WHIZARD¹

Wolfgang Kilian,² Thorsten Ohl,³ Jürgen Reuter⁴

Version 2.2.0 β , Feb 03 2014

with contributions from: Fabian Bach, Felix Braam, David Gordo
Gomez, Sebastian Schmidt, Marco Sekulla, Christian Speckner,
Daniel Wiesler

¹The original meaning of the acronym is *W, Higgs, Z, And Respective Decays*. The current program is much more than that, however.

Abstract

WHIZARD is an application of the VAMP algorithm: Adaptive multi-channel integration and event generation. The bare VAMP library is augmented by modules for Lorentz algebra, particles, phase space, etc., such that physical processes with arbitrary complex final states [well, in principle. . .] can be integrated and *unweighted* events be generated.

Chapter 1

Changes

For a comprehensive list of changes confer the ChangeLog file or the subversion log.

Chapter 2

Tools

This part contains modules needed for auxiliary purposes:

limits Compile-time (integer) constants: fixed array sizes, input field lengths, and such. Any module that uses such constants has to access them via **limits**.

mpi90 Parallel execution (currently disabled!). This module contains dummy replacements for the message passing interface subroutines.

diagnostics Error and diagnostic message handling. Any messages and errors issued by WHIZARD functions are handled by the subroutines in this module, if possible.

files Files and auxiliary routines that do not belong anywhere else.

permutations Handle permutations of integers.

unix_args Parse the command-line arguments and options. This part is system-dependent, and we provide a replacement if the functions are not available.

2.1 Preliminaries

The WHIZARD file header:

```
<File header>≡
! WHIZARD <Version> <Date>
!
! Copyright (C) 1999-2014 by
!   Wolfgang Kilian <kilian@physik.uni-siegen.de>
!   Thorsten Ohl <ohl@physik.uni-wuerzburg.de>
!   Juergen Reuter <juergen.reuter@desy.de>
!
!   with contributions from
!   Christian Speckner <cnspeckn@googlemail.com>
!   and Felix Braam, Sebastian Schmidt, Daniel Wiesler
!
! WHIZARD is free software; you can redistribute it and/or modify it
! under the terms of the GNU General Public License as published by
```

```

! the Free Software Foundation; either version 2, or (at your option)
! any later version.
!
! WHIZARD is distributed in the hope that it will be useful, but
! WITHOUT ANY WARRANTY; without even the implied warranty of
! MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the
! GNU General Public License for more details.
!
! You should have received a copy of the GNU General Public License
! along with this program; if not, write to the Free Software
! Foundation, Inc., 675 Mass Ave, Cambridge, MA 02139, USA.
!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
! This file has been stripped of most comments. For documentation, refer
! to the source 'whizard.nw'

```

We are strict with our names:

```

<Standard module head>≡
    implicit none
    private

```

This is the way to envoke the kinds module (not contained in this source)

```

<Use kinds>≡
    use kinds, only: default !NODEP!

```

And we make heavy use of variable-length strings

```

<Use strings>≡
    use iso_varying_string, string_t => varying_string !NODEP!

```

Some parameters (buffer sizes etc.) are hardcoded. They are collected in this module:

```

<limits.f90>≡
    <File header>

    module limits

    use iso_fortran_env, only: iostat_end, iostat_eor !NODEP!
    <Use kinds>

    <Standard module head>

    <Limits: public parameters>

    end module limits

```

The version string is used for checking files. Note that the string length MUST NOT be changed, because reading binary files relies on it.

```

<Limits: public parameters>≡
    integer, parameter, public :: VERSION_STRLEN = 255
    character(len=VERSION_STRLEN), parameter, public :: &
        & VERSION_STRING = "WHIZARD version <Version> (<Date>)"

```

2.2 Parallelization

This section has been removed, it was never used even in WHIZARD1. Parallelization should be reimplemented from scratch.

2.3 File utilities

This module provides miscellaneous tools associated with strings and files:

- Finding a free unit
- Selecting an output unit (stdout if undefined)
- Upper and lower case for strings
- Formatting a number for T_EX output.

```
<file_utils.f90>≡  
<File header>  
  
module file_utils  
  
    use iso_fortran_env, only: stdout => output_unit !NODEP!  
<Use kinds>  
<Use strings>  
    use limits, only: MIN_UNIT, MAX_UNIT !NODEP!  
    use, intrinsic :: iso_c_binding !NODEP!  
  
<Standard module head>  
  
<File utils: public>  
  
<File utils: interfaces>  
  
contains  
  
<File utils: procedures>  
  
end module file_utils
```

2.3.1 Finding an I/O unit

Fortran 95 (even Fortran 2003) has no notion of implicit I/O units. Therefore, we have to find a free unit by trial and error.

```
<Limits: public parameters>+≡  
    integer, parameter, public :: MIN_UNIT = 11, MAX_UNIT = 99  
<File utils: public>≡  
    public :: free_unit
```

```

<File utils: procedures>≡
function free_unit () result (unit)
  integer :: unit
  logical :: exists, is_open
  integer :: i, status
  do i = MIN_UNIT, MAX_UNIT
    inquire (unit=i, exist=exists, opened=is_open, iostat=status)
    if (status == 0) then
      if (exists .and. .not. is_open) then
        unit = i; return
      end if
    end if
  end do
  unit = -1
end function free_unit

```

```

<Use file utils>≡
use file_utils !NODEP!

```

Return the given unit, if present, otherwise the default STDOUT unit.

```

<File utils: public>+≡
public :: output_unit

<File utils: procedures>+≡
function output_unit (unit) result (u)
  integer, intent(in), optional :: unit
  integer :: u
  if (present (unit)) then
    u = unit
  else
    u = stdout
  end if
end function output_unit

```

2.3.2 Deleting a file

Fortran does not contain a command for deleting a file. Here, we provide a subroutine that deletes a file if it exists. We do not handle the subtleties, so we assume that it is writable if it exists.

```

<File utils: public>+≡
public :: delete_file

<File utils: procedures>+≡
subroutine delete_file (name)
  character(*), intent(in) :: name
  logical :: exist
  integer :: u
  inquire (file = name, exist = exist)
  if (exist) then
    u = free_unit ()
    open (unit = u, file = name)
    close (u, status = "delete")
  end if

```

```
end subroutine delete_file
```

2.3.3 String auxiliary functions

These are, unfortunately, not part of Fortran.

```
<File utils: public>+≡
public :: upper_case
public :: lower_case

<File utils: interfaces>≡
interface upper_case
  module procedure upper_case_char, upper_case_string
end interface
interface lower_case

```

2.3.4 Formatting numbers

Format a number with n significant digits for use in T_EX documents.

(File utils: public)+≡

public :: tex_format

(File utils: procedures)+≡

```
function tex_format (rval, n_digits) result (string)
  type(string_t) :: string
  real(default), intent(in) :: rval
  integer, intent(in) :: n_digits
  integer :: e, n, w, d
  real(default) :: absval
  real(default) :: mantissa
  character :: sign
  character(20) :: format
  character(80) :: cstr
  n = min (abs (n_digits), 16)
  if (rval == 0) then
    string = "0"
  else
    absval = abs (rval)
    e = log10 (absval)
    if (rval < 0) then
      sign = "-"
    else
      sign = ""
    end if
    select case (e)
    case (:-3)
      d = max (n - 1, 0)
      w = max (d + 2, 2)
      write (format, "('(F',IO,'.',IO,'A,IO,A)')") w, d
      mantissa = absval * 10._default ** (1 - e)
      write (cstr, fmt=format) mantissa, "\times 10^{", e - 1, "}"
    case (-2:0)
      d = max (n - e, 1 - e)
      w = max (d + e + 2, d + 2)
      write (format, "('(F',IO,'.',IO,')')") w, d
      write (cstr, fmt=format) absval
    case (1:2)
      d = max (n - e - 1, -e, 0)
      w = max (d + e + 2, d + 2, e + 2)
      write (format, "('(F',IO,'.',IO,')')") w, d
      write (cstr, fmt=format) absval
    case default
      d = max (n - 1, 0)
      w = max (d + 2, 2)
      write (format, "('(F',IO,'.',IO,'A,IO,A)')") w, d
      mantissa = absval * 10._default ** (- e)
      write (cstr, fmt=format) mantissa, "\times 10^{", e, "}"
    end select
    string = sign // trim (cstr)
  end if
end function tex_format
```

Write a number for use in Metapost code:

```

<File utils: public>+=
  public :: mp_format
<File utils: procedures>+=
  function mp_format (rval) result (string)
    type(string_t) :: string
    real(default), intent(in) :: rval
    character(16) :: tmp
    write (tmp, "(G16.8)")  rval
    string = lower_case (trim (adjustl (trim (tmp))))
  end function mp_format

```

2.4 Unit tests

Here, we provide functionality for automated unit tests. Each test is required to produce output which is compared against a reference file. If the two are identical, we signal success. Otherwise, we signal failure and write the output to a file.

```

<unit_tests.f90>=
  <File header>

  module unit_tests

    <Use strings>
    <Use file utils>

    <Standard module head>

    <Tests: public>

    <Tests: parameters>

    <Tests: types>

    <Tests: interfaces>

    contains

    <Tests: procedures>

  end module unit_tests

```

2.4.1 Parameters

Building blocks of file names:

```

<Tests: parameters>=
  character(*), parameter :: ref_prefix = "ref-output/"
  character(*), parameter :: ref = ".ref"

```

```

character(*), parameter :: err_prefix = "err-output/"
character(*), parameter :: err = ".out"

```

2.4.2 Type for storing test results

We store the results of the individual unit tests in a linked list. Here is the entry:

```

<Tests: public>≡
    public :: test_results_t

<Tests: types>≡
    type :: test_result_t
        logical :: success = .false.
        type(string_t) :: name
        type(string_t) :: description
        type(test_result_t), pointer :: next => null ()
    end type test_result_t

    type :: test_results_t
        private
        type(test_result_t), pointer :: first => null ()
        type(test_result_t), pointer :: last => null ()
        integer :: n_success = 0
        integer :: n_failure = 0
        contains
        <Tests: test results: TBP>
    end type test_results_t

```

Add a test result.

```

<Tests: test results: TBP>≡
    procedure, private :: add => test_results_add

<Tests: procedures>≡
    subroutine test_results_add (list, name, description, success)
        class(test_results_t), intent(inout) :: list
        character(len=*), intent(in) :: name
        character(len=*), intent(in) :: description
        logical, intent(in) :: success
        type(test_result_t), pointer :: result
        allocate (result)
        result%success = success
        result%name = name
        result%description = description
        if (associated (list%first)) then
            list%last%next => result
        else
            list%first => result
        end if
        list%last => result
        if (success) then
            list%n_success = list%n_success + 1
        else

```

```

        list%n_failure = list%n_failure + 1
    end if
end subroutine test_results_add

```

Display the current state.

<Tests: test results: TBP>+≡

```

    procedure, private :: write => test_results_write

```

<Tests: procedures>+≡

```

subroutine test_results_write (list, u)
    class(test_results_t), intent(in) :: list
    integer, intent(in) :: u
    type(test_result_t), pointer :: result
    write (u, "(A)")    "*** Test Summary ***"
    if (list%n_success > 0) then
        write (u, "(2x,A)") "Success:"
        result => list%first
        do while (associated (result))
            if (result%success) write (u, "(4x,A,': ',A)") &
                char (result%name), char (result%description)
            result => result%next
        end do
    end if
    if (list%n_failure > 0) then
        write (u, "(2x,A)") "Failure:"
        result => list%first
        do while (associated (result))
            if (.not. result%success) write (u, "(4x,A,': ',A)") &
                char (result%name), char (result%description)
            result => result%next
        end do
    end if
    write (u, "(A,I0)") "Total    = ", list%n_success + list%n_failure
    write (u, "(A,I0)") "Success = ", list%n_success
    write (u, "(A,I0)") "Failure = ", list%n_failure
    write (u, "(A)")    "*** End of test Summary ***"
end subroutine test_results_write

```

Return true if all tests were successful (or no test).

<Tests: test results: TBP>+≡

```

    procedure, private :: report => test_results_report

```

<Tests: procedures>+≡

```

subroutine test_results_report (list, success)
    class(test_results_t), intent(in) :: list
    logical, intent(out) :: success
    success = list%n_failure == 0
end subroutine test_results_report

```

Delete the list.

<Tests: test results: TBP>+≡

```

    procedure, private :: final => test_results_final

```

```

<Tests: procedures>+≡
  subroutine test_results_final (list)
    class(test_results_t), intent(inout) :: list
    type(test_result_t), pointer :: result
    do while (associated (list%first))
      result => list%first
      list%first => result%next
      deallocate (result)
    end do
    list%last => null ()
    list%n_success = 0
    list%n_failure = 0
  end subroutine test_results_final

```

2.4.3 Wrapup

This will write results, report status, and finalize. This is the only method which we need to access from outside.

```

<Tests: test results: TBP>+≡
  procedure :: wrapup => test_results_wrapup

<Tests: procedures>+≡
  subroutine test_results_wrapup (list, u, success)
    class(test_results_t), intent(inout) :: list
    integer, intent(in) :: u
    logical, intent(out), optional :: success
    call list%write (u)
    if (present (success)) call list%report (success)
    call list%final ()
  end subroutine test_results_wrapup

```

2.4.4 Tool for Unit Tests

This procedure takes a test routine as an argument. It runs the test, output directed to a temporary file. Then, it compares the file against a reference file.

The test routine must take the output unit as argument.

```

<Tests: interfaces>≡
  abstract interface
    subroutine unit_test (u)
      integer, intent(in) :: u
    end subroutine unit_test
  end interface

```

The test routine can print to screen and, optionally, to a logging unit.

```

<Tests: public>+≡
  public :: test

```

```

<Tests: procedures>+≡
subroutine test (test_proc, name, description, u_log, results)
  procedure(unit_test) :: test_proc
  character(*), intent(in) :: name
  character(*), intent(in) :: description
  integer, intent(in) :: u_log
  type(test_results_t), intent(inout) :: results
  integer :: u_test, u_ref, u_err
  logical :: exist
  character(256) :: buffer1, buffer2
  integer :: iostat1, iostat2
  logical :: success
  write (*, "(A)", advance="no") "Running test: " // name
  write (u_log, "(A)") "Test: " // name
  u_test = free_unit ()
  open (u_test, status="scratch", action="readwrite")
  call test_proc (u_test)
  rewind (u_test)
  inquire (file=ref_prefix//name//ref, exist=exist)
  if (exist) then
    u_ref = free_unit ()
    open (u_ref, file=ref_prefix//name//ref, status="old", action="read")
    COMPARE_FILES: do
      read (u_test, "(A)", iostat=iostat1) buffer1
      read (u_ref, "(A)", iostat=iostat2) buffer2
      if (iostat1 /= iostat2) then
        success = .false.
        exit COMPARE_FILES
      else if (iostat1 < 0) then
        success = .true.
        exit COMPARE_FILES
      else if (buffer1 /= buffer2) then
        success = .false.
        exit COMPARE_FILES
      end if
    end do COMPARE_FILES
    close (u_ref)
  else
    write (*, "(A)", advance="no") " ... no reference output available"
    write (u_log, "(A)") " No reference output available."
    success = .false.
  end if
  if (success) then
    write (*, "(A)") " ... success."
    write (u_log, "(A)") " Success."
  else
    write (*, "(A)") " ... failure. See: " // err_prefix//name//err
    write (u_log, "(A)") " Failure."
    rewind (u_test)
    u_err = free_unit ()
    open (u_err, file=err_prefix//name//err, &
          action="write", status="replace")
    WRITE_OUTPUT: do
      read (u_test, "(A)", end=1) buffer1

```

```

        write (u_err, "(A)") trim (buffer1)
    end do WRITE_OUTPUT
1    close (u_err)
    end if
    close (u_test)
    call results%add (name, description, success)
end subroutine test

```

2.5 Operating-system interface

For specific purposes, we need direct access to the OS (system calls). This is, of course, system dependent. The current version is valid for GNU/Linux; we expect to use a preprocessor for this module if different OSs are to be supported.

The current implementation lacks error handling.

```

<os_interface.f90>≡
  <File header>

  module os_interface

    use iso_c_binding !NODEP!
    <Use strings>
    <Use file utils>
    use system_dependencies !NODEP!
    use limits, only: DLERROR_LEN, ENVVAR_LEN !NODEP!
    use diagnostics !NODEP!
    use unit_tests

    <Standard module head>

    <OS interface: public>

    <OS interface: types>

    <OS interface: interfaces>

    contains

    <OS interface: procedures>

    <OS interface: tests>

  end module os_interface

```

2.5.1 Path variables

This is a transparent container for storing user-defined path variables.

```

<OS interface: public>≡
  public :: paths_t

```

```

<OS interface: types>≡
  type :: paths_t
    type(string_t) :: prefix
    type(string_t) :: exec_prefix
    type(string_t) :: bindir
    type(string_t) :: libdir
    type(string_t) :: includedir
    type(string_t) :: datarootdir
    type(string_t) :: localprefix
    type(string_t) :: libtool
    type(string_t) :: lhapdfdir
  end type paths_t

<OS interface: public>+≡
  public :: paths_init

<OS interface: procedures>≡
  subroutine paths_init (paths)
    type(paths_t), intent(out) :: paths
    paths%prefix = ""
    paths%exec_prefix = ""
    paths%bindir = ""
    paths%libdir = ""
    paths%includedir = ""
    paths%datarootdir = ""
    paths%localprefix = ""
    paths%libtool = ""
    paths%lhapdfdir = ""
  end subroutine paths_init

```

2.5.2 System dependencies

We store all potentially system- and user/run-dependent data in a transparent container. This includes compiler/linker names and flags, file extensions, etc.

```

<OS interface: public>+≡
  public :: os_data_t

<OS interface: types>+≡
  type :: os_data_t
    logical :: use_libtool
    logical :: use_testfiles

```

2.5.3 Dynamic linking

We define a type that holds the filehandle for a dynamically linked library (shared object), together with functions to open and close the library, and to access functions in this library.

```

<OS interface: public>+≡
    public :: dlaccess_t
<OS interface: types>+≡
    type :: dlaccess_t
        private
        type(string_t) :: filename
        type(c_ptr) :: handle = c_null_ptr
        logical :: is_open = .false.
        logical :: has_error = .false.
        type(string_t) :: error
    contains
    <OS interface: dlaccess: TBP>
end type dlaccess_t

```

Output. This is called by the output routine for the process library.

```

<OS interface: dlaccess: TBP>≡
    procedure :: write => dlaccess_write
<OS interface: procedures>+≡
    subroutine dlaccess_write (object, unit)
        class(dlaccess_t), intent(in) :: object
        integer, intent(in) :: unit
        write (unit, "(1x,A)") "DL access info:"
        !!! This is OS dependent (could be wrapped with a logical though)
        !!! write (unit, "(3x,A,A,A)") "filename = '", char (object%filename), "'"
        write (unit, "(3x,A,L1)") "is open = ", object%is_open
        if (object%has_error) then
            write (unit, "(3x,A,A,A)") "error = '", char (object%error), "'"
        else
            write (unit, "(3x,A)") "error = [none]"
        end if
    end subroutine dlaccess_write

```

The interface to the library functions:

```

<OS interface: interfaces>≡
    interface
        function dlopen (filename, flag) result (handle) bind(C)
            import
            character(c_char), dimension(*) :: filename
            integer(c_int), value :: flag
            type(c_ptr) :: handle
        end function dlopen
    end interface

    interface
        function dlclose (handle) result (status) bind(C)
            import
            type(c_ptr), value :: handle
            integer(c_int) :: status
        end function dlclose
    end interface

    interface

```

```

        function dlerror () result (str) bind(C)
            import
            type(c_ptr) :: str
        end function dlerror
    end interface

    interface
        function dlsym (handle, symbol) result (fptr) bind(C)
            import
            type(c_ptr), value :: handle
            character(c_char), dimension(*) :: symbol
            type(c_funptr) :: fptr
        end function dlsym
    end interface
end interface

```

This reads an error string and transforms it into a `string_t` object, if an error has occurred. If not, set the error flag to false and return an empty string.

```

<Limits: public parameters>+≡
    integer, parameter, public :: DLERROR_LEN = 160

<OS interface: procedures>+≡
    subroutine read_dlerror (has_error, error)
        logical, intent(out) :: has_error
        type(string_t), intent(out) :: error
        type(c_ptr) :: err_cptr
        character(len=DLERROR_LEN, kind=c_char), pointer :: err_fptr
        integer :: str_end
        err_cptr = dlerror ()
        if (c_associated (err_cptr)) then
            call c_f_pointer (err_cptr, err_fptr)
            has_error = .true.
            str_end = scan (err_fptr, c_null_char)
            if (str_end > 0) then
                error = err_fptr(1:str_end-1)
            else
                error = err_fptr
            end if
        else
            has_error = .false.
            error = ""
        end if
    end subroutine read_dlerror

```

This is the Fortran API. Init/final open and close the file, i.e., load and unload the library.

Note that a library can be opened more than once, and that for an ultimate close as many `dlclose` calls as `dlopen` calls are necessary. However, we assume that it is opened and closed only once.

```

<OS interface: public>+≡
    public :: dlaccess_init
    public :: dlaccess_final

<OS interface: dlaccess: TBP>+≡

```

```

procedure :: init => dlaccess_init
procedure :: final => dlaccess_final

<OS interface: procedures>+≡
subroutine dlaccess_init (dlaccess, prefix, libname, os_data)
  class(dlaccess_t), intent(out) :: dlaccess
  type(string_t), intent(in) :: prefix, libname
  type(os_data_t), intent(in), optional :: os_data
  type(string_t) :: filename
  logical :: exist
  dlaccess%filename = libname
  filename = prefix // "/" // libname
  inquire (file=char(filename), exist=exist)
  if (.not. exist) then
    filename = prefix // "/.libs/" // libname
    inquire (file=char(filename), exist=exist)
    if (.not. exist) then
      dlaccess%has_error = .true.
      dlaccess%error = "Library '" // filename // "' not found"
      return
    end if
  end if
  dlaccess%handle = dlopen (char (filename) // c_null_char, ior ( &
    RTLD_LAZY, RTLD_LOCAL))
  dlaccess%is_open = c_associated (dlaccess%handle)
  call read_dlerror (dlaccess%has_error, dlaccess%error)
end subroutine dlaccess_init

subroutine dlaccess_final (dlaccess)
  class(dlaccess_t), intent(inout) :: dlaccess
  integer(c_int) :: status
  if (dlaccess%is_open) then
    status = dlclose (dlaccess%handle)
    dlaccess%is_open = .false.
    call read_dlerror (dlaccess%has_error, dlaccess%error)
  end if
end subroutine dlaccess_final

```

Return true if an error has occurred.

```

<OS interface: public>+≡
public :: dlaccess_has_error

<OS interface: procedures>+≡
function dlaccess_has_error (dlaccess) result (flag)
  logical :: flag
  type(dlaccess_t), intent(in) :: dlaccess
  flag = dlaccess%has_error
end function dlaccess_has_error

```

Return the error string currently stored in the dlaccess object.

```

<OS interface: public>+≡
public :: dlaccess_get_error

```

```

<OS interface: procedures>+≡
  function dlaccess_get_error (dlaccess) result (error)
    type(string_t) :: error
    type(dlaccess_t), intent(in) :: dlaccess
    error = dlaccess%error
  end function dlaccess_get_error

```

The symbol handler returns the C address of the function with the given string name. (It is a good idea to use `bind(C)` for all functions accessed by this, such that the name string is well-defined.) Call `c_f_procpointer` to cast this into a Fortran procedure pointer with an appropriate interface.

```

<OS interface: public>+≡
  public :: dlaccess_get_c_funptr

<OS interface: procedures>+≡
  function dlaccess_get_c_funptr (dlaccess, fname) result (fptr)
    type(c_funptr) :: fptr
    type(dlaccess_t), intent(inout) :: dlaccess
    type(string_t), intent(in) :: fname
    fptr = dlsym (dlaccess%handle, char (fname) // c_null_char)
    call read_dlerror (dlaccess%has_error, dlaccess%error)
  end function dlaccess_get_c_funptr

```

2.5.4 Predicates

Return true if the library is loaded. In particular, this is false if loading was unsuccessful.

```

<OS interface: public>+≡
  public :: dlaccess_is_open

<OS interface: procedures>+≡
  function dlaccess_is_open (dlaccess) result (flag)
    logical :: flag
    type(dlaccess_t), intent(in) :: dlaccess
    flag = dlaccess%is_open
  end function dlaccess_is_open

```

2.5.5 Shell access

This is the standard system call for executing a shell command, such as invoking a compiler.

In F2008 there will be the equivalent built-in command `execute_command_line`.

```

<OS interface: public>+≡
  public :: os_system_call

<OS interface: procedures>+≡
  subroutine os_system_call (command_string, status, verbose)
    type(string_t), intent(in) :: command_string
    integer, intent(out), optional :: status
    logical, intent(in), optional :: verbose
    logical :: verb

```

```

integer :: stat
verb = .false.; if (present (verbose)) verb = verbose
if (verb) &
    call msg_message ("command: " // char (command_string))
stat = system (char (command_string) // c_null_char)
if (present (status)) then
    status = stat
else if (stat /= 0) then
    if (.not. verb) &
        call msg_message ("command: " // char (command_string))
    write (msg_buffer, "(A,I0)") "Return code = ", stat
    call msg_message ()
    call msg_fatal ("System command returned with nonzero status code")
end if
end subroutine os_system_call

```

```

<OS interface: interfaces>+≡
interface

        import
        integer(c_int) :: status
        character(c_char), dimension(*) :: command
    end function system
end interface

```

2.5.6 Querying for a directory

This queries for the existence of a directory. There is no standard way to achieve this in FORTRAN, and if we were to call into `libc`, we would need access to C macros for evaluating the result, so we resort to calling `test` as a system call.

```

<OS interface: public>+≡
public :: os_dir_exist

<OS interface: procedures>+≡
function os_dir_exist (name) result (res)
    type(string_t), intent(in) :: name
    logical :: res
    integer :: status
    call os_system_call ('test -d "' // name // '"', status=status)
    res = status == 0
end function os_dir_exist

```

2.5.7 Fortran compiler and linker

Compile a single module for use in a shared library, but without linking.

```

<OS interface: public>+≡

<OS interface: procedures>+≡
subroutine os_compile_shared (src, os_data, status)
    type(string_t), intent(in) :: src
    type(os_data_t), intent(in) :: os_data

```

```

integer, intent(out), optional :: status
type(string_t) :: command_string
if (os_data%use_libtool) then
    command_string = &
        os_data%whizard_libtool // " --mode=compile " // &
        os_data%fc // " " // &
        "-c " // &
        os_data%whizard_includes // " " // &
        os_data%fcflags // " " // &
        "" // src // os_data%fc_src_ext // ""
else
    command_string = &
        os_data%fc // " " // &

        os_data%fcflags_pic // " " // &
        os_data%whizard_includes // " " // &
        os_data%fcflags // " " // &
        "" // src // os_data%fc_src_ext // ""
end if
call os_system_call (command_string, status)
end subroutine os_compile_shared

```

Link an array of object files to build a shared object library. In the libtool case, we have to specify a `-rpath`, otherwise only a static library can be built. However, since the library is never installed, this `rpath` is irrelevant.

```

<OS interface: public>+=
    public :: os_link_shared

<OS interface: procedures>+=
    subroutine os_link_shared (objlist, lib, os_data, status)
        type(string_t), intent(in) :: objlist, lib
        type(os_data_t), intent(in) :: os_data
        integer, intent(out), optional :: status
        type(string_t) :: command_string
        if (os_data%use_libtool) then
            command_string = &
                os_data%whizard_libtool // " --mode=link " // &
                os_data%fc // " " // &
                "-module " // &

2.6 CPU timing

This is a simplified module which replaces `clock.f90` below. The time is now stored in a simple derived type which just holds a floating-point number.

```

<cputime.f90>≡
  <File header>

  module cputime

    <Use kinds>
    <Use file utils>
    <Use strings>
    use diagnostics !NODEP!
    use unit_tests

    <Standard module head>

    <CPU time: public>

    <CPU time: types>

    <CPU time: interfaces>

    contains

    <CPU time: procedures>

    <CPU time: tests>

  end module cputime

  The CPU time is a floating-point number with an arbitrary reference time. It
  is single precision (default real, not real(default)). It is measured in seconds.

  <CPU time: public>≡
    public :: time_t

  <CPU time: types>≡
    type :: time_t
      private
      logical :: known = .false.
      real :: value = 0
    contains
      <CPU time: time: TBP>
    end type time_t

  <CPU time: time: TBP>≡
    procedure :: write => time_write

```

```

<CPU time: procedures>≡
subroutine time_write (object, unit)
  class(time_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u
  u = output_unit (unit)
  write (u, "(1x,A)", advance="no") "Time in seconds ="
  if (object%known) then
    write (u, "(1x,ES10.3)") object%value
  else
    write (u, "(1x,A)") "[unknown]"
  end if
end subroutine time_write

```

Set the current time

```

<CPU time: time: TBP>+≡

2.6.1 Timer

A timer can measure real (wallclock) time differences. The base type corresponds to the result, i.e., time difference. The object contains two further times for start and stop time.

```
<CPU time: public>+≡
  public :: timer_t

<CPU time: types>+≡
  type, extends (time_t) :: timer_t
  private
    logical :: running = .false.
    type(time_t) :: t1, t2
  contains
    <CPU time: timer: TBP>
  end type timer_t
```

Output. If the timer is running, we indicate this, otherwise write just the result.

```
<CPU time: timer: TBP>≡
  procedure :: write => timer_write

<CPU time: procedures>+≡
  subroutine timer_write (object, unit)
    class(timer_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    if (object%running) then
      write (u, "(1x,A)") "Time in seconds = [running]"
    else
      call object%time_t%write (u)
    end if
  end subroutine timer_write
```

Start the timer: store the current time in the first entry and adapt the status. We forget any previous values.

```
<CPU time: timer: TBP>+≡
  procedure :: start => timer_start

<CPU time: procedures>+≡
  subroutine timer_start (timer)
    class(timer_t), intent(out) :: timer
    call timer%t1%set_current ()
    timer%running = .true.
  end subroutine timer_start
```

Restart the timer: simply adapt the status, keeping the start time.

```
<CPU time: timer: TBP>+≡
  procedure :: restart => timer_restart
```

```

<CPU time: procedures>+≡
  subroutine timer_restart (timer)
    class(timer_t), intent(inout) :: timer
    if (timer%t1%known .and. .not. timer%running) then
      timer%running = .true.
    else
      call msg_bug ("Timer: restart attempt from wrong status")
    end if
  end subroutine timer_restart

```

Stop the timer: store the current time in the second entry, adapt the status, and compute the elapsed time.

```

<CPU time: timer: TBP>+≡
  procedure :: stop => timer_stop

<CPU time: procedures>+≡
  subroutine timer_stop (timer)
    class(timer_t), intent(inout) :: timer
    call timer%t2%set_current ()
    timer%running = .false.
    call timer%evaluate ()
  end subroutine timer_stop

```

This is separate, available for the unit test.

```

<CPU time: timer: TBP>+≡
  procedure, private :: evaluate => timer_evaluate

<CPU time: procedures>+≡
  subroutine timer_evaluate (timer)
    class(timer_t), intent(inout) :: timer
    timer%time_t = timer%t2 - timer%t1
  end subroutine timer_evaluate

```

2.6.2 Unit tests

```

<CPU time: public>+≡
  public :: cputime_test

<CPU time: tests>≡
  subroutine cputime_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <CPU time: execute tests>
  end subroutine cputime_test

```

Basic tests

Check basic functions of the time object. The part which we can't check is getting the actual time from the system clock, since the output will not be reproducible. However, we can check time formats and operations.

```

<CPU time: execute tests>≡

```

```

call test (cputime_1, "cputime_1", &
          "time operations", &
          u, results)

```

2.7 Hashtables

Hash tables, like lists, are not part of Fortran and must be defined on a per-case basis. In this section we define a module that contains a hash function.

Furthermore, for reference there is a complete framework of hashtable type definitions and access functions. This code is to be replicated where hash tables are used, *mutatis mutandis*.

```

<hashes.f90>≡
  <File header>

  module hashes

    use kinds, only: i8, i32 !NODEP!
    use bytes

    <Standard module head>

    <Hashes: public>

    contains

    <Hashes: procedures>

  end module hashes

```

2.7.1 The hash function

This is the one-at-a-time hash function by Bob Jenkins (from Wikipedia), re-implemented in Fortran. The function works on an array of bytes (8-bit integers), as could be produced by, e.g., the **transfer** function, and returns a single 32-bit integer. For determining the position in a hashtable, one can pick the lower bits of the result as appropriate to the hashtable size (which should be a power of 2). Note that we are working on signed integers, so the interpretation of values differs from the C version. This should not matter in practice, however.

```

<Hashes: public>≡
  public :: hash

<Hashes: procedures>≡
  function hash (key) result (hashval)
    integer(i32) :: hashval
    integer(i8), dimension(:), intent(in) :: key
    type(word32_t) :: w
    integer :: i
    w = 0_i32
    do i = 1, size (key)
      w = w + key(i)
      w = w + ishft (w, 10)
      w = ieor (w, ishft (w, -6))
    end do
    w = w + ishft (w, 3)
    w = ieor (w, ishft (w, -11))
    w = w + ishft (w, 15)
    hashval = w
  end function hash

```

2.7.2 The hash table

We define a generic hashtable type (that depends on the `hash_data_t` type) together with associated methods.

This is a template:

```
<Hashtables: types>≡  
  type :: hash_data_t  
    integer :: i  
  end type hash_data_t
```

Associated methods:

```
<Hashtables: procedures>≡  
  subroutine hash_data_final (data)  
    type(hash_data_t), intent(inout) :: data  
  end subroutine hash_data_final  
  
  subroutine hash_data_write (data, unit)  
    type(hash_data_t), intent(in) :: data  
    integer, intent(in), optional :: unit  
    integer :: u  
    u = output_unit (unit); if (u < 0) return  
    write (u, *) data%i  
  end subroutine hash_data_write
```

Each hash entry stores the unmasked hash value, the key, and points to actual data if present. Note that this could be an allocatable scalar in principle, but making it a pointer avoids deep copy when expanding the hashtable.

```
<Hashtables: types>+≡  
  type :: hash_entry_t  
    integer(i32) :: hashval = 0  
    integer(i8), dimension(:), allocatable :: key  
    type(hash_data_t), pointer :: data => null ()  
  end type hash_entry_t
```

The hashtable object holds the actual table, the number of filled entries and the number of entries after which the size should be doubled. The mask is equal to the table size minus one and thus coincides with the upper bound of the table index, which starts at zero.

```
<Hashtables: types>+≡  
  type :: hashtable_t  
    integer :: n_entries = 0  
    real :: fill_ratio = 0  
    integer :: n_entries_max = 0  
    integer(i32) :: mask = 0  
    type(hash_entry_t), dimension(:), allocatable :: entry  
  end type hashtable_t
```

Initializer: The size has to be a power of two, the fill ratio is a real (machine-default!) number between 0 and 1.

```
<Hashtables: procedures>+≡  
  subroutine hashtable_init (hashtable, size, fill_ratio)
```

```

type(hashtable_t), intent(out) :: hashtable
integer, intent(in) :: size
real, intent(in) :: fill_ratio
hashtable%fill_ratio = fill_ratio
hashtable%n_entries_max = size * fill_ratio
hashtable%mask = size - 1
allocate (hashtable%entry (0:hashtable%mask))
end subroutine hashtable_init

```

Finalizer: This calls a `hash_data_final` subroutine which must exist.

```

<Hashtables: procedures> +=
subroutine hashtable_final (hashtable)
type(hashtable_t), intent(inout) :: hashtable
integer :: i
do i = 0, hashtable%mask
  if (associated (hashtable%entry(i)%data)) then
    call hash_data_final (hashtable%entry(i)%data)
    deallocate (hashtable%entry(i)%data)
  end if
end do
deallocate (hashtable%entry)
end subroutine hashtable_final

```

Output. Here, we refer to a `hash_data_write` subroutine.

```

<Hashtables: procedures> +=
subroutine hashtable_write (hashtable, unit)
type(hashtable_t), intent(in) :: hashtable
integer, intent(in), optional :: unit
integer :: u, i
u = output_unit (unit); if (u < 0) return
do i = 0, hashtable%mask
  if (associated (hashtable%entry(i)%data)) then
    write (u, *) i, "(hash =", hashtable%entry(i)%hashval, ")", &
      hashtable%entry(i)%key
    call hash_data_write (hashtable%entry(i)%data, unit)
  end if
end do
end subroutine hashtable_write

```

2.7.3 Hashtable insertion

Insert a single entry with the hash value as trial place. If the table is filled, first expand it.

```

<Hashtables: procedures> +=
subroutine hashtable_insert (hashtable, key, data)
type(hashtable_t), intent(inout) :: hashtable
integer(i8), dimension(:), intent(in) :: key
type(hash_data_t), intent(in), target :: data
integer(i32) :: h
if (hashtable%n_entries >= hashtable%n_entries_max) &
  call hashtable_expand (hashtable)

```

```

    h = hash (key)
    call hashtable_insert_rec (hashtable, h, h, key, data)
end subroutine hashtable_insert

```

We need this auxiliary routine for doubling the size of the hashtable. We rely on the fact that default assignment copies the data pointer, not the data themselves. The temporary array must not be finalized; it is deallocated automatically together with its allocatable components.

```

(Hashtables: procedures)+≡
subroutine hashtable_expand (hashtable)
  type(hashtable_t), intent(inout) :: hashtable
  type(hash_entry_t), dimension(:), allocatable :: table_tmp
  integer :: i, s
  allocate (table_tmp (0:hashtable%mask))
  table_tmp = hashtable%entry
  deallocate (hashtable%entry)
  s = 2 * size (table_tmp)
  hashtable%n_entries = 0
  hashtable%n_entries_max = s * hashtable%fill_ratio
  hashtable%mask = s - 1
  allocate (hashtable%entry (0:hashtable%mask))
  do i = 0, ubound (table_tmp, 1)
    if (associated (table_tmp(i)%data)) then
      call hashtable_insert_rec (hashtable, table_tmp(i)%hashval, &
        table_tmp(i)%hashval, table_tmp(i)%key, table_tmp(i)%data)
    end if
  end do
end subroutine hashtable_expand

```

Insert a single entry at a trial place h , reduced to the table size. Collision resolution is done simply by choosing the next element, recursively until the place is empty. For bookkeeping, we preserve the original hash value. For a good hash function, there should be no clustering.

