1x,A)") "Test sampler: f(x) = 3 x^2"
    case (2)
      write (u, "(1x,A)") "Test sampler: f(x) = 11 x^10"
    case (3)
      write (u, "(1x,A)") "Test sampler: f(x) = 11 x^10 * 2 * cos^2 (2 pi y)"
    end select
  end subroutine test_sampler_1_write

```

Evaluation: compute the function value. The output x parameter (only one channel) is identical to the input x , and the Jacobian is 1.

```

<MCI vamp: test sampler 1: TBP>+≡
  procedure :: evaluate => test_sampler_1_evaluate

```

<MCI vamp: tests>+≡

```

subroutine test_sampler_1_evaluate (sampler, c, x_in, val, x, f)
  class(test_sampler_1_t), intent(inout) :: sampler

  allocate (sampler%x (size (x_in)))
  sampler%x = x_in
  sampler%val = val
  x(:,1) = sampler%x
  f = 1
end subroutine test_sampler_1_rebuild

```

Extract the results.

<MCI vamp: test sampler 1: TBP>+≡

```

procedure :: fetch => test_sampler_1_fetch

```

<MCI vamp: tests>+≡

```

subroutine test_sampler_1_fetch (sampler, val, x, f)
  class(test_sampler_1_t), intent(in) :: sampler
  real(default), intent(out) :: val
  real(default), dimension(:,:), intent(out) :: x
  real(default), dimension(:), intent(out) :: f
  val = sampler%val
  x(:,1) = sampler%x

```

```

      f = 1
    end subroutine test_sampler_1_fetch

```

Two-channel, two dimension test sampler

This sampler implements the function

$$f(x, y) = 4 \sin^2(\pi x) \sin^2(\pi y) + 2 \sin^2(\pi v) \quad (13.11)$$

where

$$x = u^v \quad u = xy \quad (13.12)$$

$$y = u^{(1-v)} \quad v = \frac{1}{2} \left(1 + \frac{\log(x/y)}{\log xy} \right) \quad (13.13)$$

Each term contributes 1 to the integral. The first term in the function is peaked along a cross aligned to the coordinates x and y , while the second term is peaked along the diagonal $x = y$.

The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = |\log u| \quad (13.14)$$

```

Two-channel, one dimension test sampler

This sampler implements the function

$$f(x, y) = a * 5x^4 + b * 5(1 - x)^4 \quad (13.15)$$

Each term contributes 1 to the integral, multiplied by a or b , respectively. The first term is peaked at $x = 1$, the second one at $x = 0$.

We implement the two mappings

$$x = u^{1/5} \quad \text{and} \quad x = 1 - v^{1/5}, \quad (13.16)$$

with Jacobians

$$\frac{\partial(x)}{\partial(u)} = u^{-4/5}/5 \quad \text{and} \quad v^{-4/5}/5, \quad (13.17)$$

respectively. The first mapping concentrates points near $x = 1$, the second one near $x = 0$.

```

One-dimensional integration

Construct an integrator and use it for a one-dimensional sampler.

Note: We would like to check the precise contents of the grid allocated during integration, but the output format for reals is very long (for good reasons), so the last digits in the grid content display are numerical noise. So, we just check the integration results.

Equivalences

Construct an integrator and use it for a one-dimensional sampler with two channels.

Integrate with three iterations and in-between grid adaptations. Apply an equivalence between the two channels, so the binning of the two channels is forced to coincide. Compare this with the behavior without equivalences.

```

Chapter 14

Process Libraries

This chapter consists of two modules which organize and interface the interaction matrix elements for a variety of elementary processes.

prclib_interfaces This module deals with matrix-element code which is accessible via external libraries (Fortran libraries or generic C-compatible libraries) and must either be generated by the program or provided by the user explicitly.

The module defines and uses an abstract type `prc_writer_t` and two abstract extensions, one for a Fortran module and one for a C-compatible library. The implementation provides the specific methods for writing the appropriate parts in external matrix element code.

prc_core_def This module defines the abstract types `prc_core_def_t` and `prc_driver_t`. The implementation of the former provides the configuration for processes of a certain class, while the latter accesses the corresponding matrix element, in particular those generated by the appropriate `prc_writer_t` object.

process_libraries This module combines the functionality of the previous module with the means for holding processes definitions (the internal counterpart of appropriate declarations in the user interface), for handling matrix elements which do not need external code, and for accessing the matrix elements by the procedures for matrix-element evaluation, integration and event generation.

test_me This module provides a test implementation for the abstract types in the `prc_core_def` module. The implementation is intended for self-tests of several later modules. The implementation is internal, i.e., no external code has is generated.

All data structures which are specific for a particular way of generating code or evaluating matrix element are kept abstract and thus generic. Later modules such as `prc_omega` provide implementations, in the form of type extensions for the various abstract types.

14.1 Process library interface

The module `prclib_interfaces` handles external matrix-element code.

14.1.1 Overview

The top-level data structure is the `prclib_driver_t` data type. The associated type-bound procedures deal with the generation of external code, compilation and linking, and accessing the active external library.

An object of type `prclib_driver_t` consists of the following parts:

1. Metadata that identify name and status of the library driver, etc.
2. An array of process records (`prclib_driver_record_t`), one for each external matrix element.
3. A record of type `dlaccess_t` which handles the operating-system part of linking a dynamically loadable library.
4. A collection of procedure pointers which have a counterpart in the external library interface. Given the unique identifier of a matrix element, the procedures retrieve generic matrix-element information such as the particle content and helicity combination tables. There is also a procedure which returns pointers to the more specific procedures that a matrix element provides, called *features*.

The process records of type `prclib_driver_record_t` handle the individual matrix elements. Each record identifies a process by name (`id`), names the physics model to be loaded for this process, lists the features that the associated matrix-element code provides, and holds a `writer` object which handles all operations that depend on the process type. The numbering of process records is identical to the numbering of matrix-element codes in the external library.

The writer object is of abstract type `prc_writer_t`. The module defines two basic, also abstract, extensions: `prc_writer_f_module_t` and `prc_writer_c_lib_t`. The first version is for matrix-element code that is available in form of Fortran modules. The writer contains type-bound procedures which create appropriate `use` directives and C-compatible wrapper functions for the given set of Fortran modules and their features. The second version is for matrix-element code that is available in form of a C-compatible library (this includes Fortran libraries with proper C bindings). The writer needs not write wrapper function, but explicit interface blocks for the matrix-element features.

Each matrix-element variant is encoded in an appropriate extension of `prc_writer_t`. For instance, `O'MEGA` matrix elements provide an implementation `omega_writer_t` which extends `prc_writer_f_module_t`.

14.1.2 Workflow

We expect that the functionality provided by this module is called in the following order:

1. The caller initializes the `prclib_driver_t` object and fills the array of `prclib_record_t` entries with the appropriate process data and process-specific writer objects.

2. It calls the `generate_makefile` method to set up an appropriate makefile in the current directory. The makefile will handle source generation, compilation and linking both for the individual matrix elements (unless this has to be done manually) and for the common external driver code which interfaces those matrix element.
3. The `generate_driver_code` writes the common driver as source code to file.
4. The methods `make_source`, `make_compile`, and `make_link` individually perform the corresponding steps in building the library. Wherever possible, they simply use the generated makefile. By calling `make`, we make sure that we can avoid unnecessary recompilation. For the compilation and linking steps, the makefile will employ `libtool`.
5. The `load` method loads the library procedures into the corresponding procedure pointers, using the `dlopen` mechanism via the `dlaccess` subobject.

14.1.3 The module

```

<prclib_interfaces.f90>≡
  <File header>

  module prclib_interfaces

    use iso_c_binding !NODEP!
    use kinds !NODEP!
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use limits, only: TAB !NODEP!
    use unit_tests
    use os_interface

    <Standard module head>

    <Prclib interfaces: public>

    <Prclib interfaces: types>

    <Prclib interfaces: interfaces>

    <Prclib interfaces: test types>

    contains

    <Prclib interfaces: procedures>

    <Prclib interfaces: tests>

  end module prclib_interfaces

```

14.1.4 Writers

External matrix element code provides externally visible procedures, which we denote as *features*. The features consist of informational subroutines and functions which are mandatory (universal features) and matrix-element specific subroutines and functions (specific features). The driver interfaces the generic features directly, while it returns the specific features in form of `bind(C)` procedure pointers to the caller. For instance, function `n_in` is generic, while the matrix matrix-element value itself is specific.

To implement these tasks, the driver needs `use` directives for Fortran module procedures, interface blocks for other external stuff, wrapper code, and Makefile snippets.

Generic writer

In the `prc_writer_t` data type, we collect the procedures which implement the writing tasks. The type is abstract. The concrete implementations are defined by an extension which is specific for the process type.

The MD5 sum stored here should be the MD5 checksum of the current process component, which can be calculated once the process is configured completely. It can be used by implementations which work with external files, such as O'MEGA.

```
<Prclib interfaces: public>≡
  public :: prc_writer_t

<Prclib interfaces: types>≡
  type, abstract :: prc_writer_t
    character(32) :: md5sum = ""
    contains
    <Prclib interfaces: prc writer: TBP>
  end type prc_writer_t
```

In any case, it is useful to have a string representation of the writer type. This must be implemented by all extensions.

```
<Prclib interfaces: prc writer: TBP>≡
  procedure(get_const_string), nopass, deferred :: type_name

<Prclib interfaces: interfaces>≡
  abstract interface
    function get_const_string () result (string)
      import
      type(string_t) :: string
    end function get_const_string
  end interface
```

Return the name of a procedure that implements a given feature, as it is provided by the external matrix-element code. For a reasonable default, we take the feature name unchanged.

```
<Prclib interfaces: prc writer: TBP>+≡
  procedure, nopass :: get_procname => prc_writer_get_procname
```

```

<Prclib interfaces: procedures>≡
  function prc_writer_get_procname (feature) result (name)
    type(string_t) :: name
    type(string_t), intent(in) :: feature
    name = feature
  end function prc_writer_get_procname

```

Return the name of a procedure that implements a given feature with the bind(C) property, so it can be accessed via a C procedure pointer and handled by dlopen. We need this for all special features of a matrix element, since the interface has to return a C function pointer for it. For a default implementation, we prefix the external procedure name by the process ID.

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure :: get_c_procname => prc_writer_get_c_procname

<Prclib interfaces: procedures>+≡
  function prc_writer_get_c_procname (writer, id, feature) result (name)
    class(prc_writer_t), intent(in) :: writer
    type(string_t), intent(in) :: id, feature
    type(string_t) :: name
    name = id // "_" // feature
  end function prc_writer_get_c_procname

```

Common signature of code-writing procedures. The procedure may use the process ID, and the feature name. (Not necessarily all of them.)

```

<Prclib interfaces: interfaces>+≡
  abstract interface
    subroutine write_code_file (writer, id)
      import
      class(prc_writer_t), intent(in) :: writer
      type(string_t), intent(in) :: id
    end subroutine write_code_file
  end interface

  abstract interface
    subroutine write_code (writer, unit, id)
      import
      class(prc_writer_t), intent(in) :: writer
      integer, intent(in) :: unit
      type(string_t), intent(in) :: id
    end subroutine write_code
  end interface

  abstract interface
    subroutine write_code_os (writer, unit, id, os_data)
      import
      class(prc_writer_t), intent(in) :: writer
      integer, intent(in) :: unit
      type(string_t), intent(in) :: id
      type(os_data_t), intent(in) :: os_data
    end subroutine write_code_os
  end interface

```

```

abstract interface
  subroutine write_feature_code (writer, unit, id, feature)
    import
    class(prc_writer_t), intent(in) :: writer
    integer, intent(in) :: unit
    type(string_t), intent(in) :: id, feature
  end subroutine write_feature_code
end interface

```

There must be a procedure which writes an interface block for a given feature. If the external matrix element is implemented as a Fortran module, this is required only for the specific features which are returned as procedure pointers.

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure(write_feature_code), deferred :: write_interface

```

There must also be a procedure which writes Makefile code which is specific for the current process, but not the feature.

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure(write_code_os), deferred :: write_makefile_code

```

This procedure writes code process-specific source-code file (which need not be Fortran). It may be a no-op, if the source code is generated by Make instead.

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure(write_code_file), deferred :: write_source_code

```

Writer for Fortran-module matrix elements

If the matrix element is available as a Fortran module, we have specific requirements: (i) the features are imported via `use` directives, (ii) the specific features require `bind(C)` wrappers.

The type is still abstract, all methods must be implemented explicitly for a specific matrix-element variant.

```

<Prclib interfaces: public>+≡
  public :: prc_writer_f_module_t

<Prclib interfaces: types>+≡
  type, extends (prc_writer_t), abstract :: prc_writer_f_module_t
  contains
    <Prclib interfaces: prc writer f module: TBP>
  end type prc_writer_f_module_t

```

Return the name of the Fortran module. As a default implementation, we take the process ID unchanged.

```

<Prclib interfaces: prc writer f module: TBP>≡
  procedure, nopass :: get_module_name => prc_writer_get_module_name

<Prclib interfaces: procedures>+≡
  function prc_writer_get_module_name (id) result (name)
    type(string_t) :: name
    type(string_t), intent(in) :: id
    name = id
  end function prc_writer_get_module_name

```

Write a `use` directive that associates the driver reference with the procedure in the matrix element code. By default, we use the C name for this.

```

<Prclib interfaces: prc writer f module: TBP>+≡
  procedure :: write_use_line => prc_writer_write_use_line

<Prclib interfaces: procedures>+≡
  subroutine prc_writer_write_use_line (writer, unit, id, feature)
    class(prc_writer_f_module_t), intent(in) :: writer
    integer, intent(in) :: unit
    type(string_t) :: id, feature
    write (unit, "(2x,9A)") "use ", char (writer%get_module_name (id)), &
      ", only: ", char (writer%get_c_procname (id, feature)), &
      " => ", char (writer%get_procname (feature))
  end subroutine prc_writer_write_use_line

```

Write a wrapper routine for a feature. This also associates a C name the module procedure. The details depend on the writer variant.

```

<Prclib interfaces: prc writer f module: TBP>+≡
  procedure(prc_write_wrapper), deferred :: write_wrapper

<Prclib interfaces: interfaces>+≡
  abstract interface
    subroutine prc_write_wrapper (writer, unit, id, feature)
      import
      class(prc_writer_f_module_t), intent(in) :: writer
      integer, intent(in) :: unit
      type(string_t), intent(in) :: id, feature
    end subroutine prc_write_wrapper
  end interface

```

This is used for testing only: initialize the writer with a specific MD5 sum string.

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure :: init_test => prc_writer_init_test

<Prclib interfaces: procedures>+≡
  subroutine prc_writer_init_test (writer)
    class(prc_writer_t), intent(out) :: writer
    writer%md5sum = "1234567890abcdef1234567890abcdef"
  end subroutine prc_writer_init_test

```

Writer for C-library matrix elements

This applies if the matrix element is available as a C library or a Fortran library with `bind(C)` compatible interface. We can use the basic version.

The type is still abstract, all methods must be implemented explicitly for a specific matrix-element variant.

```

<Prclib interfaces: types>+≡
  type, extends (prc_writer_t), abstract :: prc_writer_c_lib_t
  contains
    <Prclib interfaces: prc writer c lib: TBP>
  end type prc_writer_c_lib_t

```

14.1.5 Process records in the library driver

A process record holds the process (component) ID, the physics `model_name`, and the array of `features` that are implemented by the corresponding matrix element code.

The `writer` component holds procedures. The procedures write source code for the current record, either for the driver or for the Makefile.

```

<Prclib interfaces: types>+≡
  type :: prclib_driver_record_t
    type(string_t) :: id
    type(string_t) :: model_name
    type(string_t), dimension(:), allocatable :: feature
    class(prc_writer_t), pointer :: writer => null ()
  contains
    <Prclib interfaces: prclib driver record: TBP>
  end type prclib_driver_record_t

```

Output routine. We indent the output, so it smoothly integrates into the output routine for the whole driver.

Note: the pointer `writer` is introduced as a workaround for a NAG compiler bug.

```

<Prclib interfaces: prclib driver record: TBP>≡
  procedure :: write => prclib_driver_record_write

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_record_write (object, unit)
    class(prclib_driver_record_t), intent(in) :: object
    integer, intent(in) :: unit
    integer :: j
    class(prc_writer_t), pointer :: writer
    write (unit, "(3x,A,2x,['',A,']')") &
      char (object%id), char (object%model_name)
    if (allocated (object%feature)) then
      writer => object%writer
      write (unit, "(5x,A,A)", advance="no") &
        char (writer%type_name ()), ":"
      do j = 1, size (object%feature)
        write (unit, "(1x,A)", advance="no") &
          char (object%feature(j))
      end do
      write (unit, *)
    end if
  end subroutine prclib_driver_record_write

```

Get the C procedure name for a feature.

```

<Prclib interfaces: prclib driver record: TBP>+≡
  procedure :: get_c_procname => prclib_driver_record_get_c_procname

<Prclib interfaces: procedures>+≡
  function prclib_driver_record_get_c_procname (record, feature) result (name)
    type(string_t) :: name
    class(prclib_driver_record_t), intent(in) :: record
    type(string_t), intent(in) :: feature

```

```

        name = record%writer%get_c_procname (record%id, feature)
    end function prclib_driver_record_get_c_procname

```

Write a USE directive for a given feature. Applies only if the record corresponds to a Fortran module.

```

<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_use_line => prclib_driver_record_write_use_line
<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_record_write_use_line (record, unit, feature)
        class(prclib_driver_record_t), intent(in) :: record
        integer, intent(in) :: unit
        type(string_t), intent(in) :: feature
        select type (writer => record%writer)
            class is (prc_writer_f_module_t)
                call writer%write_use_line (unit, record%id, feature)
            end select
        end subroutine prclib_driver_record_write_use_line

```

The alternative: write an interface block for a given feature, unless the record corresponds to a Fortran module.

```

<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_interface => prclib_driver_record_write_interface
<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_record_write_interface (record, unit, feature)
        class(prclib_driver_record_t), intent(in) :: record
        integer, intent(in) :: unit
        type(string_t), intent(in) :: feature
        select type (writer => record%writer)
            class is (prc_writer_f_module_t)
                class default
                    call writer%write_interface (unit, record%id, feature)
                end select
            end select
        end subroutine prclib_driver_record_write_interface

```

Write all special feature interfaces for the current record. Do this for all process variants.

```

<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_interfaces => prclib_driver_record_write_interfaces
<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_record_write_interfaces (record, unit)
        class(prclib_driver_record_t), intent(in) :: record
        integer, intent(in) :: unit
        integer :: i
        do i = 1, size (record%feature)
            call record%writer%write_interface (unit, record%id, record%feature(i))
        end do
    end subroutine prclib_driver_record_write_interfaces

```

Write the wrapper routines for this record, if it corresponds to a Fortran module.

```

<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_wrappers => prclib_driver_record_write_wrappers

```

```

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_record_write_wrappers (record, unit)
    class(prclib_driver_record_t), intent(in) :: record
    integer, intent(in) :: unit
    integer :: i
    select type (writer => record%writer)
    class is (prc_writer_f_module_t)
      do i = 1, size (record%feature)
        call writer%write_wrapper (unit, record%id, record%feature(i))
      end do
    end select
  end subroutine prclib_driver_record_write_wrappers

```

Write the Makefile code for this record.

```

<Prclib interfaces: prclib driver record: TBP>+≡
  procedure :: write_makefile_code => prclib_driver_record_write_makefile_code

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_record_write_makefile_code (record, unit, os_data)
    class(prclib_driver_record_t), intent(in) :: record
    integer, intent(in) :: unit
    type(os_data_t), intent(in) :: os_data
    call record%writer%write_makefile_code (unit, record%id, os_data)
  end subroutine prclib_driver_record_write_makefile_code

```

Write source-code files for this record. (Does nothing if the source code is handled by Makefile rules.)

```

<Prclib interfaces: prclib driver record: TBP>+≡
  procedure :: write_source_code => prclib_driver_record_write_source_code

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_record_write_source_code (record)
    class(prclib_driver_record_t), intent(in) :: record
    call record%writer%write_source_code (record%id)
  end subroutine prclib_driver_record_write_source_code

```

14.1.6 The process library driver object

A `prclib_driver_t` object provides the interface to external matrix element code. The code is provided by an external library which is either statically or dynamically linked.

The dynamic and static versions of the library are two different implementations of the abstract base type.

The `basename` identifies the library, both by file names and by Fortran variable names.

The `loaded` flag becomes true once all procedure pointers to the matrix element have been assigned.

For a dynamical external library, the communication proceeds via a `dlaccess` object.

`n_processes` is the number of external process code components that are referenced by this library. The code is addressed by index (`i_lib` in the process

library entry above). This number should be equal to the number returned by `get_n_prc`.

For each external process, there is a separate **record** which holds the data that are needed for the driver parts which are specific for a given process component. The actual pointers for the loaded library will be assigned elsewhere.

The remainder is a collection of procedure pointers, which can be assigned once all external code has been compiled and linked. The procedure pointers all take a process component code index as an argument. Most return information about the process component that should match the process definition. The `get_fptr` procedures return a function pointer, which is the actual means to compute matrix elements or retrieve associated data.

Finally, the `unload_hook` and `reload_hook` pointers allow for the insertion of additional code when a library is loaded.

```

<Prclib interfaces: public>+≡
    public :: prclib_driver_t

      call object%dlaccess%write (unit)
    end select
    write (unit, *)
    if (allocated (object%record)) then
      write (unit, "(1x,A)") "Matrix-element code entries:"
      do i = 1, object%n_processes
        call object%record(i)%write (unit)
      end do
    else
      write (unit, "(1x,A)") "Matrix-element code entries: [undefined]"
    end if
  end subroutine prclib_driver_write

```

Allocate a library as either static or dynamic. For static libraries, the procedure defers control to an external procedure which knows about the available static libraries. By default, this procedure is empty, but when we build a stand-alone executable, we replace the dummy by an actual dispatcher for the available

static libraries. If the static dispatcher was not successful, we allocate a dynamic library.

The default version of `dispatch_prclib_static` resides in the `prebuilt` section of the WHIZARD tree, in a separate library. It does nothing, but can be replaced by a different procedure that allocates a static library driver if requested by name.

Note: `intent(out)` for the `driver` argument segfaults with gfortran 4.7.

```
<Prclib interfaces: public>+≡
  public :: dispatch_prclib_driver

<Prclib interfaces: procedures>+≡
  subroutine dispatch_prclib_driver (driver, basename)
    class(prclib_driver_t), intent(inout), allocatable :: driver
    type(string_t), intent(in) :: basename
    procedure(dispatch_prclib_driver) :: dispatch_prclib_static
    if (allocated (driver)) deallocate (driver)
    call dispatch_prclib_static (driver, basename)
    if (.not. allocated (driver)) then
      allocate (prclib_driver_dynamic_t :: driver)
    end if
    driver%basename = basename
  end subroutine dispatch_prclib_driver
```

Initialize the ID array and set `n_processes` accordingly.

```
<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: init => prclib_driver_init

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_init (driver, n_processes)
    class(prclib_driver_t), intent(inout) :: driver
    integer, intent(in) :: n_processes
    driver%n_processes = n_processes
    allocate (driver%record (n_processes))
  end subroutine prclib_driver_init
```

Set the MD5 sum. This is separate because the MD5 sum may be known only after initialization.

```
<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: set_md5sum => prclib_driver_set_md5sum

<Prclib interfaces: procedures>+≡

14.1.8 Write driver file

This procedure writes the process library driver source code to the specified output unit. The individual routines for writing source-code procedures are given below.

<Prclib interfaces: prclib driver: TBP>+≡

```

procedure :: generate_driver_code => prclib_driver_generate_code

```

```

<Prclib interfaces: procedures>+≡
subroutine prclib_driver_generate_code (driver, unit)
  class(prclib_driver_t), intent(in) :: driver
  integer, intent(in) :: unit
  type(string_t) :: prefix
  integer :: i

  prefix = driver%basename // "_"

  write (unit, "(A)") "! WHIZARD matrix-element code interface"
  write (unit, "(A)") "!"
  write (unit, "(A)") "! Automatically generated file, do not edit"
  call driver%write_module (unit, prefix)
  call driver%write_lib_md5sum_fun (unit, prefix)
  call driver%write_get_n_processes_fun (unit, prefix)
  call driver%write_get_process_id_fun (unit, prefix)
  call driver%write_get_model_name_fun (unit, prefix)
  !!! JRR: WK please check: why commented out?
  !   call write_get_restrictions_fun ()
  !   call write_get_omega_flags_fun ()
  call driver%write_get_md5sum_fun (unit, prefix)
  call driver%write_string_to_array_fun (unit, prefix)
  call driver%write_get_openmp_status_fun (unit, prefix)
  call driver%write_get_int_fun (unit, prefix, var_str ("n_in"))
  call driver%write_get_int_fun (unit, prefix, var_str ("n_out"))
  call driver%write_get_int_fun (unit, prefix, var_str ("n_flv"))
  call driver%write_get_int_fun (unit, prefix, var_str ("n_hel"))
  call driver%write_get_int_fun (unit, prefix, var_str ("n_col"))
  call driver%write_get_int_fun (unit, prefix, var_str ("n_cin"))
  call driver%write_get_int_fun (unit, prefix, var_str ("n_cf"))
  call driver%write_set_int_sub (unit, prefix, var_str ("flv_state"))
  call driver%write_set_int_sub (unit, prefix, var_str ("hel_state"))
  call driver%write_set_col_state_sub (unit, prefix)
  call driver%write_set_color_factors_sub (unit, prefix)
  call driver%write_get_fptr_sub (unit, prefix)
  do i = 1, driver%n_processes
    call driver%record(i)%write_wrappers (unit)
  end do
end subroutine prclib_driver_generate_code

```

The driver module is used and required *only* if we intend to link the library statically. Then, it provides the (static) driver type as a concrete implementation of the abstract library driver. This type contains the internal dispatcher for assigning the library procedures to their appropriate procedure pointers. In the dynamical case, the assignment is done via the base-type dispatcher which invokes the DL mechanism.

However, compiling this together with the rest in any case should not do any harm.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure, nopass :: write_module => prclib_driver_write_module

<Prclib interfaces: procedures>+≡
subroutine prclib_driver_write_module (unit, prefix)

end subroutine prclib_driver_write_lib_md5sum_fun

```

14.1.9 Interface bodies for informational functions

These interfaces implement the communication between WHIZARD (the main program) and the process-library driver. The procedures are all BIND(C), so they can safely be exposed by the library and handled by the `dlopen` mechanism, which apparently understands only C calling conventions.

In the sections below, for each procedure, we provide both the interface itself and a procedure that writes the corresponding procedure as source code to the process library driver.

Process count

Return the number of processes contained in the library.

```

<Prclib interfaces: public>+≡
public :: prc_get_n_processes

<Prclib interfaces: interfaces>+≡
abstract interface
    function prc_get_n_processes () result (n) bind(C)
    import
    integer(c_int) :: n
    end function prc_get_n_processes
end interface

```

Here is the code.

```

<Prclib interfaces: prclib driver: TBP>+≡
procedure :: write_get_n_processes_fun

<Prclib interfaces: procedures>+≡
subroutine write_get_n_processes_fun (driver, unit, prefix)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    write (unit, "(A)") ""
    write (unit, "(A)") "! Return the number of processes in this library"
    write (unit, "(A)") "function " // char (prefix) &
        // "get_n_processes () result (n) bind(C)"
    write (unit, "(A)") " use iso_c_binding"
    write (unit, "(A)") " implicit none"
    write (unit, "(A)") " integer(c_int) :: n"
    write (unit, "(A,I0)") " n = ", driver%n_processes
    write (unit, "(A)") "end function " // char (prefix) &

```

```

        // "get_n_processes"
    end subroutine write_get_n_processes_fun

```

Informational string functions

These functions return constant information about the matrix-element code.

The following procedures have to return strings. With the BIND(C) constraint, we choose to return the C pointer to a string, and its length, so the procedures implement this interface. They are actually subroutines.

```

<Prclib interfaces: public>+≡
    public :: prc_get_stringptr

<Prclib interfaces: interfaces>+≡
    abstract interface
        subroutine prc_get_stringptr (i, cptr, len) bind(C)
            import
            integer(c_int), intent(in) :: i
            type(c_ptr), intent(out) :: cptr
            integer(c_int), intent(out) :: len
        end subroutine prc_get_stringptr
    end interface

```

To hide this complication, we introduce a subroutine that converts the returned C pointer to a `string_t` object. As a side effect, we deallocate the original after conversion – otherwise, we might have a memory leak.

For the conversion, we first pointer-convert the C pointer to a Fortran character array pointer, length 1 and size `len`. Using argument association and an internal subroutine, we convert this to a character array with length `len` and size 1. Using ordinary assignment, we finally convert this to `string_t`.

The function takes the pointer-returning function as an argument. The index `i` identifies the process in the library.

```

<Prclib interfaces: procedures>+≡
    subroutine get_string_via_cptr (string, i, get_stringptr)
        type(string_t), intent(out) :: string
        integer, intent(in) :: i
        procedure(prc_get_stringptr) :: get_stringptr
        type(c_ptr) :: cptr
        integer(c_int) :: pid, len
        character(kind=c_char), dimension(:), pointer :: c_array
        pid = i
        call get_stringptr (pid, cptr, len)
        if (c_associated (cptr)) then
            call c_f_pointer (cptr, c_array, shape = [len])
            call set_string (c_array)
            call get_stringptr (0_c_int, cptr, len)
        else
            string = ""
        end if
    contains
        subroutine set_string (buffer)
            character(len, kind=c_char), dimension(1), intent(in) :: buffer
            string = buffer(1)
        end subroutine
    end subroutine

```

```

    end subroutine set_string
end subroutine get_string_via_cptr

```

Since the module procedures return Fortran strings, we have to convert them. This is the necessary auxiliary routine. The routine is not BIND(C), it is not accessed from outside.

```

<Prclib interfaces: prclib driver: TBP>+≡
    procedure, nopass :: write_string_to_array_fun

<Prclib interfaces: procedures>+≡
    subroutine write_string_to_array_fun (unit, prefix)
        integer, intent(in) :: unit
        type(string_t), intent(in) :: prefix
        write (unit, "(A)") ""
        write (unit, "(A)") "! Auxiliary: convert character string &
            &to array pointer"
        write (unit, "(A)") "subroutine " // char (prefix) &
            // "string_to_array (string, a)"
        write (unit, "(A)") " use iso_c_binding"
        write (unit, "(A)") " implicit none"
        write (unit, "(A)") " character(*), intent(in) :: string"
        write (unit, "(A)") " character(kind=c_char), dimension(:), &
            &allocatable, intent(out) :: a"
        write (unit, "(A)") " integer :: i"
        write (unit, "(A)") " allocate (a (len (string)))"
        write (unit, "(A)") " do i = 1, size (a)"
        write (unit, "(A)") "     a(i) = string(i:i)"
        write (unit, "(A)") " end do"
        write (unit, "(A)") "end subroutine " // char (prefix) &
            // "string_to_array"
    end subroutine write_string_to_array_fun

```

The above routine is called by other functions. It is not in a module, so they need its interface explicitly.

```

<Prclib interfaces: procedures>+≡
    subroutine write_string_to_array_interface (unit, prefix)
        integer, intent(in) :: unit
        type(string_t), intent(in) :: prefix
        write (unit, "(2x,A)") "interface"
        write (unit, "(2x,A)") " subroutine " // char (prefix) &
            // "string_to_array (string, a)"
        write (unit, "(2x,A)") " use iso_c_binding"
        write (unit, "(2x,A)") " implicit none"
        write (unit, "(2x,A)") " character(*), intent(in) :: string"
        write (unit, "(2x,A)") " character(kind=c_char), dimension(:), &
            &allocatable, intent(out) :: a"
        write (unit, "(2x,A)") " end subroutine " // char (prefix) &
            // "string_to_array"
        write (unit, "(2x,A)") "end interface"
    end subroutine write_string_to_array_interface

```

Here are the info functions which return strings, implementing the interface prc_get_stringptr.

Return the process ID for each process.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: write_get_process_id_fun

<Prclib interfaces: procedures>+≡
  subroutine write_get_process_id_fun (driver, unit, prefix)

write (unit, "(A)") "      len = 32"
write (unit, "(A)") "contains"
write (unit, "(A)") "      subroutine copy (md5sum_tmp)"
write (unit, "(A)") "          character, dimension(32), intent(in) :: &
&md5sum_tmp"
write (unit, "(A)") "          md5sum = md5sum_tmp"
write (unit, "(A)") "      end subroutine copy"
write (unit, "(A)") "end subroutine " // char (prefix) &
// "get_md5sum_ptr"
end subroutine write_get_md5sum_fun

```

The actual call depends on the type of matrix element.

```

<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_md5sum_call => prclib_driver_record_write_md5sum_call

<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_record_write_md5sum_call (record, unit)
        class(prclib_driver_record_t), intent(in) :: record
        integer, intent(in) :: unit
        call record%writer%write_md5sum_call (unit, record%id)
    end subroutine prclib_driver_record_write_md5sum_call

```

The interface goes into the writer base type:

```

<Prclib interfaces: prc writer: TBP>+≡
    procedure(write_code), deferred :: write_md5sum_call

In the Fortran module case, we take a detour. The string returned by the
Fortran function is copied into a fixed-size array. The copy routine is an internal
subroutine of get_md5sum_ptr. We return the C address of the target array.

<Prclib interfaces: prc writer f module: TBP>+≡
    procedure :: write_md5sum_call => prc_writer_f_module_write_md5sum_call

<Prclib interfaces: procedures>+≡
    subroutine prc_writer_f_module_write_md5sum_call (writer, unit, id)
        class(prc_writer_f_module_t), intent(in) :: writer
        integer, intent(in) :: unit

```

```

type(string_t), intent(in) :: id
write (unit, "(5x,9A)") "call copy (" , &
      char (writer%get_c_procname (id, var_str ("md5sum"))), " ()"
write (unit, "(5x,9A)") "cptr = c_loc (md5sum)"
end subroutine prc_writer_f_module_write_md5sum_call

```

In the C library case, the library function returns a C pointer, which we can just copy.

```

<Prclib interfaces: prc writer c lib: TBP>≡
  procedure :: write_md5sum_call => prc_writer_c_lib_write_md5sum_call

<Prclib interfaces: procedures>+≡
  subroutine prc_writer_c_lib_write_md5sum_call (writer, unit, id)
    class(prc_writer_c_lib_t), intent(in) :: writer
    integer, intent(in) :: unit
    type(string_t), intent(in) :: id
    write (unit, "(5x,9A)") &
      "cptr = ", &
      char (writer%get_c_procname (id, var_str ("get_md5sum"))), " ()"
  end subroutine prc_writer_c_lib_write_md5sum_call

```

Actual references to the info functions

The string-valued info functions return C character arrays. For the API of the library driver, we provide convenience functions which (re)convert those arrays into `string_t` objects.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: get_process_id => prclib_driver_get_process_id
  procedure :: get_model_name => prclib_driver_get_model_name
  procedure :: get_md5sum => prclib_driver_get_md5sum

<Prclib interfaces: procedures>+≡
  function prclib_driver_get_process_id (driver, i) result (string)
    type(string_t) :: string
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    call get_string_via_cptr (string, i, driver%get_process_id_ptr)
  end function prclib_driver_get_process_id

  function prclib_driver_get_model_name (driver, i) result (string)
    type(string_t) :: string
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    call get_string_via_cptr (string, i, driver%get_model_name_ptr)
  end function prclib_driver_get_model_name

  function prclib_driver_get_md5sum (driver, i) result (string)
    type(string_t) :: string
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    call get_string_via_cptr (string, i, driver%get_md5sum_ptr)
  end function prclib_driver_get_md5sum

```

Informational logical functions

When returning a logical value, we use the C boolean type, which may differ from Fortran.

```
<Prclib interfaces: public>+≡
    public :: prc_get_log

<Prclib interfaces: interfaces>+≡
    abstract interface
        function prc_get_log (pid) result (l) bind(C)
            import
            integer(c_int), intent(in) :: pid
            logical(c_bool) :: l
        end function prc_get_log
    end interface
```

Return a logical flag which tells whether OpenMP is supported for a specific process code.

```
<Prclib interfaces: prclib driver: TBP>+≡
    procedure :: write_get_openmp_status_fun

<Prclib interfaces: procedures>+≡
    subroutine write_get_openmp_status_fun (driver, unit, prefix)
        class(prclib_driver_t), intent(in) :: driver
        integer, intent(in) :: unit
        type(string_t), intent(in) :: prefix
        integer :: i
        write (unit, "(A)") ""
        write (unit, "(A)") "! Return the OpenMP support status"
        write (unit, "(A)") "function " // char (prefix) &
            // "get_openmp_status (i) result (openmp_status) bind(C)"
        write (unit, "(A)") " use iso_c_binding"
        call driver%write_interfaces (unit, var_str ("openmp_supported"))
        write (unit, "(A)") " integer(c_int), intent(in) :: i"
        write (unit, "(A)") " logical(c_bool) :: openmp_status"
        write (unit, "(A)") " select case (i)"
        do i = 1, driver%n_processes
            write (unit, "(A,I0,9A)") " case (" , i, "); ", &
                "openmp_status = ", &
                char (driver%record(i)%get_c_procname &
                    (var_str ("openmp_supported"))), " ()"
        end do
        write (unit, "(A)") " end select"
        write (unit, "(A)") "end function " // char (prefix) &
            // "get_openmp_status"
    end subroutine write_get_openmp_status_fun
```

Informational integer functions

Various process metadata are integer values. We can use a single interface for all of them.

```
<Prclib interfaces: public>+≡
    public :: prc_get_int
```

```

<Prclib interfaces: interfaces>+≡
  abstract interface
    function prc_get_int (pid) result (n) bind(C)
      import
        integer(c_int), intent(in) :: pid
        integer(c_int) :: n
      end function prc_get_int
  end interface

```

This function returns any data of type integer, for each process.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: write_get_int_fun

<Prclib interfaces: procedures>+≡
  subroutine write_get_int_fun (driver, unit, prefix, feature)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    type(string_t), intent(in) :: feature
    integer :: i
    write (unit, "(A)") ""
    write (unit, "(9A)") "! Return the value of ", char (feature)
    write (unit, "(9A)") "function ", char (prefix), &
      "get_", char (feature), " (pid)", &
      " result (", char (feature), ") bind(C)"
    write (unit, "(9A)") " use iso_c_binding"
    call driver%write_interfaces (unit, feature)
    write (unit, "(9A)") " integer(c_int), intent(in) :: pid"
    write (unit, "(9A)") " integer(c_int) :: ", char (feature)
    write (unit, "(9A)") " select case (pid)"
    do i = 1, driver%n_processes
      write (unit, "(2x,A,I0,9A)") "case (", i, "); ", &
        char (feature), " = ", &
        char (driver%record(i)%get_c_procname (feature)), &
        " ()"
    end do
    write (unit, "(9A)") " end select"
    write (unit, "(9A)") "end function ", char (prefix), &
      "get_", char (feature)
  end subroutine write_get_int_fun

```

Write a case line that assigns the value of the external function to the current return value.

```

<Prclib interfaces: procedures>+≡
  subroutine write_case_int_fun (record, unit, i, feature)
    class(prclib_driver_record_t), intent(in) :: record
    integer, intent(in) :: unit
    integer, intent(in) :: i
    type(string_t), intent(in) :: feature
    write (unit, "(5x,A,I0,9A)") "case (", i, "); ", &
      char (feature), " = ", char (record%get_c_procname (feature))
  end subroutine write_case_int_fun

```

Flavor and helicity tables

Transferring tables is more complicated. First, a two-dimensional array.

```
<Prclib interfaces: public>+≡
    public :: prc_set_int_tab1

<Prclib interfaces: interfaces>+≡
    abstract interface
        subroutine prc_set_int_tab1 (pid, tab, shape) bind(C)
            import
            integer(c_int), intent(in) :: pid
            integer(c_int), dimension(*), intent(out) :: tab
            integer(c_int), dimension(2), intent(in) :: shape
        end subroutine prc_set_int_tab1
    end interface
```

This subroutine returns a table of integers.

```
<Prclib interfaces: prclib driver: TBP>+≡
    procedure :: write_set_int_sub

<Prclib interfaces: procedures>+≡
    subroutine write_set_int_sub (driver, unit, prefix, feature)
        class(prclib_driver_t), intent(in) :: driver
        integer, intent(in) :: unit
        type(string_t), intent(in) :: prefix
        type(string_t), intent(in) :: feature
        integer :: i
        write (unit, "(A)") ""
        write (unit, "(9A)") "! Set table: ", char (feature)
        write (unit, "(9A)") "subroutine ", char (prefix), &
            "set_", char (feature), "_ptr (pid, ", char (feature), &
            ", shape) bind(C)"
        write (unit, "(9A)") " use iso_c_binding"
        call driver%write_interfaces (unit, feature)
        write (unit, "(9A)") " integer(c_int), intent(in) :: pid"
        write (unit, "(9A)") " integer(c_int), dimension(*), intent(out) :: ", &
            char (feature)
        write (unit, "(9A)") " integer(c_int), dimension(2), intent(in) :: shape"
        write (unit, "(9A)") " integer, dimension(:,:), allocatable :: ", &
            char (feature), "_tmp"
        write (unit, "(9A)") " integer :: i, j"
        write (unit, "(9A)") " select case (pid)"
        do i = 1, driver%n_processes
            write (unit, "(2x,A,IO,A)") "case (", i, ")"
            call driver%record(i)%write_int_sub_call (unit, feature)
        end do
        write (unit, "(9A)") " end select"
        write (unit, "(9A)") "end subroutine ", char (prefix), &
            "set_", char (feature), "_ptr"
    end subroutine write_set_int_sub
```

The actual call depends on the type of matrix element.

```
<Prclib interfaces: prclib driver record: TBP>+≡
    procedure :: write_int_sub_call => prclib_driver_record_write_int_sub_call
```

```

<Prclib interfaces: procedures>+≡
subroutine prclib_driver_record_write_int_sub_call (record, unit, feature)
  class(prclib_driver_record_t), intent(in) :: record
  integer, intent(in) :: unit
  type(string_t), intent(in) :: feature
  call record%writer%write_int_sub_call (unit, record%id, feature)
end subroutine prclib_driver_record_write_int_sub_call

```

The interface goes into the writer base type:

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure(write_feature_code), deferred :: write_int_sub_call

```

In the Fortran module case, we need an extra copy in the (academical) situation where default integer and `c_int` differ. Otherwise, we just associate a Fortran array with the C pointer and let the matrix-element subroutine fill the array.

```

<Prclib interfaces: prc writer f module: TBP>+≡
  procedure :: write_int_sub_call => prc_writer_f_module_write_int_sub_call

<Prclib interfaces: procedures>+≡
subroutine prc_writer_f_module_write_int_sub_call (writer, unit, id, feature)
  class(prc_writer_f_module_t), intent(in) :: writer
  integer, intent(in) :: unit
  type(string_t), intent(in) :: id, feature
  write (unit, "(5x,9A)") "allocate (", char (feature), "_tmp ", &
    "(shape(1), shape(2)))"
  write (unit, "(5x,9A)") "call ", &
    char (writer%get_c_procname (id, feature)), &
    " (", char (feature), "_tmp)"
  write (unit, "(5x,9A)") "forall (i=1:shape(1), j=1:shape(2)) "
  write (unit, "(8x,9A)") char (feature), "(i + shape(1)*(j-1)) = ", &
    char (feature), "_tmp", "(i,j)"
  write (unit, "(5x,9A)") "end forall"
end subroutine prc_writer_f_module_write_int_sub_call

```

In the C library case, we just transfer the C pointer to the library function.

```

<Prclib interfaces: prc writer c lib: TBP>+≡
  procedure :: write_int_sub_call => prc_writer_c_lib_write_int_sub_call

<Prclib interfaces: procedures>+≡
subroutine prc_writer_c_lib_write_int_sub_call (writer, unit, id, feature)
  class(prc_writer_c_lib_t), intent(in) :: writer
  integer, intent(in) :: unit
  type(string_t), intent(in) :: id, feature
  write (unit, "(5x,9A)") "call ", &
    char (writer%get_c_procname (id, feature)), " (", char (feature), ")"
end subroutine prc_writer_c_lib_write_int_sub_call

```

Color state table

The color-state specification needs a table of integers (one array per color flow) and a corresponding array of color-ghost flags.

