Input an event. Upon input of `i_prc`, we can just read in the whole HEPEUP common block. These data are known to come first. The `i_prc` value can be deduced from the IDPRUP value by a table lookup.

Reading the common block bypasses the `cstream` which accesses the input unit. This is consistent with the LHEF specification. After the common-block data have been swallowed, we can resume reading from stream.

We don't catch actual I/O errors. However, we return a negative value in `iostat` if we reached the terminating `</LesHouchesEvents>` tag.

Since we have already read the event information from file, this input routine can transfer the common-block contents to the event record. Also, we read any further information in the event record.

Since LHEF doesn't give this information, we must assume that the MCI group, term, and channel can all be safely set to 1. This works if there is only one MCI group and term. The channel doesn't matter for the matrix element.

```

18.6.5 Version-Specific Code: 1.0

In version 1.0, the init tag contains just HEPUP data. While a `cstream` is connected to the input unit, we bypass it temporarily for the purpose of reading the HEPUP contents. This is consistent with the LHEF standard.

This routine does not read the closing tag of the init block.

```

<EIO LHEF: eio_lhef: TBP>+≡
  procedure :: read_init_10 => eio_lhef_read_init_10

<EIO LHEF: procedures>+≡
  subroutine eio_lhef_read_init_10 (eio, data)
    class(eio_lhef_t), intent(in) :: eio
    type(event_sample_data_t), intent(out) :: data
    integer :: n_proc, i
    call heprup_read_lhef (eio%unit)
    call heprup_get_run_parameters (n_processes = n_proc)
    call data%init (n_proc)
    data%n_beam = 2
    call heprup_get_run_parameters ( &
      unweighted = data%unweighted, &
      negative_weights = data%negative_weights, &
      beam_pdg = data%pdg_beam, &
      beam_energy = data%energy_beam)
    if (data%unweighted) then
      data%norm_mode = NORM_UNIT
    else
      data%norm_mode = NORM_SIGMA
    end if
  end if

```

```

do i = 1, n_proc
  call heprup_get_process_parameters (i, &
    process_id = data%proc_num_id(i), &
    cross_section = data%cross_section(i), &
    error = data%error(i))
end do
end subroutine eio_lhef_read_init_10

```

18.6.6 Version-Specific Code: 2.0

This is the init information for the 2.0 format, after the HEPUP data. We have the following tags:

- **generator** Generator name and version.
- **xsecinfo** Cross section and weights data. We have the total cross section and number of events (assuming that the event file is intact), but information on minimum and maximum weights is not available before the file is complete. We just write the mandatory tags. (Note that the default values of the other tags describe a uniform unit weight, but we can determine most values only after the sample is complete.)
- **cutsinfo** This optional tag is too specific to represent the possibilities of WHIZARD, so we skip it.
- **procinfo** This optional tag is useful for giving details of NLO calculations. Skipped.
- **mergetype** Optional, also not applicable.

```

<EIO LHEF: eio lhef: TBP>+≡
  procedure :: write_init_20 => eio_lhef_write_init_20

<EIO LHEF: procedures>+≡
  subroutine eio_lhef_write_init_20 (eio, data)
    class(eio_lhef_t), intent(in) :: eio
    type(event_sample_data_t), intent(in) :: data

```

This is additional event-specific information for the 3.0 format, after the HEP-EUP data. We can specify weights, starting from the master weight and adding alternative weights. The weight tags are already allocated, so we just have to transfer the weight values to strings, assemble them and write them to file. All weights are collected in a single tag.

Note: If efficiency turns out to be an issue, we may revert to traditional character buffer writing. However, we need to know the maximum length.

```

<EIO LHEF: eio lhef: TBP>+≡
    procedure :: write_event_30 => eio_lhef_write_event_30
<EIO LHEF: procedures>+≡
    subroutine eio_lhef_write_event_30 (eio, event)
        class(eio_lhef_t), intent(in) :: eio
        type(event_t), intent(in) :: event

                do i = 2, eio%n_alt
                    s = s // str (event%sqme_alt(i)) // " "
                end do
            end if
            s = s // str (event%weight_alt(1)) // " "
            do i = 2, eio%n_alt

```

```

        s = s // str (event%weight_alt(i)) // " "
    end do
end if
if (len_trim (s) > 0) then
    call eio%tag_weights%write (trim (s), u); write (u, *)
end if
end subroutine eio_lhef_write_event_30

```

Read extra event data. If there is a `weights` tag and if there was a `weightinfo` entry labeled `sqme_prc`, we extract the corresponding entry from the `weights` string and store this as the event's squared matrix-element value. Other tags, including tags written by the above writer, are skipped.

18.6.8 Auxiliary

Create a string from a number. We use fixed format for the reals and variable format for integers.

```
<EIO LHEF: interfaces>≡
  interface str
    module procedure str_int, str_real
  end interface

<EIO LHEF: procedures>+≡
  function str_int (i) result (s)
    integer, intent(in) :: i
    type(string_t) :: s
    character(32) :: buffer
    write (buffer, "(I0)") i
    s = var_str (trim (buffer))
  end function str_int

  function str_real (x) result (s)
    real(default), intent(in) :: x
    type(string_t) :: s
    character(32) :: buffer
    write (buffer, "(ES17.10)") x
    s = var_str (trim (adjustl (buffer)))
  end function str_real
```

Auxiliary: Read real, integer, string value.

```
<EIO LHEF: procedures>+≡
  function read_rval (s) result (rval)
    type(string_t), intent(in) :: s
    real(default) :: rval
    character(80) :: buffer
    buffer = s
    read (buffer, *) rval
  end function read_rval

  function read_ival (s) result (ival)
    type(string_t), intent(in) :: s
    integer :: ival
    character(80) :: buffer
    buffer = s
    read (buffer, *) ival
  end function read_ival
```

18.6.9 Unit tests

```
<EIO LHEF: public>+≡
  public :: eio_lhef_test
```

```

18.7 HepMC events

This section provides the interface to the HepMC C++ library for handling Monte-Carlo events.

Each C++ class of HepMC that we use is mirrored by a Fortran type, which contains as its only component the C pointer to the C++ object.

Each C++ method of HepMC that we use has a C wrapper function. This function takes a pointer to the host object as its first argument. Further arguments are either C pointers, or in the case of simple types (integer, real), interoperable C/Fortran objects.

The C wrapper functions have explicit interfaces in the Fortran module. They are called by Fortran wrapper procedures. These are treated as methods of the corresponding Fortran type.

```
(hepmc_interface.f90)≡  
  <File header>  
  
  module hepmc_interface  
  
    use iso_c_binding !NODEP!  
    <Use kinds>  
    <Use strings>  
    <Use file utils>  
    use constants !NODEP!  
    use lorentz !NODEP!  
    use unit_tests  
    use models  
    use flavors  
    use colors  
    use helicities  
    use quantum_numbers  
    use polarizations  
  
    <Standard module head>  
  
    <HepMC interface: public>  
  
    <HepMC interface: types>  
  
    <HepMC interface: interfaces>  
  
    contains  
  
    <HepMC interface: procedures>  
  
    <HepMC interface: tests>  
  
  end module hepmc_interface
```

18.7.1 Interface check

This function can be called in order to verify that we are using the actual HepMC library, and not the dummy version.

```
<HepMC interface: interfaces>≡
  interface
    logical(c_bool) function hepmc_available () bind(C)
    import
    end function hepmc_available
  end interface

<HepMC interface: public>≡
  public :: hepmc_is_available

<HepMC interface: procedures>≡
  function hepmc_is_available () result (flag)
    logical :: flag
    flag = hepmc_available ()
  end function hepmc_is_available
```

18.7.2 FourVector

The C version of four-vectors is often transferred by value, and the associated procedures are all inlined. The wrapper needs to transfer by reference, so we create FourVector objects on the heap which have to be deleted explicitly. The input is a `vector4_t` or `vector3_t` object from the `lorentz` module.

```
<HepMC interface: public>+≡
  public :: hepmc_four_vector_t

<HepMC interface: types>≡
  type :: hepmc_four_vector_t
  private
    type(c_ptr) :: obj
  end type hepmc_four_vector_t
```

In the C constructor, the zero-component (fourth argument) is optional; if missing, it is set to zero. The Fortran version has initializer form and takes either a three-vector or a four-vector. A further version extracts the four-vector from a HepMC particle object.

```
<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_four_vector_xyz (x, y, z) bind(C)
    import
    real(c_double), value :: x, y, z
    end function new_four_vector_xyz
  end interface
  interface
    type(c_ptr) function new_four_vector_xyzt (x, y, z, t) bind(C)
    import
    real(c_double), value :: x, y, z, t
    end function new_four_vector_xyzt
  end interface
```

```

<HepMC interface: public>+≡

  p3(3) = four_vector_pz (pp%obj)
  p = vector4_moving (E, vector3_moving (p3))
end subroutine hepmc_four_vector_to_vector4
```

18.7.3 Polarization

Polarization objects are temporarily used for assigning particle polarization. We add a flag `polarized`. If this is false, the polarization is not set and should not

be transferred to `hepmc_particle` objects.

```

<HepMC interface: public>+≡
    public :: hepmc_polarization_t

<HepMC interface: types>+≡
    type :: hepmc_polarization_t
    private
    logical :: polarized = .false.
    type(c_ptr) :: obj
    end type hepmc_polarization_t

```

Constructor. The C wrapper takes polar and azimuthal angle as arguments. The Fortran version allows for either a complete polarization density matrix, or for a definite (diagonal) helicity.

HepMC does not allow to specify the degree of polarization, therefore we have to map it to either 0 or 1. We choose 0 for polarization less than 0.5 and 1 for polarization greater than 0.5. Even this simplification works only for spin-1/2 and for massless particles; massive vector bosons cannot be treated this way. In particular, zero helicity is always translated as unpolarized.

```

```

18.7.6 Vertex-particle-in iterator

This iterator iterates over all incoming particles in an vertex. We store a pointer to the vertex in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

```

<HepMC interface: public>+≡
    public :: hepmc_vertex_particle_in_iterator_t

<HepMC interface: types>+≡
    type :: hepmc_vertex_particle_in_iterator_t
    private
    type(c_ptr) :: obj
    type(c_ptr) :: v_obj
    end type hepmc_vertex_particle_in_iterator_t

```

Constructor. The iterator is initialized at the first particle in the vertex.

```

<HepMC interface: interfaces>+≡
    interface
        type(c_ptr) function &
            new_vertex_particles_in_const_iterator (v_obj) bind(C)
        import
        type(c_ptr), value :: v_obj
        end function new_vertex_particles_in_const_iterator
    end interface

<HepMC interface: public>+≡
    public :: hepmc_vertex_particle_in_iterator_init

```

```

<HepMC interface: procedures>+≡
  subroutine hepmc_vertex_particle_in_iterator_init (it, v)
    type(hepmc_vertex_particle_in_iterator_t), intent(out) :: it
    type(hepmc_vertex_t), intent(in) :: v
    it%obj = new_vertex_particles_in_const_iterator (v%obj)
    it%v_obj = v%obj
  end subroutine hepmc_vertex_particle_in_iterator_init

```

Destructor. Necessary because the iterator is allocated on the heap.

```

<HepMC interface: interfaces>+≡
  interface
    subroutine vertex_particles_in_const_iterator_delete (it_obj) bind(C)
      import
      type(c_ptr), value :: it_obj
    end subroutine vertex_particles_in_const_iterator_delete
  end interface

<HepMC interface: public>+≡
  public :: hepmc_vertex_particle_in_iterator_final

```

18.7.9 Event-particle iterator

This iterator iterates over all particles in an event. We store a pointer to the event in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

```

<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_t

<HepMC interface: types>+≡
  type :: hepmc_event_particle_iterator_t
  private
  type(c_ptr) :: obj
  type(c_ptr) :: evt_obj
  end type hepmc_event_particle_iterator_t

```

Constructor. The iterator is initialized at the first particle in the event.

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_event_particle_const_iterator (evt_obj) bind(C)
      import
      type(c_ptr), value :: evt_obj
    end function new_event_particle_const_iterator
  end interface

<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_init

<HepMC interface: procedures>+≡
  subroutine hepmc_event_particle_iterator_init (it, evt)
    type(hepmc_event_particle_iterator_t), intent(out) :: it
    type(hepmc_event_t), intent(in) :: evt
    it%obj = new_event_particle_const_iterator (evt%obj)

```

```

        it%evt_obj = evt%obj
    end subroutine hepmc_event_particle_iterator_init

```

Destructor. Necessary because the iterator is allocated on the heap.

```

<HepMC interface: interfaces>+≡
    interface
        subroutine event_particle_const_iterator_delete (it_obj) bind(C)
            import
            type(c_ptr), value :: it_obj
        end subroutine event_particle_const_iterator_delete
    end interface
<HepMC interface: public>+≡
    public :: hepmc_event_particle_iterator_final
<HepMC interface: procedures>+≡
    subroutine hepmc_event_particle_iterator_final (it)
        type(hepmc_event_particle_iterator_t), intent(inout) :: it
        call event_particle_const_iterator_delete (it%obj)
    end subroutine hepmc_event_particle_iterator_final

```

Increment

```

<HepMC interface: interfaces>+≡
    interface
        subroutine event_particle_const_iterator_advance (it_obj) bind(C)
            import
            type(c_ptr), value :: it_obj
        end subroutine event_particle_const_iterator_advance
    end interface
<HepMC interface: public>+≡
    public :: hepmc_event_particle_iterator_advance
<HepMC interface: procedures>+≡
    subroutine hepmc_event_particle_iterator_advance (it)
        type(hepmc_event_particle_iterator_t), intent(inout) :: it
        call event_particle_const_iterator_advance (it%obj)
    end subroutine hepmc_event_particle_iterator_advance

```

Reset to the beginning

```

<HepMC interface: interfaces>+≡
    interface
        subroutine event_particle_const_iterator_reset (it_obj, evt_obj) bind(C)
            import
            type(c_ptr), value :: it_obj, evt_obj
        end subroutine event_particle_const_iterator_reset
    end interface
<HepMC interface: public>+≡
    public :: hepmc_event_particle_iterator_reset
<HepMC interface: procedures>+≡
    subroutine hepmc_event_particle_iterator_reset (it)
        type(hepmc_event_particle_iterator_t), intent(inout) :: it
        call event_particle_const_iterator_reset (it%obj, it%evt_obj)
    end subroutine hepmc_event_particle_iterator_reset

```

Test: return true as long as we are not past the end.

```

<HepMC interface: interfaces>+≡
  interface
    function event_particle_const_iterator_is_valid &
      (it_obj, evt_obj) result (flag) bind(C)
    import
      logical(c_bool) :: flag
      type(c_ptr), value :: it_obj, evt_obj
    end function event_particle_const_iterator_is_valid
  end interface

<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_is_valid

<HepMC interface: procedures>+≡
  function hepmc_event_particle_iterator_is_valid (it) result (flag)
    logical :: flag
    type(hepmc_event_particle_iterator_t), intent(in) :: it
    flag = event_particle_const_iterator_is_valid (it%obj, it%evt_obj)
  end function hepmc_event_particle_iterator_is_valid

```

Return the particle pointed to by the iterator. (The particle object should not be finalized, since it contains merely a pointer to the particle which is owned by the vertex.)

```

<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function event_particle_const_iterator_get (it_obj) bind(C)
    import
      type(c_ptr), value :: it_obj
    end function event_particle_const_iterator_get
  end interface

<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_get

<HepMC interface: procedures>+≡
  function hepmc_event_particle_iterator_get (it) result (prt)
    type(hepmc_particle_t) :: prt
    type(hepmc_event_particle_iterator_t), intent(in) :: it
    prt%obj = event_particle_const_iterator_get (it%obj)
  end function hepmc_event_particle_iterator_get

```

18.7.10 I/O streams

There is a specific I/O stream type for handling the output of GenEvent objects (i.e., Monte Carlo event samples) to file. Opening the file is done by the constructor, closing by the destructor.