Note that if the new key exactly matches an existing key, nothing is done.

```

(Hashtables: procedures)+≡
recursive subroutine hashtable_insert_rec (hashtable, h, hashval, key, data)
  type(hashtable_t), intent(inout) :: hashtable
  integer(i32), intent(in) :: h, hashval
  integer(i8), dimension(:), intent(in) :: key
  type(hash_data_t), intent(in), target :: data
  integer(i32) :: i
  i = iand (h, hashtable%mask)
  if (associated (hashtable%entry(i)%data)) then
    if (size (hashtable%entry(i)%key) /= size (key)) then
      call hashtable_insert_rec (hashtable, h + 1, hashval, key, data)
    else if (any (hashtable%entry(i)%key /= key)) then
      call hashtable_insert_rec (hashtable, h + 1, hashval, key, data)
    end if
  else
    hashtable%entry(i)%hashval = hashval
    allocate (hashtable%entry(i)%key (size (key)))
    hashtable%entry(i)%key = key
  end if
end subroutine hashtable_insert_rec

```

```

        hashtable%entry(i)%data => data
        hashtable%n_entries = hashtable%n_entries + 1
    end if
end subroutine hashtable_insert_rec

```

2.7.4 Hashtable lookup

The lookup function has to parallel the insert function. If the place is filled, check if the key matches. Yes: return the pointer; no: increment the hash value and check again.

```

<Hashtables: procedures>+≡
function hashtable_lookup (hashtable, key) result (ptr)
    type(hash_data_t), pointer :: ptr
    type(hashtable_t), intent(in) :: hashtable
    integer(i8), dimension(:), intent(in) :: key
    ptr => hashtable_lookup_rec (hashtable, hash (key), key)
end function hashtable_lookup

<Hashtables: procedures>+≡
recursive function hashtable_lookup_rec (hashtable, h, key) result (ptr)
    type(hash_data_t), pointer :: ptr
    type(hashtable_t), intent(in) :: hashtable
    integer(i32), intent(in) :: h
    integer(i8), dimension(:), intent(in) :: key
    integer(i32) :: i
    i = iand (h, hashtable%mask)
    if (associated (hashtable%entry(i)%data)) then
        if (size (hashtable%entry(i)%key) == size (key)) then
            if (all (hashtable%entry(i)%key == key)) then
                ptr => hashtable%entry(i)%data
            else
                ptr => hashtable_lookup_rec (hashtable, h + 1, key)
            end if
        else
            ptr => hashtable_lookup_rec (hashtable, h + 1, key)
        end if
    else
        ptr => null ()
    end if
end function hashtable_lookup_rec

<Hashtables: public>≡
public :: hashtable_test

<Hashtables: procedures>+≡
subroutine hashtable_test ()
    type(hash_data_t), pointer :: data
    type(hashtable_t) :: hashtable
    integer(i8) :: i
    call hashtable_init (hashtable, 16, 0.25)
    do i = 1, 10
        allocate (data)

```

```

        data%i = i*i
        call hashtable_insert (hashtable, (/i, i+i/), data)
    end do
    call hashtable_insert (hashtable, (/2_i8, 4_i8/), data)
    call hashtable_write (hashtable)
    data => hashtable_lookup (hashtable, (/5_i8, 10_i8/))
    if (associated (data)) then
        print *, "lookup:", data%i
    else
        print *, "lookup: --"
    end if
    data => hashtable_lookup (hashtable, (/6_i8, 12_i8/))
    if (associated (data)) then
        print *, "lookup:", data%i
    else
        print *, "lookup: --"
    end if
    data => hashtable_lookup (hashtable, (/4_i8, 9_i8/))
    if (associated (data)) then
        print *, "lookup:", data%i
    else
        print *, "lookup: --"
    end if
    call hashtable_final (hashtable)
end subroutine hashtable_test

```

2.8 Message and signal handling

We are not so ambitious as to do proper exception handling in WHIZARD, but at least it may be useful to have a common interface for diagnostics: Results, messages, warnings, and such. As module variables we keep a buffer where the current message may be written to and a level indicator which tells which messages should be written on screen and which ones should be skipped. Alternatively, a string may be directly supplied to the message routine: this overrides the buffer, avoiding the necessity of formatted I/O in trivial cases.

<diagnostics.f90>≡

<File header>

module diagnostics

use iso_c_binding !NODEP!

use system_dependencies !NODEP!

<Use kinds>

<Use strings>

use limits, only: BUFFER_SIZE, MAX_ERRORS !NODEP!

use file_utils !NODEP!

use iso_fortran_env, only: &

stdout => output_unit, stdin => input_unit !NODEP!

<Standard module head>

<Diagnostics: public>

<Diagnostics: parameters>

<Diagnostics: types>

<Diagnostics: variables>

<Diagnostics: interfaces>

contains

<Diagnostics: procedures>

end module diagnostics

Diagnostics levels:

```
<Diagnostics: parameters>≡
  integer, parameter :: &
    & TERMINATE=-2, BUG=-1, &
    & FATAL=1, ERROR=2, WARNING=3, MESSAGE=4, RESULT=5, DEBUG=6
```

```
<Diagnostics: variables>≡
  integer, save :: msg_level = RESULT
```

Mask fatal errors so that are treated as normal errors. Useful for interactive mode.

```
<Diagnostics: public>≡
  public :: mask_fatal_errors

<Diagnostics: variables>+≡
  logical, save :: mask_fatal_errors = .false.
```

How to handle bugs and unmasked fatal errors. Either execute a normal stop statement, or call the C `exit()` function, or try to cause a program crash by dereferencing a null pointer.

```
<Diagnostics: parameters>+≡
  integer, parameter :: TERM_STOP = 0, TERM_EXIT = 1, TERM_CRASH = 2

<Diagnostics: variables>+≡
  integer, save :: handle_fatal_errors = TERM_EXIT
```

Keep track of errors. This might be used for exception handling, later. The counter is incremented only for screen messages, to avoid double counting.

```
<Diagnostics: public>+≡
  public :: msg_count

<Diagnostics: variables>+≡
  integer, dimension(TERMINATE:DEBUG), save :: msg_count = 0
```

Keep a list of all errors and warnings. Since we do not know the number of entries beforehand, we use a linked list.

```
<Diagnostics: types>≡
  type :: string_list
    character(len=BUFFER_SIZE) :: string
    type(string_list), pointer :: next
  end type string_list
```

```

type :: string_list_pointer
type(string_list), pointer :: first, last
end type string_list_pointer

<Diagnostics: variables>+≡
type(string_list_pointer), dimension(TERMINATE:WARNING), save :: &
& msg_list = string_list_pointer (null(), null())

```

Add the current message buffer contents to the internal list.

```

<Diagnostics: procedures>≡
subroutine msg_add (level)
integer, intent(in) :: level
type(string_list), pointer :: message
select case (level)
case (TERMINATE:WARNING)
allocate (message)
message%string = msg_buffer
nullify (message%next)
if (.not.associated (msg_list(level)%first)) &
& msg_list(level)%first => message
if (associated (msg_list(level)%last)) &
& msg_list(level)%last%next => message
msg_list(level)%last => message
msg_count(level) = msg_count(level) + 1
end select
end subroutine msg_add

```

Initialization:

```

<Diagnostics: public>+≡
public :: msg_list_clear

<Diagnostics: procedures>+≡
subroutine msg_list_clear
integer :: level
type(string_list), pointer :: message
do level = TERMINATE, WARNING
do while (associated (msg_list(level)%first))
message => msg_list(level)%first
msg_list(level)%first => message%next
deallocate (message)
end do
nullify (msg_list(level)%last)
end do
msg_count = 0
end subroutine msg_list_clear

```

Display the summary of errors and warnings (no need to count fatals...)

```

<Diagnostics: public>+≡
public :: msg_summary

<Diagnostics: procedures>+≡
subroutine msg_summary (unit)
integer, intent(in), optional :: unit
call expect_summary (unit)
1 format (A,1x,I2,1x,A,I2,1x,A)

```

```

if (msg_count(ERROR) > 0 .and. msg_count(WARNING) > 0) then
  write (msg_buffer, 1) "There were", &
    & msg_count(ERROR), "error(s) and ", &
    & msg_count(WARNING), "warning(s)."
  call msg_message (unit=unit)
else if (msg_count(ERROR) > 0) then
  write (msg_buffer, 1) "There were", &
    & msg_count(ERROR), "error(s) and no warnings."
  call msg_message (unit=unit)
else if (msg_count(WARNING) > 0) then
  write (msg_buffer, 1) "There were no errors and ", &
    & msg_count(WARNING), "warning(s)."
  call msg_message (unit=unit)
end if
end subroutine msg_summary

```

Print the list of all messages of a given level.

<Diagnostics: public>+≡

```
public :: msg_listing
```

<Diagnostics: procedures>+≡

```

subroutine msg_listing (level, unit, prefix)
  integer, intent(in) :: level
  integer, intent(in), optional :: unit
  character(len=*), intent(in), optional :: prefix
  type(string_list), pointer :: message
  integer :: u
  u = output_unit (unit); if (u < 0) return
  if (present (unit)) u = unit
  message => msg_list(level)%first
  do while (associated (message))
    if (present (prefix)) then
      write (u, "(A)") prefix // trim (message%string)
    else
      write (u, "(A)") trim (message%string)
    end if
    message => message%next
  end do
  flush (u)
end subroutine msg_listing

```

There is a hard limit on the line length which we should export. This buffer size is used both by the message handler and by the lexer below.

<Limits: public parameters>+≡

```
integer, parameter, public :: BUFFER_SIZE = 1000
```

The message buffer:

<Diagnostics: public>+≡

```
public :: msg_buffer
```

<Diagnostics: variables>+≡

```
character(len=BUFFER_SIZE), save :: msg_buffer = " "
```

After a message is issued, the buffer should be cleared:

```
(Diagnostics: procedures)+≡
subroutine buffer_clear
  msg_buffer = " "
end subroutine buffer_clear
```

The generic handler for messages. If the unit is omitted (or = 6), the message is written to standard output if the precedence is sufficiently high (as determined by the value of `msg_level`). If the string is omitted, the buffer is used. In any case, the buffer is cleared after printing. In accordance with FORTRAN custom, the first column in the output is left blank. For messages and warnings, an additional exclamation mark and a blank is prepended. Furthermore, each message is appended to the internal message list (without prepending anything).

```
(Diagnostics: procedures)+≡

```

The specific handlers. In the case of fatal errors, bugs (failed assertions) and normal termination execution is stopped. For non-fatal errors a message is printed to standard output if no unit is given. Only if the number of `MAX_ERRORS` errors is reached, we abort the program. There are no further actions in the other cases, but this may change.

    end function cmplx2char

```

2.8.3 Signal handling

Killing the program by external signals may leave the files written by it in an undefined state. This can be avoided by catching signals and deferring program termination. Instead of masking only critical sections, we choose to mask signals globally (done in the main program) and terminate the program at predefined checkpoints only. Checkpoints are after each command, within the sampling function (so the program can be terminated after each event), and after each iteration in the phase-space generation algorithm.

Signal handling is done via a C interface to the `sigaction` system call. When a signal is raised that has been masked by the handler, the corresponding variable is set to the value of the signal. The variables are visible from the C signal handler.

The signal `SIGINT` is for keyboard interrupt (ctrl-C), `SIGTERM` is for system interrupt, e.g., at shutdown. The `SIGXCPU` and `SIGXFSZ` signals may be issued by batch systems.

```

<Diagnostics: public>+≡
    public :: wo_sigint
    public :: wo_sigterm
    public :: wo_sigxcpu
    public :: wo_sigxfsz

<Diagnostics: variables>+≡
    integer(c_int), bind(C), volatile :: wo_sigint = 0
    integer(c_int), bind(C), volatile :: wo_sigterm = 0
    integer(c_int), bind(C), volatile :: wo_sigxcpu = 0
    integer(c_int), bind(C), volatile :: wo_sigxfsz = 0

```

Here are the interfaces to the C functions. The routine `mask_term_signals` forces termination signals to be delayed. `release_term_signals` restores normal behavior. However, the program can be terminated anytime by calling `terminate_now_if_signal` which inspects the signals and terminates the program if requested..

```

<Diagnostics: public>+≡
    public :: mask_term_signals

<Diagnostics: procedures>+≡
    subroutine mask_term_signals ()
        integer(c_int) :: status
        logical :: ok

```

2.10 C wrapper for printf

The `printf` family of functions is implemented in C with an undefined number of arguments. This is not supported by the `bind(C)` interface. We therefore write wrappers for the versions of `sprintf` that we will actually use.

```
(sprintf_interface.c)≡
/*
  <File header>
*/
#include <stdio.h>

int sprintf_none(char* str, const char* format) {
  return sprintf(str, format);
}

int sprintf_int(char* str, const char* format, int val) {
  return sprintf(str, format, val);
}

int sprintf_double(char* str, const char* format, double val) {
  return sprintf(str, format, val);
}

int sprintf_str(char* str, const char* format, const char* val) {
  return sprintf(str, format, val);
}

(sprintf interfaces)≡
interface
  function sprintf_none (str, fmt) result (stat) bind(C)
    use iso_c_binding !NODEP!
    integer(c_int) :: stat
    character(c_char), dimension(*), intent(inout) :: str
    character(c_char), dimension(*), intent(in) :: fmt
  end function sprintf_none
end interface

interface
  function sprintf_int (str, fmt, val) result (stat) bind(C)
    use iso_c_binding !NODEP!
    integer(c_int) :: stat
    character(c_char), dimension(*), intent(inout) :: str
    character(c_char), dimension(*), intent(in) :: fmt
    integer(c_int), value :: val
  end function sprintf_int
end interface

interface
  function sprintf_double (str, fmt, val) result (stat) bind(C)
    use iso_c_binding !NODEP!
    integer(c_int) :: stat
    character(c_char), dimension(*), intent(inout) :: str
    character(c_char), dimension(*), intent(in) :: fmt
```

```

        real(c_double), value :: val
    end function sprintf_double
end interface

interface
    function sprintf_str(str, fmt, val) result (stat) bind(C)
        use iso_c_binding !NODEP!
        integer(c_int) :: stat
        character(c_char), dimension(*), intent(inout) :: str
        character(c_char), dimension(*), intent(in) :: fmt
        character(c_char), dimension(*), intent(in) :: val
    end function sprintf_str
end interface

```

2.11 Interface for formatted I/O

For access to formatted printing (possibly input), we interface the C `printf` family of functions. There are two important issues here:

1. `printf` takes an arbitrary number of arguments, relying on the C stack. This is not interoperable. We interface it with C wrappers that output a single integer, real or string and restrict the allowed formats accordingly.
2. Restricting format strings is essential also for preventing format string attacks. Allowing arbitrary format string would create a real security hole in a Fortran program.
3. The string returned by `sprintf` must be allocated to the right size.

`<formats.f90>`≡
<File header>

`module formats`

```

    use iso_c_binding !NODEP!
<Use kinds>
<Use strings>
<Use file utils>
    use diagnostics !NODEP!
    use unit_tests

```

2.11.1 Parsing a C format string

The C format string contains characters and format conversion specifications. The latter are initiated by a % sign. If the next letter is also a %, a percent sign is printed and no conversion is done. Otherwise, a conversion is done and applied to the next argument in the argument list. First comes an optional flag (#, 0, -, +, or space), an optional field width (decimal digits starting not with zero), an optional precision (period, then another decimal digit string), a length modifier (irrelevant for us, therefore not supported), and a conversion specifier: **d** or **i** for integer; **e**, **f**, **g** (also upper case) for double-precision real, **s** for a string.

We explicitly exclude all other conversion specifiers, and we check the specifiers against the actual arguments.

A type for passing arguments

This is a polymorphic type that can hold integer, real (double), and string arguments.

```
Formats: parameters≡
  integer, parameter :: ARGTYPE_NONE = 0
  integer, parameter :: ARGTYPE_LOG = 1
  integer, parameter :: ARGTYPE_INT = 2
  integer, parameter :: ARGTYPE_REAL = 3
  integer, parameter :: ARGTYPE_STR = 4
```

The integer and real entries are actually scalars, but we avoid relying on the allocatable-scalar feature and make them one-entry arrays. The character entry is a real array which is a copy of the string.

Logical values are mapped to strings (true or false), so this type parameter value is mostly unused.

```
Formats: public≡
  public :: sprintf_arg_t
```

```
Formats: types≡
  type :: sprintf_arg_t
  private
    integer :: type = ARGTYPE_NONE
    integer(c_int), dimension(:), allocatable :: ival
    real(c_double), dimension(:), allocatable :: rval
    character(c_char), dimension(:), allocatable :: sval
  end type sprintf_arg_t
```

```
Formats: public+≡
  public :: sprintf_arg_init
```

(Formats: interfaces)≡

```
interface sprintf_arg_init
  module procedure sprintf_arg_init_log
  module procedure sprintf_arg_init_int
  module procedure sprintf_arg_init_real
  module procedure sprintf_arg_init_str
end interface
```

(Formats: procedures)≡

```
subroutine sprintf_arg_init_log (arg, lval)
  type(sprintf_arg_t), intent(out) :: arg
  logical, intent(in) :: lval
  arg%type = ARGTYPE_STR
  if (lval) then
    allocate (arg%sval (5))
    arg%sval = (/ 't', 'r', 'u', 'e', c_null_char /)
  else
    allocate (arg%sval (6))
    arg%sval = (/ 'f', 'a', 'l', 's', 'e', c_null_char /)
  end if
end subroutine sprintf_arg_init_log

subroutine sprintf_arg_init_int (arg, ival)
  type(sprintf_arg_t), intent(out) :: arg
  integer, intent(in) :: ival
  arg%type = ARGTYPE_INT
  allocate (arg%ival (1))
  arg%ival = ival
end subroutine sprintf_arg_init_int

subroutine sprintf_arg_init_real (arg, rval)
  type(sprintf_arg_t), intent(out) :: arg
  real(default), intent(in) :: rval
  arg%type = ARGTYPE_REAL
  allocate (arg%rval (1))
  arg%rval = rval
end subroutine sprintf_arg_init_real

subroutine sprintf_arg_init_str (arg, sval)
  type(sprintf_arg_t), intent(out) :: arg
  type(string_t), intent(in) :: sval
  integer :: i
  arg%type = ARGTYPE_STR
  allocate (arg%sval (len (sval) + 1))
  do i = 1, len (sval)
    arg%sval(i) = extract (sval, i, i)
  end do
  arg%sval(len (sval) + 1) = c_null_char
end subroutine sprintf_arg_init_str
```

(Formats: procedures)+≡

```
subroutine sprintf_arg_write (arg, unit)
  type(sprintf_arg_t), intent(in) :: arg
```

```

integer, intent(in), optional :: unit
integer :: u
u = output_unit (unit)
select case (arg%type)
case (ARGTYPE_NONE)
  write (u, *) "[none]"
case (ARGTYPE_INT)
  write (u, "(1x,A,1x)", advance = "no") "[int]"
  write (u, *) arg%ival
case (ARGTYPE_REAL)
  write (u, "(1x,A,1x)", advance = "no") "[real]"
  write (u, *) arg%rval
case (ARGTYPE_STR)
  write (u, "(1x,A,1x,A)", advance = "no") "[string]", ''
  write (u, *) arg%rval, ''
end select
end subroutine sprintf_arg_write

```

Return an upper bound for the length of the printed version; in case of strings the result is exact.

(Formats: procedures)+≡

```

elemental function sprintf_arg_get_length (arg) result (length)
integer :: length
type(sprintf_arg_t), intent(in) :: arg
select case (arg%type)
case (ARGTYPE_INT)
  length = log10 (real (huge (arg%ival(1)))) + 2
case (ARGTYPE_REAL)
  length = log10 (real (radix (arg%rval(1))) ** digits (arg%rval(1))) + 8
case (ARGTYPE_STR)
  length = size (arg%sval)
case default
  length = 0
end select
end function sprintf_arg_get_length

```

(Formats: procedures)+≡

```

subroutine sprintf_arg_apply_printf (arg, fmt, result, actual_length)
type(sprintf_arg_t), intent(in) :: arg
character(c_char), dimension(:), intent(in) :: fmt
character(c_char), dimension(:), intent(inout) :: result
integer, intent(out) :: actual_length
integer(c_int) :: ival
real(c_double) :: rval
select case (arg%type)
case (ARGTYPE_NONE)
  actual_length = sprintf_none (result, fmt)
case (ARGTYPE_INT)
  ival = arg%ival(1)
  actual_length = sprintf_int (result, fmt, ival)
case (ARGTYPE_REAL)
  rval = arg%rval(1)
  actual_length = sprintf_double (result, fmt, rval)

```

```

case (ARGTYPE_STR)
  actual_length = sprintf_str (result, fmt, arg%sval)
case default
  call msg_bug ("sprintf_arg_apply_sprintf called with illegal type")
end select
if (actual_length < 0) then
  write (msg_buffer, *) "Format: '", fmt, "'"
  call msg_message ()
  write (msg_buffer, *) "Output: '", result, "'"
  call msg_message ()
  call msg_error ("I/O error in sprintf call")
  actual_length = 0
end if
end subroutine sprintf_arg_apply_sprintf

```

Container type for the output

There is a procedure which chops the format string into pieces that contain at most one conversion specifier. Pairing this with a `sprintf_arg` object, we get the actual input to the `sprintf` interface. The type below holds this input and can allocate the output string.

(Formats: types)+≡

```

type :: sprintf_interface_t
  private
  character(c_char), dimension(:), allocatable :: input_fmt
  type(sprintf_arg_t) :: arg
  character(c_char), dimension(:), allocatable :: output_str
  integer :: output_str_len = 0
end type sprintf_interface_t

```

(Formats: procedures)+≡

```

subroutine sprintf_interface_init (intf, fmt, arg)
  type(sprintf_interface_t), intent(out) :: intf
  type(string_t), intent(in) :: fmt
  type(sprintf_arg_t), intent(in) :: arg
  integer :: fmt_len, i
  fmt_len = len (fmt)
  allocate (intf%input_fmt (fmt_len + 1))
  do i = 1, fmt_len
    intf%input_fmt(i) = extract (fmt, i, i)
  end do
  intf%input_fmt(fmt_len+1) = c_null_char
  intf%arg = arg
  allocate (intf%output_str (len (fmt) + sprintf_arg_get_length (arg) + 1))
end subroutine sprintf_interface_init

```

(Formats: procedures)+≡

```

subroutine sprintf_interface_write (intf, unit)
  type(sprintf_interface_t), intent(in) :: intf
  integer, intent(in), optional :: unit
  integer :: u

```

```

u = output_unit (unit)
write (u, *) "Format string = ", "'", intf%input_fmt, "'"
write (u, "(1x,A,1x)", advance = "no") "Argument = "
call sprintf_arg_write (intf%arg, unit)
if (intf%output_str_len > 0) then
    write (u, *) "Result string = ", &
        "'", intf%output_str (1:intf%output_str_len), "'"
end if
end subroutine sprintf_interface_write

```

Return the output string:

```

<Formats: procedures>+≡
function sprintf_interface_get_result (intf) result (string)
    type(string_t) :: string
    type(sprintf_interface_t), intent(in) :: intf
    character(kind = c_char, len = max (intf%output_str_len, 0)) :: buffer
    integer :: i
    if (intf%output_str_len > 0) then
        do i = 1, intf%output_str_len
            buffer(i:i) = intf%output_str(i)
        end do
        string = buffer(1:intf%output_str_len)
    else
        string = ""
    end if
end function sprintf_interface_get_result

```

```

<Formats: procedures>+≡
subroutine sprintf_interface_apply_sprintf (intf)
    type(sprintf_interface_t), intent(inout) :: intf
    call sprintf_arg_apply_sprintf &
        (intf%arg, intf%input_fmt, intf%output_str, intf%output_str_len)
end subroutine sprintf_interface_apply_sprintf

```

Import the interfaces defined in the previous section:

```

<Formats: interfaces>+≡
<sprintf interfaces>

```

Scan the format string

Chop it into pieces that contain one conversion specifier each. The zero-th piece contains the part before the first specifier. Check the specifiers and allow only the subset that we support. Also check for an exact match between conversion specifiers and input arguments. The result is an allocated array of `sprintf_interface` object; each one contains a piece of the format string and the corresponding argument.

```

<Formats: procedures>+≡

```

2.12 Bytes and such

In a few instances we will need the notion of a byte (8-bit) and a word (32 bit), even a 64-bit word. A block of 512 bit is also needed (for MD5).

We rely on integers up to 64 bit being supported by the processor. The main difference to standard integers is the interpretation as unsigned integers.

(bytes.f90)≡

```

    <File header>

module bytes

    use kinds, only: i8, i32, i64 !NODEP!
    <Use file utils>

    <Standard module head>

    <Bytes: public>

    <Bytes: types>

    <Bytes: parameters>

    <Bytes: interfaces>

contains

    <Bytes: procedures>

end module bytes

```

2.12.1 8-bit words: bytes

This is essentially a wrapper around 8-bit integers. The wrapper emphasises their special interpretation as a sequence of bits. However, we interpret bytes as unsigned integers.

```

    <Bytes: public>≡
        public :: byte_t

    <Bytes: types>≡
        type :: byte_t
            private
                integer(i8) :: i
            end type byte_t

    <Bytes: public>+≡
        public :: byte_zero

    <Bytes: parameters>≡
        type(byte_t), parameter :: byte_zero = byte_t (0_i8)

```

Set a byte from 8-bit integer:

```

    <Bytes: public>+≡
        public :: assignment(=)

    <Bytes: interfaces>≡
        interface assignment(=)
            module procedure set_byte_from_i8
        end interface

```

```

<Bytes: procedures>+≡
  subroutine set_byte_from_i8 (b, i)
    type(byte_t), intent(out) :: b
    integer(i8), intent(in) :: i
    b%i = i
  end subroutine set_byte_from_i8

```

Write a byte in one of two formats: either as a hexadecimal number (two digits, default) or as a decimal number (one to three digits). The decimal version is nontrivial because bytes are unsigned integers. Optionally append a newline.

```

<Bytes: public>+≡
  public :: byte_write

<Bytes: interfaces>+≡
  interface byte_write
    module procedure byte_write_unit, byte_write_string
  end interface

<Bytes: procedures>+≡
  subroutine byte_write_unit (b, unit, decimal, newline)
    type(byte_t), intent(in), optional :: b
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: decimal, newline
    logical :: dc, nl
    type(word32_t) :: w
    integer :: u
    u = output_unit (unit); if (u < 0) return
    dc = .false.; if (present (decimal)) dc = decimal
    nl = .false.; if (present (newline)) nl = newline
    if (dc) then
      w = b
      write (u, '(I3)', advance='no') w%i
    else
      write (u, '(z2.2)', advance='no') b%i
    end if
    if (nl) write (u, *)
  end subroutine byte_write_unit

```

The string version is hex-only

```

<Bytes: procedures>+≡
  subroutine byte_write_string (b, s)
    type(byte_t), intent(in) :: b
    character(len=2), intent(inout) :: s
    write (s, '(z2.2)') b%i
  end subroutine byte_write_string

```

2.12.2 32-bit words

This is not exactly a 32-bit integer. A word is to be filled with bytes, and it may be partially filled. The filling is done lowest-byte first, highest-byte last. We

count the bits, so `fill` should be either 0, 8, 16, 24, or 32. In printing words, we correspondingly distinguish between printing zeros and printing blanks.

```

<Bytes: public>+≡
    public :: word32_t

<Bytes: types>+≡
    type :: word32_t
    private
        integer(i32) :: i
        integer :: fill = 0
    end type word32_t

```

Assignment: the word is filled by inserting a 32-bit integer

```

<Bytes: interfaces>+≡
    interface assignment(=)
        module procedure word32_set_from_i32
        module procedure word32_set_from_byte
    end interface

<Bytes: procedures>+≡
    subroutine word32_set_from_i32 (w, i)
        type(word32_t), intent(out) :: w
        integer(i32), intent(in) :: i
        w%i = i
        w%fill = 32
    end subroutine word32_set_from_i32

```

Reverse assignment to a 32-bit integer. We do not check the fill status.

```

<Bytes: interfaces>+≡
    interface assignment(=)
        module procedure i32_from_word32
    end interface

<Bytes: procedures>+≡
    subroutine i32_from_word32 (i, w)
        integer(i32), intent(out) :: i
        type(word32_t), intent(in) :: w
        i = w%i
    end subroutine i32_from_word32

```

Filling with a 8-bit integer is slightly tricky, because in this interpretation integers are unsigned.

```

<Bytes: procedures>+≡
    subroutine word32_set_from_byte (w, b)
        type(word32_t), intent(out) :: w
        type(byte_t), intent(in) :: b
        if (b%i >= 0_i8) then
            w%i = b%i
        else
            w%i = 2_i32*(huge(0_i8)+1_i32) + b%i
        end if
        w%fill = 32
    end subroutine word32_set_from_byte

```

Check the fill status

```
<Bytes: public>+≡
    public :: word32_empty, word32_filled, word32_fill

<Bytes: procedures>+≡
    function word32_empty (w)
        type(word32_t), intent(in) :: w
        logical :: word32_empty
        word32_empty = (w%fill == 0)
    end function word32_empty

    function word32_filled (w)
        type(word32_t), intent(in) :: w
        logical :: word32_filled
        word32_filled = (w%fill == 32)
    end function word32_filled

    function word32_fill (w)
        type(word32_t), intent(in) :: w
        integer :: word32_fill
        word32_fill = w%fill
    end function word32_fill
```

Partial assignment: append a byte to a partially filled word. (Note: no assignment if the word is filled, so check this before if necessary.)

```
<Bytes: public>+≡
    public :: word32_append_byte

<Bytes: procedures>+≡
    subroutine word32_append_byte (w, b)
        type(word32_t), intent(inout) :: w
        type(byte_t), intent(in) :: b
        type(word32_t) :: w1
        if (.not. word32_filled (w)) then
            w1 = b
            call mvbits (w1%i, 0, 8, w%i, w%fill)
            w%fill = w%fill + 8
        end if
    end subroutine word32_append_byte
```

Extract a byte from a word. The argument *i* is the position, which may be 0, 1, 2, or 3.

For the final assignment, we set the highest bit separately. Otherwise, we might trigger an overflow condition for a compiler with strict checking turned on.

```
<Bytes: public>+≡
    public :: byte_from_word32

<Bytes: procedures>+≡
    function byte_from_word32 (w, i) result (b)
        type(word32_t), intent(in) :: w
        integer, intent(in) :: i
        type(byte_t) :: b
        integer(i32) :: j
```

```

j = 0
if (i >= 0 .and. i*8 < w%fill) then
    call mvbits (w%i, i*8, 8, j, 0)
end if
b%i = int (ibclr (j, 7), kind=i8)
if (btest (j, 7)) b%i = ibset (b%i, 7)
end function byte_from_word32

```

Write a word to file or STDOUT. We understand words as unsigned integers, therefore we cannot use the built-in routine unchanged. However, we can make use of the existence of 64-bit integers and their output routine.

In hexadecimal format, the default version prints eight hex characters, highest-first. The `bytes` version prints four bytes (two-hex characters), lowest first, with spaces in-between. The decimal bytes version is analogous. In the `bytes` version, missing bytes are printed as whitespace.

```

<Bytes: public>+≡
    public :: word32_write

<Bytes: interfaces>+≡
    interface word32_write
        module procedure word32_write_unit
    end interface

<Bytes: procedures>+≡
    subroutine word32_write_unit (w, unit, bytes, decimal, newline)
        type(word32_t), intent(in) :: w
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: bytes, decimal, newline
        logical :: dc, by, nl
        type(word64_t) :: ww
        integer :: i, u
        u = output_unit (unit); if (u < 0) return
        by = .false.; if (present (bytes)) by = bytes
        dc = .false.; if (present (decimal)) dc = decimal
        nl = .false.; if (present (newline)) nl = newline
        if (by) then
            do i = 0, 3
                if (i>0) write (u, '(1x)', advance='no')
                if (8*i < w%fill) then
                    call byte_write (byte_from_word32 (w, i), unit, decimal=decimal)
                else if (dc) then
                    write (u, '(3x)', advance='no')
                else
                    write (u, '(2x)', advance='no')
                end if
            end do
        else if (dc) then
            ww = w
            write (u, '(I10)', advance='no') ww%i
        else
            select case (w%fill)
            case ( 0)
            case ( 8); write (6, '(1x,z8.2)', advance='no') ibits (w%i, 0, 8)
            case (16); write (6, '(1x,z8.4)', advance='no') ibits (w%i, 0,16)

```

```

        case (24); write (6, '(1x,z8.6)', advance='no') ibits (w%i, 0,24)
        case (32); write (6, '(1x,z8.8)', advance='no') ibits (w%i, 0,32)
        end select
    end if
    if (nl) write (u, *)
end subroutine word32_write_unit

```

2.12.3 Operations on 32-bit words

Define the usual logical operations, as well as addition (mod 2^{32}). We assume that all operands are completely filled.

(Bytes: public)+≡

```
public :: not, ior, ieor, iand, ishft, ishftc
```

```

2.12.4 64-bit words

These objects consist of two 32-bit words. They thus can hold integer numbers larger than 2^{32} (to be exact, 2^{31} since FORTRAN integers are signed). The order is low-word, high-word.

```

<Bytes: public>+≡
    public :: word64_t

<Bytes: types>+≡
    type :: word64_t
    private
    integer(i64) :: i
end type word64_t

```

Set a 64 bit word:

```

<Bytes: interfaces>+≡
    interface assignment(=)
        module procedure word64_set_from_i64
        module procedure word64_set_from_word32
    end interface

<Bytes: procedures>+≡
    subroutine word64_set_from_i64 (ww, i)
        type(word64_t), intent(out) :: ww
        integer(i64), intent(in) :: i
        ww%i = i
    end subroutine word64_set_from_i64

```

Filling with a 32-bit word:

```

<Bytes: procedures>+≡
    subroutine word64_set_from_word32 (ww, w)
        type(word64_t), intent(out) :: ww
        type(word32_t), intent(in) :: w
        if (w%i >= 0_i32) then
            ww%i = w%i
        end if
    end subroutine word64_set_from_word32

```

```

else
    ww%i = 2_i64*(huge(0_i32)+1_i64) + w%i
end if
end subroutine word64_set_from_word32

```

Extract a byte from a word. The argument *i* is the position, which may be between 0 and 7.