```

<Prclib interfaces: public>+≡
  public :: prc_set_col_state

```

```

<Prclib interfaces: interfaces>+≡
abstract interface
  subroutine prc_set_col_state (pid, col_state, ghost_flag, shape) bind(C)
  import
    integer(c_int), intent(in) :: pid
    integer(c_int), dimension(*), intent(out) :: col_state
    logical(c_bool), dimension(*), intent(out) :: ghost_flag
    integer(c_int), dimension(3), intent(in) :: shape
  end subroutine prc_set_col_state
end interface

```

```

<Prclib interfaces: prclib driver: TBP>+≡
procedure :: write_set_col_state_sub

```

```

<Prclib interfaces: procedures>+≡
subroutine write_set_col_state_sub (driver, unit, prefix)
  class(prclib_driver_t), intent(in) :: driver
  integer, intent(in) :: unit
  type(string_t), intent(in) :: prefix
  integer :: i
  type(string_t) :: feature
  feature = "col_state"
  write (unit, "(A)") ""
  write (unit, "(9A)") "! Set tables: col_state, ghost_flag"
  write (unit, "(9A)") "subroutine ", char (prefix), &
    "set_col_state_ptr (pid, col_state, ghost_flag, shape) bind(C)"
  write (unit, "(9A)") " use iso_c_binding"
  call driver%write_interfaces (unit, feature)
  write (unit, "(9A)") " integer(c_int), intent(in) :: pid"
  write (unit, "(9A)") &
    " integer(c_int), dimension(*), intent(out) :: col_state"
  write (unit, "(9A)") &
    " logical(c_bool), dimension(*), intent(out) :: ghost_flag"
  write (unit, "(9A)") &
    " integer(c_int), dimension(3), intent(in) :: shape"
  write (unit, "(9A)") &
    " integer, dimension(:,:), allocatable :: col_state_tmp"
  write (unit, "(9A)") &
    " logical, dimension(:,:), allocatable :: ghost_flag_tmp"
  write (unit, "(9A)") " integer :: i, j, k"
  write (unit, "(A)") " select case (pid)"
  do i = 1, driver%n_processes
    write (unit, "(A,I0,A)") " case (" , i, ")"
    call driver%record(i)%write_col_state_call (unit)
  end do
  write (unit, "(A)") " end select"
  write (unit, "(9A)") "end subroutine ", char (prefix), &
    "set_col_state_ptr"
end subroutine write_set_col_state_sub

```

The actual call depends on the type of matrix element.

```

<Prclib interfaces: prclib driver record: TBP>+≡
procedure :: write_col_state_call => prclib_driver_record_write_col_state_call

```

```

<Prclib interfaces: procedures>+≡
subroutine prclib_driver_record_write_col_state_call (record, unit)
  class(prclib_driver_record_t), intent(in) :: record
  integer, intent(in) :: unit
  call record%writer%write_col_state_call (unit, record%id)
end subroutine prclib_driver_record_write_col_state_call

```

The interface goes into the writer base type:

```

<Prclib interfaces: prc writer: TBP>+≡
  procedure(write_code), deferred :: write_col_state_call

```

In the Fortran module case, we need an extra copy in the (academical) situation where default integer and `c_int` differ. Otherwise, we just associate a Fortran array with the C pointer and let the matrix-element subroutine fill the array.

```

<Prclib interfaces: prc writer f module: TBP>+≡
  procedure :: write_col_state_call => prc_writer_f_module_write_col_state_call

```

```

<Prclib interfaces: procedures>+≡
subroutine prc_writer_f_module_write_col_state_call (writer, unit, id)
  class(prc_writer_f_module_t), intent(in) :: writer
  integer, intent(in) :: unit
  type(string_t), intent(in) :: id
  write (unit, "(9A)") " allocate (col_state_tmp ", &
    "(shape(1), shape(2), shape(3)))"
  write (unit, "(5x,9A)") "allocate (ghost_flag_tmp ", &
    "(shape(2), shape(3)))"
  write (unit, "(5x,9A)") "call ", &
    char (writer%get_c_procname (id, var_str ("col_state"))), &
    " (col_state_tmp, ghost_flag_tmp)"
  write (unit, "(5x,9A)") "forall (i = 1:shape(2), j = 1:shape(3))"
  write (unit, "(8x,9A)") "forall (k = 1:shape(1))"
  write (unit, "(11x,9A)") &
    "col_state(k + shape(1) * (i + shape(2)*(j-1) - 1)) ", &
    "= col_state_tmp(k,i,j)"
  write (unit, "(8x,9A)") "end forall"
  write (unit, "(8x,9A)") &
    "ghost_flag(i + shape(2)*(j-1)) = ghost_flag_tmp(i,j)"
  write (unit, "(5x,9A)") "end forall"
end subroutine prc_writer_f_module_write_col_state_call

```

In the C library case, we just transfer the C pointer to the library function.

```

<Prclib interfaces: prc writer c lib: TBP>+≡
  procedure :: write_col_state_call => prc_writer_c_lib_write_col_state_call

```

```

<Prclib interfaces: procedures>+≡
subroutine prc_writer_c_lib_write_col_state_call (writer, unit, id)
  class(prc_writer_c_lib_t), intent(in) :: writer
  integer, intent(in) :: unit
  type(string_t), intent(in) :: id
  write (unit, "(5x,9A)") "call ", &
    char (writer%get_c_procname (id, var_str ("col_state"))), &
    " (col_state, ghost_flag)"
end subroutine prc_writer_c_lib_write_col_state_call

```

Color factors

For the color-factor information, we return two integer arrays and a complex array.

```

<Prclib interfaces: public>+≡
    public :: prc_set_color_factors

<Prclib interfaces: interfaces>+≡
    abstract interface
        subroutine prc_set_color_factors &
            (pid, cf_index1, cf_index2, color_factors, shape) bind(C)
        import
        integer(c_int), intent(in) :: pid
        integer(c_int), dimension(*), intent(out) :: cf_index1, cf_index2
        complex(c_default_complex), dimension(*), intent(out) :: color_factors
        integer(c_int), dimension(1), intent(in) :: shape
    end subroutine prc_set_color_factors
end interface

```

This subroutine returns the color-flavor factor table.

```

<Prclib interfaces: prclib driver: TBP>+≡
    procedure :: write_set_color_factors_sub

<Prclib interfaces: procedures>+≡
    subroutine write_set_color_factors_sub (driver, unit, prefix)
        class(prclib_driver_t), intent(in) :: driver
        integer, intent(in) :: unit
        type(string_t), intent(in) :: prefix
        integer :: i
        type(string_t) :: feature
        feature = "color_factors"
        write (unit, "(A)") ""
        write (unit, "(A)") "! Set tables: color factors"
        write (unit, "(9A)") "subroutine ", char (prefix), &
            "set_color_factors_ptr (pid, cf_index1, cf_index2, color_factors, ", &
            "shape) bind(C)"
        write (unit, "(A)") " use iso_c_binding"
        write (unit, "(A)") " use kinds"
        write (unit, "(A)") " use omega_color"
        call driver%write_interfaces (unit, feature)
        write (unit, "(A)") " integer(c_int), intent(in) :: pid"
        write (unit, "(A)") " integer(c_int), dimension(1), intent(in) :: shape"
        write (unit, "(A)") " integer(c_int), dimension(*), intent(out) :: &
            &cf_index1, cf_index2"
        write (unit, "(A)") " complex(c_default_complex), dimension(*), &
            &intent(out) :: color_factors"
        write (unit, "(A)") " type(omega_color_factor), dimension(:), &
            &allocatable :: cf"
        write (unit, "(A)") " select case (pid)"
        do i = 1, driver%n_processes
            write (unit, "(2x,A,I0,A)") "case (", i, ")"
            call driver%record(i)%write_color_factors_call (unit)
        end do
        write (unit, "(A)") " end select"
        write (unit, "(A)") "end subroutine " // char (prefix) &

```

```

        // "set_color_factors_ptr"
    end subroutine write_set_color_factors_sub

```

The actual call depends on the type of matrix element.

```

<Prclib interfaces: prclib_driver_record: TBP>+≡
    procedure :: write_color_factors_call => prclib_driver_record_write_color_factors_call

<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_record_write_color_factors_call (record, unit)
        class(prclib_driver_record_t), intent(in) :: record
        integer, intent(in) :: unit
        call record%writer%write_color_factors_call (unit, record%id)
    end subroutine prclib_driver_record_write_color_factors_call

```

The interface goes into the writer base type:

```

<Prclib interfaces: prc_writer: TBP>+≡
    procedure(write_code), deferred :: write_color_factors_call

```

In the Fortran module case, the matrix-element procedure fills an array of `omega_color_factor` elements. We distribute this array among two integer arrays and one complex-valued array, for which we have the C pointers.

```

<Prclib interfaces: prc_writer_f_module: TBP>+≡
    procedure :: write_color_factors_call => prc_writer_f_module_write_color_factors_call

<Prclib interfaces: procedures>+≡
    subroutine prc_writer_f_module_write_color_factors_call (writer, unit, id)
        class(prc_writer_f_module_t), intent(in) :: writer
        integer, intent(in) :: unit
        type(string_t), intent(in) :: id
        write (unit, "(5x,A)") "allocate (cf (shape(1)))"
        write (unit, "(5x,9A)") "call ", &
            char (writer%get_c_procname (id, var_str ("color_factors"))), " (cf)"
        write (unit, "(5x,9A)") "cf_index1(1:shape(1)) = cf%i1"
        write (unit, "(5x,9A)") "cf_index2(1:shape(1)) = cf%i2"
        write (unit, "(5x,9A)") "color_factors(1:shape(1)) = cf%factor"
    end subroutine prc_writer_f_module_write_color_factors_call

```

In the C library case, we just transfer the C pointers to the library function. There are three arrays.

```

<Prclib interfaces: prc_writer_c_lib: TBP>+≡
    procedure :: write_color_factors_call => &
        prc_writer_c_lib_write_color_factors_call

<Prclib interfaces: procedures>+≡
    subroutine prc_writer_c_lib_write_color_factors_call (writer, unit, id)
        class(prc_writer_c_lib_t), intent(in) :: writer
        integer, intent(in) :: unit
        type(string_t), intent(in) :: id
        write (unit, "(5x,9A)") "call ", &
            char (writer%get_c_procname (id, var_str ("color_factors"))), &
            " (cf_index1, cf_index2, color_factors)"
    end subroutine prc_writer_c_lib_write_color_factors_call

```

14.1.10 Interfaces for C-library matrix element

If the matrix element code is not provided as a Fortran module but as a C or bind(C) Fortran library, we need explicit interfaces for the library functions. They are not identical to the Fortran module versions. They transfer pointers directly.

The implementation is part of the `prc_writer_c_lib` type, which serves as base type for all C-library writers. It writes specific interfaces depending on the feature.

We bind this as the method `write_standard_interface` instead of `write_interface`, because we have to override the latter. Otherwise we could not call the method because the writer type is abstract.

```
<Prclib interfaces: prc writer c lib: TBP>+=  
  procedure :: write_standard_interface => prc_writer_c_lib_write_interface  
  
<Prclib interfaces: procedures>+=  
  subroutine prc_writer_c_lib_write_interface (writer, unit, id, feature)  
    class(prc_writer_c_lib_t), intent(in) :: writer  
    integer, intent(in) :: unit  
    type(string_t), intent(in) :: id, feature  
    select case (char (feature))  
    case ("md5sum")  
      write (unit, "(2x,9A)") "interface"  
      write (unit, "(5x,9A)") "function ", &  
        char (writer%get_c_procname (id, var_str ("get_md5sum"))), &  
        " () result (cptr) bind(C)"  
      write (unit, "(7x,9A)") "import"  
      write (unit, "(7x,9A)") "implicit none"  
      write (unit, "(7x,9A)") "type(c_ptr) :: cptr"  
      write (unit, "(5x,9A)") "end function ", &  
        char (writer%get_c_procname (id, var_str ("get_md5sum")))  
      write (unit, "(2x,9A)") "end interface"  
    case ("openmp_supported")  
      write (unit, "(2x,9A)") "interface"  
      write (unit, "(5x,9A)") "function ", &  
        char (writer%get_c_procname (id, feature)), &  
        " () result (status) bind(C)"  
      write (unit, "(7x,9A)") "import"  
      write (unit, "(7x,9A)") "implicit none"  
      write (unit, "(7x,9A)") "logical(c_bool) :: status"  
      write (unit, "(5x,9A)") "end function ", &  
        char (writer%get_c_procname (id, feature))  
      write (unit, "(2x,9A)") "end interface"  
    case ("n_in", "n_out", "n_flv", "n_hel", "n_col", "n_cin", "n_cf")  
      write (unit, "(2x,9A)") "interface"  
      write (unit, "(5x,9A)") "function ", &

  write (unit, "(5x,9A)") "end subroutine ", &
    char (writer%get_c_procname (id, feature))
  write (unit, "(2x,9A)") "end interface"
end select
end subroutine prc_writer_c_lib_write_interface

```

14.1.11 Retrieving the tables

In the previous section we had the writer routines for procedures that return tables, actually C pointers to tables. Here, we write convenience routines that unpack them and move the contents to suitable Fortran arrays.

The flavor and helicity tables are two-dimensional integer arrays. We use intermediate storage for correctly transforming C to Fortran data types.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: set_flv_state => prclib_driver_set_flv_state
  procedure :: set_hel_state => prclib_driver_set_hel_state

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_set_flv_state (driver, i, flv_state)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    integer, dimension(:,:), allocatable, intent(out) :: flv_state
    integer :: n_tot, n_flv
    integer(c_int) :: pid
    integer(c_int), dimension(:,:), allocatable :: c_flv_state
    pid = i
    n_tot = driver%get_n_in (pid) + driver%get_n_out (pid)
    n_flv = driver%get_n_flv (pid)
    allocate (flv_state (n_tot, n_flv))
    allocate (c_flv_state (n_tot, n_flv))
    call driver%set_flv_state_ptr &
      (pid, c_flv_state, int ([n_tot, n_flv], kind=c_int))
    flv_state = c_flv_state
  end subroutine prclib_driver_set_flv_state

  subroutine prclib_driver_set_hel_state (driver, i, hel_state)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    integer, dimension(:,:), allocatable, intent(out) :: hel_state
    integer :: n_tot, n_hel
    integer(c_int) :: pid
    integer(c_int), dimension(:,:), allocatable, target :: c_hel_state
    pid = i
    n_tot = driver%get_n_in (pid) + driver%get_n_out (pid)
    n_hel = driver%get_n_hel (pid)
    allocate (hel_state (n_tot, n_hel))
    allocate (c_hel_state (n_tot, n_hel))
    call driver%set_hel_state_ptr &
      (pid, c_hel_state, int ([n_tot, n_hel], kind=c_int))
    hel_state = c_hel_state
  end subroutine prclib_driver_set_hel_state

```

The color-flow table is three-dimensional, otherwise similar. We simultaneously set the ghost-flag table, which consists of logical entries.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: set_col_state => prclib_driver_set_col_state

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_set_col_state (driver, i, col_state, ghost_flag)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    integer, dimension(:,:,:), allocatable, intent(out) :: col_state
    logical, dimension(:,:), allocatable, intent(out) :: ghost_flag
    integer :: n_cin, n_tot, n_col
    integer(c_int) :: pid
    integer(c_int), dimension(:,:,:), allocatable :: c_col_state
    logical(c_bool), dimension(:,:), allocatable :: c_ghost_flag
    pid = i

```

```

n_cin = driver%get_n_cin (pid)
n_tot = driver%get_n_in (pid) + driver%get_n_out (pid)
n_col = driver%get_n_col (pid)
allocate (col_state (n_cin, n_tot, n_col))
allocate (c_col_state (n_cin, n_tot, n_col))
allocate (ghost_flag (n_tot, n_col))
allocate (c_ghost_flag (n_tot, n_col))
call driver%set_col_state_ptr (pid, &
    c_col_state, c_ghost_flag, int ([n_cin, n_tot, n_col], kind=c_int))
col_state = c_col_state
ghost_flag = c_ghost_flag
end subroutine prclib_driver_set_col_state

```

The color-factor table is a sparse matrix: a two-column array of indices and one array which contains the corresponding factors.

(Prclib interfaces: prclib driver: TBP)+≡

```

procedure :: set_color_factors => prclib_driver_set_color_factors

```

(Prclib interfaces: procedures)+≡

```

subroutine prclib_driver_set_color_factors (driver, i, color_factors, cf_index)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: i
    complex(default), dimension(:), allocatable, intent(out) :: color_factors
    integer, dimension(:,:), allocatable, intent(out) :: cf_index
    integer :: n_cf
    integer(c_int) :: pid
    complex(c_default_complex), dimension(:), allocatable, target :: c_color_factors
    integer(c_int), dimension(:), allocatable, target :: c_cf_index1
    integer(c_int), dimension(:), allocatable, target :: c_cf_index2
    pid = i
    n_cf = driver%get_n_cf (pid)
    allocate (color_factors (n_cf))
    allocate (c_color_factors (n_cf))
    allocate (c_cf_index1 (n_cf))
    allocate (c_cf_index2 (n_cf))
    call driver%set_color_factors_ptr (pid, &
        c_cf_index1, c_cf_index2, &
        c_color_factors, int ([n_cf], kind=c_int))
    color_factors = c_color_factors
    allocate (cf_index (2, n_cf))
    cf_index(1,:) = c_cf_index1
    cf_index(2,:) = c_cf_index2
end subroutine prclib_driver_set_color_factors

```

14.1.12 Returning a procedure pointer

The functions that directly access the matrix element, event by event, are assigned to a process-specific driver object as procedure pointers. For the `dlopen` interface, we use C function pointers. This subroutine returns such a pointer:

(Prclib interfaces: public)+≡

```

public :: prc_get_fptr

```

```

<Prclib interfaces: interfaces>+≡
  abstract interface
    subroutine prc_get_fptr (pid, fid, fptr) bind(C)
      import
        integer(c_int), intent(in) :: pid
        integer(c_int), intent(in) :: fid
        type(c_funptr), intent(out) :: fptr
    end subroutine prc_get_fptr
  end interface

```

This procedure writes the source code for the procedure pointer returning subroutine.

All C functions that are provided by the matrix element code of a specific process are handled here. The selection consists of a double layered **select case** construct.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: write_get_fptr_sub

<Prclib interfaces: procedures>+≡
  subroutine write_get_fptr_sub (driver, unit, prefix)
    class(prclib_driver_t), intent(in) :: driver
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    integer :: i, j
    write (unit, "(A)") ""
    write (unit, "(A)") "! Return C pointer to a procedure:"
    write (unit, "(A)") "! pid = process index; fid = function index"
    write (unit, "(4A)") "subroutine ", char (prefix), "get_fptr ", &
      "(pid, fid, fptr) bind(C)"
    write (unit, "(A)") " use iso_c_binding"
    write (unit, "(A)") " use kinds"
    write (unit, "(A)") " implicit none"
    write (unit, "(A)") " integer(c_int), intent(in) :: pid"
    write (unit, "(A)") " integer(c_int), intent(in) :: fid"
    write (unit, "(A)") " type(c_funptr), intent(out) :: fptr"
    do i = 1, driver%n_processes
      call driver%record(i)%write_interfaces (unit)
    end do
    write (unit, "(A)") " select case (pid)"
    do i = 1, driver%n_processes
      write (unit, "(2x,A,IO,A)") "case (", i, ")"
      write (unit, "(5x,A)") "select case (fid)"
      associate (record => driver%record(i))
        do j = 1, size (record%feature)
          write (unit, "(5x,A,IO,9A)") "case (", j, "); ", &
            "fptr = c_funloc (", &
            char (record%get_c_procname (record%feature(j))), &
            ")"
        end do
      end associate
      write (unit, "(5x,A)") "end select"
    end do
    write (unit, "(A)") " end select"
    write (unit, "(3A)") "end subroutine ", char (prefix), "get_fptr"
  end subroutine write_get_fptr_sub

```

```
end subroutine write_get_fptr_sub
```

The procedures for which we want to return a pointer (the 'features' of the matrix element code) are actually Fortran module procedures. If we want to have a C signature, we must write wrapper functions for all of them. The procedures, their signatures, and the appropriate writer routines are specific for the process type.

To keep this generic, we do not provide the writer routines here, but just the interface for a writer routine. The actual routines are stored in the process record.

The `prefix` indicates the library, the `id` indicates the process, and `procname` is the bare name of the procedure to be written.

```
<Prclib interfaces: public>+≡
public :: write_driver_code

<Prclib interfaces: interfaces>+≡
abstract interface
  subroutine write_driver_code (unit, prefix, id, procname)
    import
    integer, intent(in) :: unit
    type(string_t), intent(in) :: prefix
    type(string_t), intent(in) :: id
    type(string_t), intent(in) :: procname
  end subroutine write_driver_code
end interface
```

14.1.13 Hooks

Interface for additional library unload / reload hooks (currently unused!)

```
<Prclib interfaces: public>+≡
public :: prclib_unload_hook
public :: prclib_reload_hook

<Prclib interfaces: interfaces>+≡
abstract interface
  subroutine prclib_unload_hook (libname)
    import
    type(string_t), intent(in) :: libname
  end subroutine prclib_unload_hook

  subroutine prclib_reload_hook (libname)
    import
    type(string_t), intent(in) :: libname
  end subroutine prclib_reload_hook
end interface
```

14.1.14 Make source, compile, link

Since we should have written a Makefile, these tasks amount to simple `make` calls. Note that the Makefile targets depend on each other, so calling `link` executes also the `source` and `compile` steps, when necessary.

The first routine writes source-code files for the individual processes. First it calls the writer routines directly for each process, then it calls `make source`. The `make` command may either post-process the files, or it may do the complete work, e.g., calling an external program that generates the files.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: make_source => prclib_driver_make_source

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_make_source (driver, os_data)
    class(prclib_driver_t), intent(in) :: driver
    type(os_data_t), intent(in) :: os_data
    integer :: i
    do i = 1, driver%n_processes
      call driver%record(i)%write_source_code ()
    end do
    call os_system_call ("make source " // os_data%makeflags &
      // " -f " // driver%basename // ".makefile")
  end subroutine prclib_driver_make_source

```

Compile matrix element source code and the driver source code.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: make_compile => prclib_driver_make_compile

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_make_compile (driver, os_data)
    class(prclib_driver_t), intent(in) :: driver
    type(os_data_t), intent(in) :: os_data
    call os_system_call ("make compile " // os_data%makeflags &
      // " -f " // driver%basename // ".makefile")
  end subroutine prclib_driver_make_compile

```

Combine all matrix-element code together with the driver in a process library on disk.

```

<Prclib interfaces: prclib driver: TBP>+≡
  procedure :: make_link => prclib_driver_make_link

<Prclib interfaces: procedures>+≡
  subroutine prclib_driver_make_link (driver, os_data)
    class(prclib_driver_t), intent(in) :: driver
    type(os_data_t), intent(in) :: os_data
    call os_system_call ("make link " // os_data%makeflags &
      // " -f " // driver%basename // ".makefile")
  end subroutine prclib_driver_make_link

```

14.1.15 Clean up generated files

The task of cleaning any generated files should also be deferred to Makefile targets. Apart from removing everything, removing specific files may be useful for partial rebuilds. (Note that removing the makefile itself can only be done once, for obvious reasons.)

If there is no makefile, do nothing.

```

<Prclib interfaces: prclib driver: TBP>+≡

```

```

procedure :: clean_library => prclib_driver_clean_library

        // " -f " // driver%basename // ".makefile")
end if
end subroutine prclib_driver_distclean

```

This Make target should remove all files that apply to a specific process. We execute this when we want to force remaking source code. Note that source targets need not have prerequisites, so just calling `make_source` would not do anything if the files exist.

```

<Prclib interfaces: prclib driver: TBP>+≡
    procedure :: clean_proc => prclib_driver_clean_proc

<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_clean_proc (driver, i, os_data)
        class(prclib_driver_t), intent(in) :: driver
        integer, intent(in) :: i
        type(os_data_t), intent(in) :: os_data
        type(string_t) :: id
        if (driver%makefile_exists ()) then
            id = driver%record(i)%id
            call os_system_call ("make clean-" // driver%record(i)%id // " " &
                // os_data%makeflags &
                // " -f " // driver%basename // ".makefile")
        end if
    end subroutine prclib_driver_clean_proc

```

14.1.16 Further Tools

Check for the appropriate makefile.

```

<Prclib interfaces: prclib driver: TBP>+≡
    procedure :: makefile_exists => prclib_driver_makefile_exists

<Prclib interfaces: procedures>+≡
    function prclib_driver_makefile_exists (driver) result (flag)
        class(prclib_driver_t), intent(in) :: driver
        logical :: flag
        inquire (file = char (driver%basename) // ".makefile", exist = flag)
    end function prclib_driver_makefile_exists

```

14.1.17 Load the library

Once the library has been linked, we can dlopen it and assign all procedure pointers to their proper places in the library driver object. The loaded flag is set only if all required pointers have become assigned.

```
<Prclib interfaces: prclib driver: TBP>+≡
    procedure :: load => prclib_driver_load

<Prclib interfaces: procedures>+≡
    subroutine prclib_driver_load (driver, os_data, noerror)

This version of test-code writer actually writes an interface and wrapper code.
The wrapped function is a no-parameter function with integer result.

The stored MD5 sum may be modified.

We will reuse this later, therefore public.

```

14.2 Abstract process core configuration

In this module, we define abstract data types that handle the method-specific part of defining a process (including all of its options) and accessing an external matrix element.

There are no unit tests, these are deferred to the `process_libraries` module below.

```
⟨prc_core_def.f90⟩≡
  ⟨File header⟩

  module prc_core_def

    ⟨Use strings⟩
    ⟨Use file utils⟩
    use diagnostics !NODEP!

    use process_constants
    use prclib_interfaces

    ⟨Standard module head⟩

    ⟨Prc core def: public⟩

    ⟨Prc core def: types⟩

    ⟨Prc core def: interfaces⟩

    contains

    ⟨Prc core def: procedures⟩

  end module prc_core_def
```

14.2.1 Process core definition type

For storing configuration data that depend on the specific process variant, we introduce a polymorphic type. At this point, we just declare an abstract base type. This allows us to defer the implementation to later modules.

There should be no components that need explicit finalization, otherwise we would have to call a finalizer from the `process_component_def_t` wrapper.

```

<Prc core def: public>≡
  public :: prc_core_def_t

<Prc core def: types>≡
  type, abstract :: prc_core_def_t
    class(prc_writer_t), allocatable :: writer
    contains
    <Prc core def: process core def: TBP>
  end type prc_core_def_t

```

Interfaces for the deferred methods.

This returns a string. No passed argument; the string is constant and depends just on the type.

```

<Prc core def: process core def: TBP>≡
  procedure (prc_core_def_get_string), nopass, deferred :: type_string

<Prc core def: interfaces>≡
  abstract interface
    function prc_core_def_get_string () result (string)
      import
      type(string_t) :: string
    end function prc_core_def_get_string
  end interface

```

The `write` method should display the content completely.

```

<Prc core def: process core def: TBP>+≡
  procedure (prc_core_def_write), deferred :: write

<Prc core def: interfaces>+≡
  abstract interface
    subroutine prc_core_def_write (object, unit)
      import
      class(prc_core_def_t), intent(in) :: object
      integer, intent(in) :: unit
    end subroutine prc_core_def_write
  end interface

```

The `read` method should fill the content completely.

```

<Prc core def: process core def: TBP>+≡
  procedure (prc_core_def_read), deferred :: read

<Prc core def: interfaces>+≡
  abstract interface
    subroutine prc_core_def_read (object, unit)
      import
      class(prc_core_def_t), intent(out) :: object
      integer, intent(in) :: unit
    end subroutine prc_core_def_read
  end interface

```

This communicates a MD5 checksum to the writer inside the `core_def` object, if there is any. Usually, this checksum is not yet known at the time when the writer is initialized.

```

<Prc core def: process core def: TBP>+≡
  procedure :: set_md5sum => prc_core_def_set_md5sum

<Prc core def: procedures>≡
  subroutine prc_core_def_set_md5sum (core_def, md5sum)
    class(prc_core_def_t), intent(inout) :: core_def
    character(32) :: md5sum
    if (allocated (core_def%writer)) core_def%writer%md5sum = md5sum
  end subroutine prc_core_def_set_md5sum

```

Allocate an appropriate driver object which corresponds to the chosen process core definition.

For internal matrix element (i.e., those which do not need external code), the driver should have access to all matrix element information from the beginning. In short, it is the matrix-element code.

For external matrix elements, the driver will get access to the external matrix element code.

```

<Prc core def: process core def: TBP>+≡
  procedure(prc_core_def_allocate_driver), deferred :: allocate_driver

<Prc core def: interfaces>+≡
  interface
    subroutine prc_core_def_allocate_driver (object, driver, basename)
      import
      class(prc_core_def_t), intent(in) :: object
      class(prc_core_driver_t), intent(out), allocatable :: driver
      type(string_t), intent(in) :: basename
    end subroutine prc_core_def_allocate_driver
  end interface

```

This flag tells whether the particular variant needs external code. We implement a default function which returns false. The flag depends only on the type, therefore we implement it as `nopass`.

```

<Prc core def: process core def: TBP>+≡
  procedure, nopass :: needs_code => prc_core_def_needs_code

<Prc core def: procedures>+≡
  function prc_core_def_needs_code () result (flag)
    logical :: flag
    flag = .false.
  end function prc_core_def_needs_code

```

This subroutine allocates an array which holds the name of all features that this process core implements. This feature applies to matrix element code that is not coded as a Fortran module but communicates via independent library functions, which follow the C calling conventions. The addresses of those functions are returned as C function pointers, which can be converted into Fortran procedure pointers. The conversion is done in code specific for the process variant; here we just retrieve the C function pointer.

The array returned here serves the purpose of writing specific driver code. The driver interfaces only those C functions which are supported for the given process core.

If the process core does not require external code, this array is meaningless.

```

<Prc core def: process core def: TBP>+≡
    procedure(prc_core_def_get_features), nopass, deferred &
        :: get_features

<Prc core def: interfaces>+≡
    abstract interface
        subroutine prc_core_def_get_features (features)
            import
            type(string_t), dimension(:), allocatable, intent(out) :: features
        end subroutine prc_core_def_get_features
    end interface

```

Assign pointers to the process-specific procedures to the driver, if the process is external.

```

<Prc core def: process core def: TBP>+≡
    procedure(prc_core_def_connect), deferred :: connect

<Prc core def: interfaces>+≡
    abstract interface
        subroutine prc_core_def_connect (def, lib_driver, i, proc_driver)
            import
            class(prc_core_def_t), intent(in) :: def
            class(prclib_driver_t), intent(in) :: lib_driver
            integer, intent(in) :: i
            class(prc_core_driver_t), intent(inout) :: proc_driver
        end subroutine prc_core_def_connect
    end interface

```

14.2.2 Process core template

We must be able to automatically allocate a process core definition object with the appropriate type, given only the type name.

To this end, we introduce a `prc_template_t` type which is simply a wrapper for an empty `prc_core_def_t` object. Choosing one of the templates from an array, we can allocate the target object.

```

<Prc core def: public>+≡
    public :: prc_template_t

<Prc core def: types>+≡
    type :: prc_template_t
        class(prc_core_def_t), allocatable :: core_def
    end type prc_template_t

```

The allocation routine. We use the `source` option of the `allocate` statement. The `mold` option would probably more appropriate, but is a F2008 feature.

```

<Prc core def: public>+≡
    public :: allocate_core_def

```

```

<Prc core def: procedures>+=
  subroutine allocate_core_def (template, name, core_def)
    type(prc_template_t), dimension(:), intent(in) :: template
    type(string_t), intent(in) :: name
    class(prc_core_def_t), allocatable :: core_def
    integer :: i
    do i = 1, size (template)
      if (template(i)%core_def%type_string () == name) then
        allocate (core_def, source = template(i)%core_def)
        return
      end if
    end do
  end subroutine allocate_core_def

```

14.2.3 Process driver

For each process component, we implement a driver object which holds the calls to the matrix element and various auxiliary routines as procedure pointers. Any actual calculation will use this object to communicate with the process.

Depending on the type of process (as described by a corresponding `prc_core_def` object), the procedure pointers may refer to external or internal code, and there may be additional procedures for certain types. The base type defined here is abstract.

```

<Prc core def: public>+=
  public :: prc_core_driver_t
<Prc core def: types>+=
  type, abstract :: prc_core_driver_t
  contains
    <Prc core def: process driver: TBP>
  end type prc_core_driver_t

```

This returns the process type. No reference to contents.

```

<Prc core def: process driver: TBP>=
  procedure(prc_core_driver_type_name), nopass, deferred :: type_name
<Prc core def: interfaces>+=
  abstract interface
    function prc_core_driver_type_name () result (type)
      import
      type(string_t) :: type
    end function prc_core_driver_type_name
  end interface

```

14.2.4 Process driver for intrinsic process

This is an abstract extension for the driver type. It has one additional method, namely a subroutine that fills the record of constant process data. For an external process, this task is performed by the external library driver instead.

```

<Prc core def: public>+=
  public :: process_driver_internal_t

```

```

<Prc core def: types>+≡
  type, extends (prc_core_driver_t), abstract :: process_driver_internal_t
  contains
    <Prc core def: process driver internal: TBP>
  end type process_driver_internal_t

<Prc core def: process driver internal: TBP>≡
  procedure(process_driver_fill_constants), deferred :: fill_constants

<Prc core def: interfaces>+≡
  abstract interface
    subroutine process_driver_fill_constants (driver, data)
      import
        class(process_driver_internal_t), intent(in) :: driver
        type(process_constants_t), intent(out) :: data
    end subroutine process_driver_fill_constants
  end interface

```

14.3 Particle Specifiers

In this module we introduce a type for specifying a particle or particle alternative. In addition to the particle specifiers (strings separated by colons), the type contains an optional flag **polarized** and a string **decay**. If the **polarized** flag is set, particle polarization information should be kept when generating events for this process. If the **decay** string is set, it is the ID of a decay process which should be applied to this particle when generating events.

In input/output form, the **polarized** flag is indicated by an asterisk (*) in brackets, and the **decay** is indicated by its ID in brackets.

The **read** and **write** procedures in this module are not type-bound but generic procedures which handle scalar and array arguments.

```

<particle_specifiers.f90>≡
  <File header>

  module particle_specifiers

    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use unit_tests

    <Standard module head>

    <Particle specifiers: public>

    <Particle specifiers: types>

    <Particle specifiers: interfaces>

    contains

    <Particle specifiers: procedures>

```

```

    <Particle specifiers: tests>

end module particle_specifiers

```

14.3.1 The type

The particle is unstable if the **decay** array is allocated. The **polarized** flag and decays may not be set simultaneously.

```

<Particle specifiers: public>≡
    public :: prt_spec_t

<Particle specifiers: types>≡
    type :: prt_spec_t
        private
        type(string_t) :: name
        logical :: polarized = .false.
        type(string_t), dimension(:), allocatable :: decay
    contains
        <Particle specifiers: prt spec: TBP>
    end type prt_spec_t

```

Output.

```

<Particle specifiers: public>+≡
    public :: prt_spec_write

<Particle specifiers: interfaces>≡
    interface prt_spec_write
        module procedure prt_spec_write1
        module procedure prt_spec_write2
    end interface prt_spec_write

<Particle specifiers: procedures>≡
    subroutine prt_spec_write1 (object, unit, advance)
        type(prt_spec_t), intent(in) :: object
        integer, intent(in), optional :: unit
        character(len=*), intent(in), optional :: advance

      write (u, "(A)", advance="no") "decays   ="
    end do
  end subroutine particle_specifiers_1

```

```

do j = 1, size (decay)
  write (u, "(1x,A)", advance="no") char (decay(j))
end do
write (u, "(A)")
end do

write (u, "(A)")
write (u, "(A)")  "* Test output end: particle_specifiers_1"
end subroutine particle_specifiers_1

```

14.4 Process library access

Processes (the code and data that are necessary for evaluating matrix elements of a particular process or process component) are organized in process libraries. In full form, process libraries contain generated and dynamically compiled and linked code, so they are actual libraries on the OS level. Alternatively, there may be simple processes that can be generated without referring to external libraries, and external libraries that are just linked in.

This module interfaces the OS to create, build, and use process libraries.

We work with two related data structures. There is the list of process configurations that stores the user input and data derived from it. A given process configuration list is scanned for creating a process library, which consists of both data and code. The creation step involves calling external programs and incorporating external code.

For the subsequent integration and event generation steps, we read the process library. We also support partial (re)creation of the process library. To this end, we should be able to reconstruct the configuration data records from the process library.

```

<process_libraries.f90>≡
  <File header>

  module process_libraries

    use iso_c_binding !NODEP!
    use kinds !NODEP!
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use md5
    use unit_tests
    use os_interface
    use lexers
    use variables
    use user_code_interface
    use models
    use flavors

    use process_constants
    use prclib_interfaces
    use prc_core_def

```

```

    use particle_specifiers

    <Standard module head>

    <Process libraries: public>

    <Process libraries: parameters>

    <Process libraries: types>

    <Process libraries: interfaces>

    <Process libraries: variables>

    <Process libraries: test declarations>

contains

    <Process libraries: procedures>

    <Process libraries: tests>

end module process_libraries

```

14.4.1 Auxiliary stuff

Here is a small subroutine that strips the left-hand side and the equals sign off an equation.

```

<Process libraries: procedures>≡
  subroutine strip_prefix (buffer)
    character(*), intent(inout) :: buffer
    type(string_t) :: string, prefix
    string = buffer
    call split (string, prefix, "=")
    buffer = string
  end subroutine strip_prefix

```

14.4.2 Process definition objects

We collect process configuration data in a derived type, `process_def_t`. A process can be a collection of several components which are treated as a single entity for the purpose of observables and event generation. Multiple process components may initially be defined by the user. The system may add additional components, e.g., subtraction terms. The common data type is `process_component_def_t`. Within each component, there are several universal data items, and a part which depend on the particular process variant. The latter is covered by an abstract type `prc_core_def_t` and its extensions.

Wrapper for components

We define a wrapper type for the configuration of individual components.

The string **basename** is used for building file, module, and function names for the current process component. Initially, it will be built from the corresponding process basename by appending an alphanumeric suffix.

The logical **initial** tells whether this is a user-defined (true) or system-generated (false) configuration.

The numbers **n_in**, **n_out**, and **n_tot** denote the incoming, outgoing and total number of particles (partons) participating in the process component, respectively. These are the nominal particles, as input by the user (recombination may change the particle content, for the output events).

The string arrays **prt_in** and **prt_out** hold the particle specifications as provided by the user. For a system-generated process component, they remain deallocated.

The **method** string is used to determine the type of process matrix element and how it is obtained.

The **description** string collects the information about particle content and method in a single human-readable string.

The pointer object **core_def** is allocated according to the actual process variant, which depends on the method. The subobject holds any additional configuration data that is relevant for the process component.

We assume that no finalizer is needed.

```

(Process libraries: public)≡
    public :: process_component_def_t

(Process libraries: types)≡

end subroutine process_component_def_show

```

Compute the MD5 sum of a process component. We reset the stored MD5 sum to the empty string (so a previous value is not included in the calculation), the write a temporary file and calculate the MD5 sum of that file.

This implies that all data that are displayed by the `write` method become part of the MD5 sum calculation.

The `model` is not part of the object, but must be included in the MD5 sum. Otherwise, modifying the model and nothing else would not trigger remaking the process-component source. Note that the model parameters may change later and therefore are not incorporated.

After the MD5 sum of the component has been computed, we communicate it to the `writer` subobject of the specific `core_def` component. Although these types are abstract, the MD5-related features are valid for the abstract types.

```

<Process libraries: process component def: TBP>+≡
    procedure :: compute_md5sum => process_component_def_compute_md5sum
<Process libraries: procedures>+≡
    subroutine process_component_def_compute_md5sum (component, model)

```

Process definition

The process component definitions are collected in a common process definition object.

The `id` is the ID string that the user has provided for identifying this process. It must be a string that is allowed as part of a Fortran variable name, since it may be used for generating code.

The number `n_in` is 1 or 2 for a decay or scattering process, respectively. This must be identical to `n_in` for all components.

The initial and extra component definitions (see above) are allocated as the `initial` and `extra` arrays, respectively. The latter are determined from the former.

The `md5sum` is used to verify the integrity of the configuration.

```

  (Process libraries: public)+≡
    public :: process_def_t
  (Process libraries: types)+≡
    type :: process_def_t
      private
      type(string_t) :: id
      integer :: num_id = 0
      type(model_t), pointer :: model => null ()
      type(string_t) :: model_name
      integer :: n_in = 0
      integer :: n_initial = 0

```

```

integer :: n_extra = 0
type(process_component_def_t), dimension(:), allocatable :: initial
type(process_component_def_t), dimension(:), allocatable :: extra

```

Initialize an entry (initialize the process definition inside). We allocate the 'initial' set of components. Extra components remain unallocated.

The model should be present as a pointer. This allows us to retrieve the model's MD5 sum. However, for various tests it is sufficient to have the name.

We create the basenames for the process components by appending a suffix which we increment for each component.

```

(Process libraries: process def: TBP)+≡
  procedure :: init => process_def_init

  def%initial(i)%basename = def%id // trim (suffix)
end do
def%initial%description = ""
end subroutine process_def_init

```

Initialize an initial component. The particle content must be specified. The process core block is not (yet) allocated.

We assume that the particle arrays match the `n_in` and `n_out` values in size. The model is referred to by name; it is identified as an existing model later. The index `i` must refer to an existing element of the component array.

Data specific for the process core of a component are imported as the `core_def` argument. We should allocate an object of class `prc_core_def_t` with the appropriate specific type, fill it, and transfer it to the process component definition here. The allocation is moved, so the original allocated object is returned empty.

(Process libraries: process def: TBP)+≡

    end function process_def_needs_code

```

Process definition list

A list of process definitions is the starting point for creating a process library. The list is built when reading the user input. When reading an existing process library, the list is used for cross-checking and updating the configuration.

We need a type for the list entry. The simplest way is to extend the process definition type, so all methods apply to the process definition directly.

```

<Process libraries: public>+≡
    public :: process_def_entry_t

```

```

<Process libraries: types>+≡
  type, extends (process_def_t) :: process_def_entry_t
  private
    type(process_def_entry_t), pointer :: next => null ()
  end type process_def_entry_t

```

This is the type for the list itself.

```

<Process libraries: types>+≡
  type :: process_def_list_t
  private
    type(process_def_entry_t), pointer :: first => null ()
    type(process_def_entry_t), pointer :: last => null ()
  contains
    <Process libraries: process def list: TBP>
  end type process_def_list_t

```

The deallocates the list iteratively. We assume that the list entries do not need finalization themselves.

```

<Process libraries: process def list: TBP>≡
  procedure :: final => process_def_list_final

<Process libraries: procedures>+≡
  subroutine process_def_list_final (list)
    class(process_def_list_t), intent(inout) :: list
    type(process_def_entry_t), pointer :: current
    nullify (list%last)
    do while (associated (list%first))
      current => list%first
      list%first => current%next
      deallocate (current)
    end do
  end subroutine process_def_list_final

```

Write the complete list.

```

<Process libraries: process def list: TBP>+≡
  procedure :: write => process_def_list_write

<Process libraries: procedures>+≡
  subroutine process_def_list_write (object, unit)
    class(process_def_list_t), intent(in) :: object
    integer, intent(in), optional :: unit
    type(process_def_entry_t), pointer :: entry
    integer :: i, u
    u = output_unit (unit)
    if (associated (object%first)) then
      i = 1
      entry => object%first
      do while (associated (entry))
        write (u, "(1x,A,IO,A)") "Process #", i, ":"
        call entry%write (u)
        i = i + 1
        entry => entry%next
        if (associated (entry)) write (u, *)
      end do
    end if
  end subroutine process_def_list_write

```

```

        end do
    else
        write (u, "(1x,A)") "Process definition list: [empty]"
    end if
end subroutine process_def_list_write

```

Short account.

```

<Process libraries: process def list: TBP>+≡
    procedure :: show => process_def_list_show

<Process libraries: procedures>+≡
    subroutine process_def_list_show (object, unit)
        class(process_def_list_t), intent(in) :: object
        integer, intent(in), optional :: unit
        type(process_def_entry_t), pointer :: entry
        integer :: u
        u = output_unit (unit)
        if (associated (object%first)) then
            write (u, "(2x,A)") "Processes:"
            entry => object%first
            do while (associated (entry))
                call entry%show (u)
                entry => entry%next
            end do
        else

```

14.4.3 Process library

The process library object is the interface between the process definition data, as provided by the user, generated or linked process code on file, and the process run data that reference the process code.

Process library entry

For each process component that is part of the library, there is a separate library entry (`process_library_entry_t`). The library entry connects a process definition with the specific code (if any) in the compiled driver library.

The `status` indicates how far the process has been processed by the system (definition, code generation, compilation, linking). A process with status `STAT_LOADED` is accessible for computing matrix elements.

The `def` pointer identifies the corresponding process definition. The process component within that definition is identified by the `i_component` index.

The `i_external` index refers to the compiled library driver. If it is zero, there is no associated matrix-element code.

The `driver` component holds the pointers to the matrix-element specific functions, in particular the matrix element function itself.