```

<HepMC interface: public>+≡
  public :: hepmc_iostream_t

<HepMC interface: types>+≡
  type :: hepmc_iostream_t
  private
    type(c_ptr) :: obj

```

```
end type hepmc_iostream_t
```

Constructor for an output stream associated to a file.

```
<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_io_gen_event_out (filename) bind(C)
    import
      character(c_char), dimension(*), intent(in) :: filename
    end function new_io_gen_event_out
  end interface

<HepMC interface: public>+≡
  public :: hepmc_iostream_open_out

<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_open_out (iostream, filename)
    type(hepmc_iostream_t), intent(out) :: iostream
    type(string_t), intent(in) :: filename
    iostream%obj = new_io_gen_event_out (char (filename) // c_null_char)
  end subroutine hepmc_iostream_open_out
```

Constructor for an input stream associated to a file.

```
<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_io_gen_event_in (filename) bind(C)
    import
      character(c_char), dimension(*), intent(in) :: filename
    end function new_io_gen_event_in
  end interface

<HepMC interface: public>+≡
  public :: hepmc_iostream_open_in

<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_open_in (iostream, filename)
    type(hepmc_iostream_t), intent(out) :: iostream
    type(string_t), intent(in) :: filename
    iostream%obj = new_io_gen_event_in (char (filename) // c_null_char)
  end subroutine hepmc_iostream_open_in
```

Destructor:

```
<HepMC interface: interfaces>+≡
  interface
    subroutine io_gen_event_delete (io_obj) bind(C)
    import
      type(c_ptr), value :: io_obj
    end subroutine io_gen_event_delete
  end interface

<HepMC interface: public>+≡
  public :: hepmc_iostream_close
```

```

<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_close (iostream)
    type(hepmc_iostream_t), intent(inout) :: iostream
    call io_gen_event_delete (iostream%obj)
  end subroutine hepmc_iostream_close

```

Write a single event to the I/O stream.

```

<HepMC interface: interfaces>+≡
  interface
    subroutine io_gen_event_write_event (io_obj, evt_obj) bind(C)
      import
      type(c_ptr), value :: io_obj, evt_obj
    end subroutine io_gen_event_write_event
  end interface

<HepMC interface: public>+≡
  public :: hepmc_iostream_write_event

<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_write_event (iostream, evt)
    type(hepmc_iostream_t), intent(inout) :: iostream
    type(hepmc_event_t), intent(in) :: evt
    call io_gen_event_write_event (iostream%obj, evt%obj)
  end subroutine hepmc_iostream_write_event

```

Read a single event from the I/O stream. Return true if successful.

```

<HepMC interface: interfaces>+≡
  interface
    logical(c_bool) function io_gen_event_read_event (io_obj, evt_obj) bind(C)
      import
      type(c_ptr), value :: io_obj, evt_obj
    end function io_gen_event_read_event
  end interface

<HepMC interface: public>+≡
  public :: hepmc_iostream_read_event

<HepMC interface: procedures>+≡
  subroutine hepmc_iostream_read_event (iostream, evt, ok)
    type(hepmc_iostream_t), intent(inout) :: iostream
    type(hepmc_event_t), intent(in) :: evt
    logical, intent(out) :: ok
    ok = io_gen_event_read_event (iostream%obj, evt%obj)
  end subroutine hepmc_iostream_read_event

```

18.7.11 Unit tests

This test example is an abridged version from the build-from-scratch example in the HepMC distribution. We create two vertices for $p \rightarrow q$ PDF splitting, then a vertex for a $qq \rightarrow W^-g$ hard-interaction process, and finally a vertex for $W^- \rightarrow qq$ decay. The setup is for LHC kinematics.

Extending the original example, we set color flow for the incoming quarks and polarization for the outgoing photon. For the latter, we have to define a particle-data object for the photon, so a flavor object can be correctly initialized.

```

<HepMC interface: public>+≡
    public :: hepmc_test

<HepMC interface: procedures>+≡

```

18.8.4 Particle Set Transfer

The master output function fills a HepMC GenEvent object that is already initialized, but has no vertices in it.

We first set up the vertex lists and enter the vertices into the HepMC event. Then, we assign first all incoming particles and then all outgoing particles to their associated vertices. Particles which have neither parent nor children entries (this should not happen) are dropped.

Finally, we insert the beam particles. If there are none, use the incoming particles instead.

```

<EIO HepMC: procedures>+≡
  subroutine hepmc_event_from_particle_set (evt, particle_set)
    type(hepmc_event_t), intent(inout) :: evt
    type(particle_set_t), intent(in) :: particle_set
    type(hepmc_vertex_t), dimension(:), allocatable :: v
    type(hepmc_particle_t), dimension(:), allocatable :: hpvt
    type(hepmc_particle_t), dimension(2) :: hbeam
    logical, dimension(:), allocatable :: is_beam
    integer, dimension(:), allocatable :: v_from, v_to

```

```

integer :: n_vertices, n_tot, i
n_tot = particle_set%n_tot
allocate (v_from (n_tot), v_to (n_tot))
call particle_set_assign_vertices (particle_set, v_from, v_to, n_vertices)
allocate (v (n_vertices))
do i = 1, n_vertices
    call hepmc_vertex_init (v(i))
    call hepmc_event_add_vertex (evt, v(i))
end do

        call hepmc_vertex_add_particle_in (v(v_to(i)), hprt(i))
    end if
end do
do i = 1, n_tot
    if (v_from(i) /= 0) then
        call hepmc_vertex_add_particle_out (v(v_from(i)), hprt(i))
    end if
end do
end subroutine hepmc_event_from_particle_set

```

Transform a particle into a `hepmc_particle` object, including color and polarization. The HepMC status is equivalent to the HEPEVT status, in particular: 0 = null entry, 1 = physical particle, 2 = decayed/fragmented SM hadron, tau or muon, 3 = other unphysical particle entry, 4 = incoming particles, 11 = intermediate resonance such as squarks. The use of 11 for intermediate resonances is as done by HERWIG, see <http://herwig.hepforge.org/trac/wiki/FaQs>.

    end select
end subroutine particle_to_hepmc

```

Initialize a particle from a HepMC particle object. The model is necessary for making a fully qualified flavor component. We have the additional flag `polarized` which tells whether the polarization information should be interpreted or ignored, and the lookup array of barcodes. Note that the lookup array is searched linearly, a possible bottleneck for large particle arrays. If necessary, the barcode array could be replaced by a hash table.

18.10 STDHEP File Formats

Here, we implement the two existing STDHEP file formats, one based on the HEPRUP/HEPEUP common blocks, the other based on the HEPEVT common block. The second one is actually the standard STDHEP format.

```

<eio_stdhep.f90>≡
  <File header>

  module eio_stdhep

    use kinds !NODEP!
    <Use file utils>
    <Use strings>
    use diagnostics !NODEP!
    use unit_tests

    use lorentz !NODEP!
    use models
    use particles
    use beams
    use processes
    use events
    use eio_data
    use eio_base
    use hep_common

    <Standard module head>

    <EIO stdhep: public>

    <EIO stdhep: types>

    <EIO stdhep: variables>

    contains

    <EIO stdhep: procedures>

    <EIO stdhep: tests>

  end module eio_stdhep

```

18.10.1 Type

```
<EIO stdhep: public>≡
  public :: eio_stdhep_t

<EIO stdhep: types>≡
  type, abstract, extends (eio_t) :: eio_stdhep_t
    logical :: writing = .false.
    integer :: unit = 0
    logical :: keep_beams = .false.
    integer(i64) :: n_events_expected = 0
  contains
    <EIO stdhep: eio stdhep: TBP>
  end type eio_stdhep_t

<EIO stdhep: public>+≡
  public :: eio_stdhep_hepevt_t

<EIO stdhep: types>+≡
  type, extends (eio_stdhep_t) :: eio_stdhep_hepevt_t
  contains
    <EIO stdhep hepevt: eio stdhep hepevt: TBP>
  end type eio_stdhep_hepevt_t

<EIO stdhep: public>+≡
  public :: eio_stdhep_hepeup_t

<EIO stdhep: types>+≡
  type, extends (eio_stdhep_t) :: eio_stdhep_hepeup_t
  contains
    <EIO stdhep hepeup: eio stdhep hepeup: TBP>
  end type eio_stdhep_hepeup_t
```

18.10.2 Specific Methods

Set parameters that are specifically used with STDHEP file formats.

```
<EIO stdhep: eio stdhep: TBP>≡
  procedure :: set_parameters => eio_stdhep_set_parameters

<EIO stdhep: procedures>≡
  subroutine eio_stdhep_set_parameters (eio, keep_beams, extension)
    class(eio_stdhep_t), intent(inout) :: eio
    logical, intent(in), optional :: keep_beams
    type(string_t), intent(in), optional :: extension
    if (present (keep_beams)) eio%keep_beams = keep_beams
    if (present (extension)) then
      eio%extension = extension
    else
      select type (eio)
        type is (eio_stdhep_hepevt_t)
          eio%extension = "stdhep"
        type is (eio_stdhep_hepeup_t)
          eio%extension = "up.stdhep"
      end select
    end if
  end subroutine
```

```

        end if
    end subroutine eio_stdhep_set_parameters

```

18.10.3 Common Methods

Output. This is not the actual event format, but a readable account of the current object status.

```

<EIO stdhep: eio stdhep: TBP>+≡
    procedure :: write => eio_stdhep_write

<EIO stdhep: procedures>+≡
    subroutine eio_stdhep_write (object, unit)
        class(eio_stdhep_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit)
        write (u, "(1x,A)") "STDHEP event stream:"
        if (object%writing) then
            write (u, "(3x,A,A)") "Writing to file   = ", char (object%filename)
        else
            write (u, "(3x,A)") "[closed]"
        end if
        write (u, "(3x,A,L1)") "Keep beams       = ", object%keep_beams
    end subroutine eio_stdhep_write

```

Finalizer: close any open file.

```

<EIO stdhep: eio stdhep: TBP>+≡
    procedure :: final => eio_stdhep_final

<EIO stdhep: procedures>+≡
    subroutine eio_stdhep_final (object)
        class(eio_stdhep_t), intent(inout) :: object
        if (object%writing) then
            write (msg_buffer, "(A,A,A)") "Events: closing STDHEP file '", &
                char (object%filename), "'"

end module slha_interface

20.0.3 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an ifile. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

<SLHA: parameters>≡

```
integer, parameter :: MODE_SKIP = 0, MODE_DATA = 1, MODE_INFO = 2
```

<SLHA: procedures>≡

```
subroutine slha_preprocess (stream, ifile)

end subroutine define_slha_syntax

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

```

SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is not defined in the block, we use the previous value from the model variable list. For the basic parameters we have to do a small recalculation, since SLHA uses the G_F - α - m_Z scheme, while WHIZARD derives them from G_F , m_W , and m_Z .

    end select
end subroutine slha_write_MINPAR

```

Mass spectrum

Set masses. Since the particles are identified by PDG code, read the line and try to set the appropriate particle mass in the current model. At the end, update parameters, just in case the W or Z mass was included.

(SLHA: procedures)+≡

```

subroutine slha_handle_MASS (parse_tree, model)
    type(parse_tree_t), intent(in) :: parse_tree
    type(model_t), intent(inout), target :: model
    type(parse_node_t), pointer :: pn_block, pn_data, pn_line, pn_code
    type(parse_node_t), pointer :: pn_mass
    integer :: pdg
    real(default) :: mass
    pn_block => slha_get_block_ptr &
        (parse_tree, var_str ("MASS"), required=.true.)

```

```

if (.not. (associated (pn_block))) return
pn_data => parse_node_get_sub_ptr (pn_block, 4)
do while (associated (pn_data))
  pn_line => parse_node_get_sub_ptr (pn_data, 2)
  pn_code => parse_node_get_sub_ptr (pn_line)
  if (associated (pn_code)) then
    pdg = get_integer_parameter (pn_code)
    pn_mass => parse_node_get_next_ptr (pn_code)
    if (associated (pn_mass)) then
      mass = get_real_parameter (pn_mass)
      call model_set_particle_mass (model, pdg, mass)
    else
      call msg_error ("SLHA: Block MASS: Missing mass value")
    end if
  else
    call msg_error ("SLHA: Block MASS: Missing PDG code")
  end if
  pn_data => parse_node_get_next_ptr (pn_data)
end do
end subroutine slha_handle_MASS

```

Widths

Set widths. For each DECAY block, extract the header, read the PDG code and width, and try to set the appropriate particle width in the current model.

(SLHA: procedures) +=

```

subroutine slha_handle_decays (parse_tree, model)
  type(parse_tree_t), intent(in) :: parse_tree
  type(model_t), intent(inout), target :: model
  type(parse_node_t), pointer :: pn_decay, pn_decay_spec, pn_code, pn_width

    pn_decay => slha_get_next_decay_ptr (pn_decay)
  end do
end subroutine slha_handle_decays

```

Mixing matrices

Read mixing matrices. We can treat all matrices by a single procedure if we just know the block name, variable prefix, and matrix dimension. The matrix dimension must be less than 10. For the pseudoscalar Higgses in NMSSM-type models we need off-diagonal matrices, so we generalize the definition.

(SLHA: procedures) +=

```

subroutine slha_handle_matrix_block &
  (parse_tree, block_name, var_prefix, dim1, dim2, model)
  type(parse_tree_t), intent(in) :: parse_tree
  character(*), intent(in) :: block_name, var_prefix
  integer, intent(in) :: dim1, dim2
  type(model_t), intent(inout), target :: model
  type(parse_node_t), pointer :: pn_block
  type(var_list_t), pointer :: var_list
  integer :: i, j
  character(len=len(var_prefix)+2) :: var_name
  var_list => model_get_var_list_ptr (model)
  pn_block => slha_get_block_ptr &
    (parse_tree, var_str (block_name), required=.false.)
  if (.not. (associated (pn_block))) return
  do i = 1, dim1
    do j = 1, dim2
      write (var_name, "(A,I1,I1)") var_prefix, i, j
      call set_matrix_element (pn_block, i, j, var_str (var_name), var_list)
    end do
  end do
end subroutine slha_handle_matrix_block

```

Higgs data

Read the block ALPHA which holds just the Higgs mixing angle.