For the final assignment, we set the highest bit separately. Otherwise, we might trigger an overflow condition for a compiler with strict checking turned on.

```

<Bytes: public>+≡
public :: byte_from_word64, word32_from_word64

<Bytes: procedures>+≡
function byte_from_word64 (ww, i) result (b)
    type(word64_t), intent(in) :: ww
    integer, intent(in) :: i
    type(byte_t) :: b
    integer(i64) :: j
    j = 0
    if (i >= 0 .and. i*8 < 64) then
        call mvbits (ww%i, i*8, 8, j, 0)
    end if
    b%i = int (ibclr (j, 7), kind=i8)
    if (btest (j, 7)) b%i = ibset (b%i, 7)
end function byte_from_word64

```

Extract a 32-bit word from a 64-bit word. The position is either 0 or 1.

```

<Bytes: procedures>+≡
function word32_from_word64 (ww, i) result (w)
    type(word64_t), intent(in) :: ww
    integer, intent(in) :: i
    type(word32_t) :: w
    integer(i64) :: j
    j = 0
    select case (i)
    case (0); call mvbits (ww%i, 0, 32, j, 0)
    case (1); call mvbits (ww%i, 32, 32, j, 0)
    end select
    w = int (ibclr (j, 31), kind=i32)
    if (btest (j, 31)) w = ibset (w%i, 31)
end function word32_from_word64

```

Print a 64-bit word. Decimal version works up to 2^{63} . The **words** version uses the 'word32' printout, separated by two spaces. The low-word is printed first. The **bytes** version also uses the 'word32' printout. This implies that the lowest byte is first. The default version prints a hexadecimal number without spaces, highest byte first.

```

<Bytes: public>+≡
public :: word64_write

```

```

<Bytes: interfaces>+≡
    interface word64_write
        module procedure word64_write_unit
    end interface

<Bytes: procedures>+≡
    subroutine word64_write_unit (ww, unit, words, bytes, decimal, newline)
        type(word64_t), intent(in) :: ww
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: words, bytes, decimal, newline
        logical :: wo, by, dc, nl
        integer :: u
        u = output_unit (unit); if (u < 0) return
        wo = .false.; if (present (words)) wo = words
        by = .false.; if (present (bytes)) by = bytes
        dc = .false.; if (present (decimal)) dc = decimal
        nl = .false.; if (present (newline)) nl = newline
        if (wo .or. by) then
            call word32_write_unit (word32_from_word64 (ww, 0), unit, by, dc)
            write (u, '(2x)', advance='no')
            call word32_write_unit (word32_from_word64 (ww, 1), unit, by, dc)
        else if (dc) then
            write (u, '(I19)', advance='no') ww%i
        else
            write (u, '(Z16)', advance='no') ww%i
        end if
        if (nl) write (u, *)
    end subroutine word64_write_unit

```

2.13 MD5 Checksums

Implementing MD5 checksums allows us to check input/file integrity on the basis of a well-known standard. The building blocks have been introduced in the `bytes` module.

```

2.13.1 Blocks

A block is a sequence of 16 words (64 bytes or 512 bits). We anticipate that blocks will be linked, so include a pointer to the next block. There is a fill status (word counter), as there is one for each word. The fill status is equal to the number of bytes that are in, so it may be between 0 and 64.

⟨MD5: types⟩≡
type :: block_t
private
type(word32_t), dimension(0:15) :: w
type(block_t), pointer :: next => null ()
integer :: fill = 0
end type block_t

Check if a block is completely filled or empty:

⟨MD5: procedures⟩≡
function block_is_empty (b)
type(block_t), intent(in) :: b
logical :: block_is_empty
block_is_empty = (b%fill == 0 .and. word32_empty (b%w(0)))
end function block_is_empty

function block_is_filled (b)
type(block_t), intent(in) :: b
logical :: block_is_filled
block_is_filled = (b%fill == 64)
end function block_is_filled

Append a single byte to a block. Works only if the block is not yet filled.

⟨MD5: procedures⟩+≡
subroutine block_append_byte (bl, by)
type(block_t), intent(inout) :: bl
type(byte_t), intent(in) :: by
if (.not. block_is_filled (bl)) then
call word32_append_byte (bl%w(bl%fill/4), by)
bl%fill = bl%fill + 1
end if
end subroutine block_append_byte

The printing routine allows for printing as sequences of words or bytes, decimal or hex.

(MD5: interfaces)≡

```
interface block_write
  module procedure block_write_unit
end interface
```

(MD5: procedures)+≡

```
subroutine block_write_unit (b, unit, bytes, decimal)
  type(block_t), intent(in) :: b
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: bytes, decimal
  logical :: by, dc
  integer :: i, u
  u = output_unit (unit); if (u < 0) return
  by = .false.; if (present (bytes)) by = bytes
  dc = .false.; if (present (decimal)) dc = decimal
  do i = 0, b%fill/4 - 1
    call newline_or_blank (u, i, by, dc)
    call word32_write (b%w(i), unit, bytes, decimal)
  end do
  if (.not. block_is_filled (b)) then
    i = b%fill/4
    if (.not. word32_empty (b%w(i))) then
      call newline_or_blank (u, i, by, dc)
      call word32_write (b%w(i), unit, bytes, decimal)
    end if
  end if
  write (u, *)
contains
  subroutine newline_or_blank (u, i, bytes, decimal)
    integer, intent(in) :: u, i
    logical, intent(in) :: bytes, decimal
    if (decimal) then
      select case (i)
        case (0)
        case (2,4,6,8,10,12,14); write (u, *)
        case default
          write (u, '(2x)', advance='no')
        end select
    else if (bytes) then
      select case (i)
        case (0)
        case (4,8,12); write (u, *)
        case default
          write (u, '(2x)', advance='no')
        end select
    else
      if (i == 8) write (u, *)
    end if
  end subroutine newline_or_blank
end subroutine block_write_unit
```

2.13.2 Messages

A message (within this module) is a linked list of blocks.

(MD5: types)+≡

```
type :: message_t
  private
  type(block_t), pointer :: first => null ()
  type(block_t), pointer :: last => null ()
  integer :: n_blocks = 0
end type message_t
```

Clear the message list

(MD5: procedures)+≡

```
subroutine message_clear (m)
  type(message_t), intent(inout) :: m
  type(block_t), pointer :: b
  nullify (m%last)
  do
    b => m%first
    if (.not.(associated (b))) exit
    m%first => b%next
    deallocate (b)
  end do
  m%n_blocks = 0
end subroutine message_clear
```

Append an empty block to the message list

(MD5: procedures)+≡

```
subroutine message_append_new_block (m)
  type(message_t), intent(inout) :: m
  if (associated (m%last)) then
    allocate (m%last%next)
    m%last => m%last%next
    m%n_blocks = m%n_blocks + 1
  else
    allocate (m%first)
    m%last => m%first
    m%n_blocks = 1
  end if
end subroutine message_append_new_block
```

Initialize: clear and allocate the first (empty) block.

(MD5: procedures)+≡

```
subroutine message_init (m)
  type(message_t), intent(inout) :: m
  call message_clear (m)
  call message_append_new_block (m)
end subroutine message_init
```

Append a single byte to a message. If necessary, allocate a new block. If the message is empty, initialize it.

(MD5: procedures)+≡

```

subroutine message_append_byte (m, b)
  type(message_t), intent(inout) :: m
  type(byte_t), intent(in) :: b
  if (.not. associated (m%last)) then
    call message_init (m)
  else if (block_is_filled (m%last)) then
    call message_append_new_block (m)
  end if
  call block_append_byte (m%last, b)
end subroutine message_append_byte

```

Append zero bytes until the current block is filled up to the required position. If we are already beyond that, append a new block and fill that one.

(MD5: procedures)+≡

```

subroutine message_pad_zero (m, i)
  type(message_t), intent(inout) :: m
  integer, intent(in) :: i
  type(block_t), pointer :: b
  integer :: j
  if (associated (m%last)) then
    b => m%last
    if (b%fill > i) then
      do j = b%fill + 1, 64 + i
        call message_append_byte (m, byte_zero)
      end do
    else
      do j = b%fill + 1, i
        call message_append_byte (m, byte_zero)
      end do
    end if
  end if
end subroutine message_pad_zero

```

This returns the number of bits within a message. We need a 64-bit word for the result since it may be more than 2^{31} . This is also required by the MD5 standard.

(MD5: procedures)+≡

```

function message_bits (m) result (length)
  type(message_t), intent(in) :: m
  type(word64_t) :: length
  type(block_t), pointer :: b
  integer(i64) :: n_blocks_filled, n_bytes_extra
  if (m%n_blocks > 0) then
    b => m%last
    if (block_is_filled (b)) then
      n_blocks_filled = m%n_blocks
      n_bytes_extra = 0
    else
      n_blocks_filled = m%n_blocks - 1
      n_bytes_extra = b%fill
    end if
    length = n_blocks_filled * 512 + n_bytes_extra * 8
  else

```

```

        length = 0_i64
    end if
end function message_bits

```

2.13.3 Message I/O

Append the contents of a string to a message. We first cast the character string into a 8-bit integer array and the append this byte by byte.

(MD5: procedures)+≡

```

subroutine message_append_string (m, s)
    type(message_t), intent(inout) :: m
    character(len=*), intent(in) :: s
    integer(i64) :: i, n_bytes
    integer(i8), dimension(:), allocatable :: buffer
    integer(i8), dimension(1) :: mold
    type(byte_t) :: b
    n_bytes = size (transfer (s, mold))
    allocate (buffer (n_bytes))
    buffer = transfer (s, mold)
    do i = 1, size (buffer)
        b = buffer(i)
        call message_append_byte (m, b)
    end do
    deallocate (buffer)
end subroutine message_append_string

```

Append the contents of a 32-bit integer to a message. We first cast the 32-bit integer into a 8-bit integer array and the append this byte by byte.

(MD5: procedures)+≡

```

subroutine message_append_i32 (m, x)
    type(message_t), intent(inout) :: m
    integer(i32), intent(in) :: x
    integer(i8), dimension(4) :: buffer
    type(byte_t) :: b
    integer :: i
    buffer = transfer (x, buffer, size(buffer))
    do i = 1, size (buffer)
        b = buffer(i)
        call message_append_byte (m, b)
    end do
end subroutine message_append_i32

```

Append one line from file to a message. Include the newline character.

(MD5: procedures)+≡

```

subroutine message_append_from_unit (m, u, iostat)
    type(message_t), intent(inout) :: m
    integer, intent(in) :: u
    integer, intent(out) :: iostat
    character(len=BUFFER_SIZE) :: buffer
    read (u, *, iostat=iostat) buffer
    call message_append_string (m, trim (buffer))

```

```

        call message_append_string (m, LF)
    end subroutine message_append_from_unit

```

Fill a message from file. (Each line counts as a string.)

(MD5: procedures)+≡

```

subroutine message_read_from_file (m, f)
    type(message_t), intent(inout) :: m
    character(len=*), intent(in) :: f
    integer :: u, iostat
    u = free_unit ()
    open (file=f, unit=u, action='read')
    do
        call message_append_from_unit (m, u, iostat=iostat)
        if (iostat < 0) exit
    end do
    close (u)
end subroutine message_read_from_file

```

Write a message. After each block, insert an empty line.

(MD5: interfaces)+≡

```

interface message_write
    module procedure message_write_unit
end interface

```

(MD5: procedures)+≡

```

subroutine message_write_unit (m, unit, bytes, decimal)
    type(message_t), intent(in) :: m
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: bytes, decimal
    type(block_t), pointer :: b
    integer :: u
    u = output_unit (unit); if (u < 0) return
    b => m%first
    if (associated (b)) then
        do
            call block_write_unit (b, unit, bytes, decimal)
            b => b%next
            if (.not. associated (b)) exit
            write (u, *)
        end do
    end if
end subroutine message_write_unit

```

2.13.4 Auxiliary functions

These four functions on three words are defined in the MD5 standard:

(MD5: procedures)+≡

```

function ff (x, y, z)
    type(word32_t), intent(in) :: x, y, z
    type(word32_t) :: ff
    ff = ior (iand (x, y), iand (not (x), z))
end function ff

```

```

function fg (x, y, z)
  type(word32_t), intent(in) :: x, y, z
  type(word32_t) :: fg
  fg = ior (iand (x, z), iand (y, not (z)))
end function fg

function fh (x, y, z)
  type(word32_t), intent(in) :: x, y, z
  type(word32_t) :: fh
  fh = ieor (ieor (x, y), z)
end function fh

function fi (x, y, z)
  type(word32_t), intent(in) :: x, y, z
  type(word32_t) :: fi
  fi = ieor (y, ior (x, not (z)))
end function fi

```

2.13.5 Auxiliary stuff

This defines and initializes the table of transformation constants:

```

<MD5: variables>≡
  type(word32_t), dimension(64), save :: t
  logical, save :: table_initialized = .false.

<MD5: procedures>+≡
  subroutine table_init
    type(word64_t) :: ww
    integer :: i
    if (.not.table_initialized) then
      do i = 1, 64
        ww = int (4294967296d0 * abs (sin (i * 1d0)), kind=i64)
        t(i) = word32_from_word64 (ww, 0)
      end do
      table_initialized = .true.
    end if
  end subroutine table_init

```

This encodes the message digest (4 words) into a 32-character string.

```

<MD5: procedures>+≡
  function digest_string (aa) result (s)
    type(word32_t), dimension (0:3), intent(in) :: aa
    character(len=32) :: s
    integer :: i, j
    do i = 0, 3
      do j = 0, 3
        call byte_write (byte_from_word32 (aa(i), j), s(i*8+j*2+1:i*8+j*2+2))
      end do
    end do
  end function digest_string

```

2.13.6 MD5 algorithm

Pad the message with a byte x80 and then pad zeros up to a full block minus two words; in these words, insert the message length (before padding) as a 64-bit word, low-word first.

(MD5: procedures)+≡

```
subroutine message_pad (m)
  type(message_t), intent(inout) :: m
  type(word64_t) :: length
  integer(i8), parameter :: ipad = -128 ! z'80'
  type(byte_t) :: b
  integer :: i
  length = message_bits (m)
  b = ipad
  call message_append_byte (m, b)
  call message_pad_zero (m, 56)
  do i = 0, 7
    call message_append_byte (m, byte_from_word64 (length, i))
  end do
end subroutine message_pad
```

Apply a series of transformations onto a state **a,b,c,d**, where the transform function uses each word of the message together with the predefined words. Finally, encode the state as a 32-character string.

(MD5: procedures)+≡

```
subroutine message_digest (m, s)
  type(message_t), intent(in) :: m
  character(len=32), intent(out) :: s
  integer(i32), parameter :: ia = 1732584193 ! z'67452301'
  integer(i32), parameter :: ib = -271733879 ! z'efcdab89'
  integer(i32), parameter :: ic = -1732584194 ! z'98badcfe'
  integer(i32), parameter :: id = 271733878 ! z'10325476'
  type(word32_t) :: a, b, c, d
  type(word32_t) :: aa, bb, cc, dd
  type(word32_t), dimension(0:15) :: x
  type(block_t), pointer :: bl
  call table_init
  a = ia; b = ib; c = ic; d = id
  bl => m%first
  do
    if (.not.associated (bl)) exit
    x = bl%w
    aa = a; bb = b; cc = c; dd = d
    call transform (ff, a, b, c, d, 0, 7, 1)
    call transform (ff, d, a, b, c, 1, 12, 2)
    call transform (ff, c, d, a, b, 2, 17, 3)
    call transform (ff, b, c, d, a, 3, 22, 4)
    call transform (ff, a, b, c, d, 4, 7, 5)
    call transform (ff, d, a, b, c, 5, 12, 6)
    call transform (ff, c, d, a, b, 6, 17, 7)
    call transform (ff, b, c, d, a, 7, 22, 8)
    call transform (ff, a, b, c, d, 8, 7, 9)
    call transform (ff, d, a, b, c, 9, 12, 10)
```

```

call transform (ff, c, d, a, b, 10, 17, 11)
call transform (ff, b, c, d, a, 11, 22, 12)
call transform (ff, a, b, c, d, 12, 7, 13)

call transform (fi, a, b, c, d, 4, 6, 61)
call transform (fi, d, a, b, c, 11, 10, 62)
call transform (fi, c, d, a, b, 2, 15, 63)
call transform (fi, b, c, d, a, 9, 21, 64)

```

```

        a = a + aa
        b = b + bb
        c = c + cc
        d = d + dd
        bl => bl%next
    end do
    s = digest_string ((/a, b, c, d/))
contains
<MD5: Internal subroutine transform>
end subroutine message_digest

```

And this is the actual transformation that depends on one of the previous functions, four words, and three integers. The implicit arguments are *x*, the word from the message to digest, and *t*, the entry in the predefined table.

```

<MD5: Internal subroutine transform>≡
subroutine transform (f, a, b, c, d, k, s, i)
    interface
        function f (x, y, z)
            import word32_t
            type(word32_t), intent(in) :: x, y, z
            type(word32_t) :: f
        end function f
    end interface
    type(word32_t), intent(inout) :: a
    type(word32_t), intent(in) :: b, c, d
    integer, intent(in) :: k, s, i
    a = b + ishftc (a + f(b, c, d) + x(k) + t(i), s)
end subroutine transform

```

2.13.7 User interface

```

<MD5: public>≡
public :: md5sum

<MD5: interfaces>+≡
interface md5sum
    module procedure md5sum_from_string
    module procedure md5sum_from_unit
end interface

```

This function computes the MD5 sum of the input string and returns it as a 32-character string

```

<MD5: procedures>+≡
function md5sum_from_string (s) result (digest)
    character(len=*), intent(in) :: s
    character(len=32) :: digest
    type(message_t) :: m
    call message_append_string (m, s)
    call message_pad (m)
    call message_digest (m, digest)
    call message_clear (m)
end function md5sum_from_string

```

This funct. reads from unit u (an unformatted sequence of integers) and computes the MD5 sum.

<MD5: procedures>+≡

```
function md5sum_from_unit (u) result (digest)
  integer, intent(in) :: u
  character(len=32) :: digest
  type(message_t) :: m
  character :: char
  integer :: iostat
  READ_CHARS: do
    read (u, "(A)", advance="no", iostat=iostat) char
    select case (iostat)
    case (0)
      call message_append_string (m, char)
    case (EOR)
      call message_append_string (m, LF)
    case (EOF)
      exit READ_CHARS
    case default
      call msg_fatal &
        ("Computing MD5 sum: I/O error while reading from scratch file")
    end select
  end do READ_CHARS
  call message_pad (m)
  call message_digest (m, digest)
  call message_clear (m)
end function md5sum_from_unit
```

2.13.8 Unit tests

<MD5: public>+≡

```
public :: md5_test
```

<MD5: procedures>+≡

```
subroutine md5_test (u, results)
  integer, intent(in) :: u
  type(test_results_t), intent(inout) :: results
<MD5: execute tests>
end subroutine md5_test
```

This function checks the implementation by computing the checksum of certain strings and comparing them with the known values.

<MD5: execute tests>≡

```
call test (md5_1, "md5_1", &
  "check MD5 sums", &
  u, results)
```

<MD5: tests>≡

```
subroutine md5_1 (u)
  integer, intent(in) :: u

end module permutations

2.14.1 Permutations

A permutation is an array of integers. Each integer between one and `size` should occur exactly once.

<Permutations: public>≡

public :: permutation_t

<Permutations: types>≡

type :: permutation_t

private

integer, dimension(:), allocatable :: p

end type permutation_t

Initialize with the identity permutation.

<Permutations: public>+≡

public :: permutation_init

public :: permutation_final

<Permutations: procedures>≡

elemental subroutine permutation_init (p, size)

type(permutation_t), intent(inout) :: p

integer, intent(in) :: size

integer :: i

allocate (p%p (size))

forall (i = 1:size)

p%p(i) = i

end forall

end subroutine permutation_init

elemental subroutine permutation_final (p)

type(permutation_t), intent(inout) :: p

deallocate (p%p)

end subroutine permutation_final

I/O:

<Permutations: public>+≡

public :: permutation_write

<Permutations: procedures>+≡

subroutine permutation_write (p, u)

type(permutation_t), intent (in) :: p

integer, intent(in) :: u

integer :: i

do i = 1, size (p%p)

if (size (p%p) < 10) then

write (u, "(1x,I1)", advance="no") p%p(i)

```

        else
            write (u,"(1x,I3)", advance="no") p%p(i)
        end if
    end do
    write (u, *)
end subroutine permutation_write

```

Administration:

```

<Permutations: public>+≡
    public :: permutation_size

<Permutations: procedures>+≡
    elemental function permutation_size (perm) result (s)
        type(permutation_t), intent(in) :: perm
        integer :: s
        s = size (perm%p)
    end function permutation_size

```

Extract an entry in a permutation.

```

<Permutations: public>+≡
    public :: permute

<Permutations: procedures>+≡
    elemental function permute (i, p) result (j)
        integer, intent(in) :: i
        type(permutation_t), intent(in) :: p
        integer :: j
        if (i > 0 .and. i <= size (p%p)) then
            j = p%p(i)
        else
            j = 0
        end if
    end function permute

```

Check whether a permutation is valid: Each integer in the range occurs exactly once.

```

<Permutations: public>+≡
    public :: permutation_ok

<Permutations: procedures>+≡
    elemental function permutation_ok (perm) result (ok)
        type(permutation_t), intent(in) :: perm
        logical :: ok
        integer :: i
        logical, dimension(:), allocatable :: set
        ok = .true.
        allocate (set (size (perm%p)))
        set = .false.
        do i = 1, size (perm%p)
            ok = (perm%p(i) > 0 .and. perm%p(i) <= size (perm%p))
            if (.not.ok) return
            set(perm%p(i)) = .true.
        end do
    end function permutation_ok

```

```

    ok = all (set)
end function permutation_ok

```

Find the permutation that transforms the second array into the first one. We assume that this is possible and unique and all bounds are set correctly.

This cannot be elemental.

```

<Permutations: public>+=
  public :: permutation_find

<Permutations: procedures>+=
  subroutine permutation_find (perm, a1, a2)
    type(permutation_t), intent(inout) :: perm
    integer, dimension(:), intent(in) :: a1, a2
    integer :: i, j
    if (allocated (perm%p)) deallocate (perm%p)
    allocate (perm%p (size (a1)))
    do i = 1, size (a1)
      do j = 1, size (a2)
        if (a1(i) == a2(j)) then
          perm%p(i) = j
          exit
        end if
        perm%p(i) = 0
      end do
    end do
  end subroutine permutation_find

```

Find all permutations that transform an array of integers into itself. The resulting permutation list is allocated with the correct length and filled.

The first step is to count the number of different entries in `code`. Next, we scan `code` again and assign a mask to each different entry, true for all identical entries. Finally, we recursively permute the identity for each possible mask.

The permutation is done as follows: A list of all permutations of the initial one with respect to the current mask is generated, then the permutations are generated in turn for each permutation in this list with the next mask. The result is always stored back into the main list, starting from the end of the current list.

```

<Permutations: public>+=
  public :: permutation_array_make

<Permutations: procedures>+=
  subroutine permutation_array_make (pa, code)
    type(permutation_t), dimension(:), allocatable, intent(out) :: pa
    integer, dimension(:), intent(in) :: code
    logical, dimension(size(code)) :: mask
    logical, dimension(:,:), allocatable :: imask
    integer, dimension(:), allocatable :: n_i
    type(permutation_t) :: p_init
    type(permutation_t), dimension(:), allocatable :: p_tmp
    integer :: psize, i, j, k, n_different, n, nn_k
    psize = size (code)
    mask = .true.
    n_different = 0

```

```

do i=1, psize
  if (mask(i)) then
    n_different = n_different + 1
    mask = mask .and. (code /= code(i))
  end if
end do
allocate (imask(psize, n_different), n_i(n_different))
mask = .true.
k = 0
do i=1, psize
  if (mask(i)) then
    k = k + 1
    imask(:,k) = (code == code(i))
    n_i(k) = factorial (count(imask(:,k)))
    mask = mask .and. (code /= code(i))
  end if
end do
n = product (n_i)
allocate (pa (n))
call permutation_init (p_init, psize)
pa(1) = p_init
nn_k = 1
do k = 1, n_different
  allocate (p_tmp (n_i(k)))
  do i = nn_k, 1, -1
    call permutation_array_with_mask (p_tmp, imask(:,k), pa(i))
    do j = n_i(k), 1, -1
      pa((i-1)*n_i(k) + j) = p_tmp(j)
    end do
  end do
  deallocate (p_tmp)
  nn_k = nn_k * n_i(k)
end do
call permutation_final (p_init)
deallocate (imask, n_i)
end subroutine permutation_array_make

```

Make a list of permutations of the elements marked true in the **mask** array. The final permutation list must be allocated with the correct length ($n!$). The third argument is the initial permutation to start with, which must have the same length as the **mask** array (this is not checked).

(*Permutations: procedures*) +=

```

subroutine permutation_array_with_mask (pa, mask, p_init)
  type(permutation_t), dimension(:), intent(inout) :: pa
  logical, dimension(:), intent(in) :: mask
  type(permutation_t), intent(in) :: p_init
  integer :: plen
  integer :: i, ii, j, fac_i, k, x
  integer, dimension(:), allocatable :: index
  plen = size (pa)
  allocate (index(count(mask)))
  ii = 0
  do i = 1, size (mask)

```

```

        if (mask(i)) then
            ii = ii + 1
            index(ii) = i
        end if
    end do
    pa = p_init
    ii = 0
    fac_i = 1
    do i = 1, size (mask)
        if (mask(i)) then
            ii = ii + 1
            fac_i = fac_i * ii
            x = permute (i, p_init)
            do j = 1, plen
                k = ii - mod (((j-1)*fac_i)/plen, ii)
                call insert (pa(j), x, k, ii, index)
            end do
        end if
    end do
    deallocate (index)
contains
    subroutine insert (p, x, k, n, index)
        type(permutation_t), intent(inout) :: p
        integer, intent(in) :: x, k, n
        integer, dimension(:), intent(in) :: index
        integer :: i
        do i = n, k+1, -1
            p%p(index(i)) = p%p(index(i-1))
        end do
        p%p(index(k)) = x
    end subroutine insert
end subroutine permutation_array_with_mask

```

The factorial function is needed for pre-determining the number of permutations that will be generated:

```

<Permutations: procedures> +=
function factorial (n) result (f)
    integer, intent(in) :: n
    integer :: f
    integer :: i
    f = 1
    do i=2, abs(n)
        f = f*i
    end do
end function factorial

```

2.14.2 Operations on binary codes

Binary codes are needed for phase-space trees. Since the permutation function uses permutations, and no other special type is involved, we put the functions here.

This is needed for phase space trees: permute bits in a tree binary code. If no permutation is given, leave as is. (We may want to access the permutation directly here if this is efficiency-critical.)

```

<Permutations: public>+=
  public :: tc_permute

<Permutations: procedures>+=
  function tc_permute (k, perm, mask_in) result (pk)
    integer(TC), intent(in) :: k, mask_in
    type(permutation_t), intent(in) :: perm
    integer(TC) :: pk
    integer :: i
    pk = iand (k, mask_in)
    do i = 1, size (perm%p)
      !      if (btest(k,i-1)) pk = ibset (pk, permute (perm,i) - 1)
        if (btest(k,i-1)) pk = ibset (pk, perm%p(i)-1)
    end do
  end function tc_permute

```

This routine returns the number of set bits in the tree code value *k*. Hence, it is the number of externals connected to the current line. If *mask* is present, the complement of the tree code is also considered, and the smaller number is returned. This gives the true distance from the external states, taking into account the initial particles. The complement number is increased by one, since for a scattering diagram the vertex with the sum of all final-state codes is still one point apart from the initial particles.

```

<Permutations: public>+=
  public :: tc_decay_level

<Permutations: interfaces>=
  interface tc_decay_level
    module procedure decay_level_simple
    module procedure decay_level_complement
  end interface

<Permutations: procedures>+=
  function decay_level_complement (k, mask) result (l)
    integer(TC), intent(in) :: k, mask
    integer :: l
    l = min (decay_level_simple (k), &
             & decay_level_simple (ieor (k, mask)) + 1)
  end function decay_level_complement

  function decay_level_simple (k) result(l)
    integer(TC), intent(in) :: k
    integer :: l
    integer :: i
    l = 0
    do i=0, bit_size(k)-1
      if (btest(k,i)) l = l+1
    end do
  end function decay_level_simple

```

2.15 Sorting

This small module provides functions for sorting integer or real arrays.

```
<sorting.f90>≡  
  <File header>  
  
  module sorting  
  
    <Use kinds>  
    use diagnostics !NODEP!  
    use unit_tests  
  
    <Standard module head>  
  
    <Sorting: public>  
  
    <Sorting: interfaces>  
  
    contains  
  
    <Sorting: procedures>  
  
    <Sorting: tests>  
  
  end module sorting
```

2.15.1 Implementation

The `sort` function returns, for a given integer or real array, the array sorted by increasing value. The current implementation is *mergesort*, which has $O(n \ln n)$ behavior in all cases, and is stable for elements of equal value.

The `sort_abs` variant sorts by increasing absolute value, where for identical absolute value, the positive number comes first.

```
<Sorting: public>≡  
  public :: sort  
  public :: sort_abs  
  
<Sorting: interfaces>≡  
  interface sort  
    module procedure sort_int  
    module procedure sort_real  
  end interface  
  
  interface sort_abs  
    module procedure sort_int_abs  
  end interface
```

This variant of integer sort returns The body is identical, just the interface differs.

```
<Sorting: procedures>≡  
  function sort_int (val_in) result (val)  
    integer, dimension(:), intent(in) :: val_in
```

```

        integer, dimension(size(val_in)) :: val
    <Sorting: sort>
end function sort_int

function sort_real (val_in) result (val)
    real(default), dimension(:), intent(in) :: val_in
    real(default), dimension(size(val_in)) :: val
    <Sorting: sort>
end function sort_real

function sort_int_abs (val_in) result (val)
    integer, dimension(:), intent(in) :: val_in
    integer, dimension(size(val_in)) :: val
    <Sorting: sort abs>
end function sort_int_abs

<Sorting: sort>≡
    val = val_in( order (val_in) )

<Sorting: sort abs>≡
    val = val_in( order_abs (val_in) )

The order function returns, for a given integer or real array, the array of indices
of the elements sorted by increasing value.

<Sorting: public>+≡
    public :: order
    public :: order_abs

<Sorting: interfaces>+≡
    interface order
        module procedure order_int
        module procedure order_real
    end interface

    interface order_abs
        module procedure order_int_abs
    end interface

<Sorting: procedures>+≡
    function order_int (val) result (idx)
        integer, dimension(:), intent(in) :: val
        integer, dimension(size(val)) :: idx
    <Sorting: order>
    end function order_int

    function order_real (val) result (idx)
        real(default), dimension(:), intent(in) :: val
        integer, dimension(size(val)) :: idx
    <Sorting: order>
    end function order_real

    function order_int_abs (val) result (idx)
        integer, dimension(:), intent(in) :: val
        integer, dimension(size(val)) :: idx
    <Sorting: order abs>

```

```
end function order_int_abs
```

We start by individual elements, merge them to pairs, merge those to four-element subarrays, and so on. The last subarray can extend only up to the original array bound, of course, and the second of the subarrays to merge should contain at least one element.

```

<Sorting: order>≡
  <Sorting: order1>
    call merge (idx(b1:e2), idx(b1:e1), idx(b2:e2), val)
  <Sorting: order2>

<Sorting: order abs>≡
  <Sorting: order1>
    call merge_abs (idx(b1:e2), idx(b1:e1), idx(b2:e2), val)
  <Sorting: order2>

<Sorting: order1>≡
  integer :: n, i, s, b1, b2, e1, e2
  n = size (idx)
  forall (i = 1:n)
    idx(i) = i
  end forall
  s = 1
  do while (s < n)
    do b1 = 1, n-s, 2*s
      b2 = b1 + s
      e1 = b2 - 1
      e2 = min (e1 + s, n)
    end do
    s = 2 * s
  end do

<Sorting: order2>≡
  end do
  s = 2 * s
end do

```

The merging step does the actual sorting. We take two sorted array sections and merge them to a sorted result array. We are working on the indices, and comparing is done by taking the associated `val` which is real or integer.

```

<Sorting: interfaces>+≡
  interface merge
    module procedure merge_int
    module procedure merge_real
  end interface

  interface merge_abs
    module procedure merge_int_abs
  end interface

<Sorting: procedures>+≡
  subroutine merge_int (res, src1, src2, val)
    integer, dimension(:), intent(out) :: res
    integer, dimension(:), intent(in) :: src1, src2
    integer, dimension(:), intent(in) :: val
    integer, dimension(size(res)) :: tmp
  end subroutine
<Sorting: merge>

```

```

end subroutine merge_int

subroutine merge_real (res, src1, src2, val)
  integer, dimension(:), intent(out) :: res
  integer, dimension(:), intent(in) :: src1, src2
  real(default), dimension(:), intent(in) :: val
  integer, dimension(size(res)) :: tmp
  <Sorting: merge>
end subroutine merge_real

subroutine merge_int_abs (res, src1, src2, val)
  integer, dimension(:), intent(out) :: res
  integer, dimension(:), intent(in) :: src1, src2
  integer, dimension(:), intent(in) :: val
  integer, dimension(size(res)) :: tmp
  <Sorting: merge abs>
end subroutine merge_int_abs

```

```

<Sorting: merge>≡
  <Sorting: merge1>
    if (val(src1(i1)) <= val(src2(i2))) then
  <Sorting: merge2>

```

We keep the elements if the absolute values are strictly ordered. If they are equal in magnitude, we keep them if the larger value comes first, or if they are equal.

```

<Sorting: merge abs>≡
  <Sorting: merge1>
    if (abs (val(src1(i1))) < abs (val(src2(i2))) .or. &
        (abs (val(src1(i1))) == abs (val(src2(i2))) .and. &
        val(src1(i1)) >= val(src2(i2)))) then
  <Sorting: merge2>

<Sorting: merge1>≡
  integer :: i1, i2, i
  i1 = 1
  i2 = 1
  do i = 1, size (tmp)

<Sorting: merge2>≡
    tmp(i) = src1(i1); i1 = i1 + 1
    if (i1 > size (src1)) then
      tmp(i+1:) = src2(i2:)
      exit
    end if
  else
    tmp(i) = src2(i2); i2 = i2 + 1
    if (i2 > size (src2)) then
      tmp(i+1:) = src1(i1:)
      exit
    end if
  end if
end do
res = tmp

```

2.15.2 Concatenating arrays

Not precisely a sorting function, but useful: Concatenate two arrays.

```
<Sorting: public>+≡
    public :: concat

<Sorting: interfaces>+≡
    interface concat
        module procedure concat_int
        module procedure concat_real
    end interface

<Sorting: procedures>+≡
    function concat_int (val1, val2) result (val12)
        integer, dimension(:), intent(in) :: val1, val2
        integer, dimension(size(val1)+size(val2)) :: val12
    <Sorting: concat>
    end function concat_int

    function concat_real (val1, val2) result (val12)
        real(default), dimension(:), intent(in) :: val1, val2
        integer, dimension(size(val1)+size(val2)) :: val12
    <Sorting: concat>
    end function concat_real

<Sorting: concat>≡
    val12(:size(val1)) = val1
    val12(size(val1)+1:) = val2
```

2.15.3 Unit tests

```
<Sorting: public>+≡
    public :: sorting_test

<Sorting: procedures>+≡
    subroutine sorting_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Sorting: execute tests>
    end subroutine sorting_test
```

This checks whether the sorting routine works correctly.

```
<Sorting: execute tests>≡
    call test (sorting_1, "sorting_1", &
        "check sorting routines", &
        u, results)

<Sorting: tests>≡
    subroutine sorting_1 (u)
        integer, intent(in) :: u
        integer, parameter :: NMAX = 10
        real(default), dimension(NMAX) :: rval
        integer, dimension(NMAX) :: ival
        real, dimension(NMAX,NMAX) :: harvest_r
```

```

        end do
    end do

    write (u, "(A)")
    write (u, "(A)") "* Test output end: sorting_1"

end subroutine sorting_1

```

Chapter 3

Text handling

WHIZARD has to handle complex structures in input (and output) data. Doing this in a generic and transparent way requires a generic lexer and parser. The necessary modules are implemented here:

ifiles Implementation of line-oriented internal files in a more flexible way (linked lists of variable-length strings) than the Fortran builtin features.

lexers Read text and transform it into a token stream.

syntax_rules Define the rules for interpreting tokens, to be used by the parser.

parser Categorize tokens (keyword, string, number etc.) and use a set of syntax rules to transform the input into a parse tree.

3.1 Internal files

The internal files introduced here (`ifile`) are a replacement for the built-in internal files, which are fixed-size arrays of fixed-length character strings. The `ifile` type is a doubly-linked list of variable-length character strings with line numbers.

```
<ifiles.f90>≡  
  <File header>  
  
  module ifiles  
  
    <Use strings>  
    <Use file utils>  
    use limits, only: EOF !NODEP!  
  
    <Standard module head>  
  
    <Ifiles: public>  
  
    <Ifiles: types>  
  
    <Ifiles: interfaces>  
  
    contains  
  
    <Ifiles: subroutines>  
  
  end module ifiles
```

3.1.1 iostat codes

```
<Limits: public parameters>+≡  
  integer, parameter, public :: EOF = iostat_end, EOR = iostat_eor
```

3.1.2 The line type

The line entry type is for internal use, it is the list entry to be collected in an `ifile` object.

```
<Ifiles: types>≡  
  type :: line_entry_t  
    private  
    type(line_entry_t), pointer :: previous => null ()  
    type(line_entry_t), pointer :: next => null ()  
    type(string_t) :: string  
    integer :: index  
  end type line_entry_t
```

Create a new list entry, given a varying string as input. The line number and pointers are not set, these make sense only within an `ifile`.

```
<Ifiles: subroutines>≡  
  subroutine line_entry_create (line, string)
```

```

    type(line_entry_t), pointer :: line
    type(string_t), intent(in) :: string
    allocate (line)
    line%string = string
end subroutine line_entry_create

```

Destroy a single list entry: Since the pointer components should not be deallocated explicitly, just deallocate the object itself.

```

<Ifiles: subroutines>+≡
    subroutine line_entry_destroy (line)
        type(line_entry_t), pointer :: line
        deallocate (line)
    end subroutine line_entry_destroy

```

3.1.3 The ifile type

The internal file is a linked list of line entries.

```

<Ifiles: public>≡
    public :: ifile_t

<Ifiles: types>+≡
    type :: ifile_t
    private
        type(line_entry_t), pointer :: first => null ()
        type(line_entry_t), pointer :: last => null ()
        integer :: n_lines = 0
    end type ifile_t

```

We need no explicit initializer, but a routine which recursively deallocates the contents may be appropriate. After this, existing line pointers may become undefined, so they should be nullified before the file is destroyed.

```

<Ifiles: public>+≡
    public :: ifile_clear

<Ifiles: subroutines>+≡
    subroutine ifile_clear (ifile)
        type(ifile_t), intent(inout) :: ifile
        type(line_entry_t), pointer :: current
        do while (associated (ifile%first))
            current => ifile%first
            ifile%first => current%next
            call line_entry_destroy (current)
        end do
        nullify (ifile%last)
        ifile%n_lines = 0
    end subroutine ifile_clear

```

The finalizer is just an alias for the above.

```

<Ifiles: public>+≡
    public :: ifile_final

```

```

<Ifiles: interfaces>+=
  interface ifile_final
    module procedure ifile_clear
  end interface

```

3.1.4 I/O on ifiles

Fill an ifile from an ordinary external file, i.e., I/O unit. If the ifile is not empty, the old contents will be destroyed. We can read a fixed-length character string, an ISO varying string, an ordinary internal file (character-string array), or from an external unit. In the latter case, lines are appended until EOF is reached. Finally, there is a variant which reads from another ifile, effectively copying it.

```

<Ifiles: public>+=
  public :: ifile_read

<Ifiles: interfaces>+=
  interface ifile_read
    module procedure ifile_read_from_string
    module procedure ifile_read_from_char
    module procedure ifile_read_from_unit
    module procedure ifile_read_from_char_array
    module procedure ifile_read_from_ifile
  end interface

<Ifiles: subroutines>+=
  subroutine ifile_read_from_string (ifile, string)
    type(ifile_t), intent(inout) :: ifile
    type(string_t), intent(in) :: string
    call ifile_clear (ifile)
    call ifile_append (ifile, string)
  end subroutine ifile_read_from_string

  subroutine ifile_read_from_char (ifile, char)
    type(ifile_t), intent(inout) :: ifile
    character(*), intent(in) :: char
    call ifile_clear (ifile)
    call ifile_append (ifile, char)
  end subroutine ifile_read_from_char

  subroutine ifile_read_from_char_array (ifile, char)
    type(ifile_t), intent(inout) :: ifile
    character(*), dimension(:), intent(in) :: char
    call ifile_clear (ifile)
    call ifile_append (ifile, char)
  end subroutine ifile_read_from_char_array

  subroutine ifile_read_from_unit (ifile, unit, iostat)
    type(ifile_t), intent(inout) :: ifile
    integer, intent(in) :: unit
    integer, intent(out), optional :: iostat
    call ifile_clear (ifile)
    call ifile_append (ifile, unit, iostat)
  end subroutine ifile_read_from_unit

```

```

subroutine ifile_read_from_ifile (ifile, ifile_in)
  type(ifile_t), intent(inout) :: ifile
  type(ifile_t), intent(in) :: ifile_in
  call ifile_clear (ifile)
  call ifile_append (ifile, ifile_in)
end subroutine ifile_read_from_ifile

```

Append to an ifile. The same as reading, but without resetting the ifile. In addition, there is a routine for appending a whole ifile.