```

<Process libraries: types>+≡
type :: process_library_entry_t
private
integer :: status = STAT_UNKNOWN
type(process_def_t), pointer :: def => null ()
integer :: i_component = 0
integer :: i_external = 0
class(prc_core_driver_t), allocatable :: driver
contains
<Process libraries: process library entry: TBP>
end type process_library_entry_t

```

Here are the available status codes. An entry starts with `UNKNOWN` status. Once the association with a valid process definition is established, the status becomes `CONFIGURED`. If matrix element source code is to be generated by the system or provided from elsewhere, `CODE_GENERATED` indicates that this is done. The `COMPILED` status is next, it also applies to processes which are accessed as pre-compiled binaries. Finally, the library is linked and process pointers are set; this is marked as `LOADED`.

For a process library, the initial status is OPEN, since process definitions may be added. After configuration, the process content is fixed and the status becomes CONFIGURED. The further states are as above, always referring to the lowest status among the process entries.

```

(Process libraries: parameters)+≡
  integer, parameter :: STAT_UNKNOWN = 0
  integer, parameter :: STAT_OPEN = 1
  integer, parameter :: STAT_CONFIGURED = 2
  integer, parameter :: STAT_SOURCE = 3
  integer, parameter :: STAT_COMPILED = 4
  integer, parameter :: STAT_LINKED = 5
  integer, parameter :: STAT_ACTIVE = 6

```

These are the associated code letters, for output:

```

(Process libraries: parameters)+≡
  character, dimension(0:6), parameter :: STATUS_LETTER = &
    ["?", "o", "f", "s", "c", "l", "a"]

```

This produces a condensed account of the library entry. The status is indicated by a letter in brackets, then the ID and component index of the associated process definition, finally the library index, if available.

```

(Process libraries: process library entry: TBP)+≡
  procedure :: to_string => process_library_entry_to_string

(Process libraries: procedures)+≡
  function process_library_entry_to_string (object) result (string)
    type(string_t) :: string
    class(process_library_entry_t), intent(in) :: object
    character(32) :: buffer
    string = "[" // STATUS_LETTER(object%status) // "]"
    select case (object%status)
    case (STAT_UNKNOWN)
    case default
      if (associated (object%def)) then
        write (buffer, "(IO)") object%i_component
        string = string // " " // object%def%id // "." // trim (buffer)
      end if
      if (object%i_external /= 0) then
        write (buffer, "(IO)") object%i_external
        string = string // " = ext:" // trim (buffer)
      else
        string = string // " = int"
      end if
      if (allocated (object%driver)) then
        string = string // " (" // object%driver%type_name () // ")"
      end if
    end select
  end function process_library_entry_to_string

```

Initialize with data. Used for the unit tests.

```

(Process libraries: process library entry: TBP)+≡
  procedure :: init => process_library_entry_init

```

```

<Process libraries: procedures>+≡
  subroutine process_library_entry_init (object, &
    status, def, i_component, i_external)
    class(process_library_entry_t), intent(out) :: object
    integer, intent(in) :: status
    type(process_def_t), target, intent(in) :: def
    integer, intent(in) :: i_component
    integer, intent(in) :: i_external
    object%status = status
    object%def => def
    object%i_component = i_component
    object%i_external = i_external
  end subroutine process_library_entry_init

```

Assign pointers for all process-specific features. We have to combine the method from the `core_def` specification, the assigned pointers within the library driver, the index within that driver, and the process driver which should receive the links.

```

<Process libraries: process library entry: TBP>+≡
  procedure :: connect => process_library_entry_connect

<Process libraries: procedures>+≡
  subroutine process_library_entry_connect (entry, lib_driver, i)
    class(process_library_entry_t), intent(inout) :: entry
    class(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i
    call entry%def%initial(entry%i_component)%connect &
      (lib_driver, i, entry%driver)
  end subroutine process_library_entry_connect

```

The process library object

The `process_library_t` type is an extension of the `process_def_list_t` type. Thus, it automatically contains the process definition list.

The `basename` identifies the library generically.

The `external` flag is true if any process within the library needs external code, so the library must correspond to an actual code library (statically or dynamically linked).

The `entry` array contains all process components that can be handled by this library. Each entry refers to the process (component) definition and to the associated external matrix element code, if there is any.

The `driver` object is needed only if `external` is true. This object handles all interactions with external matrix-element code.

The `md5sum` summarizes the complete `process_def_list_t` base object. It can be used to check if the library configuration has changed.

```

<Process libraries: public>+≡
  public :: process_library_t

<Process libraries: types>+≡
  type, extends (process_def_list_t) :: process_library_t
  private

```

```

type(string_t) :: basename
integer :: n_entries = 0
logical :: external = .false.
integer :: status = STAT_UNKNOWN
logical :: static = .false.
logical :: driver_exists = .false.
logical :: makefile_exists = .false.
type(process_library_entry_t), dimension(:), allocatable :: entry
class(prclib_driver_t), allocatable :: driver
character(32) :: md5sum = ""
contains
  <Process libraries: process library: TBP>
end type process_library_t

```

For the output, we write first the metadata and the DL access record, then the library entries in short form, and finally the process definition list which is the base object.

```

<Process libraries: process library: TBP>≡
  procedure :: write => process_library_write

<Process libraries: procedures>+≡
  subroutine process_library_write (object, unit)
    class(process_library_t), intent(in) :: object

  call object%process_def_list_t%show (u)
end subroutine process_library_show

```

The initializer defines just the basename. We may now add process definitions to the library.

```

<Process libraries: process library: TBP>+≡
procedure :: init => process_library_init

<Process libraries: procedures>+≡
subroutine process_library_init (lib, basename)
  class(process_library_t), intent(out) :: lib
  type(string_t), intent(in) :: basename
  lib%basename = basename
  lib%status = STAT_OPEN
  call msg_message ("Process library '" // char (basename) &
    // "' : initialized")
end subroutine process_library_init

```

This alternative initializer declares the library as static. We should now add process definitions to the library, but all external process code exists already. We need the driver object, and we should check the defined processes against the stored ones.

```

<Process libraries: process library: TBP>+≡
procedure :: init_static => process_library_init_static

<Process libraries: procedures>+≡

```

```

subroutine process_library_init_static (lib, basename)
  class(process_library_t), intent(out) :: lib
  type(string_t), intent(in) :: basename
  lib%basename = basename
  lib%status = STAT_OPEN
  lib%static = .true.
  call msg_message ("Static process library '" // char (basename) &
    // "' : initialized")
end subroutine process_library_init_static

```

The `configure` procedure scans the allocated entries in the process definition list. The configuration proceeds in three passes.

In the first pass, we scan the process definition list and count the number of process components and the number of components which need external code. This is used to allocate the `entry` array.

In the second pass, we initialize the `entry` elements which connect process definitions, process driver objects, and external code.

In the third pass, we initialize the library driver object, allocating an entry for each external matrix element.

NOTE: Currently we handle only `initial` process components; `extra` components are ignored.

```

  end if
end subroutine process_library_write_driver

```

Update the compilation status of an external library.

Strictly speaking, this is not necessary for a one-time run, since the individual library methods will update the status themselves. However, it allows us to identify compilation steps that we can skip because the file exists or is already loaded, for the whole library or for particular entries.

Independently, the building process is controlled by a makefile. Thus, previous files are reused if they are not modified by the current compilation.

1. If it is not already loaded, attempt to load the library. If successful, check the overall MD5 sum. If it matches, just keep it loaded and mark as ACTIVE. If not, check the MD5 sum for all linked process components. Where it matches, mark the entry as COMPILED. Then, unload the library and mark as CONFIGURED.

Thus, we can identify compiled files for all matrix elements which are accessible via the previous compiled library, even if it is no longer up to date.

2. If the library is now in CONFIGURED state, look for valid source files. Each entry that is just in CONFIGURED state will advance to SOURCE if the MD5 sum matches. Finally, advance the whole library to SOURCE if all entries are at least in this condition.

<Process libraries: process library: TBP>+≡

procedure :: update_status => process_library_update_status

<Process libraries: procedures>+≡

```

subroutine process_library_update_status (lib, os_data)
  class(process_library_t), intent(inout) :: lib
  type(os_data_t), intent(in) :: os_data
  character(32) :: md5sum_file

        i_component = entry%i_component
        if (i_external /= 0) then
          select case (entry%status)

```

```

        case (STAT_CONFIGURED)
            md5sum_file = lib%driver%get_md5sum_source (i_external)
            if (entry%def%get_md5sum (i_component) == md5sum_file) then
                entry%status = STAT_SOURCE
            end if
        end select
    end if
end associate
end do
if (all (lib%entry%status >= STAT_SOURCE)) then
    md5sum_file = lib%driver%get_md5sum_driver ()
    if (lib%md5sum == md5sum_file) then
        lib%status = STAT_SOURCE
    end if
end if
end select
end if
end subroutine process_library_update_status

```

This procedure triggers code generation for all processes where this is possible.

We generate code only for external processes of status `STAT_CONFIGURED`, which then advance to `STAT_SOURCE`. If, for a particular process, the status is already advanced, we do not remove previous files, so `make` will consider them as up to date if they exist. Otherwise, we remove those files to force a fresh `make`.

Finally, if any source code has been generated, we need a driver file.

```

<Process libraries: process library: TBP>+≡
    procedure :: make_source => process_library_make_source

<Process libraries: procedures>+≡
    subroutine process_library_make_source (lib, os_data)
        class(process_library_t), intent(inout) :: lib
        type(os_data_t), intent(in) :: os_data
        integer :: i, i_external
        if (lib%external .and. .not. lib%static) then
            select case (lib%status)
            case (STAT_CONFIGURED)
                call msg_message ("Process library '" // char (lib%basename) &

        end if
        lib%entry%status = STAT_ACTIVE
        lib%status = STAT_ACTIVE
    end select
end subroutine process_library_load

```

This is the actual loading part for the process methods.

(Process libraries: process library: TBP)+≡

```

    procedure :: load_entries => process_library_load_entries

```

(Process libraries: procedures)+≡

```

    subroutine process_library_load_entries (lib)
    class(process_library_t), intent(inout) :: lib
    integer :: i
    do i = 1, size (lib%entry)
        associate (entry => lib%entry(i))
            if (entry%i_external /= 0) then
                call entry%connect (lib%driver, entry%i_external)
            end if
        end associate
    end do
end subroutine process_library_load_entries

```

Unload the library, if possible. This reverts the status to “linked”.

(Process libraries: process library: TBP)+≡

```

    procedure :: unload => process_library_unload

```

```

<Process libraries: procedures>+≡
subroutine process_library_unload (lib)
  class(process_library_t), intent(inout) :: lib
  select case (lib%status)
  case (STAT_ACTIVE)
    if (lib%external) then
      call msg_message ("Process library '" // char (lib%basename) &
        // "': unloading")
      call lib%driver%unload ()
    end if
    lib%entry%status = STAT_LINKED
    lib%status = STAT_LINKED
  end select
end subroutine process_library_unload

```

Unload, clean all generated files and revert the library status. If `distclean` is set, also remove the makefile and the driver source.

```

<Process libraries: process library: TBP>+≡
  procedure :: clean => process_library_clean

<Process libraries: procedures>+≡
subroutine process_library_clean (lib, os_data, distclean)
  class(process_library_t), intent(inout) :: lib
  type(os_data_t), intent(in) :: os_data
  logical, intent(in) :: distclean
  call lib%unload ()
  if (lib%external .and. .not. lib%static) then
    call msg_message ("Process library '" // char (lib%basename) &
      // "': removing old files")
    if (distclean) then
      call lib%driver%distclean (os_data)
    else
      call lib%driver%clean (os_data)
    end if
  end if
  where (lib%entry%i_external /= 0)
    lib%entry%status = STAT_CONFIGURED
  elsewhere
    lib%entry%status = STAT_LINKED
  end where
  if (lib%external) then
    lib%status = STAT_CONFIGURED
  else
    lib%status = STAT_LINKED
  end if
end subroutine process_library_clean

```

Unload and revert the library status to INITIAL. This allows for appending new processes. No files are deleted.

```

<Process libraries: process library: TBP>+≡
  procedure :: open => process_library_open

<Process libraries: procedures>+≡
subroutine process_library_open (lib)

```

```

class(process_library_t), intent(inout) :: lib
select case (lib%status)
case (STAT_OPEN)
case default
    call lib%unload ()
    if (.not. lib%static) then
        lib%entry%status = STAT_OPEN
        lib%status = STAT_OPEN
        call msg_message ("Process library '" // char (lib%basename) &
            // "': open")
    else
        call msg_error ("Static process library '" // char (lib%basename) &
            // "': processes can't be appended")
    end if
end select
end subroutine process_library_open

```

14.4.4 Use the library

Return the base name of the library

```

(Process libraries: process library: TBP)+≡
    procedure :: get_name => process_library_get_name

(Process libraries: procedures)+≡
    function process_library_get_name (lib) result (name)
        class(process_library_t), intent(in) :: lib
        type(string_t) :: name
        name = lib%basename
    end function process_library_get_name

```

Once activated, we view the process library object as an interface for accessing the matrix elements.

```

(Process libraries: process library: TBP)+≡
    procedure :: is_active => process_library_is_active

(Process libraries: procedures)+≡
    function process_library_is_active (lib) result (flag)
        logical :: flag
        class(process_library_t), intent(in) :: lib
        flag = lib%status == STAT_ACTIVE
    end function process_library_is_active

```

Retrieve constants using the process library driver. We assume that the process code has been loaded, if external.

```

(Process libraries: process library entry: TBP)+≡
    procedure :: fill_constants => process_library_entry_fill_constants

(Process libraries: procedures)+≡
    subroutine process_library_entry_fill_constants (entry, driver, data)
        class(process_library_entry_t), intent(in) :: entry
        class(prclib_driver_t), intent(in) :: driver
        type(process_constants_t), intent(out) :: data
    end subroutine process_library_entry_fill_constants

```

```

integer :: i
if (entry%i_external /= 0) then
  i = entry%i_external
  data%id = driver%get_process_id (i)
  data%model_name = driver%get_model_name (i)
  data%md5sum = driver%get_md5sum (i)
  data%openmp_supported = driver%get_openmp_status (i)
  data%n_in = driver%get_n_in (i)
  data%n_out = driver%get_n_out (i)
  data%n_flv = driver%get_n_flv (i)
  data%n_hel = driver%get_n_hel (i)
  data%n_col = driver%get_n_col (i)
  data%n_cin = driver%get_n_cin (i)
  data%n_cf = driver%get_n_cf (i)
  call driver%set_flv_state (i, data%flv_state)
  call driver%set_hel_state (i, data%hel_state)
  call driver%set_col_state (i, data%col_state, data%ghost_flag)
  call driver%set_color_factors (i, data%color_factors, data%cf_index)
else
  select type (proc_driver => entry%driver)
  class is (process_driver_internal_t)
    call proc_driver%fill_constants (data)
  end select
end if
end subroutine process_library_entry_fill_constants

```

Retrieve the constants and a connected driver for a process, identified by a process ID and a subprocess index. We scan the process entries until we have found a match.

```

<Process libraries: process library: TBP>+≡
  procedure :: connect_process => process_library_connect_process

<Process libraries: procedures>+≡
  subroutine process_library_connect_process &
    (lib, id, i_component, data, proc_driver)
    class(process_library_t), intent(in) :: Lib
    type(string_t), intent(in) :: id
    integer, intent(in) :: i_component
    type(process_constants_t), intent(out) :: data
    class(prc_core_driver_t), allocatable, intent(out) :: proc_driver
    integer :: i
    do i = 1, size (lib%entry)
      associate (entry => lib%entry(i))
        if (entry%def%id == id .and. entry%i_component == i_component) then
          call entry%fill_constants (lib%driver, data)
          allocate (proc_driver, source=entry%driver)
          return
        end if
      end associate
    end do
    ! If we arrive here: Process not found
  end subroutine process_library_connect_process

```

14.4.5 Test

This is the master for calling self-test procedures.

```
<Process libraries: public>+≡
    public :: process_libraries_test

<Process libraries: tests>≡
    subroutine process_libraries_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Process libraries: execute tests>
    end subroutine process_libraries_test
```

Empty process list

Test 1: Write an empty process list.

```
<Process libraries: execute tests>≡
    call test (process_libraries_1, "process_libraries_1", &
        "empty process list", &
        u, results)

<Process libraries: tests>+≡
    subroutine process_libraries_1 (u)
        integer, intent(in) :: u
        type(process_def_list_t) :: process_def_list

        write (u, "(A)")  "* Test output: process_libraries_1"
        write (u, "(A)")  "* Purpose: Display an empty process definition list"
        write (u, "(A)")

        call process_def_list%write (u)

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: process_libraries_1"
    end subroutine process_libraries_1
```

Process definition list

Test 2: Process definition list with processes and components. Construct the list, write to file, read it in again, and display. Finalize and delete the list after use.

We define a trivial 'test' type for the process variant. The test type contains just one (meaningless) data item, which is an integer.

```
<Process libraries: test declarations>≡
    type, extends (prc_core_def_t) :: prcdef_2_t
        integer :: data = 0
        logical :: file = .false.
    contains
    <Process libraries: prcdef 2: TBP>
    end type prcdef_2_t
```

The process variant is named 'test'.

```
<Process libraries: prcdef 2: TBP>+≡  
    procedure, nopass :: type_string => prcdef_2_type_string

```

Build workflow for test matrix element

Test 5: We write source code for a dummy process.

We define another trivial type for the process variant. The test type contains just no variable data, but produces code on file.

```

<Process libraries: test declarations>+≡
  type, extends (prc_core_def_t) :: prcdef_5_t
  contains
    <Process libraries: prcdef 5: TBP>
  end type prcdef_5_t

```

The process variant is named `test_file`.

```

<Process libraries: prcdef 5: TBP>≡
  procedure, nopass :: type_string => prcdef_5_type_string

<Process libraries: tests>+≡
  function prcdef_5_type_string () result (string)
    type(string_t) :: string
    string = "test_file"
  end function prcdef_5_type_string

```

We reuse the writer `test_writer_4` from the previous module.

```

<Process libraries: prcdef 5: TBP>+≡
  procedure :: init => prcdef_5_init

<Process libraries: tests>+≡
  subroutine prcdef_5_init (object)
    class(prcdef_5_t), intent(out) :: object
    allocate (test_writer_4_t :: object%writer)
  end subroutine prcdef_5_init

```

Nothing to write.

```
<Process libraries: prcdef 5: TBP>+≡  
  procedure :: write => prcdef_5_write  
  
<Process libraries: tests>+≡  
  subroutine prcdef_5_write (object, unit)  
    class(prcdef_5_t), intent(in) :: object  
    integer, intent(in) :: unit  
  end subroutine prcdef_5_write
```

Nothing to read.

```
<Process libraries: prcdef 5: TBP>+≡  
  procedure :: read => prcdef_5_read  
  
<Process libraries: tests>+≡  
  subroutine prcdef_5_read (object, unit)  
    class(prcdef_5_t), intent(out) :: object  
    integer, intent(in) :: unit  
  end subroutine prcdef_5_read
```

Allocate the driver with the appropriate type.

```
<Process libraries: prcdef 5: TBP>+≡  
  procedure :: allocate_driver => prcdef_5_allocate_driver  
  
<Process libraries: tests>+≡  
  subroutine prcdef_5_allocate_driver (object, driver, basename)  
    class(prcdef_5_t), intent(in) :: object  
    class(prc_core_driver_t), intent(out), allocatable :: driver  
    type(string_t), intent(in) :: basename  
    allocate (prctest_5_t :: driver)  
  end subroutine prcdef_5_allocate_driver
```

This time we need code:

```
<Process libraries: prcdef 5: TBP>+≡  
  procedure, nopass :: needs_code => prcdef_5_needs_code  
  
<Process libraries: tests>+≡  
  function prcdef_5_needs_code () result (flag)  
    logical :: flag  
    flag = .true.  
  end function prcdef_5_needs_code
```

For the test case, we implement a single feature proc1.

```
<Process libraries: prcdef 5: TBP>+≡  
  procedure, nopass :: get_features => prcdef_5_get_features  
  
<Process libraries: tests>+≡  
  subroutine prcdef_5_get_features (features)  
    type(string_t), dimension(:), allocatable, intent(out) :: features  
    allocate (features (1))  
    features = [ var_str ("proc1") ]  
  end subroutine prcdef_5_get_features
```

Nothing to connect.

```
<Process libraries: prcdef 5: TBP>+≡
  procedure :: connect => prcdef_5_connect

<Process libraries: tests>+≡
  subroutine prcdef_5_connect (def, lib_driver, i, proc_driver)
    class(prcdef_5_t), intent(in) :: def
    class(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i
    class(prc_core_driver_t), intent(inout) :: proc_driver
  end subroutine prcdef_5_connect
```

The driver type.

```
<Process libraries: types>+≡
  type, extends (prc_core_driver_t) :: prctest_5_t
  contains
  <Process libraries: prctest 5: TBP>
  end type prctest_5_t
```

Return the type name.

```
<Process libraries: prctest 5: TBP>≡
  procedure, nopass :: type_name => prctest_5_type_name

<Process libraries: tests>+≡
  function prctest_5_type_name () result (type)
    type(string_t) :: type
    type = "test_file"
  end function prctest_5_type_name
```

    function prcdef_6_needs_code () result (flag)
        logical :: flag
        flag = .true.
    end function prcdef_6_needs_code
```

For the test case, we implement a single feature proc1.

```
<Process libraries: prcdef 6: TBP>+≡
    procedure, nopass :: get_features => prcdef_6_get_features

<Process libraries: tests>+≡
    subroutine prcdef_6_get_features (features)
        type(string_t), dimension(:), allocatable, intent(out) :: features
        allocate (features (1))
        features = [ var_str ("proc1") ]
    end subroutine prcdef_6_get_features
```

The interface of the only specific feature.

```
<Process libraries: interfaces>≡
    abstract interface
        subroutine proc1_t (n) bind(C)
            import
            integer(c_int), intent(out) :: n
        end subroutine proc1_t
    end interface
```

Connect the feature proc1 with the process driver.

```
<Process libraries: prcdef 6: TBP>+≡
    procedure :: connect => prcdef_6_connect

<Process libraries: tests>+≡
    subroutine prcdef_6_connect (def, lib_driver, i, proc_driver)
        class(prcdef_6_t), intent(in) :: def
        class(prclib_driver_t), intent(in) :: lib_driver
        integer, intent(in) :: i
        class(prc_core_driver_t), intent(inout) :: proc_driver
        integer(c_int) :: pid, fid
```

```

type(c_funptr) :: fptr
select type (proc_driver)
type is (prctest_6_t)
    pid = i
    fid = 1
    call lib_driver%get_fptr (pid, fid, fptr)
    call c_f_procpointer (fptr, proc_driver%proc1)
end select
end subroutine prcdef_6_connect

```

The driver type.

```

<Process libraries: types>+≡
type, extends (prc_core_driver_t) :: prctest_6_t
    procedure(proc1_t), nopass, pointer :: proc1 => null ()
contains
    <Process libraries: prctest 6: TBP>
end type prctest_6_t

```

Return the type name.

```

<Process libraries: prctest 6: TBP>≡
    procedure, nopass :: type_name => prctest_6_type_name

<Process libraries: tests>+≡
function prctest_6_type_name () result (type)
    type(string_t) :: type
    type = "test_file"
end function prctest_6_type_name

```

Here is the actual test:

14.5 Process Library Stacks

For storing and handling multiple libraries, we define process library stacks. These are ordinary stacks where new entries are pushed onto the top.

```

<prclib_stacks.f90>≡
  <File header>

  module prclib_stacks

    <Use strings>
    <Use file utils>
    use unit_tests
    use os_interface
    use models

    use process_libraries

```

```

    <Standard module head>

    <Prclib stacks: public>

    <Prclib stacks: types>

contains

    <Prclib stacks: procedures>

    <Prclib stacks: tests>

end module prclib_stacks

```

14.5.1 The stack entry type

A stack entry is a process library object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, process libraries should be prepared as process entry objects.

```

<Prclib stacks: public>≡
    public :: prclib_entry_t

<Prclib stacks: types>≡
    type, extends (process_library_t) :: prclib_entry_t
        type(prclib_entry_t), pointer :: next => null ()
    end type prclib_entry_t

```

14.5.2 The prclib stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

```

<Prclib stacks: public>+≡
    public :: prclib_stack_t

<Prclib stacks: types>+≡
    type :: prclib_stack_t
        integer :: n = 0
        type(prclib_entry_t), pointer :: first => null ()
    contains
        <Prclib stacks: prclib stack: TBP>
    end type prclib_stack_t

```

Finalizer. Iteratively deallocate the stack entries. The resulting empty stack can be immediately recycled, if necessary.

```

<Prclib stacks: prclib stack: TBP>≡
    procedure :: final => prclib_stack_final

<Prclib stacks: procedures>≡
    subroutine prclib_stack_final (object)
        class(prclib_stack_t), intent(inout) :: object
        type(prclib_entry_t), pointer :: lib
        do while (associated (object%first))

```

```

        lib => object%first
        object%first => lib%next
        call lib%final ()
        deallocate (lib)
    end do
    object%n = 0
end subroutine prclib_stack_final

```

Output. The entries on the stack will be ordered LIFO, i.e., backwards.

```

<Prclib stacks: prclib stack: TBP>+≡
    procedure :: write => prclib_stack_write
<Prclib stacks: procedures>+≡
    subroutine prclib_stack_write (object, unit)
        class(prclib_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        type(prclib_entry_t), pointer :: lib

            write (u, "(1x,A)") "Process library stack:"
            lib => object%first
            do while (associated (lib))
                call write_separator (u)
                call lib%write (u)
                lib => lib%next
            end do
        end select
        call write_separator_double (u)
    end subroutine prclib_stack_write

```

14.5.3 Operating on Stacks

We take a library entry pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the library entry is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

<Prclib stacks: prclib stack: TBP>+≡
    procedure :: push => prclib_stack_push
<Prclib stacks: procedures>+≡
    subroutine prclib_stack_push (stack, lib)
        class(prclib_stack_t), intent(inout) :: stack
        type(prclib_entry_t), intent(inout), pointer :: lib
        lib%next => stack%first
        stack%first => lib
        lib => null ()
        stack%n = stack%n + 1
    end subroutine prclib_stack_push

```

14.5.4 Accessing Contents

Return a pointer to the topmost stack element. The result type is just the bare `process_library_t`. There is no `target` attribute required since the stack elements are allocated via pointers.

```
<Prclib stacks: prclib stack: TBP>+≡
  procedure :: get_first_ptr => prclib_stack_get_first_ptr

<Prclib stacks: procedures>+≡
  function prclib_stack_get_first_ptr (stack) result (ptr)
    class(prclib_stack_t), intent(in) :: stack
    type(process_library_t), pointer :: ptr
    ptr => stack%first%process_library_t
  end function prclib_stack_get_first_ptr
```

Return a complete list of the libraries (names) in the stack. The list is in the order in which the elements got pushed onto the stack, so the 'first' entry is listed last.

```
<Prclib stacks: prclib stack: TBP>+≡
  procedure :: get_names => prclib_stack_get_names

<Prclib stacks: procedures>+≡
  subroutine prclib_stack_get_names (stack, libname)
    class(prclib_stack_t), intent(in) :: stack
    type(string_t), dimension(:), allocatable, intent(out) :: libname
    type(prclib_entry_t), pointer :: lib
    integer :: i
    allocate (libname (stack%n))
    i = stack%n
    lib => stack%first
    do while (associated (lib))
      libname(i) = lib%get_name ()
      i = i - 1
      lib => lib%next
    end do
  end subroutine prclib_stack_get_names
```

Return a pointer to the library with given name.

```
<Prclib stacks: prclib stack: TBP>+≡
  procedure :: get_library_ptr => prclib_stack_get_library_ptr

<Prclib stacks: procedures>+≡
  function prclib_stack_get_library_ptr (stack, libname) result (ptr)
    class(prclib_stack_t), intent(in) :: stack
    type(string_t), intent(in) :: libname
    type(process_library_t), pointer :: ptr
    type(prclib_entry_t), pointer :: current
    current => stack%first
    do while (associated (current))
      if (current%get_name () == libname) then
        ptr => current%process_library_t
        return
      end if
      current => current%next
    end do
```

```

end do
ptr => null ()
end function prclib_stack_get_library_ptr

```

14.5.5 Auxiliary stuff

Write a separator line.

```

<Prclib stacks: procedures>+≡
subroutine write_separator (u)
integer, intent(in) :: u
write (u, "(A)") repeat ("-", 72)
end subroutine write_separator

subroutine write_separator_double (u)
integer, intent(in) :: u
write (u, "(A)") repeat ("=", 72)
end subroutine write_separator_double

```

14.5.6 Unit tests

```

<Prclib stacks: public>+≡
public :: prclib_stacks_test

<Prclib stacks: tests>≡
subroutine prclib_stacks_test (u, results)
integer, intent(in) :: u
type(test_results_t), intent(inout) :: results
<Prclib stacks: execute tests>
end subroutine prclib_stacks_test

```

Write an empty process library stack

The most trivial test is to write an uninitialized process library stack.

```

<Prclib stacks: execute tests>≡
call test (prclib_stacks_1, "prclib_stacks_1", &
"write an empty process library stack", &
u, results)

<Prclib stacks: tests>+≡
subroutine prclib_stacks_1 (u)
integer, intent(in) :: u
type(prclib_stack_t) :: stack

write (u, "(A)")  "* Test output: prclib_stacks_1"
write (u, "(A)")  "* Purpose: display an empty process library stack"
write (u, "(A)")

call stack%write (u)

write (u, "(A)")

```

```

        write (u, "(A)")  "* Test output end: prclib_stacks_1"

end subroutine prclib_stacks_1

```

Fill a process library stack

Fill a process library stack with two (identical) processes.

```

<Prclib_stacks: execute tests>+≡
    call test (prclib_stacks_2, "prclib_stacks_2", &
        "fill a process library stack", &
        u, results)

<Prclib_stacks: tests>+≡
    subroutine prclib_stacks_2 (u)
        integer, intent(in) :: u
        type(prclib_stack_t) :: stack
        type(prclib_entry_t), pointer :: lib

        write (u, "(A)")  "* Test output: prclib_stacks_2"
        write (u, "(A)")  "* Purpose: fill a process library stack"
        write (u, "(A)")

        write (u, "(A)")  "* Initialize two (empty) libraries &
            &and push them on the stack"
        write (u, "(A)")

        allocate (lib)
        call lib%init (var_str ("lib1"))
        call stack%push (lib)

        allocate (lib)
        call lib%init (var_str ("lib2"))
        call stack%push (lib)

        call stack%write (u)

        write (u, "(A)")
        write (u, "(A)")  "* Cleanup"

        call stack%final ()

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: prclib_stacks_2"

    end subroutine prclib_stacks_2

```

14.6 Trivial matrix element for tests

For the purpose of testing the workflow, we implement here two matrix elements with the simplest possible structure.

This matrix element generator can only generate a single scattering process and a single decay process. The scattering process is a quartic interaction of a massless, neutral and colorless scalar s with unit coupling results in a trivial $2 \rightarrow 2$ scattering process. The matrix element is implemented internally, so we do not need the machinery of external process libraries. The decay process is a decay of s into a pair of colored fermions f .

```

<prc_test.f90>≡
  <File header>

  module prc_test

    use iso_c_binding !NODEP!
    use kinds !NODEP!
  <Use strings>
    use unit_tests
    use os_interface

    use process_constants
    use prclib_interfaces
    use prc_core_def
    use particle_specifiers
    use process_libraries

  <Standard module head>

  <Test ME: public>

  <Test ME: types>

  contains

  <Test ME: procedures>

  <Test ME: tests>

  end module prc_test

```

14.6.1 Process definition

For the process definition we implement an extension of the `prc_core_def_t` abstract type.

```

<Test ME: public>≡
  public :: prc_test_def_t

<Test ME: types>≡
  type, extends (prc_core_def_t) :: prc_test_def_t
    type(string_t) :: model_name
    type(string_t), dimension(:), allocatable :: prt_in
    type(string_t), dimension(:), allocatable :: prt_out
  contains
    <Test ME: test me def: TBP>
  end type prc_test_def_t

```

```

<Test ME: test me def: TBP>≡
    procedure, nopass :: type_string => prc_test_def_type_string
<Test ME: procedures>≡
    function prc_test_def_type_string () result (string)
        type(string_t) :: string
        string = "test_me"
    end function prc_test_def_type_string

```

There is no 'feature' here since there is no external code.

```

<Test ME: test me def: TBP>+≡
    procedure, nopass :: get_features => prc_test_def_get_features
<Test ME: procedures>+≡
    subroutine prc_test_def_get_features (features)
        type(string_t), dimension(:), allocatable, intent(out) :: features
        allocate (features (0))
    end subroutine prc_test_def_get_features

```

Initialization: set some data (not really useful).

```

<Test ME: test me def: TBP>+≡
    procedure :: init => prc_test_def_init
<Test ME: procedures>+≡
    subroutine prc_test_def_init (object, model_name, prt_in, prt_out)
        class(prc_test_def_t), intent(out) :: object
        type(string_t), intent(in) :: model_name
        type(string_t), dimension(:), intent(in) :: prt_in
        type(string_t), dimension(:), intent(in) :: prt_out
        object%model_name = model_name
        allocate (object%prt_in (size (prt_in)))
        object%prt_in = prt_in
        allocate (object%prt_out (size (prt_out)))
        object%prt_out = prt_out
    end subroutine prc_test_def_init

```

Write/read process- and method-specific data. (No-op)

```

<Test ME: test me def: TBP>+≡
    procedure :: write => prc_test_def_write
<Test ME: procedures>+≡
    subroutine prc_test_def_write (object, unit)
        class(prc_test_def_t), intent(in) :: object
        integer, intent(in) :: unit
    end subroutine prc_test_def_write

```

```

<Test ME: test me def: TBP>+≡
    procedure :: read => prc_test_def_read
<Test ME: procedures>+≡
    subroutine prc_test_def_read (object, unit)
        class(prc_test_def_t), intent(out) :: object
        integer, intent(in) :: unit
    end subroutine prc_test_def_read

```

Allocate the driver for test ME matrix elements. We get the actual component ID (basename), and we can transfer all process-specific data from the process definition.

```

<Test ME: test me def: TBP>+≡
  procedure :: allocate_driver => prc_test_def_allocate_driver

<Test ME: procedures>+≡
  subroutine prc_test_def_allocate_driver (object, driver, basename)
    class(prc_test_def_t), intent(in) :: object
    class(prc_core_driver_t), intent(out), allocatable :: driver
    type(string_t), intent(in) :: basename
    allocate (prc_test_t :: driver)
    select type (driver)
    type is (prc_test_t)
      driver%id = basename
      driver%model_name = object%model_name
      select case (size (object%prt_in))
      case (1); driver%scattering = .false.
      case (2); driver%scattering = .true.
      end select
    end select
  end subroutine prc_test_def_allocate_driver

```

Nothing to connect. This subroutine will not be called.

```

<Test ME: test me def: TBP>+≡
  procedure :: connect => prc_test_def_connect

<Test ME: procedures>+≡
  subroutine prc_test_def_connect (def, lib_driver, i, proc_driver)
    class(prc_test_def_t), intent(in) :: def
    class(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i
    class(prc_core_driver_t), intent(inout) :: proc_driver
  end subroutine prc_test_def_connect

```

14.6.2 Driver

```

<Test ME: public>+≡
  public :: prc_test_t

<Test ME: types>+≡
  type, extends (process_driver_internal_t) :: prc_test_t
    type(string_t) :: id
    type(string_t) :: model_name
    logical :: scattering = .true.
  contains
    <Test ME: test me driver: TBP>
  end type prc_test_t

```

In contrast to generic matrix-element implementations, we can hard-wire the amplitude method as a type-bound procedure.

```

<Test ME: test me driver: TBP>≡
  procedure, nopass :: get_amplitude => prc_test_get_amplitude

```

```

<Test ME: procedures>+≡
function prc_test_get_amplitude (p) result (amp)
  complex(default) :: amp
  real(default), dimension(:,:), intent(in) :: p
  amp = 1
end function prc_test_get_amplitude

```

The reported type is the same as for the `prc_test_def_t` type.

```

<Test ME: test me driver: TBP>+≡
procedure, nopass :: type_name => prc_test_type_name

<Test ME: procedures>+≡
function prc_test_type_name () result (string)
  type(string_t) :: string
  string = "test_me"
end function prc_test_type_name

```

Fill process constants.

```

<Test ME: test me driver: TBP>+≡
procedure :: fill_constants => prc_test_fill_constants

<Test ME: procedures>+≡
subroutine prc_test_fill_constants (driver, data)
  class(prc_test_t), intent(in) :: driver
  type(process_constants_t), intent(out) :: data
  data%id = driver%id
  data%model_name = driver%model_name
  if (driver%scattering) then
    data%n_in = 2
    data%n_out = 2
    data%n_flv = 1
    data%n_hel = 1
    data%n_col = 1
    data%n_cin = 2
    data%n_cf = 1
    allocate (data%flv_state (4, 1))
    data%flv_state = 25
    allocate (data%hel_state (4, 1))
    data%hel_state = 0
    allocate (data%col_state (2, 4, 1))
    data%col_state = 0
    allocate (data%ghost_flag (4, 1))
    data%ghost_flag = .false.
    allocate (data%color_factors (1))
    data%color_factors = 1
    allocate (data%cf_index (2, 1))
    data%cf_index = 1
  else
    data%n_in = 1
    data%n_out = 2
    data%n_flv = 1
    data%n_hel = 2
    data%n_col = 1
    data%n_cin = 2
  end if
end subroutine prc_test_fill_constants

```

```

data%n_cf = 1
allocate (data%flv_state (3, 1))
data%flv_state(:,1) = [25, 6, -6]
allocate (data%hel_state (3, 2))
data%hel_state(:,1) = [0, 1,-1]
data%hel_state(:,2) = [0,-1, 1]
allocate (data%col_state (2, 3, 1))
data%col_state = reshape ([0,0, 1,0, 0,-1], [2,3,1])
allocate (data%ghost_flag (3, 1))
data%ghost_flag = .false.
allocate (data%color_factors (1))
data%color_factors = 3
allocate (data%cf_index (2, 1))
data%cf_index = 1
end if
end subroutine prc_test_fill_constants

```

14.6.3 Shortcut

Since this module is there for testing purposes, we set up a subroutine that does all the work at once: create a library with the two processes (scattering and decay), configure and load, and set up the driver.

```

<Test ME: public>+≡
public :: prc_test_create_library

<Test ME: procedures>+≡
subroutine prc_test_create_library &
  (libname, lib, scattering, decay, procname1, procname2)
  type(string_t), intent(in) :: libname
  type(process_library_t), intent(out) :: lib
  logical, intent(in), optional :: scattering, decay
  type(string_t), intent(in), optional :: procname1, procname2
  type(string_t) :: model_name, procname
  type(string_t), dimension(:), allocatable :: prt_in, prt_out
  class(prc_core_def_t), allocatable :: def
  type(process_def_entry_t), pointer :: entry
  type(os_data_t) :: os_data
  logical :: sca, dec
  sca = .true.; if (present (scattering)) sca = scattering
  dec = .false.; if (present (decay)) dec = decay

  call lib%init (libname)
  model_name = "Test"

  if (sca) then
    if (present (procname1)) then
      procname = procname1
    else
      procname = libname
    end if
    allocate (prt_in (2), prt_out (2))
    prt_in = [var_str ("s"), var_str ("s")]
    prt_out = [var_str ("s"), var_str ("s")]
  end if
end subroutine prc_test_create_library

```

```

        allocate (prc_test_def_t :: def)
        select type (def)
        type is (prc_test_def_t)
            call def%init (model_name, prt_in, prt_out)
        end select
        allocate (entry)
        call entry%init (procname, model_name = model_name, &
            n_in = 2, n_components = 1)
        call entry%import_component (1, n_out = size (prt_out), &
            prt_in = new_prt_spec (prt_in), &
            prt_out = new_prt_spec (prt_out), &

            variant = def)
        call lib%append (entry)
    end if

    if (dec) then
        if (present (procname2)) then
            procname = procname2
        else
            procname = libname
        end if
        if (allocated (prt_in)) deallocate (prt_in, prt_out)
        allocate (prt_in (1), prt_out (2))
        prt_in = [var_str ("s")]
        prt_out = [var_str ("f"), var_str ("fbar")]
        allocate (prc_test_def_t :: def)
        select type (def)
        type is (prc_test_def_t)
            call def%init (model_name, prt_in, prt_out)
        end select
        allocate (entry)
        call entry%init (procname, model_name = model_name, &
            n_in = 1, n_components = 1)
        call entry%import_component (1, n_out = size (prt_out), &
            prt_in = new_prt_spec (prt_in), &
            prt_out = new_prt_spec (prt_out), &
            method = var_str ("test_decay"), &
            variant = def)
        call lib%append (entry)
    end if

    call lib%configure ()
    call lib%load (os_data)
end subroutine prc_test_create_library

```

14.6.4 Test

This is the master for calling self-test procedures.

```

<Test ME: public>+≡
public :: prc_test_test

```

```

<Test ME: tests>≡
  subroutine prc_test_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Test ME: execute tests>
  end subroutine prc_test_test

```

Generate and load the scattering process

The process is $ss \rightarrow ss$, where s is a trivial scalar particle, for vanishing mass and unit coupling. We initialize the process, build the library, and compute the particular matrix element for momenta of unit energy and right-angle scattering. (The scattering is independent of angle.) The matrix element is equal to unity.

```

Generate and load the decay process

The process is $s \rightarrow f\bar{f}$, where s is a trivial scalar particle and f is a colored fermion. We initialize the process, build the library, and compute the particular matrix element for a fixed momentum configuration. (The decay is independent of angle.) The matrix element is equal to unity.

```

Chapter 15

Integration and Process Objects

This is the central part of the WHIZARD package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

integration_results This module handles results from integrating processes. It records passes and iterations, calculates statistical averages, and provides the user output of integration results.

prc_core Here, we define the abstract `prc_core_t` type which handles all specific features of kinematics matrix-element evaluation that depend on a particular class of processes.

parton_states A `parton_state_t` object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

processes Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: `prc_core` for matrix-element evaluation, `prc_core_def` for the associated configuration and driver, `sf_base` for beams and structure-functions, `phs_base` for phase space, and `mci_base` for integration and event generation.

process_stacks Process stacks collect process objects.

15.1 Integration results

We record integration results and errors in a dedicated type. This allows us to do further statistics such as weighted average, chi-squared, grouping by integration passes, etc.

Note WHIZARD 2.2.0: This code is taken from the previous `processes` module essentially unchanged and converted into a separate module. It lacks an overhaul and, in particular, self-tests.

```

<integration_results.f90>≡
  module integration_results

    use limits, only: GML_MIN_RANGE_RATIO !NODEP!
    <Use kinds>
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use md5
    ! use cputime
    use os_interface
    use mci_base

    <Standard module head>

    <Integration results: public>

    <Integration results: parameters>

    <Integration results: types>

    <Integration results: interfaces>

    contains

    <Integration results: procedures>

  end module integration_results

```

15.1.1 Integration results entry

This object collects the results of an integration pass and makes them available to the outside.

The results object has to distinguish the process type:

We store the process type, the index of the integration pass and the absolute iteration index, the number of iterations contained in this result (for averages), and the integral (cross section or partial width), error estimate, efficiency and time estimate.

For intermediate results, we set a flag if this result is an improvement w.r.t. previous ones.

The process type indicates decay or scattering. Dummy entries (skipped iterations) have a process type of `PRC_UNKNOWN`.