(SLHA: procedures) +=

```

subroutine slha_handle_ALPHA (parse_tree, model)
  type(parse_tree_t), intent(in) :: parse_tree
  type(model_t), intent(inout), target :: model
  type(parse_node_t), pointer :: pn_block, pn_line, pn_data, pn_item
  type(var_list_t), pointer :: var_list
  real(default) :: al_h
  var_list => model_get_var_list_ptr (model)
  pn_block => slha_get_block_ptr &
    (parse_tree, var_str ("ALPHA"), required=.false.)
  if (.not. (associated (pn_block))) return
  pn_data => parse_node_get_sub_ptr (pn_block, 4)
  pn_line => parse_node_get_sub_ptr (pn_data, 2)
  pn_item => parse_node_get_sub_ptr (pn_line)
  if (associated (pn_item)) then
    al_h = get_real_parameter (pn_item)
    call var_list_set_real (var_list, var_str ("al_h"), al_h, &
      is_known=.true., ignore=.true.)
  end if
end subroutine slha_handle_ALPHA

```

Read the block HMX for the Higgs mixing parameters

(SLHA: procedures) +=

```

subroutine slha_handle_HMX (parse_tree, model)
  type(parse_tree_t), intent(in) :: parse_tree
  type(model_t), intent(inout), target :: model
  type(parse_node_t), pointer :: pn_block

```

```

type(var_list_t), pointer :: var_list
var_list => model_get_var_list_ptr (model)
pn_block => slha_get_block_ptr &
    (parse_tree, var_str ("HMX"), required=.false.)
if (.not. (associated (pn_block))) return
call set_data_item (pn_block, 1, var_str ("mu_h"), var_list)
call set_data_item (pn_block, 2, var_str ("tanb_h"), var_list)
end subroutine slha_handle_HMX

```

Read the block NMSSMRUN for the specific NMSSM parameters

```

<SLHA: procedures>+=
subroutine slha_handle_NMSSMRUN (parse_tree, model)
type(parse_tree_t), intent(in) :: parse_tree
type(model_t), intent(inout), target :: model
type(parse_node_t), pointer :: pn_block
type(var_list_t), pointer :: var_list
var_list => model_get_var_list_ptr (model)
pn_block => slha_get_block_ptr &

call set_data_item (pn_block, 5, var_str ("nmu"), var_list)
end subroutine slha_handle_NMSSMRUN

```

20.0.7 Parser

Read a SLHA file from stream, including preprocessing, and make up a parse tree.

```

<SLHA: procedures>+=
subroutine slha_parse_stream (stream, parse_tree)
type(stream_t), intent(inout), target :: stream
type(parse_tree_t), intent(out) :: parse_tree
type(ifile_t) :: ifile
type(lexer_t) :: lexer
type(stream_t), target :: stream_tmp
call slha_preprocess (stream, ifile)
call stream_init (stream_tmp, ifile)
call lexer_init_slha (lexer)
call lexer_assign_stream (lexer, stream_tmp)
call parse_tree_init (parse_tree, syntax_slha, lexer)
call lexer_final (lexer)
call stream_final (stream_tmp)
call ifile_final (ifile)
end subroutine slha_parse_stream

```

Read a SLHA file chosen by name. Check first the current directory, then the directory where SUSY input files should be located.

```

<SLHA: procedures>+=

```

```

subroutine slha_parse_file (file, os_data, parse_tree)
  type(string_t), intent(in) :: file
  type(os_data_t), intent(in) :: os_data
  type(parse_tree_t), intent(out) :: parse_tree
  logical :: exist
  type(string_t) :: filename
  type(stream_t), target :: stream
  call msg_message ("Reading SLHA input file '" // char (file) // "'")
  filename = file
  inquire (file=char(filename), exist=exist)
  if (.not. exist) then
    filename = os_data%whizard_susypath // "/" // file
    inquire (file=char(filename), exist=exist)
    if (.not. exist) then
      call msg_fatal ("SLHA input file '" // char (file) // "' not found")
      return
    end if
  end if
  call stream_init (stream, char (filename))
  call slha_parse_stream (stream, parse_tree)
  call stream_final (stream)
end subroutine slha_parse_file

```

20.0.8 API

Read the SLHA file, parse it, and interpret the parse tree. The model parameters retrieved from the file will be inserted into the appropriate model, which is loaded and modified in the background. The pointer to this model is returned as the last argument.

```

<SLHA: public>+≡
  public :: slha_read_file

<SLHA: procedures>+≡
  subroutine slha_read_file &
    (file, os_data, model_list, model, input, spectrum, decays)

Chapter 21

Integration and simulation

This layer of modules is just below the top-level API. We lay out specific data types for integration and simulation and implement the corresponding algorithms as methods acting on them. This helps to keep the command-level implementation concise and simple.

21.1 Iterations

This module defines a container for the list of iterations and calls, to be submitted to integration.

```
<iterations.f90>≡  
  <File header>  
  
  module iterations  
  
    <Use strings>  
    <Use file utils>  
    use limits, only: ITERATIONS_DEFAULT_LIST_SIZE !NODEP!  
    use diagnostics !NODEP!  
    use unit_tests  
    use processes  
  
    <Standard module head>  
  
    <Iterations: public>  
  
    <Iterations: types>  
  
    <Iterations: interfaces>  
  
    contains  
  
    <Iterations: procedures>  
  
    <Iterations: tests>  
  
  end module iterations
```

21.1.1 The iterations list

Each integration pass has a number of iterations and a number of calls per iteration. The last pass produces the end result; the previous passes are used for adaptation.

The flags `adapt_grid` and `adapt_weight` are used only if `custom_adaptation` is set. Otherwise, default settings are used that depend on the integration pass.

```
<Iterations: types>≡
  type :: iterations_spec_t
  private
    integer :: n_it = 0
    integer :: n_calls = 0
    logical :: custom_adaptation = .false.
    logical :: adapt_grids = .false.
    logical :: adapt_weights = .false.
  end type iterations_spec_t
```

We build up a list of iterations.

```
<Iterations: public>≡
  public :: iterations_list_t
```

```
<Iterations: types>+≡
  type :: iterations_list_t
  private
    integer :: n_pass = 0
    type(iterations_spec_t), dimension(:), allocatable :: pass
  contains
    <Iterations: iterations list: TBP>
  end type iterations_list_t
```

```
<Iterations: iterations list: TBP>≡
  procedure :: init => iterations_list_init
```

```
<Iterations: procedures>≡
  subroutine iterations_list_init (it_list, n_it, n_calls, adapt, adapt_code)
    class(iterations_list_t), intent(inout) :: it_list
    integer, dimension(:), intent(in) :: n_it, n_calls
    logical, dimension(:), intent(in), optional :: adapt
    type(string_t), dimension(:), intent(in), optional :: adapt_code
    it_list%n_pass = size (n_it)
    if (allocated (it_list%pass)) deallocate (it_list%pass)
    allocate (it_list%pass (it_list%n_pass))
    it_list%pass%n_it = n_it
    it_list%pass%n_calls = n_calls
    if (present (adapt)) then
      it_list%pass%custom_adaptation = adapt
      if (any (verify (adapt_code, "wg") /= 0)) then
        call msg_error ("iteration specification: " &
          // "adaptation code letters must be 'w' or 'g'")
      end if
      it_list%pass%adapt_grids = scan (adapt_code, "g") /= 0
      it_list%pass%adapt_weights = scan (adapt_code, "w") /= 0
    end if
  end subroutine iterations_list_init
```

Fill all zero entries by corresponding entries from a default iterations list:

```

<CCC Iterations: public>≡
    public :: iterations_list_complete

<CCC Iterations: procedures>≡
    subroutine iterations_list_complete (it_list, it_list_default)
        type(iterations_list_t), intent(inout) :: it_list
        type(iterations_list_t), intent(in) :: it_list_default
        if (it_list%n_pass >= 1) then
            if (it_list%pass(1)%n_it == 0) &
                it_list%pass(1)%n_it = it_list_default%pass(1)%n_it
            if (it_list%pass(1)%n_calls == 0) &
                it_list%pass(1)%n_calls = it_list_default%pass(1)%n_calls
        end if
        if (it_list%n_pass >= 2) then
            where (it_list%pass%n_it == 0) &
                it_list%pass%n_it = it_list_default%pass(2)%n_it
            where (it_list%pass%n_calls == 0) &
                it_list%pass%n_calls = it_list_default%pass(2)%n_calls
        end if
    end subroutine iterations_list_complete

<Iterations: iterations list: TBP>+≡
    procedure :: clear => iterations_list_clear

<Iterations: procedures>+≡
    subroutine iterations_list_clear (it_list)
        class(iterations_list_t), intent(inout) :: it_list
        it_list%n_pass = 0
        deallocate (it_list%pass)
    end subroutine iterations_list_clear

```

Write the list of iterations as a message.

```

<Iterations: iterations list: TBP>+≡
    procedure :: write => iterations_list_write

<Iterations: procedures>+≡
    subroutine iterations_list_write (it_list, unit)
        class(iterations_list_t), intent(in) :: it_list
        integer, intent(in), optional :: unit
        integer :: u
        type(string_t) :: buffer
        character(30) :: ibuf
        integer :: i
        u = output_unit (unit)
        buffer = "iterations = "
        if (it_list%n_pass > 0) then
            do i = 1, it_list%n_pass
                if (i > 1) buffer = buffer // ", "
                write (ibuf, "(I0,':',I0)") &
                    it_list%pass(i)%n_it, it_list%pass(i)%n_calls
                buffer = buffer // trim (ibuf)
                if (it_list%pass(i)%custom_adaptation) then

```

```

        buffer = buffer // ':'
        if (it_list%pass(i)%adapt_grids) buffer = buffer // "g"
        if (it_list%pass(i)%adapt_weights) buffer = buffer // "w"
        buffer = buffer // ','
    end if
end do
else
    buffer = buffer // "[undefined]"
end if
!    call msg_message (char (buffer), unit)
    write (u, "(A)") char (buffer)
end subroutine iterations_list_write

```

21.1.2 Tools

Transform the iterations list into arrays that indicate pass index and number of calls for each iteration.

<CCC Iterations: public>+≡

```

public :: iterations_list_get_pass_array
public :: iterations_list_get_n_calls_array

```

<CCC Iterations: procedures>+≡

```

function iterations_list_get_pass_array (it_list) result (pass)
    integer, dimension(:), allocatable :: pass
    type(iterations_list_t), intent(in) :: it_list
    integer :: it, i
    allocate (pass (sum (it_list%pass%n_it)))
    it = 0
    do i = 1, it_list%n_pass
        pass(it+1 : it+it_list%pass(i)%n_it) = i
        it = it + it_list%pass(i)%n_it
    end do
end function iterations_list_get_pass_array

function iterations_list_get_n_calls_array (it_list) result (n_calls)
    integer, dimension(:), allocatable :: n_calls
    type(iterations_list_t), intent(in) :: it_list
    integer :: it, i
    allocate (n_calls (sum (it_list%pass%n_it)))
    it = 0
    do i = 1, it_list%n_pass
        n_calls(it+1 : it+it_list%pass(i)%n_it) = it_list%pass(i)%n_calls
        it = it + it_list%pass(i)%n_it
    end do

write (u, "(A)")
write (u, "(A)")  "* Test output end: iterations_2"

end subroutine iterations_2

```

21.2 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```

<user_files.f90>≡
  <File header>

  module user_files

    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use ifiles
    use analysis

    <Standard module head>

    <User files: public>

    <User files: types>

    <User files: interfaces>

    contains

    <User files: procedures>

  end module user_files

```

21.2.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡
  type :: file_t
  private
  type(string_t) :: name
  integer :: unit = -1
  logical :: reading = .false.
  logical :: writing = .false.
  type(file_t), pointer :: prev => null ()
  type(file_t), pointer :: next => null ()
end type file_t
```

The initializer opens the file.

```
<User files: procedures>≡
  subroutine file_init (file, name, action, status, position)
    type(file_t), intent(out) :: file
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    file%unit = free_unit ()
    file%name = name
    open (unit = file%unit, file = char (file%name), &
          action = action, status = status, position = position)
    select case (action)
    case ("read")
      file%reading = .true.
    case ("write")
      file%writing = .true.
    case ("readwrite")
      file%reading = .true.
      file%writing = .true.
    end select
  end subroutine file_init
```

The finalizer closes it.

```
<User files: procedures>+≡
  subroutine file_final (file)
    type(file_t), intent(inout) :: file
    close (unit = file%unit)
    file%unit = -1
  end subroutine file_final
```

Check if a file is open with correct status.

```
<User files: procedures>+≡
  function file_is_open (file, action) result (flag)
    logical :: flag
    type(file_t), intent(in) :: file
    character(*), intent(in) :: action
    select case (action)
    case ("read")
```

```

        flag = file%reading
    case ("write")
        flag = file%writing
    case ("readwrite")
        flag = file%reading .and. file%writing
    case default
        call msg_bug ("Checking file '" // char (file%name) &
            // "' : illegal action specifier")
    end select
end function file_is_open

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the `advancing` option.

<User files: procedures>+≡

```

subroutine file_write_string (file, string, advancing)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: string
    logical, intent(in), optional :: advancing
    if (file%writing) then
        if (present (string)) then
            if (present (advancing)) then
                if (advancing) then
                    write (file%unit, "(A)") char (string)
                else
                    write (file%unit, "(A)", advance="no") char (string)
                end if
            else
                write (file%unit, "(A)") char (string)
            end if
        else
            write (file%unit, *)
        end if
    else
        call msg_error ("Writing to file: File '" // char (file%name) &
            // "' is not open for writing.")
    end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

<User files: procedures>+≡

```

subroutine file_write_ifile (file, ifile)
    type(file_t), intent(in) :: file
    type(ifile_t), intent(in) :: ifile
    type(line_p) :: line
    call line_init (line, ifile)
    do while (line_is_associated (line))
        call file_write_string (file, line_get_string_advance (line))
    end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

<User files: procedures>+≡

```

subroutine file_write_analysis (file, tag)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: tag
  if (file%writing) then
    if (present (tag)) then
      call analysis_write (tag, unit = file%unit)
    else
      call analysis_write (unit = file%unit)
    end if
  else
    call msg_error ("Writing analysis to file: File ' " // char (file%name) &
      // "' is not open for writing.")
  end if
end subroutine file_write_analysis

```

21.2.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
  public :: file_list_t

<User files: types>+≡
  type :: file_list_t
    type(file_t), pointer :: first => null ()
    type(file_t), pointer :: last => null ()
  end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
  public :: file_list_final

<User files: procedures>+≡
  subroutine file_list_final (file_list)
    type(file_list_t), intent(inout) :: file_list
    type(file_t), pointer :: current
    do while (associated (file_list%first))
      current => file_list%first
      file_list%first => current%next
      call file_final (current)
      deallocate (current)
    end do
    file_list%last => null ()
  end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```

<User files: procedures>+≡
  function file_list_get_file_ptr (file_list, name) result (current)
    type(file_t), pointer :: current
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    current => file_list%first

```

```

do while (associated (current))
  if (current%name == name) return
  current => current%next
end do
end function file_list_get_file_ptr

```

Check if a file is open, public version:

```

<User files: public>+≡
  public :: file_list_is_open

<User files: procedures>+≡
  function file_list_is_open (file_list, name, action) result (flag)
    logical :: flag
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action
    type(file_t), pointer :: current
    current => file_list_get_file_ptr (file_list, name)
    if (associated (current)) then
      flag = file_is_open (current, action)
    else
      flag = .false.
    end if
  end function file_list_is_open

```

Append a new file entry, i.e., open this file. Error if it is already open.

```

<User files: public>+≡
  public :: file_list_open

<User files: procedures>+≡
  subroutine file_list_open (file_list, name, action, status, position)
    type(file_list_t), intent(inout) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    type(file_t), pointer :: current
    if (.not. associated (file_list_get_file_ptr (file_list, name))) then
      allocate (current)
      call msg_message ("Opening file '" // char (name) // "' for output")
      call file_init (current, name, action, status, position)
      if (associated (file_list%last)) then
        file_list%last%next => current
        current%prev => file_list%last
      else
        file_list%first => current
      end if
      file_list%last => current
    else
      call msg_error ("Opening file: File '" // char (name) &
        // "' is already open.")
    end if
  end subroutine file_list_open

```

Delete a file entry, i.e., close this file. Error if it is not open.

```
<User files: public>+≡
    public :: file_list_close

<User files: procedures>+≡
    subroutine file_list_close (file_list, name)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            if (associated (current%prev)) then
                current%prev%next => current%next
            else
                file_list%first => current%next
            end if
            if (associated (current%next)) then
                current%next%prev => current%prev
            else
                file_list%last => current%prev
            end if
            call msg_message ("Closing file '" // char (name) // "' for output")
            call file_final (current)
            deallocate (current)
        else
            call msg_error ("Closing file: File '" // char (name) &
                // "' is not open.")
        end if
    end subroutine file_list_close
```

Write a string to file. Error if it is not open.