(Ifiles: public)+≡

```

public :: ifile_append

```

(Ifiles: interfaces)+≡

```

interface ifile_append
  module procedure ifile_append_from_string
  module procedure ifile_append_from_char
  module procedure ifile_append_from_unit
  module procedure ifile_append_from_char_array
  module procedure ifile_append_from_ifile
end interface

```

(Ifiles: subroutines)+≡

```

subroutine ifile_append_from_string (ifile, string)
  type(ifile_t), intent(inout) :: ifile
  type(string_t), intent(in) :: string
  type(line_entry_t), pointer :: current
  call line_entry_create (current, string)
  current%index = ifile%n_lines + 1
  if (associated (ifile%last)) then
    current%previous => ifile%last
    ifile%last%next => current
  else
    ifile%first => current
  end if
  ifile%last => current
  ifile%n_lines = current%index
end subroutine ifile_append_from_string

subroutine ifile_append_from_char (ifile, char)
  type(ifile_t), intent(inout) :: ifile
  character(*), intent(in) :: char
  call ifile_append_from_string (ifile, var_str (trim (char)))
end subroutine ifile_append_from_char

subroutine ifile_append_from_char_array (ifile, char)
  type(ifile_t), intent(inout) :: ifile
  character(*), dimension(:), intent(in) :: char
  integer :: i
  do i = 1, size (char)
    call ifile_append_from_string (ifile, var_str (trim (char(i))))
  end do
end subroutine ifile_append_from_char_array

subroutine ifile_append_from_unit (ifile, unit, iostat)
  type(ifile_t), intent(inout) :: ifile

```

```

integer, intent(in) :: unit
integer, intent(out), optional :: iostat
type(string_t) :: buffer
integer :: ios
ios = 0
READ_LOOP: do
    call get (unit, buffer, iostat = ios)
    if (ios == EOF .or. ios > 0) exit READ_LOOP
    call ifile_append_from_string (ifile, buffer)
end do READ_LOOP
if (present (iostat)) then
    iostat = ios
else if (ios > 0) then
    call get (unit, buffer) ! trigger error again
end if
end subroutine ifile_append_from_unit

subroutine ifile_append_from_ifile (ifile, ifile_in)
type(ifile_t), intent(inout) :: ifile
type(ifile_t), intent(in) :: ifile_in
type(line_entry_t), pointer :: current
current => ifile_in%first
do while (associated (current))
    call ifile_append_from_string (ifile, current%string)
    current => current%next
end do
end subroutine ifile_append_from_ifile

```

Write the ifile contents to an external unit

```

<Ifiles: public>+≡
public :: ifile_write

<Ifiles: subroutines>+≡
subroutine ifile_write (ifile, unit, iostat)
type(ifile_t), intent(in) :: ifile
integer, intent(in), optional :: unit
integer, intent(out), optional :: iostat
integer :: u
type(line_entry_t), pointer :: current
u = output_unit (unit); if (u < 0) return
current => ifile%first
do while (associated (current))
    call put_line (u, current%string, iostat)
    current => current%next
end do
end subroutine ifile_write

```

Convert the ifile to an array of strings, which is allocated by this function:

```

<Ifiles: public>+≡
public :: ifile_to_string_array

<Ifiles: subroutines>+≡
subroutine ifile_to_string_array (ifile, string)
type(ifile_t), intent(in) :: ifile

```

```

type(string_t), dimension(:), intent(inout), allocatable :: string
type(line_entry_t), pointer :: current
integer :: i
allocate (string (ifile_get_length (ifile)))
current => ifile%first
do i = 1, ifile_get_length (ifile)
    string(i) = current%string
    current => current%next
end do
end subroutine ifile_to_string_array

```

3.1.5 Ifile tools

```

<Ifiles: public>+≡
public :: ifile_get_length

<Ifiles: subroutines>+≡
function ifile_get_length (ifile) result (length)
    integer :: length
    type(ifile_t), intent(in) :: ifile
    length = ifile%n_lines
end function ifile_get_length

```

3.1.6 Line pointers

Instead of the implicit pointer used in ordinary file access, we define explicit pointers, so there can be more than one at a time.

```

<Ifiles: public>+≡
public :: line_p

<Ifiles: types>+≡
type :: line_p
private
type(line_entry_t), pointer :: p => null ()
end type line_p

```

Assign a file pointer to the first or last line in an ifile:

```

<Ifiles: public>+≡
public :: line_init

<Ifiles: subroutines>+≡
subroutine line_init (line, ifile, back)
    type(line_p), intent(inout) :: line
    type(ifile_t), intent(in) :: ifile
    logical, intent(in), optional :: back
    if (present (back)) then
        if (back) then
            line%p => ifile%last
        else
            line%p => ifile%first
        end if
    else

```

```

        line%p => ifile%first
    end if
end subroutine line_init

```

Remove the pointer association:

```

<Ifiles: public>+≡
    public :: line_final
<Ifiles: subroutines>+≡
    subroutine line_final (line)
        type(line_p), intent(inout) :: line
        nullify (line%p)
    end subroutine line_final

```

Go one step forward

```

<Ifiles: public>+≡
    public :: line_advance
<Ifiles: subroutines>+≡
    subroutine line_advance (line)
        type(line_p), intent(inout) :: line
        if (associated (line%p)) line%p => line%p%next
    end subroutine line_advance

```

Go one step backward

```

<Ifiles: public>+≡
    public :: line_backspace
<Ifiles: subroutines>+≡
    subroutine line_backspace (line)
        type(line_p), intent(inout) :: line
        if (associated (line%p)) line%p => line%p%previous
    end subroutine line_backspace

```

Check whether we are accessing a valid line

```

<Ifiles: public>+≡
    public :: line_is_associated
<Ifiles: subroutines>+≡
    function line_is_associated (line) result (ok)
        logical :: ok
        type(line_p), intent(in) :: line
        ok = associated (line%p)
    end function line_is_associated

```

3.1.7 Access lines via pointers

We do not need the ifile as an argument to these functions, because the `line` type will point to an existing ifile.

```

<Ifiles: public>+≡
    public :: line_get_string

```

```

<Ifiles: subroutines>+=
function line_get_string (line) result (string)
  type(string_t) :: string
  type(line_p), intent(in) :: line
  if (associated (line%p)) then
    string = line%p%string
  else
    string = ""
  end if
end function line_get_string

```

Variant where the line pointer is advanced after reading.

```

<Ifiles: public>+=
public :: line_get_string_advance
<Ifiles: subroutines>+=
function line_get_string_advance (line) result (string)
  type(string_t) :: string
  type(line_p), intent(inout) :: line
  if (associated (line%p)) then
    string = line%p%string
    call line_advance (line)
  else
    string = ""
  end if
end function line_get_string_advance

```

```

<Ifiles: public>+=
public :: line_get_index
<Ifiles: subroutines>+=
function line_get_index (line) result (index)
  integer :: index
  type(line_p), intent(in) :: line
  if (associated (line%p)) then
    index = line%p%index
  else
    index = 0
  end if
end function line_get_index

```

```

<Ifiles: public>+=
public :: line_get_length
<Ifiles: subroutines>+=
function line_get_length (line) result (length)
  integer :: length
  type(line_p), intent(in) :: line
  if (associated (line%p)) then
    length = len (line%p%string)
  else
    length = 0
  end if
end function line_get_length

```

3.2 Lexer

The lexer purpose is to read from a line-separated character input stream (usually a file) and properly chop the stream into lexemes (tokens). [The parser will transform lexemes into meaningful tokens, to be stored in a parse tree, therefore we do not use the term 'token' here.] The input is read line-by-line, but interpreted free-form, except for quotes and the comment syntax. (Fortran 2003 would allow us to use a stream type for reading.)

In an object-oriented approach, we can dynamically create and destroy lexers, including the lexer setup.

The main lexer function is to return a lexeme according to the basic lexer rules (quotes, comments, whitespace, special classes). There is also a routine to write back a lexeme to the input stream (but only once).

For the rules, we separate the possible characters into classes. Whitespace usually consists of blank, tab, and line-feed, where any number of consecutive whitespace is equivalent to one. Quoted strings are enclosed by a pair of quote characters, possibly multiline. Comments are similar to quotes, but interpreted as whitespace. Numbers are identified (not distinguishing real and integer) but not interpreted. Other character classes make up identifiers.

```
<lexers.f90>≡  
  <File header>  
  
  module lexers  
  
    <Use strings>  
    <Use file utils>  
    use limits, only: EOF, EOR !NODEP!  
    use limits, only: LF !NODEP!  
    use limits, only: WHITESPACE_CHARS, LCLETTERS, UCLETTERS, DIGITS !NODEP!  
    use diagnostics !NODEP!  
    use ifiles, only: ifile_t  
    use ifiles, only: line_p, line_is_associated, line_init, line_final  
    use ifiles, only: line_get_string_advance  
    use unit_tests  
  
    <Standard module head>  
  
    <Lexer: public>  
  
    <Lexer: parameters>  
  
    <Lexer: types>  
  
    <Lexer: interfaces>  
  
    contains  
  
    <Lexer: procedures>  
  
    <Lexer: tests>  
  
  end module lexers
```

3.2.1 Input streams

For flexible input, we define a generic stream type that refers to either an external file, an external unit which is already open, a string, an `ifile` object (internal file, i.e., string list), or a line pointer to an `ifile` object. The stream type actually follows the idea of a formatted external file, which is line-oriented. Thus, the stream reader always returns a whole record (input line).

Note that only in the string version, the stream contents are stored inside the stream object. In the `ifile` version, the stream contains only the line pointer, while in the external-file case, the line pointer is implicitly created by the runtime library.

```
<Lexer: public>≡
    public :: stream_t

<Lexer: types>≡
    type :: stream_t
        type(string_t), pointer :: filename => null ()
        integer, pointer :: unit => null ()
        type(string_t), pointer :: string => null ()
        type(ifile_t), pointer :: ifile => null ()
        type(line_p), pointer :: line => null ()
        integer :: record = 0
        logical :: eof = .false.
    end type stream_t
```

The initializers refer to the specific version. The stream should be undefined before calling this.

```
<Lexer: public>+≡
    public :: stream_init

<Lexer: interfaces>≡
    interface stream_init
        module procedure stream_init_filename
        module procedure stream_init_unit
        module procedure stream_init_string
        module procedure stream_init_ifile
        module procedure stream_init_line
    end interface

<Lexer: procedures>≡
    subroutine stream_init_filename (stream, filename)
        type(stream_t), intent(out) :: stream
        character(*), intent(in) :: filename
        integer :: unit
        unit = free_unit ()
        open (unit=unit, file=filename, status="old", action="read")
        call stream_init_unit (stream, unit)
        allocate (stream%filename)
        stream%filename = filename
    end subroutine stream_init_filename

    subroutine stream_init_unit (stream, unit)
        type(stream_t), intent(out) :: stream
        integer, intent(in) :: unit
```

```

        allocate (stream%unit)
        stream%unit = unit
        stream%eof = .false.
    end subroutine stream_init_unit

subroutine stream_init_string (stream, string)
    type(stream_t), intent(out) :: stream
    type(string_t), intent(in) :: string
    allocate (stream%string)
    stream%string = string
end subroutine stream_init_string

subroutine stream_init_ifile (stream, ifile)
    type(stream_t), intent(out) :: stream
    type(ifile_t), intent(in) :: ifile
    type(line_p) :: line
    call line_init (line, ifile)
    call stream_init_line (stream, line)
    allocate (stream%ifile)
    stream%ifile = ifile
end subroutine stream_init_ifile

subroutine stream_init_line (stream, line)
    type(stream_t), intent(out) :: stream
    type(line_p), intent(in) :: line
    allocate (stream%line)
    stream%line = line
end subroutine stream_init_line

```

The finalizer restores the initial state. If an external file was opened, it is closed.

```

<Lexer: public>+≡
    public :: stream_final

<Lexer: procedures>+≡
    subroutine stream_final (stream)
        type(stream_t), intent(inout) :: stream
        if (associated (stream%filename)) then
            close (stream%unit)
            deallocate (stream%unit)
            deallocate (stream%filename)
        else if (associated (stream%unit)) then
            deallocate (stream%unit)
        else if (associated (stream%string)) then
            deallocate (stream%string)
        else if (associated (stream%ifile)) then
            call line_final (stream%line)
            deallocate (stream%line)
            deallocate (stream%ifile)
        else if (associated (stream%line)) then
            call line_final (stream%line)
            deallocate (stream%line)
        end if
    end subroutine stream_final

```

This returns the next record from the input stream. Depending on the stream type, the stream pointers are modified: Reading from external unit, the external file is advanced (implicitly). Reading from string, the string is replaced by an empty string. Reading from ifile, the line pointer is advanced. Note that the `iostat` argument is mandatory.

<Lexer: public>+≡

`public :: stream_get_record`

<Lexer: procedures>+≡

```
subroutine stream_get_record (stream, string, iostat)
  type(stream_t), intent(inout) :: stream
  type(string_t), intent(out) :: string
  integer, intent(out) :: iostat
  if (associated (stream%unit)) then
    if (stream%eof) then
      iostat = EOF
    else
      call get (stream%unit, string, iostat=iostat)
      if (iostat == EOR) then
        iostat = 0
        stream%record = stream%record + 1
      end if
      if (iostat == EOF) then
        iostat = 0
        stream%eof = .true.
        if (len (string) /= 0) stream%record = stream%record + 1
      end if
    end if
  else if (associated (stream%string)) then
    if (len (stream%string) /= 0) then
      string = stream%string
      stream%string = ""
      iostat = 0
      stream%record = stream%record + 1
    else
      string = ""
      iostat = EOF
    end if
  else if (associated (stream%line)) then
    if (line_is_associated (stream%line)) then
      string = line_get_string_advance (stream%line)
      iostat = 0
      stream%record = stream%record + 1
    else
      string = ""
      iostat = EOF
    end if
  else
    call msg_bug (" Attempt to read from uninitialized input stream")
  end if
end subroutine stream_get_record
```

Return the current stream source as a message string.

<Lexer: public>+≡

```

public :: stream_get_source_info_string
<Lexer: procedures>+≡
function stream_get_source_info_string (stream) result (string)
  type(string_t) :: string
  type(stream_t), intent(in) :: stream
  character(20) :: buffer
  if (associated (stream%filename)) then
    string = "File '" // stream%filename // "' (unit = "
    write (buffer, "(I0)") stream%unit
    string = string // trim (buffer) // ")"
  else if (associated (stream%unit)) then
    write (buffer, "(I0)") stream%unit
    string = "Unit " // trim (buffer)
  else if (associated (stream%string)) then
    string = "Input string"
  else if (associated (stream%ifile) .or. associated (stream%line)) then
    string = "Internal file"
  else
    string = ""
  end if
end function stream_get_source_info_string

```

Return the index of the record just read as a message string.

```

<Lexer: public>+≡
public :: stream_get_record_info_string
<Lexer: procedures>+≡
function stream_get_record_info_string (stream) result (string)
  type(string_t) :: string
  type(stream_t), intent(in) :: stream
  character(20) :: buffer
  string = stream_get_source_info_string (stream)
  if (string /= "") string = string // ", "
  write (buffer, "(I0)") stream%record
  string = string // "line " // trim (buffer)
end function stream_get_record_info_string

```

3.2.2 Keyword list

The lexer should be capable of identifying a token as a known keyword. To this end, we store a list of keywords:

```

<Lexer: public>+≡
public :: keyword_list_t
<Lexer: types>+≡
type :: keyword_entry_t
  private
  type(string_t) :: string
  type(keyword_entry_t), pointer :: next => null ()
end type keyword_entry_t

type :: keyword_list_t

```

```

        private
        type(keyword_entry_t), pointer :: first => null ()
        type(keyword_entry_t), pointer :: last => null ()
    end type keyword_list_t

```

Add a new string to the keyword list, unless it is already there:

```

<Lexer: public>+≡
    public :: keyword_list_add

<Lexer: procedures>+≡
    subroutine keyword_list_add (keylist, string)
        type(keyword_list_t), intent(inout) :: keylist
        type(string_t), intent(in) :: string
        type(keyword_entry_t), pointer :: k_entry_new
        if (.not. keyword_list_contains (keylist, string)) then
            allocate (k_entry_new)
            k_entry_new%string = string
            if (associated (keylist%first)) then
                keylist%last%next => k_entry_new
            else
                keylist%first => k_entry_new
            end if
            keylist%last => k_entry_new
        end if
    end subroutine keyword_list_add

```

Return true if a string is a keyword.

```

<Lexer: public>+≡
    public :: keyword_list_contains

<Lexer: procedures>+≡
    function keyword_list_contains (keylist, string) result (found)
        type(keyword_list_t), intent(in) :: keylist
        type(string_t), intent(in) :: string
        logical :: found
        found = .false.
        call check_rec (keylist%first)
    contains
        recursive subroutine check_rec (k_entry)
            type(keyword_entry_t), pointer :: k_entry
            if (associated (k_entry)) then
                if (k_entry%string /= string) then
                    call check_rec (k_entry%next)
                else
                    found = .true.
                end if
            end if
        end subroutine check_rec
    end function keyword_list_contains

```

Write the keyword list

```

<Lexer: public>+≡
    public :: keyword_list_write

```

```

<Lexer: interfaces>+≡
    interface keyword_list_write
        module procedure keyword_list_write_unit
    end interface

<Lexer: procedures>+≡
    subroutine keyword_list_write_unit (keylist, unit)
        type(keyword_list_t), intent(in) :: keylist
        integer, intent(in) :: unit
        write (unit, "(A)") "Keyword list:"
        if (associated (keylist%first)) then
            call keyword_write_rec (keylist%first)
            write (unit, *)
        else
            write (unit, "(1x,A)") "[empty]"
        end if
    contains
        recursive subroutine keyword_write_rec (k_entry)
            type(keyword_entry_t), intent(in), pointer :: k_entry
            if (associated (k_entry)) then
                write (unit, "(1x,A)", advance="no") char (k_entry%string)
                call keyword_write_rec (k_entry%next)
            end if
        end subroutine keyword_write_rec
    end subroutine keyword_list_write_unit

```

Clear the keyword list

```

<Lexer: public>+≡
    public :: keyword_list_final

<Lexer: procedures>+≡
    subroutine keyword_list_final (keylist)
        type(keyword_list_t), intent(inout) :: keylist
        call keyword_destroy_rec (keylist%first)
        nullify (keylist%last)
    contains
        recursive subroutine keyword_destroy_rec (k_entry)
            type(keyword_entry_t), pointer :: k_entry
            if (associated (k_entry)) then
                call keyword_destroy_rec (k_entry%next)
                deallocate (k_entry)
            end if
        end subroutine keyword_destroy_rec
    end subroutine keyword_list_final

```

3.2.3 Lexeme templates

This type is handled like a rudimentary regular expression. It determines the lexer behavior when matching a string. The actual objects made from this type and the corresponding matching routines are listed below.

```

<Lexer: types>+≡
    type :: template_t

```

```

private
integer :: type
character(256) :: charset1, charset2
integer :: len1, len2
end type template_t

```

These are the types that valid lexemes can have:

```

<Lexer: public>+≡
public :: T_KEYWORD, T_IDENTIFIER, T_QUOTED, T_NUMERIC

<Lexer: parameters>≡
integer, parameter :: T_KEYWORD = 1
integer, parameter :: T_IDENTIFIER = 2, T_QUOTED = 3, T_NUMERIC = 4

```

These are special types:

```

<Lexer: parameters>+≡
integer, parameter :: EMPTY = 0, WHITESPACE = 10
integer, parameter :: NO_MATCH = 11, IO_ERROR = 12, OVERFLOW = 13
integer, parameter :: UNMATCHED_QUOTE = 14

```

In addition, we have EOF which is a negative integer, normally -1 . Printout for debugging:

```

<Lexer: procedures>+≡
subroutine lexeme_type_write (type, unit)
integer, intent(in) :: type
integer, intent(in) :: unit
select case (type)
case (EMPTY);      write(unit,"(A)",advance="no") " EMPTY      "
case (WHITESPACE); write(unit,"(A)",advance="no") " WHITESPACE "
case (T_IDENTIFIER);write(unit,"(A)",advance="no") " IDENTIFIER "
case (T_QUOTED);   write(unit,"(A)",advance="no") " QUOTED      "
case (T_NUMERIC);  write(unit,"(A)",advance="no") " NUMERIC      "
case (IO_ERROR);   write(unit,"(A)",advance="no") " IO_ERROR    "
case (OVERFLOW);   write(unit,"(A)",advance="no") " OVERFLOW    "
case (UNMATCHED_QUOTE); write(unit,"(A)",advance="no") " UNMATCHEDQ "
case (NO_MATCH);   write(unit,"(A)",advance="no") " NO_MATCH    "
case (EOF);        write(unit,"(A)",advance="no") " EOF          "
case default;      write(unit,"(A)",advance="no") " [illegal]   "
end select
end subroutine lexeme_type_write

subroutine template_write (tt, unit)
type(template_t), intent(in) :: tt
integer, intent(in) :: unit
call lexeme_type_write (tt%type, unit)
write (unit, "(A)", advance="no") " '" // tt%charset1(1:tt%len1) // "'"
write (unit, "(A)", advance="no") " '" // tt%charset2(1:tt%len2) // "'"
end subroutine template_write

```

The matching functions all return the number of matched characters in the provided string. If this number is zero, the match has failed.

The `template` functions are declared `pure` because they appear in `forall` loops below.

A template for whitespace:

```

<Lexer: procedures>+≡
  pure function template_whitespace (chars) result (tt)
    character(*), intent(in) :: chars
    type(template_t) :: tt
    tt = template_t (WHITESPACE, chars, "", len (chars), 0)
  end function template_whitespace

```

Just match the string against the character set.

```

<Lexer: procedures>+≡
  subroutine match_whitespace (tt, s, n)
    type(template_t), intent(in) :: tt
    character(*), intent(in) :: s
    integer, intent(out) :: n
    n = verify (s, tt%charset1(1:tt%len1)) - 1
    if (n < 0) n = len (s)
  end subroutine match_whitespace

```

A template for normal identifiers. To match, a lexeme should have a first character in class `chars1` and an arbitrary number of further characters in class `chars2`. If the latter is empty, we are looking for a single-character lexeme.

```

<Lexer: procedures>+≡
  pure function template_identifier (chars1, chars2) result (tt)
    character(*), intent(in) :: chars1, chars2
    type(template_t) :: tt
    tt = template_t (T_IDENTIFIER, chars1, chars2, len(chars1), len(chars2))
  end function template_identifier

```

Here, the first letter must match, the others may or may not.

```

<Lexer: procedures>+≡
  subroutine match_identifier (tt, s, n)
    type(template_t), intent(in) :: tt
    character(*), intent(in) :: s
    integer, intent(out) :: n
    if (verify (s(1:1), tt%charset1(1:tt%len1)) == 0) then
      n = verify (s(2:), tt%charset2(1:tt%len2))
      if (n == 0) n = len (s)
    else
      n = 0
    end if
  end subroutine match_identifier

```

A template for quoted strings. The same template applies for comments. The first character set indicates the left quote (could be a sequence of several characters), the second one the matching right quote.

```

<Lexer: procedures>+≡
  pure function template_quoted (chars1, chars2) result (tt)
    character(*), intent(in) :: chars1, chars2
    type(template_t) :: tt
    tt = template_t (T_QUOTED, chars1, chars2, len (chars1), len (chars2))
  end function template_quoted

```

Here, the beginning of the string must exactly match the first character set, then we look for the second one. If found, return. If there is a first quote but no second one, return a negative number, indicating this error condition.

```

<Lexer: procedures>+≡
subroutine match_quoted (tt, s, n, range)
  type(template_t), intent(in) :: tt
  character(*), intent(in) :: s
  integer, intent(out) :: n
  integer, dimension(2), intent(out) :: range
  character(tt%len1) :: ch1
  character(tt%len2) :: ch2
  integer :: i
  ch1 = tt%charset1
  if (s(1:tt%len1) == ch1) then
    ch2 = tt%charset2
    do i = tt%len1 + 1, len (s) - tt%len2 + 1
      if (s(i:i+tt%len2-1) == ch2) then
        n = i + tt%len2 - 1
        range(1) = tt%len1 + 1
        range(2) = i - 1
        return
      end if
    end do
    n = -1
    range = 0
  else
    n = 0
    range = 0
  end if
end subroutine match_quoted

```

A template for real numbers. The first character set is the set of allowed exponent letters. In accordance with the other functions we return the lexeme as a string but do not read it.

```

<Lexer: procedures>+≡
pure function template_numeric (chars) result (tt)
  character(*), intent(in) :: chars
  type(template_t) :: tt
  tt = template_t (T_NUMERIC, chars, "", len (chars), 0)
end function template_numeric

```

A numeric lexeme may be real or integer. We purposely do not allow for a preceding sign. If the number is followed by an exponent, this is included, otherwise the rest is ignored.

There is a possible pitfall with this behavior: while the string `1e3` will be interpreted as a single number, the analogous string `1a3` will be split into the number `1` and an identifier `a3`. There is no easy way around such an ambiguity. We should make sure that the syntax does not contain identifiers like `a3` or `e3`.

```

<Lexer: procedures>+≡
subroutine match_numeric (tt, s, n)
  type(template_t), intent(in) :: tt
  character(*), intent(in) :: s

```

```

integer, intent(out) :: n
integer :: i, n0
character(10), parameter :: digits = "0123456789"
character(2), parameter :: signs = "-+"
n = verify (s, digits) - 1
if (n < 0) then
    n = 0
    return
else if (s(n+1:n+1) == ".") then
    i = verify (s(n+2:), digits) - 1
    if (i < 0) then
        n = len (s)
        return
    else if (i > 0 .or. n > 0) then
        n = n + 1 + i
    end if
end if
n0 = n
if (n > 0) then
    if (verify (s(n+1:n+1), tt%charset1(1:tt%len1)) == 0) then
        n = n + 1
        if (verify (s(n+1:n+1), signs) == 0) n = n + 1
        i = verify (s(n+1:), digits) - 1
        if (i < 0) then
            n = len (s)
        else if (i == 0) then
            n = n0
        else
            n = n + i
        end if
    end if
end if
end subroutine match_numeric

```

The generic matching routine. With Fortran 2003 we would define separate types and use a SELECT TYPE instead.

<Lexer: procedures>+≡

```

subroutine match_template (tt, s, n, range)
    type(template_t), intent(in) :: tt
    character(*), intent(in) :: s
    integer, intent(out) :: n
    integer, dimension(2), intent(out) :: range
    select case (tt%type)
    case (WHITESPACE)
        call match_whitespace (tt, s, n)
        range = 0
    case (T_IDENTIFIER)
        call match_identifier (tt, s, n)
        range(1) = 1
        range(2) = len_trim (s)
    case (T_QUOTED)
        call match_quoted (tt, s, n, range)
    case (T_NUMERIC)

```

```

        call match_numeric (tt, s, n)
        range(1) = 1
        range(2) = len_trim (s)
    case default
        call msg_bug ("Invalid lexeme template encountered")
    end select
end subroutine match_template

```

Match against an array of templates. Return the index of the first template that matches together with the number of characters matched and the range of the relevant substring. If all fails, these numbers are zero.

<Lexer: procedures>+≡

```

subroutine match (tt, s, n, range, ii)
    type(template_t), dimension(:), intent(in) :: tt
    character(*), intent(in) :: s
    integer, intent(out) :: n
    integer, dimension(2), intent(out) :: range
    integer, intent(out) :: ii
    integer :: i
    do i = 1, size (tt)
        call match_template (tt(i), s, n, range)
        if (n /= 0) then
            ii = i
            return
        end if
    end do
    n = 0
    ii = 0
end subroutine match

```

3.2.4 The lexer setup

This object contains information about character classes. As said above, one class consists of quoting chars (matching left and right), another one of comment chars (similar), a class of whitespace, and several classes of characters that make up identifiers. When creating the lexer setup, the character classes are transformed into lexeme templates which are to be matched in a certain predefined order against the input stream.

BLANK should always be taken as whitespace, some things may depend on this. TAB is also fixed by convention, but may in principle be modified. Newline (DOS!) and linefeed are also defined as whitespace.

<Limits: public parameters>+≡

```

character, parameter, public :: BLANK = ' ', TAB = achar(9)
character, parameter, public :: CR = achar(13), LF = achar(10)
character, parameter, public :: BACKSLASH = achar(92)
character(*), parameter, public :: WHITESPACE_CHARS = BLANK// TAB // CR // LF
character(*), parameter, public :: LCLETTERS = "abcdefghijklmnopqrstuvwxyz"
character(*), parameter, public :: UCLETTERS = "ABCDEFGHIJKLMNOPQRSTUVWXYZ"
character(*), parameter, public :: DIGITS = "0123456789"

```

The lexer setup, containing the list of lexeme templates. No defaults yet. The type with index zero will be assigned to the NO_MATCH lexeme.

The keyword list is not stored, just a pointer to it. We anticipate that the keyword list is part of the syntax table, and the lexer needs not alter it. Furthermore, the lexer is typically finished before the syntax table is.

```

(Lexer: parameters)+≡
    integer, parameter :: CASE_KEEP = 0, CASE_UP = 1, CASE_DOWN = 2

(Lexer: types)+≡
    type :: lexer_setup_t
    private
    type(template_t), dimension(:), allocatable :: tt
    integer, dimension(:), allocatable :: type
    integer :: keyword_case = CASE_KEEP
    type(keyword_list_t), pointer :: keyword_list => null ()
end type lexer_setup_t

```

Fill the lexer setup object. Some things are hardcoded here (whitespace, alphanumeric identifiers), some are free: comment chars (but these must be single, and comments must be terminated by line-feed), quote chars and matches (must be single), characters to be read as one-character lexeme, special classes (characters of one class that should be glued together as identifiers).

```

(Lexer: procedures)+≡
    subroutine lexer_setup_init (setup, &
        comment_chars, quote_chars, quote_match, &
        single_chars, special_class, &
        keyword_list, upper_case_keywords)
    type(lexer_setup_t), intent(inout) :: setup
    character(*), intent(in) :: comment_chars
    character(*), intent(in) :: quote_chars, quote_match
    character(*), intent(in) :: single_chars
    character(*), dimension(:), intent(in) :: special_class
    type(keyword_list_t), pointer :: keyword_list
    logical, intent(in), optional :: upper_case_keywords
    integer :: n, i
    if (present (upper_case_keywords)) then
        if (upper_case_keywords) then
            setup%keyword_case = CASE_UP
        else
            setup%keyword_case = CASE_DOWN
        end if
    else
        setup%keyword_case = CASE_KEEP
    end if
    n = 1 + len (comment_chars) + len (quote_chars) + 1 &
        + len (single_chars) + size (special_class) + 1
    allocate (setup%tt(n))
    allocate (setup%type(0:n))
    n = 0
    setup%type(n) = NO_MATCH
    n = n + 1
    setup%tt(n) = template_whitespace (WHITESPACE_CHARS)

```

```

setup%tt(n+1) = template_identifier &
    (LCLETTERS//UCLETTERS, LCLETTERS//DIGITS//"_"/UCLETTERS)
setup%type(n+1) = T_IDENTIFIER
n = n + 1
if (n /= size (setup%tt)) &
    call msg_bug ("Size mismatch in lexer setup")
setup%keyword_list => keyword_list
end subroutine lexer_setup_init

```

The destructor is needed only if the object is not itself part of an allocatable array

```

<Lexer: procedures>+≡
subroutine lexer_setup_final (setup)
    type(lexer_setup_t), intent(inout) :: setup
    deallocate (setup%tt, setup%type)
    setup%keyword_list => null ()
end subroutine lexer_setup_final

```

For debugging: Write the lexer setup

```

<Lexer: procedures>+≡
subroutine lexer_setup_write (setup, unit)
    type(lexer_setup_t), intent(in) :: setup
    integer, intent(in) :: unit
    integer :: i
    write (unit, "(A)") "Lexer setup:"
    if (allocated (setup%tt)) then
        do i = 1, size (setup%tt)
            call template_write (setup%tt(i), unit)
        end do
    end if
end subroutine lexer_setup_write

```

```

        write (unit, '(A)', advance = "no") " -> "
        call lexeme_type_write (setup%type(i), unit)
        write (unit, *)
    end do
else
    write (unit, *) "[empty]"
end if
if (associated (setup%keyword_list)) then
    call keyword_list_write (setup%keyword_list, unit)
end if
end subroutine lexer_setup_write

```

3.2.5 The lexeme type

An object of this type is returned by the lexer. Apart from the lexeme string, it gives information about the relevant substring (first and last character index) and the lexeme type. Interpreting the string is up to the parser.

```

<Lexer: public>+≡
    public :: lexeme_t

<Lexer: types>+≡
    type :: lexeme_t
    private
        integer :: type = EMPTY
        type(string_t) :: s
        integer :: b = 0, e = 0
    end type lexeme_t

```

Debugging aid:

```

<Lexer: public>+≡
    public :: lexeme_write

<Lexer: procedures>+≡
    subroutine lexeme_write (t, unit)
        type(lexeme_t), intent(in) :: t
        integer, intent(in) :: unit
        integer :: u
        u = output_unit (unit); if (u < 0) return
        select case (t%type)
        case (T_KEYWORD)
            write (u, *) "KEYWORD:  ' " // char (t%s) // "' "
        case (T_IDENTIFIER)
            write (u, *) "IDENTIFIER: ' " // char (t%s) // "' "
        case (T_QUOTED)
            write (u, *) "QUOTED:    ' " // char (t%s) // "' "
        case (T_NUMERIC)
            write (u, *) "NUMERIC:   ' " // char (t%s) // "' "
        case (UNMATCHED_QUOTE)
            write (u, *) "Unmatched quote: "// char (t%s)
        case (OVERFLOW); write (u, *) "Overflow: "// char (t%s)
        case (EMPTY);   write (u, *) "Empty lexeme"
        case (NO_MATCH); write (u, *) "No match"
        case (IO_ERROR); write (u, *) "IO error"
    end subroutine

```

```

        case (EOF);      write (u, *) "EOF"
        case default
            write (u, *) "Error"
        end select
    end subroutine lexeme_write

```

Store string and type in a lexeme. The range determines the beginning and end of the relevant part of the string. Check for a keyword.

<Lexer: procedures>+≡

```

subroutine lexeme_set (t, keyword_list, s, range, type, keyword_case)
    type(lexeme_t), intent(out) :: t
    type(keyword_list_t), pointer :: keyword_list
    type(string_t), intent(in) :: s
    type(string_t) :: keyword
    integer, dimension(2), intent(in) :: range
    integer, intent(in) :: type
    integer, intent(in), optional :: keyword_case
    t%type = type
    if (present (keyword_case)) then
        select case (keyword_case)
            case (CASE_KEEP);   keyword = s
            case (CASE_UP);     keyword = upper_case (s)
            case (CASE_DOWN);   keyword = lower_case (s)
        end select
    else
        keyword = s
    end if
    if (type == T_IDENTIFIER) then
        if (associated (keyword_list)) then
            if (keyword_list_contains (keyword_list, keyword)) &
                t%type = T_KEYWORD
            end if
        end if
        select case (t%type)
            case (T_KEYWORD);   t%s = keyword
            case default;       t%s = s
        end select
        t%b = range(1)
        t%e = range(2)
    end subroutine lexeme_set

subroutine lexeme_clear (t)
    type(lexeme_t), intent(out) :: t
    t%type = EMPTY
    t%s = ""
end subroutine lexeme_clear

```

Retrieve the lexeme string, the relevant part of it, and the type. The last function returns true if there is a break condition reached (error or EOF).

<Lexer: public>+≡

```

public :: lexeme_get_string
public :: lexeme_get_contents
public :: lexeme_get_delimiters

```

```

public :: lexeme_get_type
<Lexer: procedures>+≡
function lexeme_get_string (t) result (s)
  type(string_t) :: s
  type(lexeme_t), intent(in) :: t
  s = t%s
end function lexeme_get_string

function lexeme_get_contents (t) result (s)
  type(string_t) :: s
  type(lexeme_t), intent(in) :: t
  s = extract (t%s, t%b, t%e)
end function lexeme_get_contents

function lexeme_get_delimiters (t) result (del)
  type(string_t), dimension(2) :: del
  type(lexeme_t), intent(in) :: t
  del(1) = extract (t%s, finish = t%b-1)
  del(2) = extract (t%s, start = t%e+1)
end function lexeme_get_delimiters

function lexeme_get_type (t) result (type)
  integer :: type
  type(lexeme_t), intent(in) :: t
  type = t%type
end function lexeme_get_type

```

Check for a generic break condition (error/eof) and for eof in particular.

```

<Lexer: public>+≡
public :: lexeme_is_break
public :: lexeme_is_eof

<Lexer: procedures>+≡
function lexeme_is_break (t) result (break)
  logical :: break
  type(lexeme_t), intent(in) :: t
  select case (t%type)
    case (EOF, IO_ERROR, OVERFLOW, NO_MATCH)
      break = .true.
    case default
      break = .false.
  end select
end function lexeme_is_break

function lexeme_is_eof (t) result (ok)
  logical :: ok
  type(lexeme_t), intent(in) :: t
  ok = t%type == EOF
end function lexeme_is_eof

```

3.2.6 The lexer object

We store the current lexeme and the current line. The line buffer is set each time a new line is read from file. The working buffer has one character more, to hold any trailing blank. Pointers to line and column are for debugging, they will be used to make up readable error messages for the parser.

```
<Lexer: public>+≡  
    public :: lexer_t
```

```
<Lexer: types>+≡  
    type :: lexer_t  
    private  
    type(lexer_setup_t) :: setup  
    type(stream_t), pointer :: stream => null ()  
    type(lexeme_t) :: lexeme  
    type(string_t) :: previous_line2  
    type(string_t) :: previous_line1  
    type(string_t) :: current_line  
    integer :: lines_read = 0  
    integer :: current_column = 0  
    integer :: previous_column = 0  
    type(string_t) :: buffer  
    type(lexer_t), pointer :: parent => null ()  
end type lexer_t
```

Create-setup wrapper

```
<Lexer: public>+≡  
    public :: lexer_init
```

```
<Lexer: procedures>+≡  
    subroutine lexer_init (lexer, &  
        comment_chars, quote_chars, quote_match, &  
        single_chars, special_class, &  
        keyword_list, upper_case_keywords, &  
        parent)  
        type(lexer_t), intent(inout) :: lexer  
        character(*), intent(in) :: comment_chars  
        character(*), intent(in) :: quote_chars, quote_match  
        character(*), intent(in) :: single_chars  
        character(*), dimension(:), intent(in) :: special_class  
        type(keyword_list_t), pointer :: keyword_list  
        logical, intent(in), optional :: upper_case_keywords  
        type(lexer_t), target, intent(in), optional :: parent  
        call lexer_setup_init (lexer%setup, &  
            comment_chars = comment_chars, &  
            quote_chars = quote_chars, &  
            quote_match = quote_match, &  
            single_chars = single_chars, &  
            special_class = special_class, &  
            keyword_list = keyword_list, &  
            upper_case_keywords = upper_case_keywords)  
        if (present (parent)) lexer%parent => parent  
        call lexer_clear (lexer)  
    end subroutine lexer_init
```

Clear the lexer state, but not the setup. This should be done when the lexing starts, but it is not known whether the lexer was used before.

```

<Lexer: public>+≡
    public :: lexer_clear

<Lexer: procedures>+≡
    subroutine lexer_clear (lexer)
        type(lexer_t), intent(inout) :: lexer
        call lexeme_clear (lexer%lexeme)
        lexer%previous_line2 = ""
        lexer%previous_line1 = ""
        lexer%current_line = ""
        lexer%lines_read = 0
        lexer%current_column = 0
        lexer%previous_column = 0
        lexer%buffer = ""
    end subroutine lexer_clear

```

Reset lexer state and delete setup

```

<Lexer: public>+≡
    public :: lexer_final

<Lexer: procedures>+≡
    subroutine lexer_final (lexer)
        type(lexer_t), intent(inout) :: lexer
        call lexer_clear (lexer)
        call lexer_setup_final (lexer%setup)
    end subroutine lexer_final

```

3.2.7 The lexer routine

For lexing we need to associate an input stream to the lexer.

```

<Lexer: public>+≡
    public :: lexer_assign_stream

<Lexer: procedures>+≡
    subroutine lexer_assign_stream (lexer, stream)
        type(lexer_t), intent(inout) :: lexer
        type(stream_t), intent(in), target :: stream
        lexer%stream => stream
    end subroutine lexer_assign_stream

```

The lexer. The lexer function takes the lexer and returns the currently stored lexeme. If there is none, it is read from buffer, matching against the lexeme templates in the lexer setup. Empty lexemes, i.e., comments and whitespace, are discarded and the buffer is read again until we have found a nonempty lexeme (which may also be EOF or an error condition).