```

<Integration results: types>≡
  type :: integration_entry_t
    private
    integer :: process_type = PRC_UNKNOWN
    integer :: pass = 0
    integer :: it = 0
    integer :: n_it = 0

```

```

integer :: n_calls = 0
logical :: improved = .false.
real(default) :: integral = 0
real(default) :: error = 0
real(default) :: efficiency = 0
real(default) :: chi2 = 0
real(default), dimension(:,:), allocatable :: grove_weight
!   type(time_t) :: time_start
!   type(time_t) :: time_end
end type integration_entry_t

```

The possible values of the type indicator:

```

<Integration results: parameters>≡
integer, parameter, public :: PRC_UNKNOWN = 0
integer, parameter, public :: PRC_DECAY = 1
integer, parameter, public :: PRC_SCATTERING = 2

```

Initialize with all relevant data

```

<Integration results: procedures>≡
subroutine integration_entry_init (entry, &
    process_type, pass, it, n_it, n_calls, improved, &
    integral, error, efficiency, chi2, grove_weight) !, &
!   time_start, time_end)
type(integration_entry_t), intent(out) :: entry
integer, intent(in) :: process_type, pass, it, n_it, n_calls
logical, intent(in) :: improved

  logical :: flag
  type(integration_entry_t), intent(in) :: entry
  flag = entry%improved
end function integration_entry_has_improved

elemental function integration_entry_get_n_groves (entry) result (n_groves)
  integer :: n_groves
  type(integration_entry_t), intent(in) :: entry
  if (allocated (entry%grove_weight)) then
    n_groves = size (entry%grove_weight, 1)
  else
    n_groves = 0
  end if
end function integration_entry_get_n_groves

```

Output. This writes the header line for the result account below:

```

(Integration results: procedures) +=
  subroutine write_header (process_type, unit, logfile)
    integer, intent(in) :: process_type
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: logfile
    character(5) :: phys_unit
    integer :: u
    u = output_unit (unit); if (u < 0) return
    select case (process_type)
    case (PRC_DECAY);      phys_unit = "[GeV]"
    case (PRC_SCATTERING); phys_unit = "[fb] "
    case default
      phys_unit = ""

```

```

end select
write (msg_buffer, "(A)") &
    "It      Calls  Integral" // phys_unit // &
    " Error" // phys_unit // &
    " Err[%]   Acc  Eff[%]   Chi2 N[It] |"
call msg_message (unit=u, logfile=logfile)
end subroutine write_header

```

This writes a separator for result display:

```

<Integration results: procedures>+=
subroutine write_hline (unit)
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit); if (u < 0) return
    write (u, "(A)")  "|" // (repeat("-", 77)) // "|"
    flush (u)
end subroutine write_hline

subroutine write_dline (unit)
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit); if (u < 0) return
    write (u, "(A)")  "|" // (repeat("=", 77)) // "|"
    flush (u)
end subroutine write_dline

```

This writes the standard result account into one screen line. The verbose version uses multiple lines and prints the unabridged values. Dummy entries are not written.

```

<Integration results: procedures>+=
subroutine integration_entry_write (entry, unit, verbose)
    type(integration_entry_t), intent(in) :: entry

```

Compute the average for all entries in the specified integration pass. The integrals are weighted w.r.t. their individual errors.

The quoted error of the result is the expected error, computed from the weighted average of the given individual errors.

This should be compared to the actual distribution of the results, from which we also can compute an error estimate if there is more than one iteration. The ratio of the distribution error and the averaged error, is the χ^2 value.

All error distributions are assumed Gaussian, of course. The χ^2 value is a partial check for this assumption. If it is significantly greater than unity, there is something wrong with the individual errors.

The efficiency returned is the one of the last entry in the integration pass.

[Disabled: For the time estimate, we simply take the minimum of all which should correspond to the best efficiency.]

If any error vanishes, averaging by this algorithm would fail. In this case, we simply average the entries and use the deviations from this average (if any) to estimate the error.

15.1.2 Combined integration results

We collect a list of results which grows during the execution of the program. This is implemented as an array which grows if necessary; so we can easily compute averages.

We implement this as an extension of the `mci_results_t` which is defined in `mci_base` as an abstract type. We thus decouple the implementation of the integrator from the implementation of the results display, but nevertheless can record intermediate results during integration. This implies that the present extension implements a `record` method.

```

<Integration results: public>≡
    public :: integration_results_t

<Integration results: types>+≡
    type, extends (mci_results_t) :: integration_results_t
    private
    integer :: process_type = PRC_UNKNOWN
    integer :: current_pass = 0
    integer :: n_pass = 0
    integer :: n_it = 0
    logical :: screen = .false.
    integer :: unit = 0
    real(default) :: error_threshold = 0
    type(integration_entry_t), dimension(:), allocatable :: entry
    type(integration_entry_t), dimension(:), allocatable :: average
    contains
    <Integration results: integration results: TBP>
end type integration_results_t

```

The array is extended in chunks of 10 entries.

```

<Integration results: parameters>+≡
    integer, parameter :: RESULTS_CHUNK_SIZE = 10

```

The standard does not require to explicitly initialize the integers; however, some gfortran version has a bug here and misses the default initialization in the type

definition.

<Integration results: integration results: TBP>≡

```
procedure :: init => integration_results_init
```

<Integration results: procedures>+≡

```
subroutine integration_results_init (results, process_type)
  class(integration_results_t), intent(out) :: results
  integer, intent(in) :: process_type
  results%process_type = process_type
  results%n_pass = 0
  results%n_it = 0
  allocate (results%entry (RESULTS_CHUNK_SIZE))
  allocate (results%average (RESULTS_CHUNK_SIZE))
end subroutine integration_results_init
```

Set additional parameters: the `error_threshold` declares that any error value (in absolute numbers) smaller than this is to be considered zero.

<Integration results: integration results: TBP>+≡

```
procedure :: set_error_threshold => integration_results_set_error_threshold
```

<Integration results: procedures>+≡

```
subroutine integration_results_set_error_threshold (results, error_threshold)
  class(integration_results_t), intent(inout) :: results
  real(default), intent(in) :: error_threshold
  results%error_threshold = error_threshold
end subroutine integration_results_set_error_threshold
```

Output (ASCII format). The `verbose` format is used for writing the header in grid files.

end if
write (u, *) "end(integration_results)"
end if
flush (u)
end subroutine integration_results_write

```

During integration, we do not want to print all results at once, but each intermediate result as soon as we get it. Thus, the previous procedure is chopped in pieces. First piece: store the output unit and a flag whether we want to print to standard output as well. Then write the header if the results are still empty, i.e., before integration has started. The second piece writes a single result to the saved output channels. We call this from the `record` method, which can be called from the integrator directly. The third piece writes the average result, once a pass has been completed. The fourth piece writes a footer (if any), assuming that this is the final result.

15.1.3 Access results

Return true if the results object has entries.

<Integration results: integration results: TBP>+≡

```

procedure :: exist => integration_results_exist

```

<Integration results: procedures>+≡

```

function integration_results_exist (results) result (flag)
    logical :: flag
    class(integration_results_t), intent(in) :: results
    flag = results%n_pass > 0
end function integration_results_exist

```

Retrieve information from the results record. If **last** is set and true, take the last iteration. If it is set instead, take this iteration. If **pass** is set, take this average. If none is set, take the final average.

If the result would be invalid, the entry is not assigned. Due to default initialization, this returns a null entry.

<Integration results: integration results: TBP>+≡

```

15.2 Abstract process core

In this module we provide abstract data types for process classes. Each process class represents a set of processes which are handled by a common “method”, e.g., by the O’MEGA matrix-element generator. The process class is also able to select a particular implementation for the phase-space and integration modules.

For a complete implementation of a process class, we have to provide extensions of the following abstract types:

prc_core_def_t process and matrix-element configuration

prc_writer_t (optional) writing external matrix-element code

prc_driver_t accessing the matrix element (internal or external)

prc_core_t evaluating kinematics and matrix element. The process core also selects phase-space and integrator implementations as appropriate for the process class and configuration.

In the actual process-handling data structures, each process component contains an instance of such a process class as its core. This allows us to keep the `processes` module below, which supervises matrix-element evaluation, integration, and event generation, free of any reference to concrete implementations (for the process class, phase space, and integrator).

There are no unit tests, these are deferred to the `processes` module.

```

<prc_core.f90>≡
  <File header>
  module prc_core

    <Use kinds>
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use lorentz !NODEP!
    use interactions

    use sf_base
    use process_constants
    use mci_base

    use prc_core_def
    use process_libraries

    <Standard module head>

    <Prc core: public>

    <Prc core: types>

    <Prc core: interfaces>

    contains

    <Prc core: procedures>

  end module prc_core

```

15.2.1 The process core

The process core is of abstract data type. Different types of matrix element will be represented by different implementations.

```

<Prc core: public>≡
  public :: prc_core_t

<Prc core: types>≡
  type, abstract :: prc_core_t
    class(prc_core_def_t), pointer :: def => null ()
    logical :: data_known = .false.
    type(process_constants_t) :: data
    class(prc_core_driver_t), allocatable :: driver
  contains
    <Prc core: process core: TBP>

```

```
end type prc_core_t
```

In any case there must be an output routine.

```
<Prc core: process core: TBP>≡
  procedure(prc_core_write), deferred :: write
<Prc core: interfaces>≡
  abstract interface
    subroutine prc_core_write (object, unit)
      import
      class(prc_core_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine prc_core_write
  end interface
```

For initialization, we assign a pointer to the process entry in the relevant library. This allows us to access all process functions via the implementation of `prc_core_t`.

We declare the `object` as `intent(inout)`, since just after allocation it may be useful to store some extra data in the object, which we can then use in the actual initialization. This applies to extensions of `prc_core` which override the `init` method.

```
<Prc core: process core: TBP>+≡
  procedure :: init => prc_core_init
  procedure :: base_init => prc_core_init
<Prc core: procedures>≡
  subroutine prc_core_init (object, def, lib, id, i_component)
    class(prc_core_t), intent(inout) :: object
    class(prc_core_def_t), intent(in), target :: def
    type(process_library_t), intent(in), target :: lib
    type(string_t), intent(in) :: id
    integer, intent(in) :: i_component
    object%def => def
    call lib%connect_process (id, i_component, object%data, object%driver)
    object%data_known = .true.
  end subroutine prc_core_init
```

Return true if a MC dataset should be attached to this process component. False if it shares the dataset with another component.

```
<Prc core: process core: TBP>+≡
  procedure(prc_core_get_flag), deferred :: needs_mcset
<Prc core: interfaces>+≡
  abstract interface
    function prc_core_get_flag (object) result (flag)
      import
      class(prc_core_t), intent(in) :: object
      logical :: flag
    end function prc_core_get_flag
  end interface
```

Return an integer number

```

(Prc core: interfaces)+≡
  abstract interface
    function prc_core_get_integer (object) result (i)
      import
      class(prc_core_t), intent(in) :: object
      integer :: i
    end function prc_core_get_integer
  end interface

```

Return the number of distinct terms requested by this process component.

```

(Prc core: process core: TBP)+≡
  procedure(prc_core_get_integer), deferred :: get_n_terms

```

Tell whether a particular combination of flavor/helicity/color state is allowed for the matrix element.

```

(Prc core: process core: TBP)+≡
  procedure(prc_core_is_allowed), deferred :: is_allowed

(Prc core: interfaces)+≡
  abstract interface
    function prc_core_is_allowed (object, i_term, f, h, c) result (flag)
      import
      class(prc_core_t), intent(in) :: object
      integer, intent(in) :: i_term, f, h, c
      logical :: flag
    end function prc_core_is_allowed
  end interface

```

Set the constant process data for a specific term. By default, these are the constants stored inside the object, ignoring the term index. Type extensions may override this and provide term-specific data.

```

(Prc core: process core: TBP)+≡
  procedure :: get_constants => prc_core_get_constants

(Prc core: procedures)+≡
  subroutine prc_core_get_constants (object, data, i_term)
    class(prc_core_t), intent(in) :: object
    type(process_constants_t), intent(out) :: data
    integer, intent(in) :: i_term
    data = object%data
  end subroutine prc_core_get_constants

```

The strong coupling is not among the process constants. The default implementation is to return a negative number, which indicates that α_s is not available. This may be overridden by an implementation that provides an (event-specific) value. The value can be stored in the tmp workspace.

```

(Prc core: process core: TBP)+≡
  procedure :: get_alpha_s => prc_core_get_alpha_s

(Prc core: procedures)+≡
  function prc_core_get_alpha_s (object, tmp) result (alpha)
    class(prc_core_t), intent(in) :: object

```

```

class(workspace_t), intent(in), allocatable :: tmp
real(default) :: alpha
alpha = -1
end function prc_core_get_alpha_s

```

Allocate the workspace associated to a process component. The default is that there is no workspace, so we do nothing. A type extension may override this and allocate a workspace object of appropriate type, which can be used in further calculations.

In any case, the `intent(out)` attribute deletes any previously allocated workspace.

```

<Prc core: process core: TBP>+≡
  procedure :: allocate_workspace => prc_core_ignore_workspace

<Prc core: procedures>+≡
  subroutine prc_core_ignore_workspace (object, tmp)
    class(prc_core_t), intent(in) :: object
    class(workspace_t), intent(inout), allocatable :: tmp
  end subroutine prc_core_ignore_workspace

```

Initialize the structure-function instance that corresponds to a process component. In ordinary cases, this amounts to a straightforward copy of the given template, but the process core may also choose to modify the setup, and it may access its own workspace.

The `sf_chain_instance` is the object that we want to prepare. The `sf_chain` argument is a template for its structure. For the initialization, we also need the number of channels `n_channel`.

Note: crash with nagfor 5.3.1 if `sf_chain_instance` is declared `intent(out)`, as would be more appropriate.

```

<Prc core: process core: TBP>+≡
  procedure :: init_sf_chain => prc_core_init_sf_chain

<Prc core: procedures>+≡
  subroutine prc_core_init_sf_chain &
    (object, sf_chain_instance, sf_chain, n_channel, tmp)
    class(prc_core_t), intent(in) :: object
    type(sf_chain_instance_t), intent(inout), target :: sf_chain_instance
    type(sf_chain_t), intent(in), target :: sf_chain
    integer, intent(in) :: n_channel
    class(workspace_t), intent(inout), allocatable :: tmp
    call sf_chain_instance%init (sf_chain, n_channel)
  end subroutine prc_core_init_sf_chain

```

Compute the momenta in the hard interaction, taking the seed kinematics as input. The `i_term` index tells us which term we want to compute. (The standard method is to just transfer the momenta to the hard interaction.)

```

<Prc core: process core: TBP>+≡
  procedure(prc_core_compute_hard_kinematics), deferred :: &
    compute_hard_kinematics

```

```

<Prc core: interfaces>+≡
  abstract interface
    subroutine prc_core_compute_hard_kinematics &
      (object, p_seed, i_term, int_hard, tmp)
    import
    class(prc_core_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(in) :: p_seed
    integer, intent(in) :: i_term
    type(interaction_t), intent(inout) :: int_hard
    class(workspace_t), intent(inout), allocatable :: tmp
  end subroutine prc_core_compute_hard_kinematics
end interface

```

Compute the momenta in the effective interaction, taking the hard kinematics as input. (This is called only if parton recombination is to be applied for the process variant.)

```

<Prc core: process core: TBP>+≡
  procedure(prc_core_compute_eff_kinematics), deferred :: &
    compute_eff_kinematics

<Prc core: interfaces>+≡
  abstract interface
    subroutine prc_core_compute_eff_kinematics &
      (object, i_term, int_hard, int_eff, tmp)
    import
    class(prc_core_t), intent(in) :: object
    integer, intent(in) :: i_term
    type(interaction_t), intent(in) :: int_hard
    type(interaction_t), intent(inout) :: int_eff
    class(workspace_t), intent(inout), allocatable :: tmp
  end subroutine prc_core_compute_eff_kinematics
end interface

```

Recover the missing pieces. We know the incoming momenta of the `p_seed` array and the outgoing momenta of the `int_eff` interaction. We have to recover the outgoing momenta of `p_seed` and the incoming momenta of `int_eff`.

(The trivial case is that these are identical.)

Furthermore, if `int_hard` and `int_eff` are not aliased, we have to set the momenta there. In the trivial case, `int_eff` is a pointer to `int_hard`, so `int_hard` should not be touched at all.

```

<Prc core: process core: TBP>+≡
  procedure(prc_core_recover_kinematics), deferred :: &
    recover_kinematics

<Prc core: interfaces>+≡
  abstract interface
    subroutine prc_core_recover_kinematics &
      (object, p_seed, int_hard, int_eff, tmp)
    import
    class(prc_core_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(inout) :: p_seed
    type(interaction_t), intent(inout) :: int_hard
    type(interaction_t), intent(inout) :: int_eff

```

```

        class(workspace_t), intent(inout), allocatable :: tmp
    end subroutine prc_core_recover_kinematics
end interface

```

The process core must implement this function. Here, *j* is the index of the particular term we want to compute. The amplitude may depend on the factorization and renormalization scales.

The *tmp* (workspace) argument may be used if it is provided by the caller. Otherwise, the routine should compute the result directly.

```

<Prc core: process core: TBP>+≡
    procedure(prc_core_compute_amplitude), deferred :: compute_amplitude

<Prc core: interfaces>+≡
    abstract interface
        function prc_core_compute_amplitude &
            (object, j, p, f, h, c, fac_scale, ren_scale, tmp) result (amp)
        import
        class(prc_core_t), intent(in) :: object
        integer, intent(in) :: j
        type(vector4_t), dimension(:), intent(in) :: p
        integer, intent(in) :: f, h, c
        real(default), intent(in) :: fac_scale, ren_scale
        class(workspace_t), intent(inout), allocatable, optional :: tmp
        complex(default) :: amp
    end function prc_core_compute_amplitude
end interface

```

15.2.2 Storage for intermediate results

The abstract *workspace_t* type allows process cores to set up temporary workspace. The object is an extra argument for each of the individual calculations between kinematics setup and matrix-element evaluation.

```

<Prc core: public>+≡
    public :: workspace_t

<Prc core: types>+≡
    type, abstract :: workspace_t
    contains
        procedure(workspace_write), deferred :: write
    end type workspace_t

```

For debugging, we should at least have an output routine.

```

<Prc core: interfaces>+≡
    abstract interface
        subroutine workspace_write (object, unit)
        import
        class(workspace_t), intent(in) :: object
        integer, intent(in), optional :: unit
    end subroutine workspace_write
end interface

```

15.2.3 Helicity selection data

This is intended for use with O'MEGA, but may also be made available to other process methods. We set thresholds for counting the times a specific helicity amplitude is zero. When the threshold is reached, we skip this amplitude in subsequent calls.

For initializing the helicity counters, we need an object that holds the two parameters, the threshold (large real number) and the cutoff (integer).

A helicity value suppressed by more than **threshold** (a value which multiplies **epsilon**, to be compared with the average of the current amplitude, default is 10^{10}) is treated as zero. A matrix element is assumed to be zero and not called again if it has been zero **cutoff** times.

```

<Prc core: public>+≡
    public :: helicity_selection_t

<Prc core: types>+≡
    type :: helicity_selection_t
        logical :: active = .false.
        real(default) :: threshold = 0
        integer :: cutoff = 0
    contains
        <Prc core: helicity selection: TBP>
    end type helicity_selection_t

```

Output. If the selection is inactive, print nothing.

```

<Prc core: helicity selection: TBP>≡
    procedure :: write => helicity_selection_write

<Prc core: procedures>+≡
    subroutine helicity_selection_write (object, unit)
        class(helicity_selection_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit)
        if (object%active) then
            write (u, "(3x,A)") "Helicity selection data:"
            write (u, "(5x,A,ES17.10)") &
                "threshold =", object%threshold
            write (u, "(5x,A,I0)") &
                "cutoff    = ", object%cutoff
        end if
    end subroutine helicity_selection_write

```

15.3 Process observables

We define an abstract **subevt_expr_t** object as an extension of the **subevt_t** type. The object contains a local variable list, variable instances (as targets for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the **subevt**.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression `selection` which determines whether the object passes user-defined cuts.

The intention is that we fill the `subevt_t` base object and compute the variables once we have evaluated a kinematical phase space point (or a complete event). We then evaluate the expressions and can use the results in further calculations.

The `process_expr_t` extension contains furthermore scale and weight expressions. The `event_expr_t` extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

```

<subevt_expr.f90>≡
  <File header>
  module subevt_expr

    <Use kinds>
    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use unit_tests
    use os_interface

    use ifiles
    use lexers
    use parser

    use lorentz !NODEP!
    use subevents
    use variables
    use expressions
    use models
    use flavors
    use interactions
    use particles

    <Standard module head>

    <Subevt expr: public>

    <Subevt expr: types>

    <Subevt expr: interfaces>

    contains

    <Subevt expr: procedures>

    <Subevt expr: tests>

  end module subevt_expr

```

15.3.1 Abstract base type

```

<Subevt expr: types>≡
  type, extends (subevt_t), abstract :: subevt_expr_t
    logical :: subevt_filled = .false.
    type(var_list_t) :: var_list
    real(default) :: sqrts_hat = 0
    integer :: n_in = 0
    integer :: n_out = 0
    integer :: n_tot = 0
    logical :: has_selection = .false.
    type(eval_tree_t) :: selection
  contains
    <Subevt expr: subevt expr: TBP>
  end type subevt_expr_t

```

Output: Base and extended version. We already have a `write` routine for the `subevt_t` parent type.

```

<Subevt expr: subevt expr: TBP>≡
  procedure :: base_write => subevt_expr_write

<Subevt expr: procedures>≡
  subroutine subevt_expr_write (object, unit)
    class(subevt_expr_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(1x,A)") "Local variables:"
    call write_separator (u)
    call var_list_write (object%var_list, u, follow_link=.false.)
    call write_separator (u)
    if (object%subevt_filled) then
      call object%subevt_t%write (u)
      if (object%has_selection) then
        call write_separator (u)
        write (u, "(1x,A)") "Selection expression:"

      end if
    else
      write (u, "(1x,A)") "subevt: [undefined]"
    end if
  end subroutine subevt_expr_write

```

Finalizer.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure (subevt_expr_final), deferred :: final
  procedure :: base_final => subevt_expr_final

<Subevt expr: procedures>+≡
  subroutine subevt_expr_final (object)
    class(subevt_expr_t), intent(inout) :: object
    call var_list_final (object%var_list)
    if (object%has_selection) then

```

```

        call eval_tree_final (object%selection)
    end if
end subroutine subevt_expr_final

```

15.3.2 Initialization

Initialization: define local variables and establish pointers.

The common variables are `sqrts` (the nominal beam energy, fixed), `sqrts_hat` (the actual energy), `n_in`, `n_out`, and `n_tot` for the `subevt`. With the exception of `sqrts`, all are implemented as pointers to subobjects.

```

<Subevt expr: subevt expr: TBP>+≡
    procedure (subevt_expr_setup_vars), deferred :: setup_vars
    procedure :: base_setup_vars => subevt_expr_setup_vars

<Subevt expr: procedures>+≡
    subroutine subevt_expr_setup_vars (expr, sqrts)
        class(subevt_expr_t), intent(inout), target :: expr
        real(default), intent(in) :: sqrts
        call var_list_final (expr%var_list)
        call var_list_append_real (expr%var_list, &
            var_str ("sqrts"), sqrts, &
            locked = .true., verbose = .false., intrinsic = .true.)
        call var_list_append_real_ptr (expr%var_list, &
            var_str ("sqrts_hat"), expr%sqrts_hat, &
            is_known = expr%subevt_filled, &
            locked = .true., verbose = .false., intrinsic = .true.)
        call var_list_append_int_ptr (expr%var_list, &
            var_str ("n_in"), expr%n_in, &
            is_known = expr%subevt_filled, &
            locked = .true., verbose = .false., intrinsic = .true.)
        call var_list_append_int_ptr (expr%var_list, &
            var_str ("n_out"), expr%n_out, &
            is_known = expr%subevt_filled, &
            locked = .true., verbose = .false., intrinsic = .true.)
        call var_list_append_int_ptr (expr%var_list, &
            var_str ("n_tot"), expr%n_tot, &
            is_known = expr%subevt_filled, &
            locked = .true., verbose = .false., intrinsic = .true.)
    end subroutine subevt_expr_setup_vars

```

Link a variable list to the local one. This could be done event by event, but before evaluating expressions.

```

<Subevt expr: subevt expr: TBP>+≡
    procedure :: link_var_list => subevt_expr_link_var_list

<Subevt expr: procedures>+≡
    subroutine subevt_expr_link_var_list (expr, var_list)
        class(subevt_expr_t), intent(inout) :: expr
        type(var_list_t), intent(in), target :: var_list
        call var_list_link (expr%var_list, var_list)
    end subroutine subevt_expr_link_var_list

```

Compile the selection expression. If the pointer is disassociated, there is no expression.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: setup_selection => subvt_expr_setup_selection

<Subvt expr: procedures>+≡
  subroutine subvt_expr_setup_selection (expr, pn_selection)
    class(subvt_expr_t), intent(inout), target :: expr
    type(parse_node_t), intent(in), pointer :: pn_selection
    if (associated (pn_selection)) then
      call eval_tree_init_lexpr (expr%selection, &
        pn_selection, expr%var_list, expr%subvt_t)
      expr%has_selection = .true.
    end if
  end subroutine subvt_expr_setup_selection

```

15.3.3 Evaluation

Reset to initial state, i.e., mark the subvt as invalid.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: reset => subvt_expr_reset
  procedure :: base_reset => subvt_expr_reset

<Subvt expr: procedures>+≡
  subroutine subvt_expr_reset (expr)
    class(subvt_expr_t), intent(inout) :: expr
    expr%subvt_filled = .false.
  end subroutine subvt_expr_reset

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: base_evaluate => subvt_expr_evaluate

<Subvt expr: procedures>+≡
  subroutine subvt_expr_evaluate (expr, passed)
    class(subvt_expr_t), intent(inout) :: expr
    logical, intent(out) :: passed
    if (expr%has_selection) then
      call eval_tree_evaluate (expr%selection)
      if (eval_tree_result_is_known (expr%selection)) then
        passed = eval_tree_get_log (expr%selection)
      else
        passed = .false.  ! should be an error?
      end if
    else
      passed = .true.
    end if
  end subroutine subvt_expr_evaluate

```

15.3.4 Implementation for partonic events

This implementation contains the expressions that we can evaluate for the partonic process during integration.

```

```

Filling the partonic state consists of two parts. The first routine prepares the subevt without assigning momenta. It takes the particles from an `interaction_t`. It needs the indices and flavors for the beam, incoming, and outgoing particles.

We can assume that the particle content of the subevt does not change. Therefore, we set the event variables `n_in`, `n_out`, `n_tot` already in this initialization step.

```

<Subevt expr: parton expr: TBP>+≡
  procedure :: setup_subevt => parton_expr_setup_subevt

<Subevt expr: procedures>+≡
  subroutine parton_expr_setup_subevt (expr, int, &
    i_beam, i_in, i_out, f_beam, f_in, f_out)
    class(parton_expr_t), intent(inout) :: expr
    type(interaction_t), intent(in), target :: int
    integer, dimension(:), intent(in) :: i_beam, i_in, i_out
    type(flavor_t), dimension(:), intent(in) :: f_beam, f_in, f_out
    allocate (expr%i_beam (size (i_beam)))

```

```

allocate (expr%i_in (size (i_in)))
allocate (expr%i_out (size (i_out)))
expr%i_beam = i_beam
expr%i_in = i_in
expr%i_out = i_out
call interaction_to_subevt (int, &
    expr%i_beam, expr%i_in, expr%i_out, expr%subevt_t)
call subevt_set_pdg_beam      (expr%subevt_t, flavor_get_pdg (f_beam))
call subevt_set_pdg_incoming (expr%subevt_t, flavor_get_pdg (f_in))

15.3.5 Implementation for full events

This implementation contains the expressions that we can evaluate for the full event. It also contains data that pertain to the event, suitable for communication with external event formats. These data simultaneously serve as pointer targets for the variable lists hidden in the expressions (eval trees).

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

```

```

Fill the event expression: take the particle data and kinematics from a `particle_set` object.

We allow the particle content to change for each event. Therefore, we set the event variables each time.

Also increment the event index; initialize it if necessary.

```

<Subevt expr: event expr: TBP>+≡
  procedure :: fill_subevt => event_expr_fill_subevt

<Subevt expr: procedures>+≡
  subroutine event_expr_fill_subevt (expr, particle_set)
    class(event_expr_t), intent(inout) :: expr
    type(particle_set_t), intent(in) :: particle_set
    call particle_set_to_subevt (particle_set, expr%subevt_t)
    expr%sqrts_hat = subevt_get_sqrts_hat (expr%subevt_t)
    expr%n_in = particle_set_get_n_in (particle_set)
    expr%n_out = particle_set_get_n_out (particle_set)
    expr%n_tot = expr%n_in + expr%n_out
    expr%subevt_filled = .true.
    if (expr%has_index) then
      expr%index = expr%index + 1
    else
      expr%index = 1
      expr%has_index = .true.
    end if
  end subroutine event_expr_fill_subevt

```

Evaluate, if the event passes the selection. For absent expressions we take default values.

```

<Subevt expr: event expr: TBP>+≡
  procedure :: evaluate => event_expr_evaluate

<Subevt expr: procedures>+≡
  subroutine event_expr_evaluate (expr, passed, reweight, analysis_flag)

15.4 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states, depending on the the beam setup allows. The result is used for integration.

The `matrix` evaluator is the counterpart of `trace` which is kept exclusive in all observable quantum numbers. The `flows` evaluator is furthermore exclusive in colors, but neglecting all color interference. The `matrix` and `flows` evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. However, this causes memory corruption in gfortran 4.6.3. The extra `has_XXX` flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the `processes` module below.

⟨Parton states: types⟩

contains

⟨Parton states: procedures⟩

end module parton_states

```

15.4.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

⟨Parton states: types⟩≡
    type, abstract :: parton_state_t
        logical :: has_trace = .false.
        logical :: has_matrix = .false.
        logical :: has_flows = .false.
        type(evaluator_t) :: trace
        type(evaluator_t) :: matrix
        type(evaluator_t) :: flows
    contains
    ⟨Parton states: parton state: TBP⟩

```

```
end type parton_state_t
```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both implemented as a pointer. The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```
⟨Parton states: public⟩≡
  public :: isolated_state_t

⟨Parton states: types⟩+≡
  type, extends (parton_state_t) :: isolated_state_t
    logical :: sf_chain_is_allocated = .false.
    type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()
    logical :: int_is_allocated = .false.
    type(interaction_t), pointer :: int_eff => null ()
  contains
    ⟨Parton states: isolated state: TBP⟩
  end type isolated_state_t
```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

```
⟨Parton states: types⟩+≡
  public :: connected_state_t

⟨Parton states: types⟩+≡
  type, extends (parton_state_t) :: connected_state_t
    logical :: has_flows_sf = .false.
    type(evaluator_t) :: flows_sf
    logical :: has_expr = .false.
    type(parton_expr_t) :: expr
  contains
    ⟨Parton states: connected state: TBP⟩
  end type connected_state_t
```

Output: each evaluator is written only when it is active. The `sf_chain` is only written if it is explicitly allocated.

```

15.4.2 Common Initialization

Initialize the isolated parton state. In this version, the effective structure-function chain `sf_chain_eff` and the effective interaction `int_eff` both are trivial pointers to the seed structure-function chain and to the hard interaction, respectively.

```

(Parton states: isolated state: TBP)≡
  procedure :: init => isolated_state_init_pointers

(Parton states: procedures)+≡
  subroutine isolated_state_init_pointers (state, sf_chain, int)
    class(isolated_state_t), intent(out) :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(interaction_t), intent(in), target :: int
    state%sf_chain_eff => sf_chain
    state%int_eff => int
  end subroutine isolated_state_init_pointers

```

15.4.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask_in`.

There are two options: explicitly computing the color factor table (`use_cf` false; `nc` defined), or taking the color factor table from the hard matrix element data.

```

(Parton states: isolated state: TBP)+≡

```

Setup the evaluator for the transition matrix, exclusive in helicities where this is requested.

For all unstable final-state particles we keep polarization according to the applicable decay options. If the process is a decay itself, this applies also to the initial state.

For all polarized final-state particles, we keep polarization including off-diagonal entries. We drop helicity completely for unpolarized final-state parti-

cles.

For the initial state, if the particle has not been handled yet, we apply the provided `qn_mask_in` which communicates the beam properties.

15.4.4 Evaluator initialization: connected state

Setup a trace evaluator as a product of two evaluators (incoming state, effective interaction). In the result, all quantum numbers are summed over.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`.

(Parton states: connected state: TBP) +=

```

    procedure :: setup_connected_trace => connected_state_setup_connected_trace
  (Parton states: procedures)+≡
    subroutine connected_state_setup_connected_trace (state, isolated, int)
      class(connected_state_t), intent(inout), target :: state
      type(isolated_state_t), intent(in), target :: isolated
      type(interaction_t), intent(in), optional, target :: int
      type(quantum_numbers_mask_t) :: mask
      type(interaction_t), pointer :: src_int
      mask = new_quantum_numbers_mask (.true., .true., .true.)
      if (present (int)) then
        src_int => int
      else
        src_int => isolated%sf_chain_eff%get_out_int_ptr ()
      end if
      call evaluator_init_product &
        (state%trace, src_int, isolated%trace, mask, mask)
      state%has_trace = .true.
    end subroutine connected_state_setup_connected_trace

```

Setup a matrix evaluator as a product of two evaluators (incoming state, effective interaction). In the intermediate state, color and helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

```

  (Parton states: connected state: TBP)+≡
    procedure :: setup_connected_matrix => connected_state_setup_connected_matrix
  (Parton states: procedures)+≡
    subroutine connected_state_setup_connected_matrix (state, isolated, int)
      class(connected_state_t), intent(inout), target :: state
      type(isolated_state_t), intent(in), target :: isolated
      type(interaction_t), intent(in), optional, target :: int
      type(quantum_numbers_mask_t) :: mask
      type(interaction_t), pointer :: src_int
      mask = new_quantum_numbers_mask (.false., .true., .true.)
      if (present (int)) then
        src_int => int
      else
        src_int => isolated%sf_chain_eff%get_out_int_ptr ()
      end if
      call evaluator_init_product &
        (state%matrix, src_int, isolated%matrix, mask)
      state%has_matrix = .true.
    end subroutine connected_state_setup_connected_matrix

```

Setup a matrix evaluator as a product of two evaluators (incoming state, effective interaction). In the intermediate state, only helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`, after creating an intermediate interaction that includes a correlated color state. We assume that for a caller-provided `int`, this is not necessary.

```

  (Parton states: connected state: TBP)+≡
    procedure :: setup_connected_flows => connected_state_setup_connected_flows

```

(Parton states: procedures)+≡

```

subroutine connected_state_setup_connected_flows (state, isolated, int)

  end if
  call evaluator_init_product &
    (state%flows, src_int, isolated%flows, mask)
  state%has_flows = .true.
end subroutine connected_state_setup_connected_flows

```

15.4.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

(Parton states: connected state: TBP)+≡

```

procedure :: setup_subevt => connected_state_setup_subevt

```

(Parton states: procedures)+≡

```

subroutine connected_state_setup_subevt (state, sf_chain, f_beam, f_in, f_out)
  class(connected_state_t), intent(inout), target :: state

        call state%expr%setup_weight (pn_weight)
    end subroutine connected_state_setup_expressions

```

Reset the expression object: invalidate the subevt.

```

(Parton states: connected state: TBP)+≡
    procedure :: reset_expressions => connected_state_reset_expressions

(Parton states: procedures)+≡
    subroutine connected_state_reset_expressions (state)
        class(connect_state_t), intent(inout) :: state
        if (state%has_expr) call state%expr%reset ()
    end subroutine connected_state_reset_expressions

```

15.4.6 Evaluation

Transfer momenta to the trace evaluator and fill the `subevt` with this effective kinematics, if applicable.

Note: we may want to apply a boost for the `subevt`.

```

(Parton states: parton state: TBP)+≡
  procedure :: receive_kinematics => parton_state_receive_kinematics
(Parton states: procedures)+≡
  subroutine parton_state_receive_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
    type(interaction_t), pointer :: int
    if (state%has_trace) then
      call evaluator_receive_momenta (state%trace)
      select type (state)
        class is (connected_state_t)
          if (state%has_expr) then
            int => evaluator_get_int_ptr (state%trace)
            call state%expr%fill_subevt (int)
          end if
        end select
      end if
    end subroutine parton_state_receive_kinematics

```

Recover kinematics: We assume that the trace evaluator is filled with momenta. Send those momenta back to the sources, then fill the variables and subevent as above.

The incoming momenta of the connected state are not connected to the isolated state but to the beam interaction. Therefore, the incoming momenta within the isolated state do not become defined, yet. Instead, we reconstruct the beam (and ISR) momentum configuration.

```

(Parton states: parton state: TBP)+≡
  procedure :: send_kinematics => parton_state_send_kinematics
(Parton states: procedures)+≡
  subroutine parton_state_send_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
    type(interaction_t), pointer :: int
    real(default) :: s_hat
    if (state%has_trace) then
      call evaluator_send_momenta (state%trace)
      select type (state)
        class is (connected_state_t)
          int => evaluator_get_int_ptr (state%trace)
          call state%expr%fill_subevt (int)
        end select
      end if
    end subroutine parton_state_send_kinematics

```

Evaluate the expressions. The routine evaluates first the cut expression. If the event passes, it evaluates the other expressions. Where no expressions are defined, default values are inserted.

```

    integer, intent(in) :: u
    write (u, "(A)") repeat ("=", 72)
  end subroutine write_separator_double

```

15.5 Complete Elementary Processes

This module combines hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the **computed** state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the **observed** state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible subsequent decay processes on the parton level, which are full-fledged process objects themselves.

15.5.1 The Process Object

A process object is the workspace for creating process instances for event generation. After initialization, its contents are filled by integration passes which shape the integration grids and compute cross sections. Processes are set up initially from user-level configuration data. After calculating integrals and thus developing integration grid data, the program may use a process object or a copy of it for the purpose of generating events

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The **type** determines whether we are considering a decay or a scattering process.

The **meta** object describes the process and its environment. All contents become fixed when the object is initialized.

The **config** object holds physical and technical configuration data that have been obtained during process initialization, and which are common to all process components.

The individual process components are configured in the **component** objects. These objects contain more configuration parameters and workspace, as needed for the specific process variant.

The **term** objects describe parton configurations which are technically used as phase-space points. Each process component may split into several terms with distinct kinematics and particle content. Furthermore, each term may project on a different physical state, e.g., by particle recombination. The **term** object provides the framework for this projection, for applying cuts, weight, and thus completing the process calculation.

The **beam_config** object describes the incoming particles, either the decay mother or the scattering beams. It also contains the structure-function information.

The **mci_entry** objects configure a MC input parameter set and integrator, each. The number of parameters depends on the process component and on the beam and structure-function setup.

```

⟨Processes: public⟩≡
    public :: process_t

⟨Processes: process type⟩≡
    type :: process_t
    private
    type(process_metadata_t) :: &
        meta

```

```

```

Process setup

Initialize a process. We need a process library, the name of the process, and a run ID.

```

<Processes: process: TBP>+=
  procedure :: init => process_init

<Processes: procedures>+=
  subroutine process_init &
    (process, proc_id, run_id, lib, os_data, qcd, rng_factory, model_list)
    class(process_t), intent(out) :: process
    type(string_t), intent(in) :: proc_id
    type(string_t), intent(in) :: run_id
    type(process_library_t), intent(in), target :: lib
    type(os_data_t), intent(in) :: os_data
    type(qcd_t), intent(in) :: qcd
    class(rng_factory_t), intent(inout), allocatable :: rng_factory
    type(model_list_t), intent(inout) :: model_list
    if (.not. lib%is_active ()) then
      call msg_bug ("Process init: inactive library not handled yet")
    end if
    if (.not. lib%contains (proc_id)) then
      call msg_fatal ("Process library doesn't contain process '" &
        // char (proc_id) // "'")
    end if
    return
  end if

```

```

    associate (meta => process%meta)
      call meta%init (proc_id, run_id, lib)
      call process%config%init (meta, os_data, qcd, rng_factory, model_list)
      allocate (process%component (meta%n_components))
    end associate
end subroutine process_init

```

Store a snapshot of a variable list. We link this snapshot to the current model instance and use it to update the model parameters in this instance. After update, synchronize the var list, i.e., fetch any new values of derived parameters.

```

<Processes: process: TBP>+=
  procedure :: set_var_list => process_set_var_list

<Processes: procedures>+=
  subroutine process_set_var_list (process, var_list)
    class(process_t), intent(inout) :: process
    type(var_list_t), intent(in) :: var_list
    call var_list_init_snapshot (process%meta%var_list, var_list)
    call var_list_set_original_pointers (process%meta%var_list, &
      model_get_var_list_ptr (process%config%model))
    call var_list_restore (process%meta%var_list)

                component%i_term(j) = k + j
                call process%term(k+j)%init (k+j, i, j, core, model)
            end do
        end associate
    end associate
    k = k + n_entry(i)
end do
process%config%n_terms = n_tot
end subroutine process_setup_terms

```

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam_data_t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by extending the code in the `beams` module.

```

(Processes: process: TBP)+≡
!   generic :: setup_beams => setup_beams_sqrts
procedure :: setup_beams_sqrts => process_setup_beams_sqrts

(Processes: procedures)+≡

            call process%component(i)%configure_phs &
                (sqrts, process%beam_config, rebuild, ignore_mismatch)
        end do
    end subroutine process_configure_phs

```

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

```

<Processes: process: TBP>+≡
    procedure :: init_sf_chain => process_init_sf_chain
    generic :: set_sf_channel => set_sf_channel_single
    procedure :: set_sf_channel_single => process_set_sf_channel

```

```

generic :: set_sf_channel => set_sf_channel_array
procedure :: set_sf_channel_array => process_set_sf_channel_array

(Processes: procedures) +=
  subroutine process_init_sf_chain (process, sf_config)
    class(process_t), intent(inout) :: process
    type(sf_config_t), dimension(:), intent(in) :: sf_config
    call process%beam_config%init_sf_chain (sf_config)
  end subroutine process_init_sf_chain

  subroutine process_set_sf_channel (process, c, sf_channel)
    class(process_t), intent(inout) :: process
    integer, intent(in) :: c
    type(sf_channel_t), intent(in) :: sf_channel
    call process%beam_config%set_sf_channel (c, sf_channel)
  end subroutine process_set_sf_channel

  subroutine process_set_sf_channel_array (process, sf_channel)
    class(process_t), intent(inout) :: process
    type(sf_channel_t), dimension(:), intent(in) :: sf_channel
    integer :: c
    do c = 1, size (sf_channel)
      call process%beam_config%set_sf_channel (c, sf_channel(c))
    end do
  end subroutine process_set_sf_channel_array

```

Notify about the structure-function setup.

```

(Processes: process: TBP) +=
  procedure :: sf_startup_message => process_sf_startup_message

(Processes: procedures) +=
  subroutine process_sf_startup_message (process, sf_string, unit)
    class(process_t), intent(in) :: process
    type(string_t), intent(in) :: sf_string
    integer, intent(in), optional :: unit
    call process%beam_config%sf_startup_message (sf_string, unit)
  end subroutine process_sf_startup_message

```

As soon as both the kinematics configuration and the structure-function setup are complete, we match parameterizations (channels) for both. The matching entries are (re)set in the component phase-space configuration, while the structure-function configuration is left intact.

```

(Processes: process: TBP) +=
  procedure :: match_channels => process_match_channels

(Processes: procedures) +=
  subroutine process_match_channels (process)
    class(process_t), intent(inout) :: process
    integer :: i
    do i = 1, process%meta%n_components
      call process%component(i)%match_channels (process%beam_config)
    end do
  end subroutine process_match_channels

```

Determine the MC parameter set structure and the MCI configuration for each process component. We need data from the structure-function and phase-space setup, so those should be complete before this is called. We also make a random-number generator instance for each MCI group.

```

    process%config%pn_weight => pn_weight
  end subroutine process_set_weight

```

MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

```

<Processes: process: TBP>+≡
  procedure :: compute_md5sum => process_compute_md5sum

<Processes: procedures>+≡
  subroutine process_compute_md5sum (process)
    class(process_t), intent(inout) :: process
    integer :: i
    call process%config%compute_md5sum ()
    do i = 1, process%config%n_components
      call process%component(i)%compute_md5sum ()
    end do
  end subroutine process_compute_md5sum

```

```

call process%beam_config%compute_md5sum ()
do i = 1, process%config%n_mci
  call process%mc_entry(i)%compute_md5sum &
    (process%config, process%component, process%beam_config)
end do
end subroutine process_compute_md5sum

```

Integration and event generation

The sampler test should just evaluate the squared matrix element `n_calls` times, discarding the results, and return. This can be done before integration, e.g., for timing estimates.

```

<Processes: process: TBP>+=
  procedure :: sampler_test => process_sampler_test

<Processes: procedures>+=
  subroutine process_sampler_test (process, instance, i_mci, n_calls)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout), target :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_calls
    call process%mc_entry(i_mci)%sampler_test (instance, n_calls)
  end subroutine process_sampler_test

```

Integrate the process, using a previously initialized process instance. We select one of the available MCI integrators by its index `i_mci` and thus integrate over (structure functions and) phase space for the associated (group of) process component(s).