```
<User files: public>+≡
    public :: file_list_write

<User files: interfaces>≡
    interface file_list_write
        module procedure file_list_write_string
        module procedure file_list_write_ifile
    end interface

<User files: procedures>+≡
    subroutine file_list_write_string (file_list, name, string, advancing)

```

21.3.1 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()
    type(parse_node_t), pointer :: fac_scale_expr => null ()

```

```

    type(parse_node_t), pointer :: ren_scale_expr => null ()
    type(parse_node_t), pointer :: weight_expr => null ()
    type(parse_node_t), pointer :: selection_lexpr => null ()
    type(parse_node_t), pointer :: reweight_expr => null ()
    type(parse_node_t), pointer :: analysis_lexpr => null ()

```

21.3.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init

<RT data: procedures>+≡
  subroutine rt_data_local_init (local, global, env)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(in), target :: global
    integer, intent(in), optional :: env
    call var_list_link (local%var_list, global%var_list)
    if (associated (global%model)) then
      call var_list_init_copies (local%var_list, &
        model_get_var_list_ptr (global%model), &

```

```

        derived_only = .true.)
    end if
    call local%init_pointer_variables ()
    local%os_data = global%os_data
!    if (present (env)) local%environment = env
end subroutine rt_data_local_init

```

This copies global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡
    procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
    subroutine rt_data_copy_globals (global, local)
        class(rt_data_t), intent(in) :: global
        class(rt_data_t), intent(inout) :: local
        local%model_list = global%model_list
        local%prclib_stack = global%prclib_stack
        local%process_stack = global%process_stack
    end subroutine rt_data_copy_globals

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
    procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: procedures>+≡
    subroutine rt_data_init_pointer_variables (local)
        class(rt_data_t), intent(inout), target :: local
        logical, target, save :: known = .true.
        call var_list_append_string_ptr &
            (local%var_list, var_str ("fc"), local%os_data%fc, known, &
             intrinsic=.true.)
        call var_list_append_string_ptr &
            (local%var_list, var_str ("fcflags"), local%os_data%fcflags, known, &
             intrinsic=.true.)
    end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+≡
    procedure :: link => rt_data_link

```

```

<RT data: procedures>+=
subroutine rt_data_link (local, global)
  class(rt_data_t), intent(inout), target :: local
  class(rt_data_t), intent(in), target :: global
  local%lexer => global%lexer
  call global%copy_globals (local)
  local%os_data = global%os_data
  call var_list_link (local%var_list, global%var_list)
  if (associated (global%model)) then
    local%model => &
      local%model_list%get_model_ptr (model_get_name (global%model))
    call var_list_synchronize (local%var_list, &
      model_get_var_list_ptr (local%model), reset_pointers = .true.)
    call local%particle_stack%init (local%model)
  end if
  if (associated (global%prclib)) then
    local%prclib => &
      local%prclib_stack%get_library_ptr (global%prclib%get_name ())
  end if
  local%it_list = global%it_list
!   local%beam_data = global%beam_data
  local%beam_structure = global%beam_structure
  local%lhpdf_status = global%lhpdf_status
  local%pn = global%pn
  if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
  if (allocated (global%sample_fmt)) then
    allocate (local%sample_fmt (size (global%sample_fmt)), &
      source = global%sample_fmt)
  end if
  local%out_files => global%out_files
!   local%beam_polarization => global%beam_polarization
!   local%analysis_data_unit = global%analysis_data_unit
end subroutine rt_data_link

```

Restore the previous state of data; in particular, the variable list. This applies only to model variables (which are copies); other variables are automatically restored when local variables are removed.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!), and we synchronize the local variable list with it. The other local variables are also kept.

Some command (`read_slha`) reads in model variables as local entities. In this case, the original values of model variables should not be restored, but the global variable list should be synchronized. However, this matters only if the local model is identical to the global model; otherwise, restoring will apply to a different model.

Finally, model list, process library stack, and process stack are copied back. Thus, they behave like global objects: all changes in the local environment are kept in the global context. Note that these are shallow copies.

```

<RT data: rt data: TBP>+=
  procedure :: restore => rt_data_restore
<RT data: procedures>+=

```

```

subroutine rt_data_restore (global, local, keep_model_vars, keep_local)
  class(rt_data_t), intent(inout) :: global
  class(rt_data_t), intent(inout) :: local
  logical, intent(in), optional :: keep_model_vars, keep_local
  logical :: same_model, restore, delete
  delete = .true.; if (present (keep_local)) delete = .not. keep_local
  if (delete) then
    call var_list_undefine (local%var_list, follow_link=.false.)
  else
    if (associated (local%model)) then
      call model_pointer_to_instance (local%model)
      call var_list_synchronize (local%var_list, &
        model_get_var_list_ptr (local%model), reset_pointers = .true.)
    end if
  end if
  if (associated (global%model)) then

    type(test_results_t), intent(inout) :: results
    <RT data: execute tests>
  end subroutine rt_data_test
```

Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```
<RT data: rt data: TBP>+≡

Save and restore

Set up a local runtime data block, change some contents, restore the global block.

For a model variable, the save-restore procedure is nontrivial. We first allocate a local copy of this variable and set a pointer to the original model variable. We set a new value, update the dependent variables and synchronize them with the local variable list, if modified. When restoring the old data, we recover the model variables from the stored values and delete the local instances.

```

write (u, "(A)")
write (u, "(A)")  "* Test output end: rt_data_5"

end subroutine rt_data_5

```

Local Model

Locally modify a model and restore the global one. We need an auxiliary function to determine the status of a model particle:

```

<RT data: tests>+≡
function is_stable (pdg, rt_data) result (flag)
  integer, intent(in) :: pdg
  type(rt_data_t), intent(in) :: rt_data
  logical :: flag
  type(flavor_t) :: flv
  call flavor_init (flv, pdg, rt_data%model)
  flag = flavor_is_stable (flv)
end function is_stable

function is_polarized (pdg, rt_data) result (flag)
  integer, intent(in) :: pdg
  type(rt_data_t), intent(in) :: rt_data
  logical :: flag
  type(flavor_t) :: flv
  call flavor_init (flv, pdg, rt_data%model)
  flag = flavor_is_polarized (flv)
end function is_polarized

<RT data: execute tests>+≡
call test (rt_data_6, "rt_data_6", &
  "local model", &
  u, results)

<RT data: tests>+≡
subroutine rt_data_6 (u)
  integer, intent(in) :: u
  type(rt_data_t), target :: rt_data, local
  type(var_list_t), pointer :: model_vars
  type(var_entry_t), pointer :: var_entry

```

```

type(string_t) :: var_name

```

21.4 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

This module provides no new types, just procedures.

```
<dispatch.f90>≡  
  <File header>  
  
  module dispatch  
  
    <Use kinds>  
    use kinds, only: i16 !NODEP!  
    <Use strings>  
    use limits, only: MZ_REF, ALPHA_QCD_MZ_REF !NODEP!  
    use constants, only: PI !NODEP!  
    <Use file utils>  
    use diagnostics !NODEP!  
    use os_interface  
    use unit_tests  
    use sm_qcd  
    use variables  
    use flavors  
    use interactions  
    use models  
    use process_constants  
    use pdf_builtin !NODEP!  
    use sf_mappings  
    use sf_base  
    use sf_pdf_builtin  
    use sf_lhapdf  
    use sf_circe1  
    use sf_circe2  
    use sf_lumi_linker  
    use sf_isr  
    use sf_epa  
    use sf_ewa  
    use sf_escan  
    use sf_beam_events  
    use sf_user  
    use rng_base  
    use rng_tao  
    use mci_base  
    use mci_midpoint  
    use mci_vamp  
    use phs_base  
    use mappings  
    use phs_forests  
    use phs_single  
    use phs_wood  
    use prc_core_def  
    use prc_test
```

```

use eio_weights
use rt_data

```

⟨Standard module head⟩

⟨Dispatch: public⟩

`contains`

⟨Dispatch: procedures⟩

⟨Dispatch: tests⟩

`end module dispatch`

21.4.1 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable.

Note: `core_def` has `intent(inout)` because gfortran 4.7.1 crashes for `intent(out)`.

⟨Dispatch: public⟩≡

```
public :: dispatch_core_def
```

⟨Dispatch: procedures⟩≡

```

subroutine dispatch_core_def (core_def, prt_in, prt_out, global)
  class(prc_core_def_t), allocatable, intent(inout) :: core_def
  type(string_t), dimension(:), intent(in) :: prt_in
  type(string_t), dimension(:), intent(in) :: prt_out
  type(rt_data_t), intent(in) :: global
  type(string_t) :: method
  type(string_t) :: model_name
  type(string_t) :: restrictions
  logical :: openmp_support
  logical :: report_progress
  logical :: diags, diags_color
  type(string_t) :: extra_options
  associate (var_list => global%var_list)
    method = var_list_get_sval (var_list, var_str ("method"))
  end associate
end subroutine

```

```

model_name = var_list_get_sval (var_list, var_str ("$model_name"))
select case (char (method))
case ("unit_test")
    allocate (prc_test_def_t :: core_def)
    select type (core_def)
    type is (prc_test_def_t)
        call core_def%init (model_name, prt_in, prt_out)
    end select
case ("omega")
    diags = var_list_get_lval (var_list, &
        var_str ("?diags"))
    diags_color = var_list_get_lval (var_list, &
        var_str ("?diags_color"))
    restrictions = var_list_get_sval (var_list, &
        var_str ("$restrictions"))
    openmp_support = var_list_get_lval (var_list, &
        var_str ("?omega_openmp"))
    report_progress = var_list_get_lval (var_list, &
        var_str ("?report_progress"))
    extra_options = var_list_get_sval (var_list, &
        var_str ("$omega_flags"))
    allocate (omega_def_t :: core_def)
    select type (core_def)
    type is (omega_def_t)
        call core_def%init (model_name, prt_in, prt_out, &
            restrictions, openmp_support, report_progress, &
            extra_options, diags, diags_color)
    end select
case default
    call msg_fatal ("Process configuration: method '" &
        // char (method) // "' not implemented")
end select
end associate
end subroutine dispatch_core_def

```

21.4.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

(Dispatch: public)+≡

```
public :: dispatch_core
```

(Dispatch: procedures)+≡

```

subroutine dispatch_core (core, core_def, model, &
    helicity_selection, qcd, use_color_factors)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_def_t), intent(in) :: core_def
    type(model_t), intent(in), target, optional :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    logical, intent(in), optional :: use_color_factors
    select type (core_def)

```

```

type is (prc_test_def_t)
  allocate (test_t :: core)
type is (omega_def_t)
  allocate (prc_omega_t :: core)
  select type (core)
    type is (prc_omega_t)
      call core%set_parameters (model, &
        helicity_selection, qcd, use_color_factors)
    end select
class default
  call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

21.4.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

```

<Dispatch: public>+≡
  public :: dispatch_core_update
  public :: dispatch_core_restore

<Dispatch: procedures>+≡
  subroutine dispatch_core_update (core, model, helicity_selection, qcd, &
    saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    type(model_t), intent(in), optional, target :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    class(prc_core_t), allocatable, intent(inout), optional :: saved_core
    if (present (saved_core)) then
      allocate (saved_core, source = core)
    end if
    select type (core)
      type is (test_t)
      type is (prc_omega_t)
        call core%set_parameters (model, helicity_selection, qcd)
        call core%activate_parameters ()
      class default
        call msg_bug ("Process core update: unexpected process definition type")
    end select
  end subroutine dispatch_core_update

  subroutine dispatch_core_restore (core, saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_t), allocatable, intent(inout) :: saved_core
    call move_alloc (from = saved_core, to = core)
    select type (core)
      type is (test_t)

```

```

type is (prc_omega_t)
  call core%activate_parameters ()
class default
  call msg_bug ("Process core restore: unexpected process definition type")
end select
end subroutine dispatch_core_restore

```

21.4.4 Integrator allocation

Allocate an integrator according to the variable `$integration_method`.

```

<Dispatch: public>+≡
  public :: dispatch_mci

<Dispatch: procedures>+≡
  subroutine dispatch_mci (mci, global, process_id)
    class(mci_t), allocatable, intent(inout) :: mci
    type(rt_data_t), intent(in) :: global
    type(string_t), intent(in) :: process_id
    type(string_t) :: run_id

21.4.6 Random-number generator

Allocate a random-number generator factory according to the variable `$rng_method`, using the current seed in the global record. We take only the lower 15 bits of the seed, so the actual value fits into a positive 16-bit signed integer.

Since we want to guarantee that all random-number generators in a run are independent, we increment the global seed by one after creating the rng factory. If the user wants to have identical sequences, he can always set the seed manually, before it is used.

```
(Dispatch: public)+≡
    public :: dispatch_rng_factory

(Dispatch: procedures)+≡
    subroutine dispatch_rng_factory (rng_factory, global)
        class(rng_factory_t), allocatable, intent(out) :: rng_factory
        type(rt_data_t), intent(inout) :: global
        type(string_t) :: rng_method
        integer :: seed
        character(30) :: buffer
        integer(i16) :: s
        rng_method = var_list_get_sval (global%var_list, var_str ("$rng_method"))
        seed = var_list_get_ival (global%var_list, var_str ("seed"))

            // "' not supported yet")
    end select
end function strfun_mode

```

Dispatch a whole structure-function chain, given beam data and beam structure data.

This could be done generically, but we should look at the specific combination of structure functions in order to select appropriate mappings.

The `beam_structure` argument gets copied because we want to expand it to canonical form (one valid structure-function entry per record) before proceeding further.

Note: Should add global mappings, as appropriate for a specific combination of structure functions.

21.4.9 QCD coupling

Allocate the `alpha` (running coupling) component of the `qcd` block with a concrete implementation, depending on the variable settings in the `global` record.

If a fixed α_s is requested, we do not allocate the `qcd%alpha` object. In this case, the matrix element code will just take the model parameter as-is, which implies fixed α_s . If the object is allocated, the α_s value is computed and updated for each matrix-element call.

```

```

21.5 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

<process_configurations.f90>≡
<File header>

```
module process_configurations
```

<Use strings>

```

use diagnostics !NODEP!

```

21.5.1 Data Type

```

<Process configurations: public>≡
    public :: process_configuration_t

<Process configurations: types>≡
    type :: process_configuration_t
        type(process_def_entry_t), pointer :: entry => null ()
        type(string_t) :: id
        integer :: num_id = 0
    contains
        <Process configurations: process configuration: TBP>
    end type process_configuration_t

```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

```

<Process configurations: process configuration: TBP>≡
    procedure :: init => process_configuration_init

<Process configurations: procedures>≡
    subroutine process_configuration_init &
        (config, prc_name, n_in, n_components, global)
        class(process_configuration_t), intent(out) :: config
        type(string_t), intent(in) :: prc_name
        integer, intent(in) :: n_in
        integer, intent(in) :: n_components
        type(rt_data_t), intent(in) :: global
        type(model_t), pointer :: model

        else
            call config%entry%init (prc_name, &
                model = model, n_in = n_in, n_components = n_components)
        end if
    end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

```

<Process configurations: process configuration: TBP>+=
    procedure :: setup_component => process_configuration_setup_component

```

<Process configurations: procedures>+≡

```

subroutine process_configuration_setup_component &

      // "' : active process library undefined")
  end if

```

```
end subroutine process_configuration_record
```

21.5.2 Test

This is the master for calling self-test procedures.