The initial state of the lexer contains an empty lexeme, so reading from buffer is forced. The empty state is restored after returning the lexeme. A nonempty lexeme is present in the lexer only if `lex_back` has been executed before.

The workspace is the `lexer%buffer`, treated as a sort of input stream. We chop off lexemes from the beginning, adjusting the buffer to the left. Whenever the buffer is empty, or we are matching against an open quote which has not terminated, we read a new line and append it to the right. This may result in special conditions, which for simplicity are also returned as lexemes: I/O error, buffer overflow, end of file. If the latter happens during reading a quoted string, we return an unmatched-quote lexeme. Obviously, the special-condition lexemes have to be caught by the parser.

Note that reading further lines is only necessary when reading a quoted string. Otherwise, the line-feed that ends each line is interpreted as whitespace which terminates a preceding lexeme, so there are no other valid multiline lexemes.

To enable meaningful error messages, we also keep track of the line number of the last line read, and the beginning and the end of the current lexeme with respect to this line.

The lexer is implemented as a function that returns the next lexeme (i.e., token). It uses the `lexer` setup and modifies the buffers and pointers stored within the lexer, a side effect. The lexer reads from an input stream object, which also is modified by this reading, e.g., a line pointer is advanced.

```

(Lexer: public)+≡
    public :: lex

(Lexer: procedures)+≡
    subroutine lex (lexeme, lexer)
        type(lexeme_t), intent(out) :: lexeme
        type(lexer_t), intent(inout) :: lexer
        integer :: iostat1, iostat2
        integer :: pos
        integer, dimension(2) :: range
        integer :: template_index, type
        if (.not. associated (lexer%stream)) &
            call msg_bug ("Lexer called without assigned stream")
        GET_LEXEME: do while (lexeme_get_type (lexer%lexeme) == EMPTY)
            if (len (lexer%buffer) /= 0) then
                iostat1 = 0
            else
                call lexer_read_line (lexer, iostat1)
            end if
            select case (iostat1)
            case (0)
                MATCH_BUFFER: do
                    call match (lexer%setup%tt, char (lexer%buffer), &
                                pos, range, template_index)
                    if (pos >= 0) then
                        type = lexer%setup%type(template_index)
                        exit MATCH_BUFFER
                    else
                        pos = 0
                        call lexer_read_line (lexer, iostat2)
                        select case (iostat2)
                        case (EOF); type = UNMATCHED_QUOTE; exit MATCH_BUFFER
                        case (1);  type = IO_ERROR;      exit MATCH_BUFFER
                        case (2);  type = OVERFLOW;       exit MATCH_BUFFER

```

```

        end select
    end if
    end do MATCH_BUFFER
    case (EOF); type = EOF
    case (1);   type = IO_ERROR
    case (2);   type = OVERFLOW
    end select
    call lexeme_set (lexer%lexeme, lexer%setup%keyword_list, &
        extract (lexer%buffer, finish=pos), range, type, &
        lexer%setup%keyword_case)
    lexer%buffer = remove (lexer%buffer, finish=pos)
    lexer%previous_column = lexer%current_column
    lexer%current_column = lexer%current_column + pos
end do GET_LEXEME
lexeme = lexer%lexeme
call lexeme_clear (lexer%lexeme)
end subroutine lex

```

Read a line and append it to the input buffer. If the input buffer overflows, return `iostat=2`. Otherwise, `iostat=1` indicates an I/O error, and `iostat=-1` the EOF.

The input stream may either be an external unit or a `ifile` object. In the latter case, a line is read and the line pointer is advanced.

Note that inserting LF between input lines is the Unix convention. Since we are doing this explicitly when gluing lines together, we can pattern-match against LF without having to worry about the system.

```

<Lexer: procedures>+≡
subroutine lexer_read_line (lexer, iostat)
    type(lexer_t), intent(inout) :: lexer
    integer, intent(out) :: iostat
    type(string_t) :: current_line
    current_line = lexer%current_line
    call stream_get_record (lexer%stream, lexer%current_line, iostat)
    if (iostat == 0) then
        lexer%lines_read = lexer%lines_read + 1
        lexer%previous_line2 = lexer%previous_line1
        lexer%previous_line1 = current_line
        lexer%buffer = lexer%buffer // lexer%current_line // LF
        lexer%previous_column = 0
        lexer%current_column = 0
    end if
end subroutine lexer_read_line

```

Once in a while we have read one lexeme to many, which can be pushed back into the input stream. Do not do this more than once.

```

<Lexer: public>+≡
public :: lexer_put_back

<Lexer: procedures>+≡
subroutine lexer_put_back (lexer, lexeme)
    type(lexer_t), intent(inout) :: lexer
    type(lexeme_t), intent(in) :: lexeme
    if (lexeme_get_type (lexer%lexeme) == EMPTY) then

```

```

        lexer%lexeme = lexeme
    else
        call msg_bug (" Lexer: lex_back fails; probably called twice")
    end if
end subroutine lexer_put_back

```

3.2.8 Diagnostics

For debugging: print just the setup

```

<Lexer: public>+≡
    public :: lexer_write_setup

<Lexer: procedures>+≡
    subroutine lexer_write_setup (lexer, unit)
        type(lexer_t), intent(in) :: lexer
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit); if (u < 0) return
        call lexer_setup_write (lexer%setup, u)
    end subroutine lexer_write_setup

```

This is useful for error printing: show the current line with index and a pointer to the current column within the line.

```

<Lexer: public>+≡
    public :: lexer_show_location

<Lexer: procedures>+≡
    subroutine lexer_show_location (lexer)
        type(lexer_t), intent(in) :: lexer
        type(string_t) :: loc_str
        if (associated (lexer%parent)) then
            call lexer_show_source (lexer%parent)
            call msg_message ("[includes]")
        else
            call msg_message ()
        end if
        if (associated (lexer%stream)) then
            call msg_message &
                (char (stream_get_record_info_string (lexer%stream)) // ":")
        end if
        if (lexer%lines_read >= 4) call msg_result ("[...]")
        if (lexer%lines_read >= 3) call msg_result (char (lexer%previous_line2))
        if (lexer%lines_read >= 2) call msg_result (char (lexer%previous_line1))
        if (lexer%lines_read >= 1) then
            call msg_result (char (lexer%current_line))
            loc_str = repeat (" ", lexer%previous_column)
            loc_str = loc_str // "^"
            if (lexer%current_column > lexer%previous_column) then
                loc_str = loc_str &
                    // repeat ("-", max (lexer%current_column &
                        - lexer%previous_column - 1, 0)) &
                    // "^"
            end if
        end if
    end subroutine lexer_show_location

```

```

        call msg_result (char (loc_str))
    end if
end subroutine lexer_show_location

```

This just prints the current stream source.

```

<Lexer: procedures>+≡
recursive subroutine lexer_show_source (lexer)
    type(lexer_t), intent(in) :: lexer
    type(string_t) :: loc_str
    if (associated (lexer%parent)) then
        call lexer_show_source (lexer%parent)
        call msg_message ("[includes]")
    else
        call msg_message ()
    end if
    if (associated (lexer%stream)) then
        call msg_message &
            (char (stream_get_source_info_string (lexer%stream)) // ":")
    end if
end subroutine lexer_show_source

```

3.2.9 Unit tests

```

<Lexer: public>+≡
public :: lexer_test

<Lexer: procedures>+≡
subroutine lexer_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
<Lexer: execute tests>
end subroutine lexer_test

```

Test the lexer by lexing and printing all lexemes from unit u, one per line, using preset conventions.

```

<Lexer: execute tests>≡
    call test (lexer_1, "lexer_1", &
        "check lexer", u, results)

<Lexer: tests>≡
subroutine lexer_1 (u)
    integer, intent(in) :: u
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    type(string_t) :: string
    type(lexeme_t) :: lexeme
    string = "abcdefghij"
    call lexer_init (lexer, &
        comment_chars = "", &
        quote_chars = "<'\"", &
        quote_match = ">'\"", &
        single_chars = "?*+=,(),", &

```

```

        special_class = (/ "." /), &
        keyword_list = null ()
    call stream_init (stream, string)
    call lexer_assign_stream (lexer, stream)
do
    call lex (lexeme, lexer)
    call lexeme_write (lexeme, u)
    if (lexeme_is_break (lexeme)) exit
end do
    call stream_final (stream)
    call lexer_final (lexer)
end subroutine lexer_1

```

3.3 Syntax rules

This module provides tools to handle syntax rules in an abstract way.

```
<syntax_rules.f90>≡  
<File header>  
  
module syntax_rules  
  
  <Use strings>  
  <Use file utils>  
  use limits, only: UNQUOTED !NODEP!  
  use diagnostics !NODEP!  
  use ifiles, only: line_p, line_init, line_get_string_advance, line_final  
  use ifiles, only: ifile_t, ifile_get_length  
  use lexers  
  
  <Standard module head>  
  
  <Syntax: public>  
  
  <Syntax: parameters>  
  
  <Syntax: types>  
  
  <Syntax: interfaces>  
  
contains  
  
  <Syntax: subroutines>  
  
end module syntax_rules
```

3.3.1 Syntax rules

Syntax rules are used by the parser. They determine how to translate the stream of lexemes as returned by the lexer into the parse tree node. A rule may be terminal, i.e., replace a matching lexeme into a terminal node. The node will contain the lexeme interpreted as a recognized token:

- a keyword: unquoted fixed character string;
- a real number, to be determined at runtime;
- an integer, to be determined at runtime;
- a boolean value, to be determined at runtime;
- a quoted token (e.g., string), to be determined at runtime;
- an identifier (unquoted string that is not a recognized keyword), to be determined at runtime.

It may be nonterminal, i.e., contain a sequence of child rules. These are matched consecutively (and recursively) against the input stream; the resulting node will be a branch node.

- the file, i.e., the input stream as a whole;
- a sequence of syntax elements, where the last syntax element may be optional, or optional repetitive;

Sequences carry a flag that tells whether the last child is optional or may be repeated an arbitrary number of times, corresponding to the regexp modifiers `?`, `*`, and `+`.

We also need an alternative rule; this will be replaced by the node generated by one of its children that matches; thus, it does not create a node of its own.

- an alternative of syntax elements.

We also define special types of sequences as convenience macros:

- a list: a sequence where the elements are separated by a separator keyword (e.g., commas), the separators are thrown away when parsing the list;
- a group: a sequence of three tokens, where the first and third ones are left and right delimiters, the delimiters are thrown away;
- an argument list: a delimited list, containing both delimiters and separators.

It would be great to have a polymorphic type for this purpose, but until Fortran 2003 is out we have to emulate this.

Here are the syntax element codes:

```

<Syntax: public>≡
  public :: S_UNKNOWN
  public :: S_LOGICAL, S_INTEGER, S_REAL, S_COMPLEX, S_QUOTED
  public :: S_IDENTIFIER, S_KEYWORD
  public :: S_SEQUENCE, S_LIST, S_GROUP, S_ARGS
  public :: S_ALTERNATIVE
  public :: S_IGNORE

<Syntax: parameters>≡
  integer, parameter :: &
    S_UNKNOWN = 0, &
    S_LOGICAL = 1, S_INTEGER = 2, S_REAL = 3, S_COMPLEX = 4, &
    S_QUOTED = 5, S_IDENTIFIER = 6, S_KEYWORD = 7, &
    S_SEQUENCE = 8, S_LIST = 9, S_GROUP = 10, S_ARGS = 11, &
    S_ALTERNATIVE = 12, &
    S_IGNORE = 99

```

We need arrays of rule pointers, therefore this construct.

```

<Syntax: types>≡
  type :: rule_p
  private
    type(syntax_rule_t), pointer :: p => null ()
  end type rule_p

```

Return the association status of the rule pointer:

```

<Syntax: subroutines>≡
  elemental function rule_is_associated (rp) result (ok)
    logical :: ok
    type (rule_p), intent(in) :: rp
    ok = associated (rp%p)
  end function rule_is_associated

```

The rule type is one of the types listed above, represented by an integer code. The keyword, for a non-keyword rule, is an identifier used for the printed syntax table. The array of children is needed for nonterminal rules. In that case, there is a modifier for the last element (blank, "?", "*", or "+"), mirrored in the flags **opt** and **rep**. Then, we have the character constants used as separators and delimiters for this rule. Finally, the **used** flag can be set to indicate that this rule is the child of another rule.

```

<Syntax: types>+≡
  public :: syntax_rule_t

<Syntax: types>+≡
  type :: syntax_rule_t
    private
    integer :: type = S_UNKNOWN
    logical :: used = .false.
    type(string_t) :: keyword
    type(string_t) :: separator
    type(string_t), dimension(2) :: delimiter
    type(rule_p), dimension(:), allocatable :: child
    character(1) :: modifier = ""
    logical :: opt = .false., rep = .false.
  end type syntax_rule_t

```

Initializer: Set type and key for a rule, but do not (yet) allocate anything.

Finalizer: not needed (no pointer components).

```

<Syntax: subroutines>+≡
  subroutine syntax_rule_init (rule, key, type)
    type(syntax_rule_t), intent(inout) :: rule
    type(string_t), intent(in) :: key
    integer, intent(in) :: type
    rule%keyword = key
    rule%type = type
    select case (rule%type)
    case (S_GROUP)
      call syntax_rule_set_delimiter (rule)
    case (S_LIST)
      call syntax_rule_set_separator (rule)
    case (S_ARGS)
      call syntax_rule_set_delimiter (rule)
      call syntax_rule_set_separator (rule)
    end select
  end subroutine syntax_rule_init

```

3.3.2 I/O

These characters will not be enclosed in quotes when writing syntax rules:

```
<Limits: public parameters>+≡  
    character(*), parameter, public :: &  
        UNQUOTED = "(),|_"/LCLETTERS/UCLETTERS/DIGITS
```

Write an account of the rule. Setting `short` true will suppress the node type. Setting `key_only` true will suppress the definition. Setting `advance` false will suppress the trailing newline.

```
<Syntax: public>+≡  
    public :: syntax_rule_write  
  
<Syntax: subroutines>+≡  
    subroutine syntax_rule_write (rule, unit, short, key_only, advance)  
        type(syntax_rule_t), intent(in) :: rule  
        integer, intent(in), optional :: unit  
        logical, intent(in), optional :: short, key_only, advance  
        logical :: typ, def, adv  
        integer :: u  
        u = output_unit (unit); if (u < 0) return  
        typ = .true.; if (present (short)) typ = .not. short  
        def = .true.; if (present (key_only)) def = .not. key_only  
        adv = .true.; if (present (advance)) adv = advance  
        select case (rule%type)  
        case (S_UNKNOWN); call write_atom ("???", typ)  
        case (S_IGNORE); call write_atom ("IGNORE", typ)  
        case (S_LOGICAL); call write_atom ("LOGICAL", typ)  
        case (S_INTEGER); call write_atom ("INTEGER", typ)  
        case (S_REAL); call write_atom ("REAL", typ)  
        case (S_COMPLEX); call write_atom ("COMPLEX", typ)  
        case (S_IDENTIFIER); call write_atom ("IDENTIFIER", typ)  
        case (S_KEYWORD); call write_atom ("KEYWORD", typ)  
        case (S_QUOTED)  
            call write_quotes (typ, def, del = rule%delimiter)  
        case (S_SEQUENCE)  
            call write_sequence ("SEQUENCE", typ, def, size (rule%child))  
        case (S_GROUP)  
            call write_sequence ("GROUP", typ, def, size (rule%child), &  
                del = rule%delimiter)  
        case (S_LIST)  
            call write_sequence ("LIST", typ, def, size (rule%child), &

        if (present (del)) call write_maybe_quoted (char (del(1)))
        do i = 1, n
            if (i > 1 .and. present (sep)) &
                call write_maybe_quoted (char (sep))
            write (u, "(1x,A)", advance="no") &
                char (wkey (syntax_rule_get_sub_ptr(rule, i)))
            if (i == n) write (u, "(A)", advance="no") trim (rule%modifier)
        end do
    end if
end subroutine write_sequence

```

```

        end do
        if (present (del)) call write_maybe_quoted (char (del(2)))
    end if
end subroutine write_sequence
end subroutine syntax_rule_write

```

In the printed representation, the keyword strings are enclosed as <...>, unless they are bare keywords. Bare keywords are enclosed as '...' if they contain a character which is not a letter, digit, or underscore. If they contain a single-quote character, they are enclosed as "...". (A keyword must not contain both single- and double-quotes.)

```

<Syntax: subroutines>+≡
function wkey (rule) result (string)
    type(string_t) :: string
    type(syntax_rule_t), intent(in) :: rule
    select case (rule%type)
    case (S_KEYWORD)
        if (verify (rule%keyword, UNQUOTED) == 0) then
            string = rule%keyword
        else if (scan (rule%keyword, "'") == 0) then
            string = "'" // rule%keyword // "'"
        else
            string = '...' // rule%keyword // '...'
        end if
    case default
        string = "<" // rule%keyword // ">"
    end select
end function wkey

```

3.3.3 Completing syntax rules

Set the separator and delimiter entries, using defaults:

```

<Syntax: subroutines>+≡
subroutine syntax_rule_set_separator (rule, separator)
    type(syntax_rule_t), intent(inout) :: rule
    type(string_t), intent(in), optional :: separator
    if (present (separator)) then
        rule%separator = separator
    else
        rule%separator = ","
    end if
end subroutine syntax_rule_set_separator

subroutine syntax_rule_set_delimiter (rule, delimiter)
    type(syntax_rule_t), intent(inout) :: rule
    type(string_t), dimension(2), intent(in), optional :: delimiter
    if (present (delimiter)) then
        rule%delimiter = delimiter
    else
        rule%delimiter = (/ "(", ")" /)
    end if
end subroutine syntax_rule_set_delimiter

```

```
end subroutine syntax_rule_set_delimiter
```

Set the modifier entry and corresponding flags:

<Syntax: subroutines>+≡

```
function is_modifier (string) result (ok)
  logical :: ok
  type(string_t), intent(in) :: string
  select case (char (string))
    case (" ", "?", "*", "+"); ok = .true.
    case default; ok = .false.
  end select
end function is_modifier

subroutine syntax_rule_set_modifier (rule, modifier)
  type(syntax_rule_t), intent(inout) :: rule
  type(string_t), intent(in) :: modifier
  rule%modifier = char (modifier)
  select case (rule%modifier)
    case (" ")
    case ("?"); rule%opt = .true.
    case ("*"); rule%opt = .true.; rule%rep = .true.
    case ("+"); rule%rep = .true.
    case default
      call msg_bug (" Syntax: sequence modifier '" // rule%modifier &
        // "' is not one of '+' '*' '?'")
  end select
end subroutine syntax_rule_set_modifier
```

Check a finalized rule for completeness

<Syntax: subroutines>+≡

```
subroutine syntax_rule_check (rule)
  type(syntax_rule_t), intent(in) :: rule
  if (rule%keyword == "") call msg_bug ("Rule key not set")
  select case (rule%type)
    case (S_UNKNOWN); call bug (" Undefined rule")
    case (S_IGNORE, S_LOGICAL, S_INTEGER, S_REAL, S_COMPLEX, &
      S_IDENTIFIER, S_KEYWORD)
    case (S_QUOTED)
      if (any (rule%delimiter == "")) call bug (" Missing quote character(s)")
    case (S_SEQUENCE)
    case (S_GROUP)
      if (any (rule%delimiter == "")) call bug (" Missing delimiter(s)")
    case (S_LIST)
      if (rule%separator == "") call bug (" Missing separator")
    case (S_ARGS)
      if (any (rule%delimiter == "")) call bug (" Missing delimiter(s)")
      if (rule%separator == "") call bug (" Missing separator")
    case (S_ALTERNATIVE)
    case default
      call bug (" Undefined syntax code")
  end select
  select case (rule%type)
    case (S_SEQUENCE, S_GROUP, S_LIST, S_ARGS, S_ALTERNATIVE)
```

```

        if (allocated (rule%child)) then
            if (.not.all (rule_is_associated (rule%child))) &
                call bug (" Child rules not all associated")
        else
            call bug (" Parent rule without children")
        end if
    case default
        if (allocated (rule%child)) call bug (" Non-parent rule with children")
    end select
contains
    subroutine bug (string)
        character(*), intent(in) :: string
        call msg_bug (" Syntax table: Rule " // char (rule%keyword) // ": " &
            // string)
    end subroutine bug
end subroutine syntax_rule_check

```

3.3.4 Accessing rules

This is the API for syntax rules:

<Syntax: public>+≡

```
public :: syntax_rule_get_type
```

<Syntax: subroutines>+≡

```
function syntax_rule_get_type (rule) result (type)
    integer :: type
    type(syntax_rule_t), intent(in) :: rule
    type = rule%type
end function syntax_rule_get_type

```

<Syntax: public>+≡

```
public :: syntax_rule_get_key
```

<Syntax: subroutines>+≡

```
function syntax_rule_get_key (rule) result (key)
    type(string_t) :: key
    type(syntax_rule_t), intent(in) :: rule
    key = rule%keyword
end function syntax_rule_get_key

```

<Syntax: public>+≡

```
public :: syntax_rule_get_separator
public :: syntax_rule_get_delimiter
```

<Syntax: subroutines>+≡

```
function syntax_rule_get_separator (rule) result (separator)
    type(string_t) :: separator
    type(syntax_rule_t), intent(in) :: rule
    separator = rule%separator
end function syntax_rule_get_separator

```

```
function syntax_rule_get_delimiter (rule) result (delimiter)
    type(string_t), dimension(2) :: delimiter

```

```

    type(syntax_rule_t), intent(in) :: rule
    delimiter = rule%delimiter
end function syntax_rule_get_delimiter

```

Accessing child rules. If we use `syntax_rule_get_n_sub` for determining loop bounds, we do not need a check in the second routine.

```

<Syntax: public>+≡
    public :: syntax_rule_get_n_sub
    public :: syntax_rule_get_sub_ptr

<Syntax: subroutines>+≡
    function syntax_rule_get_n_sub (rule) result (n)
        integer :: n
        type(syntax_rule_t), intent(in) :: rule
        if (allocated (rule%child)) then
            n = size (rule%child)
        else
            n = 0
        end if
    end function syntax_rule_get_n_sub

    function syntax_rule_get_sub_ptr (rule, i) result (sub)
        type(syntax_rule_t), pointer :: sub
        type(syntax_rule_t), intent(in), target :: rule
        integer, intent(in) :: i
        sub => rule%child(i)%p
    end function syntax_rule_get_sub_ptr

    subroutine syntax_rule_set_sub (rule, i, sub)
        type(syntax_rule_t), intent(inout) :: rule
        integer, intent(in) :: i
        type(syntax_rule_t), intent(in), target :: sub
        rule%child(i)%p => sub
    end subroutine syntax_rule_set_sub

```

Return the modifier flags:

```

<Syntax: public>+≡
    public :: syntax_rule_last_optional
    public :: syntax_rule_last_repetitive

<Syntax: subroutines>+≡
    function syntax_rule_last_optional (rule) result (opt)
        logical :: opt
        type(syntax_rule_t), intent(in) :: rule
        opt = rule%opt
    end function syntax_rule_last_optional
    function syntax_rule_last_repetitive (rule) result (rep)
        logical :: rep
        type(syntax_rule_t), intent(in) :: rule
        rep = rule%rep
    end function syntax_rule_last_repetitive

```

Return true if the rule is atomic, i.e., logical, real, keyword etc.

```
<Syntax: public>+≡
    public :: syntax_rule_is_atomic

<Syntax: subroutines>+≡
    function syntax_rule_is_atomic (rule) result (atomic)
        logical :: atomic
        type(syntax_rule_t), intent(in) :: rule
        select case (rule%type)
            case (S_LOGICAL, S_INTEGER, S_REAL, S_COMPLEX, S_IDENTIFIER, &
                 S_KEYWORD, S_QUOTED)
                atomic = .true.
            case default
                atomic = .false.
        end select
    end function syntax_rule_is_atomic
```

3.3.5 Syntax tables

A syntax table contains the tree of syntax rules and, for direct parser access, the list of valid keywords.

Types

The syntax contains an array of rules and a list of keywords. The array is actually used as a tree, where the top rule is the first array element, and the other rules are recursively pointed to by this first rule. (No rule should be used twice or be unused.) The keyword list is derived from the rule tree.

Objects of this type need the target attribute if they are associated with a lexer. The keyword list will be pointed to by this lexer.

```
<Syntax: public>+≡
    public :: syntax_t

<Syntax: types>+≡
    type :: syntax_t
        private
        type(syntax_rule_t), dimension(:), allocatable :: rule
        type(keyword_list_t) :: keyword_list
    end type syntax_t
```

Constructor/destructor

Initialize and finalize syntax tables

```
<Syntax: public>+≡
    public :: syntax_init
    public :: syntax_final
```

There are two ways to create a syntax: hard-coded from rules or dynamically from file.

```

<Syntax: interfaces>≡
interface syntax_init
  module procedure syntax_init_from_ifile
end interface

```

The syntax definition is read from an ifile object which contains the syntax definitions in textual form, one rule per line. This interface allows for determining the number of rules beforehand.

To parse the rule definitions, we make up a temporary lexer. Obviously, we cannot use a generic parser yet, so we have to hardcode the parsing process.

```

<Syntax: subroutines>+=
subroutine syntax_init_from_ifile (syntax, ifile)
  type(syntax_t), intent(out), target :: syntax
  type(ifile_t), intent(in) :: ifile
  type(lexer_t) :: lexer
  type(line_p) :: line
  type(string_t) :: string
  integer :: n_token
  integer :: i
  call lexer_init (lexer, &
    comment_chars = "", &
    quote_chars = "<'\"", &
    quote_match = ">'\"", &
    single_chars = "?*+|=,()", &
    special_class = (/ "." /), &
    keyword_list = null ())
  allocate (syntax%rule (ifile_get_length (ifile)))
  call line_init (line, ifile)
  do i = 1, size (syntax%rule)
    string = line_get_string_advance (line)
    call set_rule_type_and_key (syntax%rule(i), string, lexer)
  end do
  call line_init (line, ifile)
  do i = 1, size (syntax%rule)
    string = line_get_string_advance (line)
    select case (syntax%rule(i)%type)
    case (S_QUOTED, S_SEQUENCE, S_GROUP, S_LIST, S_ARGS, S_ALTERNATIVE)
      n_token = get_n_token (string, lexer)
      call set_rule_contents &
        (syntax%rule(i), syntax, n_token, string, lexer)
    end select
  end do
  call line_final (line)
  call lexer_final (lexer)
  call syntax_make_keyword_list (syntax)
  if (.not. all (syntax%rule%used)) then
    do i = 1, size (syntax%rule)
      if (.not. syntax%rule(i)%used) then
        call syntax_rule_write (syntax%rule(i), 6)
      end if
    end do
  end do
end do

```

```

        call msg_bug (" Syntax table: unused rules")
    end if
end subroutine syntax_init_from_ifile

```

For a given rule defined in the input, the first task is to determine its type and key. With these, we can initialize the rule in the table, postponing the association of children.

```

<Syntax: subroutines>+=
subroutine set_rule_type_and_key (rule, string, lexer)
    type(syntax_rule_t), intent(inout) :: rule
    type(string_t), intent(in) :: string
    type(lexer_t), intent(inout) :: lexer
    type(stream_t), target :: stream
    type(lexeme_t) :: lexeme
    type(string_t) :: key
    character(2) :: type
    call lexer_clear (lexer)
    call stream_init (stream, string)
    call lexer_assign_stream (lexer, stream)
    call lex (lexeme, lexer)
    type = lexeme_get_string (lexeme)
    call lex (lexeme, lexer)
    key = lexeme_get_contents (lexeme)
    call stream_final (stream)
    if (trim (key) /= "") then
        select case (type)
            case ("IG"); call syntax_rule_init (rule, key, S_IGNORE)
            case ("LO"); call syntax_rule_init (rule, key, S_LOGICAL)
            case ("IN"); call syntax_rule_init (rule, key, S_INTEGER)
            case ("RE"); call syntax_rule_init (rule, key, S_REAL)
            case ("CO"); call syntax_rule_init (rule, key, S_COMPLEX)
            case ("ID"); call syntax_rule_init (rule, key, S_IDENTIFIER)
            case ("KE"); call syntax_rule_init (rule, key, S_KEYWORD)
            case ("QU"); call syntax_rule_init (rule, key, S_QUOTED)
            case ("SE"); call syntax_rule_init (rule, key, S_SEQUENCE)
            case ("GR"); call syntax_rule_init (rule, key, S_GROUP)
            case ("LI"); call syntax_rule_init (rule, key, S_LIST)
            case ("AR"); call syntax_rule_init (rule, key, S_ARGS)

```

This routine completes the syntax table object. We assume that the rule array is set up. We associate the top rule with the first entry in the rule array and build up the keyword list.

The keyword list includes delimiters and separators. Filling it can only be done after all rules are set. We scan the rule tree. For each keyword that we find, we try to add it to the keyword list; the pointer to the last element is carried along with the recursive scanning. Before appending a keyword, we check whether it is already in the list.

(Syntax: subroutines)+≡

```

subroutine syntax_make_keyword_list (syntax)
  type(syntax_t), intent(inout), target :: syntax
  type(syntax_rule_t), pointer :: rule
  rule => syntax%rule(1)
  call rule_scan_rec (rule, syntax%keyword_list)

        call msg_bug (" Syntax table: Rule " // char (key) // " not found")
    end function syntax_get_rule_ptr

```

Return a pointer to the keyword list

```

<Syntax: public>+≡
    public :: syntax_get_keyword_list_ptr

<Syntax: subroutines>+≡
    function syntax_get_keyword_list_ptr (syntax) result (keyword_list)
        type(keyword_list_t), pointer :: keyword_list
        type(syntax_t), intent(in), target :: syntax
        keyword_list => syntax%keyword_list
    end function syntax_get_keyword_list_ptr

```

3.3.7 I/O

Write a readable representation of the syntax table

```

<Syntax: public>+≡
    public :: syntax_write

<Syntax: subroutines>+≡
    subroutine syntax_write (syntax, unit)
        type(syntax_t), intent(in) :: syntax
        integer, intent(in), optional :: unit
        integer :: u
        integer :: i
        u = output_unit (unit); if (u < 0) return
        write (u, "(A)") "Syntax table:"
        if (allocated (syntax%rule)) then
            do i = 1, size (syntax%rule)
                call syntax_rule_write (syntax%rule(i), u)
            end do
        end if
    end subroutine syntax_write

```

```
        end do
    else
        write (u, "(1x,A)") "[not allocated]"
    end if
    call keyword_list_write (syntax%keyword_list, u)
end subroutine syntax_write
```

3.4 The parser

On a small scale, the parser interprets the string tokens returned by the lexer; they are interpreted as numbers, keywords and such and stored as a typed object. On a large scale, a text is read, parsed, and a syntax rule set is applied such that the tokens are stored as a parse tree. Syntax errors are spotted in this process, so the resulting parse tree is syntactically correct by definition.

```
<parser.f90>≡  
<File header>  
  
module parser  
  
  <Use kinds>  
  <Use strings>  
  use limits, only: DIGITS !NODEP!  
  <Use file utils>  
  use diagnostics !NODEP!  
  use md5  
  use unit_tests  
  use lexers  
  use syntax_rules  
  
  <Standard module head>  
  
  <Parser: public>  
  
  <Parser: types>  
  
  <Parser: interfaces>  
  
contains  
  
  <Parser: procedures>  
  
  <Parser: tests>  
  
end module parser
```

3.4.1 The token type

Tokens are elements of the parsed input that carry a value: logical, integer, real, quoted string, (unquoted) identifier, or known keyword. Note that non-keyword tokens also have an abstract key attached to them.

This is an obvious candidate for polymorphism.

```
<Parser: types>≡  
  type :: token_t  
    private  
    integer :: type = S_UNKNOWN  
    logical, pointer :: lval => null ()  
    integer, pointer :: ival => null ()  
    real(default), pointer :: rval => null ()  
    complex(default), pointer :: cval => null ()
```

```

        type(string_t), pointer :: sval => null ()
        type(string_t), pointer :: kval => null ()
        type(string_t), dimension(:), pointer :: quote => null ()
    end type token_t

```

Create a token from the lexeme returned by the lexer: Allocate storage and try to interpret the lexeme according to the type that is requested by the parser. For a keyword token, match the lexeme against the requested key. If successful, set the token type, value, and key. Otherwise, set the type to S_UNKNOWN.

(Parser: procedures)≡

```

subroutine token_init (token, lexeme, requested_type, key)
    type(token_t), intent(out) :: token
    type(lexeme_t), intent(in) :: lexeme
    integer, intent(in) :: requested_type

subroutine token_mismatch (token, type)
  type(token_t), intent(in) :: token
  character(*), intent(in) :: type
  write (6, "(A)", advance="no") "Token: "
  call token_write (token)
  call msg_bug (" Token type mismatch; value required as " // type)
end subroutine token_mismatch

```

3.4.3 The parse tree: nodes

The parser will generate a parse tree from the input stream. Each node in this parse tree points to the syntax rule that was applied. (Since syntax rules are stored in a pointer-type array within the syntax table, they qualify as targets.) A leaf node contains a token. A branch node has subnodes. The subnodes are stored as a list, so each node also has a `next` pointer.

```

<Parser: public>≡
public :: parse_node_t

<Parser: types>+≡
type :: parse_node_t
private
  type(syntax_rule_t), pointer :: rule => null ()
  type(token_t) :: token
  integer :: n_sub = 0
  type(parse_node_t), pointer :: sub_first => null ()
  type(parse_node_t), pointer :: sub_last => null ()
  type(parse_node_t), pointer :: next => null ()
contains
  <Parser: parse node: TBP>
end type parse_node_t

```

Container for parse node pointers, useful for creating pointer arrays:

```

<Parser: public>+≡
public :: parse_node_p

<Parser: types>+≡
type :: parse_node_p
  type(parse_node_t), pointer :: ptr => null ()
end type parse_node_p

```

Output. The first version writes a node together with its sub-node tree, organized by indentation.

```

(Parser: parse node: TBP)≡
    procedure :: write => parse_node_write_rec

(Parser: public)+≡
    public :: parse_node_write_rec

(Parser: procedures)+≡
    recursive subroutine parse_node_write_rec (node, unit, short, depth)
        class(parse_node_t), intent(in), target :: node
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: short
        integer, intent(in), optional :: depth
        integer :: u, d
        type(parse_node_t), pointer :: current
        u = output_unit (unit); if (u < 0) return
        d = 0; if (present (depth)) d = depth
        call parse_node_write (node, u, short=short)
        current => node%sub_first
        do while (associated (current))
            write (u, "(A)", advance = "no") repeat ("| ", d)
            call parse_node_write_rec (current, unit, short, d+1)
            current => current%next
        end do
    end subroutine parse_node_write_rec

```

This does the actual output for a single node, without recursion.

```

(Parser: public)+≡
    public :: parse_node_write

(Parser: procedures)+≡
    subroutine parse_node_write (node, unit, short)
        class(parse_node_t), intent(in) :: node
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: short
        integer :: u
        type(parse_node_t), pointer :: current
        u = output_unit (unit); if (u < 0) return
        write (u, "(' + ')", advance = "no")
        if (associated (node%rule)) then
            call syntax_rule_write (node%rule, u, &
                short=short, key_only=.true., advance=.false.)
        if (token_is_valid (node%token)) then
            write (u, "(' = ')", advance="no")
            call token_write (node%token, u)
        else if (associated (node%sub_first)) then
            write (u, "(' = ')", advance="no")
            current => node%sub_first
            do while (associated (current))
                call syntax_rule_write (current%rule, u, &
                    short=.true., key_only=.true., advance=.false.)
                current => current%next
            end do
        write (u, *)
    end subroutine parse_node_write

```

```

        else
            write (u, *)
        end if
    else
        write (u, *) "[empty]"
    end if
end subroutine parse_node_write

```

Finalize the token and recursively finalize and deallocate all sub-nodes.

```

<Parser: public>+≡
    public :: parse_node_final

<Parser: procedures>+≡
    recursive subroutine parse_node_final (node, recursive)
        type(parse_node_t), intent(inout) :: node
        type(parse_node_t), pointer :: current
        logical, intent(in), optional :: recursive
        logical :: rec
        rec = .true.; if (present (recursive)) rec = recursive
        call token_final (node%token)
        if (rec) then
            do while (associated (node%sub_first))
                current => node%sub_first
                node%sub_first => node%sub_first%next
                call parse_node_final (current)
                deallocate (current)
            end do
        end if
    end subroutine parse_node_final

```

3.4.4 Filling nodes

The constructors allocate and initialize the node. There are two possible initializers (in a later version, should correspond to different type extensions).