The finalizer should be called after all integration passes have been completed. It will, for instance, write a summary of the integration results.

```

<Processes: process: TBP>+=
  procedure :: integrate => process_integrate
  procedure :: final_integration => process_final_integration

<Processes: procedures>+=
  subroutine process_integrate (process, instance, i_mci, n_it, n_calls, &
    adapt_grids, adapt_weights, final)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_it
    integer, intent(in) :: n_calls
    logical, intent(in), optional :: adapt_grids
    logical, intent(in), optional :: adapt_weights
    logical, intent(in), optional :: final
    call process%mc_entry(i_mci)%integrate (instance, n_it, n_calls, &
      adapt_grids, adapt_weights, final)
  end subroutine process_integrate

  subroutine process_final_integration (process, i_mci)
    class(process_t), intent(inout) :: process
    integer, intent(in) :: i_mci

```

```

        call process%mci_entry(i_mci)%final_integration ()
    end subroutine process_final_integration

```

Run LaTeX/Metapost to generate a ps/pdf file for the integration history. We (re)write the driver file – just in case it has been missed before – then we compile it.

```

(Processes: process: TBP)+=
    procedure :: display_integration_history => &
        process_display_integration_history

```

Prepare event generation for the specified MCI entry. This implies, in particular, checking the phase-space file.

```

<Processes: process: TBP>+≡
  procedure :: prepare_simulation => process_prepare_simulation

<Processes: procedures>+≡
  subroutine process_prepare_simulation (process, i_mci)
    class(process_t), intent(inout) :: process
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%prepare_simulation ()
  end subroutine process_prepare_simulation

```

Generate a weighted event. We select one of the available MCI integrators by its index `i_mci` and thus generate an event for the associated (group of) process component(s). The arguments exactly correspond to the initializer and finalizer above.

The resulting event is stored in the `procoess_instance` object, which also holds the workspace of the integrator.

Note: The `process` object is declared `intent(inout)` because it contains the random number state, which changes for each event. Otherwise, all volatile data are inside the `instance` object.

```

<Processes: process: TBP>+≡
  procedure :: generate_weighted_event => process_generate_weighted_event
  procedure :: generate_unweighted_event => process_generate_unweighted_event

<Processes: procedures>+≡
  subroutine process_generate_weighted_event (process, instance, i_mci)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%generate_weighted_event (instance)

```

```

end subroutine process_generate_weighted_event

subroutine process_generate_unweighted_event (process, instance, i_mci)
  class(process_t), intent(inout) :: process
  type(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_mci
  call process%mci_entry(i_mci)%generate_unweighted_event (instance)
end subroutine process_generate_unweighted_event

```

This replaces the event generation methods for the situation that the process instance object has been filled by other means (i.e., reading and/or recalculating its contents). We just have to fill in missing MCI data, especially the event weight.

```

<Processes: process: TBP>+≡
  procedure :: recover_event => process_recover_event

<Processes: procedures>+≡
  subroutine process_recover_event (process, instance, i_term)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    call process%mci_entry(instance%i_mci)%recover_event (instance, i_term)
  end subroutine process_recover_event

```

Retrieve process data

Tell whether integral (and error) are known.

```

    md5sum = process%config%md5sum
  end function process_get_md5sum_cfg

```

15.5.2 Metadata

This information describes the process and its environment. It is fixed upon initialization.

The `id` string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The `num_id` is meaningful if nonzero. It is used for communication with external programs or file standards which do not support string IDs.

The `run_id` string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The `var_list` is a snapshot of the variable list, taken at the point where the process was initialized.

The `lib` pointer accesses the process library where the process definition and the process driver are located.

The `lib_index` is the index of entry in the process library that corresponds to the current process.

The `component_id` array identifies the individual process components.

The `component_description` is an array of human-readable strings that characterize the process components, for instance `a, b => c, d`.

```

15.5.3 Generic Configuration Data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the variable list.

The number **n_in** is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number **n_components** is the number of components that constitute the current process.

The number **n_terms** is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number **n_mci** is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The **model** pointer identifies the physics model and its parameters. This is a pointer to an external object.

The **rng_factory** component spawns independent random-number generators for use in integration, event generation, and event postprocessing.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the `effective_state` subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The `md5sum` is taken and used to verify the process configuration when re-reading data from file.

```

<Processes: process part types>+=
  type :: process_config_data_t
    private

        call write_separator (u)
        write (u, "(3x,A,A,A)") "MD5 sum (config) = ", config%md5sum, ""
    end if
end subroutine process_config_data_write

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

Using the model name that the library gives us, we try to load the model here. Reading from the global model library, we are sure that we are looking at the model associated to the process, not the selected one at the user level. However, when the mode names are the same, the models will be identical.

Instead of storing a model pointer, we create an instance which contains the current values of model parameters. The captured values are now disconnected from user-level changes and will stay for the lifetime of the process object. Allocating the model via a pointer guarantees the `target` attribute.

The RNG factory object is imported by moving the allocation.

```

<Processes: process config data: TBP>+=
    procedure :: init => process_config_data_init

<Processes: procedures>+=
    subroutine process_config_data_init &
        (config, meta, os_data, qcd, rng_factory, model_list)
        class(process_config_data_t), intent(out) :: config
        type(process_metadata_t), intent(in) :: meta
        type(os_data_t), intent(in) :: os_data
        type(qcd_t), intent(in) :: qcd
        class(rng_factory_t), intent(inout), allocatable :: rng_factory
        type(model_list_t), intent(inout) :: model_list
        type(string_t) :: filename
        type(model_t), pointer :: model
        config%n_in = meta%lib%get_n_in (meta%id)
        config%n_components = size (meta%component_id)
        config%os_data = os_data
        config%qcd = qcd
        call move_alloc (from = rng_factory, to = config%rng_factory)
        config%model_name = meta%lib%get_model_name (meta%id)
        if (config%model_name /= "") then
            filename = config%model_name // ".mdl"
            call model_list%read_model (config%model_name, &
                filename, config%os_data, model)
            allocate (config%model)
            call model_init_instance (config%model, model)
        end if
    end subroutine process_config_data_init

```

Since the captured model is a separate object allocated via a pointer, we need a finalizer.

```

<Processes: process config data: TBP>+=
    procedure :: final => process_config_data_final

<Processes: procedures>+=
    subroutine process_config_data_final (config)
        class(process_config_data_t), intent(inout) :: config

```

```

    if (associated (config%model)) then
        call model_final (config%model)
        deallocate (config%model)
    end if
end subroutine process_config_data_final

```

Compute the MD5 sum of the configuration data. This encodes, in particular, the model and the expressions for cut, scales, weight, etc. It should not contain the IDs and number of components, etc., since the MD5 sum should be useful for integrating individual components.

This is done only once. If the MD5 sum is nonempty, the calculation is skipped.

```

<Processes: process config data: TBP>+≡
    procedure :: compute_md5sum => process_config_data_compute_md5sum

<Processes: procedures>+≡
    subroutine process_config_data_compute_md5sum (config)
        class(process_config_data_t), intent(inout) :: config
        integer :: u
        if (config%md5sum == "") then
            u = free_unit ()
            open (u, status = "scratch", action = "readwrite")
            call config%write (u, counters = .false., os_data = .false., &
                rng_factory = .false., model = .true., expressions = .true.)
            rewind (u)
            config%md5sum = md5sum (u)
            close (u)
        end if
    end subroutine process_config_data_compute_md5sum

```

15.5.4 Beam configuration

The object `data` holds all details about the initial beam configuration. The allocatable array `sf` holds the structure-function configuration blocks. There are `n_strfun` entries in the structure-function chain (not counting the initial beam object). We maintain `n_channel` independent parameterizations of this chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is `n_sfpar`.

The flag `azimuthal_dependence` tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag `lab_is_cm_frame` is obvious.

```

<Processes: process part types>+≡
    type :: process_beam_config_t
        private
        type(beam_data_t) :: data

  open (u, status = "scratch", action = "readwrite")
  call beam_config%write (u)
  rewind (u)
  beam_config%md5sum = md5sum (u)
  close (u)
end if
end subroutine process_beam_config_compute_md5sum

```

15.5.5 Multi-channel integration

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly the values that apply to the current pass. Previous values are archived in the `results` object.

The `results` object records results, broken down in passes and iterations.

```

<Processes: process part types>+≡
type :: process_mci_entry_t
  integer :: i_mci = 0
  integer, dimension(:), allocatable :: i_component
  integer :: process_type = PRC_UNKNOWN
  integer :: n_par = 0
  integer :: n_par_sf = 0
  integer :: n_par_phs = 0
  character(32) :: md5sum = ""
  integer :: pass = 0
  integer :: n_it = 0
  integer :: n_calls = 0
  logical :: activate_timer = .false.
  real(default) :: error_threshold = 0
  class(mci_t), allocatable :: mci
  type(integration_results_t) :: results
contains
  <Processes: process mci entry: TBP>
end type process_mci_entry_t

```

Finalizer for the `mci` component.

```

<Processes: process mci entry: TBP>≡
procedure :: final => process_mci_entry_final

```

```

<Processes: procedures>+≡

      call object%results%write (u)
    end if
  end subroutine process_mci_entry_write

```

Initialize. From the existing configuration, we obtain the number of channels and the number of parameters, separately for the structure-function chain and for the associated process component. We assume that the phase-space object has already been configured.

The allocation of the MCI integrator with the appropriate concrete type is the duty of the process core.

We assume that there is only one component associated with a MCI entry. This restriction should be relaxed.

```

<Processes: process mci entry: TBP>+≡

      call mci_entry%mci%set_md5sum (mci_entry%md5sum)
    end if
  end subroutine process_mci_entry_compute_md5sum

```

Test the MCI sampler by calling it a given number of time, discarding the results. The instance should be initialized.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

```

<Processes: process mci entry: TBP>+≡
  procedure :: sampler_test => process_mci_entry_sampler_test

<Processes: procedures>+≡
  subroutine process_mci_entry_sampler_test (mci_entry, instance, n_calls)
    class(process_mci_entry_t), intent(inout) :: mci_entry
    type(process_instance_t), intent(inout), target :: instance
    integer, intent(in) :: n_calls
    call instance%choose_mci (mci_entry%i_mci)
    call mci_entry%mci%sampler_test (instance, n_calls)
  end subroutine process_mci_entry_sampler_test

```

Integrate. The instance should be initialized.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

```

(Processes: process mci entry: TBP)+≡

```

15.5.6 Process Components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components have different types. In short, `process_component_t` is a wrapper for the actual process variants.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

<Processes: process part types>+≡
  type :: process_component_t
    private
    type(process_component_def_t), pointer :: config => null ()
    integer :: index = 0
    class(prc_core_t), allocatable :: core
    class(mci_t), allocatable :: mci_template
    integer, dimension(:), allocatable :: i_term
    integer :: i_mci = 0
    class(phs_config_t), allocatable :: phs_config

```

```

        character(32) :: md5sum_phs = ""
contains
    <Processes: process component: TBP>
end type process_component_t

```

Finalizer. The MCI template may (potentially) need a finalizer. The process configuration finalizer may include closing an open scratch file.

```

    <Processes: process component: TBP>≡
        procedure :: final => process_component_final

    <Processes: procedures>+≡
        subroutine process_component_final (object)
            class(process_component_t), intent(inout) :: object

    integer :: i
    associate (data => component%core%data)
      allocate (flv_state_in (data%n_in))
      do i = 1, data%n_in
        if (all (data%flv_state(i,:) == data%flv_state(i,1))) then
          flv_state_in(i) = data%flv_state(i,1)
        else
          flv_state_in(i) = UNDEFINED
        end if
      end do
    end associate
  end function process_component_get_flv_state_in
```

15.5.7 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`. In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`.

This is the total number of independent entries in the density matrix. For each combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

```

<Processes: process part types>+≡
  type :: process_term_t
    integer :: i_term_global = 0
    integer :: i_component = 0
    integer :: i_term = 0
    integer :: n_allowed = 0
    type(process_constants_t) :: data
    real(default) :: alpha_s = 0
    integer, dimension(:), allocatable :: flv, hel, col
    logical :: rearrange = .false.
    type(interaction_t) :: int
    type(interaction_t), pointer :: int_eff => null ()
  contains
    <Processes: process term: TBP>
  end type process_term_t

```

For the output, we skip the process constants and the tables of allowed quantum numbers. Those can also be read off from the interaction object.

```

<Processes: process term: TBP>≡
  procedure :: write => process_term_write

<Processes: procedures>+≡
  subroutine process_term_write (term, unit)
    class(process_term_t), intent(in) :: term

```

```

integer, intent(in), optional :: unit
integer :: u, i
u = output_unit (unit)
write (u, "(1x,A,I0)") "Term #", term%i_term_global
write (u, "(3x,A,I0)") "Process component index      = ", &
    term%i_component
write (u, "(3x,A,I0)") "Term index w.r.t. component = ", &
    term%i_term
write (u, "(3x,A,L1)") "Rearrange partons          = ", &
    term%rearrange
call write_separator (u)
write (u, "(1x,A)") "Hard interaction:"
call write_separator (u)
call interaction_write (term%int, u)
if (term%rearrange) then
    call write_separator (u)
    write (u, "(1x,A)") "Rearranged hard interaction:"
    call write_separator (u)
    call interaction_write (term%int_eff, u)
end if
end subroutine process_term_write

```

Finalizer: the `int` and potentially `int_eff` components have a finalizer that we must call.

```

<Processes: process term: TBP>+≡
    procedure :: final => process_term_final

<Processes: procedures>+≡
    subroutine process_term_final (term)
        class(process_term_t), intent(inout) :: term
        call interaction_final (term%int)
        if (term%rearrange) then
            call interaction_final (term%int_eff)
            deallocate (term%int_eff)
        end if
    end subroutine process_term_final

```

Initialize the term. We copy the process constants from the `core` object and set up the `int` hard interaction accordingly.

The `alpha_s` value is useful for writing external event records. This is the constant value which may be overridden by a event-specific running value. If the model does not contain the strong coupling, the value is zero.

Note: `intent(inout)` for `term` is a workaround for a NAG compiler bug.

```

<Processes: process term: TBP>+≡
    procedure :: init => process_term_init

<Processes: procedures>+≡
    subroutine process_term_init &
        (term, i_term_global, i_component, i_term, core, model)
        class(process_term_t), intent(inout), target :: term
        integer, intent(in) :: i_term_global
        integer, intent(in) :: i_component
        integer, intent(in) :: i_term
    end subroutine process_term_init

```

```

class(prc_core_t), intent(in) :: core
type(model_t), intent(in), target :: model
type(var_list_t), pointer :: var_list
term%i_term_global = i_term_global
term%i_component = i_component
term%i_term = i_term
call core%get_constants (term%data, i_term)
var_list => model_get_var_list_ptr (model)
if (var_list_exists (var_list, var_str ("alphas"))) then
    term%alpha_s = var_list_get_rval (var_list, var_str ("alphas"))
else
    term%alpha_s = -1
end if
call term%setup_interaction (core, model)
!   if (term%rearrange) then
!       call term%setup_effective_interaction (core, term%int, term%int_eff)
!   end if
end subroutine process_term_init

```

We fetch the process constants which determine the quantum numbers and use those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

```

<Processes: process term: TBP>+≡
    procedure :: setup_interaction => process_term_setup_interaction

<Processes: procedures>+≡
    subroutine process_term_setup_interaction (term, core, model)
        class(process_term_t), intent(inout) :: term

            end if
        end do
    end do
end do
call interaction_freeze (term%int)
end associate
end subroutine process_term_setup_interaction

```

15.5.8 Default Iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

<Processes: process: TBP>+≡
    procedure :: get_n_pass_default => process_get_n_pass_default
    procedure :: adapt_grids_default => process_adapt_grids_default
    procedure :: adapt_weights_default => process_adapt_weights_default

<Processes: procedures>+≡
    function process_get_n_pass_default (process) result (n_pass)
        class(process_t), intent(in) :: process
        integer :: n_pass
        integer :: n_eff
        type(process_component_def_t), pointer :: config
        config => process%component(1)%config
        n_eff = config%get_n_tot () - 2
        select case (n_eff)
        case (1)

```

```

        n_pass = 1
    case default
        n_pass = 2
    end select
end function process_get_n_pass_default

function process_adapt_grids_default (process, pass) result (flag)
    class(process_t), intent(in) :: process
    integer, intent(in) :: pass
    logical :: flag
    integer :: n_eff
    type(process_component_def_t), pointer :: config
    config => process%component(1)%config
    n_eff = config%get_n_tot () - 2
    select case (n_eff)
    case (1)
        flag = .false.
    case default
        select case (pass)
        case (1); flag = .true.
        case (2); flag = .false.
        end select
    end select
end function process_adapt_grids_default

function process_adapt_weights_default (process, pass) result (flag)
    class(process_t), intent(in) :: process
    integer, intent(in) :: pass
    logical :: flag
    integer :: n_eff
    type(process_component_def_t), pointer :: config
    config => process%component(1)%config
    n_eff = config%get_n_tot () - 2
    select case (n_eff)
    case (1)
        flag = .false.
    case default
        select case (pass)
        case (1); flag = .true.
        case (2); flag = .false.
        end select
    end select
end function process_adapt_weights_default

```

The number of iterations and calls per iteration depends on the number of outgoing particles.

15.5.10 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```

<Processes: process: TBP>+=
  procedure :: compute_amplitude => process_compute_amplitude

15.5.11 Process instances

Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

`sf_chain` is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

`phs` is an instance of the phase space for the elementary process.

The array `f` contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either `sf_chain` or `phs` are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component ('owned' by the object) or as a pointer.

```
<Processes: types>≡
  type :: kinematics_t
    integer :: n_in = 0
    integer :: n_channel = 0
    integer :: selected_channel = 0
    type(sf_chain_instance_t), pointer :: sf_chain => null ()
    class(phs_t), pointer :: phs => null ()
    real(default), dimension(:), pointer :: f => null ()
    real(default) :: phs_factor
    logical :: sf_chain_allocated = .false.
    logical :: phs_allocated = .false.
    logical :: f_allocated = .false.
  contains
    <Processes: kinematics: TBP>
  end type kinematics_t
```

Output. Show only those components which are marked as owned.

```
<Processes: kinematics: TBP>≡
  procedure :: write => kinematics_write

    success = .true.
  else
    k%phs_factor = 0
    success = .false.
  end if
end subroutine kinematics_compute

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

```

<Processes: kinematics: TBP>+≡
  procedure :: get_incoming_momenta => kinematics_get_incoming_momenta

<Processes: procedures>+≡
subroutine kinematics_get_incoming_momenta (k, p)
  class(kinematics_t), intent(in) :: k
  type(vector4_t), dimension(:), intent(out) :: p
  type(interaction_t), pointer :: int
  integer :: i
  int => k%sf_chain%get_out_int_ptr ()
  do i = 1, k%n_in
    p(i) = interaction_get_momentum (int, k%sf_chain%get_out_i (i))
  end do
end subroutine kinematics_get_incoming_momenta

```

This inverts the remainder of the above `compute` method. We know the momenta and recover the rest, as far as needed. If we select a channel, we can complete the inversion and reconstruct the MC parameter set.

```

  end subroutine kinematics_return_beam_momenta

```

Process component instance

The actual calculation of a sampling point is done from here.

The `config` pointer accesses the corresponding configuration in the `process` object.

The `active` flag indicates that we are currently computing this component, together with all other components that share the same MC parameter set. Inactive components are using a different MC parameter set and are not in use for this sampling point.

The `k_seed` subobject contains the kinematics (structure-function chain, phase space, etc.) that implements the ‘seed’ configuration of momenta. This version of the process kinematics is accessed by the MCI setup.

`p_seed` is the array of momenta that we compute from the MC input parameters, via the `k_seed` subobject. Depending on the process variant, these may or may not coincide with the momenta that enter the process terms associated to this component.

The `tmp` object can be used for storing intermediate results. Its precise type and contents depend on the process variant.

```

<Processes: types>+≡
  type :: component_instance_t
    type(process_component_t), pointer :: config => null ()
    logical :: active = .false.
    type(kinematics_t) :: k_seed
    type(vector4_t), dimension(:), allocatable :: p_seed
    logical :: sqme_known = .false.
    real(default) :: sqme = 0
    class(workspace_t), allocatable :: tmp
  contains
    <Processes: component instance: TBP>
  end type component_instance_t

```

In the header, fetch the component index from the configuration record. `process_component_t` configuration block.

We write the `sf_chain` subobject only upon request, since its instances appear elsewhere.

```

<Processes: component instance: TBP>≡

```

Compute the momenta in the hard interactions, one for each term that constitutes this process component. In simple cases this amounts to just copying momenta. In more advanced cases, we may generate distinct sets of momenta from the seed kinematics.

The interactions in the term instances are accessed individually. We may choose to calculate all terms at once together with the seed kinematics, use `component%tmp` for storage, and just fill the interactions here.

```

(Processes: component instance: TBP)+≡
  procedure :: compute_hard_kinematics => &
    component_instance_compute_hard_kinematics

(Processes: procedures)+≡
  subroutine component_instance_compute_hard_kinematics &
    (component, term, skip_term)

  end subroutine component_instance_compute_hard_kinematics

```

```

        end associate
    end associate
end subroutine component_instance_compute_hard_kinematics

```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

```

<Processes: component instance: TBP>+≡
    procedure :: recover_seed_kinematics => &
        component_instance_recover_seed_kinematics

<Processes: procedures>+≡
    subroutine component_instance_recover_seed_kinematics (component, term)

    end associate
    component%sqme_known = .true.
  end subroutine component_instance_evaluate_sqme

```

Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The `k_term` object is the instance of the kinematics setup (structure-function chain, phase space, etc.) that applies specifically to this term. In ordinary cases, it consists of straight pointers to the seed kinematics.

The `amp` array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The `int_hard` interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The `isolated` object holds the effective parton state for the elementary interaction. The amplitude entries are computed from `int_hard`.

The `connected` evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The `checked` flag is set once we have applied cuts on this term. The result of this is stored in the `passed` flag. Once the term has passed cuts, we calculate the various scale and weight expressions.

```

```

For initialization, we make use of defined assignment for the `interaction_t` type. This creates a deep copy.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (`rearrange`) as effective structure-function chain and interaction, respectively.

Finally, we set up the `subevt` component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

    call term%connected%reset_expressions ()
    term%active = .false.
  end subroutine term_instance_reset

```

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain.

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

```

(Processes: term instance: TBP)+≡
  procedure :: compute_eff_kinematics => &
    term_instance_compute_eff_kinematics

(Processes: procedures)+≡
  subroutine term_instance_compute_eff_kinematics (term, component)

```

Check the term whether it passes cuts and, if successful, evaluate scales and weights. The factorization scale is also given to the term kinematics, enabling structure-function evaluation.

```

<Processes: term instance: TBP>+≡
  procedure :: evaluate_expressions => &
    term_instance_evaluate_expressions

<Processes: procedures>+≡
  subroutine term_instance_evaluate_expressions (term)
    class(term_instance_t), intent(inout) :: term
    call term%connected%evaluate_expressions (term%passed, &
      term%scale, term%fac_scale, term%ren_scale, term%weight)
    term%checked = .true.
  end subroutine term_instance_evaluate_expressions

```

Evaluate the trace: first evaluate the hard interaction, then the trace evaluator. We use the `evaluate_interaction` method of the process component which generated this term. The `subevt` and `cut` expressions are not yet filled.

The `component` argument is `intent(inout)` because the `compute_amplitude` method may modify the `tmp` workspace object.

```

<Processes: term instance: TBP>+≡
  procedure :: evaluate_interaction => term_instance_evaluate_interaction

<Processes: procedures>+≡
  subroutine term_instance_evaluate_interaction (term, component)
    class(term_instance_t), intent(inout) :: term
    type(component_instance_t), dimension(:), intent(inout) :: component
    integer :: i_component, i_term, i
    i_component = term%config%i_component
    i_term = term%config%i_term
    associate (core => component(i_component)%config%core)
      do i = 1, term%config%n_allowed
        term%amp(i) = core%compute_amplitude (i_term, &
          interaction_get_momenta (term%int_hard), &
          term%config%flv(i), term%config%hel(i), term%config%col(i), &
          term%fac_scale, term%ren_scale, &
          component(i_component)%tmp)
      end do
      call interaction_set_matrix_element (term%int_hard, term%amp)
    end associate
  end subroutine term_instance_evaluate_interaction

```

Evaluate the trace. First evaluate the structure-function chain (i.e., the density matrix of the incoming partons). Do this twice, in case the `sf-chain` instances

within `k_term` and `isolated` differ. Next, evaluate the hard interaction, then compute the convolution with the initial state.

```

(Processes: term instance: TBP)+≡
  procedure :: evaluate_trace => term_instance_evaluate_trace

(Processes: procedures)+≡
  subroutine term_instance_evaluate_trace (term)
    class(term_instance_t), intent(inout) :: term
    call term%k_term%evaluate_sf_chain (term%fac_scale)
    call term%isolated%evaluate_sf_chain (term%fac_scale)
    call term%isolated%evaluate_trace ()
    call term%connected%evaluate_trace ()
  end subroutine term_instance_evaluate_trace

```

Evaluate the extra data that we need for processing the object as a physical event.

```

(Processes: term instance: TBP)+≡
  procedure :: evaluate_event_data => term_instance_evaluate_event_data

(Processes: procedures)+≡
  subroutine term_instance_evaluate_event_data (term)
    class(term_instance_t), intent(inout) :: term
    call term%isolated%evaluate_event_data ()
    call term%connected%evaluate_event_data ()
  end subroutine term_instance_evaluate_event_data

```

Return data that might be useful for external processing. The factorization scale:

```

(Processes: term instance: TBP)+≡
  procedure :: get_fac_scale => term_instance_get_fac_scale

(Processes: procedures)+≡
  function term_instance_get_fac_scale (term) result (fac_scale)
    class(term_instance_t), intent(in) :: term
    real(default) :: fac_scale
    fac_scale = term%fac_scale
  end function term_instance_get_fac_scale

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

(Processes: term instance: TBP)+≡
  procedure :: get_alpha_s => term_instance_get_alpha_s

(Processes: procedures)+≡
  function term_instance_get_alpha_s (term, component) result (alpha_s)
    class(term_instance_t), intent(in) :: term
    type(component_instance_t), dimension(:), intent(in) :: component
    real(default) :: alpha_s
    integer :: i_component
    i_component = term%config%i_component

```

```

    associate (core => component(i_component)%config%core)
        alpha_s = core%get_alpha_s (component(i_component)%tmp)
    end associate
    if (alpha_s < 0) alpha_s = term%config%alpha_s
end function term_instance_get_alpha_s

```

MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

```

<Processes: types>+≡
    type :: mci_work_t
        type(process_mci_entry_t), pointer :: config => null ()
        real(default), dimension(:), allocatable :: x
        class(mci_instance_t), pointer :: mci => null ()
    contains
        <Processes: mci work: TBP>
    end type mci_work_t

```

First write configuration data, then the current values.

```

<Processes: mci work: TBP>≡
    procedure :: write => mci_work_write

<Processes: procedures>+≡
    subroutine mci_work_write (mci_work, unit)
        class(mci_work_t), intent(in) :: mci_work
        integer, intent(in), optional :: unit
        integer :: u, i
        u = output_unit (unit)
        write (u, "(1x,A,I0,A)") "Active MCI instance #", &
            mci_work%config%i_mci, " ="
        write (u, "(2x)", advance="no")
        do i = 1, mci_work%config%n_par
            write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
            if (i == mci_work%config%n_par_sf) &
                write (u, "(1x,'|')", advance="no")
        end do
        write (u, *)
        if (associated (mci_work%mci)) then
            call mci_work%mci%write (u)
        end if
    end subroutine mci_work_write

```

The `mci` component may require finalization.

```

<Processes: mci work: TBP>+≡
    procedure :: final => mci_work_final

<Processes: procedures>+≡
    subroutine mci_work_final (mci_work)
        class(mci_work_t), intent(inout) :: mci_work

```

```

        if (associated (mci_work%mci)) then
            call mci_work%mci%final ()
            deallocate (mci_work%mci)
        end if
    end subroutine mci_work_final

```

Initialize with the maximum length that we will need. Contents are not initialized.

The integrator inside the `mci_entry` object is responsible for allocating and initializing its own instance, which is referred to by a pointer in the `mci_work` object.

```

<Processes: mci work: TBP>+≡
    procedure :: init => mci_work_init

<Processes: procedures>+≡
    subroutine mci_work_init (mci_work, mci_entry)
        class(mci_work_t), intent(out) :: mci_work
        type(process_mci_entry_t), intent(in), target :: mci_entry
        mci_work%config => mci_entry
        allocate (mci_work%x (mci_entry%n_par))
        if (allocated (mci_entry%mci)) then
            call mci_entry%mci%allocate_instance (mci_work%mci)
            call mci_work%mci%init (mci_entry%mci)
        end if
    end subroutine mci_work_init

```

Set parameters explicitly, either all at once, or separately for the structure-function and process parts.

```

<Processes: mci work: TBP>+≡
    procedure :: set => mci_work_set
    procedure :: set_x_strfun => mci_work_set_x_strfun
    procedure :: set_x_process => mci_work_set_x_process

<Processes: procedures>+≡
    subroutine mci_work_set (mci_work, x)

        call mci_work%mci%final_simulation ()
    end subroutine mci_work_final_simulation

```

The process instance

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary

(parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `sqme` value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The `weight` value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the `sqme` value times Jacobian weights from the integration, or unity, respectively.

The `i_mci` index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The `sf_chain` subobject is a realization of the beam and structure-function configuration in the `process` object. It is not used for calculation directly but serves as the template for the sf-chain instances that are contained in the `component` objects.

The `component` subobjects determine the state of each component.

The `term` subobjects are workspace for evaluating kinematics, matrix elements, cuts etc.

The `mci_work` subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the `mci_work` array is selected by the `i_mci` index above.

```

<Processes: public>+≡
    public :: process_instance_t

<Processes: types>+≡
    type, extends (mci_sampler_t) :: process_instance_t
        type(process_t), pointer :: process => null ()
        integer :: evaluation_status = STAT_UNDEFINED
        real(default) :: sqme = 0
        real(default) :: weight = 0
        real(default) :: excess = 0
        integer :: i_mci = 0
        integer :: selected_channel = 0
        type(sf_chain_t) :: sf_chain
        type(component_instance_t), dimension(:), allocatable :: component

```

Initialization connects the instance with a process. All initial information is transferred from the process object. The process object contains templates for the interaction subobjects (beam and term), but no evaluators. The initialization routine creates evaluators for the matrix element trace, other evaluators are left untouched.

The **instance** object must have the **target** attribute (also in any caller) since the initialization routine assigns various pointers to subobject of **instance**.

```

(Processes: process instance: TBP)+≡
  procedure :: init => process_instance_init

(Processes: procedures)+≡
  subroutine process_instance_init (instance, process)
    class(process_instance_t), intent(out), target :: instance
    type(process_t), intent(in), target :: process
    integer :: i, i_component
    instance%process => process
    call instance%setup_sf_chain (process%beam_config)
    allocate (instance%mci_work (process%config%n_mci))
    do i = 1, size (instance%mci_work)
      call instance%mci_work(i)%init (process%mci_entry(i))
    end do
    allocate (instance%component (process%config%n_components))

            component%k_seed, &
            process%beam_config, &
            process%component(i_component)%core, &
            process%meta%var_list)
          call term%setup_expressions (process%meta, process%config)
        end associate
      end associate
    end do
    instance%evaluation_status = STAT_INITIAL
  end subroutine process_instance_init

```

Subroutine of the initialization above: initialize the beam and structure-function chain template. We establish pointers to the configuration data, so **beam_config** must have a **target** attribute.

The resulting chain is not used directly for calculation. It will acquire instances which are stored in the process-component instance objects.

```

(Processes: process instance: TBP)+≡
  procedure :: setup_sf_chain => process_instance_setup_sf_chain

(Processes: procedures)+≡
  subroutine process_instance_setup_sf_chain (instance, config)
    class(process_instance_t), intent(inout) :: instance
    type(process_beam_config_t), intent(in), target :: config
    integer :: n_strfun

```

```

n_strfun = config%n_strfun
if (n_strfun /= 0) then
  call instance%sf_chain%init (config%data, config%sf)
else
  call instance%sf_chain%init (config%data)
end if
end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

<Processes: process instance: TBP>+≡
  procedure :: setup_event_data => process_instance_setup_event_data

<Processes: procedures>+≡
  subroutine process_instance_setup_event_data (instance, model)
    class(process_instance_t), intent(inout), target :: instance
    type(model_t), intent(in), optional, target :: model
    type(model_t), pointer :: current_model
    integer :: i, i_component
    if (present (model)) then
      current_model => model
    else
      current_model => instance%process%config%model
    end if
    do i = 1, size (instance%term)
      associate (term => instance%term(i))
        i_component = term%config%i_component
        associate (component => instance%process%component(i_component))
          call term%setup_event_data (component%core, current_model)
        end associate
      end associate
    end do
  end subroutine process_instance_setup_event_data

```

Choose a MC parameter set and the corresponding integrator.

The choice persists beyond calls of the `reset` method above. This method is automatically called here.

```

<Processes: process instance: TBP>+≡
  procedure :: choose_mci => process_instance_choose_mci

<Processes: procedures>+≡
  subroutine process_instance_choose_mci (instance, i_mci)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    integer :: i, j
    instance%i_mci = i_mci
    call instance%reset ()

```

```
end subroutine process_instance_choose_mci
```

Explicitly set a MC parameter set. Works only if we are in initial state. We assume that the length of the parameter set is correct.

After setting the parameters, activate the components and terms that correspond to the chosen MC parameter set.

```
<Processes: process instance: TBP>+=
  procedure :: set_mcpar => process_instance_set_mcpar

<Processes: procedures>+=
  subroutine process_instance_set_mcpar (instance, x)
    class(process_instance_t), intent(inout) :: instance
    real(default), dimension(:), intent(in) :: x
    integer :: i, j
    if (instance%evaluation_status == STAT_INITIAL) then
      associate (mci_work => instance%mci_work(instance%i_mci))
        call mci_work%set (x)
      end associate
      call instance%activate ()
    else
      ! error?
    end if
  end subroutine process_instance_set_mcpar
```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The sf-chain instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```
<Processes: process instance: TBP>+=
  procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

<Processes: procedures>+=
  subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%receive_beam_momenta ()
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_receive_beam_momenta
```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```
<Processes: process instance: TBP>+=
  procedure :: set_beam_momenta => process_instance_set_beam_momenta

<Processes: procedures>+=
  subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
```

```

type(vector4_t), dimension(:), intent(in) :: p
integer :: i
if (instance%evaluation_status >= STAT_INITIAL) then
    call instance%sf_chain%set_beam_momenta (p)
    instance%evaluation_status = STAT_BEAM_MOMENTA
end if
end subroutine process_instance_set_beam_momenta

```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```

<Processes: process instance: TBP>+≡
    procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

<Processes: procedures>+≡
    subroutine process_instance_recover_beam_momenta (instance, i_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_term
        integer :: i
        if (.not. instance%process%beam_config%lab_is_cm_frame) then
            if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
                i = instance%term(i_term)%config%i_component
                call instance%component(i)%return_beam_momenta ()
            end if
        end if
    end subroutine process_instance_recover_beam_momenta

```

Explicitly choose MC integration channel. We assume here that the channel count is identical for all active components.

```

<Processes: process instance: TBP>+≡
    procedure :: select_channel => process_instance_select_channel

<Processes: procedures>+≡
    subroutine process_instance_select_channel (instance, channel)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
        instance%selected_channel = channel
    end subroutine process_instance_select_channel

```

First step of process evaluation: set up seed kinematics. That is, for each active process component, compute a momentum array from the MC input parameters.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Processes: process instance: TBP>+≡
    procedure :: compute_seed_kinematics => &
        process_instance_compute_seed_kinematics

<Processes: procedures>+≡
    subroutine process_instance_compute_seed_kinematics (instance, skip_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in), optional :: skip_term

```

```

integer :: channel, skip_component, i
logical :: success
channel = instance%selected_channel
if (channel == 0) then
    call msg_bug ("Compute seed kinematics: undefined integration channel")
end if
if (present (skip_term)) then
    skip_component = instance%term(skip_term)%config%i_component
else
    skip_component = 0
end if
if (instance%evaluation_status >= STAT_ACTIVATED) then
    success = .true.
    do i = 1, size (instance%component)
        if (i == skip_component) cycle
        if (instance%component(i)%active) then
            call instance%component(i)%compute_seed_kinematics &
                (instance%mc_work(instance%i_mci), channel, success)
            if (.not. success) exit
        end if
    end do
    if (success) then
        instance%evaluation_status = STAT_SEED_KINEMATICS
    else
        instance%evaluation_status = STAT_FAILED_KINEMATICS
    end if
else
    ! error?
end if
end subroutine process_instance_compute_seed_kinematics

```

Inverse: recover missing parts of the kinematics from the momentum configuration, which we know for a single term and component. Given a channel, reconstruct the MC parameter set.

(Processes: process instance: TBP)+≡

```

procedure :: recover_mcpair => process_instance_recover_mcpair

```

(Processes: procedures)+≡

```

subroutine process_instance_recover_mcpair (instance, i_term)
class(process_instance_t), intent(inout) :: instance
integer, intent(in) :: i_term
integer :: channel
integer :: i
if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
    channel = instance%selected_channel
    if (channel == 0) then
        call msg_bug ("Recover MC parameters: undefined integration channel")
    end if
    i = instance%term(i_term)%config%i_component
    call instance%component(i)%recover_mcpair &
        (instance%mc_work(instance%i_mci), channel)
else
    ! error?
end if

```

```
end subroutine process_instance_recover_mcpair
```

Second step of process evaluation: compute all momenta, for all active components, from the seed kinematics.

```
<Processes: process instance: TBP>+=
  procedure :: compute_hard_kinematics => &
    process_instance_compute_hard_kinematics

<Processes: procedures>+=
  subroutine process_instance_compute_hard_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: i
    if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
      do i = 1, size (instance%component)
        if (instance%component(i)%active) then
          call instance%component(i)% &
            compute_hard_kinematics (instance%term, skip_term)
        end if
      end do
      instance%evaluation_status = STAT_HARD_KINEMATICS
    else
      ! failed kinematics
    end if
  end subroutine process_instance_compute_hard_kinematics
```

Inverse: recover seed kinematics. We know the beam momentum configuration and the outgoing momenta of the effective interaction, for one specific term.

```
<Processes: process instance: TBP>+=
  procedure :: recover_seed_kinematics => &
    process_instance_recover_seed_kinematics

<Processes: procedures>+=
  subroutine process_instance_recover_seed_kinematics (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
      associate (i_component => instance%term(i_term)%config%i_component)
        call instance%component(i_component)% &
          recover_seed_kinematics (instance%term(i_term))
      end associate
    else
      ! error?
    end if
  end subroutine process_instance_recover_seed_kinematics
```

Third step of process evaluation: compute the effective momentum configurations, for all active terms, from the hard kinematics.

```
<Processes: process instance: TBP>+=
  procedure :: compute_eff_kinematics => &
    process_instance_compute_eff_kinematics
```

```

<Processes: procedures>+≡
subroutine process_instance_compute_eff_kinematics (instance, skip_term)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in), optional :: skip_term
  integer :: i
  if (instance%evaluation_status >= STAT_HARD_KINEMATICS) then
    do i = 1, size (instance%term)
      if (present (skip_term)) then
        if (i == skip_term) cycle
      end if
      if (instance%term(i)%active) then
        call instance%term(i)% &
          compute_eff_kinematics (instance%component)
      end if
    end do
    instance%evaluation_status = STAT_EFF_KINEMATICS
  else
    ! failed kinematics
  end if
end subroutine process_instance_compute_eff_kinematics

```

Inverse: recover the hard kinematics from effective kinematics for one term, then compute effective kinematics for the other terms.

```

<Processes: process instance: TBP>+≡
  procedure :: recover_hard_kinematics => &
    process_instance_recover_hard_kinematics

<Processes: procedures>+≡
subroutine process_instance_recover_hard_kinematics (instance, i_term)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_term
  integer :: i
  if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
    call instance%term(i_term)%recover_hard_kinematics (instance%component)
    do i = 1, size (instance%term)
      if (i /= i_term) then
        if (instance%term(i)%active) then
          call instance%term(i)% &
            compute_eff_kinematics (instance%component)
        end if
      end if
    end do
    instance%evaluation_status = STAT_EFF_KINEMATICS
  else
    ! error?
  end if
end subroutine process_instance_recover_hard_kinematics

```

Fourth step of process evaluation: check cuts for all terms. Where successful, compute any scales and weights. Otherwise, deactivate the term. If any of the terms has passed, set the state to STAT_PASSED_CUTS.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate_expressions => &

```

```

        process_instance_evaluate_expressions
    (Processes: procedures)+≡
    subroutine process_instance_evaluate_expressions (instance)
    class(process_instance_t), intent(inout) :: instance
    integer :: i
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
    do i = 1, size (instance%term)
    if (instance%term(i)%active) then
    call instance%term(i)%evaluate_expressions ()
    end if
    end do
    if (any (instance%term%passed)) then
    instance%evaluation_status = STAT_PASSED_CUTS
    else
    instance%evaluation_status = STAT_FAILED_CUTS
    end if
    else
    ! failed kinematics
    end if
    end subroutine process_instance_evaluate_expressions

```

Fifth step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

```

    (Processes: process instance: TBP)+≡
    procedure :: evaluate_trace => process_instance_evaluate_trace
    (Processes: procedures)+≡
    subroutine process_instance_evaluate_trace (instance)
    class(process_instance_t), intent(inout) :: instance
    integer :: i
    if (instance%evaluation_status >= STAT_PASSED_CUTS) then
    do i = 1, size (instance%term)
    if (instance%term(i)%passed) then
    call instance%term(i)%evaluate_interaction (instance%component)
    call instance%term(i)%evaluate_trace ()
    end if
    end do
    instance%sqme = 0
    do i = 1, size (instance%component)
    if (instance%component(i)%active) then
    call instance%component(i)%evaluate_sqme (instance%term)
    instance%sqme = instance%sqme + instance%component(i)%sqme
    end if
    end do
    instance%evaluation_status = STAT_EVALUATED_TRACE
    else
    ! failed kinematics, failed cuts
    instance%sqme = 0
    end if
    end subroutine process_instance_evaluate_trace

```

Final step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

If `weight` is provided, we already know the kinematical event weight (the MCI weight which depends on the kinematics sampling algorithm, but not on the matrix element), so we do not need to take it from the MCI record.

```

(Processes: process instance: TBP)+≡
  procedure :: evaluate_event_data => process_instance_evaluate_event_data

(Processes: procedures)+≡
  subroutine process_instance_evaluate_event_data (instance, weight)
    class(process_instance_t), intent(inout) :: instance
    real(default), intent(in), optional :: weight
    integer :: i
    if (instance%evaluation_status >= STAT_EVALUATED_TRACE) then
      do i = 1, size(instance%term)
        if (instance%term(i)%passed) then
          call instance%term(i)%evaluate_event_data ()
        end if
      end do
      if (present (weight)) then
        instance%weight = weight
      else
        instance%weight = &
          instance%mci_work(instance%i_mci)%mci%get_event_weight ()
        instance%excess = &
          instance%mci_work(instance%i_mci)%mci%get_event_excess ()
      end if
      instance%evaluation_status = STAT_EVENT_COMPLETE
    else
      ! failed kinematics etc.
      instance%weight = 0
    end if
  end subroutine process_instance_evaluate_event_data

```

For unweighted event generation, we should reset the reported event weight to unity (signed) or zero. The latter case is appropriate for an event which failed for whatever reason.

```

(Processes: process instance: TBP)+≡
  procedure :: normalize_weight => process_instance_normalize_weight

(Processes: procedures)+≡
  subroutine process_instance_normalize_weight (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%weight /= 0) then
      instance%weight = sign (1._default, instance%weight)
    end if
  end subroutine process_instance_normalize_weight

```

This is a convenience routine that performs the computations of the steps 1 to 5 in a single step. The arguments are the input for `set_mcpair`. After this, the evaluation status should be either `STAT_FAILED_KINEMATICS`, `STAT_FAILED_CUTS` or `STAT_EVALUATED_TRACE`.

Before calling this, we should call `choose_mci`.

```

(Processes: process instance: TBP)+≡
  procedure :: evaluate_sqme => process_instance_evaluate_sqme

(Processes: procedures)+≡
  subroutine process_instance_evaluate_sqme (instance, channel, x)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    real(default), dimension(:), intent(in) :: x
    call instance%reset ()
    call instance%set_mcpair (x)
    call instance%select_channel (channel)
    call instance%compute_seed_kinematics ()
    call instance%compute_hard_kinematics ()
    call instance%compute_eff_kinematics ()
    call instance%evaluate_expressions ()
    call instance%evaluate_trace ()
  end subroutine process_instance_evaluate_sqme

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

```

(Processes: process instance: TBP)+≡
  procedure :: recover => process_instance_recover

(Processes: procedures)+≡
  subroutine process_instance_recover (instance, channel, i_term, update_sqme)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    integer, intent(in) :: i_term
    logical, intent(in) :: update_sqme
    call instance%activate ()
    instance%evaluation_status = STAT_EFF_KINEMATICS
    call instance%recover_hard_kinematics (i_term)
    call instance%recover_seed_kinematics (i_term)
    call instance%select_channel (channel)
    call instance%recover_mcpair (i_term)
    call instance%recover_beam_momenta (i_term)
    call instance%compute_seed_kinematics (i_term)
    call instance%compute_hard_kinematics (i_term)
    call instance%compute_eff_kinematics (i_term)
    call instance%evaluate_expressions ()
    if (update_sqme) call instance%evaluate_trace ()
  end subroutine process_instance_recover

```

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the x array, and the f Jacobian array are exposed by the `sampler_t` object.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate => process_instance_evaluate

<Processes: procedures>+≡
  subroutine process_instance_evaluate (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call sampler%evaluate_sqme (c, x_in)
    call sampler%fetch (val, x, f)
  end subroutine process_instance_evaluate

```

The `rebuild` method should rebuild the kinematics section out of the `x_in` parameter set. The integrand value `val` should not be computed, but is provided as input.