```
<Process configurations: public>+≡
  public :: process_configurations_test

<Process configurations: tests>≡
  subroutine process_configurations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Process configurations: execute tests>
  end subroutine process_configurations_test
```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

```
<Process configurations: public>+≡
  public :: prepare_test_library

<Process configurations: tests>+≡
  subroutine prepare_test_library (global, libname, mode, procname)
    type(rt_data_t), intent(inout), target :: global
    type(string_t), intent(in) :: libname
    integer, intent(in) :: mode
    type(string_t), intent(in), dimension(:), optional :: procname

    type(prclib_entry_t), pointer :: lib
    type(string_t) :: prc_name
    type(string_t), dimension(:), allocatable :: prt_in, prt_out
    integer :: n_components
    type(process_configuration_t) :: prc_config

    allocate (lib)

21.6 Compilation

This module manages compilation and loading of of process libraries. It is needed as a separate module because integration depends on it.

```

<compilations.f90>≡
  <File header>

  module compilations

    <Use strings>
    <Use file utils>
    use diagnostics !NODEP!
    use limits, only: TAB !NODEP!
    use os_interface
    use unit_tests
    use md5
    use variables
    use models
    use process_libraries
    use prclib_stacks
    use rt_data
    use process_configurations

    <Standard module head>

    <Compilations: public>

    <Compilations: types>

    <Compilations: interfaces>

    contains

    <Compilations: procedures>

    <Compilations: tests>

  end module compilations

```

21.6.1 The data type

The compilation item handles the compilation and loading of a single process library.

```

<Compilations: types>≡

```

```

type :: compilation_item_t
  type(string_t) :: libname
  type(process_library_t), pointer :: lib => null ()
  logical :: recompile_library = .false.
contains
  <Compilations: compilation item: TBP>
end type compilation_item_t

```

Initialize:

```

<Compilations: compilation item: TBP>≡
  procedure :: init => compilation_item_init

<Compilations: procedures>≡
  subroutine compilation_item_init (comp, libname, stack, var_list)
    class(compilation_item_t), intent(out) :: comp
    type(string_t), intent(in) :: libname
    type(prclib_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in) :: var_list
    comp%libname = libname
    comp%lib => stack%get_library_ptr (comp%libname)
    if (.not. associated (comp%lib)) then
      call msg_fatal ("Process library '" // char (comp%libname) &
        // "' has not been declared.")
    end if
    comp%recompile_library = &
      var_list_get_lval (var_list, var_str ("?recompile_library"))
  end subroutine compilation_item_init

```

Compile the current library. The force flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

```

<Compilations: compilation item: TBP>+≡
  procedure :: compile => compilation_item_compile

<Compilations: procedures>+≡
  subroutine compilation_item_compile (comp, os_data, force)
    class(compilation_item_t), intent(inout) :: comp
    type(os_data_t), intent(in) :: os_data

    class(compilation_item_t), intent(inout) :: comp
    type(os_data_t), intent(in) :: os_data
    if (associated (comp%lib)) then
      call comp%lib%load (os_data)
    end if
  end subroutine compilation_item_load
```

Message as a separate call:

```
<Compilations: compilation item: TBP>+≡
  procedure :: success => compilation_item_success

<Compilations: procedures>+≡
  subroutine compilation_item_success (comp)
    class(compilation_item_t), intent(in) :: comp
    if (associated (comp%lib)) then
      call msg_message ("Process library '" // char (comp%libname) &
        // "' : ... success.")
    end if
  end subroutine compilation_item_success
```

21.6.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```
<Compilations: public>≡
  public :: compile_library

<Compilations: procedures>+≡
  subroutine compile_library (libname, global)
    type(string_t), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
    type(compilation_item_t) :: comp
    logical :: force
    force = var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
    call comp%init (libname, global%prclib_stack, global%var_list)
    call comp%compile (global%os_data, force)
    if (signal_is_pending ()) return
    call comp%load (global%os_data)
    if (signal_is_pending ()) return
    call comp%success ()
  end subroutine compile_library
```

21.6.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```
<Compilations: types>+≡
  type :: compilation_t
    private
    type(string_t) :: exe_name
    type(string_t), dimension(:), allocatable :: lib_name
    contains
    <Compilations: compilation: TBP>
  end type compilation_t
```

Output.

```
<Compilations: compilation: TBP>≡
  procedure :: write => compilation_write

<Compilations: procedures>+≡
  subroutine compilation_write (object, unit)
    class(compilation_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit)
    write (u, "(1x,A)") "Compilation object:"
    write (u, "(3x,3A)") "executable          = '", &
      char (object%exe_name), "'
    write (u, "(3x,A)", advance="no") "process libraries ="
    do i = 1, size (object%lib_name)
      write (u, "(1x,3A)", advance="no") "' '", char (object%lib_name(i)), "'
    end do
    write (u, *)
  end subroutine compilation_write
```

Initialize: we know the names of the executable and of the libraries.

```
<Compilations: compilation: TBP>+≡
  procedure :: init => compilation_init

<Compilations: procedures>+≡
  subroutine compilation_init (compilation, exe_name, lib_name)
    class(compilation_t), intent(out) :: compilation
    type(string_t), intent(in) :: exe_name
    type(string_t), dimension(:), intent(in) :: lib_name
    compilation%exe_name = exe_name
    allocate (compilation%lib_name (size (lib_name)))
    compilation%lib_name = lib_name
  end subroutine compilation_init
```

Write the dispatcher subroutine for the compiled libraries. Also write a subroutine which returns the names of the compiled libraries.

```
<Compilations: compilation: TBP>+≡
  procedure :: write_dispatcher => compilation_write_dispatcher
```

{*Compilations: procedures*}+≡

```

subroutine compilation_write_dispatcher (compilation)

      // " -f " // compilation%exe_name // ".makefile")
  end subroutine compilation_make_compile

```

Link the dispatcher together with all matrix-element code and the WHIZARD and O'MEGA main libraries, to generate a static executable.

```

<Compilations: compilation: TBP>+≡
  procedure :: make_link => compilation_make_link

<Compilations: procedures>+≡
  subroutine compilation_make_link (compilation, os_data)
    class(compilation_t), intent(in) :: compilation
    type(os_data_t), intent(in) :: os_data
    call os_system_call ("make link " // os_data%makeflags &
      // " -f " // compilation%exe_name // ".makefile")
  end subroutine compilation_make_link

```

```
end subroutine compilation_make_link
```

Cleanup.

```
<Compilations: compilation: TBP>+≡
  procedure :: make_clean_exe => compilation_make_clean_exe

<Compilations: procedures>+≡
  subroutine compilation_make_clean_exe (compilation, os_data)
    class(compilation_t), intent(in) :: compilation
    type(os_data_t), intent(in) :: os_data
    call os_system_call ("make clean-exe " // os_data%makeflags &
      // " -f " // compilation%exe_name // ".makefile")
  end subroutine compilation_make_clean_exe
```

21.6.4 API for executable compilation

This is a shorthand for compiling and loading an executable, including the enclosed libraries. The `compilation` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```
<Compilations: public>+≡
  public :: compile_executable

<Compilations: procedures>+≡
  subroutine compile_executable (exename, libname, global)
    type(string_t), intent(in) :: exename
    type(string_t), dimension(:), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
    type(compilation_t) :: compilation
    type(compilation_item_t) :: item
    logical :: force
    integer :: i
    force = var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
    call compilation%init (exename, [libname])
    if (signal_is_pending ()) return
    call compilation%write_dispatcher ()
    if (signal_is_pending ()) return
    call compilation%write_makefile (global%os_data)
    if (signal_is_pending ()) return
    do i = 1, size (libname)
      call item%init (libname(i), global%prclib_stack, global%var_list)
      call item%compile (global%os_data, force=force)
      if (signal_is_pending ()) return
      call item%success ()
    end do
    call compilation%make_compile (global%os_data)
    if (signal_is_pending ()) return
    call compilation%make_link (global%os_data)
  end subroutine compile_executable
```

21.6.5 Test

This is the master for calling self-test procedures.

```
<Compilations: public>+≡
    public :: compilations_test
<Compilations: tests>≡
    subroutine compilations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
        <Compilations: execute tests>
    end subroutine compilations_test
```

Intrinsic Matrix Element

Compile an intrinsic test matrix element (`prc_test` type).

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```
<Compilations: execute tests>≡
    call test (compilations_1, "compilations_1", &
        "intrinsic test processes", &
        u, results)
<Compilations: tests>+≡
    subroutine compilations_1 (u)
        integer, intent(in) :: u
        type(string_t) :: libname, procname
        type(rt_data_t), target :: global

        write (u, "(A)")  "* Test output: compilations_1"
        write (u, "(A)")  "* Purpose: configure and compile test process"
        write (u, "(A)")

        call syntax_model_file_init ()

        call global%global_init ()

        libname = "compilation_1"
        procname = "prc_comp_1"
        call prepare_test_library (global, libname, 1, [procname])

        call compile_library (libname, global)

        call global%write_libraries (u)

        call global%final ()
        call syntax_model_file_final ()

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: compilations_1"

    end subroutine compilations_1
```

External Matrix Element

Compile an external test matrix element (omega type)

```
(Compilations: execute tests)+≡
    call test (compilations_2, "compilations_2", &
        "external process (omega)", &
        u, results)

(Compilations: tests)+≡
    subroutine compilations_2 (u)
        integer, intent(in) :: u
        type(string_t) :: libname, procname
        type(rt_data_t), target :: global

        write (u, "(A)")  "* Test output: compilations_2"
        write (u, "(A)")  "* Purpose: configure and compile test process"
        write (u, "(A)")

        call syntax_model_file_init ()

        call global%global_init ()
        call var_list_set_log (global%var_list, var_str ("?omega_openmp"), &
            .false., is_known = .true.)

        libname = "compilation_2"
        procname = "prc_comp_2"
        call prepare_test_library (global, libname, 2, [procname,procname])

        call compile_library (libname, global)

        call global%write_libraries (u)

        call global%final ()
        call syntax_model_file_final ()

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: compilations_2"

    end subroutine compilations_2
```

External Matrix Element

Compile an external test matrix element (omega type) and create driver files for a static executable.

```
(Compilations: execute tests)+≡
    call test (compilations_3, "compilations_3", &
        "static executable: driver", &
        u, results)

(Compilations: tests)+≡
    subroutine compilations_3 (u)
        integer, intent(in) :: u
        type(string_t) :: libname, procname, exename
        type(rt_data_t), target :: global
```

```

type(compilation_t) :: compilation
integer :: u_file
character(80) :: buffer

write (u, "(A)")  "* Test output: compilations_3"
write (u, "(A)")  "* Purpose: make static executable"
write (u, "(A)")

write (u, "(A)")  "* Initialize library"
write (u, "(A)")

```

External Matrix Element

Compile an external test matrix element (*omega* type) and incorporate this in a new static WHIZARD executable. In this version, we use the wrapper `compile_executable` procedure.

```

(Compilations: static tests) +=
  call test (compilations_static_2, "compilations_static_2", &
    "static executable: shortcut", &
    u, results)

(Compilations: tests) +=
  subroutine compilations_static_2 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    type(compilation_item_t) :: item
    type(compilation_t) :: compilation
    logical :: exist
    integer :: u_file

    write (u, "(A)")  "* Test output: compilations_static_2"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library and compile"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()
    call var_list_set_log (global%var_list, var_str ("?omega_openmp"), &
      .false., is_known = .true.)

```

```

libname = "compilations_static_2_lib"
procname = "prc_comp_stat_2"
exename = "compilations_static_2"

call prepare_test_library (global, libname, 2, [procname,procname])

call compile_executable (exename, [libname], global)

write (u, "(A)")  "* Check executable (should be present)"
write (u, "(A)")

inquire (file = char (exename), exist = exist)
write (u, "(A,A,L1)")  char (exename), " exists = ", exist

write (u, "(A)")
write (u, "(A)")  "* Cleanup"

u_file = free_unit ()
open (u_file, file = char (exename), status = "old", action = "write")
close (u_file, status = "delete")

call global%final ()
call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_static_2"

end subroutine compilations_static_2

```

21.7 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

```

<integrations.f90>≡

21.7.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

⟨Integrations: public⟩≡
    public :: integration_t

⟨Integrations: types⟩≡
    type :: integration_t
    private
    type(string_t) :: process_id

```

```

        type(string_t) :: run_id
        type(process_t), pointer :: process => null ()
        logical :: rebuild_phs = .false.
        logical :: ignore_phs_mismatch = .false.
!!! JRR: WK please check
!!! What about all these components?
!     type(string_t) :: phs_filename

21.7.4 API for integration objects

This initializer does everything except assigning cuts/scale/weight expressions. If ok is false, initialization failed, and the integration should be skipped.

If `me_only` is set, prepare just matrix-element evaluation: no phase space, no iterations.

<Integrations: integration: TBP>+≡

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

    subroutine integrations_history_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Integrations: execute history tests>
    end subroutine integrations_history_test

```

Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (21.1)$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (21.2)$$

f is the flux of the incoming particles with mass $m = 125 \text{ GeV}$ and energy $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (21.3)$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (21.4)$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (21.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function $f(x) = x$ for both beams. Together with the $1/x_1x_2$ factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the m_s mass which we set to zero here.

```

21.8 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

`<event_streams.f90>`≡
<File header>

```

module event_streams

  <Use kinds>
  <Use strings>
  <Use file utils>
  use diagnostics !NODEP!
  use unit_tests
  use variables
  use models
  use processes

```

```

    use events
    use eio_data
    use eio_base
    use rt_data
    use dispatch

    <Standard module head>

    <Event streams: public>

    <Event streams: parameters>

    <Event streams: types>

contains

    <Event streams: tests>

    <Event streams: procedures>

end module event_streams

```

21.8.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```

<Event streams: types>≡
    type :: event_stream_entry_t
        class(eio_t), allocatable :: eio
    end type event_stream_entry_t

```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```

<Event streams: public>≡
    public :: event_stream_array_t

<Event streams: types>+≡
    type :: event_stream_array_t
        type(event_stream_entry_t), dimension(:), allocatable :: entry
        integer :: i_in = 0
    contains
        <Event streams: event stream array: TBP>
    end type event_stream_array_t

```

Output.

```

<Event streams: event stream array: TBP>≡
    procedure :: write => event_stream_array_write

<Event streams: procedures>≡
    subroutine event_stream_array_write (object, unit)
        class(event_stream_array_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = output_unit (unit)
    end subroutine

```

```

write (u, "(1x,A)") "Event stream array:"
if (allocated (object%entry)) then
  select case (size (object%entry))
  case (0)
    write (u, "(3x,A)") "[empty]"
  case default
    do i = 1, size (object%entry)
      if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
      call object%entry(i)%eio%write (u)
    end do
  end select
else
  write (u, "(3x,A)") "[undefined]"
end if
end subroutine event_stream_array_write

```

Finalize all streams.

```

(Event streams: event stream array: TBP)+≡
  procedure :: final => event_stream_array_final

(Event streams: procedures)+≡
  subroutine event_stream_array_final (es_array)
    class(event_stream_array_t), intent(inout) :: es_array
    integer :: i
    do i = 1, size (es_array%entry)
      call es_array%entry(i)%eio%final ()
    end do
  end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

```

(Event streams: event stream array: TBP)+≡
  procedure :: init => event_stream_array_init

(Event streams: procedures)+≡
  subroutine event_stream_array_init &

    object%has_integral = .true.
  end if
end subroutine mci_set_init
```

21.9.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

```
<Simulations: types>+≡
  type :: core_safe_t
    class(prc_core_t), allocatable :: core
  end type core_safe_t
```

21.9.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration is not yet done, do it.

```
<Simulations: procedures>+≡
  subroutine prepare_process (process, process_id, integrate, global)
    type(process_t), pointer, intent(out) :: process
    type(string_t), intent(in) :: process_id
    logical, intent(in) :: integrate
    type(rt_data_t), intent(inout), target :: global
    process => global%process_stack%get_process_ptr (process_id)
    if (.not. associated (process)) then
      if (integrate) then
        call msg_message ("Simulate: process '" &
          // char (process_id) // "' needs integration")
      else
        call msg_message ("Simulate: process '" &
          // char (process_id) // "' needs initialization")
      end if
      call integrate_process (process_id, global, init_only = .not. integrate)
      if (signal_is_pending ()) return
      process => global%process_stack%get_process_ptr (process_id)
      if (associated (process)) then
        if (integrate) then
          call msg_message ("Simulate: integration done")
          call global%process_stack%fill_result_vars (process_id)
        else
          call msg_message ("Simulate: process initialization done")
        end if
      else
        call msg_fatal ("Simulate: process '" &
          // char (process_id) // "' could not be initialized: aborting")
      end if
    end if
  end subroutine prepare_process
```

21.9.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array

is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

```

<Simulations: types>+≡
  type, extends (event_t) :: entry_t
  private
    type(string_t) :: process_id
    type(string_t) :: library
    type(string_t) :: run_id
    logical :: has_integral = .false.
    real(default) :: integral = 0
    real(default) :: error = 0
    real(default) :: process_weight = 0
    type(counter_t) :: counter
    integer :: n_in = 0
    integer :: n_mci = 0
    type(mci_set_t), dimension(:), allocatable :: mci_set
    type(selector_t) :: mci_selector
    type(core_safe_t), dimension(:), allocatable :: core_safe
    type(model_t), pointer :: model => null ()
    type(qcd_t) :: qcd
  contains
    <Simulations: entry: TBP>
  end type entry_t

```

Output. Write just the configuration, the event is written by a separate routine.