First, leaf (terminal) nodes. The token constructor does the actual work, looking at the requested type and key for the given rule and matching against the lexeme contents. If it fails, the token will keep the type `S_UNKNOWN` and remain empty. Otherwise, we have a valid node which contains the new token.

If the lexeme argument is absent, the token is left empty.

```

<Parser: procedures>+≡
    subroutine parse_node_create_leaf (node, rule, lexeme)
        type(parse_node_t), pointer :: node
        type(syntax_rule_t), intent(in), target :: rule
        type(lexeme_t), intent(in) :: lexeme
        allocate (node)
        node%rule => rule
        call token_init (node%token, lexeme, &
            syntax_rule_get_type (rule), syntax_rule_get_key (rule))
        if (.not. token_is_valid (node%token)) deallocate (node)
    end subroutine parse_node_create_leaf

```

This version allows us to manually create a leaf node that holds a keyword.

```

(Parser: public)+≡
    public :: parse_node_create_key

(Parser: procedures)+≡
    subroutine parse_node_create_key (node, rule)
        type(parse_node_t), intent(out) :: node
        type(syntax_rule_t), intent(in), target :: rule
        node%rule => rule
        call token_init_key (node%token, syntax_rule_get_key (rule))
    end subroutine parse_node_create_key

```

This version allows us to manually create a leaf node that holds a fixed value.
Only one of the optional values should be provided.

```

(Parser: public)+≡
    public :: parse_node_create_value

(Parser: procedures)+≡
    subroutine parse_node_create_value (node, rule, ival, rval, cval, sval, lval)
        type(parse_node_t), intent(out) :: node
        type(syntax_rule_t), intent(in), target :: rule
        integer, intent(in), optional :: ival
        real(default), intent(in), optional :: rval
        complex(default), intent(in), optional :: cval
        type(string_t), intent(in), optional :: sval
        logical, intent(in), optional :: lval
        node%rule => rule
        call parse_node_set_value (node, ival, rval, cval, sval, lval)
    end subroutine parse_node_create_value

```

Directly set the value without changing anything else.

```

(Parser: public)+≡
    public :: parse_node_set_value

(Parser: procedures)+≡
    subroutine parse_node_set_value (node, ival, rval, cval, sval, lval)
        type(parse_node_t), intent(inout) :: node
        integer, intent(in), optional :: ival
        real(default), intent(in), optional :: rval
        complex(default), intent(in), optional :: cval
        type(string_t), intent(in), optional :: sval
        logical, intent(in), optional :: lval
        type(string_t) :: key
        if (present (ival)) then
            node%token = ival
        else if (present (rval)) then
            node%token = rval
        else if (present (cval)) then
            node%token = cval
        else if (present (lval)) then
            node%token = lval
        else if (present (sval)) then
            node%token = sval
        end if
    end subroutine parse_node_set_value

```

```
end subroutine parse_node_set_value
```

Second, branch nodes. We first assign the rule:

```
<Parser: public>+≡
  public :: parse_node_create_branch

<Parser: procedures>+≡
  subroutine parse_node_create_branch (node, rule)
    type(parse_node_t), pointer :: node
    type(syntax_rule_t), intent(in), target :: rule
    allocate (node)
    node%rule => rule
  end subroutine parse_node_create_branch
```

Append a sub-node. The sub-node must exist and be a valid target, otherwise nothing is done.

```
<Parser: public>+≡
  public :: parse_node_append_sub

<Parser: procedures>+≡
  subroutine parse_node_append_sub (node, sub)
    type(parse_node_t), intent(inout) :: node
    type(parse_node_t), pointer :: sub
    if (associated (sub)) then
      if (associated (node%sub_last)) then
        node%sub_last%next => sub
      else
        node%sub_first => sub
      end if
      node%sub_last => sub
    end if
  end subroutine parse_node_append_sub
```

For easy access, once the list is complete we count the number of sub-nodes. If there are no subnodes, the whole node is deleted.

```
<Parser: public>+≡
  public :: parse_node_freeze_branch

<Parser: procedures>+≡
  subroutine parse_node_freeze_branch (node)
    type(parse_node_t), pointer :: node
    type(parse_node_t), pointer :: current
    node%n_sub = 0
    current => node%sub_first
    do while (associated (current))
      node%n_sub = node%n_sub + 1
      current => current%next
    end do
    if (node%n_sub == 0) deallocate (node)
  end subroutine parse_node_freeze_branch
```

Replace the syntax rule. This makes sense only if the parse node adheres to the syntax of the new rule.

```

(Parser: public)+≡
    public :: parse_node_replace_rule

(Parser: procedures)+≡
    subroutine parse_node_replace_rule (node, rule)
        type(parse_node_t), pointer :: node
        type(syntax_rule_t), intent(in), target :: rule
        node%rule => rule
    end subroutine parse_node_replace_rule

```

Replace the last subnode by the target node. Since the subnodes are stored as a linked list, we can do this only if we copy the subnodes. Furthermore, the target node must also be copied, and the `next` pointer of the copy is nullified. This ensures that we cannot modify the originals at the subnode level.

All copies are shallow copies. This implies that further modifications at the sub-subnode level will affect the original nodes and must therefore be forbidden.

Use with care, this invites to memory mismanagement. The copy nodes can be deallocated, but not finalized, since its subnodes are the same objects as the subnodes of the target node.

```

(Parser: public)+≡
    public :: parse_node_replace_last_sub

(Parser: procedures)+≡
    subroutine parse_node_replace_last_sub (node, pn_target)
        type(parse_node_t), intent(inout), target :: node
        type(parse_node_t), intent(in), target :: pn_target
        type(parse_node_t), pointer :: current, current_copy, previous
        integer :: i
        select case (node%n_sub)
            case (1)
                allocate (current_copy)
                current_copy = pn_target
                node%sub_first => current_copy
            case (2:)
                current => node%sub_first
                allocate (current_copy)
                current_copy = current
                node%sub_first => current_copy
                previous => current_copy
                do i = 1, node%n_sub - 2
                    current => current%next
                    allocate (current_copy)
                    current_copy = current
                    previous%next => current_copy
                    previous => current_copy
                end do
                allocate (current_copy)
                current_copy = pn_target
                previous%next => current_copy
            case default
                call parse_node_write (node)
        end select
    end subroutine parse_node_replace_last_sub

```

```

        call msg_bug ("replace_last_sub' called for non-branch parse node")
    end select
    current_copy%next => null ()
    node%sub_last => current_copy
end subroutine parse_node_replace_last_sub

```

3.4.5 Accessing nodes

Return the node contents. Check if pointers are associated. No check when accessing a sub-node; assume that `parse_node_n_sub` is always used for the upper bound.

The token extractor returns a pointer.

(Parser: public)+≡

```

public :: parse_node_get_rule_ptr
public :: parse_node_get_n_sub
public :: parse_node_get_sub_ptr
public :: parse_node_get_next_ptr
public :: parse_node_get_last_sub_ptr

```

(Parser: procedures)+≡

```

function parse_node_get_rule_ptr (node) result (rule)
    type(syntax_rule_t), pointer :: rule
    type(parse_node_t), intent(in), target :: node
    if (associated (node%rule)) then
        rule => node%rule
    else
        rule => null ()
        call parse_node_undefined (node, "rule")
    end if
end function parse_node_get_rule_ptr

```

```

function parse_node_get_n_sub (node) result (n)
    integer :: n
    type(parse_node_t), intent(in) :: node
    n = node%n_sub
end function parse_node_get_n_sub

```

```

function parse_node_get_sub_ptr (node, n, tag, required) result (sub)
    type(parse_node_t), pointer :: sub
    type(parse_node_t), intent(in), target :: node
    integer, intent(in), optional :: n
    character(*), intent(in), optional :: tag
    logical, intent(in), optional :: required
    integer :: i
    sub => node%sub_first
    if (present (n)) then
        do i = 2, n
            if (associated (sub)) then
                sub => sub%next
            else
                return
            end if
        end do
    end if
end function parse_node_get_sub_ptr

```

```

end if
call parse_node_check (sub, tag, required)
end function parse_node_get_sub_ptr

function parse_node_get_next_ptr (sub, n, tag, required) result (next)
  type(parse_node_t), pointer :: next
  type(parse_node_t), intent(in), target :: sub
  integer, intent(in), optional :: n
  character(*), intent(in), optional :: tag
  logical, intent(in), optional :: required
  integer :: i
  next => sub%next
  if (present (n)) then
    do i = 2, n
      if (associated (next)) then
        next => next%next
      else
        exit
      end if
    end do
  end if
  call parse_node_check (next, tag, required)
end function parse_node_get_next_ptr

function parse_node_get_last_sub_ptr (node, tag, required) result (sub)
  type(parse_node_t), pointer :: sub
  type(parse_node_t), intent(in), target :: node
  character(*), intent(in), optional :: tag
  logical, intent(in), optional :: required
  sub => node%sub_last
  call parse_node_check (sub, tag, required)
end function parse_node_get_last_sub_ptr

<Parser: procedures>+≡
subroutine parse_node_undefined (node, obj)
  type(parse_node_t), intent(in) :: node
  character(*), intent(in) :: obj
  call parse_node_write (node, 6)
  call msg_bug (" Parse-tree node: " // obj // " requested, but undefined")
end subroutine parse_node_undefined

```

Check if a parse node has a particular tag, and if it is associated:

```

<Parser: public>+≡
public :: parse_node_check

<Parser: procedures>+≡
subroutine parse_node_check (node, tag, required)
  type(parse_node_t), pointer :: node
  character(*), intent(in), optional :: tag
  logical, intent(in), optional :: required
  if (associated (node)) then
    if (present (tag)) then
      if (parse_node_get_rule_key (node) /= tag) &
        call parse_node_mismatch (tag, node)
    end if
  end if
end subroutine parse_node_check

```

```

        end if
    else
        if (present (required)) then
            if (required) &
                call msg_bug (" Missing node, expected <" // tag // ">")
            end if
        end if
    end if
end subroutine parse_node_check

```

This is called by a parse-tree scanner if the expected and the actual nodes do not match

```

(Parser: public)+≡
    public :: parse_node_mismatch

(Parser: procedures)+≡
    subroutine parse_node_mismatch (string, parse_node)
        character(*), intent(in) :: string
        type(parse_node_t), intent(in) :: parse_node
        call parse_node_write (parse_node)
        call msg_bug (" Syntax mismatch, expected <" // string // ">.")
    end subroutine parse_node_mismatch

```

The following functions are wrappers for extracting the token contents.

```

(Parser: public)+≡
    public :: parse_node_get_logical

3.4.6 The parse tree

The parse tree is a tree of nodes, where leaf nodes hold a valid token, while branch nodes point to a list of sub-nodes.

```

(Parser: public)+≡
    public :: parse_tree_t
(Parser: types)+≡
    type :: parse_tree_t
    private
    type(parse_node_t), pointer :: root_node => null ()
end type parse_tree_t

```

The parser. Its arguments are the parse tree (which should be empty initially), the lexer (which should be already set up), the syntax table (which should be valid), and the input stream. The input stream is completely parsed, using the lexer setup and the syntax rules as given, and the parse tree is built accordingly.

If `check_eof` is absent or true, the parser will complain about trailing garbage. Otherwise, it will ignore it.

By default, the input stream is matched against the top rule in the specified syntax. If `key` is given, it is matched against the rule with the specified key instead.

Failure at the top level means that no rule could match at all; in this case the error message will show the top rule.

```

(Parser: public)+≡
    public :: parse_tree_init
(Parser: procedures)+≡
    subroutine parse_tree_init &
        (parse_tree, syntax, lexer, key, check_eof)

    ok = .false.
  end if
end subroutine parse_args

```

The IGNORE syntax reads one lexeme and discards it if it is numeric, logical or string/identifier (but not a keyword). This is a successful match. Otherwise, the match fails. The node pointer is returned disassociated in any case.

```

(Parser: internal subroutines of parse_tree_init)+≡
subroutine parse_ignore (node, ok)
  type(parse_node_t), pointer :: node
  logical, intent(out) :: ok
  call lex (lexeme, lexer)
  select case (lexeme_get_type (lexeme))
  case (T_NUMERIC, T_IDENTIFIER, T_QUOTED)
    ok = .true.
  case default
    ok = .false.
  end select
  node => null ()
end subroutine parse_ignore

```

If the match fails and we cannot step back:

```

(Parser: internal subroutines of parse_tree_init)+≡
subroutine parse_error (rule, lexeme)
  type(syntax_rule_t), intent(in) :: rule
  type(lexeme_t), intent(in) :: lexeme
  character(80) :: buffer
  integer :: u, iostat
  call lexer_show_location (lexer)
  u = free_unit ()
  open (u, status = "scratch")
  write (u, "(A)", advance="no") "Expected syntax:"

```

```

call syntax_rule_write (rule, u)
write (u, "(A)", advance="no") "Found token:"
call lexeme_write (lexeme, u)
rewind (u)
do
  read (u, "(A)", iostat=iostat) buffer
  if (iostat /= 0) exit
  call msg_message (trim (buffer))
end do
call msg_fatal (" Syntax error " &
  // "(at or before the location indicated above)")
end subroutine parse_error

```

The finalizer recursively deallocates all nodes and their contents. For each node, `parse_node_final` is called on the sub-nodes, which in turn deallocates the token or sub-node array contained within each of them. At the end, only the top node remains to be deallocated.

```

(Parser: public)+≡
  public :: parse_tree_final

(Parser: procedures)+≡
  subroutine parse_tree_final (parse_tree)
    type(parse_tree_t), intent(inout) :: parse_tree
    if (associated (parse_tree%root_node)) then
      call parse_node_final (parse_tree%root_node)
      deallocate (parse_tree%root_node)
    end if
  end subroutine parse_tree_final

```

Print the parse tree. Print one token per line, indented according to the depth of the node.

The **verbose** version includes type identifiers for the nodes.

```

(Parser: public)+≡
  public :: parse_tree_write

(Parser: procedures)+≡
  subroutine parse_tree_write (parse_tree, unit, verbose)
    type(parse_tree_t), intent(in) :: parse_tree
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose
    integer :: u
    logical :: short
    u = output_unit (unit); if (u < 0) return
    short = .true.; if (present (verbose)) short = .not. verbose
    write (u, "(A)") "Parse tree:"
    if (associated (parse_tree%root_node)) then
      call parse_node_write_rec (parse_tree%root_node, unit, short, 1)
    else
      write (u, *) "[empty]"
    end if
  end subroutine parse_tree_write

```

This is a generic error that can be issued if the parse tree does not meet the expectations of the parser. This most certainly indicates a bug.

```

(Parser: public)+≡
    public :: parse_tree_bug

(Parser: procedures)+≡
    subroutine parse_tree_bug (node, keys)
        type(parse_node_t), intent(in) :: node
        character(*), intent(in) :: keys
        call parse_node_write (node)
        call msg_bug (" Inconsistency in parse tree: expected " // keys)
    end subroutine parse_tree_bug

```

3.4.7 Access the parser

For scanning the parse tree we give access to the top node, as a node pointer. Of course, there should be no write access.

```

(Parser: public)+≡
    public :: parse_tree_get_root_ptr

(Parser: procedures)+≡
    function parse_tree_get_root_ptr (parse_tree) result (node)
        type(parse_node_t), pointer :: node
        type(parse_tree_t), intent(in), target :: parse_tree
        node => parse_tree%root_node
    end function parse_tree_get_root_ptr

```

3.4.8 Tools

This operation traverses the parse tree and simplifies any occurrences of a set of syntax rules. If such a parse node has only one sub-node, it is replaced by that subnode. (This makes sense only of the rules to eliminate have no meaningful token.)

```

(Parser: public)+≡
    public :: parse_tree_reduce

(Parser: procedures)+≡
    subroutine parse_tree_reduce (parse_tree, rule_key)
        type(parse_tree_t), intent(inout) :: parse_tree
        type(string_t), dimension(:), intent(in) :: rule_key

```

3.5 XML Parser

The XML parser is actually independent from the previous modules of `lexer` and `parser`. However, for a generic I/O interface we make use of the `stream_t` facility.

We need the XML parser for reading and writing LHEF data files. Only a subset of XML is actually relevant. The parser is of the “pull” type, i.e., the program steers the reading of XML data in a context-sensitive manner.

```
<xml.f90>≡
  <File header>

  module xml

    <Use strings>
    <Use file utils>
    use limits, only: BLANK, TAB !NODEP!
    use diagnostics !NODEP!
    use unit_tests
    use ifiles
    use lexers

    <Standard module head>

    <XML: public>

    <XML: types>

    contains

    <XML: procedures>

    <XML: tests>

  end module xml
```

3.5.1 Cached Stream

The stream type as defined in the `lexer` module is versatile regarding the choice of input channel, but it does not allow reading a section more than once. Here, we define an extension where we can return a string to the stream, which is stored in a cache variable, and presented to the caller for the next read.

```
<XML: public>≡
  public :: cstream_t

<XML: types>≡
  type, extends (stream_t) :: cstream_t
    logical :: cache_is_empty = .true.
    type(string_t) :: cache
    contains
    <XML: cstream: TBP>
  end type cstream_t
```

The initializers are simply inherited. We require a generic.

```

<XML: cstream: TBP>≡
  generic :: init => init_filename, init_unit, init_string, &
    init_ifile, init_line
  procedure :: init_filename => cstream_init_filename
  procedure :: init_unit => cstream_init_unit
  procedure :: init_string => cstream_init_string
  procedure :: init_ifile => cstream_init_ifile
  procedure :: init_line => cstream_init_line

<XML: procedures>≡
  subroutine cstream_init_filename (cstream, filename)
    class(cstream_t), intent(out) :: cstream
    character(*), intent(in) :: filename
    call stream_init (cstream%stream_t, filename)
  end subroutine cstream_init_filename

  subroutine cstream_init_unit (cstream, unit)
    class(cstream_t), intent(out) :: cstream
    integer, intent(in) :: unit
    call stream_init (cstream%stream_t, unit)
  end subroutine cstream_init_unit

  subroutine cstream_init_string (cstream, string)
    class(cstream_t), intent(out) :: cstream
    type(string_t), intent(in) :: string
    call stream_init (cstream%stream_t, string)
  end subroutine cstream_init_string

  subroutine cstream_init_ifile (cstream, ifile)
    class(cstream_t), intent(out) :: cstream
    type(ifile_t), intent(in) :: ifile
    call stream_init (cstream%stream_t, ifile)
  end subroutine cstream_init_ifile

  subroutine cstream_init_line (cstream, line)
    class(cstream_t), intent(out) :: cstream
    type(line_p), intent(in) :: line
    call stream_init (cstream%stream_t, line)
  end subroutine cstream_init_line

```

Finalizer: also inherited

```

<XML: cstream: TBP>+≡
  procedure :: final => cstream_final

<XML: procedures>+≡
  subroutine cstream_final (cstream)
    class(cstream_t), intent(inout) :: cstream
    cstream%cache_is_empty = .true.
    call stream_final (cstream%stream_t)
  end subroutine cstream_final

```

Get record: now, if there is a cache string, return this instead of the record from the stream.

```

<XML: cstream: TBP>+=
  procedure :: get_record => cstream_get_record

<XML: procedures>+=
  subroutine cstream_get_record (cstream, string, iostat)
    class(cstream_t), intent(inout) :: cstream
    type(string_t), intent(out) :: string
    integer, intent(out) :: iostat
    if (cstream%cache_is_empty) then
      call stream_get_record (cstream%stream_t, string, iostat)
    else
      string = cstream%cache
      cstream%cache_is_empty = .true.
      iostat = 0
    end if
  end subroutine cstream_get_record

```

Revert: return the (partially read) record to the stream, putting it in the cache.

```

<XML: cstream: TBP>+=
  procedure :: revert_record => cstream_revert_record

<XML: procedures>+=
  subroutine cstream_revert_record (cstream, string)
    class(cstream_t), intent(inout) :: cstream
    type(string_t), intent(in) :: string
    if (cstream%cache_is_empty) then
      cstream%cache = string
      cstream%cache_is_empty = .false.
    else
      call msg_bug ("CStream: attempt to revert twice")
    end if
  end subroutine cstream_revert_record

```

3.5.2 Attributes

A tag attribute has a name and a value; both are strings. When the attribute is defined, the `known` flag indicates this.

```

<XML: types>+=
  type :: attribute_t
    type(string_t) :: name
    type(string_t) :: value
    logical :: known = .false.
  contains
    <XML: attribute: TBP>
  end type attribute_t

```

Output in standard format, non-advancing. (If the value is unknown, we indicate this by a question mark, which is non-standard.)

```

<XML: attribute: TBP>=
  procedure :: write => attribute_write

```

```

<XML: procedures>+≡
  subroutine attribute_write (object, unit)
    class(attribute_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(A,'=')", advance = "no") char (object%name)
    if (object%known) then
      write (u, "(A,A,A)", advance = "no") '""', char (object%value), '''
    else
      write (u, "(?'')", advance = "no")
    end if
  end subroutine attribute_write

```

This is a genuine constructor. The value is optional.

```

<XML: public>+≡
  public :: xml_attribute

<XML: procedures>+≡
  function xml_attribute (name, value) result (attribute)
    type(string_t), intent(in) :: name
    type(string_t), intent(in), optional :: value
    type(attribute_t) :: attribute
    attribute%name = name
    if (present (value)) then
      attribute%value = value
      attribute%known = .true.
    else
      attribute%known = .false.
    end if
  end function xml_attribute

```

Set a value explicitly.

```

<XML: attribute: TBP>+≡
  procedure :: set_value => attribute_set_value

<XML: procedures>+≡
  subroutine attribute_set_value (attribute, value)
    class(attribute_t), intent(inout) :: attribute
    type(string_t), intent(in) :: value
    attribute%value = value
    attribute%known = .true.
  end subroutine attribute_set_value

```

Extract a value. If unset, return "?"

```

<XML: attribute: TBP>+≡
  procedure :: get_value => attribute_get_value

<XML: procedures>+≡
  function attribute_get_value (attribute) result (value)
    class(attribute_t), intent(in) :: attribute
    type(string_t) :: value
    if (attribute%known) then
      value = attribute%value
    end if
  end function attribute_get_value

```

```

3.5.3 The Tag Type

The basic entity is the internal representation of an XML tag. The tag has a name, a well-defined set of attributes which may be mandatory or optional, and a flag that determines whether there is content or not. The content itself is not stored in the data structure.

```

<XML: public>+≡
    public :: xml_tag_t

<XML: types>+≡
    type :: xml_tag_t
        type(string_t) :: name
        type(attribute_t), dimension(:), allocatable :: attribute
        logical :: has_content = .false.
    contains
        <XML: tag: TBP>
    end type xml_tag_t

```

Initialization. There are different versions, depending on content.

```

<XML: tag: TBP>≡
    generic :: init => init_no_attributes
    procedure :: init_no_attributes => tag_init_no_attributes

<XML: procedures>+≡
    subroutine tag_init_no_attributes (tag, name, has_content)
        class(xml_tag_t), intent(out) :: tag
        type(string_t), intent(in) :: name
        logical, intent(in), optional :: has_content
        tag%name = name
        allocate (tag%attribute (0))
        if (present (has_content)) tag%has_content = has_content
    end subroutine tag_init_no_attributes

```

This version sets attributes.

```

<XML: tag: TBP>+≡
    generic :: init => init_with_attributes
    procedure :: init_with_attributes => tag_init_with_attributes

<XML: procedures>+≡
    subroutine tag_init_with_attributes (tag, name, attribute, has_content)
        class(xml_tag_t), intent(out) :: tag
        type(string_t), intent(in) :: name
        type(attribute_t), dimension(:), intent(in) :: attribute
        logical, intent(in), optional :: has_content
        tag%name = name
        allocate (tag%attribute (size (attribute)))
        tag%attribute = attribute
    end subroutine tag_init_with_attributes

```

```

        if (present (has_content)) tag%has_content = has_content
    end subroutine tag_init_with_attributes

```

Set an attribute value explicitly.

```

<XML: tag: TBP>+≡
    procedure :: set_attribute => tag_set_attribute
<XML: procedures>+≡
    subroutine tag_set_attribute (tag, i, value)
        class(xml_tag_t), intent(inout) :: tag
        integer, intent(in) :: i
        type(string_t), intent(in) :: value
        call tag%attribute(i)%set_value (value)
    end subroutine tag_set_attribute

```

Get an attribute value.

```

<XML: tag: TBP>+≡
    procedure :: get_attribute => tag_get_attribute
<XML: procedures>+≡
    function tag_get_attribute (tag, i) result (value)
        class(xml_tag_t), intent(in) :: tag
        integer, intent(in) :: i
        type(string_t) :: value
        value = tag%attribute(i)%get_value ()
    end function tag_get_attribute

```

Output to an I/O unit, default STDOUT. We use non-advancing output.

```

<XML: tag: TBP>+≡
    generic :: write => write_without_content
    procedure :: write_without_content => tag_write
<XML: procedures>+≡
    subroutine tag_write (tag, unit)
        class(xml_tag_t), intent(in) :: tag
        integer, intent(in), optional :: unit
        integer :: u, i
        u = output_unit (unit)
        write (u, "('<',A)", advance = "no") char (tag%name)
        do i = 1, size (tag%attribute)
            write (u, "(ix)", advance = "no")
            call tag%attribute(i)%write (u)
        end do
        if (tag%has_content) then
            write (u, "('>')", advance = "no")
        else
            write (u, "(' />')", advance = "no")
        end if
    end subroutine tag_write

```

If there is content, we should write the context next (arbitrary format), the write the corresponding closing tag. Again, non-advancing.

```

<XML: tag: TBP>+≡
    procedure :: close => tag_close

```

```

<XML: procedures>+≡
  subroutine tag_close (tag, unit)
    class(xml_tag_t), intent(in) :: tag
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "('</',A,'>')", advance = "no") char (tag%name)
  end subroutine tag_close

```

Given content as a single string, we can write tag, content, and closing at once

```

<XML: tag: TBP>+≡
  generic :: write => write_with_content
  procedure :: write_with_content => tag_write_with_content

<XML: procedures>+≡
  subroutine tag_write_with_content (tag, content, unit)
    class(xml_tag_t), intent(in) :: tag
    type(string_t), intent(in) :: content
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    call tag%write (u)
    write (u, "(A)", advance = "no") char (content)
    call tag%close (u)
  end subroutine tag_write_with_content

```

Input from stream. We know what we are looking for, so we check if the name matches, then fill attributes. We report an error if (a) an I/O error occurs, (b) we reach EOF before encountering the tag, (c) if the tag is incomplete.

Trailing text after reading a tag is put back to the input stream.

We assume that the tag is not broken across records, and that there is only one tag within the record. This is more restricted than standard XML.

```

<XML: tag: TBP>+≡
  procedure :: read => tag_read

<XML: procedures>+≡
  subroutine tag_read (tag, cstream, success)
    class(xml_tag_t), intent(inout) :: tag
    type(cstream_t), intent(inout) :: cstream
    logical, intent(out) :: success

                xml_attribute (var_str ("a2"), var_str ("bar"))])
call tag%read (cstream, success)
call tag%write (u)
write (u, *)
deallocate (tag)
call cstream%final ()

write (u, "(A)")
write (u, "(A)") "* Test output end: xml_4"

end subroutine xml_4

```

Chapter 4

Physics library

This part consists of two modules:

constants Physical and mathematical parameters that never change. The file has been moved to the **src/misc** subdirectory of the **WHIZARD** project.

c_particles A simple data type for particles which is C compatible.

lorentz Define three-vectors, four-vectors and Lorentz transformations and common operations for them.

sm_physics Here, running functions are stored for special kinematical setup like running coupling constants, Catani-Seymour dipoles, or Sudakov factors.

4.1 C-compatible Particle Type

For easy communication with C code, we introduce a simple C-compatible type for particles. It has the contents of the `prt_t` type defined in the `subevents` module below (except the source information).

The `c_prt` type is transparent, and its contents should be regarded as part of the interface.

```

⟨c_particles.f90⟩≡
  ⟨File header⟩

  module c_particles

    use iso_c_binding !NODEP!
    ⟨Use file utils⟩

    ⟨Standard module head⟩

    ⟨C Particles: public⟩

    ⟨C Particles: types⟩

    contains

    ⟨C Particles: procedures⟩
  end module c_particles

⟨C Particles: public⟩≡
  public :: c_prt_t

⟨C Particles: types⟩≡
  type, bind(C) :: c_prt_t
    integer(c_int) :: type = 0
    integer(c_int) :: pdg = 0
    integer(c_int) :: polarized = 0
    integer(c_int) :: h = 0
    real(c_double) :: pe = 0
    real(c_double) :: px = 0
    real(c_double) :: py = 0
    real(c_double) :: pz = 0
    real(c_double) :: p2 = 0
  end type c_prt_t

```

This is for debugging only, there is no C binding. It is a simplified version of `prt_write`.

```

⟨C Particles: public⟩+≡
  public :: c_prt_write

⟨C Particles: procedures⟩≡
  subroutine c_prt_write (prt, unit)
    type(c_prt_t), intent(in) :: prt
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit); if (u < 0) return
    write (u, "(1x,A)", advance="no") "prt("

```

```

write (u, "(I0,':')", advance="no") prt%type
if (prt%polarized /= 0) then
  write (u, "(I0,'/',I0,'|')", advance="no") prt%pdg, prt%h
else
  write (u, "(I0,'|')", advance="no") prt%pdg
end if
write (u, "(ES14.7,';',ES14.7,';',ES14.7,';',ES14.7)", advance="no") &
  prt%pe, prt%px, prt%py, prt%pz
write (u, "('|',ES19.12)", advance="no") prt%p2
write (u, "(A)" " ")
end subroutine c_prt_write

```

4.2 Lorentz algebra

Define Lorentz vectors, three-vectors, boosts, and some functions to manipulate them.

To make maximum use of this, all functions, if possible, are declared elemental (or pure, if this is not possible).

```
<lorentz.f90>≡  
  <File header>  
  
  module lorentz  
  
    <Use kinds>  
    use constants, only: pi, twopi, degree !NODEP!  
    <Use file utils>  
    use diagnostics !NODEP!  
    use c_particles  
  
    <Standard module head>  
  
    <Lorentz: public>  
  
    <Lorentz: public operators>  
  
    <Lorentz: public functions>  
  
    <Lorentz: types>  
  
    <Lorentz: parameters>  
  
    <Lorentz: interfaces>  
  
    contains  
  
    <Lorentz: procedures>  
  end module lorentz
```

4.2.1 Three-vectors

First of all, let us introduce three-vectors in a trivial way. The functions and overloaded elementary operations clearly are too much overhead, but we like to keep the interface for three-vectors and four-vectors exactly parallel. By the way, we might attach a label to a vector by extending the type definition later.

```
<Lorentz: public>≡  
  public :: vector3_t  
  
<Lorentz: types>≡  
  type :: vector3_t  
    private  
    real(default), dimension(3) :: p  
  end type vector3_t
```

Output a vector

```

(Lorentz: public)+≡
    public :: vector3_write

(Lorentz: procedures)≡
    subroutine vector3_write (p, unit)
        type(vector3_t), intent(in) :: p
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit); if (u < 0) return
        write(u, 1) 'P = ', p%p
    1    format (1x,A,3(1x,ES19.12))
    end subroutine vector3_write

```

This is a three-vector with zero components

```

(Lorentz: public)+≡
    public :: vector3_null

(Lorentz: parameters)≡
    type(vector3_t), parameter :: vector3_null = &
        vector3_t ((/ 0._default, 0._default, 0._default /))

```

Canonical three-vector:

```

(Lorentz: public)+≡
    public :: vector3_canonical

(Lorentz: procedures)+≡
    elemental function vector3_canonical (k) result (p)
        type(vector3_t) :: p
        integer, intent(in) :: k
        p = vector3_null
        p%p(k) = 1
    end function vector3_canonical

```

A moving particle (k -axis, or arbitrary axis). Note that the function for the generic momentum cannot be elemental.

```

(Lorentz: public)+≡
    public :: vector3_moving

(Lorentz: interfaces)≡
    interface vector3_moving
        module procedure vector3_moving_canonical
        module procedure vector3_moving_generic
    end interface

(Lorentz: procedures)+≡
    elemental function vector3_moving_canonical (p, k) result(q)
        type(vector3_t) :: q
        real(default), intent(in) :: p
        integer, intent(in) :: k
        q = vector3_null
        q%p(k) = p
    end function vector3_moving_canonical
    pure function vector3_moving_generic (p) result(q)

```

```

    real(default), dimension(3), intent(in) :: p
    type(vector3_t) :: q
    q%p = p
end function vector3_moving_generic

```

Equality and inequality

```

<Lorentz: public operators>≡
    public :: operator(==), operator(/=)

<Lorentz: interfaces>+≡
    interface operator(==)
        module procedure vector3_eq
    end interface
    interface operator(/=)
        module procedure vector3_neq
    end interface

<Lorentz: procedures>+≡
    elemental function vector3_eq (p, q) result (r)
        logical :: r
        type(vector3_t), intent(in) :: p,q
        r = all (p%p == q%p)
    end function vector3_eq
    elemental function vector3_neq (p, q) result (r)
        logical :: r
        type(vector3_t), intent(in) :: p,q
        r = any (p%p /= q%p)
    end function vector3_neq

```

Define addition and subtraction

```

<Lorentz: public operators>+≡
    public :: operator(+), operator(-)

<Lorentz: interfaces>+≡
    interface operator(+)
        module procedure add_vector3
    end interface
    interface operator(-)
        module procedure sub_vector3
    end interface

<Lorentz: procedures>+≡
    elemental function add_vector3 (p, q) result (r)
        type(vector3_t) :: r
        type(vector3_t), intent(in) :: p,q
        r%p = p%p + q%p
    end function add_vector3
    elemental function sub_vector3 (p, q) result (r)
        type(vector3_t) :: r
        type(vector3_t), intent(in) :: p,q
        r%p = p%p - q%p
    end function sub_vector3

```

The multiplication sign is overloaded with scalar multiplication; similarly division:

```

(Lorentz: public operators)+≡
    public :: operator(*), operator(/)

(Lorentz: interfaces)+≡
    interface operator(*)
        module procedure prod_integer_vector3, prod_vector3_integer
        module procedure prod_real_vector3, prod_vector3_real
    end interface
    interface operator(/)
        module procedure div_vector3_real, div_vector3_integer
    end interface

(Lorentz: procedures)+≡
    elemental function prod_real_vector3 (s, p) result (q)
        type(vector3_t) :: q
        real(default), intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = s * p%p
    end function prod_real_vector3
    elemental function prod_vector3_real (p, s) result (q)
        type(vector3_t) :: q
        real(default), intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = s * p%p
    end function prod_vector3_real
    elemental function div_vector3_real (p, s) result (q)
        type(vector3_t) :: q
        real(default), intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = p%p/s
    end function div_vector3_real
    elemental function prod_integer_vector3 (s, p) result (q)
        type(vector3_t) :: q
        integer, intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = s * p%p
    end function prod_integer_vector3
    elemental function prod_vector3_integer (p, s) result (q)
        type(vector3_t) :: q
        integer, intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = s * p%p
    end function prod_vector3_integer
    elemental function div_vector3_integer (p, s) result (q)
        type(vector3_t) :: q
        integer, intent(in) :: s
        type(vector3_t), intent(in) :: p
        q%p = p%p/s
    end function div_vector3_integer

```

The multiplication sign can also indicate scalar products:

```

(Lorentz: interfaces)+≡

```

```

interface operator(*)
  module procedure prod_vector3
end interface

<Lorentz: procedures>+≡
  elemental function prod_vector3 (p, q) result (s)
    real(default) :: s
    type(vector3_t), intent(in) :: p,q
    s = dot_product (p%p, q%p)
  end function prod_vector3

<Lorentz: public functions>≡
  public :: cross_product

<Lorentz: interfaces>+≡
  interface cross_product
    module procedure vector3_cross_product
  end interface

<Lorentz: procedures>+≡
  elemental function vector3_cross_product (p, q) result (r)
    type(vector3_t) :: r
    type(vector3_t), intent(in) :: p,q
    integer :: i
    do i=1,3
      r%p(i) = dot_product (p%p, matmul(epsilon_three(i,:,:), q%p))
    end do
  end function vector3_cross_product

```

Exponentiation is defined only for integer powers. Odd powers mean take the square root; so `p**1` is the length of `p`.

```

<Lorentz: public operators>+≡
  public :: operator(**)

<Lorentz: interfaces>+≡
  interface operator(**)
    module procedure power_vector3
  end interface

<Lorentz: procedures>+≡
  elemental function power_vector3 (p, e) result (s)
    real(default) :: s
    type(vector3_t), intent(in) :: p
    integer, intent(in) :: e
    s = dot_product (p%p, p%p)
    if (e/=2) then
      if (mod(e,2)==0) then
        s = s**(e/2)
      else
        s = sqrt(s)**e
      end if
    end if
  end function power_vector3

```

Finally, we need a negation.

```

<Lorentz: interfaces>+≡
  interface operator(-)
    module procedure negate_vector3
  end interface

<Lorentz: procedures>+≡
  elemental function negate_vector3 (p) result (q)
    type(vector3_t) :: q
    type(vector3_t), intent(in) :: p
    integer :: i
    do i = 1, 3
      if (p%p(i) == -p%p(i)) then
        q%p(i) = 0
      else
        q%p(i) = -p%p(i)
      end if
    end do
  end function negate_vector3