```

<Processes: process instance: TBP>+≡
  procedure :: rebuild => process_instance_rebuild

<Processes: procedures>+≡
  subroutine process_instance_rebuild (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(in) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call msg_bug ("process_instance_rebuild not implemented yet")
  end subroutine process_instance_rebuild

```

This is another method required by the `sampler_t` base type: fetch the data that are relevant for the MCI record.

```

<Processes: process instance: TBP>+≡
  procedure :: fetch => process_instance_fetch

<Processes: procedures>+≡
  subroutine process_instance_fetch (sampler, val, x, f)
    class(process_instance_t), intent(in) :: sampler
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    integer :: i, cc
    integer :: n_channel
    val = 0
    FIND_COMPONENT: do i = 1, size (sampler%component)
      associate (component => sampler%component(i))
        if (component%active) then
          associate (k => component%k_seed)
            n_channel = k%n_channel
          end associate
        end if
      end associate
    end do
  end subroutine process_instance_fetch

```

```

        do cc = 1, n_channel
            call k%get_mcpair (cc, x(:,cc))
        end do
        f = k%f
        val = sampler%sqme * k%phs_factor
    end associate
    exit FIND_COMPONENT
end if
end associate
end do FIND_COMPONENT
end subroutine process_instance_fetch

```

Initialize and finalize event generation for the specified MCI entry.

```

<Processes: process instance: TBP>+≡
    procedure :: init_simulation => process_instance_init_simulation
    procedure :: final_simulation => process_instance_final_simulation

    end subroutine process_instance_final_simulation

```

15.5.12 Accessing the process instance

Once the seed kinematics is complete, we can retrieve the MC input parameters for all channels, not just the seed channel.

Note: We choose the first active component. This makes sense only if the seed kinematics is identical for all active components.

```

<Processes: process instance: TBP>+≡
    procedure :: get_mcpair => process_instance_get_mcpair

<Processes: procedures>+≡
    subroutine process_instance_get_mcpair (instance, channel, x)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
        real(default), dimension(:), intent(out) :: x
        integer :: i
        if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
            do i = 1, size (instance%component)
                if (instance%component(i)%active) then
                    call instance%component(i)%k_seed%get_mcpair (channel, x)
                    return
                end if
            end do
        end if
    end subroutine process_instance_get_mcpair

```

```

        end do
        x = 0
        ! error?
    else
        x = 0
        ! error?
    end if
end subroutine process_instance_get_mcpair

```

Return true if the `sqme` value is known. This also implies that the event is kinematically valid and has passed all cuts.

```

<Processes: process instance: TBP>+≡
    procedure :: has_evaluated_trace => process_instance_has_evaluated_trace

<Processes: procedures>+≡
    function process_instance_has_evaluated_trace (instance) result (flag)
        class(process_instance_t), intent(in) :: instance
        logical :: flag
        flag = instance%evaluation_status >= STAT_EVALUATED_TRACE
    end function process_instance_has_evaluated_trace

```

Return true if the event is complete. In particular, the event must be kinematically valid, passed all cuts, and the event data have been computed.

```

<Processes: process instance: TBP>+≡
    procedure :: is_complete_event => process_instance_is_complete_event

<Processes: procedures>+≡
    function process_instance_is_complete_event (instance) result (flag)
        class(process_instance_t), intent(in) :: instance
        logical :: flag

    alpha_s = instance%term(i_term)%get_alpha_s (instance%component)
  end function process_instance_get_alpha_s

```

15.5.13 Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

```

<Processes: process instance: TBP>+=
  procedure :: get_trace => process_instance_get_trace
  procedure :: set_trace => process_instance_set_trace

<Processes: procedures>+=
  subroutine process_instance_get_trace (instance, pset, i_term)
    class(process_instance_t), intent(in), target :: instance
    type(particle_set_t), intent(out) :: pset
    integer, intent(in) :: i_term
    type(interaction_t), pointer :: int
    logical :: ok
    int => instance%get_trace_int_ptr (i_term)
    call particle_set_init (pset, ok, int, int, FM_IGNORE_HELICITY, &
      [0._default, 0._default], .false., .true.)
  end subroutine process_instance_get_trace

  subroutine process_instance_set_trace (instance, pset, i_term, recover_beams)
    class(process_instance_t), intent(inout), target :: instance
    type(particle_set_t), intent(in) :: pset
    integer, intent(in) :: i_term
    logical, intent(in), optional :: recover_beams
    type(interaction_t), pointer :: int
    integer :: n_in
    int => instance%get_trace_int_ptr (i_term)
    n_in = instance%process%get_n_in ()
    call particle_set_fill_interaction (pset, int, n_in, recover_beams)
  end subroutine process_instance_set_trace

```

15.5.14 Auxiliary stuff

Write a separator line.

```

<Processes: procedures>+=
  subroutine write_separator (u)
    integer, intent(in) :: u
    write (u, "(A)") repeat ("-", 72)
  end subroutine write_separator

  subroutine write_separator_double (u)
    integer, intent(in) :: u
    write (u, "(A)") repeat ("=", 72)
  end subroutine write_separator_double

```

The `pacify` subroutine has the purpose of setting numbers to zero which are (by comparing with a `tolerance` parameter) considered equivalent with zero. We do this in some unit tests. Here, we apply this to the phase space subobject of the process instance.

```

<Processes: public>+=
  public :: pacify

```

```

<Processes: interfaces>+=
  interface pacify
    module procedure pacify_process_instance
  end interface pacify

<Processes: procedures>+=
  subroutine pacify_process_instance (instance)
    type(process_instance_t), intent(inout) :: instance
    integer :: i
    do i = 1, size (instance%component)
      call pacify (instance%component(i)%k_seed%phs)
    end do
  end subroutine pacify_process_instance

```

15.5.15 Unit tests

```

<Processes: public>+=
  public :: processes_test

<Processes: tests>+=
  subroutine processes_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Processes: execute tests>
  end subroutine processes_test

```

Test process type

For the following tests, we define a simple implementation of the abstract `prc_core_t`, designed such as to complement the `prc_test_t` process definition type.

Note that it is not given that the actual process is defined as `prc_test_t` type. We enforce this by calling `prc_test_create_library`. The driver component in the process core will then become of type `prc_test_t`.

```

<Processes: public>+=
  public :: test_t

<Processes: test types>+=
  type, extends (prc_core_t) :: test_t
  contains
    procedure :: write => test_write
    procedure :: needs_mcset => test_needs_mcset
    procedure :: get_n_terms => test_get_n_terms
    procedure :: is_allowed => test_is_allowed
    procedure :: compute_hard_kinematics => test_compute_hard_kinematics
    procedure :: compute_eff_kinematics => test_compute_eff_kinematics
    procedure :: recover_kinematics => test_recover_kinematics
    procedure :: compute_amplitude => test_compute_amplitude
  end type test_t

```

```

<Processes: tests>+≡
  subroutine test_write (object, unit)
    class(test_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(3x,A)") "test type implementing prc_test"
  end subroutine test_write

```

This process type always needs a MC parameter set and a single term. This only state is always allowed.

```

<Processes: tests>+≡
  function test_needs_mcset (object) result (flag)
    class(test_t), intent(in) :: object
    logical :: flag
    flag = .true.
  end function test_needs_mcset

  function test_get_n_terms (object) result (n)
    class(test_t), intent(in) :: object
    integer :: n
    n = 1
  end function test_get_n_terms

  function test_is_allowed (object, i_term, f, h, c) result (flag)
    class(test_t), intent(in) :: object
    integer, intent(in) :: i_term, f, h, c
    logical :: flag
    flag = .true.
  end function test_is_allowed

```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

```

<Processes: tests>+≡
  subroutine test_compute_hard_kinematics &
    (object, p_seed, i_term, int_hard, tmp)
    class(test_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(in) :: p_seed
    integer, intent(in) :: i_term
    type(interaction_t), intent(inout) :: int_hard
    class(workspace_t), intent(inout), allocatable :: tmp
    call interaction_set_momenta (int_hard, p_seed)
  end subroutine test_compute_hard_kinematics

```

This procedure is not called for `test_t`, just a placeholder.

```

<Processes: tests>+≡
  subroutine test_compute_eff_kinematics &
    (object, i_term, int_hard, int_eff, tmp)
    class(test_t), intent(in) :: object
    integer, intent(in) :: i_term
    type(interaction_t), intent(in) :: int_hard
    type(interaction_t), intent(inout) :: int_eff

```

```

class(workspace_t), intent(inout), allocatable :: tmp
end subroutine test_compute_eff_kinematics

```

Transfer the incoming momenta of `p_seed` directly to the effective interaction, and vice versa for the outgoing momenta.

`int_hard` is left untouched since `int_eff` is an alias (via pointer) to it.

(Processes: tests)+≡

```

subroutine test_recover_kinematics &
  (object, p_seed, int_hard, int_eff, tmp)
  class(test_t), intent(in) :: object
  type(vector4_t), dimension(:), intent(inout) :: p_seed
  type(interaction_t), intent(inout) :: int_hard
  type(interaction_t), intent(inout) :: int_eff
  class(workspace_t), intent(inout), allocatable :: tmp
  integer :: n_in
  n_in = interaction_get_n_in (int_eff)
  call interaction_set_momenta (int_eff, p_seed(1:n_in), outgoing = .false.)
  p_seed(n_in+1:) = interaction_get_momenta (int_eff, outgoing = .true.)
end subroutine test_recover_kinematics

```

Compute the amplitude. The driver ignores all quantum numbers and, in fact, returns a constant. Nevertheless, we properly transfer the momentum vectors.

(Processes: tests)+≡

```

function test_compute_amplitude &
  (object, j, p, f, h, c, fac_scale, ren_scale, tmp) result (amp)
  class(test_t), intent(in) :: object
  integer, intent(in) :: j
  type(vector4_t), dimension(:), intent(in) :: p
  integer, intent(in) :: f, h, c
  real(default), intent(in) :: fac_scale, ren_scale
  class(workspace_t), intent(inout), allocatable, optional :: tmp
  complex(default) :: amp
  real(default), dimension(:,:), allocatable :: parray
  integer :: i, n_tot
  select type (driver => object%driver)
  type is (prc_test_t)
    if (driver%scattering) then
      n_tot = 4
    else
      n_tot = 3
    end if
    allocate (parray (0:3,n_tot))
    forall (i = 1:n_tot) parray(:,i) = vector4_get_components (p(i))
    amp = driver%get_amplitude (parray)
  end select
end function test_compute_amplitude

```

Write an empty process object

The most trivial test is to write an uninitialized process object.

(Processes: execute tests)≡

```

call test (processes_1, "processes_1", &
          "write an empty process object", &
          u, results)
<Processes: tests>+≡
subroutine processes_1 (u)
  integer, intent(in) :: u
  type(process_t) :: process

  write (u, "(A)")  "* Test output: processes_1"
  write (u, "(A)")  "* Purpose: display an empty process object"
  write (u, "(A)")

  call process%write (u)

  write (u, "(A)")
  write (u, "(A)")  "* Test output end: processes_1"

end subroutine processes_1

```

Initialize a process object

Initialize a process and display it.

```

<Processes: execute tests>+≡
call test (processes_2, "processes_2", &
          "initialize a simple process object", &
          u, results)
<Processes: tests>+≡
subroutine processes_2 (u)
  integer, intent(in) :: u

Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```

15.6 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack

terminology makes sense.

```

<process_stacks.f90>≡
  <File header>

  module process_stacks

    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use unit_tests
    use os_interface
    use sm_qcd
    use variables
    use models
    use rng_base

    use process_libraries
    use prc_test
    use processes

    <Standard module head>

    <Process stacks: public>

    <Process stacks: types>

    contains

    <Process stacks: procedures>

    <Process stacks: tests>

  end module process_stacks

```

15.6.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```

<Process stacks: public>≡
  public :: process_entry_t

<Process stacks: types>≡
  type, extends (process_t) :: process_entry_t
    type(process_entry_t), pointer :: next => null ()
  end type process_entry_t

```

15.6.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

```

(Process stacks: public)+≡
    public :: process_stack_t

(Process stacks: types)+≡
    type :: process_stack_t
        integer :: n = 0
        type(process_entry_t), pointer :: first => null ()
        type(var_list_t), pointer :: var_list => null ()
    contains
        (Process stacks: process stack: TBP)
    end type process_stack_t

```

Finalizer. Iteratively deallocate the stack entries. The resulting empty stack can be immediately recycled, if necessary.

```

(Process stacks: process stack: TBP)≡
    procedure :: final => process_stack_final

(Process stacks: procedures)≡
    subroutine process_stack_final (object)
        class(process_stack_t), intent(inout) :: object
        type(process_entry_t), pointer :: process
        if (associated (object%var_list)) then
            call var_list_final (object%var_list)
            deallocate (object%var_list)
        end if
        do while (associated (object%first))
            process => object%first
            object%first => process%next
            call process%final ()
            deallocate (process)
        end do
        object%n = 0
    end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

(Process stacks: process stack: TBP)+≡
    procedure :: write => process_stack_write

(Process stacks: procedures)+≡
    subroutine process_stack_write (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        type(process_entry_t), pointer :: process
        integer :: u
        u = output_unit (unit)
        call write_separator_double (u)
        select case (object%n)
        case (0)
            write (u, "(1x,A)") "Process stack: [empty]"
            call write_separator_double (u)
        case default
            write (u, "(1x,A)") "Process stack:"

```

```

        process => object%first
    do while (associated (process))
        call process%write (u)
        process => process%next
    end do
end select
end subroutine process_stack_write

```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write_var_list => process_stack_write_var_list

<Process stacks: procedures>+≡
    subroutine process_stack_write_var_list (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        if (associated (object%var_list)) then
            call var_list_write (object%var_list, unit)
        end if
    end subroutine process_stack_write_var_list

```

Short output.

```

<Process stacks: process stack: TBP>+≡
    procedure :: show => process_stack_show

<Process stacks: procedures>+≡
    subroutine process_stack_show (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        type(process_entry_t), pointer :: process
        integer :: u
        u = output_unit (unit)
        select case (object%n)
        case (0)
        case default
            process => object%first
            do while (associated (process))
                call process%show (u, verbose=.false.)
                process => process%next
            end do
        end select
    end subroutine process_stack_show

```

15.6.3 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

<Process stacks: process stack: TBP>+≡
    procedure :: push => process_stack_push

```

```

<Process stacks: procedures>+≡
  subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    process%next => stack%first
    stack%first => process
    process => null ()
    stack%n = stack%n + 1
  end subroutine process_stack_push

```

Initialize the process variable list and link it to a global variable list.

```

<Process stacks: process stack: TBP>+≡
  procedure :: init_var_list => process_stack_init_var_list

<Process stacks: procedures>+≡
  subroutine process_stack_init_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(inout), optional :: var_list
    allocate (stack%var_list)
    if (present (var_list)) call var_list_link (var_list, stack%var_list)
  end subroutine process_stack_init_var_list

```

Initialize process variables for a given process ID, without setting values.

```

<Process stacks: process stack: TBP>+≡
  procedure :: init_result_vars => process_stack_init_result_vars

<Process stacks: procedures>+≡
  subroutine process_stack_init_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    call var_list_init_num_id (stack%var_list, id)
    call var_list_init_process_results (stack%var_list, id)
  end subroutine process_stack_init_result_vars

```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```

<Process stacks: process stack: TBP>+≡
  procedure :: fill_result_vars => process_stack_fill_result_vars

<Process stacks: procedures>+≡
  subroutine process_stack_fill_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    type(process_t), pointer :: process
    process => stack%get_process_ptr (id)
    if (associated (process)) then
      call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
      if (process%has_integral ()) then

write (u, "(A)")  "* Test output end: process_stacks_3"

end subroutine process_stacks_3
```

Chapter 16

Events

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

event_transforms Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

decays Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

showers (not re-activated yet) Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

events Combine all pieces to generate full events.

16.1 Abstract Event Transforms

```
(event_transforms.f90)≡  
  <File header>  
  
  module event_transforms  
  
    <Use kinds>  
    <Use strings>  
    <Use file utils>  
    use diagnostics !NODEP!  
    use unit_tests  
    use os_interface
```

```

use sm_qcd
use models
use state_matrices
use interactions
use particles
use subevents
use process_libraries
use prc_core
use prc_test
use rng_base
use mci_base
use mci_midpoint
use phs_base
use phs_single
use processes
use process_stacks

⟨Standard module head⟩

⟨Event transforms: public⟩

⟨Event transforms: types⟩

⟨Event transforms: interfaces⟩

contains

⟨Event transforms: procedures⟩

⟨Event transforms: tests⟩

end module event_transforms

```

16.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified setting that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include a **previous** and **next** pointers.

```

⟨Event transforms: public⟩≡
  public :: evt_t

⟨Event transforms: types⟩≡
  type, abstract :: evt_t
    type(process_t), pointer :: process => null ()
    type(process_instance_t), pointer :: process_instance => null ()
    type(model_t), pointer :: model => null ()

```

```

class(rng_t), allocatable :: rng
integer :: rejection_count = 0
logical :: particle_set_exists = .false.
type(particle_set_t) :: particle_set
class(evt_t), pointer :: previous => null ()
class(evt_t), pointer :: next => null ()
contains
  <Event transforms: evt: TBP>
end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡
  procedure :: final => evt_final
  procedure :: base_final => evt_final

<Event transforms: procedures>≡
  subroutine evt_final (object)
    class(evt_t), intent(inout) :: object
    if (allocated (object%rng)) call object%rng%final ()
    if (object%particle_set_exists) &
      call particle_set_final (object%particle_set)
  end subroutine evt_final

```

Output. We can print r.n.g. info.

```

<Event transforms: evt: TBP>+≡
  procedure :: base_write => evt_write

<Event transforms: procedures>+≡
  subroutine evt_write (object, unit, verbose)
    class(evt_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose
    integer :: u
    u = output_unit (unit)
    if (associated (object%process)) then
      write (u, "(3x,A,A,A)") "Associated process: '", &
        char (object%process%get_id ()), "'"
    end if
    if (allocated (object%rng)) then
      call object%rng%write (u, 1)
      write (u, "(3x,A,I0)") "Number of tries = ", object%rejection_count
    end if
    if (object%particle_set_exists) then
      call write_separator (u)
      call particle_set_write (object%particle_set, u)
    end if
  end subroutine evt_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

```

(Event transforms: evt: TBP)+≡
  procedure :: connect => evt_connect
  procedure :: base_connect => evt_connect

(Event transforms: procedures)+≡
  subroutine evt_connect (evt, process_instance, model, process_stack)
    class(evt_t), intent(inout), target :: evt
    type(process_instance_t), intent(in), target :: process_instance
    type(model_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    evt%process => process_instance%process
    evt%process_instance => process_instance
    evt%model => model
    call evt%process%make_rng (evt%rng)
  end subroutine evt_connect

```

Reset internal state.

```

(Event transforms: evt: TBP)+≡
  procedure :: reset => evt_reset
  procedure :: base_reset => evt_reset

(Event transforms: procedures)+≡
  subroutine evt_reset (evt)
    class(evt_t), intent(inout) :: evt
    evt%rejection_count = 0
    evt%particle_set_exists = .false.
  end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_prepare_new_event), deferred :: prepare_new_event

(Event transforms: interfaces)≡
  interface
    subroutine evt_prepare_new_event (evt, i_mci, i_term)
      import
      class(evt_t), intent(inout) :: evt
      integer, intent(in) :: i_mci, i_term
    end subroutine evt_prepare_new_event
  end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)

```

```

import
class(evt_t), intent(inout) :: evt
real(default), intent(out) :: probability
end subroutine evt_generate_weighted
end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted
(Event transforms: procedures)+≡
  subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set
(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_make_particle_set
  end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

(Event transforms: evt: TBP)+≡
  procedure :: set_particle_set => evt_set_particle_set

```

```

(Event transforms: procedures)+≡
subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
  class(evt_t), intent(inout) :: evt
  type(particle_set_t), intent(in) :: particle_set
  integer, intent(in) :: i_term, i_mci
  call evt%prepare_new_event (i_mci, i_term)
  evt%particle_set = particle_set
  evt%particle_set_exists = .true.
end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. (We need two interactions, one with color summed over, and one with the probability distributed among flows.)

We use the two values from the random number generator for factorizing the state. For testing purposes, we can provide those numbers explicitly.

```

(Event transforms: evt: TBP)+≡
  procedure :: factorize_interactions => evt_factorize_interactions

(Event transforms: procedures)+≡
subroutine evt_factorize_interactions &
  (evt, int_matrix, int_flows, factorization_mode, keep_correlations, r)
  class(evt_t), intent(inout) :: evt
  type(interaction_t), intent(in), target :: int_matrix, int_flows
  integer, intent(in) :: factorization_mode
  logical, intent(in) :: keep_correlations
  real(default), dimension(:), intent(in), optional :: r
  real(default), dimension(2) :: x
  if (present (r)) then
    if (size (r) == 2) then
      x = r
    else
      call msg_bug ("event factorization: size of r array must be 2")
    end if
  else
    call evt%rng%generate (x)
  end if
  call particle_set_init (evt%particle_set, evt%particle_set_exists, &
    int_matrix, int_flows, factorization_mode, x, &
    keep_correlations, keep_virtual=.true.)
  evt%particle_set_exists = .true.
end subroutine evt_factorize_interactions

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

```

(Event transforms: evt: TBP)+≡
  procedure :: tag_incoming => evt_tag_incoming

```

```

<Event transforms: procedures>+≡
  subroutine evt_tag_incoming (evt)
    class(evt_t), intent(inout) :: evt
    integer :: i_term, n_in
    integer, dimension(:), allocatable :: beam_index, in_index
    n_in = evt%process%get_n_in ()
    i_term = 1
    allocate (beam_index (n_in))
    call evt%process_instance%get_beam_index (i_term, beam_index)
    call particle_set_reset_status (evt%particle_set, &
      beam_index, PRT_BEAM)
    allocate (in_index (n_in))
    call evt%process_instance%get_in_index (i_term, in_index)
    call particle_set_reset_status (evt%particle_set, &
      in_index, PRT_INCOMING)
  end subroutine evt_tag_incoming

```

16.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

<Event transforms: public>+≡
  public :: evt_trivial_t

<Event transforms: types>+≡
  type, extends (evt_t) :: evt_trivial_t
    contains
    <Event transforms: evt trivial: TBP>
  end type evt_trivial_t

```

The finalizer is trivial. Some output:

```

<Event transforms: evt trivial: TBP>≡
  procedure :: write => evt_trivial_write

<Event transforms: procedures>+≡
  subroutine evt_trivial_write (object, unit, verbose)
    class(evt_trivial_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose
    integer :: u
    u = output_unit (unit)
    call write_separator_double (u)
    write (u, "(1x,A)") "Event transform: trivial (hard process)"
    call write_separator (u)
    call object%base_write (u)
  end subroutine evt_trivial_write

```

Nothing to do here:

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: prepare_new_event => evt_trivial_prepare_new_event

```

```

(Event transforms: procedures)+≡
subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
  class(evt_trivial_t), intent(inout) :: evt
  integer, intent(in) :: i_mci, i_term
  call evt%reset ()
end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: generate_weighted => evt_trivial_generate_weighted

(Event transforms: procedures)+≡
subroutine evt_trivial_generate_weighted (evt, probability)
  class(evt_trivial_t), intent(inout) :: evt
  real(default), intent(out) :: probability
  probability = 1
end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is.

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: make_particle_set => evt_trivial_make_particle_set

(Event transforms: procedures)+≡
subroutine evt_trivial_make_particle_set &
  (evt, factorization_mode, keep_correlations, r)
  class(evt_trivial_t), intent(inout) :: evt
  integer, intent(in) :: factorization_mode
  logical, intent(in) :: keep_correlations
  real(default), dimension(:), intent(in), optional :: r
  integer :: i_term
  type(interaction_t), pointer :: int_matrix, int_flows
  if (evt%process_instance%is_complete_event ()) then
    call evt%process_instance%select_i_term (i_term)
    int_matrix => evt%process_instance%get_matrix_int_ptr (i_term)
    int_flows => evt%process_instance%get_flows_int_ptr (i_term)
    call evt%factorize_interactions (int_matrix, int_flows, &
      factorization_mode, keep_correlations, r)
    call evt%tag_incoming ()
  else
    call msg_bug ("Event factorization: event is incomplete")
  end if
end subroutine evt_trivial_make_particle_set

```

16.1.3 Auxiliary stuff

Write a separator line.

```

(Event transforms: procedures)+≡
subroutine write_separator (u)
  integer, intent(in) :: u
  write (u, "(A)") repeat ("-", 72)
end subroutine write_separator

```

```

subroutine write_separator_double (u)
  integer, intent(in) :: u
  write (u, "(A)") repeat ("=", 72)
end subroutine write_separator_double

```

16.1.4 Unit tests

```

<Event transforms: public>+≡
  public :: event_transforms_test

<Event transforms: tests>≡
  subroutine event_transforms_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Event transforms: execute tests>
  end subroutine event_transforms_test

```

Test trivial event transform

The trivial transform, as an instance of the abstract transform, does nothing but to trigger event generation for an elementary process.

```

<Event transforms: execute tests>≡
  call test (event_transforms_1, "event_transforms_1", &
    "trivial event transform", &
    u, results)

<Event transforms: tests>+≡
  subroutine event_transforms_1 (u)
    integer, intent(in) :: u
    type(os_data_t) :: os_data
    type(qcd_t) :: qcd
    class(rng_factory_t), allocatable :: rng_factory
    type(model_list_t) :: model_list
    type(model_t), pointer :: model
    type(process_library_t), target :: lib
    type(string_t) :: libname, procname1, run_id
    class(prc_core_t), allocatable :: core_template
    class(mci_t), allocatable :: mci_template
    class(phs_config_t), allocatable :: phs_config_template
    real(default) :: sqrts
    type(process_t), allocatable, target :: process
    type(process_instance_t), allocatable, target :: process_instance
    class(evt_t), allocatable :: evt
    integer :: factorization_mode
    logical :: keep_correlations

    write (u, "(A)")  "* Test output: event_transforms_1"
    write (u, "(A)")  "* Purpose: handle trivial transform"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize environment and parent process"
    write (u, "(A)")

```

```

call syntax_model_file_init ()

```

16.2.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

⟨Decays: types⟩≡
  type, abstract :: any_config_t
  contains
    ⟨Decays: any config: TBP⟩
  end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
  procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
  interface
    subroutine any_config_final (object)
      import
        class(any_config_t), intent(inout) :: object
    end subroutine any_config_final
  end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
  procedure (any_config_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_config_write (object, unit, indent, verbose)
      import
        class(any_config_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        logical, intent(in), optional :: verbose
    end subroutine any_config_write
  end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_config_t
    class(any_config_t), allocatable :: c
  end type particle_config_t

```

16.2.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above. This also works around a compiler bug in gfortran.

```

<Decays: types>+≡
  type, abstract :: any_t
    contains
      <Decays: any: TBP>
  end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final

```

```

<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
      class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
      import
      class(any_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
    end subroutine any_write
  end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_out_t
    class(any_t), allocatable :: c
  end type particle_out_t

```

16.2.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+≡
  type :: decay_term_config_t
    type(particle_config_t), dimension(:), allocatable :: prt
    contains
    <Decays: decay term config: TBP>
  end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>≡
  procedure :: final => decay_term_config_final

<Decays: procedures>≡
  recursive subroutine decay_term_config_final (object)
    class(decay_term_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%prt)) then
      do i = 1, size (object%prt)
        if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
      end do
    end if
  end subroutine decay_term_config_final

```

```

        end do
    end if
end subroutine decay_term_config_final

```

Output, with optional indentation

<Decays: decay term config: TBP>+≡

```

    procedure :: write => decay_term_config_write

```

<Decays: procedures>+≡

```

recursive subroutine decay_term_config_write (object, unit, indent, verbose)
    class(decay_term_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose

    end subroutine decay_term_generate
```

16.2.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```

<Decays: types>+≡
  type :: decay_root_config_t
    type(string_t) :: process_id
    type(process_t), pointer :: process => null ()
    type(model_t), pointer :: model => null ()
    type(decay_term_config_t), dimension(:), allocatable :: term_config
  contains
    <Decays: decay root config: TBP>
  end type decay_root_config_t

```

The finalizer is recursive since there may be cascade decays.

```

<Decays: decay root config: TBP>≡
  procedure :: final => decay_root_config_final

<Decays: procedures>+≡
  recursive subroutine decay_root_config_final (object)
    class(decay_root_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%term_config)) then
      do i = 1, size (object%term_config)
        call object%term_config(i)%final ()
      end do
    end if
  end subroutine decay_root_config_final

```

The output routine is also recursive, and it contains an adjustable indentation.

```

<Decays: decay root config: TBP>+≡
  procedure :: write => decay_root_config_write
  procedure :: write_header => decay_root_config_write_header
  procedure :: write_terms => decay_root_config_write_terms

        end if
    end subroutine decay_root_config_init

```

Declare a decay term, given an array of flavors.

```

<Decays: decay root config: TBP>+≡
    procedure :: init_term => decay_root_config_init_term

<Decays: procedures>+≡
    recursive subroutine decay_root_config_init_term &
        (decay, i, flv, stable, model, process_stack)
        class(decay_root_config_t), intent(inout) :: decay

```

```

integer, intent(in) :: i
type(flavor_t), dimension(:,:), intent(in) :: flv
logical, dimension(:), intent(in) :: stable
type(model_t), intent(in), target :: model
type(process_stack_t), intent(in), optional :: process_stack
call decay%term_config(i)%init (flv, stable, model, process_stack)
end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

```

<Decays: decay root config: TBP>+≡
  procedure :: connect => decay_root_config_connect

<Decays: procedures>+≡
  recursive subroutine decay_root_config_connect &
    (decay, process, model, process_stack)
    class(decay_root_config_t), intent(out) :: decay
    type(process_t), intent(in), target :: process
    type(model_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(flavor_t), dimension(:,:), allocatable :: flv
    logical, dimension(:), allocatable :: stable
    real(default), dimension(:), allocatable :: integral_mci
    integer :: i, j, n_mci
    call decay%init (model, process%get_id (), process%get_n_terms ())
    do i = 1, size (decay%term_config)
      call process%get_term_flv_out (i, flv)
      call flavor_set_model (flv, model)
      allocate (stable (size (flv, 1)))
      stable = flavor_is_stable (flv(:,1))
      call decay%init_term (i, flv, stable, model, process_stack)
      deallocate (flv)
    end do
    decay%process => process
  end subroutine decay_root_config_connect

```

Recursively compute widths, errors, and branching ratios.

```

<Decays: decay root config: TBP>+≡
  procedure :: compute => decay_root_config_compute

<Decays: procedures>+≡
  recursive subroutine decay_root_config_compute (decay)
    class(decay_root_config_t), intent(inout) :: decay
    integer :: i
    do i = 1, size (decay%term_config)
      call decay%term_config(i)%compute ()
    end do
  end subroutine decay_root_config_compute

```

```

    end do
end subroutine decay_root_config_compute

```

16.2.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```

⟨Decays: types⟩+≡
  type, abstract :: decay_gen_t
    type(decay_term_t), dimension(:), allocatable :: term
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
  contains
    ⟨Decays: decay_gen: TBP⟩
  end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

⟨Decays: types⟩+≡
  type, extends (decay_gen_t) :: decay_root_t
    type(decay_root_config_t), pointer :: config => null ()
  contains
    ⟨Decays: decay root: TBP⟩
  end type decay_root_t

```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```

⟨Decays: decay_gen: TBP⟩≡
  procedure :: base_final => decay_gen_final

⟨Decays: procedures⟩+≡
  recursive subroutine decay_gen_final (object)
    class(decay_gen_t), intent(inout) :: object
    integer :: i
    if (allocated (object%term)) then
      do i = 1, size (object%term)
        call object%term(i)%final ()
      end do
    end if
  end subroutine decay_gen_final

```

No extra finalization for the decay root.

```

⟨Decays: decay root: TBP⟩≡
  procedure :: final => decay_root_final

```

```

<Decays: procedures>+≡
  subroutine decay_root_final (object)
    class(decay_root_t), intent(inout) :: object
    call object%base_final ()
  end subroutine decay_root_final

```

Output.

```

<Decays: decay root: TBP>+≡
  procedure :: write => decay_root_write

<Decays: procedures>+≡

    end if
  end subroutine decay_gen_write_process_instances

```

```

        end if
    end subroutine decay_gen_write_process_instances

```

Generic initializer. All can be done recursively.

```

<Decays: decay gen: TBP>+≡
    procedure :: base_init => decay_gen_init

<Decays: procedures>+≡
    recursive subroutine decay_gen_init (decay, term_config)
        class(decay_gen_t), intent(out) :: decay
        type(decay_term_config_t), dimension(:), intent(in), target :: term_config
        integer :: i
        allocate (decay%term (size (term_config)))
        do i = 1, size (decay%term)
            call decay%term(i)%init (term_config(i))
        end do
    end subroutine decay_gen_init

```

Specific initializer. We assign the configuration object, which should correspond to a completely initialized decay configuration tree. We also connect to an existing process instance. Then, we recursively link the child interactions to the parent process.

```

<Decays: decay root: TBP>+≡
    procedure :: init => decay_root_init

<Decays: procedures>+≡
    subroutine decay_root_init (decay_root, config, process_instance)
        class(decay_root_t), intent(out) :: decay_root
        type(decay_root_config_t), intent(in), target :: config
        type(process_instance_t), intent(in), target :: process_instance
        integer :: i
        call decay_root%base_init (config%term_config)
        decay_root%config => config
        decay_root%process_instance => process_instance
        call decay_root%make_term_rng (config%process)
        call decay_root%link_term_interactions ()
    end subroutine decay_root_init

```

Implement random-number generators for unstable decay selection in all terms. This is not recursive.

We also make use of the fact that `process` is a pointer; the (state of the RNG factory inside the) target process will be modified by the rng-spawning method, but not the pointer.

```

<Decays: decay gen: TBP>+≡
    procedure :: make_term_rng => decay_gen_make_term_rng

<Decays: procedures>+≡
    subroutine decay_gen_make_term_rng (decay, process)
        class(decay_gen_t), intent(inout) :: decay
        type(process_t), intent(in), pointer :: process
        integer :: i
        do i = 1, size (decay%term)
            call decay%term(i)%make_rng (process)
        end do
    end subroutine decay_gen_make_term_rng

```

```

end do
end subroutine decay_gen_make_term_rng

```

Recursively link interactions of the enclosed decay terms to the corresponding terms in the current process instance.

Note: A bug in nagfor requires the extra `i_term` variable.

```

<Decays: decay gen: TBP>+≡
  procedure :: link_term_interactions => decay_gen_link_term_interactions

<Decays: procedures>+≡
  recursive subroutine decay_gen_link_term_interactions (decay)
    class(decay_gen_t), intent(inout) :: decay
    integer :: i, i_term
    type(interaction_t), pointer :: trace
    associate (instance => decay%process_instance)
      do i = 1, size (decay%term)
        i_term = i
        trace => instance%get_trace_int_ptr (i_term)
        call decay%term(i_term)%link_interactions (trace)
      end do
    end associate
  end subroutine decay_gen_link_term_interactions

```

Select a decay chain: decay modes and process components.

```

<Decays: decay root: TBP>+≡
  procedure :: select_chain => decay_root_select_chain

<Decays: procedures>+≡
  subroutine decay_root_select_chain (decay_root)
    class(decay_root_t), intent(inout) :: decay_root
    type(connected_state_t), pointer :: origin
    if (decay_root%selected_term > 0) then
      call decay_root%term(decay_root%selected_term)%select_chain ()
    else
      call msg_bug ("Decays: no term selected for parent process")
    end if
  end subroutine decay_root_select_chain

```

Generate a decay tree, i.e., for the selected term in the parent process, recursively generate a decay event for all unstable particles.

Factor out the trace of the connected state of the parent process. This trace should not be taken into account for unweighting the decay chain, since it was already used for unweighting the parent event, or it determines the overall event weight.

```

<Decays: decay root: TBP>+≡
  procedure :: generate => decay_root_generate

<Decays: procedures>+≡
  subroutine decay_root_generate (decay_root)
    class(decay_root_t), intent(inout) :: decay_root
    type(connected_state_t), pointer :: connected_state
    if (decay_root%selected_term > 0) then
      connected_state => decay_root%process_instance%get_connected_state_ptr &

```

```

        (decay_root%selected_term)
        call connected_state%normalize_matrix_by_trace ()
        call decay_root%term(decay_root%selected_term)%generate ()
    else
        call msg_bug ("Decays: no term selected for parent process")
    end if
end subroutine decay_root_generate

```

16.2.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

```

<Decays: types>+≡
    type, extends (decay_root_config_t) :: decay_config_t
        real(default) :: weight = 0
        real(default) :: integral = 0
        real(default) :: abs_error = 0
        real(default) :: rel_error = 0
        type(selector_t) :: mci_selector
    contains
        <Decays: decay config: TBP>
    end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
    procedure :: write => decay_config_write

<Decays: procedures>+≡
    recursive subroutine decay_config_write (object, unit, indent, verbose)
        class(decay_config_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        logical, intent(in), optional :: verbose
        integer :: u, ind
        u = output_unit (unit)
        ind = 0; if (present (indent)) ind = indent
        call write_indent (u, ind)
        write (u, "(1x,A)") "Decay:"
        call object%write_header (unit, indent)
        call write_indent (u, ind)
        write (u, 2) "branching ratio =", object%weight * 100
        call write_indent (u, ind)
        write (u, 1) "partial width  =", object%integral
        call write_indent (u, ind)
        write (u, 1) "error (abs)    =", object%abs_error
        call write_indent (u, ind)
        write (u, 1) "error (rel)    =", object%rel_error
1    format (3x,A,ES19.12)
2    format (3x,A,F11.6,1x,'%')

```

```

    call object%write_terms (unit, indent, verbose)
end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should be used instead.

```

<Decays: decay config: TBP>+≡
  procedure :: connect => decay_config_connect

<Decays: procedures>+≡
  recursive subroutine decay_config_connect &
    (decay, process, model, process_stack)
    class(decay_config_t), intent(out) :: decay
    type(process_t), intent(in), target :: process
    type(model_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(flavor_t), dimension(:, :), allocatable :: flv
    logical, dimension(:), allocatable :: stable
    real(default), dimension(:), allocatable :: integral_mci
    integer :: i, j, n_mci
    call decay%decay_root_config_t%connect (process, model, process_stack)
    decay%integral = process%get_integral ()
    decay%abs_error = process%get_error ()
    n_mci = process%get_n_mci ()
    allocate (integral_mci (n_mci))
    do i = 1, n_mci
      integral_mci(i) = process%get_integral_mci (i)
    end do
    call decay%mc_selector%init (integral_mci)
  end subroutine decay_config_connect

```

Compute embedded branchings and the relative error. This method does not apply to the decay root.

```

<Decays: decay config: TBP>+≡
  procedure :: compute => decay_config_compute

<Decays: procedures>+≡
  recursive subroutine decay_config_compute (decay)
    class(decay_config_t), intent(inout) :: decay
    call decay%decay_root_config_t%compute ()
    if (decay%integral == 0) then
      call decay%write ()
      call msg_fatal ("Decay configuration: partial width is zero")
    end if
    decay%rel_error = decay%abs_error / decay%integral
  end subroutine decay_config_compute

```

16.2.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

⟨Decays: types⟩+≡
  type, extends (decay_gen_t) :: decay_t
    type(decay_config_t), pointer :: config => null ()
    class(rng_t), allocatable :: rng
    contains
      ⟨Decays: decay: TBP⟩
    end type decay_t

```

The finalizer is recursive.

```

⟨Decays: decay: TBP⟩≡
  procedure :: final => decay_final

⟨Decays: procedures⟩+≡
  recursive subroutine decay_final (object)
    class(decay_t), intent(inout) :: object
    integer :: i
    call object%base_final ()
    do i = 1, object%config%process%get_n_mci ()
      call object%process_instance%final_simulation (i)
    end do
    call object%process_instance%final ()
    deallocate (object%process_instance)
  end subroutine decay_final

```

Output.

```

⟨Decays: decay: TBP⟩+≡
  procedure :: write => decay_write

⟨Decays: procedures⟩+≡
  recursive subroutine decay_write (object, unit, indent, recursive)
    class(decay_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent, recursive
    integer :: i, u, ind
    u = output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call object%config%write (unit, indent, verbose = .false.)
    if (allocated (object%rng)) then
      call object%rng%write (u, ind + 1)
    end if
    call write_indent (u, ind)
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI    = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI    = [undefined]"
    end if
    call write_indent (u, ind)
    if (object%selected_term > 0) then

```

```

        write (u, "(3x,A,I0)") "Selected term  = ", object%selected_term
        call object%term(object%selected_term)%write (u, ind + 1)
    else
        write (u, "(3x,A)") "Selected term  = [undefined]"
    end if
end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
    procedure :: init => decay_init

<Decays: procedures>+≡
    recursive subroutine decay_init (decay, config)
        class(decay_t), intent(out) :: decay
        type(decay_config_t), intent(in), target :: config
        integer :: i
        call decay%base_init (config%term_config)
        decay%config => config
        allocate (decay%process_instance)
        call decay%process_instance%init (decay%config%process)
        call decay%process_instance%setup_event_data (decay%config%model)
        do i = 1, decay%config%process%get_n_mci ()
            call decay%process_instance%init_simulation (i)
        end do
        call decay%config%process%make_rng (decay%rng)
        call decay%make_term_rng (decay%config%process)
    end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
    procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
    recursive subroutine decay_link_interactions (decay, i_prt, trace)
        class(decay_t), intent(inout) :: decay
        integer, intent(in) :: i_prt
        type(interaction_t), intent(in), target :: trace
        type(interaction_t), pointer :: beam_int
        integer :: n_in, n_vir
        beam_int => decay%process_instance%get_beam_int_ptr ()
        n_in = interaction_get_n_in (trace)
        n_vir = interaction_get_n_vir (trace)
        call interaction_set_source_link (beam_int, 1, trace, &
            n_in + n_vir + i_prt)
        call decay%link_term_interactions ()
    end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

Note: in the current implementation of process instances, term selection is non-functional (choosing always the first term).

```

<Decays: decay: TBP>+≡
  procedure :: select_chain => decay_select_chain

<Decays: procedures>+≡
  recursive subroutine decay_select_chain (decay)
    class(decay_t), intent(inout) :: decay
    real(default) :: x
    integer :: i
    call decay%rng%generate (x)
    decay%selected_mci = decay%config%mci_selector%select (x)
    ! call decay%process_instance%select_i_term (decay%selected_term)
    decay%selected_term = 1
    do i = 1, size (decay%term)
      call decay%term(i)%select_chain ()
    end do
  end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

<Decays: decay: TBP>+≡
  procedure :: generate => decay_generate

<Decays: procedures>+≡
  recursive subroutine decay_generate (decay)
    class(decay_t), intent(inout) :: decay
    type(isolated_state_t), pointer :: isolated_state
    integer :: i
    call decay%process_instance%receive_beam_momenta ()
    call decay%config%process%generate_unweighted_event &
      (decay%process_instance, decay%selected_mci)
    if (signal_is_pending ()) return
    call decay%process_instance%evaluate_event_data ()
    isolated_state => &
      decay%process_instance%get_isolated_state_ptr (decay%selected_term)
    call isolated_state%normalize_matrix_by_trace ()
    do i = 1, size (decay%term)
      call decay%term(i)%generate ()
      if (signal_is_pending ()) return
    end do
  end subroutine decay_generate

```

16.2.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```

<Decays: types>+≡
  type, extends (any_config_t) :: stable_config_t
    type(flavor_t), dimension(:), allocatable :: flv
  contains
    <Decays: stable config: TBP>
  end type stable_config_t

```

The finalizer is empty:

```

<Decays: stable config: TBP>≡
  procedure :: final => stable_config_final

<Decays: procedures>+≡
  subroutine stable_config_final (object)
    class(stable_config_t), intent(inout) :: object
  end subroutine stable_config_final

```

Output.