The `verbose` option is unused, it is required by the interface of the base-object method.

```

<Simulations: entry: TBP>≡
  procedure :: write_config => entry_write_config

<Simulations: procedures>+≡
  subroutine entry_write_config (object, unit)
    class(entry_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit)
    write (u, "(3x,A,A,A)") "Process   = ", char (object%process_id), ""
    write (u, "(3x,A,A,A)") "Library   = ", char (object%library), ""

            call object%core_safe(i)%core%write (u)
        end do
    end if
end subroutine entry_write_config

```

Finalizer. The `instance` pointer component of the `event_t` base type points to a target which we did explicitly allocate in the `entry_init` procedure. Therefore, we finalize and explicitly deallocate it here. Then we call the finalizer of the base type.

```

<Simulations: entry: TBP>+≡
    procedure :: final => entry_final

<Simulations: procedures>+≡
    subroutine entry_final (object)
        class(entry_t), intent(inout) :: object
        integer :: i
        if (associated (object%instance)) then
            do i = 1, object%n_mci
                call object%instance%final_simulation (i)
            end do
            call object%instance%final ()
            deallocate (object%instance)
        end if
        call object%event_t%final ()
    end subroutine entry_final

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the `process_instance` pointer. Assign data by looking at the process object and at the environment.

If `n_alt` is set, we prepare for additional alternate sqme and weight entries.

If the process object is not found initially: if `integrate` is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If `generate` is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the `instance` and `process` pointers of the base type by the `connect` method, so we can reference them later.

```

21.9.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
  type, extends (entry_t) :: alt_entry_t
  contains
    <Simulations: alt entry: TBP>
  end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

21.9.7 The simulation type

Each simulation object corresponds to an event sample, identified by the `sample_id`.

The simulation may cover several processes simultaneously. All process-specific data, including the event records, are stored in the `entry` subobjects. The `current` index indicates which record was selected last.

```

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If `integrate` is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If

`integrate` is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If `generate` is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the luminosity setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the luminosity, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

```

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```

<Simulations: simulation: TBP>+≡
generic :: read_event => read_event_eio

22.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```
<Commands: types>≡
  type, abstract :: command_t
    type(parse_node_t), pointer :: pn => null ()
    class(command_t), pointer :: next => null ()
    type(parse_node_t), pointer :: pn_opt => null ()
    type(command_list_t), pointer :: options => null ()
    type(rt_data_t), pointer :: local => null ()
  contains
    <Commands: command: TBP>
  end type command_t
```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```
<Commands: command: TBP>≡
  procedure :: final => command_final

<Commands: procedures>≡
  recursive subroutine command_final (cmd)
    class(command_t), intent(inout) :: cmd
    if (associated (cmd%options)) then
      call cmd%options%final ()
      deallocate (cmd%options)
      deallocate (cmd%local)
    else
      cmd%local => null ()
    end if
  end subroutine command_final
```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

```
<Commands: procedures>+≡
  subroutine dispatch_command (command, pn)
    class(command_t), intent(inout), pointer :: command
    type(parse_node_t), intent(in), target :: pn
    select case (char (parse_node_get_rule_key (pn)))

case default
    print *, char (parse_node_get_rule_key (pn))
    call msg_bug ("Command not implemented")
end select
command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

<Commands: command: TBP>+≡
    procedure (command_write), deferred :: write

<Commands: interfaces>≡
    abstract interface
        subroutine command_write (cmd, unit, indent)
            import
            class(command_t), intent(in) :: cmd
            integer, intent(in), optional :: unit, indent
        end subroutine command_write
    end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

<Commands: command: TBP>+≡
    procedure (command_compile), deferred :: compile

```

```

<Commands: interfaces>+≡
  abstract interface
    subroutine command_compile (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_compile
  end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

<Commands: command: TBP>+≡
  procedure (command_execute), deferred :: execute

<Commands: interfaces>+≡
  abstract interface
    subroutine command_execute (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_execute
  end interface

```

Auxiliary for output:

```

<Commands: procedures>+≡
  subroutine write_indent (unit, indent)
    integer, intent(in) :: unit
    integer, intent(in), optional :: indent
    if (present (indent)) then
      write (unit, "(A)", advance="no") repeat (" ", indent)
    end if
  end subroutine write_indent

```

22.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```

<Commands: command: TBP>+≡
  procedure :: write_options => command_write_options

<Commands: procedures>+≡
  recursive subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options

```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```

<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
  recursive subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call cmd%options%compile (cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
    else
      cmd%local => global
    end if
  end subroutine command_compile_options

```

Execute options. First prepare the local environment, then execute the command list.

```

<Commands: command: TBP>+≡
  procedure :: execute_options => cmd_execute_options

<Commands: procedures>+≡
  recursive subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call cmd%local%link (global)
      call cmd%options%execute (cmd%local)
    end if
  end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the global environment.

```

<Commands: command: TBP>+≡
  procedure :: reset_options => cmd_reset_options

<Commands: procedures>+≡
  subroutine cmd_reset_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call global%restore (cmd%local)
    end if
  end subroutine cmd_reset_options

```

22.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

```
<Commands: types>+=  
  type, extends (command_t) :: cmd_model_t  
    private  
      type(string_t) :: name  
    contains  
      <Commands: cmd model: TBP>  
    end type cmd_model_t
```

Output

```
<Commands: cmd model: TBP>=  
  procedure :: write => cmd_model_write  
  
<Commands: procedures>+=  
  subroutine cmd_model_write (cmd, unit, indent)  
    class(cmd_model_t), intent(in) :: cmd  
    integer, intent(in), optional :: unit, indent  
    integer :: u  
    u = output_unit (unit); if (u < 0) return  
    call write_indent (u, indent)  
    write (u, "(1x,A,1x,'"',A,'\"') "model =", char (cmd%name)  
  end subroutine cmd_model_write
```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed.

```
<Commands: cmd model: TBP>+=  
  procedure :: compile => cmd_model_compile  
  
<Commands: procedures>+=  
  subroutine cmd_model_compile (cmd, global)  
    class(cmd_model_t), intent(inout) :: cmd  
    type(rt_data_t), intent(inout), target :: global  
    type(parse_node_t), pointer :: pn_name  
    type(string_t) :: filename  
    pn_name => parse_node_get_sub_ptr (cmd%pn, 3)  
    cmd%name = parse_node_get_string (pn_name)  
    filename = cmd%name // ".mdl"  
    call global%read_model (cmd%name, filename)  
  end subroutine cmd_model_compile
```

Execute: Insert a pointer into the global data record and reassign the variable list.

```
<Commands: cmd model: TBP>+=  
  procedure :: execute => cmd_model_execute  
  
<Commands: procedures>+=  
  subroutine cmd_model_execute (cmd, global)  
    class(cmd_model_t), intent(inout) :: cmd  
    type(rt_data_t), intent(inout), target :: global  
    type(model_t), pointer :: mdl
```

```

type(var_list_t), pointer :: model_vars
logical :: new_model
new_model = .true.
if (associated (global%model)) then
    new_model = model_get_name (global%model) /= cmd%name
end if
if (new_model) then
    if (global%model_list%model_exists (cmd%name)) then
        call msg_message ("Switching to model '" &
            // char (cmd%name) &
            // "': reassigning model parameters")
        call global%select_model (cmd%name)
    else
        call msg_fatal ("Switching to model '" &
            // char (cmd%name) &
            // "': unknown model name")
    end if
end if
end subroutine cmd_model_execute

```

Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_library_t
private
type(string_t) :: name
contains
<Commands: cmd library: TBP>
end type cmd_library_t

```

Output.

```

<Commands: cmd library: TBP>≡
procedure :: write => cmd_library_write

<Commands: procedures>+≡
subroutine cmd_library_write (cmd, unit, indent)
class(cmd_library_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = output_unit (unit)
call write_indent (u, indent)
write (u, "(1x,A,1x,'"',A,'\"') "library =", char (cmd%name)
end subroutine cmd_library_write

```

Compile. Get the library name.

```

<Commands: cmd library: TBP>+≡
procedure :: compile => cmd_library_compile

```

```

⟨Commands: procedures⟩+≡
  subroutine cmd_library_compile (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_name
    pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
    cmd%name = parse_node_get_string (pn_name)
  end subroutine cmd_library_compile

```

Execute: Initialize a new library and push it on the library stack (if it does not yet exist). Insert a pointer to the library into the global data record. Then, try to load the library unless the `rebuild` flag is set.

```

⟨Commands: cmd library: TBP⟩+≡
  procedure :: execute => cmd_library_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_library_execute (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(prclib_entry_t), pointer :: lib_entry
    type(process_library_t), pointer :: lib
    logical :: rebuild_library, recompile_library
    lib => global%prclib_stack%get_library_ptr (cmd%name)
    !!! JRR: WK please check
    rebuild_library = &
      var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
    !!! recompile_library = &
    !!!   var_list_get_lval (global%var_list, var_str ("?recompile_library"))
    if (.not. (associated (lib))) then
      allocate (lib_entry)
      call lib_entry%init (cmd%name)
      lib => lib_entry%process_library_t
      call global%add_prclib (lib_entry)
    else
      call global%update_prclib (lib)
    end if
    if (associated (lib) .and. .not. rebuild_library) then
      call lib%update_status (global%os_data)
    end if
  end subroutine cmd_library_execute

```

Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to `O'MEGA`, they are reconverted to strings.

This also includes the choice of method for the corresponding process: `omega` for `O'MEGA` matrix elements, `test` for special processes generated by `WHIZARD`, `external` for using an external matrix element and `dipole` for generating dipole subtraction terms.

```

⟨Commands: types⟩+≡

```

```

type, extends (command_t) :: cmd_process_t
  private
  type(string_t) :: id
  integer :: n_in = 0
  integer :: n_out = 0
  type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
  type(parse_node_p), dimension(:), allocatable :: pn_pdg_out
  contains
  <Commands: cmd process: TBP>
end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming and outgoing particles.

```

<Commands: cmd process: TBP>≡
  procedure :: write => cmd_process_write

<Commands: procedures>+≡
  subroutine cmd_process_write (cmd, unit, indent)
    class(cmd_process_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A,I0,A)") "process: ", char (cmd%id), " (", &
      size (cmd%pn_pdg_in), " -> ", size (cmd%pn_pdg_out), ")"
    call cmd%write_options (u, indent)
  end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

<Commands: cmd process: TBP>+≡
  procedure :: compile => cmd_process_compile

<Commands: procedures>+≡
  subroutine cmd_process_compile (cmd, global)
    class(cmd_process_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_id, pn_in, pn_out, pn_codes
    integer :: i
    pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_in => parse_node_get_next_ptr (pn_id, 2)
    pn_out => parse_node_get_next_ptr (pn_in, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_out)
    call cmd%compile_options (global)
    cmd%id = parse_node_get_string (pn_id)
    !!! JRR: WK please check is this still
    !   call process_library_check_name_consistency (cmd%id, global%prc_lib)
    cmd%n_in = parse_node_get_n_sub (pn_in)

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

end subroutine cmd_var_write
```

Compile the lhs and determine the variable name and type. Check whether this variable can be created or modified as requested, and append the value to the variable list, if appropriate. The value is initially undefined. The rhs is assigned to a pointer, to be compiled and evaluated when the command is executed.

```

SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_slha_t
  private
  type(string_t) :: file
  logical :: write_mode = .false.
  contains
  <Commands: cmd slha: TBP>
end type cmd_slha_t

```

Output.

```

<Commands: cmd slha: TBP>≡
  procedure :: write => cmd_slha_write

<Commands: procedures>+≡
  subroutine cmd_slha_write (cmd, unit, indent)
    class(cmd_slha_t), intent(in) :: cmd

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_expect_t
    private
        type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
        ⟨Commands: cmd expect: TBP⟩
    end type cmd_expect_t

```

Simply tell the status.

```

⟨Commands: cmd expect: TBP⟩≡
    procedure :: write => cmd_expect_write

⟨Commands: procedures⟩+≡
    subroutine cmd_expect_write (cmd, unit, indent)
        class(cmd_expect_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        if (associated (cmd%pn_lexpr)) then
            write (u, "(1x,A)") "expect: [expression associated]"
        else
            write (u, "(1x,A)") "expect: [undefined]"
        end if
    end subroutine cmd_expect_write

```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

```

⟨Commands: cmd expect: TBP⟩+≡
  procedure :: compile => cmd_expect_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_expect_compile (cmd, global)
    class(cmd_expect_t), intent(inout) :: cmd

Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

```
(Commands: types)+≡  
  type :: sentry_expr_t  
    type(eval_tree_t), dimension(:), allocatable :: expr  
    contains  
    (Commands: sentry_expr: TBP)  
  end type sentry_expr_t
```

Compile parse nodes into evaluation trees.

```
(Commands: sentry_expr: TBP)≡  
  procedure :: compile => sentry_expr_compile  
  
(Commands: procedures)+≡  
  subroutine sentry_expr_compile (sentry, pn, global)  
    class(sentry_expr_t), intent(out) :: sentry  
    type(parse_node_t), intent(in), target :: pn  
    type(rt_data_t), intent(in), target :: global  
    type(parse_node_t), pointer :: pn_sentry, pn_expr, pn_extra  
    integer :: n_expr, i  
    n_expr = parse_node_get_n_sub (pn)  
    allocate (sentry%expr (n_expr))  
    if (n_expr > 0) then  
      i = 0  
      pn_expr => parse_node_get_sub_ptr (pn)  
      do i = 1, n_expr  
        call eval_tree_init_expr (sentry%expr(i), pn_expr, global%var_list)  
        pn_extra => parse_node_get_next_ptr (pn_expr)  
        if (associated (pn_extra)) then  
          pn_sentry => parse_node_get_sub_ptr (pn_extra, 2)  
          pn_expr => parse_node_get_sub_ptr (pn_sentry)  
        end if  
      end do  
    end if  
  end subroutine sentry_expr_compile
```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

```

    global%pn%ren_scale_expr => cmd%pn_expr
  end subroutine cmd_ren_scale_execute

```

Weight

Define a weight expression. The weight is applied to a process to be integrated, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

<Commands: types>+=
  type, extends (command_t) :: cmd_weight_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd weight: TBP>
  end type cmd_weight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd weight: TBP>=
  procedure :: write => cmd_weight_write

<Commands: procedures>+=
  subroutine cmd_weight_write (cmd, unit, indent)
    class(cmd_weight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "weight expression: [defined]"
  end subroutine cmd_weight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd weight: TBP>+=
  procedure :: compile => cmd_weight_compile