```

The sum function can be useful:

```

<Lorentz: public functions>+≡
  public :: sum

<Lorentz: interfaces>+≡
  interface sum
    module procedure sum_vector3
  end interface

<Lorentz: procedures>+≡
  pure function sum_vector3 (p) result (q)
    type(vector3_t) :: q
    type(vector3_t), dimension(:), intent(in) :: p
    integer :: i
    do i=1, 3
      q%p(i) = sum (p%p(i))
    end do
  end function sum_vector3

```

Any component:

```

<Lorentz: public>+≡
  public :: vector3_get_component

<Lorentz: procedures>+≡
  elemental function vector3_get_component (p, k) result (c)
    type(vector3_t), intent(in) :: p
    integer, intent(in) :: k
    real(default) :: c
    c = p%p(k)
  end function vector3_get_component

```

Extract all components. This is not elemental.

```

<Lorentz: public>+≡
  public :: vector3_get_components

```

```

<Lorentz: procedures>+≡
  pure function vector3_get_components (p) result (a)
    type(vector3_t), intent(in) :: p
    real(default), dimension(3) :: a
    a = p%p
  end function vector3_get_components

```

This function returns the direction of a three-vector, i.e., a normalized three-vector. If the vector is null, we return a null vector.

```

<Lorentz: public functions>+≡
  public :: direction

<Lorentz: interfaces>+≡
  interface direction
    module procedure vector3_get_direction
  end interface

<Lorentz: procedures>+≡
  elemental function vector3_get_direction (p) result (q)
    type(vector3_t) :: q
    type(vector3_t), intent(in) :: p
    real(default) :: pp
    pp = p**1
    if (pp /= 0) then
      q%p = p%p / pp
    else
      q%p = 0
    end if
  end function vector3_get_direction

```

4.2.2 Four-vectors

In four-vectors the zero-component needs special treatment, therefore we do not use the standard operations. Sure, we pay for the extra layer of abstraction by losing efficiency; so we have to assume that the time-critical applications do not involve four-vector operations.

```

<Lorentz: public>+≡
  public :: vector4_t

<Lorentz: types>+≡
  type :: vector4_t
  private
    real(default), dimension(0:3) :: p = &
      (/ 0._default, 0._default, 0._default, 0._default /)
  end type vector4_t

```

Output a vector

```

<Lorentz: public>+≡
  public :: vector4_write

```

<Lorentz: procedures>+≡

```

subroutine vector4_write (p, unit, show_mass)
  type(vector4_t), intent(in) :: p
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: show_mass
  integer :: u
  u = output_unit (unit); if (u < 0) return
  write(u, 1) 'E = ', p%p(0)
  write(u, 1) 'P = ', p%p(1:)
  if (present (show_mass)) then
    if (show_mass) &
      write (u, 1) 'M = ', p**1
  end if
1  format (1x,A,3(1x,ES19.12))
end subroutine vector4_write

```

Binary I/O

<Lorentz: public>+≡

```

public :: vector4_write_raw
public :: vector4_read_raw

```

<Lorentz: procedures>+≡

```

subroutine vector4_write_raw (p, u)
  type(vector4_t), intent(in) :: p
  integer, intent(in) :: u
  write (u) p%p
end subroutine vector4_write_raw

subroutine vector4_read_raw (p, u, iostat)
  type(vector4_t), intent(out) :: p
  integer, intent(in) :: u
  integer, intent(out), optional :: iostat
  read (u, iostat=iostat) p%p
end subroutine vector4_read_raw

```

This is a four-vector with zero components

<Lorentz: public>+≡

```

public :: vector4_null

```

<Lorentz: parameters>+≡

```

type(vector4_t), parameter :: vector4_null = &
  vector4_t ((/ 0._default, 0._default, 0._default, 0._default /))

```

Canonical four-vector:

<Lorentz: public>+≡

```

public :: vector4_canonical

```

<Lorentz: procedures>+≡

```

elemental function vector4_canonical (k) result (p)
  type(vector4_t) :: p
  integer, intent(in) :: k
  p = vector4_null
  p%p(k) = 1
end function vector4_canonical

```

A particle at rest:

```

(Lorentz: public)+≡
    public :: vector4_at_rest

(Lorentz: procedures)+≡
    elemental function vector4_at_rest (m) result (p)
        type(vector4_t) :: p
        real(default), intent(in) :: m
        p = vector4_t ((/ m, 0._default, 0._default, 0._default /))
    end function vector4_at_rest

```

A moving particle (k -axis, or arbitrary axis)

```

(Lorentz: public)+≡
    public :: vector4_moving

(Lorentz: interfaces)+≡
    interface vector4_moving
        module procedure vector4_moving_canonical
        module procedure vector4_moving_generic
    end interface

(Lorentz: procedures)+≡
    elemental function vector4_moving_canonical (E, p, k) result (q)
        type(vector4_t) :: q
        real(default), intent(in) :: E, p
        integer, intent(in) :: k
        q = vector4_at_rest(E)
        q%p(k) = p
    end function vector4_moving_canonical
    elemental function vector4_moving_generic (E, p) result (q)
        type(vector4_t) :: q
        real(default), intent(in) :: E
        type(vector3_t), intent(in) :: p
        q%p(0) = E
        q%p(1:) = p%p
    end function vector4_moving_generic

```

Equality and inequality

```

(Lorentz: interfaces)+≡
    interface operator(==)
        module procedure vector4_eq
    end interface
    interface operator(/=)
        module procedure vector4_neq
    end interface

(Lorentz: procedures)+≡
    elemental function vector4_eq (p, q) result (r)
        logical :: r
        type(vector4_t), intent(in) :: p,q
        r = all (p%p == q%p)
    end function vector4_eq
    elemental function vector4_neq (p, q) result (r)
        logical :: r
        type(vector4_t), intent(in) :: p,q

```

```

    r = any (p%p /= q%p)
end function vector4_neq

```

Addition and subtraction:

```

(Lorentz: interfaces)+≡
    interface operator(+)
        module procedure add_vector4
    end interface
    interface operator(-)
        module procedure sub_vector4
    end interface

(Lorentz: procedures)+≡
    elemental function add_vector4 (p,q) result (r)
        type(vector4_t) :: r
        type(vector4_t), intent(in) :: p,q
        r%p = p%p + q%p
    end function add_vector4
    elemental function sub_vector4 (p,q) result (r)
        type(vector4_t) :: r
        type(vector4_t), intent(in) :: p,q
        r%p = p%p - q%p
    end function sub_vector4

```

We also need scalar multiplication and division:

```

(Lorentz: interfaces)+≡
    interface operator(*)
        module procedure prod_real_vector4, prod_vector4_real
        module procedure prod_integer_vector4, prod_vector4_integer
    end interface
    interface operator(/)
        module procedure div_vector4_real
        module procedure div_vector4_integer
    end interface

(Lorentz: procedures)+≡
    elemental function prod_real_vector4 (s, p) result (q)
        type(vector4_t) :: q
        real(default), intent(in) :: s
        type(vector4_t), intent(in) :: p
        q%p = s * p%p
    end function prod_real_vector4
    elemental function prod_vector4_real (p, s) result (q)
        type(vector4_t) :: q
        real(default), intent(in) :: s
        type(vector4_t), intent(in) :: p
        q%p = s * p%p
    end function prod_vector4_real
    elemental function div_vector4_real (p, s) result (q)
        type(vector4_t) :: q
        real(default), intent(in) :: s
        type(vector4_t), intent(in) :: p
        q%p = p%p/s
    end function div_vector4_real

```

```

elemental function prod_integer_vector4 (s, p) result (q)
  type(vector4_t) :: q
  integer, intent(in) :: s
  type(vector4_t), intent(in) :: p
  q%p = s * p%p
end function prod_integer_vector4
elemental function prod_vector4_integer (p, s) result (q)
  type(vector4_t) :: q
  integer, intent(in) :: s
  type(vector4_t), intent(in) :: p
  q%p = s * p%p
end function prod_vector4_integer
elemental function div_vector4_integer (p, s) result (q)
  type(vector4_t) :: q
  integer, intent(in) :: s
  type(vector4_t), intent(in) :: p
  q%p = p%p/s
end function div_vector4_integer

```

Scalar products and squares in the Minkowski sense:

```

(Lorentz: interfaces)+≡
  interface operator(*)
    module procedure prod_vector4
  end interface
  interface operator(**)
    module procedure power_vector4
  end interface

(Lorentz: procedures)+≡
  elemental function prod_vector4 (p, q) result (s)
    real(default) :: s
    type(vector4_t), intent(in) :: p,q
    s = p%p(0)*q%p(0) - dot_product(p%p(1:), q%p(1:))
  end function prod_vector4

```

The power operation for four-vectors is signed, i.e., p^{**1} is positive for timelike and negative for spacelike vectors. Note that $(p^{**1})^{**2}$ is not necessarily equal to p^{**2} .

```

(Lorentz: procedures)+≡
  elemental function power_vector4 (p, e) result (s)
    real(default) :: s
    type(vector4_t), intent(in) :: p
    integer, intent(in) :: e
    s = p*p
    if (e/=2) then
      if (mod(e,2)==0) then
        s = s**(e/2)
      elseif (s>=0) then
        s = sqrt(s)**e
      else
        s = -(sqrt(abs(s))**e)
      end if
    end if
  end if

```

```
end function power_vector4
```

Finally, we introduce a negation

```
<Lorentz: interfaces>+≡
  interface operator(-)
    module procedure negate_vector4
  end interface
<Lorentz: procedures>+≡
  elemental function negate_vector4 (p) result (q)
    type(vector4_t) :: q
    type(vector4_t), intent(in) :: p
    integer :: i
    do i = 0, 3
      if (p%p(i) == -p%p(i)) then
        q%p(i) = 0
      else
        q%p(i) = -p%p(i)
      end if
    end do
  end function negate_vector4
```

The sum function can be useful:

```
<Lorentz: interfaces>+≡
  interface sum
    module procedure sum_vector4
  end interface
```

There used to be a mask here, but the Intel compiler crashes with it

```
<Lorentz: procedures>+≡
  pure function sum_vector4 (p) result (q)
    type(vector4_t) :: q
    type(vector4_t), dimension(:), intent(in) :: p
    integer :: i
    do i=0, 3
      q%p(i) = sum (p%p(i))
    end do
  end function sum_vector4
!   pure function sum_vector4_mask (p, mask) result (q)
!     type(vector4_t) :: q
!     type(vector4_t), dimension(:), intent(in) :: p
!     logical, dimension(:), intent(in) :: mask
!     integer :: i
!     do i=0, 3
!       q%p(i) = sum (p%p(i), mask=mask)
!     end do
!   end function sum_vector4_mask
```

4.2.3 Conversions

Manually set a component of the four-vector:

```
<Lorentz: public>+≡
  public :: vector4_set_component
```

```

<Lorentz: procedures>+≡
  subroutine vector4_set_component (p, k, c)
    type(vector4_t), intent(inout) :: p
    integer, intent(in) :: k
    real(default), intent(in) :: c
    p%p(k) = c
  end subroutine vector4_set_component

```

Any component:

```

<Lorentz: public>+≡
  public :: vector4_get_component

<Lorentz: procedures>+≡
  elemental function vector4_get_component (p, k) result (c)
    real(default) :: c
    type(vector4_t), intent(in) :: p
    integer, intent(in) :: k
    c = p%p(k)
  end function vector4_get_component

```

Extract all components. This is not elemental.

```

<Lorentz: public>+≡
  public :: vector4_get_components

<Lorentz: procedures>+≡
  pure function vector4_get_components (p) result (a)
    real(default), dimension(0:3) :: a
    type(vector4_t), intent(in) :: p
    a = p%p
  end function vector4_get_components

```

This function returns the space part of a four-vector, such that we can apply three-vector operations on it:

```

<Lorentz: public functions>+≡
  public :: space_part

<Lorentz: interfaces>+≡
  interface space_part
    module procedure vector4_get_space_part
  end interface

<Lorentz: procedures>+≡
  elemental function vector4_get_space_part (p) result (q)
    type(vector3_t) :: q
    type(vector4_t), intent(in) :: p
    q%p = p%p(1:)
  end function vector4_get_space_part

```

This function returns the direction of a four-vector, i.e., a normalized three-vector. If the four-vector has zero space part, we return a null vector.

```

<Lorentz: interfaces>+≡
  interface direction
    module procedure vector4_get_direction
  end interface

```

```

(Lorentz: procedures)+≡
  elemental function vector4_get_direction (p) result (q)
    type(vector3_t) :: q
    type(vector4_t), intent(in) :: p
    real(default) :: qq
    q%p = p%p(1:)
    qq = q**1
    if (qq /= 0) then
      q%p = q%p / qq
    else
      q%p = 0
    end if
  end function vector4_get_direction

```

This function returns the four-vector as an ordinary array. A second version for an array of four-vectors.

```

(Lorentz: public functions)+≡
  public :: array_from_vector4

(Lorentz: interfaces)+≡
  interface array_from_vector4
    module procedure array_from_vector4_1
    module procedure array_from_vector4_2
  end interface

(Lorentz: procedures)+≡
  pure function array_from_vector4_1 (p) result (a)
    type(vector4_t), intent(in) :: p
    real(default), dimension(0:3) :: a
    a = p%p
  end function array_from_vector4_1

  pure function array_from_vector4_2 (p) result (a)
    type(vector4_t), dimension(:), intent(in) :: p
    real(default), dimension(0:3, size(p)) :: a
    integer :: i
    forall (i=1:size(p))
      a(0:3,i) = p(i)%p
    end forall
  end function array_from_vector4_2

```

Transform the momentum of a `c_prt` object into a four-vector:

```

(Lorentz: public)+≡
  public :: vector4_from_c_prt

(Lorentz: procedures)+≡
  elemental function vector4_from_c_prt (c_prt) result (p)
    type(vector4_t) :: p
    type(c_prt_t), intent(in) :: c_prt
    p%p(0) = c_prt%pe
    p%p(1) = c_prt%px
    p%p(2) = c_prt%py
    p%p(3) = c_prt%pz
  end function vector4_from_c_prt

```

Initialize a `c_prt_t` object with the components of a four-vector as its kinematical entries. Compute the invariant mass, or use the optional mass-squared value instead.

```

(Lorentz: public)+≡
    public :: vector4_to_c_prt

(Lorentz: procedures)+≡
    elemental function vector4_to_c_prt (p, p2) result (c_prt)
        type(c_prt_t) :: c_prt
        type(vector4_t), intent(in) :: p
        real(default), intent(in), optional :: p2
        c_prt%pe = p%p(0)
        c_prt%px = p%p(1)
        c_prt%py = p%p(2)
        c_prt%pz = p%p(3)
        if (present (p2)) then
            c_prt%p2 = p2
        else
            c_prt%p2 = p ** 2
        end if
    end function vector4_to_c_prt

```

4.2.4 Angles

Return the angles in a canonical system. The angle ϕ is defined between $0 \leq \phi < 2\pi$. In degenerate cases, return zero.

```

(Lorentz: public functions)+≡
    public :: azimuthal_angle

(Lorentz: interfaces)+≡
    interface azimuthal_angle
        module procedure vector3_azimuthal_angle
        module procedure vector4_azimuthal_angle
    end interface

(Lorentz: procedures)+≡
    elemental function vector3_azimuthal_angle (p) result (phi)
        real(default) :: phi
        type(vector3_t), intent(in) :: p
        if (any(p%p(1:2)/=0)) then
            phi = atan2(p%p(2), p%p(1))
            if (phi < 0) phi = phi + twopi
        else
            phi = 0
        end if
    end function vector3_azimuthal_angle
    elemental function vector4_azimuthal_angle (p) result (phi)
        real(default) :: phi
        type(vector4_t), intent(in) :: p
        phi = vector3_azimuthal_angle (space_part (p))
    end function vector4_azimuthal_angle

```

Azimuthal angle in degrees

```

(Lorentz: public functions)+≡
    public :: azimuthal_angle_deg

(Lorentz: interfaces)+≡
    interface azimuthal_angle_deg
        module procedure vector3_azimuthal_angle_deg
        module procedure vector4_azimuthal_angle_deg
    end interface

(Lorentz: procedures)+≡
    elemental function vector3_azimuthal_angle_deg (p) result (phi)
        real(default) :: phi
        type(vector3_t), intent(in) :: p
        phi = vector3_azimuthal_angle (p) / degree
    end function vector3_azimuthal_angle_deg
    elemental function vector4_azimuthal_angle_deg (p) result (phi)
        real(default) :: phi
        type(vector4_t), intent(in) :: p
        phi = vector4_azimuthal_angle (p) / degree
    end function vector4_azimuthal_angle_deg

```

The azimuthal distance of two vectors. This is the difference of the azimuthal angles, but cannot be larger than π : The result is between $-\pi < \Delta\phi \leq \pi$.

```

(Lorentz: public functions)+≡
    public :: azimuthal_distance

(Lorentz: interfaces)+≡
    interface azimuthal_distance
        module procedure vector3_azimuthal_distance
        module procedure vector4_azimuthal_distance
    end interface

(Lorentz: procedures)+≡
    elemental function vector3_azimuthal_distance (p, q) result (dphi)
        real(default) :: dphi
        type(vector3_t), intent(in) :: p,q
        dphi = vector3_azimuthal_angle (q) - vector3_azimuthal_angle (p)
        if (dphi <= -pi) then
            dphi = dphi + twopi
        else if (dphi > pi) then
            dphi = dphi - twopi
        end if
    end function vector3_azimuthal_distance
    elemental function vector4_azimuthal_distance (p, q) result (dphi)
        real(default) :: dphi
        type(vector4_t), intent(in) :: p,q
        dphi = vector3_azimuthal_distance &
            (space_part (p), space_part (q))
    end function vector4_azimuthal_distance

```

The same in degrees:

```

(Lorentz: public functions)+≡
    public :: azimuthal_distance_deg

```

```

<Lorentz: interfaces>+≡
  interface azimuthal_distance_deg
    module procedure vector3_azimuthal_distance_deg
    module procedure vector4_azimuthal_distance_deg
  end interface
<Lorentz: procedures>+≡
  elemental function vector3_azimuthal_distance_deg (p, q) result (dphi)
    real(default) :: dphi
    type(vector3_t), intent(in) :: p,q
    dphi = vector3_azimuthal_distance (p, q) / degree
  end function vector3_azimuthal_distance_deg
  elemental function vector4_azimuthal_distance_deg (p, q) result (dphi)
    real(default) :: dphi
    type(vector4_t), intent(in) :: p,q
    dphi = vector4_azimuthal_distance (p, q) / degree
  end function vector4_azimuthal_distance_deg

```

The polar angle is defined $0 \leq \theta \leq \pi$. Note that ATAN2 has the reversed order of arguments: ATAN2(Y,X). Here, x is the 3-component while y is the transverse momentum which is always nonnegative. Therefore, the result is nonnegative as well.

```

<Lorentz: public functions>+≡
  public :: polar_angle
<Lorentz: interfaces>+≡
  interface polar_angle
    module procedure polar_angle_vector3
    module procedure polar_angle_vector4
  end interface
<Lorentz: procedures>+≡
  elemental function polar_angle_vector3 (p) result (theta)
    real(default) :: theta
    type(vector3_t), intent(in) :: p
    if (any(p%p/=0)) then
      theta = atan2 (sqrt(p%p(1)**2 + p%p(2)**2), p%p(3))
    else
      theta = 0
    end if
  end function polar_angle_vector3
  elemental function polar_angle_vector4 (p) result (theta)
    real(default) :: theta
    type(vector4_t), intent(in) :: p
    theta = polar_angle (space_part (p))
  end function polar_angle_vector4

```

This is the cosine of the polar angle: $-1 \leq \cos \theta \leq 1$.

```

<Lorentz: public functions>+≡
  public :: polar_angle_ct
<Lorentz: interfaces>+≡
  interface polar_angle_ct
    module procedure polar_angle_ct_vector3
    module procedure polar_angle_ct_vector4
  end interface

```

```

<Lorentz: procedures>+≡
  elemental function polar_angle_ct_vector3 (p) result (ct)
    real(default) :: ct
    type(vector3_t), intent(in) :: p
    if (any(p%p/=0)) then
      ct = p%p(3) / p**1
    else
      ct = 1
    end if
  end function polar_angle_ct_vector3
  elemental function polar_angle_ct_vector4 (p) result (ct)
    real(default) :: ct

        IL%L(1:,1:) = transpose(L%L(1:,1:))
    end function lorentz_transformation_inverse

```

4.2.8 Invariants

These are used below. The first array index is varying fastest in FORTRAN; therefore the extra minus in the odd-rank tensor epsilon.

```

<Lorentz: parameters>+≡
    integer, dimension(3,3), parameter :: delta_three = &
        & reshape( source = (/ 1,0,0, 0,1,0, 0,0,1 /), &
        & shape = (/3,3/) )
    integer, dimension(3,3,3), parameter :: epsilon_three = &
        & reshape( source = (/ 0, 0,0, 0,0,-1, 0,1,0,&
        & 0, 0,1, 0,0, 0, -1,0,0,&
        & 0,-1,0, 1,0, 0, 0,0,0 /),&
        & shape = (/3,3,3/) )

```

This could be of some use:

```

<Lorentz: public>+≡
    public :: identity

<Lorentz: parameters>+≡
    type(lorentz_transformation_t), parameter :: &
        & identity = &
        & lorentz_transformation_t ( &
        & reshape( source = (/ 1._default, 0._default, 0._default, 0._default, &
        & 0._default, 1._default, 0._default, 0._default, &
        & 0._default, 0._default, 1._default, 0._default, &
        & 0._default, 0._default, 0._default, 1._default /),&
        & shape = (/ 4,4 /) ) )

```

```

(Lorentz: public)+≡
  public :: space_reflection

(Lorentz: parameters)+≡
  type(lorentz_transformation_t), parameter :: &
    & space_reflection = &
    & lorentz_transformation_t ( &
    & reshape( source = (/ 1._default, 0._default, 0._default, 0._default, &
    &                                0._default,-1._default, 0._default, 0._default, &
    &                                0._default, 0._default,-1._default, 0._default, &
    &                                0._default, 0._default, 0._default,-1._default /),&
    &                                shape = (/ 4,4 /) ) )

```

4.2.9 Boosts

We build Lorentz transformations from boosts and rotations. In both cases we can supply a three-vector which defines the axis and (hyperbolic) angle. For a boost, this is the vector $\vec{\beta} = \vec{p}/E$, such that a particle at rest with mass m is boosted to a particle with three-vector \vec{p} . Here, we have

$$\beta = \tanh \chi = p/E, \quad \gamma = \cosh \chi = E/m, \quad \beta\gamma = \sinh \chi = p/m \quad (4.1)$$

```

(Lorentz: public functions)+≡
  public :: boost

(Lorentz: interfaces)+≡
  interface boost
    module procedure boost_from_rest_frame
    module procedure boost_from_rest_frame_vector3
    module procedure boost_generic
    module procedure boost_canonical
  end interface

```

In the first form, the argument is some four-momentum, the space part of which determines a direction, and the associated mass (which is not checked against the four-momentum). The boost vector $\gamma\vec{\beta}$ is then given by \vec{p}/m . This boosts from the rest frame of a particle to the current frame. To be explicit, if \vec{p} is the momentum of a particle and m its mass, $L(\vec{p}/m)$ is the transformation that turns $(m; \vec{0})$ into $(E; \vec{p})$. Conversely, the inverse transformation boosts a vector *into* the rest frame of a particle, in particular $(E; \vec{p})$ into $(m; \vec{0})$.

```

(Lorentz: procedures)+≡
  elemental function boost_from_rest_frame (p, m) result (L)
    type(lorentz_transformation_t) :: L
    type(vector4_t), intent(in) :: p
    real(default), intent(in) :: m
    L = boost_from_rest_frame_vector3 (space_part (p), m)
  end function boost_from_rest_frame
  elemental function boost_from_rest_frame_vector3 (p, m) result (L)
    type(lorentz_transformation_t) :: L
    type(vector3_t), intent(in) :: p
    real(default), intent(in) :: m
    type(vector3_t) :: beta_gamma
    real(default) :: bg2, g, c
    integer :: i,j

```

```

if (m /= 0) then
  beta_gamma = p / m
  bg2 = beta_gamma**2
else
  bg2 = 0
end if
if (bg2 /= 0) then
  g = sqrt(1 + bg2); c = (g-1)/bg2
  L%L(0,0) = g
  L%L(0,1:) = beta_gamma%p
  L%L(1:,0) = L%L(0,1:)
  do i=1,3
    do j=1,3
      L%L(i,j) = delta_three(i,j) + c*beta_gamma%p(i)*beta_gamma%p(j)
    end do
  end do
else
  L = identity
end if
end function boost_from_rest_frame_vector3

```

A canonical boost is a boost along one of the coordinate axes, which we may supply as an integer argument. Here, $\gamma\beta$ is scalar.

(*Lorentz: procedures*) +=

```

elemental function boost_canonical (beta_gamma, k) result (L)
  type(lorentz_transformation_t) :: L
  real(default), intent(in) :: beta_gamma
  integer, intent(in) :: k
  real(default) :: g
  g = sqrt(1 + beta_gamma**2)
  L = identity
  L%L(0,0) = g
  L%L(0,k) = beta_gamma
  L%L(k,0) = L%L(0,k)
  L%L(k,k) = L%L(0,0)
end function boost_canonical

```

Instead of a canonical axis, we can supply an arbitrary axis which need not be normalized. If it is zero, return the unit matrix.

(*Lorentz: procedures*) +=

```

elemental function boost_generic (beta_gamma, axis) result (L)
  type(lorentz_transformation_t) :: L
  real(default), intent(in) :: beta_gamma
  type(vector3_t), intent(in) :: axis
  if (any(axis%p/=0)) then
    L = boost_from_rest_frame_vector3 (beta_gamma * axis, axis**1)
  else
    L = identity
  end if
end function boost_generic

```

4.2.10 Rotations

For a rotation, the vector defines the rotation axis, and its length the rotation angle.

```
(Lorentz: public functions)+≡
    public :: rotation
```

```
(Lorentz: interfaces)+≡
    interface rotation
        module procedure rotation_generic
        module procedure rotation_canonical
        module procedure rotation_generic_cs
        module procedure rotation_canonical_cs
    end interface
```

If $\cos \phi$ and $\sin \phi$ is already known, we do not have to calculate them. Of course, the user has to ensure that $\cos^2 \phi + \sin^2 \phi = 1$, and that the given axis **n** is normalized to one. In the second form, the length of **axis** is the rotation angle.

```
(Lorentz: procedures)+≡
    elemental function rotation_generic_cs (cp, sp, axis) result (R)
        type(lorentz_transformation_t) :: R
        real(default), intent(in) :: cp, sp
        type(vector3_t), intent(in) :: axis
        integer :: i,j
        R = identity

  else
    R = identity
  end if
else
  R = identity
end if
end function rotation_to_2nd_canonical

```

4.2.11 Composite Lorentz transformations

This function returns the transformation that, given a pair of vectors $p_{1,2}$, (a) boosts from the rest frame of the c.m. system (with invariant mass m) into the lab frame where p_i are defined, and (b) turns the given axis (or the canonical vectors $\pm e_k$) in the rest frame into the directions of $p_{1,2}$ in the lab frame. Note that the energy components are not used; for a consistent result one should have $(p_1 + p_2)^2 = m^2$.

```

<Lorentz: public functions>+≡
  public :: transformation

<Lorentz: interfaces>+≡
  interface transformation
    module procedure transformation_rec_generic
    module procedure transformation_rec_canonical
  end interface

    L = L * rotation_to_2nd (k, space_part (inverse (L) * p1))
end function transformation_rec_canonical

```

4.2.12 Applying Lorentz transformations

Multiplying vectors and Lorentz transformations is straightforward.

```

<Lorentz: interfaces>+≡
  interface operator(*)
    module procedure prod_LT_vector4
    module procedure prod_LT_LT
    module procedure prod_vector4_LT
  end interface

<Lorentz: procedures>+≡
  elemental function prod_LT_vector4 (L, p) result (np)
    type(vector4_t) :: np
    type(lorentz_transformation_t), intent(in) :: L
    type(vector4_t), intent(in) :: p
    np%p = matmul (L%L, p%p)
  end function prod_LT_vector4
  elemental function prod_LT_LT (L1, L2) result (NL)
    type(lorentz_transformation_t) :: NL
    type(lorentz_transformation_t), intent(in) :: L1, L2
    NL%L = matmul (L1%L, L2%L)
  end function prod_LT_LT
  elemental function prod_vector4_LT (p, L) result (np)
    type(vector4_t) :: np
    type(vector4_t), intent(in) :: p
    type(lorentz_transformation_t), intent(in) :: L
    np%p = matmul (p%p, L%L)
  end function prod_vector4_LT

```

4.2.13 Special Lorentz transformations

These routines have their application in the generation and extraction of angles in the phase-space sampling routine. Since this part of the program is time-critical, we calculate the composition of transformations directly instead of multiplying rotations and boosts.

This Lorentz transformation is the composition of a rotation by ϕ around the 3 axis, a rotation by θ around the 2 axis, and a boost along the 3 axis:

$$L = B_3(\beta\gamma) R_2(\theta) R_3(\phi) \quad (4.2)$$

Instead of the angles we provide sine and cosine.

```

<Lorentz: public functions>+≡
  public :: LT_compose_r3_r2_b3

<Lorentz: procedures>+≡
  elemental function LT_compose_r3_r2_b3 &
    (cp, sp, ct, st, beta_gamma) result (L)
    type(lorentz_transformation_t) :: L

```

```

real(default), intent(in) :: cp, sp, ct, st, beta_gamma
real(default) :: gamma
if (beta_gamma==0) then
  L%L(0,0) = 1
  L%L(1:,0) = 0
  L%L(0,1:) = 0
  L%L(1,1:) = (/ ct*cp, -ct*sp, st /)
  L%L(2,1:) = (/ sp, cp, 0._default /)
  L%L(3,1:) = (/ -st*cp, st*sp, ct /)
else
  gamma = sqrt(1 + beta_gamma**2)
  L%L(0,0) = gamma
  L%L(1,0) = 0
  L%L(2,0) = 0
  L%L(3,0) = beta_gamma
  L%L(0,1:) = beta_gamma * (/ -st*cp, st*sp, ct /)
  L%L(1,1:) = (/ ct*cp, -ct*sp, st /)
  L%L(2,1:) = (/ sp, cp, 0._default /)
  L%L(3,1:) = gamma * (/ -st*cp, st*sp, ct /)
end if
end function LT_compose_r3_r2_b3

```

Different ordering:

$$L = B_3(\beta\gamma) R_3(\phi) R_2(\theta) \quad (4.3)$$

(Lorentz: public functions)+≡

```
public :: LT_compose_r2_r3_b3
```

(Lorentz: procedures)+≡

```

elemental function LT_compose_r2_r3_b3 &
  (ct, st, cp, sp, beta_gamma) result (L)
type(lorentz_transformation_t) :: L
real(default), intent(in) :: ct, st, cp, sp, beta_gamma
real(default) :: gamma
if (beta_gamma==0) then
  L%L(0,0) = 1
  L%L(1:,0) = 0
  L%L(0,1:) = 0
  L%L(1,1:) = (/ ct*cp, -sp, st*cp /)
  L%L(2,1:) = (/ ct*sp, cp, st*sp /)
  L%L(3,1:) = (/ -st, 0._default, ct /)
else
  gamma = sqrt(1 + beta_gamma**2)
  L%L(0,0) = gamma
  L%L(1,0) = 0
  L%L(2,0) = 0
  L%L(3,0) = beta_gamma
  L%L(0,1:) = beta_gamma * (/ -st, 0._default, ct /)
  L%L(1,1:) = (/ ct*cp, -sp, st*cp /)
  L%L(2,1:) = (/ ct*sp, cp, st*sp /)
  L%L(3,1:) = gamma * (/ -st, 0._default, ct /)
end if
end function LT_compose_r2_r3_b3

```

This function returns the previous Lorentz transformation applied to an arbitrary four-momentum and extracts the space part of the result:

$$\vec{n} = [B_3(\beta\gamma) R_2(\theta) R_3(\phi) p]_{\text{space part}} \quad (4.4)$$

The second variant applies if there is no rotation

```

(Lorentz: public functions)+≡
  public :: axis_from_p_r3_r2_b3, axis_from_p_b3

(Lorentz: procedures)+≡
  elemental function axis_from_p_r3_r2_b3 &

    real(default) :: gamma
    n%p = p%p(1:3)
    if (beta_gamma/=0) then
      gamma = sqrt(1 + beta_gamma**2)
      n%p(3) = n%p(3) * gamma + p%p(0) * beta_gamma
    end if
  end function axis_from_p_b3

```

4.2.14 Special functions

The standard phase space function:

```

(Lorentz: public functions)+≡
  public :: lambda

(Lorentz: procedures)+≡
  elemental function lambda (m1sq, m2sq, m3sq)
    real(default) :: lambda
    real(default), intent(in) :: m1sq, m2sq, m3sq
    lambda = (m1sq - m2sq - m3sq)**2 - 4*m2sq*m3sq
  end function lambda

```

Return a pair of head-to-head colliding momenta, given the collider energy, particle masses, and optionally the momentum of the c.m. system.

<Lorentz: public functions>+≡

public :: colliding_momenta

<Lorentz: procedures>+≡

```
function colliding_momenta (sqrts, m, p_cm) result (p)
  type(vector4_t), dimension(2) :: p
  real(default), intent(in) :: sqrts
  real(default), dimension(2), intent(in), optional :: m
  real(default), intent(in), optional :: p_cm
  real(default), dimension(2) :: dmsq
  real(default) :: ch, sh
  real(default), dimension(2) :: E0, p0
  integer, dimension(2), parameter :: sgn = (/1, -1/)
  if (sqrts == 0) then
    call msg_fatal (" Colliding beams: sqrts is zero (please set sqrts)")
    p = vector4_null; return
  else if (sqrts <= 0) then
    call msg_fatal (" Colliding beams: sqrts is negative")
    p = vector4_null; return
  end if
  if (present (m)) then
    dmsq = sgn * (m(1)**2-m(2)**2)
    E0 = (sqrts + dmsq/sqrts) / 2
    if (any (E0 < m)) then
      call msg_fatal &
        (" Colliding beams: beam energy is less than particle mass")
      p = vector4_null; return
    end if
    p0 = sgn * sqrt (E0**2 - m**2)
  else
    E0 = sqrts / 2
    p0 = sgn * E0
  end if
  if (present (p_cm)) then
    sh = p_cm / sqrts
    ch = sqrt (1 + sh**2)
    p = vector4_moving (E0 * ch + p0 * sh, E0 * sh + p0 * ch, 3)
  else
    p = vector4_moving (E0, p0, 3)
  end if
end function colliding_momenta
```

This subroutine is for the purpose of numerical checks and comparisons. The idea is to set a number to zero if it is numerically equivalent with zero. The equivalence is established by comparing with a **tolerance** argument. We implement this for vectors and transformations.

<Lorentz: public functions>+≡

public :: pacify

end subroutine pacify_LT

```

4.3 Special Physics functions

Here, we declare functions that are specific for the Standard Model, including QCD: fixed and running α_s , Catani-Seymour dipole terms, loop functions, etc.

To make maximum use of this, all functions, if possible, are declared elemental (or pure, if this is not possible).

```

<sm_physics.f90>≡
  <File header>

  module sm_physics

    <Use kinds>
    use constants !NODEP!
    <Use file utils>
    use limits, only: MZ_REF, ALPHA_QCD_MZ_REF, LAMBDA_QCD_REF !NODEP!
    use diagnostics !NODEP!
    use lorentz !NODEP!

    <Standard module head>

    <SM physics: public>

    <SM physics: parameters>

    contains

    <SM physics: procedures>

  end module sm_physics

```

4.3.1 Running α_s

First we set a reference value for $\alpha_s(M_Z) = 0.1178$.

```

<Limits: public parameters>+≡
  real(default), public, parameter :: MZ_REF = 91.188_default
  real(default), public, parameter :: ALPHA_QCD_MZ_REF = 0.1178_default
  real(default), public, parameter :: LAMBDA_QCD_REF = 200.e-3_default

```

Then we define the coefficients of the beta function of QCD (as a reference cf. the Particle Data Group), where n_f is the number of active flavors in two different schemes:

$$\beta_0 = 11 - \frac{2}{3}n_f \quad (4.5)$$

$$\beta_1 = 51 - \frac{19}{3}n_f \quad (4.6)$$

$$\beta_2 = 2857 - \frac{5033}{9}n_f + \frac{325}{27}n_f^2 \quad (4.7)$$

$$b_0 = \frac{1}{12\pi} (11C_A - 2n_f) \quad (4.8)$$

$$b_1 = \frac{1}{24\pi^2} (17C_A^2 - 5C_An_f - 3C_Fn_f) \quad (4.9)$$

$$b_2 = \frac{1}{(4\pi)^3} \left(\frac{2857}{54} C_A^3 - \frac{1415}{54} C_A^2 n_f - \frac{205}{18} C_A C_F n_f + C_F^2 n_f + \frac{79}{54} C_A n_f^2 + \frac{11}{9} C_F n_f^2 \right) \quad (4.10)$$

$\langle SM \text{ physics: public} \rangle \equiv$

```
public :: beta0, beta1, beta2, coeff_b0, coeff_b1, coeff_b2
```

$\langle SM \text{ physics: procedures} \rangle \equiv$

```
pure function beta0 (nf)
  real(default), intent(in) :: nf
  real(default) :: beta0
  beta0 = 11.0_default - two/three * nf
end function beta0

pure function beta1 (nf)
  real(default), intent(in) :: nf
  real(default) :: beta1
  beta1 = 51.0_default - 19.0_default/three * nf
end function beta1

end select
end function running_as_lam

```

4.3.2 Catani-Seymour Parameters

These are fundamental constants of the Catani-Seymour dipole formalism. Since the corresponding parameters for the gluon case depend on the number of flavors which is treated as an argument, there we do have functions and not parameters.

$$\gamma_q = \gamma_{\bar{q}} = \frac{3}{2}C_F \quad \gamma_g = \frac{11}{6}C_A - \frac{2}{3}T_R N_f \quad (4.11)$$

$$K_q = K_{\bar{q}} = \left(\frac{7}{2} - \frac{\pi^2}{6} \right) C_F \quad K_g = \left(\frac{67}{18} - \frac{\pi^2}{6} \right) C_A - \frac{10}{9}T_R N_f \quad (4.12)$$

(SM physics: parameters)≡

```

real(kind=default), parameter, public :: gamma_q = three/two * CF, &
    k_q = (7.0_default/two - pi**2/6.0_default) * CF

```

(SM physics: public)+≡

```

public :: gamma_g, k_g

```

```

<SM physics: procedures>+≡
  elemental function gamma_g (nf) result (gg)
    real(kind=default), intent(in) :: nf
    real(kind=default) :: gg
    gg = 11.0_default/6.0_default * CA - two/three * TR * nf
  end function gamma_g

  elemental function k_g (nf) result (kg)
    real(kind=default), intent(in) :: nf
    real(kind=default) :: kg
    kg = (67.0_default/18.0_default - pi**2/6.0_default) * CA - &
          10.0_default/9.0_default * TR * nf
  end function k_g

```

4.3.3 Mathematical Functions

The dilogarithm. This simplified version is bound to double precision, and restricted to argument values less or equal to unity, so we do not need complex algebra. The wrapper converts it to default precision (which is, of course, a no-op if double=default).

The routine calculates the dilogarithm through mapping on the area where there is a quickly convergent series (adapted from an F77 routine by Hans Kuijf, 1988): Map x such that x is not in the neighbourhood of 1. Note that $|z| = -\ln(1-x)$ is always smaller than 1.10, but $\frac{1 \cdot 10^{19}}{19!} \text{Bernoulli}_{19} = 2.7 \times 10^{-15}$.