```

<Decays: stable config: TBP>+≡
  procedure :: write => stable_config_write

<Decays: procedures>+≡
  recursive subroutine stable_config_write (object, unit, indent, verbose)
    class(stable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    u = output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"
    write (u, "(1x,A)", advance = "no") char (flavor_get_name (object%flv(1)))
    do i = 2, size (object%flv)
      write (u, "(':',',',A)", advance = "no") &
        char (flavor_get_name (object%flv(i)))
    end do
    write (u, *)
  end subroutine stable_config_write

```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```

<Decays: stable config: TBP>+≡
  procedure :: init => stable_config_init

<Decays: procedures>+≡
  subroutine stable_config_init (config, flv)
    class(stable_config_t), intent(out) :: config
    type(flavor_t), dimension(:), intent(in) :: flv
    integer, dimension (size (flv)) :: pdg
    logical, dimension (size (flv)) :: mask
    integer :: i
    pdg = flavor_get_pdg (flv)

```

```

mask(1) = .true.
forall (i = 2 : size (pdg))
  mask(i) = all (pdg(i) /= pdg(1:i-1))
end forall
allocate (config%flv (count (mask)))
config%flv = pack (flv, mask)
end subroutine stable_config_init

```

Here is the corresponding object instance. Except for the pointer to the configuration, there is no content.

```

<Decays: types>+≡
  type, extends (any_t) :: stable_t
    type(stable_config_t), pointer :: config => null ()
  contains
    <Decays: stable: TBP>
  end type stable_t

```

The finalizer does nothing.

```

<Decays: stable: TBP>≡
  procedure :: final => stable_final

<Decays: procedures>+≡
  subroutine stable_final (object)
    class(stable_t), intent(inout) :: object
  end subroutine stable_final

```

We can delegate output to the configuration object.

```

<Decays: stable: TBP>+≡
  procedure :: write => stable_write

<Decays: procedures>+≡
  subroutine stable_write (object, unit, indent)
    class(stable_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    call object%config%write (unit, indent)
  end subroutine stable_write

```

Initializer: just assign the configuration.

```

<Decays: stable: TBP>+≡
  procedure :: init => stable_init

<Decays: procedures>+≡
  subroutine stable_init (stable, config)
    class(stable_t), intent(out) :: stable
    type(stable_config_t), intent(in), target :: config
    stable%config => config
  end subroutine stable_init

```

16.2.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: types>+≡
  type, extends (any_config_t) :: unstable_config_t
    type(flavor_t) :: flv
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: selector
    type(decay_config_t), dimension(:), allocatable :: decay_config
  contains
    <Decays: unstable config: TBP>
  end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
  procedure :: final => unstable_config_final

<Decays: procedures>+≡
  recursive subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%final ()
      end do
    end if
  end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
  procedure :: write => unstable_config_write

<Decays: procedures>+≡
  recursive subroutine unstable_config_write (object, unit, indent, verbose)
    class(unstable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    logical :: verb
    u = output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
      char (flavor_get_name (object%flv))
    call write_indent (u, ind)
    write (u, 1) "total width =", object%integral
  end subroutine unstable_config_write

```

```

        call write_indent (u, ind)
        write (u, 1) "error (abs) =", object%abs_error
        call write_indent (u, ind)
        write (u, 1) "error (rel) =", object%rel_error
1   format (5x,A,ES19.12)
        if (verb .and. allocated (object%decay_config)) then
            do i = 1, size (object%decay_config)
                call object%decay_config(i)%write (u, ind + 1)
            end do
        end if
    end subroutine unstable_config_write

```

Initializer. For the unstable particle, the flavor is unique.

```

<Decays: unstable config: TBP>+≡
    procedure :: init => unstable_config_init
<Decays: procedures>+≡
    subroutine unstable_config_init (config, flv)
        class(unstable_config_t), intent(out) :: config
        type(flavor_t), intent(in) :: flv
        config%flv = flv
    end subroutine unstable_config_init

```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```

<Decays: unstable config: TBP>+≡
    procedure :: init_decays => unstable_config_init_decays
<Decays: procedures>+≡
    recursive subroutine unstable_config_init_decays &
        (unstable, decay_id, model, process_stack)
        class(unstable_config_t), intent(inout) :: unstable
        type(string_t), dimension(:), intent(in) :: decay_id
        type(model_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        integer :: i
        allocate (unstable%decay_config (size (decay_id)))
        do i = 1, size (decay_id)
            associate (decay => unstable%decay_config(i))
                if (present (process_stack)) then
                    call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
                        model, process_stack)
                else
                    call decay%init (model, decay_id(i))
                end if
            end associate
        end do
    end subroutine unstable_config_init_decays

```

Compute the total width and branching ratios, initializing the decay selector.

```

<Decays: unstable config: TBP>+≡
    procedure :: compute => unstable_config_compute

```

```

<Decays: procedures>+≡
recursive subroutine unstable_config_compute (unstable)
  class(unstable_config_t), intent(inout) :: unstable
  integer :: i
  do i = 1, size (unstable%decay_config)
    call unstable%decay_config(i)%compute ()
  end do
  unstable%integral = sum (unstable%decay_config%integral)
  if (unstable%integral <= 0) then
    call unstable%write ()
    call msg_fatal ("Decay configuration: computed total width is zero")
  end if
  unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
  unstable%rel_error = unstable%abs_error / unstable%integral
  call unstable%selector%init (unstable%decay_config%integral)
  do i = 1, size (unstable%decay_config)
    unstable%decay_config(i)%weight &
      = unstable%selector%get_weight (i)
  end do
end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: types>+≡
type, extends (any_t) :: unstable_t
  type(unstable_config_t), pointer :: config => null ()
  class(rng_t), allocatable :: rng
  integer :: selected_decay = 0
  type(decay_t), dimension(:), allocatable :: decay
contains
  <Decays: unstable: TBP>
end type unstable_t

```

Recursive finalizer.

```

<Decays: unstable: TBP>≡
procedure :: final => unstable_final

<Decays: procedures>+≡
recursive subroutine unstable_final (object)
  class(unstable_t), intent(inout) :: object
  integer :: i
  if (allocated (object%decay)) then
    do i = 1, size (object%decay)
      call object%decay(i)%final ()
    end do
  end if
end subroutine unstable_final

```

Output.

```

<Decays: unstable: TBP>+≡
procedure :: write => unstable_write

<Decays: procedures>+≡
recursive subroutine unstable_write (object, unit, indent)

```

```

class(unstable_t), intent(in) :: object
integer, intent(in), optional :: unit, indent
integer :: u, i, ind
u = output_unit (unit)
ind = 0; if (present (indent)) ind = indent
call object%config%write (u, ind, verbose=.false.)
if (allocated (object%rng)) then
  call object%rng%write (u, ind + 2)
end if
call write_indent (u, ind)
if (object%selected_decay > 0) then
  write (u, "(5x,A,I0)") "Sel. decay = ", object%selected_decay
  call object%decay(object%selected_decay)%write (u, ind + 1)
else
  write (u, "(5x,A)") "Sel. decay = [undefined]"
end if
end subroutine unstable_write

```

Write the embedded process instances.

```

  real(default) :: x
  call unstable%rng%generate (x)
  unstable%selected_decay = unstable%config%selector%select (x)
  call unstable%decay(unstable%selected_decay)%select_chain ()
end subroutine unstable_select_chain

```

Generate a decay event.

```

<Decays: unstable: TBP>+≡
  procedure :: generate => unstable_generate

<Decays: procedures>+≡
recursive subroutine unstable_generate (unstable)
  class(unstable_t), intent(inout) :: unstable
  call unstable%decay(unstable%selected_decay)%generate ()
end subroutine unstable_generate

```

16.2.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and

several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+≡
  type, extends (connected_state_t) :: decay_chain_entry_t
    integer :: index = 0
    type(decay_config_t), pointer :: config => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
    type(decay_chain_entry_t), pointer :: previous => null ()
  end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: types>+≡
  type :: decay_chain_t
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_term = 0
    type(evaluator_t) :: correlated_trace
    type(decay_chain_entry_t), pointer :: last => null ()
  contains
    <Decays: decay chain: TBP>
  end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay chain: TBP>≡
  procedure :: final => decay_chain_final

<Decays: procedures>+≡
  subroutine decay_chain_final (object)
    class(decay_chain_t), intent(inout) :: object
    type(decay_chain_entry_t), pointer :: entry

```

```

do while (associated (object%last))
  entry => object%last
  object%last => entry%previous
  call entry%final ()
  deallocate (entry)
end do
call evaluator_final (object%correlated_trace)
end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

<Decays: decay chain: TBP>+≡
  procedure :: write => decay_chain_write

<Decays: procedures>+≡
  subroutine decay_chain_write (object, unit)
    class(decay_chain_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    call write_separator_double (u)
    write (u, "(1x,A)") "Decay chain:"
    call write_entries (object%last)
    call write_separator_double (u)
    write (u, "(1x,A)") "Evaluator (correlated trace of the decay chain):"
    call write_separator (u)
    call evaluator_write (object%correlated_trace, u)
    call write_separator_double (u)
contains
  recursive subroutine write_entries (entry)
    type(decay_chain_entry_t), intent(in), pointer :: entry
    if (associated (entry)) then
      call write_entries (entry%previous)
      call write_separator_double (u)
      write (u, "(1x,A,I0)") "Decay #", entry%index
      call entry%config%write_header (u)
      write (u, "(3x,A,I0)") "Selected MCI    = ", entry%selected_mci
      write (u, "(3x,A,I0)") "Selected term  = ", entry%selected_term
      call entry%config%term_config(entry%selected_term)%write (u, indent=1)
      call entry%write (u)
    end if
  end subroutine write_entries
end subroutine decay_chain_write

```

Build a decay chain, recursively following the selected decays and terms in a decay tree. Before start, we finalize the chain, deleting any previous contents.

```

<Decays: decay chain: TBP>+≡
  procedure :: build => decay_chain_build

<Decays: procedures>+≡
  subroutine decay_chain_build (chain, decay_root)
    class(decay_chain_t), intent(inout), target :: chain
    type(decay_root_t), intent(in) :: decay_root
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    type(interaction_t), pointer :: int_last_decay

```

```

call chain%final ()
if (decay_root%selected_term > 0) then
  chain%process_instance => decay_root%process_instance
  chain%selected_term = decay_root%selected_term
  call chain%build_term_entries (decay_root%term(decay_root%selected_term))
end if
int_last_decay => chain%last%get_matrix_int_ptr ()
allocate (qn_mask (interaction_get_n_tot (int_last_decay)))
call quantum_numbers_mask_init (qn_mask, &
  mask_f = .true., mask_c = .true., mask_h = .true.)
call evaluator_init_qn_sum (chain%correlated_trace, int_last_decay, qn_mask)
end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable particles.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_term_entries (chain, term)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_term_t), intent(in) :: term
    integer :: i
    do i = 1, size (term%particle_out)
      select type (unstable => term%particle_out(i)%c)
        type is (unstable_t)
          if (unstable%selected_decay > 0) then
            call chain%build_decay_entries &
              (unstable%decay(unstable%selected_decay))
          end if
        end select
      end do
    end do
  end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_decay_entries => decay_chain_build_decay_entries

```

<Decays: procedures>+≡

```

recursive subroutine decay_chain_build_decay_entries (chain, decay)
  class(decay_chain_t), intent(inout) :: chain
  type(decay_t), intent(in) :: decay
  type(decay_chain_entry_t), pointer :: entry
  type(connected_state_t), pointer :: previous_state
  type(isolated_state_t), pointer :: current_decay
  allocate (entry)
  if (associated (chain%last)) then
    entry%previous => chain%last
    entry%index = entry%previous%index + 1
    previous_state => entry%previous%connected_state_t
  else
    entry%index = 1
    previous_state => &
      chain%process_instance%get_connected_state_ptr (chain%selected_term)
  end if
  entry%config => decay%config
  entry%selected_mci = decay%selected_mci
  entry%selected_term = decay%selected_term
  current_decay => decay%process_instance%get_isolated_state_ptr &
    (decay%selected_term)
  call entry%setup_connected_trace &
    (current_decay, previous_state%get_trace_int_ptr ())
  call entry%setup_connected_matrix &
    (current_decay, previous_state%get_matrix_int_ptr ())
  call entry%setup_connected_flows &
    (current_decay, previous_state%get_flows_int_ptr ())
  call chain%build_term_entries (decay%term(decay%selected_term))
  chain%last => entry
end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

<Decays: decay chain: TBP>+≡

```

procedure :: evaluate => decay_chain_evaluate

```

<Decays: procedures>+≡

```

subroutine decay_chain_evaluate (chain)
  class(decay_chain_t), intent(inout) :: chain
  call evaluate (chain%last)
  call evaluator_receive_momenta (chain%correlated_trace)
  call evaluator_evaluate (chain%correlated_trace)
contains
  recursive subroutine evaluate (entry)
    type(decay_chain_entry_t), intent(inout), pointer :: entry
    if (associated (entry)) then
      call evaluate (entry%previous)
      call entry%receive_kinematics ()
      call entry%evaluate_trace ()
    end if
  end subroutine evaluate

```

```

        call entry%evaluate_event_data ()
    end if
end subroutine evaluate
end subroutine decay_chain_evaluate

```

Return the probability of a decay chain. This is given as the trace of the density matrix with intermediate helicity correlations, normalized by the product of the uncorrelated density matrix traces. This works only if an event has been evaluated and the `correlated_trace` evaluator is filled. By definition, this evaluator has only one matrix element, and this must be real.

```

⟨Decays: decay chain: TBP⟩+≡
    procedure :: get_probability => decay_chain_get_probability

⟨Decays: procedures⟩+≡
    function decay_chain_get_probability (chain) result (x)
        class(decay_chain_t), intent(in) :: chain
        real(default) :: x
        x = evaluator_get_matrix_element (chain%correlated_trace, 1)
    end function decay_chain_get_probability

```

16.2.12 Decay as Event Transform

The `evt_decay` object combines decay configuration, decay tree, and chain in a single object, as an implementation of the `evt` (event transform) abstract type.

```

⟨Decays: public⟩≡
    public :: evt_decay_t

⟨Decays: types⟩+≡
    type, extends (evt_t) :: evt_decay_t
        type(decay_root_config_t) :: decay_root_config
        type(decay_root_t) :: decay_root
        type(decay_chain_t) :: decay_chain
    contains
        ⟨Decays: evt decay: TBP⟩
    end type evt_decay_t

```

Output. We display the currently selected decay tree, which includes configuration data, and the decay chain, i.e., the evaluators.

```

⟨Decays: evt decay: TBP⟩≡
    procedure :: write => evt_decay_write

⟨Decays: procedures⟩+≡
    subroutine evt_decay_write (object, unit, &
        show_decay_tree, &
        show_processes, &
        verbose)
        class(evt_decay_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: show_decay_tree, show_processes, verbose
        logical :: dec, prc, verb
        integer :: u
        u = output_unit (unit)
    end subroutine evt_decay_write

```

```

dec = .true.; if (present (show_decay_tree)) dec = show_decay_tree
prc = .false.; if (present (show_processes)) prc = show_processes
verb = .false.; if (present (verbose)) verb = verbose
call write_separator_double (u)
write (u, "(1x,A)") "Event transform: partonic decays"
call write_separator_double (u)
call object%base_write (u)
if (dec) then
  call write_separator (u)
  call object%decay_root%write (u)
  if (verb) then
    call object%decay_chain%write (u)
  end if
  if (prc) then
    call object%decay_root%write_process_instances (u, verb)
  end if
else
  call write_separator_double (u)
end if
end subroutine evt_decay_write

```

Connect with a process instance and process. This initializes the decay configuration. The process stack is used to look for process objects that implement daughter decays.

When all processes are assigned, configure the decay tree instance, using the decay tree configuration. First obtain the branching ratios, then allocate the decay tree. This is done once for all events.

```

<Decays: evt decay: TBP>+≡
  procedure :: connect => evt_decay_connect

<Decays: procedures>+≡
  subroutine evt_decay_connect (evt, process_instance, model, process_stack)
    class(evt_decay_t), intent(inout), target :: evt
    type(process_instance_t), intent(in), target :: process_instance
    type(model_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    call evt%base_connect (process_instance, model)
    call evt%decay_root_config%connect &
      (process_instance%process, model, process_stack)
    call evt%decay_root_config%compute ()
    call evt%decay_root%init (evt%decay_root_config, evt%process_instance)
  end subroutine evt_decay_connect

```

Prepare a new event: Select a decay chain and build the corresponding chain object.

```

<Decays: evt decay: TBP>+≡
  procedure :: prepare_new_event => evt_decay_prepare_new_event

<Decays: procedures>+≡

```

16.3.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The `safety_factor` reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The `sigma` and `n` values, if nontrivial, allow for reweighting the events according to the requested `norm_mode`.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the `event_expr_t` objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

⟨Events: types⟩≡

```

type :: event_config_t
  logical :: unweighted = .false.
  integer :: norm_mode = NORM_UNDEFINED
  integer :: factorization_mode = FM_IGNORE_HELICITY
  logical :: keep_correlations = .false.
  real(default) :: sigma = 1

end if

```

```
end subroutine event_config_write
```

16.3.2 Event normalization

The parameters for event normalization. For unweighted events, `NORM_UNIT` is intended as default, while for weighted events, it is `NORM_SIGMA`.

Note: the unit test for this is in `eio_data_2` below.

```
<Events: parameters>≡
integer, parameter, public :: NORM_UNDEFINED = 0
integer, parameter, public :: NORM_UNIT = 1
integer, parameter, public :: NORM_N_EVT = 2
integer, parameter, public :: NORM_SIGMA = 3
integer, parameter, public :: NORM_S_N = 4
```

These functions translate between the user representation and the internal one.

```
<Events: public>≡
public :: event_normalization_mode
public :: event_normalization_string

<Events: procedures>+≡
function event_normalization_mode (string, unweighted) result (mode)
integer :: mode
type(string_t), intent(in) :: string
logical, intent(in) :: unweighted
select case (lower_case (char (string)))
case ("auto")
if (unweighted) then
mode = NORM_UNIT
else
mode = NORM_SIGMA
end if
case ("1")
mode = NORM_UNIT
case ("1/n")
mode = NORM_N_EVT
case ("sigma")
mode = NORM_SIGMA
case ("sigma/n")
mode = NORM_S_N
case default
call msg_fatal ("Event normalization: unknown value '" &
// char (string) // "'")
end select
end function event_normalization_mode

function event_normalization_string (norm_mode) result (string)
integer, intent(in) :: norm_mode
type(string_t) :: string
select case (norm_mode)
case (NORM_UNDEFINED); string = "[undefined]"
case (NORM_UNIT); string = "'1'"
case (NORM_N_EVT); string = "'1/n'"

```

```

        case (NORM_SIGMA);    string = "'sigma'"
        case (NORM_S_N);     string = "'sigma/n'"
        case default;        string = "???"
    end select
end function event_normalization_string

```

We place this here as a generic helper, so we can update event weights whenever we need, not just in connection with an event sample data object.

<Events: public>+≡

```
public :: event_normalization_update
```

<Events: procedures>+≡

```

subroutine event_normalization_update (weight, sigma, n, mode_new, mode_old)
    real(default), intent(inout) :: weight
    real(default), intent(in) :: sigma
    integer, intent(in) :: n
    integer, intent(in) :: mode_new, mode_old
    if (mode_new /= mode_old) then
        if (sigma > 0 .and. n > 0) then
            weight = weight / factor (mode_old) * factor (mode_new)
        else
            call msg_fatal ("Event normalization update: null sample")
        end if
    end if
contains
    function factor (mode)
        real(default) :: factor
        integer, intent(in) :: mode
        select case (mode)
        case (NORM_UNIT);    factor = 1._default

        case (NORM_SIGMA);   factor = sigma
        case (NORM_S_N);     factor = sigma / n
        case default
            call msg_fatal ("Event normalization update: undefined mode")
        end select
    end function factor
end subroutine event_normalization_update

```

16.3.3 The event type

Each event has a single elementary process as its core. This process may be dressed by a shower, a decay chain etc. For this core we implement pointers to a process instance.

The actual (dressed) event record is implemented as a **particle_set** object.

A list of event transforms (class **evt_t**) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The **particle_set** pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the **ref** value is the number in the file, while the **prc** value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of **alt** values is copied from an array of alternative event records. These values should represent calculated values.

The **sqme** and **weight** values mirror corresponding values in the **expr** sub-object. The idea is that when generating or reading events, the event record is filled first, then the **expr** object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the **expr** subobject. In particular, evaluating the event-selection expression sets the **passed** flag. Furthermore, the **expr** subobject collects data that can be used in the analysis and should be written to file, including copies of **sqme** and **weight**.

```

    end if
end subroutine event_write

```

16.3.4 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```

<Events: event: TBP>+≡
    procedure :: basic_init => event_init

<Events: procedures>+≡
    subroutine event_init (event, var_list, n_alt)
        class(event_t), intent(out) :: event
        type(var_list_t), intent(in), optional :: var_list
        integer, intent(in), optional :: n_alt
        type(string_t) :: norm_string
        if (present (var_list)) then
            event%config%unweighted = var_list_get_lval (var_list, &
                var_str ("?unweighted"))
            norm_string = var_list_get_sval (var_list, &
                var_str ("sample_normalization"))
            event%config%norm_mode = &
                event_normalization_mode (norm_string, event%config%unweighted)
            if (event%config%unweighted) then
                event%config%safety_factor = var_list_get_rval (var_list, &
                    var_str ("safety_factor"))
            end if
        else
            event%config%norm_mode = NORM_SIGMA
        end if
        if (present (n_alt)) then
            event%n_alt = n_alt
            allocate (event%sqme_alt (n_alt))
            allocate (event%weight_alt (n_alt))
            call event%expr%init (n_alt)
        end if
        allocate (evt_trivial_t :: event%transform_first)
        event%transform_last => event%transform_first
    end subroutine event_init

```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

```

<Events: event: TBP>+≡
  procedure :: set_sigma => event_set_sigma
  procedure :: set_n => event_set_n

<Events: procedures>+≡
  elemental subroutine event_set_sigma (event, sigma)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: sigma
    event%config%sigma = sigma
  end subroutine event_set_sigma

  elemental subroutine event_set_n (event, n)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: n
    event%config%n = n
  end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
  procedure :: import_transform => event_import_transform

<Events: procedures>+≡
  subroutine event_import_transform (event, evt)
    class(event_t), intent(inout) :: event
    class(evt_t), intent(inout), pointer :: evt
    event%transform_last%next => evt
    evt%previous => event%transform_last
    event%transform_last => evt
    evt => null ()
  end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

```

```

<Events: procedures>+≡
subroutine event_connect (event, process_instance, model, process_stack)
  class(event_t), intent(inout), target :: event
  type(process_instance_t), intent(in), target :: process_instance
  type(model_t), intent(in), target :: model
  type(process_stack_t), intent(in), optional :: process_stack
  type(string_t) :: id
  integer :: num_id
  class(evt_t), pointer :: evt
  event%process => process_instance%process
  event%instance => process_instance
  id = event%process%get_id ()
  if (id /= "") call event%expr%set_process_id (id)
  num_id = event%process%get_num_id ()
  if (num_id /= 0) call event%expr%set_process_num_id (num_id)
  call event%expr%setup_vars (event%process%get_sqrts ())
  call event%expr%link_var_list (event%process%get_var_list_ptr ())
  call event%process%make_rng (event%rng)
  evt => event%transform_first
  do while (associated (evt))
    call evt%connect (process_instance, model, process_stack)
    evt => evt%next
  end do
end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
  procedure :: set_selection => event_set_selection
  procedure :: set_reweight => event_set_reweight
  procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡

<Events: procedures>+≡
  subroutine event_setup_expressions (event)
    class(event_t), intent(inout), target :: event
    call event%expr%setup_selection (event%config%pn_selection)
    call event%expr%setup_analysis (event%config%pn_analysis)
    call event%expr%setup_reweight (event%config%pn_reweight)
  end subroutine event_setup_expressions

```

16.3.5 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

<Events: event: TBP>+≡
  procedure :: evaluate_transforms => event_evaluate_transforms

<Events: procedures>+≡
  subroutine event_evaluate_transforms (event, r)
    class(event_t), intent(inout) :: event
    real(default), dimension(:), intent(in), optional :: r
    class(evt_t), pointer :: evt
    integer :: i_term
    event%particle_set_exists = .false.
    call event%check ()
    if (event%instance%is_complete_event ()) then
      call event%instance%select_i_term (i_term)
      event%selected_i_term = i_term

        end if
    end subroutine event_check

```

16.3.8 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we accept the latter.

Note: We should apply decays, shower, hadronization before the transfer. This is not (re-)implemented yet.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the

event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
  procedure :: generate => event_generate

<Events: procedures>+≡
  subroutine event_generate (event, i_mci, r)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci

16.3.9 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
  procedure :: select => event_select

<Events: procedures>+≡
  subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event

```

```

integer, intent(in) :: i_mci, i_term, channel
if (associated (event%instance)) then
    event%selected_i_mci = i_mci
    event%selected_i_term = i_term
    event%selected_channel = channel
else
    call msg_bug ("Event: select term: process instance undefined")
end if
end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. Thus, with the current implementation, event readers can only be used for reading hard events. However, once we have reconstructed the master process, we may apply all event transforms to generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
    procedure :: set_particle_set_hard_proc => event_set_particle_set_hard_proc

<Events: procedures>+≡
    subroutine event_set_particle_set_hard_proc (event, particle_set)
        class(event_t), intent(inout) :: event
        type(particle_set_t), intent(in) :: particle_set
        class(evt_t), pointer :: evt
        evt => event%transform_first
        call evt%set_particle_set (particle_set, &
            event%selected_i_mci, event%selected_i_term)
        event%particle_set => evt%particle_set
        call event%accept_particle_set ()
        evt => evt%next
        do while (associated (evt))
            call evt%reset ()
            evt => evt%next
        end do
    end subroutine event_set_particle_set_hard_proc

```

Mark the particle set as existing, assuming that it has just been filled somehow.

```

<Events: event: TBP>+≡
    procedure :: accept_particle_set => event_accept_particle_set

<Events: procedures>+≡
    subroutine event_accept_particle_set (event)
        class(event_t), intent(inout) :: event
        event%particle_set_exists = .true.
    end subroutine event_accept_particle_set

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

<Events: event: TBP>+≡
  procedure :: recalculate => event_recalculate

<Events: procedures>+≡

16.3.10 Access content

Pointer to the associated process object.

```

<Events: event: TBP>+≡
    procedure :: get_process_ptr => event_get_process_ptr

<Events: procedures>+≡
    function event_get_process_ptr (event) result (ptr)
        class(event_t), intent(in) :: event
        type(process_t), pointer :: ptr
        ptr => event%process
    end function event_get_process_ptr

```

Tell whether the particle set is defined:

```

<Events: event: TBP>+≡
    procedure :: has_particle_set => event_has_particle_set

<Events: procedures>+≡
    function event_has_particle_set (event) result (flag)
        class(event_t), intent(in) :: event
        logical :: flag
        flag = event%particle_set_exists
    end function event_has_particle_set

```

Pointer to the particle set.

```

<Events: event: TBP>+≡
    procedure :: get_particle_set_ptr => event_get_particle_set_ptr

<Events: procedures>+≡
    function event_get_particle_set_ptr (event) result (ptr)
        class(event_t), intent(in), target :: event

Chapter 17

Matrix Element Implementations

In this chapter, we define concrete implementations for the workflow, from matrix-element code generation via matrix-element access to integration and event generation.

17.1 O’MEGA Interface

The standard method for process computation with WHIZARD is the O’MEGA matrix element generator.

This section implements the interface to the code generator (via the makefile) and the driver for the features provided by the O’MEGA matrix element.

```
<prc_omega.f90>≡  
  <File header>  
  
  module prc_omega  
  
    use iso_c_binding !NODEP!  
    use kinds !NODEP!  
    <Use file utils>  
    <Use strings>  
    use limits, only: TAB !NODEP!  
    use diagnostics !NODEP!  
    use unit_tests  
    use os_interface  
    use lorentz !NODEP!  
    use sm_qcd  
    use interactions  
    use variables  
    use models  
  
    use process_constants  
    use prclib_interfaces  
    use prc_core_def  
    use particle_specifiers  
    use process_libraries
```

```

    use prc_core

    <Standard module head>

    <Omega interface: public>

    <Omega interface: types>

    <Omega interface: interfaces>

    contains

    <Omega interface: procedures>

    <Omega interface: tests>

    end module prc_omega

```

17.1.1 Process definition

For the process definition we implement an extension of the `prc_core_def_t` abstract type.

```

<Omega interface: public>≡
    public :: omega_def_t

<Omega interface: types>≡
    type, extends (prc_core_def_t) :: omega_def_t
    contains
    <Omega interface: omega def: TBP>
    end type omega_def_t

<Omega interface: omega def: TBP>≡
    procedure, nopass :: type_string => omega_def_type_string

<Omega interface: procedures>≡
    function omega_def_type_string () result (string)
        type(string_t) :: string
        string = "omega"
    end function omega_def_type_string

```

Initialization: allocate the writer for the O'MEGA matrix element. Also set any data for this process that the writer needs.

```

<Omega interface: omega def: TBP>+≡
    procedure :: init => omega_def_init

<Omega interface: procedures>+≡
    subroutine omega_def_init (object, model_name, prt_in, prt_out, &
        restrictions, openmp_support, report_progress, extra_options, &
        diags, diags_color)
        class(omega_def_t), intent(out) :: object
        type(string_t), intent(in) :: model_name
        type(string_t), dimension(:), intent(in) :: prt_in
        type(string_t), dimension(:), intent(in) :: prt_out
        type(string_t), intent(in), optional :: restrictions
    end subroutine omega_def_init

```

```

logical, intent(in), optional :: openmp_support
logical, intent(in), optional :: report_progress
logical, intent(in), optional :: diags, diags_color
type(string_t), intent(in), optional :: extra_options
type(string_t) :: process_string
integer :: n_in
allocate (omega_writer_t :: object%writer)
select type (writer => object%writer)
type is (omega_writer_t)
    call writer%init (model_name, prt_in, prt_out, &
        restrictions, openmp_support, report_progress, &
        extra_options, diags, diags_color)
end select
end subroutine omega_def_init

```

Write/read process- and method-specific data.

```

<Omega interface: omega def: TBP>+≡
    procedure :: write => omega_def_write

```

```

<Omega interface: procedures>+≡
    subroutine omega_def_write (object, unit)
        class(omega_def_t), intent(in) :: object
        integer, intent(in) :: unit
        select type (writer => object%writer)
        type is (omega_writer_t)
            call writer%write (unit)
        end select
    end subroutine omega_def_write

```

```

<Omega interface: omega def: TBP>+≡
    procedure :: read => omega_def_read

```

```

<Omega interface: procedures>+≡
    subroutine omega_def_read (object, unit)
        class(omega_def_t), intent(out) :: object
        integer, intent(in) :: unit
        call msg_bug ("O'Mega process definition: input not supported yet")
    end subroutine omega_def_read

```

Allocate the driver for O'MEGAmatrix elements.

```

<Omega interface: omega def: TBP>+≡
    procedure :: allocate_driver => omega_def_allocate_driver

```

```

<Omega interface: procedures>+≡
    subroutine omega_def_allocate_driver (object, driver, basename)
        class(omega_def_t), intent(in) :: object
        class(prc_core_driver_t), intent(out), allocatable :: driver
        type(string_t), intent(in) :: basename
        allocate (omega_driver_t :: driver)
    end subroutine omega_def_allocate_driver

```

We need code:

```

<Omega interface: omega def: TBP>+≡
    procedure, nopass :: needs_code => omega_def_needs_code

```

```

<Omega interface: procedures>+≡
  function omega_def_needs_code () result (flag)
    logical :: flag
    flag = .true.
  end function omega_def_needs_code

```

These are the features that an O'MEGA matrix element provides.

```

<Omega interface: omega def: TBP>+≡
  procedure, nopass :: get_features => omega_def_get_features

<Omega interface: procedures>+≡
  subroutine omega_def_get_features (features)
    type(string_t), dimension(:), allocatable, intent(out) :: features
    allocate (features (6))
    features = [ &
      var_str ("init"), &
      var_str ("update_alpha_s"), &
      var_str ("reset_helicity_selection"), &
      var_str ("is_allowed"), &
      var_str ("new_event"), &
      var_str ("get_amplitude")]
  end subroutine omega_def_get_features

```

The interface of the specific features.

```

<Omega interface: interfaces>≡
  abstract interface
    subroutine init_t (par) bind(C)
      import
      real(c_default_float), dimension(*), intent(in) :: par
    end subroutine init_t
  end interface

  abstract interface
    subroutine update_alpha_s_t (alpha_s) bind(C)
      import
      real(c_default_float), intent(in) :: alpha_s
    end subroutine update_alpha_s_t
  end interface

  abstract interface
    subroutine reset_helicity_selection_t (threshold, cutoff) bind(C)
      import
      real(c_default_float), intent(in) :: threshold
      integer(c_int), intent(in) :: cutoff
    end subroutine reset_helicity_selection_t
  end interface

  abstract interface
    subroutine is_allowed_t (flv, hel, col, flag) bind(C)
      import
      integer(c_int), intent(in) :: flv, hel, col
      logical(c_bool), intent(out) :: flag
    end subroutine is_allowed_t

```

```

end interface

abstract interface
  subroutine new_event_t (p) bind(C)
    import
    real(c_default_float), dimension(0:3,*), intent(in) :: p
  end subroutine new_event_t
end interface

abstract interface
  subroutine get_amplitude_t (flv, hel, col, amp) bind(C)
    import
    integer(c_int), intent(in) :: flv, hel, col
    complex(c_default_complex), intent(out):: amp
  end subroutine get_amplitude_t
end interface

```

Connect the O'MEGA features with the process driver.

```

<Omega interface: omega def: TBP>+≡
  procedure :: connect => omega_def_connect

<Omega interface: procedures>+≡
  subroutine omega_def_connect (def, lib_driver, i, proc_driver)
    class(omega_def_t), intent(in) :: def
    class(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i
    class(prc_core_driver_t), intent(inout) :: proc_driver
    integer(c_int) :: pid, fid
    type(c_funptr) :: fptr
    select type (proc_driver)
    type is (omega_driver_t)
      pid = i
      fid = 1
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%init)
      fid = 2
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%update_alpha_s)
      fid = 3
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%reset_helicity_selection)
      fid = 4
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%is_allowed)
      fid = 5
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%new_event)
      fid = 6
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%get_amplitude)
    end select
  end subroutine omega_def_connect

```

17.1.2 The O'MEGA writer

The O'MEGA writer is responsible for inserting the appropriate lines in the make-file that call O'MEGA, and for writing interfaces and wrappers.

```
<Omega interface: types>+≡
  type, extends (prc_writer_f_module_t) :: omega_writer_t
    type(string_t) :: model_name
    type(string_t) :: process_mode
    type(string_t) :: process_string
    type(string_t) :: restrictions
    logical :: openmp_support = .false.
    logical :: report_progress = .false.
    logical :: diags = .false.
    logical :: diags_color = .false.
    type(string_t) :: extra_options
  contains
    <Omega interface: omega writer: TBP>
  end type omega_writer_t
```

The reported type is the same as for the omega_def_t type.

```
<Omega interface: omega writer: TBP>≡
  procedure, nopass :: type_name => omega_writer_type_name

<Omega interface: procedures>+≡
  function omega_writer_type_name () result (string)
    type(string_t) :: string
    string = "omega"
  end function omega_writer_type_name
```

Taking into account the prefix for O'MEGA module names.

```
<Omega interface: omega writer: TBP>+≡
  procedure, nopass :: get_module_name => omega_writer_get_module_name

<Omega interface: procedures>+≡
  function omega_writer_get_module_name (id) result (name)
    type(string_t) :: name
    type(string_t), intent(in) :: id
    name = "opr_" // id
  end function omega_writer_get_module_name
```

Output. This is called by omega_def_write.

```
<Omega interface: omega writer: TBP>+≡
  procedure :: write => omega_writer_write

<Omega interface: procedures>+≡
  subroutine omega_writer_write (object, unit)
    class(omega_writer_t), intent(in) :: object
    integer, intent(in) :: unit
    write (unit, "(5x,A,A)") "Mode string      = ", &
      ''' // char (object%process_mode) // '''
    write (unit, "(5x,A,A)") "Process string  = ", &
      ''' // char (object%process_string) // '''
    write (unit, "(5x,A,A)") "Restrictions   = ", &
      ''' // char (object%restrictions) // '''
```

```

write (unit, "(5x,A,L1)") "OpenMP support    = ", object%openmp_support

17.1.3 Driver

(Omega interface: types)+≡

```
type, extends (prc_core_driver_t) :: omega_driver_t
```

```

    procedure(init_t), nopass, pointer :: &
        init => null ()
    procedure(update_alpha_s_t), nopass, pointer :: &
        update_alpha_s => null ()
    procedure(reset_helicity_selection_t), nopass, pointer :: &
        reset_helicity_selection => null ()
    procedure(is_allowed_t), nopass, pointer :: &
        is_allowed => null ()
    procedure(new_event_t), nopass, pointer :: &
        new_event => null ()
    procedure(get_amplitude_t), nopass, pointer :: &
        get_amplitude => null ()
contains
    <Omega interface: omega driver: TBP>
end type omega_driver_t

```

The reported type is the same as for the `omega_def_t` type.

```

<Omega interface: omega driver: TBP>≡
    procedure, nopass :: type_name => omega_driver_type_name

<Omega interface: procedures>+≡
    function omega_driver_type_name () result (string)
        type(string_t) :: string
        string = "omega"
    end function omega_driver_type_name

```

17.1.4 High-level process definition

This procedure wraps the details filling a process-component definition entry as appropriate for an O'MEGA matrix element.

NOTE: For calling the `import_component` method, we must explicitly address the `process_def_t` parent object. The natural way to call the method of the extended type triggers a bug in gfortran 4.6. The string array arguments `prt_in` and `prt_out` become corrupted and cause a segfault.

```

<Omega interface: procedures>+≡
    subroutine omega_make_process_component (entry, component_index, &
        model_name, prt_in, prt_out, restrictions, openmp_support, &
        report_progress, extra_options, diags, diags_color)
    class(process_def_entry_t), intent(inout) :: entry
    integer, intent(in) :: component_index
    type(string_t), intent(in) :: model_name
    type(string_t), dimension(:), intent(in) :: prt_in
    type(string_t), dimension(:), intent(in) :: prt_out
    type(string_t), intent(in), optional :: restrictions
    logical, intent(in), optional :: openmp_support
    logical, intent(in), optional :: report_progress
    logical, intent(in), optional :: diags, diags_color
    type(string_t), intent(in), optional :: extra_options
    class(prc_core_def_t), allocatable :: def
    allocate (omega_def_t :: def)
    select type (def)
    type is (omega_def_t)

```

```

        call def%init (model_name, prt_in, prt_out, &
                      restrictions, openmp_support, report_progress, &
                      extra_options, diags, diags_color)
    end select
    call entry%process_def_t%import_component (component_index, &
        n_out = size (prt_out), &
        prt_in = new_prt_spec (prt_in), &
        prt_out = new_prt_spec (prt_out), &
        method = var_str ("omega"), &
        variant = def)
end subroutine omega_make_process_component

```

17.1.5 The prc_omega_t wrapper

This is an instance of the generic `prc_core_t` object. It contains a pointer to the process definition (`omega_def_t`), a data component (`process_constants_t`), and the matrix-element driver (`omega_driver_t`).

```

<Omega interface: public>+≡
    public :: prc_omega_t

<Omega interface: types>+≡
    type, extends (prc_core_t) :: prc_omega_t
        real(default), dimension(:), allocatable :: par
        type(helicity_selection_t) :: helicity_selection
        type(qcd_t) :: qcd
        logical :: use_color_factors = .false.
    contains
        <Omega interface: prc omega: TBP>
    end type prc_omega_t

```

The workspace associated to a `prc_omega_t` object contains a single flag. The flag is used to suppress re-evaluating the matrix element for each quantum-number combination, after the first amplitude belonging to a given kinematics has been computed.

We can also store the value of a running coupling once it has been calculated for an event. The default value is negative, which indicates an undefined value in this context.

```

<Omega interface: types>+≡
    type, extends (workspace_t) :: omega_state_t
        logical :: new_kinematics = .true.
        real(default) :: alpha_qcd = -1
    contains
        procedure :: write => omega_state_write
    end type omega_state_t

<Omega interface: procedures>+≡
    subroutine omega_state_write (object, unit)
        class(omega_state_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit)
    end subroutine omega_state_write

```

```

        write (u, "(3x,A,L1)") "0'Mega state: new kinematics = ", &
            object%new_kinematics
    end subroutine omega_state_write

```

Allocate the workspace with the above specific type.

```

<Omega interface: prc omega: TBP>≡
    procedure :: allocate_workspace => prc_omega_allocate_workspace

<Omega interface: procedures>+≡
    subroutine prc_omega_allocate_workspace (object, tmp)
        class(prc_omega_t), intent(in) :: object
        class(workspace_t), intent(inout), allocatable :: tmp
        allocate (omega_state_t :: tmp)
    end subroutine prc_omega_allocate_workspace

```

The following procedures are inherited from the base type as deferred, thus must be implemented. The corresponding unit tests are skipped here; the procedures are tested when called from the `processes` module.

Output: print just the ID of the associated matrix element. Then display any stored parameters and the helicity selection data. (The latter are printed only if active.)

```

<Omega interface: prc omega: TBP>+≡
    procedure :: write => prc_omega_write

<Omega interface: procedures>+≡
    subroutine prc_omega_write (object, unit)
        class(prc_omega_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = output_unit (unit)
        write (u, "(3x,A)", advance="no") "0'Mega process core:"
        if (object%data_known) then
            write (u, "(1x,A)") char (object%data%id)
        else
            write (u, "(1x,A)") "[undefined]"
        end if
        if (allocated (object%par)) then
            write (u, "(3x,A)") "Parameter array:"
            do i = 1, size (object%par)
                write (u, "(5x,I0,1x,ES17.10)") i, object%par(i)
            end do
        end if
        call object%helicity_selection%write (u)
        call object%qcd%write (u)
    end subroutine prc_omega_write

```

Temporarily store the parameter array inside the `prc_omega` object, so we can use it later during the actual initialization. Also store threshold and cutoff for helicity selection.

```

<Omega interface: prc omega: TBP>+≡
    procedure :: set_parameters => prc_omega_set_parameters

```

```

<Omega interface: procedures>+≡
  subroutine prc_omega_set_parameters (prc_omega, model, &
    helicity_selection, qcd, use_color_factors)
    class(prc_omega_t), intent(inout) :: prc_omega
    type(model_t), intent(in), target, optional :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    logical, intent(in), optional :: use_color_factors
    if (present (model)) then
      if (allocated (prc_omega%par)) deallocate (prc_omega%par)

      prc_omega%helicity_selection = helicity_selection
    end if
    if (present (qcd)) then
      prc_omega%qcd = qcd
    end if
    if (present (use_color_factors)) then
      prc_omega%use_color_factors = use_color_factors
    end if
  end subroutine prc_omega_set_parameters

```

To fully initialize the process core, we perform base initialization, then initialize the external matrix element code.

This procedure overrides the `init` method of the base type, which we nevertheless can access via its binding `base_init`. When done, we have an allocated driver. The driver will call the `init` procedure for the external matrix element, and thus transfer the parameter set to where it finally belongs.

If requested, we initialize the helicity selection counter.

```

<Omega interface: prc omega: TBP>+≡
  procedure :: init => prc_omega_init

<Omega interface: procedures>+≡
  subroutine prc_omega_init (object, def, lib, id, i_component)
    class(prc_omega_t), intent(inout) :: object
    class(prc_core_def_t), intent(in), target :: def
    type(process_library_t), intent(in), target :: lib
    type(string_t), intent(in) :: id
    integer, intent(in) :: i_component
    call object%base_init (def, lib, id, i_component)
    call object%activate_parameters ()
  end subroutine prc_omega_init

```

Activate the stored parameters by transferring them to the external matrix element. Also reset the helicity selection, if requested.

```

<Omega interface: prc omega: TBP>+≡
  procedure :: activate_parameters => prc_omega_activate_parameters

<Omega interface: procedures>+≡
  subroutine prc_omega_activate_parameters (object)
    class (prc_omega_t), intent(inout) :: object

              c_default_float), &
              int (object%helicity_selection%cutoff, c_int))
        else
          call driver%reset_helicity_selection &
            (0._c_default_float, 0_c_int)
        end if
      end if
    end select
  end subroutine prc_omega_reset_helicity_selection

```

Compute the amplitude. For the tree-level process, we can ignore the scale settings. The term index `j` is also irrelevant.

We first call `new_event` for the given momenta (which we must unpack), then retrieve the amplitude value for the given quantum numbers.

If the `tmp` status flag is present, we can make sure that we call `new_event` only once for a given kinematics. After the first call, we unset the `new_kinematics` flag.

```

<Omega interface: prc omega: TBP>+≡

<Omega interface: tests>+≡
  subroutine prc_omega_diags_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Omega interface: execute diags tests>
end subroutine prc_omega_diags_test

```

Generate, compile and load a simple process matrix element

The process is $e^+e^- \rightarrow \mu^+\mu^-$ for vanishing masses and $e = 0.3$. We initialize the process, build the library, and compute a particular matrix element for momenta of unit energy and right-angle scattering. The matrix element, as it happens, is equal to e^2 . (Note that are no conversion factors applied, so this result is exact.)