<Commands: procedures>+=
  subroutine cmd_weight_compile (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_weight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd weight: TBP⟩+≡
  procedure :: execute => cmd_weight_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_weight_execute (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%weight_expr => cmd%pn_expr
  end subroutine cmd_weight_execute

```

Selection

Define a selection expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_selection_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()
  contains
  ⟨Commands: cmd selection: TBP⟩
end type cmd_selection_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

⟨Commands: cmd selection: TBP⟩≡
  procedure :: write => cmd_selection_write

⟨Commands: procedures⟩+≡
  subroutine cmd_selection_write (cmd, unit, indent)
    class(cmd_selection_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "selection expression: [defined]"
  end subroutine cmd_selection_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd selection: TBP⟩+≡
  procedure :: compile => cmd_selection_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_selection_compile (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_selection_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd selection: TBP⟩+≡
  procedure :: execute => cmd_selection_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_reweight_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()
  contains
  ⟨Commands: cmd reweight: TBP⟩
end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

⟨Commands: cmd reweight: TBP⟩≡
  procedure :: write => cmd_reweight_write

⟨Commands: procedures⟩+≡
  subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd reweight: TBP⟩+≡
  procedure :: compile => cmd_reweight_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd reweight: TBP⟩+≡
    procedure :: execute => cmd_reweight_execute

⟨Commands: procedures⟩+≡
    subroutine cmd_reweight_execute (cmd, global)
        class(cmd_reweight_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        global%pn%reweight_expr => cmd%pn_expr
    end subroutine cmd_reweight_execute

```

Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_alt_setup_t
        private
        type(parse_node_p), dimension(:), allocatable :: setup
    contains
        ⟨Commands: cmd alt setup: TBP⟩
    end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

⟨Commands: cmd alt setup: TBP⟩≡
    procedure :: write => cmd_alt_setup_write

⟨Commands: procedures⟩+≡
    subroutine cmd_alt_setup_write (cmd, unit, indent)
        class(cmd_alt_setup_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
    end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

⟨Commands: cmd alt setup: TBP⟩+≡
    procedure :: compile => cmd_alt_setup_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_alt_setup_compile (cmd, global)
        class(cmd_alt_setup_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_list, pn_setup
        integer :: i
        pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
        if (associated (pn_list)) then

```

```

        allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
        i = 1
        pn_setup => parse_node_get_sub_ptr (pn_list)
        do while (associated (pn_setup))
            cmd%setup(i)%ptr => pn_setup
            i = i + 1
            pn_setup => parse_node_get_next_ptr (pn_setup)
        end do
    else
        allocate (cmd%setup (0))
    end if
end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

<Commands: cmd alt setup: TBP>+≡
    procedure :: execute => cmd_alt_setup_execute

<Commands: procedures>+≡
    subroutine cmd_alt_setup_execute (cmd, global)

        integer :: u, i
        u = output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)", advance="no") "integrate ("
        do i = 1, cmd%n_proc
            if (i > 1) write (u, "(A,1x)", advance="no") ", "

```

```

        write (u, "(A)", advance="no") char (cmd%process_id(i))
    end do
    write (u, "(A)") ")"
end subroutine cmd_integrate_write

```

Compile.

```

⟨Commands: cmd integrate: TBP⟩+≡
    procedure :: compile => cmd_integrate_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_integrate_compile (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_proclist, pn_proc
        integer :: i
        pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
        cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
        call cmd%compile_options (global)
        cmd%n_proc = parse_node_get_n_sub (pn_proclist)
        allocate (cmd%process_id (cmd%n_proc))
        pn_proc => parse_node_get_sub_ptr (pn_proclist)
        do i = 1, cmd%n_proc
            cmd%process_id(i) = parse_node_get_string (pn_proc)
            call global%process_stack%init_result_vars (cmd%process_id(i))
            pn_proc => parse_node_get_next_ptr (pn_proc)
        end do
    end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

⟨Commands: cmd integrate: TBP⟩+≡
    procedure :: execute => cmd_integrate_execute

⟨Commands: procedures⟩+≡
    subroutine cmd_integrate_execute (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        integer :: i

    call set_drawing_options (drawing_options, cmd%local%var_list)

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_graph_t
  private
  type(string_t) :: id
  !   type(parse_node_t), pointer :: pn_id
  !   logical :: use_id_expr = .false.
  integer :: n_elements = 0
  !   type(cmd_plot_t), dimension(:), allocatable :: el
  type(string_t), dimension(:), allocatable :: element_id
  contains
  <Commands: cmd graph: TBP>
end type cmd_graph_t

```

Finalizer for the eval trees.

```

<CCC Commands: procedures>+≡
  subroutine cmd_graph_final (graph)
  type(cmd_graph_t), intent(inout) :: graph
  integer :: i
  if (allocated (graph%el)) then
    do i = 1, size (graph%el)
      call cmd_plot_final (graph%el(i))
    end do
    deallocate (graph%el)
  end if
  if (associated (graph%options)) then
    call command_list_final (graph%options)
    deallocate (graph%options)
  end if
end subroutine cmd_graph_final

```

Output. Just print the ID.

```

<Commands: cmd graph: TBP>≡
  procedure :: write => cmd_graph_write

<Commands: procedures>+≡
  subroutine cmd_graph_write (cmd, unit, indent)
  class(cmd_graph_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u, i
  u = output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,A,A,I0,A)") "graph: ", char (cmd%id), &
    " (", cmd%n_elements, " entries)"
end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

<Commands: cmd graph: TBP>+≡
  procedure :: compile => cmd_graph_compile

```

```

<Commands: procedures>+≡
subroutine cmd_graph_compile (cmd, global)
  class(cmd_graph_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
  integer :: i

  pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
  pn_tag => parse_node_get_sub_ptr (pn_term)
  cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
  call cmd%compile_options (global)
  select case (char (parse_node_get_rule_key (pn_tag)))
  case ("analysis_id")
    cmd%id = parse_node_get_string (pn_tag)
  case default
    call msg_bug ("graph: name expression not implemented (yet)")
!    cmd%use_id_expr = .true.
!    cmd%pn_id => pn_tag
  end select
  pn_def => parse_node_get_next_ptr (pn_term, 2)
  cmd%n_elements = parse_node_get_n_sub (pn_def)
  allocate (cmd%element_id (cmd%n_elements))
  pn_term => parse_node_get_sub_ptr (pn_def)
  pn_tag => parse_node_get_sub_ptr (pn_term)
!   pn_opt => parse_node_get_next_ptr (pn_tag)
!   call cmd_plot_init (cmd%el(1), pn_tag, pn_opt, global)
  cmd%element_id(1) = parse_node_get_string (pn_tag)
  pn_app => parse_node_get_next_ptr (pn_term)
  do i = 2, cmd%n_elements
    pn_term => parse_node_get_sub_ptr (pn_app, 2)
    pn_tag => parse_node_get_sub_ptr (pn_term)
!    pn_opt => parse_node_get_next_ptr (pn_tag)
!    call cmd_plot_init (cmd%el(i), pn_tag, pn_opt, global)
    cmd%element_id(i) = parse_node_get_string (pn_tag)
    pn_app => parse_node_get_next_ptr (pn_app)
  end do

end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

<Commands: cmd graph: TBP>+≡
  procedure :: execute => cmd_graph_execute

<Commands: procedures>+≡
subroutine cmd_graph_execute (cmd, global)
  class(cmd_graph_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global

```

```

type(graph_options_t) :: graph_options
type(drawing_options_t) :: drawing_options
integer :: i, type

call graph_options_init (graph_options)
call set_graph_options (graph_options, cmd%local%var_list)
call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

do i = 1, cmd%n_elements
!   if (cmd%el(i)%use_id_expr) then
!       cmd%el(i)%id = &
!           eval_string (cmd%el(i)%pn_id, cmd%el(i)%local%var_list)
!   end if
!   type = analysis_store_get_object_type (cmd%el(i)%id)
!   select case (type)
!       case (AN_HISTOGRAM)
!           call drawing_options_init_histogram (drawing_options)
!       case (AN_PLOT)
!           call drawing_options_init_plot (drawing_options)
!       end select
!   call set_drawing_options (drawing_options, cmd%local%var_list)
!   if (associated (cmd%el(i)%options)) then
!       call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
!   end if
!   call analysis_fill_graph (cmd%id, i, cmd%element_id(i))
!       drawing_options)
end do
end subroutine cmd_graph_execute

```

Analysis

Hold the analysis ID either as a string or as an expression:

```

<CCC Commands: types>≡
type :: analysis_id_t
type(string_t) :: tag
type(parse_node_t), pointer :: pn_sexpr => null ()
end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_analysis_t
private
type(parse_node_t), pointer :: pn_lexpr => null ()
contains
<Commands: cmd analysis: TBP>
end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

<Commands: cmd analysis: TBP>≡

```

```

    procedure :: write => cmd_analysis_write
<Commands: procedures>+≡
    subroutine cmd_analysis_write (cmd, unit, indent)
        class(cmd_analysis_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)") "analysis: [defined]"
    end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd analysis: TBP>+≡
    procedure :: compile => cmd_analysis_compile

<Commands: procedures>+≡
    subroutine cmd_analysis_compile (cmd, global)
        class(cmd_analysis_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
    end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd analysis: TBP>+≡
    procedure :: execute => cmd_analysis_execute

<Commands: procedures>+≡
    subroutine cmd_analysis_execute (cmd, global)
        class(cmd_analysis_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        global%pn%analysis_lexpr => cmd%pn_lexpr
    end subroutine cmd_analysis_execute

```

Write histograms and plots

The data type encapsulating the command:

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_write_analysis_t
        private
        !     type(analysis_id_t), dimension(:), allocatable :: id
        type(string_t), dimension(:), allocatable :: tag
        contains
        <Commands: cmd write analysis: TBP>
    end type cmd_write_analysis_t

<CCC Commands: procedures>+≡
    subroutine cmd_write_analysis_final (write_analysis)
        type(cmd_write_analysis_t), intent(inout) :: write_analysis
        if (allocated (write_analysis%id)) deallocate (write_analysis%id)
        if (allocated (write_analysis%tag)) deallocate (write_analysis%tag)
    end subroutine cmd_write_analysis_final

```

```

        if (associated (write_analysis%options)) then
            call command_list_final (write_analysis%options)
            deallocate (write_analysis%options)
        end if
    end subroutine cmd_write_analysis_final

```

Output. Just the keyword.

```

<Commands: cmd write analysis: TBP>≡
    procedure :: write => cmd_write_analysis_write

<Commands: procedures>+≡
    subroutine cmd_write_analysis_write (cmd, unit, indent)
        class(cmd_write_analysis_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)") "write_analysis"
    end subroutine cmd_write_analysis_write

```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
    procedure :: compile => cmd_write_analysis_compile

<Commands: procedures>+≡
    subroutine cmd_write_analysis_compile (cmd, global)
        class(cmd_write_analysis_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
        integer :: n, i
        pn_clause => parse_node_get_sub_ptr (cmd%pn)
        pn_args => parse_node_get_sub_ptr (pn_clause, 2)
        cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
        call cmd%compile_options (global)
        if (associated (pn_args)) then
            n = parse_node_get_n_sub (pn_args)
            allocate (cmd%tag (n))
!            allocate (cmd%id (n))
            do i = 1, n
                pn_id => parse_node_get_sub_ptr (pn_args, i)
                if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
                    cmd%tag(i) = parse_node_get_string (pn_id)
!                    cmd%id(i)%tag = parse_node_get_string (pn_id)

                    else
                        call msg_bug ("write_analysis: name expression not implemented")
!                        cmd%id(i)%pn_sexpr => pn_id
                        end if
            end do
!        else
!            allocate (cmd%id (0))
!        end if
    end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

(Limits: public parameters)+≡
character(*), parameter, public :: &
    DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
    FORBIDDEN_ENDINGS1 = (/ "o", "a" /)
character(len=2), dimension(5), parameter, public :: &
    FORBIDDEN_ENDINGS2 = (/ "mp", "ps", "vg", "lo", "la" /)
character(len=3), dimension(15), parameter, public :: &
    FORBIDDEN_ENDINGS3 = (/ "aux", "dvi", "evt", "evx", "f03", "f90", &
        "f95", "log", "ltp", "mpx", "pdf", "phs", "sin", "tex", "vbg" /)

```

Execute. If the `data_filename` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. Otherwise, we use the parameters and macros for custom data processing.

```

        else

```

```

        call file_list_write (global%out_files, file, string, advance)
    end if
end if
end subroutine cmd_printf_execute

```

Record data

The expression syntax already contains a **record** keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_record_t
    private
        type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
        ⟨Commands: cmd record: TBP⟩
    end type cmd_record_t

```

Finalizer for the eval trees.

```

⟨CCC Commands: procedures⟩+≡
    subroutine cmd_record_final (record)
        type(cmd_record_t), intent(inout) :: record
    end subroutine cmd_record_final

```

Output. With the compile hack below, there is nothing of interest to print here.

```

⟨Commands: cmd record: TBP⟩≡
    procedure :: write => cmd_record_write

⟨Commands: procedures⟩+≡
    subroutine cmd_record_write (cmd, unit, indent)
        class(cmd_record_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)") "record"
    end subroutine cmd_record_write

```

Compile. This is a hack which transforms the **record** command into a **record** expression, which we handle in the **expressions** module.

```

⟨Commands: cmd record: TBP⟩+≡
    procedure :: compile => cmd_record_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_record_compile (cmd, global)
        class(cmd_record_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
        call parse_node_create_branch (pn_lexpr, &
            syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))
        call parse_node_create_branch (pn_lsinglet, &

```

```

        syntax_get_rule_ptr (syntax_cmd_list, var_str ("lsinglet")))
    call parse_node_append_sub (pn_lexpr, pn_lsinglet)
    call parse_node_create_branch (pn_lterm, &
        syntax_get_rule_ptr (syntax_cmd_list, var_str ("lterm")))
    call parse_node_append_sub (pn_lsinglet, pn_lterm)

        lval = eval_log (cmd%pn_lexpr, global%var_list)
    end subroutine cmd_record_execute

```

Decay properties

This record holds decay properties for a particle. To be used for `unstable` and `stable` declarations, which contain an array of that type.

```

<CCC Commands: types>+≡
    type :: decay_properties_t
        type(parse_node_t), pointer :: pn_pdg => null ()
        type(string_t) :: prt
        type(flavor_t) :: flv
        integer :: n_proc = 0
        type(string_t), dimension(:), allocatable :: process_id
        real(default), dimension(:), allocatable :: br
        logical :: invalid = .false.
    end type decay_properties_t

```

The finalizer is generic:

```

<CCC Commands: procedures>+≡
    subroutine decay_properties_final (decay)
        type(decay_properties_t), intent(inout) :: decay
    end subroutine decay_properties_final

```

Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_unstable_t

```

```

private
integer :: n_proc = 0
type(string_t), dimension(:), allocatable :: process_id
type(parse_node_t), pointer :: pn_prt_in => null ()
contains
  <Commands: cmd unstable: TBP>
end type cmd_unstable_t

```

Output: we know the process IDs.

```

  <Commands: cmd unstable: TBP>≡
    procedure :: write => cmd_unstable_write

  <Commands: procedures>+≡
    subroutine cmd_unstable_write (cmd, unit, indent)
      class(cmd_unstable_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u, i
      u = output_unit (unit); if (u < 0) return
      call write_indent (u, indent)
      write (u, "(1x,A,1x,I0,1x,A)", advance="no") &
        "unstable:", 1, "("
      do i = 1, cmd%n_proc
        if (i > 1) write (u, "(A,1x)", advance="no") " ,"
        write (u, "(A)", advance="no") char (cmd%process_id(i))
      end do
      write (u, "(A)") ")"
    end subroutine cmd_unstable_write

```

Compile. Initiate an eval tree for the decaying particle and determine the decay channel process IDs.

```

  <Commands: cmd unstable: TBP>+≡
    procedure :: compile => cmd_unstable_compile

  <Commands: procedures>+≡

```

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `fs_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

```

```

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Note: this temporary implementation uses only the `n_events` variable for counting. The full implementation should also accept the `luminosity` variable.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

end subroutine cmd_iterations_execute
```

Range expressions

We need a special type for storing and evaluating range expressions.

(Commands: parameters)≡

```
integer, parameter :: STEP_NONE = 0
integer, parameter :: STEP_ADD = 1
integer, parameter :: STEP_SUB = 2
integer, parameter :: STEP_MUL = 3
integer, parameter :: STEP_DIV = 4
integer, parameter :: STEP_COMP_ADD = 11
integer, parameter :: STEP_COMP_MUL = 13
```

There is an abstract base type and two implementations: scan over integers and scan over reals.

(Commands: types)+≡

```
type, abstract :: range_t
  type(parse_node_t), pointer :: pn_expr => null ()
  type(parse_node_t), pointer :: pn_term => null ()
  type(parse_node_t), pointer :: pn_factor => null ()
  type(parse_node_t), pointer :: pn_value => null ()
  type(parse_node_t), pointer :: pn_literal => null ()
  type(parse_node_t), pointer :: pn_beg => null ()
  type(parse_node_t), pointer :: pn_end => null ()
```

```

    type(parse_node_t), pointer :: pn_step => null ()
    type(eval_tree_t) :: expr_beg
    type(eval_tree_t) :: expr_end
    type(eval_tree_t) :: expr_step
    integer :: step_mode = 0
    integer :: n_step = 0
contains
  <Commands: range: TBP>
end type range_t

```

These are the implementations:

```

<Commands: types>+≡
  type, extends (range_t) :: range_int_t
    integer :: i_beg = 0
    integer :: i_end = 0
    integer :: i_step = 0
contains
  <Commands: range int: TBP>
end type range_int_t

  type, extends (range_t) :: range_real_t
    real(default) :: r_beg = 0
    real(default) :: r_end = 0
    real(default) :: r_step = 0
    real(default) :: lr_beg = 0
    real(default) :: lr_end = 0
    real(default) :: lr_step = 0
contains
  <Commands: range real: TBP>
end type range_real_t

```

Finalize the allocated dummy node. The other nodes are just pointers.

```

<Commands: range: TBP>≡
  procedure :: final => range_final

<Commands: procedures>+≡
  subroutine range_final (object)
    class(range_t), intent(inout) :: object
    if (associated (object%pn_expr)) then
      call parse_node_final (object%pn_expr, recursive = .false.)
      call parse_node_final (object%pn_term, recursive = .false.)
      call parse_node_final (object%pn_factor, recursive = .false.)
      call parse_node_final (object%pn_value, recursive = .false.)
      call parse_node_final (object%pn_literal, recursive = .false.)
      deallocate (object%pn_expr)
      deallocate (object%pn_term)
      deallocate (object%pn_factor)
      deallocate (object%pn_value)
      deallocate (object%pn_literal)
    end if
  end subroutine range_final

```

Output.

```

            // "' not implemented")
    end select
end subroutine range_init

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

<Commands: range: TBP>+≡

```

    procedure :: create_value_node => range_create_value_node

```

<Commands: procedures>+≡

Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

Note: for the integer/real range array, the obvious implementation as a polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are apparently broken.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_scan_t
    private
    type(string_t) :: name
    integer :: n_values = 0
    type(parse_node_p), dimension(:), allocatable :: scan_cmd
!    class(range_t), dimension(:), allocatable :: range
    type(range_int_t), dimension(:), allocatable :: range_int
    type(range_real_t), dimension(:), allocatable :: range_real
    contains
    <Commands: cmd scan: TBP>
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

<Commands: cmd scan: TBP>≡
    procedure :: final => cmd_scan_final

<Commands: procedures>+≡
    recursive subroutine cmd_scan_final (cmd)
    class(cmd_scan_t), intent(inout) :: cmd

            cmd%n_values
    end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the

local parse tree.

  end subroutine cmd_scan_execute

```

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of **else if** constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_if_t
  private
  type(parse_node_t), pointer :: pn_if_lexpr => null ()
  type(command_list_t), pointer :: if_body => null ()
  type(cmd_if_t), dimension(:), pointer :: elsif_cmd => null ()
  type(command_list_t), pointer :: else_body => null ()
  contains
  ⟨Commands: cmd if: TBP⟩

```

```
end type cmd_if_t
```

Finalizer. There are no local options, therefore we can simply override the default finalizer.

```
<Commands: cmd if: TBP>≡
  procedure :: final => cmd_if_final

<Commands: procedures>+≡
  recursive subroutine cmd_if_final (cmd)
    class(cmd_if_t), intent(inout) :: cmd
    integer :: i
    if (associated (cmd%if_body)) then
      call command_list_final (cmd%if_body)
      deallocate (cmd%if_body)
    end if
    if (associated (cmd%elsif_cmd)) then
      do i = 1, size (cmd%elsif_cmd)
        call cmd_if_final (cmd%elsif_cmd(i))
      end do
      deallocate (cmd%elsif_cmd)
    end if
    if (associated (cmd%else_body)) then
      call command_list_final (cmd%else_body)
      deallocate (cmd%else_body)
    end if
  end subroutine cmd_if_final
```

Output. Recursively write the command lists.

```
<Commands: cmd if: TBP>+≡
  procedure :: write => cmd_if_write

    call cmd%command_list%execute (global)
    call msg_message &
      ("End of included '" // char (cmd%file) // "'")
  end if
end subroutine cmd_include_execute

```

Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```
<Commands: types>+≡
    type, extends (command_t) :: cmd_quit_t
        private
        logical :: has_code = .false.
        type(parse_node_t), pointer :: pn_code_expr => null ()
        contains
        <Commands: cmd quit: TBP>
    end type cmd_quit_t
```

Output.

```
<Commands: cmd quit: TBP>≡
    procedure :: write => cmd_quit_write

<Commands: procedures>+≡
    subroutine cmd_quit_write (cmd, unit, indent)
        class(cmd_quit_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,L1)") "quit: has_code = ", cmd%has_code
    end subroutine cmd_quit_write
```

Compile: allocate a quit object which serves as a placeholder.

```
<Commands: cmd quit: TBP>+≡
    procedure :: compile => cmd_quit_compile

<Commands: procedures>+≡
    subroutine cmd_quit_compile (cmd, global)
        class(cmd_quit_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_arg
        pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
        if (associated (pn_arg)) then
            cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
            cmd%has_code = .true.
        end if
    end subroutine cmd_quit_compile
```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```
<Commands: cmd quit: TBP>+≡
    procedure :: execute => cmd_quit_execute

<Commands: procedures>+≡
    subroutine cmd_quit_execute (cmd, global)
        class(cmd_quit_t), intent(inout) :: cmd
```

```

type(rt_data_t), intent(inout), target :: global
logical :: is_known
if (cmd%has_code) then
    global%quit_code = eval_int (cmd%pn_code_expr, global%var_list, &
        is_known=is_known)
    if (.not. is_known) then
        call msg_error ("Undefined return code of quit/exit command")
    end if
end if
global%quit = .true.
end subroutine cmd_quit_execute

```

22.2.2 The command list

The command list holds a list of commands and relevant global data.

```

<Commands: public>+≡
    public :: command_list_t

<Commands: types>+≡
    type :: command_list_t
        ! not private anymore as required by the whizard-c-interface
        class(command_t), pointer :: first => null ()
        class(command_t), pointer :: last => null ()
        contains
        <Commands: command list: TBP>
    end type command_list_t

```

Output.

```

<Commands: command list: TBP>≡
    procedure :: write => command_list_write

<Commands: procedures>+≡
    recursive subroutine command_list_write (cmd_list, unit, indent)
        class(command_list_t), intent(in) :: cmd_list
        integer, intent(in), optional :: unit, indent
        class(command_t), pointer :: cmd
        cmd => cmd_list%first
        do while (associated (cmd))
            call cmd%write (unit, indent)
            cmd => cmd%next
        end do
    end subroutine command_list_write

```

Append a new command to the list and free the original pointer.

```

<Commands: command list: TBP>+≡
    procedure :: append => command_list_append

<Commands: procedures>+≡
    subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
        if (associated (cmd_list%last)) then

```

```

        cmd_list%last%next => command
    else
        cmd_list%first => command
    end if
    cmd_list%last => command
    command => null ()
end subroutine command_list_append

```

Finalize.

```

<Commands: command list: TBP>+≡
    procedure :: final => command_list_final

<Commands: procedures>+≡
    recursive subroutine command_list_final (cmd_list)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), pointer :: command
        do while (associated (cmd_list%first))
            command => cmd_list%first
            cmd_list%first => cmd_list%first%next
            call command%final ()
            deallocate (command)
        end do
        cmd_list%last => null ()
    end subroutine command_list_final

```

22.2.3 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```

<Commands: command list: TBP>+≡
    procedure :: compile => command_list_compile

<Commands: procedures>+≡
    recursive subroutine command_list_compile (cmd_list, pn, global)
        class(command_list_t), intent(inout), target :: cmd_list
        type(parse_node_t), intent(in), target :: pn
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_cmd
        class(command_t), pointer :: command
        integer :: i
        pn_cmd => parse_node_get_sub_ptr (pn)
        do i = 1, parse_node_get_n_sub (pn)
            call dispatch_command (command, pn_cmd)
            call command%compile (global)
            call cmd_list%append (command)
            call terminate_now_if_signal ()
            pn_cmd => parse_node_get_next_ptr (pn_cmd)
        end do
    end subroutine command_list_compile

```

22.2.4 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```
<Commands: command list: TBP>+≡
    procedure :: execute => command_list_execute

<Commands: procedures>+≡
    recursive subroutine command_list_execute (cmd_list, global)
        class(command_list_t), intent(in) :: cmd_list
        type(rt_data_t), intent(inout), target :: global
        class(command_t), pointer :: command
        command => cmd_list%first
        COMMAND_COND: do while (associated (command))
            call command%execute_options (global)
            call command%execute (global)
            call command%reset_options (global)
            call terminate_now_if_signal ()
            if (global%quit) exit COMMAND_COND
            command => command%next
        end do COMMAND_COND
    end subroutine command_list_execute
```

22.2.5 Command list syntax

```
<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡
    public :: syntax_cmd_list_init

<Commands: procedures>+≡
    subroutine syntax_cmd_list_init ()
        type(ifile_t) :: ifile
        call define_cmd_list_syntax (ifile)
        call syntax_init (syntax_cmd_list, ifile)
        call ifile_final (ifile)
    end subroutine syntax_cmd_list_init

<Commands: public>+≡
    public :: syntax_cmd_list_final

<Commands: procedures>+≡
    subroutine syntax_cmd_list_final ()
        call syntax_final (syntax_cmd_list)
    end subroutine syntax_cmd_list_final

<Commands: public>+≡
    public :: syntax_cmd_list_write
```

<Commands: procedures>+≡

```
subroutine syntax_cmd_list_write (unit)
  integer, intent(in), optional :: unit
  call syntax_write (syntax_cmd_list, unit)
end subroutine syntax_cmd_list_write
```

<Commands: procedures>+≡

```
subroutine define_cmd_list_syntax (ifile)
  type(ifile_t), intent(inout) :: ifile
  call ifile_append (ifile, "SEQ command_list = command*")
  call ifile_append (ifile, "ALT command = " &

<Standard module head>

<WHIZARD: public>

<WHIZARD: types>

<WHIZARD: variables>

  save

<WHIZARD: interfaces>

contains

<WHIZARD: procedures>

end module whizard

```

22.3.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```
<WHIZARD: public>≡
  public :: whizard_options_t

<WHIZARD: types>≡
  type :: whizard_options_t
    type(string_t) :: preload_model
    type(string_t) :: preload_library
    logical :: rebuild_library = .false.
  ! logical :: rebuild_user
    logical :: rebuild_phs = .false.
    logical :: rebuild_grids = .false.
    logical :: rebuild_events = .false.
  end type whizard_options_t
```

22.3.2 The whizard object

An object of type `whizard_t` is the top-level wrapper for a `WHIZARD` instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```
<WHIZARD: public>+≡
  public :: whizard_t

<WHIZARD: types>+≡
  type :: whizard_t
    type(whizard_options_t) :: options
    type(rt_data_t) :: global
  contains
    <WHIZARD: whizard: TBP>
  end type whizard_t
```

22.3.3 Initialization and finalization

```
<WHIZARD: whizard: TBP>≡
  procedure :: init => whizard_init
```

```

<WHIZARD: procedures>≡
subroutine whizard_init (whizard, options)
  class(whizard_t), intent(out), target :: whizard
  type(whizard_options_t), intent(in) :: options
  call init_syntax_tables ()
  whizard%options = options
  call whizard%global%global_init ()
  call whizard%init_rebuild_flags ()
  call whizard%preload_model ()
  call whizard%preload_library ()
end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: final => whizard_final

<WHIZARD: procedures>+≡
subroutine whizard_final (whizard)
  class(whizard_t), intent(inout), target :: whizard
  call whizard%global%final ()
  !!! JRR: WK please check
  !   call user_code_final ()
  !   call decay_store_final ()
  !!! No longer existent
  !   call process_store_final ()
  !   call model_list_final ()
  call final_syntax_tables ()
end subroutine whizard_final

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: procedures>+≡
subroutine whizard_init_rebuild_flags (whizard)
  class(whizard_t), intent(inout), target :: whizard
  associate (var_list => whizard%global%var_list, options => whizard%options)
    call var_list_append_log &
      (var_list, var_str ("?rebuild_library"), options%rebuild_library, &
      intrinsic=.true.)
    call var_list_append_log &
      (var_list, var_str ("?rebuild_phase_space"), options%rebuild_phs, &
      intrinsic=.true.)
    call var_list_append_log &
      (var_list, var_str ("?rebuild_grids"), options%rebuild_grids, &
      intrinsic=.true.)
    call var_list_append_log &
      (var_list, var_str ("?rebuild_events"), options%rebuild_events, &
      intrinsic=.true.)
  end associate
end subroutine whizard_init_rebuild_flags

```

This procedure preloads a model, if a model name is given.

```

<WHIZARD: whizard: TBP>+=
  procedure :: preload_model => whizard_preload_model
<WHIZARD: procedures>+=
  subroutine whizard_preload_model (whizard)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t) :: model_name, filename
    model_name = whizard%options%preload_model
    if (model_name /= "") then
      filename = model_name // ".mdl"
      call whizard%global%read_model (model_name, filename)
      if (associated (whizard%global%model)) then
        call msg_message ("Preloaded model: " &
          // char (model_name))
      else
        call msg_fatal ("Preloading model " // char (model_name) &
          // " failed")
      end if
    else
      call msg_message ("No model preloaded")
    end if
  end subroutine whizard_preload_model

```

This procedure preloads a library, if a library name is given.

Note: This version just opens a new library with that name. It does not load (yet) an existing library on file, as previous WHIZARD versions would do.

```

<WHIZARD: whizard: TBP>+=
  procedure :: preload_library => whizard_preload_library
<WHIZARD: procedures>+=
  subroutine whizard_preload_library (whizard)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t) :: library_name, filename
    type(string_t), dimension(:), allocatable :: libname_static
    type(prclib_entry_t), pointer :: lib_entry
    type(process_library_t), pointer :: lib
    integer :: i
    call get_prclib_static (libname_static)
    do i = 1, size (libname_static)
      allocate (lib_entry)
      call lib_entry%init_static (libname_static(i))
      call whizard%global%add_prclib (lib_entry)
    end do
    library_name = whizard%options%preload_library
    if (library_name /= "") then
      allocate (lib_entry)
      call lib_entry%init (library_name)
      call whizard%global%add_prclib (lib_entry)
      call msg_message ("Preloaded library: " // char (library_name))
    else
      call msg_message ("No library preloaded")
    end if
  end subroutine whizard_preload_library

```

22.3.4 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags.

```