For GNU make, makeflags is set to -j1. This eliminates a potential clash with a -j<n> flag if this test is called from a parallel make.

```

<Omega interface: execute tests>≡
  call test (prc_omega_1, "prc_omega_1", &
    "build and load simple OMega process", &
    u, results)

Check prc_omega_t wrapper and options

The process is $e^-e^+ \rightarrow e^-e^+$ for vanishing masses and $e = 0.3$. We build the library using the high-level procedure `omega_make_process_component` and

the “black box” `prc_omega_t` object. Two variants with different settings for restrictions and OpenMP.

For GNU make, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

```

QCD coupling

The process is $u\bar{u} \rightarrow d\bar{d}$ for vanishing masses. We compute the amplitude for a fixed configuration once, then reset α_s , then compute again.

For GNU make, makeflags is set to -j1. This eliminates a potential clash with a -j<n> flag if this test is called from a parallel make.

```

Chapter 18

Event I/O

In this chapter we provide a generic handler for event I/O and the various implementations: raw, HepMC, Les Houches, etc.

18.1 Event Sample Data

We define a simple and transparent container for (meta)data that are associated with an event sample.

```
<eio_data.f90>≡  
<File header>  
  
module eio_data  
  
    use kinds !NODEP!  
<Use file utils>  
<Use strings>  
    use diagnostics !NODEP!  
    use unit_tests  
  
    use events  
  
<EIO data: public>  
  
<EIO data: types>  
  
contains  
  
<EIO data: procedures>  
  
<EIO data: tests>  
  
end module eio_data
```

18.1.1 Event Sample Data

These are data that apply to an event sample as a whole. They are given in an easily portable form (no fancy structure) and are used for initializing event

formats.

There are two MD5 sums here. `md5sum_proc` depends only on the definition of the contributing processes. A sample with matching checksum can be rescanned with modified model parameters, beam structure etc, to recalculate observables. `md5sum_config` includes all relevant data. Rescanning a sample with matching checksum will produce identical observables. (A third checksum might be added which depends on the event sample itself. This is not needed, so far.)

If alternate weights are part of the event sample (`n_alt` nonzero), there is a configuration MD5 sum for each of them.

```

(EIO data: public)≡
  public :: event_sample_data_t

(EIO data: types)≡
  type :: event_sample_data_t
    character(32) :: md5sum_proc = ""
    character(32) :: md5sum_cfg = ""
    logical :: unweighted = .true.
    logical :: negative_weights = .false.
    integer :: norm_mode = NORM_UNDEFINED
    integer :: n_beam = 0
    integer, dimension(2) :: pdg_beam = 0
    real(default), dimension(2) :: energy_beam = 0
    integer :: n_proc = 0
    integer :: n_evt = 0
    integer :: split_n_evt = 0
    integer :: split_index = 0
    real(default) :: total_cross_section = 0
    integer, dimension(:), allocatable :: proc_num_id
    integer :: n_alt = 0
    character(32), dimension(:), allocatable :: md5sum_alt
    real(default), dimension(:), allocatable :: cross_section

18.2 Abstract I/O Handler

This module defines an abstract object for event I/O and the associated methods.

There are **output** and **input** methods which write or read a single event from/to the I/O stream, respectively. The I/O stream itself may be a file, a common block, or an externally linked structure, depending on the concrete implementation.

A **write** method prints the current content of the implementation-dependent event record in human-readable form.

The **init_in/init_out** and **final** prepare and finalize the I/O stream, respectively. There is also a **switch_inout** method which turns an input stream into an output stream where events can be appended.

Optionally, output files can be split in chunks of well-defined size. The `split_out` method takes care of this.

```

<eio_base.f90>≡
  <File header>

  module eio_base

    use kinds !NODEP!
    <Use file utils>
    <Use strings>
    use diagnostics !NODEP!
    use unit_tests

    use lorentz !NODEP!
    use models
    use particles
    use beams
    use processes
    use events
    use eio_data

    <Standard module head>

    <EIO base: public>

    <EIO base: types>

    <EIO base: interfaces>

    <EIO base: test types>

    contains

    <EIO base: procedures>

    <EIO base: tests>

  end module eio_base

```

18.2.1 Process pointer

For handling multiple processes, we need an array of process pointers. This requires a wrapper:

```

<EIO base: public>≡
  public :: process_ptr_t

<EIO base: types>≡
  type :: process_ptr_t
    type(process_t), pointer :: ptr => null ()
  end type process_ptr_t

```

18.2.2 Type

We can assume that most implementations will need the file extension as a fixed string and, if they support file splitting, the current file index.

```
<EIO base: public>+≡
    public :: eio_t

<EIO base: types>+≡
    type, abstract :: eio_t
        type(string_t) :: sample
        type(string_t) :: extension
        type(string_t) :: filename
        logical :: split = .false.
        integer :: split_n_evt = 0
        integer :: split_index = 0
    contains
        <EIO base: eio: TBP>
    end type eio_t
```

Write to screen. If possible, this should display the contents of the current event, i.e., the last one that was written or read.

```
<EIO base: eio: TBP>≡
    procedure (eio_write), deferred :: write

<EIO base: interfaces>≡
    abstract interface
        subroutine eio_write (object, unit)
            import
            class(eio_t), intent(in) :: object
            integer, intent(in), optional :: unit
        end subroutine eio_write
    end interface
```

Finalize. This should write/read footer data and close input/output channels.

```
<EIO base: eio: TBP>+≡
    procedure (eio_final), deferred :: final

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_final (object)
            import
            class(eio_t), intent(inout) :: object
        end subroutine eio_final
    end interface
```

Determine splitting parameters from the event sample data.

```
<EIO base: eio: TBP>+≡
    procedure :: set_splitting => eio_set_splitting

<EIO base: procedures>≡
    subroutine eio_set_splitting (eio, data)
        class(eio_t), intent(inout) :: eio
        type(event_sample_data_t), intent(in) :: data
        eio%split = data%split_n_evt > 0
```

```

    if (eio%split) then
        eio%split_n_evt = data%split_n_evt
        eio%split_index = data%split_index
    end if
end subroutine eio_set_splitting

```

Generate a filename, taking a possible split index into account.

```

<EIO base: eio: TBP>+≡
    procedure :: set_filename => eio_set_filename

<EIO base: procedures>+≡
    subroutine eio_set_filename (eio)
        class(eio_t), intent(inout) :: eio
        character(32) :: buffer
        if (eio%split) then
            write (buffer, "(I0,'.')") eio%split_index
            eio%filename = eio%sample // "." // trim (buffer) // eio%extension
        else
            eio%filename = eio%sample // "." // eio%extension
        end if
    end subroutine eio_set_filename

```

Initialize for output. We provide process pointers. This should open an event file if appropriate and write header data. Some methods may require event sample data.

```

<EIO base: eio: TBP>+≡
    procedure (eio_init_out), deferred :: init_out

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_init_out (eio, sample, process_ptr, data, success)
            import
            class(eio_t), intent(inout) :: eio
            type(string_t), intent(in) :: sample
            type(process_ptr_t), dimension(:), intent(in) :: process_ptr
            type(event_sample_data_t), intent(in), optional :: data
            logical, intent(out), optional :: success
        end subroutine eio_init_out
    end interface

```

Initialize for input. We provide process names. This should open an event file if appropriate and read header data. The md5sum can be used to check the integrity of the configuration, it it provides a checksum to compare with. In case the extension has changed the extension is also given as an argument.

The data argument is intent(inout): we may read part of it and keep other parts and/or check them against the data in the file.

```

<EIO base: eio: TBP>+≡
    procedure (eio_init_in), deferred :: init_in

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_init_in (eio, sample, process_ptr, data, success, extension)
            import

```

```

        class(eio_t), intent(inout) :: eio
        type(string_t), intent(in) :: sample
        type(string_t), intent(in), optional :: extension
        type(process_ptr_t), dimension(:), intent(in) :: process_ptr
        type(event_sample_data_t), intent(inout), optional :: data
        logical, intent(out), optional :: success
    end subroutine eio_init_in
end interface

```

Re-initialize for output. This should change the status of any event file from input to output and position it for appending new events.

```

<EIO base: eio: TBP>+≡
    procedure (eio_switch_inout), deferred :: switch_inout

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_switch_inout (eio, success)
            import
            class(eio_t), intent(inout) :: eio
            logical, intent(out), optional :: success
        end subroutine eio_switch_inout
    end interface

```

This is similar: split the output, i.e., close the current file and open a new one. The default implementation does nothing. For the feature to work, an implementation must override this.

```

<EIO base: eio: TBP>+≡
    procedure :: split_out => eio_split_out

<EIO base: procedures>+≡
    subroutine eio_split_out (eio)
        class(eio_t), intent(inout) :: eio
    end subroutine eio_split_out

```

Output an event. All data can be taken from the `event` record. The index `i_prc` identifies the process among the processes that are contained in the current sample. The `reading` flag, if present, indicates that the event was read from file, not generated.

```

<EIO base: eio: TBP>+≡
    procedure (eio_output), deferred :: output

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_output (eio, event, i_prc, reading)
            import
            class(eio_t), intent(inout) :: eio
            type(event_t), intent(in), target :: event
            integer, intent(in) :: i_prc
            logical, intent(in), optional :: reading
        end subroutine eio_output
    end interface

```

Input an event. This should fill all event data that cannot be inferred from the associated process.

The input is broken down into two parts. First we read the `i_prc` index. So we know which process to expect in the subsequent event. If we have reached end of file, we also will know. Then, we read the event itself.

The parameter `iostat` is supposed to be set as the Fortran standard requires, negative for EOF and positive for error.

```

<EIO base: eio: TBP>+≡
  procedure (eio_input_i_prc), deferred :: input_i_prc
  procedure (eio_input_event), deferred :: input_event

<EIO base: interfaces>+≡
  abstract interface
    subroutine eio_input_i_prc (eio, i_prc, iostat)
      import
      class(eio_t), intent(inout) :: eio
      integer, intent(out) :: i_prc
      integer, intent(out) :: iostat
    end subroutine eio_input_i_prc
  end interface

  abstract interface
    subroutine eio_input_event (eio, event, iostat)
      import
      class(eio_t), intent(inout) :: eio
      type(event_t), intent(inout), target :: event
      integer, intent(out) :: iostat
    end subroutine eio_input_event
  end interface

```

18.2.3 Unit tests

```

<EIO base: public>+≡
  public :: eio_base_test

<EIO base: tests>≡
  subroutine eio_base_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <EIO base: execute tests>
  end subroutine eio_base_test

```

Test type for event I/O

The contents simulate the contents of an external file. We have the `sample` string as the file name, `sqrts` and the array of `process_ids` as metadata, and the array of momenta `event_p` as the list of events. The second index is the event index. The `event_i` component is the pointer to the current event, `event_n` is the total number of stored events.

```

<EIO base: test types>≡
  type, extends (eio_t) :: eio_test_t

```

```

    real(default) :: sqrts
    type(string_t) :: process_id
    integer :: event_n = 0
    integer :: event_i = 0
    integer :: i_prc = 0
    type(vector4_t), dimension(:,,:), allocatable :: event_p
contains
    <EIO base: eio test: TBP>
end type eio_test_t

```

Write to screen. Pretend that this is an actual event format.

```

<EIO base: eio test: TBP>≡
    procedure :: write => eio_test_write

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

18.5 HEP Common Blocks

Long ago, to transfer data between programs one had to set up a common block and link both programs as libraries to the main executable. The HEP community standardizes several of those common blocks.

The modern way of data exchange uses data files with standard formats. However, the LHEF standard data format derives from a common block (actually, two).

WHIZARD used to support those common blocks, and LHEF was implemented via writing/reading blocks. We still keep this convention, but intend to eliminate common blocks (or any other static storage) from the workflow in the future. This will gain flexibility towards concurrent running of program images.

We encapsulate everything here in a module. The module holds the variables which are part of the common block.

Note: This code is taken essentially unchanged from WHIZARD 2.1 and does not (yet) provide unit tests.

```

    <HEP common: parameters>

    <HEP common: variables>

    <HEP common: common blocks>

contains

    <HEP common: procedures>

end module hep_common

```

18.5.1 Event characteristics

The maximal number of particles in an event record.

```

<HEP common: parameters>≡
    integer, parameter :: MAXNUP = 500

```

The number of particles in this event.

```

<HEP common: variables>≡
    integer :: NUP

```

The process ID for this event.

```

<HEP common: variables>+≡
    integer :: IDPRUP

```

The weight of this event (± 1 for unweighted events).

```

<HEP common: variables>+≡
    double precision :: XWGTUP

```

The factorization scale that is used for PDF calculation (-1 if undefined).

```

<HEP common: variables>+≡
    double precision :: SCALUP

```

The QED and QCD couplings α used for this event (-1 if undefined).

```

<HEP common: variables>+≡
    double precision :: AQEDUP
    double precision :: AQCDUP

```

18.5.2 Particle characteristics

The PDG code:

```

<HEP common: variables>+≡
    integer, dimension(MAXNUP) :: IDUP

```

The status code. Incoming: -1 , outgoing: $+1$. Intermediate t-channel propagator: -2 (currently not used by WHIZARD). Intermediate resonance whose mass should be preserved: 2 . Intermediate resonance for documentation: 3 (currently not used). Beam particles: -9 .

```

<HEP common: variables>+≡
    integer, dimension(MAXNUP) :: ISTUP

```

Index of first and last mother.

```

<HEP common: variables>+≡
    integer, dimension(2,MAXNUP) :: MOTHUP

```

Color line index of the color and anticolor entry for the particle. The standard recommends using large numbers; we start from MAXNUP+1.

```
<HEP common: variables>+≡
integer, dimension(2,MAXNUP) :: ICOLUP
```

Momentum, energy, and invariant mass: (p_x, p_y, p_z, E, M) . For space-like particles, M is the negative square root of the absolute value of the invariant mass.

```
<HEP common: variables>+≡
double precision, dimension(5,MAXNUP) :: PUP
```

Invariant lifetime (distance) from production to decay in mm.

```
<HEP common: variables>+≡
double precision, dimension(MAXNUP) :: VTIMUP
```

Cosine of the angle between the spin-vector and a particle and the 3-momentum of its mother, given in the lab frame. If undefined/unpolarized: 9.

```
<HEP common: variables>+≡
double precision, dimension(MAXNUP) :: SPINUP
```

18.5.3 The HEPUP common block

This common block is filled once per run.

Run characteristics

The maximal number of different processes.

```
<HEP common: parameters>+≡
integer, parameter :: MAXPUP = 100
```

The beam PDG codes.

```
<HEP common: variables>+≡
integer, dimension(2) :: IDBMUP
```

The beam energies in GeV.

```
<HEP common: variables>+≡
double precision, dimension(2) :: EBMUP
```

The PDF group and set for the two beams. (Undefined: use -1; LHAPDF: use group = 0).

```
<HEP common: variables>+≡
integer, dimension(2) :: PDFGUP
integer, dimension(2) :: PDFSUP
```

The (re)weighting model. 1: events are weighted, the shower generator (SHG) selects processes according to the maximum weight (in pb) and unweights events. 2: events are weighted, the SHG selects processes according to their cross section (in pb) and unweights events. 3: events are unweighted and simply run through the SHG. 4: events are weighted, and the SHG keeps the weight. Negative numbers: negative weights are allowed (and are reweighted to ± 1 by the SHG, if allowed).

WHIZARD only supports modes 3 and 4, as the SHG is not given control over process selection. This is consistent with writing events to file, for offline showering.

```
<HEP common: variables>+≡
integer :: IDWTUP
```

The number of different processes.

```
<HEP common: variables>+≡  
integer :: NPRUP
```

Process characteristics

Cross section and error in pb. (Cross section is needed only for IDWTUP = 2, so here both values are given for informational purposes only.)

```
<HEP common: variables>+≡  
double precision, dimension(MAXPUP) :: XSECUP  
double precision, dimension(MAXPUP) :: XERRUP
```

Maximum weight, i.e., the maximum value that XWGTUP can take. Also unused for the supported weighting models. It is ± 1 for unweighted events.

```
<HEP common: variables>+≡  
double precision, dimension(MAXPUP) :: XMAXUP
```

Internal ID of the selected process, matches IDPRUP below.

```
<HEP common: variables>+≡  
integer, dimension(MAXPUP) :: LPRUP
```

The common block

```
<HEP common: common blocks>≡  
common /HEPRUP/ &  
IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP, &  
XSECUP, XERRUP, XMAXUP, LPRUP  
save /HEPRUP/
```

Fill the run characteristics of the common block. The initialization sets the beam properties, number of processes, and weighting model.

```
<HEP common: public>≡  
public :: heprup_init
```

```
<HEP common: procedures>≡  
subroutine heprup_init &  
    (beam_pdg, beam_energy, n_processes, unweighted, negative_weights)  
    integer, dimension(2), intent(in) :: beam_pdg  
    real(default), dimension(2), intent(in) :: beam_energy  
    integer, intent(in) :: n_processes  
    logical, intent(in) :: unweighted  
    logical, intent(in) :: negative_weights  
    IDBMUP = beam_pdg  
    EBMUP = beam_energy  
    PDFGUP = -1  
    PDFSUP = -1  
    if (unweighted) then  
        IDWTUP = 3  
    else  
        IDWTUP = 4  
    end if  
    if (negative_weights) IDWTUP = - IDWTUP  
    NPRUP = n_processes
```

```
end subroutine heprup_init
```

Extract parameters from the common block. We leave it to the caller to specify which parameters it actually needs.

```
<HEP common: public>+≡
  public :: heprup_get_run_parameters

<HEP common: procedures>+≡
  subroutine heprup_get_run_parameters &
    (beam_pdg, beam_energy, n_processes, unweighted, negative_weights)
    integer, dimension(2), intent(out), optional :: beam_pdg
    real(default), dimension(2), intent(out), optional :: beam_energy
    integer, intent(out), optional :: n_processes
    logical, intent(out), optional :: unweighted
    logical, intent(out), optional :: negative_weights
    if (present (beam_pdg)) beam_pdg = IDBMUP
    if (present (beam_energy)) beam_energy = EBMUP
    ! PDFGUP = -1
    ! PDFSUP = -1
    if (present (n_processes)) n_processes = NPRUP
    if (present (unweighted)) then
      select case (abs (IDWTUP))
        case (3)
          unweighted = .true.
        case (4)
          unweighted = .false.
        case default
          unweighted = .false. ! don't know
      end select
    end if
    if (present (negative_weights)) then
      negative_weights = IDWTUP < 0
    end if
  end subroutine heprup_get_run_parameters
```

Specify PDF set info. Since we support only LHAPDF, the group entry is zero.

```
<HEP common: public>+≡
  public :: heprup_set_lhapdf_id

<HEP common: procedures>+≡
  subroutine heprup_set_lhapdf_id (i_beam, pdf_id)
    integer, intent(in) :: i_beam, pdf_id
    PDFGUP(i_beam) = 0
    PDFSUP(i_beam) = pdf_id
  end subroutine heprup_set_lhapdf_id
```

Fill the characteristics for a particular process. Only the process ID is mandatory. Note that WHIZARD computes cross sections in fb, so we have to rescale to pb. The maximum weight is meaningless for unweighted events.

```
<HEP common: public>+≡
  public :: heprup_set_process_parameters

        write (u, "(3x,A6,' = ',I9,3x,1x,I9,3x,8x,A)") "PDFGUP", PDFGUP, &
            "PDF author group [-1 = undefined]"
        write (u, "(3x,A6,' = ',I9,3x,1x,I9,3x,8x,A)") "PDFSUP", PDFSUP, &
            "PDF set ID [-1 = undefined]"
        write (u, "(3x,A6,' = ',I9,3x,1x,9x,3x,8x,A)") "IDWTUP", IDWTUP, &
            "LHA code for event weight mode"
        write (u, "(3x,A6,' = ',I9,3x,1x,9x,3x,8x,A)") "NPRUP ", NPRUP, &
            "Number of user subprocesses"
        do i = 1, NPRUP
            write (u, "(1x,A,I0)") "Subprocess #", i
            write (u, "(3x,A6,' = ',ES12.5,1x,12x,8x,A)") "XSECUP", XSECUP(i), &
                "Cross section in pb"
            write (u, "(3x,A6,' = ',ES12.5,1x,12x,8x,A)") "XERRUP", XERRUP(i), &
                "Cross section error in pb"
            write (u, "(3x,A6,' = ',ES12.5,1x,12x,8x,A)") "XMAXUP", XMAXUP(i), &
                "Maximum event weight (cf. IDWTUP)"
            write (u, "(3x,A6,' = ',I9,3x,1x,12x,8x,A)") "LPRUP ", LPRUP(i), &
                "Subprocess ID"
        end do
    end subroutine heprup_write_verbose

```

18.5.5 Run parameter output (other formats)

This routine writes the initialization block according to the LHEF standard. It uses the current contents of the HEPRUP block.

```

<HEP common: public>+≡
    public :: heprup_write_lhef

<HEP common: procedures>+≡
    subroutine heprup_write_lhef (unit)
        integer, intent(in), optional :: unit

```

```

integer :: u, i
u = output_unit (unit); if (u < 0) return
write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
      IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
do i = 1, NPRUP
  write (u, "(3(1x,ES17.10),1x,I0)") &
    XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
end do
end subroutine heprup_write_lhef

```

This routine is a complete dummy at the moment. It uses the current contents of the HEPRUP block. At the end, it should depend on certain input flags for the different ASCII event formats.

```

<HEP common: public>+≡
  public :: heprup_write_ascii

<HEP common: procedures>+≡
  subroutine heprup_write_ascii (unit)
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit); if (u < 0) return
    write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
      IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
    do i = 1, NPRUP
      write (u, "(3(1x,ES17.10),1x,I0)") &
        XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
    end do
  end subroutine heprup_write_ascii

```

Run parameter input (LHEF)

In a LHEF file, the parameters are written in correct order on separate lines, but we should not count on the precise format. List-directed input should just work.

```

<HEP common: public>+≡
  public :: heprup_read_lhef

<HEP common: procedures>+≡
  subroutine heprup_read_lhef (u)
    integer, intent(in) :: u
    integer :: i
    read (u, *) &
      IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
    do i = 1, NPRUP
      read (u, *) &
        XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
    end do
  end subroutine heprup_read_lhef

```

18.5.6 The HEPEUP common block

```
<HEP common: common blocks>+≡
common /HEPEUP/ &
    NUP, IDPRUP, XWGTUP, SCALUP, AQEDUP, AQCDUP, &
    IDUP, ISTUP, MOTHUP, ICOLUP, PUP, VTIMUP, SPINUP
save /HEPEUP/
```

Initialization

Fill the event characteristics of the common block. The initialization sets only the number of particles and initializes the rest with default values. The other routine sets the optional parameters.

```
<HEP common: public>+≡
public :: hepeup_init
public :: hepeup_set_event_parameters

<HEP common: procedures>+≡
subroutine hepeup_init (n_tot)
    integer, intent(in) :: n_tot
    NUP = n_tot
    IDPRUP = 0
    XWGTUP = 1
    SCALUP = -1
    AQEDUP = -1
    AQCDUP = -1
end subroutine hepeup_init

subroutine hepeup_set_event_parameters &
    (proc_id, weight, scale, alpha_qed, alpha_qcd)
    integer, intent(in), optional :: proc_id
    real(default), intent(in), optional :: weight, scale, alpha_qed, alpha_qcd
    if (present (proc_id)) IDPRUP = proc_id
    if (present (weight)) XWGTUP = weight
    if (present (scale)) SCALUP = scale
    if (present (alpha_qed)) AQEDUP = alpha_qed
    if (present (alpha_qcd)) AQCDUP = alpha_qcd
end subroutine hepeup_set_event_parameters
```

Extract event information. The caller determines the parameters.

```
<HEP common: public>+≡
public :: hepeup_get_event_parameters

<HEP common: procedures>+≡
subroutine hepeup_get_event_parameters &
    (proc_id, weight, scale, alpha_qed, alpha_qcd)
    integer, intent(out), optional :: proc_id
    real(default), intent(out), optional :: weight, scale, alpha_qed, alpha_qcd
    if (present (proc_id)) proc_id = IDPRUP
    if (present (weight)) weight = XWGTUP
    if (present (scale)) scale = SCALUP
    if (present (alpha_qed)) alpha_qed = AQEDUP
    if (present (alpha_qcd)) alpha_qcd = AQCDUP
```

```
end subroutine hepeup_get_event_parameters
```

Particle data

Below we need the particle status codes which are actually defined in the `subevents` module.

Set the entry for a specific particle. All parameters are set with the exception of lifetime and spin, where default values are stored.

```
<HEP common: public>+≡
  public :: hepeup_set_particle

<HEP common: procedures>+≡
  subroutine hepeup_set_particle (i, pdg, status, parent, col, p, m2)
    integer, intent(in) :: i
    integer, intent(in) :: pdg, status
    integer, dimension(:), intent(in) :: parent
    type(vector4_t), intent(in) :: p
    integer, dimension(2), intent(in) :: col
    real(default), intent(in) :: m2
    if (i > MAXNUP) then
      call msg_error (arr=(/ &
var_str ("Too many particles in HEPEUP common block. If this happened "), &
var_str ("during event output, your events will be invalid; please consider "), &
var_str ("switching to a modern event format like HEPMC. If you are not "), &
var_str ("using an old, HEPEUP based format and nevertheless get this error,"), &
var_str ("please notify the WHIZARD developers,") &
      /))
      return
    end if
    IDUP(i) = pdg
    select case (status)
    case (PRT_BEAM);          ISTUP(i) = -9
    case (PRT_INCOMING);      ISTUP(i) = -1
    case (PRT_BEAM_REMNANT);  ISTUP(i) = 3
    case (PRT_OUTGOING);      ISTUP(i) = 1
    case (PRT_RESONANT);      ISTUP(i) = 2
    case (PRT_VIRTUAL);       ISTUP(i) = 3
    case default;             ISTUP(i) = 0
    end select
    select case (size (parent))
    case (0);      MOTHUP(:,i) = 0
    case (1);      MOTHUP(1,i) = parent(1); MOTHUP(2,i) = 0
    case default;  MOTHUP(:,i) = (/ parent(1), parent(size (parent)) /)
    end select
    if (col(1) > 0) then
      ICOLUP(1,i) = 500 + col(1)
    else
      ICOLUP(1,i) = 0
    end if
    if (col(2) > 0) then
      ICOLUP(2,i) = 500 + col(2)
    else
      ICOLUP(2,i) = 0
    end if
  end subroutine
```

```

end if
PUP(1:3,i) = vector3_get_components (space_part (p))
PUP(4,i) = energy (p)
PUP(5,i) = sign (sqrt (abs (m2)), m2)
VTIMUP(i) = 0
SPINUP(i) = 9
end subroutine hepeup_set_particle

```

Set the lifetime, actually $c\tau$ measured in mm, where τ is the invariant lifetime.

```

<HEP common: public>+=
  public :: hepeup_set_particle_lifetime

<HEP common: procedures>+=
  subroutine hepeup_set_particle_lifetime (i, lifetime)
    integer, intent(in) :: i
    real(default), intent(in) :: lifetime
    VTIMUP(i) = lifetime
  end subroutine hepeup_set_particle_lifetime

```

Set the particle spin entry. We need the cosine of the angle of the spin axis with respect to the three-momentum of the parent particle.

If the particle has a full polarization density matrix given, we need the particle momentum and polarization as well as the mother-particle momentum. The polarization is transformed into a spin vector (which is sensible only for spin-1/2 or massless particles), which then is transformed into the lab frame (by a rotation of the 3-axis to the particle momentum axis). Finally, we compute the scalar product of this vector with the mother-particle three-momentum.

This puts severe restrictions on the applicability of this definition, and Lorentz invariance is lost. Unfortunately, the Les Houches Accord requires this computation.

```

<HEP common: public>+=
  public :: hepeup_set_particle_spin

<HEP common: interfaces>=
  interface hepeup_set_particle_spin
    module procedure hepeup_set_particle_spin_pol
  end interface

<HEP common: procedures>+=
  subroutine hepeup_set_particle_spin_pol (i, p, pol, p_mother)
    integer, intent(in) :: i
    type(vector4_t), intent(in) :: p
    type(polarization_t), intent(in) :: pol
    type(vector4_t), intent(in) :: p_mother
    type(vector3_t) :: s3, p3
    type(vector4_t) :: s4
    s3 = vector3_moving (polarization_get_axis (pol))
    p3 = space_part (p)
    s4 = rotation_to_2nd (3, p3) * vector4_moving (0._default, s3)
    SPINUP(i) = enclosed_angle_ct (s4, p_mother)
  end subroutine hepeup_set_particle_spin_pol

```

Extract particle data. The caller decides which ones to retrieve.

Status codes: beam remnants share the status code with virtual particles. However, for the purpose of WHIZARD we should identify them. We use the PDG code for this.

```

<HEP common: public>+≡
  public :: hepeup_get_particle

```

18.5.7 The HEPEVT common block

For the LEP Monte Carlos, a standard common block has been proposed in AKV89. We strongly recommend its use. (The description is an abbreviated transcription of AKV89, Vol. 3, pp. 327-330).

NMXHEP is the maximum number of entries:

```
<HEP common: variables>+≡  
integer, parameter :: NMXHEP = 4000
```

NEVHEP is normally the event number, but may take special values as follows:

0 the program does not keep track of event numbers. -1 a special initialization record. -2 a special final record.

```
<HEP common: variables>+≡  
integer :: NEVHEP
```

NHEP holds the number of entries for this event.

```
<HEP common: variables>+≡  
integer :: NHEP
```

The entry ISTHEP(N) gives the status code for the Nth entry, with the following semantics: 0 a null entry. 1 an existing entry, which has not decayed or fragmented. 2 a decayed or fragmented entry, which is retained for event history information. 3 documentation line. 4- 10 reserved for future standards. 11-200 at the disposal of each model builder. 201- at the disposal of users.

```
<HEP common: variables>+≡  
integer, dimension(NMXHEP) :: ISTHEP
```

The Particle Data Group has proposed standard particle codes, which are to be stored in IDHEP(N).

```
<HEP common: variables>+≡  
integer, dimension(NMXHEP) :: IDHEP
```

JMOHEP(1,N) points to the mother of the Nth entry, if any. It is set to zero for initial entries. JMOHEP(2,N) points to the second mother, if any.

```
<HEP common: variables>+≡  
integer, dimension(2, NMXHEP) :: JMOHEP
```

JDAHEP(1,N) and JDAHEP(2,N) point to the first and last daughter of the Nth entry, if any. These are zero for entries which have not yet decayed. The other daughters are stored in between these two.

```
<HEP common: variables>+≡  
integer, dimension(2, NMXHEP) :: JDAHEP
```

In PHEP we store the momentum of the particle, more specifically this means that PHEP(1,N), PHEP(2,N), and PHEP(3,N) contain the momentum in the x , y , and z direction (as defined by the machine people), measured in GeV/c. PHEP(4,N) contains the energy in GeV and PHEP(5,N) the mass in GeV/ c^2 . The latter may be negative for spacelike partons.

```
<HEP common: variables>+≡
```

```
double precision, dimension(5, NMXHEP) :: PHEP
```

Finally VHEP is the place to store the position of the production vertex. VHEP(1,N), VHEP(2,N), and VHEP(3,N) contain the x , y , and z coordinate (as defined by the machine people), measured in mm. VHEP(4,N) contains the production time in mm/c.

```
<HEP common: variables>+≡
double precision, dimension(4, NMXHEP) :: VHEP
```

As an amendment to the proposed standard common block HEPEVT, we also have a polarisation common block HEPSPN, as described in AKV89. SHEP(1,N), SHEP(2,N), and SHEP(3,N) give the x , y , and z component of the spinvector s of a fermion in the fermions restframe.

Furthermore, we add the polarization of the corresponding outgoing particles:

```
<HEP common: variables>+≡
integer, dimension(NMXHEP) :: hepevt_pol
```

By convention, SHEP(4,N) is always 1. All this is taken from StdHep 4.06 manual and written using Fortran90 conventions.

```
<HEP common: common blocks>+≡
common /HEPEVT/ &
    NEVHEP, NHEP, ISTHEP, IDHEP, &
    JMOHEP, JDAHEP, PHEP, VHEP
save /HEPEVT/
```

Here we store HEPEVT parameters of the WHIZARD 1 realization which are not part of the HEPEVT common block.

```
<HEP common: variables>+≡
integer :: hepevt_n_out, hepevt_n_remnants
```

```
<HEP common: variables>+≡
double precision :: hepevt_weight, hepevt_function_value
double precision :: hepevt_function_ratio
```

Filling HEPEVT: If the event count is not provided, set NEVHEP to zero. If the event count is -1 or -2, the record corresponds to initialization and finalization, and the event is irrelevant.

Note that the event count may be larger than 2^{31} (2 GEvents). In that case, cut off the upper bits since NEVHEP is probably limited to default integer.

```
<HEP common: public>+≡
public :: hepevt_init
public :: hepevt_set_event_parameters
```

```
<HEP common: procedures>+≡
subroutine hepevt_init (n_tot, n_out)
integer, intent(in) :: n_tot, n_out
NHEP = n_tot
NEVHEP = 0
hepevt_n_out = n_out
```

```

    hepevt_n_remnants = 0
    hepevt_weight      = 1
    hepevt_function_value = 0
    hepevt_function_ratio = 1
end subroutine hepevt_init

subroutine hepevt_set_event_parameters &
    (weight, function_value, function_ratio, i_evt)
    integer, intent(in), optional :: i_evt
    real(default), intent(in), optional :: weight, function_value, &
        function_ratio
    integer(i32), parameter :: huge32 = huge (0_i32)
    if (present (i_evt)) NEVHEP = i_evt
    if (present (weight)) hepevt_weight = weight
    if (present (function_value)) hepevt_function_value = &
        function_value
    if (present (function_ratio)) hepevt_function_ratio = &
        function_ratio
end subroutine hepevt_set_event_parameters

```

Set the entry for a specific particle. All parameters are set with the exception of lifetime and spin, where default values are stored.

```

    end do
  end subroutine hepeup_write_lha

```

This routine writes event output according to the HEPEVT standard. It uses the current contents of the HEPEVT block and some additional parameters according to the standard in WHIZARD 1. For the long ASCII format, the value of the sample function (i.e. the product of squared matrix element, structure functions and phase space factor is printed out). The option of reweighting matrix elements with respect to some reference cross section is not implemented in WHIZARD 2, therefore the second entry in the long ASCII format (the function ratio) is always one. The ATHENA format is an implementation of the HEPEVT format that is readable by the ATLAS ATHENA software framework. It is very similar to the WHIZARD 1 HEPEVT format, except that it contains an event counter, a particle counter inside the event, and has the HEPEVT ISTHEP status before the PDG code. The MOKKA format is a special ASCII format that contains the information to be parsed to the MOKKA LC fast simulation software.

18.5.11 Data Transfer: particle sets

The WHIZARD format for handling particle data in events is `particle_set_t`. We have to interface this to the common blocks.

We first create a new particle set that contains only the particles that are supported by the LHEF format. These are: beam, incoming, resonant, outgoing. We drop particles with unknown, virtual or beam-remnant status.

From this set we fill the common block. Event information such as process ID and weight is not transferred here; this has to be done by the caller. The spin information is set only if the particle has a unique mother, and if its polarization is fully defined.

```

<HEP common: public>+≡
  public :: hepeup_from_particle_set

<HEP common: procedures>+≡
  subroutine hepeup_from_particle_set (particle_set, keep_beams)
    type(particle_set_t), intent(in), target :: particle_set
    logical, intent(in), optional :: keep_beams
    type(particle_t), pointer :: prt
    type(particle_set_t), target :: pset_hepevt
    integer :: i, n_parents
    integer, dimension(1) :: i_mother
    call particle_set_to_hepevt_form (particle_set, pset_hepevt, keep_beams)
    call hepeup_init (pset_hepevt%n_tot)
    do i = 1, pset_hepevt%n_tot
      prt => pset_hepevt%prt(i)
      call hepeup_set_particle (i, &
        particle_get_pdg (prt), &
        particle_get_status (prt), &
        particle_get_parents (prt), &
        particle_get_color (prt), &
        particle_get_momentum (prt), &
        particle_get_p2 (prt))
      n_parents = particle_get_n_parents (prt)
      if (n_parents == 1) then
        i_mother = particle_get_parents (prt)
        select case (particle_get_polarization_status (prt))
          case (PRT_GENERIC_POLARIZATION)
            call hepeup_set_particle_spin (i, &
              particle_get_momentum (prt), &
              particle_get_polarization (prt), &
              particle_get_momentum (pset_hepevt%prt(i_mother(1))))
        end select
      end if
    end do
    call particle_set_final (pset_hepevt)
  end subroutine hepeup_from_particle_set

```

Input. The particle set should be allocated properly, but we replace the particle contents.

If there are no beam particles in the event, we try to reconstruct beam particles and beam remnants. We assume for simplicity that the beam particles, if any, are the first two particles. If they are absent, the first two particles should be the incoming partons.

```

<HEP common: public>+≡
  public :: hepeup_to_particle_set

```

```

<HEP common: procedures>+≡
subroutine hepeup_to_particle_set (particle_set, recover_beams)
  type(particle_set_t), intent(inout), target :: particle_set
  logical, intent(in), optional :: recover_beams
  type(particle_t), dimension(:), allocatable :: prt
  integer, dimension(:), allocatable :: child
  integer :: i, j, k, pdg, status
  type(flavor_t) :: flv
  type(color_t) :: col
  integer, dimension(2) :: c
  type(vector4_t) :: p
  real(default) :: p2
  integer, dimension(1) :: i_mother
  logical :: reconstruct
  integer :: off
  if (present (recover_beams)) then
    reconstruct = recover_beams .and. .not. all (ISTUP(1:2) == PRT_BEAM)
  else
    reconstruct = .false.
  end if
  if (reconstruct) then
    off = 4
  else
    off = 0
  end if
  allocate (prt (NUP + off), child (NUP + off))
  if (reconstruct) then
    do k = 1, 2
      call particle_reset_status (prt(k), PRT_BEAM)
      call particle_set_children (prt(k), [k+2,k+4])
    end do
    do k = 3, 4
      call particle_reset_status (prt(k), PRT_BEAM_REMNANT)
      call particle_set_parents (prt(k), [k-2])
    end do
  end if
  do i = 1, NUP
    k = i + off
    call hepeup_get_particle (i, pdg, status, col = c, p = p, m2 = p2)
    call particle_reset_status (prt(k), status)
    call flavor_init (flv, pdg)
    call particle_set_flavor (prt(k), flv)
    call color_init (col, c)
    call particle_set_color (prt(k), col)
    call particle_set_momentum (prt(k), p, p2)
    call particle_set_parents (prt(k), MOTHUP(:,i) + off)
    child = [(j, j = 1 + off, NUP + off)]
    where (MOTHUP(1,:NUP) /= i .and. MOTHUP(2,:NUP) /= i) child = 0
    call particle_set_children (prt(k), child)
  end do
  if (reconstruct) then
    do k = 5, 6
      call particle_set_parents (prt(k), [k-4])
    end do
  end if
end subroutine

```

```

else
    call handle_beams (prt)
end if
call particle_set_replace (particle_set, prt)
end subroutine hepeup_to_particle_set

```

Beams and beam remnants require a special handling. WHIZARD's interactions are set up such that in the list of children of beam particles, the remnant comes before the interacting parton. To enforce this, we may have to reorder things.

The beam particles will always be the first two particles.

```

<HEP common: procedures>+≡
subroutine handle_beams (prt)
    type(particle_t), dimension(:), intent(inout) :: prt
    integer :: i
    integer, dimension(2) :: child
    do i = 1, 2
        select case (particle_get_status (prt(i)))
        case (PRT_BEAM)
            child = particle_get_children (prt(i))
            if (particle_get_status (prt(child(2))) == PRT_BEAM_REMNANT) then
                call particle_set_children (prt(i), child([2,1]))
            end if
        end select
    end do
end subroutine handle_beams

```

The HEPEVT common block is quite similar, but does contain less information, e.g. no color flows (it was LEP time). The spin information is set only if the particle has a unique mother, and if its polarization is fully defined.

```

<HEP common: public>+≡
public :: hepevt_from_particle_set

<HEP common: procedures>+≡
subroutine hepevt_from_particle_set (particle_set, keep_beams)
    type(particle_set_t), intent(in), target :: particle_set
    type(particle_t), pointer :: prt
    type(particle_set_t), target :: pset_hepevt
    logical, intent(in), optional :: keep_beams
    integer :: i
    call particle_set_to_hepevt_form (particle_set, pset_hepevt, keep_beams)
    call hepevt_init (pset_hepevt%n_tot, pset_hepevt%n_out)
    do i = 1, pset_hepevt%n_tot
        prt => pset_hepevt%prt(i)
        call hepevt_set_particle (i, &
            particle_get_pdg (prt), &
            particle_get_status (prt), &
            particle_get_parents (prt), &
            particle_get_children (prt), &
            particle_get_momentum (prt), &
            particle_get_p2 (prt), &
            particle_get_helicity (prt))
    end do
    call particle_set_final (pset_hepevt)

```

```
end subroutine hepevt_from_particle_set
```

18.5.12 Data Transfer: events

Fill the HEPEUP block, given a WHIZARD event object.

```
<HEP common: public>+≡
  public :: hepeup_from_event

<HEP common: procedures>+≡
  subroutine hepeup_from_event (event, keep_beams, process_index)
    type(event_t), intent(in), target :: event
    logical, intent(in), optional :: keep_beams
    integer, intent(in), optional :: process_index
    type(particle_set_t), pointer :: particle_set
    real(default) :: scale, alpha_qcd
    if (event%has_particle_set ()) then
      particle_set => event%get_particle_set_ptr ()
      call hepeup_from_particle_set (particle_set, keep_beams)
      if (present (process_index)) &
        call hepeup_set_event_parameters (proc_id = process_index)
      scale = event%get_fac_scale ()
      if (scale /= 0) &
        call hepeup_set_event_parameters (scale = scale)
      alpha_qcd = event%get_alpha_s ()
      if (alpha_qcd /= 0) &
        call hepeup_set_event_parameters (alpha_qcd = alpha_qcd)
      if (event%weight_prc_is_known) then
        call hepeup_set_event_parameters (weight = event%weight_prc)
      else
        call msg_bug ("HEPEUP: process weight is unknown")
      end if
    else
      call msg_bug ("HEPEUP: event incomplete")
    end if
  end subroutine hepeup_from_event
```

Reverse.

Note: The current implementation sets the particle set of the hard process and is therefore not useful if the event on file is dressed. This should be reconsidered.

```
<HEP common: public>+≡
  public :: hepeup_to_event

<HEP common: procedures>+≡
  subroutine hepeup_to_event (event, process_index, recover_beams)
    type(event_t), intent(inout), target :: event
    integer, intent(out), optional :: process_index
    logical, intent(in), optional :: recover_beams
    real(default) :: weight, scale, alpha_qcd
    type(particle_set_t) :: particle_set
    call hepeup_to_particle_set (particle_set, recover_beams)
    call event%set_particle_set_hard_proc (particle_set)
```

```

call particle_set_final (particle_set)
if (present (process_index)) then
  call hepeup_get_event_parameters (proc_id = process_index)
end if
call hepeup_get_event_parameters (weight = weight, &
  scale = scale, alpha_qcd = alpha_qcd)
call event%set (weight_ref = weight)
!   if (scale > 0) call event%set_scales (scale)
!   if (alpha_qcd > 0) call event%set_alpha_qcd (alpha_qcd)
end subroutine hepeup_to_event

```

Fill the HEPEVT (event) common block:

```

<HEP common: public>+≡
  public :: hepevt_from_event

<HEP common: procedures>+≡
  subroutine hepevt_from_event (event, i_evt, keep_beams)
    type(event_t), intent(in), target :: event
    integer, intent(in), optional :: i_evt
    logical, intent(in), optional :: keep_beams
    type(particle_set_t), pointer :: particle_set
    if (event%has_particle_set ()) then
      particle_set => event%get_particle_set_ptr ()
      call hepevt_from_particle_set (particle_set, keep_beams)
      if (event%weight_prc_is_known .and. event%sqme_prc_is_known) then
        call hepevt_set_event_parameters ( &
          weight = event%weight_prc, &
          function_value = event%sqme_prc)
      else
        call msg_bug ("HEPEVT: event weight and/or sqme unknown")
      end if
      if (present (i_evt)) &
        call hepevt_set_event_parameters (i_evt = i_evt)
    else
      call msg_bug ("HEPEVT: event incomplete")
    end if
  end subroutine hepevt_from_event

```

18.6 LHEF Input/Output

The LHEF event record is standardized. It is an ASCII format. We try our best at using it for both input and output.

```