```

4.3.6 Functions for Catani-Seymour dipoles

For the automated Catani-Seymour dipole subtraction, we need the following functions.

```

⟨SM physics: public⟩+≡
  public :: ff_dipole

⟨SM physics: procedures⟩+≡
  pure subroutine ff_dipole (v_ijk,y_ijk,p_ij,pp_k,p_i,p_j,p_k)
    type(vector4_t), intent(in) :: p_i, p_j, p_k
    type(vector4_t), intent(out) :: p_ij, pp_k
    real(kind=default), intent(out) :: y_ijk
    real(kind=default) :: z_i
    real(kind=default), intent(out) :: v_ijk
    z_i = (p_i*p_k) / ((p_k*p_j) + (p_k*p_i))
    y_ijk = (p_i*p_j) / ((p_i*p_j) + (p_i*p_k) + (p_j*p_k))
    p_ij = p_i + p_j - y_ijk/(1.0_default - y_ijk) * p_k
    pp_k = (1.0/(1.0_default - y_ijk)) * p_k
    !!! We don't multiply by alpha_s right here:
    v_ijk = 8.0_default * PI * CF * &
      (2.0 / (1.0 - z_i*(1.0 - y_ijk)) - (1.0 + z_i))
  end subroutine ff_dipole

```

```

⟨SM physics: public⟩+≡
  public :: fi_dipole

```

```

⟨SM physics: procedures⟩+≡
  pure subroutine fi_dipole (v_ija,x_ija,p_ij,pp_a,p_i,p_j,p_a)
    type(vector4_t), intent(in) :: p_i, p_j, p_a
    type(vector4_t), intent(out) :: p_ij, pp_a
    real(kind=default), intent(out) :: x_ija
    real(kind=default) :: z_i
    real(kind=default), intent(out) :: v_ija
    z_i = (p_i*p_a) / ((p_a*p_j) + (p_a*p_i))
    x_ija = ((p_i*p_a) + (p_j*p_a) - (p_i*p_j)) &

```

```

      / ((p_i*p_a) + (p_j*p_a))
p_ij = p_i + p_j - (1.0_default - x_ija) * p_a
pp_a = x_ija * p_a
!!! We don't not multiply by alpha_s right here:
v_ija = 8.0_default * PI * CF * &
      (2.0 / (1.0 - z_i + (1.0 - x_ija)) - (1.0 + z_i)) / x_ija
end subroutine fi_dipole

```

```

<SM physics: public>+≡
public :: if_dipole

<SM physics: procedures>+≡
pure subroutine if_dipole (v_kja,u_j,p_aj,pp_k,p_k,p_j,p_a)
  type(vector4_t), intent(in) :: p_k, p_j, p_a
  type(vector4_t), intent(out) :: p_aj, pp_k
  real(kind=default), intent(out) :: u_j
  real(kind=default) :: x_kja
  real(kind=default), intent(out) :: v_kja
  u_j = (p_a*p_j) / ((p_a*p_j) + (p_a*p_k))
  x_kja = ((p_a*p_k) + (p_a*p_j) - (p_j*p_k)) &
    / ((p_a*p_j) + (p_a*p_k))
  p_aj = x_kja * p_a
  pp_k = p_k + p_j - (1.0_default - x_kja) * p_a
  v_kja = 8.0_default * PI * CF * &
    (2.0 / (1.0 - x_kja + u_j) - (1.0 + x_kja)) / x_kja
end subroutine if_dipole

```

This function depends on a variable number of final state particles whose kinematics all get changed by the initial-initial dipole insertion.

```

<SM physics: public>+≡
public :: ii_dipole

<SM physics: procedures>+≡
pure subroutine ii_dipole (v_jab,v_j,p_in,p_out,flag_1or2)
  type(vector4_t), dimension(:), intent(in) :: p_in
  type(vector4_t), dimension(size(p_in)-1), intent(out) :: p_out
  logical, intent(in) :: flag_1or2
  real(kind=default), intent(out) :: v_j
  real(kind=default), intent(out) :: v_jab
  type(vector4_t) :: p_a, p_b, p_j
  type(vector4_t) :: k, kk
  type(vector4_t) :: p_aj
  real(kind=default) :: x_jab
  integer :: i
  !!! flag_1or2 decides whether this a 12 or 21 dipole
  if (flag_1or2) then
    p_a = p_in(1)
    p_b = p_in(2)
  else
    p_b = p_in(1)
    p_a = p_in(2)
  end if
  !!! We assume that the unresolved particle has always the last
  !!! momentum

```

```

p_j = p_in(size(p_in))
x_jab = ((p_a*p_b) - (p_a*p_j) - (p_b*p_j)) / (p_a*p_b)
v_j = (p_a*p_j) / (p_a * p_b)
p_aj = x_jab * p_a
k = p_a + p_b - p_j
kk = p_aj + p_b
do i = 3, size(p_in)-1
  p_out(i) = p_in(i) - 2.0*((k+kk)*p_in(i))/((k+kk)*(k+kk)) * (k+kk) + &
    (2.0 * (k*p_in(i)) / (k*k)) * kk
end do
if (flag_1or2) then
  p_out(1) = p_aj
  p_out(2) = p_b
else
  p_out(1) = p_b
  p_out(2) = p_aj
end if
v_jab = 8.0_default * PI * CF * &
  (2.0 / (1.0 - x_jab) - (1.0 + x_jab)) / x_jab
end subroutine ii_dipole

```

4.3.7 Distributions for integrated dipoles and such

The Dirac delta distribution, modified for Monte-Carlo sampling:

```

<SM physics: public>+≡
  public :: delta

<SM physics: procedures>+≡
  elemental function delta (x,eps) result (z)
    real(kind=default), intent(in) :: x, eps
    real(kind=default) :: z
    if (x > 1.0_default - eps) then
      z = 1.0_default/eps
    else
      z = 0
    end if
  end function delta

```

The $+$ -distribution, $P_+(x) = \left(\frac{1}{1-x}\right)_+$, for the regularization of soft-collinear singularities. The constant part for the Monte-Carlo sampling is the integral over the splitting function divided by the weight for the WHIZARD numerical integration over the interval.

```

<SM physics: public>+≡
  public :: plus_distr

<SM physics: procedures>+≡
  elemental function plus_distr (x,eps) result (plusd)
    real(kind=default), intent(in) :: x, eps
    real(kind=default) :: plusd
    if (x > (1.0_default - eps)) then
      plusd = log(eps)/eps
    else
      plusd = one/(one-x)
    end if
  end function plus_distr

```

```

end if
end function plus_distr

```

The splitting function in $D = 4$ dimensions, regularized as $+$ -distributions if necessary:

$$P^{qq}(x) = P^{\bar{q}q}(x) = C_F \cdot \left(\frac{1+x^2}{1-x} \right)_+ \quad (4.13)$$

$$P^{qg}(x) = P^{\bar{q}g}(x) = C_F \cdot \frac{1+(1-x)^2}{x} \quad (4.14)$$

$$P^{gg}(x) = P^{g\bar{q}}(x) = T_R \cdot [x^2 + (1-x)^2] \quad (4.15)$$

$$P^{gg}(x) = 2C_A \left[\left(\frac{1}{1-x} \right)_+ + \frac{1-x}{x} - 1 + x(1-x) \right] + \delta(1-x) \left(\frac{11}{6}C_A - \frac{2}{3}N_f T_R \right) \quad (4.16)$$

Since the number of flavors summed over in the gluon splitting function might depend on the physics case under consideration it is implemented as an input variable.

```

⟨SM physics: public⟩+≡
  public :: pqq

⟨SM physics: procedures⟩+≡
  elemental function pqq (x,eps) result (pqqx)
    real(kind=default), intent(in) :: x, eps
    real(kind=default) :: pqqx
    if (x > (1.0_default - eps)) then
      pqqx = (eps-one)/two + two*log(eps)/eps - three*(eps-one)/eps/two
    else
      pqqx = (one + x**2)/(one-x)
    end if
    pqqx = CF * pqqx
  end function pqq

⟨SM physics: public⟩+≡
  public :: pgq

⟨SM physics: procedures⟩+≡
  elemental function pgq (x) result (pgqx)
    real(kind=default), intent(in) :: x
    real(kind=default) :: pgqx
    pgqx = TR * (x**2 + (one - x)**2)
  end function pgq

⟨SM physics: public⟩+≡
  public :: pqg

⟨SM physics: procedures⟩+≡
  elemental function pqg (x) result (pqgx)
    real(kind=default), intent(in) :: x
    real(kind=default) :: pqgx
    pqgx = CF * (one + (one - x)**2) / x
  end function pqg

```

```

⟨SM physics: public⟩+≡
  public :: pgg
⟨SM physics: procedures⟩+≡
  elemental function pgg (x, nf, eps) result (pggx)
    real(kind=default), intent(in) :: x, nf, eps
    real(kind=default) :: pggx
    pggx = two * CA * ( plus_distr (x, eps) + (one-x)/x - one + &
                        x*(one-x)) + delta (x, eps) * gamma_g(nf)
  end function pgg

```

For the qq and gg cases, there exist “regularized” versions of the splitting functions:

$$P_{\text{reg}}^{qq}(x) = -C_F \cdot (1 + x) \quad (4.17)$$

$$P_{\text{reg}}^{gg}(x) = 2C_A \left[\frac{1-x}{x} - 1 + x(1-x) \right] \quad (4.18)$$

$$(4.19)$$

```

⟨SM physics: public⟩+≡
  public :: pqq_reg
⟨SM physics: procedures⟩+≡
  elemental function pqq_reg (x) result (pqqregx)
    real(kind=default), intent(in) :: x
    real(kind=default) :: pqqregx
    pqqregx = - CF * (one + x)
  end function pqq_reg

```

```

⟨SM physics: public⟩+≡
  public :: pgg_reg
⟨SM physics: procedures⟩+≡
  elemental function pgg_reg (x) result (pggregx)
    real(kind=default), intent(in) :: x
    real(kind=default) :: pgregx
    pgregx = two * CA * ((one - x)/x - one + x*(one - x))
  end function pgg_reg

```

Here, we collect the expressions needed for integrated Catani-Seymour dipoles, and the so-called flavor kernels. We always distinguish between the “ordinary” Catani-Seymour version, and the one including a phase-space slicing parameter, α .

The standard flavor kernels \bar{K}^{ab} are:

$$\bar{K}^{qg}(x) = \bar{K}^{\bar{q}g}(x) = P^{qg}(x) \log((1-x)/x) + CF \times x \quad (4.20)$$

$$\bar{K}^{gq}(x) = \bar{K}^{g\bar{q}}(x) = P^{gq}(x) \log((1-x)/x) + TR \times 2x(1-x) \quad (4.21)$$

$$\bar{K}^{qq} = C_F \left[\left(\frac{2}{1-x} \log \frac{1-x}{x} \right)_+ - (1+x) \log((1-x)/x) + (1-x) \right] - (5 - \pi^2) \cdot C_F \cdot \delta(1-x) \quad (4.22)$$

$$\bar{K}^{gg} = 2C_A \left[\left(\frac{1}{1-x} \log \frac{1-x}{x} \right)_+ + \left(\frac{1-x}{x} - 1 + x(1-x) \right) \log((1-x)/x) \right] - \delta(1-x) \left[(f \right. \quad (4.23)$$

```

⟨SM physics: public⟩+≡
  public :: kbarqg

⟨SM physics: procedures⟩+≡

4.4 QCD Coupling

We provide various distinct implementations of the QCD coupling. In this module, we define an abstract data type and three implementations: fixed, running with $\alpha_s(M_Z)$ as input, and running with Λ_{QCD} as input. We use the functions defined above in the module `sm_physics` but provide a common interface. Later modules may define additional implementations.

```

⟨sm_qcd.f90⟩≡
  ⟨File header⟩

  module sm_qcd

    ⟨Use kinds⟩
    ⟨Use file utils⟩

```

```

    use limits, only: MZ_REF, ALPHA_QCD_MZ_REF, LAMBDA_QCD_REF !NODEP!
    use diagnostics !NODEP!
    use md5
    use unit_tests

    use sm_physics !NODEP!

    <Standard module head>

    <SM qcd: public>

    <SM qcd: types>

    <SM qcd: interfaces>

contains

    <SM qcd: procedures>

    <SM qcd: tests>

end module sm_qcd

```

4.4.1 Coupling: Abstract Data Type

This is the abstract version of the QCD coupling implementation.

```

<SM qcd: public>≡
    public :: alpha_qcd_t

<SM qcd: types>≡
    type, abstract :: alpha_qcd_t
    contains
    <SM qcd: alpha qcd: TBP>
end type alpha_qcd_t

```

There must be an output routine.

```

<SM qcd: alpha qcd: TBP>≡
    procedure (alpha_qcd_write), deferred :: write

<SM qcd: interfaces>≡
    abstract interface
        subroutine alpha_qcd_write (object, unit)
            import
            class(alpha_qcd_t), intent(in) :: object
            integer, intent(in), optional :: unit
        end subroutine alpha_qcd_write
    end interface

```

This method computes the running coupling, given a certain scale. All parameters (reference value, order of the approximation, etc.) must be set before calling this.

```

<SM qcd: alpha qcd: TBP>+≡
    procedure (alpha_qcd_get), deferred :: get

```

```

⟨SM qcd: interfaces⟩+≡
  abstract interface
    function alpha_qcd_get (alpha_qcd, scale) result (alpha)
      import
      class(alpha_qcd_t), intent(in) :: alpha_qcd
      real(default), intent(in) :: scale
      real(default) :: alpha
    end function alpha_qcd_get
  end interface

```

4.4.2 Fixed Coupling

In this version, the α_s value is fixed, the `scale` argument of the `get` method is ignored. There is only one parameter, the value. By default, this is the value at M_Z .

```

⟨SM qcd: public⟩+≡
  public :: alpha_qcd_fixed_t

⟨SM qcd: types⟩+≡
  type, extends (alpha_qcd_t) :: alpha_qcd_fixed_t
    real(default) :: val = ALPHA_QCD_MZ_REF
  contains
    ⟨SM qcd: alpha qcd fixed: TBP⟩
  end type alpha_qcd_fixed_t

```

Output.

```

⟨SM qcd: alpha qcd fixed: TBP⟩≡
  procedure :: write => alpha_qcd_fixed_write

⟨SM qcd: procedures⟩≡
  subroutine alpha_qcd_fixed_write (object, unit)
    class(alpha_qcd_fixed_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(3x,A)") "QCD parameters (fixed coupling):"
    write (u, "(5x,A,ES12.5)") "alpha = ", object%val
  end subroutine alpha_qcd_fixed_write

```

Calculation: the scale is ignored in this case.

```

⟨SM qcd: alpha qcd fixed: TBP⟩+≡
  procedure :: get => alpha_qcd_fixed_get

⟨SM qcd: procedures⟩+≡
  function alpha_qcd_fixed_get (alpha_qcd, scale) result (alpha)
    class(alpha_qcd_fixed_t), intent(in) :: alpha_qcd
    real(default), intent(in) :: scale
    real(default) :: alpha
    alpha = alpha_qcd%val
  end function alpha_qcd_fixed_get

```

4.4.3 Running Coupling

In this version, the α_s value runs relative to the value at a given reference scale. There are two parameters: the value of this scale (default: M_Z), the value of α_s at this scale, and the number of effective flavors. Furthermore, we have the order of the approximation.

```

<SM qcd: public>+≡
    public :: alpha_qcd_from_scale_t

<SM qcd: types>+≡
    type, extends (alpha_qcd_t) :: alpha_qcd_from_scale_t
        real(default) :: mu_ref = MZ_REF
        real(default) :: ref = ALPHA_QCD_MZ_REF
        integer :: order = 0
        integer :: nf = 5
    contains
        <SM qcd: alpha qcd from scale: TBP>
    end type alpha_qcd_from_scale_t

```

Output.

```

<SM qcd: alpha qcd from scale: TBP>≡
    procedure :: write => alpha_qcd_from_scale_write

<SM qcd: procedures>+≡
    subroutine alpha_qcd_from_scale_write (object, unit)
        class(alpha_qcd_from_scale_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit)
        write (u, "(3x,A)") "QCD parameters (running coupling):"
        write (u, "(5x,A,ES12.5)") "Scale mu = ", object%mu_ref
        write (u, "(5x,A,ES12.5)") "alpha(mu) = ", object%ref
        write (u, "(5x,A,I0)") "LL order = ", object%order
        write (u, "(5x,A,I0)") "N(flv) = ", object%nf
    end subroutine alpha_qcd_from_scale_write

```

Calculation: here, we call the function for running α_s that was defined in `sm_physics` above. The function does not take into account thresholds, so the number of flavors should be the correct one for the chosen scale. Normally, this should be the Z boson mass.

```

<SM qcd: alpha qcd from scale: TBP>+≡
    procedure :: get => alpha_qcd_from_scale_get

<SM qcd: procedures>+≡
    function alpha_qcd_from_scale_get (alpha_qcd, scale) result (alpha)
        class(alpha_qcd_from_scale_t), intent(in) :: alpha_qcd
        real(default), intent(in) :: scale
        real(default) :: alpha
        alpha = running_as (scale, &
            alpha_qcd%ref, alpha_qcd%mu_ref, alpha_qcd%order, &
            real (alpha_qcd%nf, kind=default))
    end function alpha_qcd_from_scale_get

```

4.4.4 Running Coupling, determined by Λ_{QCD}

In this version, the input are the value Λ_{QCD} and the order of the approximation.

```

⟨SM qcd: public⟩+≡
  public :: alpha_qcd_from_lambda_t
⟨SM qcd: types⟩+≡
  type, extends (alpha_qcd_t) :: alpha_qcd_from_lambda_t
    real(default) :: lambda = LAMBDA_QCD_REF
    integer :: order = 0
    integer :: nf = 5
  contains
    ⟨SM qcd: alpha qcd from lambda: TBP⟩
  end type alpha_qcd_from_lambda_t

```

Output.

```

⟨SM qcd: alpha qcd from lambda: TBP⟩≡
  procedure :: write => alpha_qcd_from_lambda_write
⟨SM qcd: procedures⟩+≡
  subroutine alpha_qcd_from_lambda_write (object, unit)
    class(alpha_qcd_from_lambda_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(3x,A)") "QCD parameters (Lambda_QCD as input):"
    write (u, "(5x,A,ES12.5)") "Lambda_QCD = ", object%lambda
    write (u, "(5x,A,I0)") "LL order = ", object%order
    write (u, "(5x,A,I0)") "N(flav) = ", object%nf
  end subroutine alpha_qcd_from_lambda_write

```

Calculation: here, we call the second function for running α_s that was defined in `sm_physics` above. The Λ value should be the one that is appropriate for the chosen number of effective flavors. Again, thresholds are not incorporated.

```

⟨SM qcd: alpha qcd from lambda: TBP⟩+≡
  procedure :: get => alpha_qcd_from_lambda_get
⟨SM qcd: procedures⟩+≡
  function alpha_qcd_from_lambda_get (alpha_qcd, scale) result (alpha)
    class(alpha_qcd_from_lambda_t), intent(in) :: alpha_qcd
    real(default), intent(in) :: scale
    real(default) :: alpha
    alpha = running_as_lam (real (alpha_qcd%nf, kind=default), scale, &
      alpha_qcd%lambda, alpha_qcd%order)
  end function alpha_qcd_from_lambda_get

```

4.4.5 Wrapper type

We could get along with a polymorphic QCD type, but a monomorphic wrapper type with a polymorphic component is easier to handle and probably safer (w.r.t. compiler bugs). However, we keep the object transparent, so we can set the type-specific parameters directly (by a `dispatch` routine).

```

⟨SM qcd: public⟩+≡

```

```

    public :: qcd_t
  <SM qcd: types>+≡
    type :: qcd_t
      class(alpha_qcd_t), allocatable :: alpha
      character(32) :: md5sum = ""
    contains
      <SM qcd: qcd: TBP>
    end type qcd_t

```

Output. We first print the polymorphic `alpha` which contains a headline, then any extra components.

```

  <SM qcd: qcd: TBP>≡
    procedure :: write => qcd_write

  <SM qcd: procedures>+≡
    subroutine qcd_write (qcd, unit, show_md5sum)
      class(qcd_t), intent(in) :: qcd
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: show_md5sum
      logical :: show_md5
      integer :: u
      u = output_unit (unit)
      show_md5 = .true.; if (present (show_md5sum)) show_md5 = show_md5sum
      if (allocated (qcd%alpha)) then
        call qcd%alpha%write (u)
      else
        write (u, "(3x,A)") "QCD parameters (coupling undefined)"
      end if
      if (show_md5 .and. qcd%md5sum /= "") &
        write (u, "(5x,A,A,A)") "md5sum = '", qcd%md5sum, "'"
    end subroutine qcd_write

```

Compute a MD5 sum for the `alpha_s` setup. This is done by writing them to a temporary file, using a standard format.

```

  <SM qcd: qcd: TBP>+≡
    procedure :: compute_alphas_md5sum => qcd_compute_alphas_md5sum

  <SM qcd: procedures>+≡
    subroutine qcd_compute_alphas_md5sum (qcd)
      class(qcd_t), intent(inout) :: qcd
      integer :: unit
      if (allocated (qcd%alpha)) then
        unit = free_unit ()
        open (unit, status="scratch", action="readwrite")
        call qcd%alpha%write (unit)
        rewind (unit)
        qcd%md5sum = md5sum (unit)
        close (unit)
      end if
    end subroutine qcd_compute_alphas_md5sum

```

Retrieve the MD5 sum of the qcd setup.

```

⟨SM qcd: qcd: TBP⟩+≡
  procedure :: get_md5sum => qcd_get_md5sum

⟨SM qcd: procedures⟩+≡
  function qcd_get_md5sum (qcd) result (md5sum)

Chapter 5

Physics Analysis

This part contains the structures and tools that are necessary for defining parameters, particle sets, analysis objects such as histograms, and expressions that deal with them.

These are the modules:

analysis Observables, histograms, and plots.

pdg_arrays Useful for particle aliases (e.g., 'quark' for u, d, s etc.)

pvt_lists Particle lists/arrays used for analyzing events.

variables Store values of various kind, used by expressions and accessed by the command interface.

expressions Expressions of values of all kinds. Includes the API for recording analysis data.

5.1 Analysis tools

This module defines structures useful for data analysis. These include observables, histograms, and plots.

Observables are quantities that are calculated and summed up event by event. At the end, one can compute the average and error.

Histograms have their bins in addition to the observable properties. Histograms are usually written out in tables and displayed graphically.

In plots, each record creates its own entry in a table. This can be used for scatter plots if called event by event, or for plotting dependencies on parameters if called once per integration run.

Graphs are container for histograms and plots, which carry their own graphics options.

The type layout is still somewhat obfuscated. This would become much simpler if type extension could be used.

```
<analysis.f90>≡
  <File header>

    <Analysis: interfaces>

    <Analysis: variables>

    contains

    <Analysis: procedures>

    <Analysis: tests>

  end module analysis
```

5.1.1 Output formats

These formats share a common field width (alignment).

```
<Limits: public parameters>+≡
    character(*), parameter, public :: HISTOGRAM_HEAD_FORMAT = "1x,A15,3x"
    character(*), parameter, public :: HISTOGRAM_INTG_FORMAT = "3x,I9,3x"
    character(*), parameter, public :: HISTOGRAM_DATA_FORMAT = "ES19.12"
```

5.1.2 Graph options

These parameters are used for displaying data. They apply to a whole graph, which may contain more than one plot element.

The GAMELAN code chunks are part of both `graph_options` and `drawing_options`. The `drawing_options` copy is used in histograms and plots, also as graph elements. The `graph_options` copy is used for `graph` objects as a whole. Both copies are usually identical.

```
<Analysis: public>≡

  end subroutine drawing_options_set

```

There are separate commands for drawing the curve and for drawing errors. The symbols are applied to the latter. First of all, we may have to compute a

baseline:

<Analysis: procedures>+≡

```
function drawing_options_get_calc_command (dro) result (cmd)
  type(string_t) :: cmd
  type(drawing_options_t), intent(in) :: dro
  if (dro%with_base) then
    cmd = "calculate " // dro%dataset // ".base (" // dro%dataset // ") " &
      // "(x, #0);"
  else
    cmd = ""
  end if
end function drawing_options_get_calc_command
```

Return the drawing command.

<Analysis: procedures>+≡

```
function drawing_options_get_draw_command (dro) result (cmd)
  type(string_t) :: cmd
  type(drawing_options_t), intent(in) :: dro
  if (dro%fill) then
    cmd = "fill"
  else if (dro%draw) then
    cmd = "draw"
  else
    cmd = ""
  end if
  if (dro%fill .or. dro%draw) then
    if (dro%piecewise) cmd = cmd // " piecewise"
    if (dro%draw .and. dro%with_base) cmd = cmd // " cyclic"
    cmd = cmd // " from (" // dro%dataset
    if (dro%with_base) then
      if (dro%piecewise) then
        cmd = cmd // ", " // dro%dataset // ".base\" ! "
      else
        cmd = cmd // " ~ " // dro%dataset // ".base\" ! "
      end if
    end if
    cmd = cmd // ")"
    if (dro%fill) then
      cmd = cmd // " " // dro%fill_options
      if (dro%draw) cmd = cmd // " outlined"
    end if
    if (dro%draw) cmd = cmd // " " // dro%draw_options
    cmd = cmd // ";"
  end if
end function drawing_options_get_draw_command
```

The error command draws error bars, if any.

<Analysis: procedures>+≡

```
function drawing_options_get_err_command (dro) result (cmd)
  type(string_t) :: cmd
  type(drawing_options_t), intent(in) :: dro
  if (dro%err) then

5.1.4 Observables

The observable type holds the accumulated observable values and weight sums which are necessary for proper averaging.

(Analysis: types)+≡

```

type :: observable_t
    private
    real(default) :: sum_values = 0
    real(default) :: sum_squared_values = 0
    real(default) :: sum_weights = 0
    real(default) :: sum_squared_weights = 0
    integer :: count = 0
    type(string_t) :: obs_label
    type(string_t) :: obs_unit
    type(graph_options_t) :: graph_options

```

```
end type observable_t
```

Initialize with defined properties

<Analysis: procedures>+≡

```
subroutine observable_init (obs, obs_label, obs_unit, graph_options)
  type(observable_t), intent(out) :: obs
  type(string_t), intent(in), optional :: obs_label, obs_unit
  type(graph_options_t), intent(in), optional :: graph_options
  if (present (obs_label)) then
    obs%obs_label = obs_label
  else
    obs%obs_label = ""
  end if
  if (present (obs_unit)) then
    obs%obs_unit = obs_unit
  else
    obs%obs_unit = ""
  end if
  if (present (graph_options)) then
    obs%graph_options = graph_options
  else
    call graph_options_init (obs%graph_options)
  end if
end subroutine observable_init
```

Reset all numeric entries.

<Analysis: procedures>+≡

```
subroutine observable_clear (obs)
  type(observable_t), intent(inout) :: obs
  obs%sum_values = 0
  obs%sum_squared_values = 0
  obs%sum_weights = 0
  obs%sum_squared_weights = 0
  obs%count = 0
end subroutine observable_clear
```

Record a a value. Always successful for observables.

<Analysis: interfaces>≡

```
interface observable_record_value
  module procedure observable_record_value_unweighted
  module procedure observable_record_value_weighted
end interface
```

<Analysis: procedures>+≡

```
subroutine observable_record_value_unweighted (obs, value, success)
  type(observable_t), intent(inout) :: obs
  real(default), intent(in) :: value
  logical, intent(out), optional :: success
  obs%sum_values = obs%sum_values + value
  obs%sum_squared_values = obs%sum_squared_values + value**2
  obs%sum_weights = obs%sum_weights + 1
  obs%sum_squared_weights = obs%sum_squared_weights + 1
```

```

    obs%count = obs%count + 1
    if (present (success)) success = .true.
end subroutine observable_record_value_unweighted

subroutine observable_record_value_weighted (obs, value, weight, success)
  type(observable_t), intent(inout) :: obs
  real(default), intent(in) :: value, weight
  logical, intent(out), optional :: success
  obs%sum_values = obs%sum_values + value * weight
  obs%sum_squared_values = obs%sum_squared_values + value**2 * weight
  obs%sum_weights = obs%sum_weights + abs (weight)
  obs%sum_squared_weights = obs%sum_squared_weights + weight**2
  obs%count = obs%count + 1
  if (present (success)) success = .true.
end subroutine observable_record_value_weighted

```

Here are the statistics formulas:

1. Unweighted case: Given a sample of n values x_i , the average is

$$\langle x \rangle = \frac{\sum x_i}{n} \quad (5.1)$$

and the error estimate

$$\Delta x = \sqrt{\frac{1}{n-1} \langle \sum (x_i - \langle x \rangle)^2 \rangle} \quad (5.2)$$

$$= \sqrt{\frac{1}{n-1} \left(\frac{\sum x_i^2}{n} - \frac{(\sum x_i)^2}{n^2} \right)} \quad (5.3)$$

2. Weighted case: Instead of weight 1, each event comes with weight w_i .

$$\langle x \rangle = \frac{\sum x_i w_i}{\sum w_i} \quad (5.4)$$

and

$$\Delta x = \sqrt{\frac{1}{n-1} \left(\frac{\sum x_i^2 w_i}{\sum w_i} - \frac{(\sum x_i w_i)^2}{(\sum w_i)^2} \right)} \quad (5.5)$$

For $w_i = 1$, this specializes to the previous formula.

<Analysis: procedures>+≡

```

    c // "number of points: " &
    // int2char (plot_get_n_entries (plot)))
end subroutine plot_get_header

```

5.1.8 Graphs

A graph is a container for several graph elements. Each graph element is either a plot or a histogram. There is an appropriate base type below (the `analysis_object_t`), but to avoid recursion, we define a separate base type here. Note that there is no actual recursion: a graph is an analysis object, but a graph cannot contain graphs.

(If we could use type extension, the implementation would be much more transparent.)

Graph elements

Graph elements cannot be filled by the `record` command directly. The contents are always copied from elementary histograms or plots.

```

<Analysis: types>+≡
  type :: graph_element_t

```

```

private
integer :: type = AN_UNDEFINED
type(histogram_t), pointer :: h => null ()
type(plot_t), pointer :: p => null ()
end type graph_element_t

```

<Analysis: procedures>+≡

```

subroutine graph_element_final (el)
type(graph_element_t), intent(inout) :: el
select case (el%type)
case (AN_HISTOGRAM)
deallocate (el%h)
case (AN_PLOT)
call plot_final (el%p)
deallocate (el%p)
end select
el%type = AN_UNDEFINED
end subroutine graph_element_final

```

Return the number of entries in the graph element:

<Analysis: procedures>+≡

```

function graph_element_get_n_entries (el) result (n)
integer :: n
type(graph_element_t), intent(in) :: el
select case (el%type)
case (AN_HISTOGRAM); n = histogram_get_n_entries (el%h)
case (AN_PLOT);      n = plot_get_n_entries (el%p)
case default;       n = 0
end select
end function graph_element_get_n_entries

```

Return a pointer to the graph / drawing options.

<Analysis: procedures>+≡

```

function graph_element_get_graph_options_ptr (el) result (ptr)
type(graph_options_t), pointer :: ptr
type(graph_element_t), intent(in) :: el
select case (el%type)
case (AN_HISTOGRAM); ptr => histogram_get_graph_options_ptr (el%h)
case (AN_PLOT);      ptr => plot_get_graph_options_ptr (el%p)
case default;       ptr => null ()
end select
end function graph_element_get_graph_options_ptr

function graph_element_get_drawing_options_ptr (el) result (ptr)
type(drawing_options_t), pointer :: ptr
type(graph_element_t), intent(in) :: el
select case (el%type)
case (AN_HISTOGRAM); ptr => histogram_get_drawing_options_ptr (el%h)
case (AN_PLOT);      ptr => plot_get_drawing_options_ptr (el%p)
case default;       ptr => null ()
end select
end function graph_element_get_drawing_options_ptr

```

Output, simple wrapper for the plot/histogram writer.

<Analysis: procedures>+≡

```

subroutine graph_element_write (el, unit)
  type(graph_element_t), intent(in) :: el
  integer, intent(in), optional :: unit
  type(graph_options_t), pointer :: gro
  type(string_t) :: id
  integer :: u
  u = output_unit (unit); if (u < 0) return
  gro => graph_element_get_graph_options_ptr (el)
  id = graph_options_get_id (gro)
  write (u, "(A,A)" ' #', repeat("-", 78)
  select case (el%type)
  case (AN_HISTOGRAM)
    write (u, "(A)", advance="no")  "# Histogram: "
    write (u, "(1x,A)" char (id)
    call histogram_write (el%h, unit)
  case (AN_PLOT)
    write (u, "(A)", advance="no")  "# Plot: "
    write (u, "(1x,A)" char (id)
    call plot_write (el%p, unit)
  end select
end subroutine graph_element_write

```

<Analysis: procedures>+≡

```

subroutine graph_element_write_gml_reader (el, filename, unit)
  type(graph_element_t), intent(in) :: el
  type(string_t), intent(in) :: filename
  integer, intent(in), optional :: unit
  select case (el%type)
  case (AN_HISTOGRAM); call histogram_write_gml_reader (el%h, filename, unit)
  case (AN_PLOT);      call plot_write_gml_reader (el%p, filename, unit)
  end select
end subroutine graph_element_write_gml_reader

```

The graph type

The actual graph type contains its own `graph_options`, which override the individual settings. The `drawing_options` are set in the graph elements. This distinction motivates the separation of the two types.

<Analysis: types>+≡

```

type :: graph_t
  private
  type(graph_element_t), dimension(:), allocatable :: el
  type(graph_options_t) :: graph_options
end type graph_t

```

Initializer/finalizer

The graph is created with a definite number of elements. The elements are filled one by one, optionally with modified drawing options.

<Analysis: procedures>+≡

```
subroutine graph_init (g, id, n_elements, graph_options)
  type(graph_t), intent(out) :: g
  type(string_t), intent(in) :: id
  integer, intent(in) :: n_elements
  type(graph_options_t), intent(in), optional :: graph_options
  allocate (g%el (n_elements))
  if (present (graph_options)) then
    g%graph_options = graph_options
  else
    call graph_options_init (g%graph_options)
  end if
  call graph_options_set (g%graph_options, id = id)
end subroutine graph_init
```

<Analysis: procedures>+≡

```
subroutine graph_insert_histogram (g, i, h, drawing_options)
  type(graph_t), intent(inout), target :: g
  integer, intent(in) :: i
  type(histogram_t), intent(in) :: h
  type(drawing_options_t), intent(in), optional :: drawing_options
  type(graph_options_t), pointer :: gro
  type(drawing_options_t), pointer :: dro
  type(string_t) :: id
  g%el(i)%type = AN_HISTOGRAM
  allocate (g%el(i)%h)
  call histogram_init_histogram (g%el(i)%h, h, drawing_options)
  gro => histogram_get_graph_options_ptr (g%el(i)%h)
  dro => histogram_get_drawing_options_ptr (g%el(i)%h)
  id = graph_options_get_id (gro)
  call drawing_options_set (dro, dataset = "dat." // id)
end subroutine graph_insert_histogram
```

<Analysis: procedures>+≡

```
subroutine graph_insert_plot (g, i, p, drawing_options)
  type(graph_t), intent(inout) :: g
  integer, intent(in) :: i
  type(plot_t), intent(in) :: p
  type(drawing_options_t), intent(in), optional :: drawing_options
  type(graph_options_t), pointer :: gro
  type(drawing_options_t), pointer :: dro
  type(string_t) :: id
  g%el(i)%type = AN_PLOT
  allocate (g%el(i)%p)
  call plot_init_plot (g%el(i)%p, p, drawing_options)
  gro => plot_get_graph_options_ptr (g%el(i)%p)
  dro => plot_get_drawing_options_ptr (g%el(i)%p)
  id = graph_options_get_id (gro)
  call drawing_options_set (dro, dataset = "dat." // id)
end subroutine graph_insert_plot
```

Finalizer.

<Analysis: procedures>+≡

```

subroutine graph_final (g)
  type(graph_t), intent(inout) :: g
  integer :: i
  do i = 1, size (g%el)
    call graph_element_final (g%el(i))
  end do
  deallocate (g%el)
end subroutine graph_final

```

Access contents

The number of elements.

<Analysis: procedures>+≡

```

function graph_get_n_elements (graph) result (n)
  integer :: n
  type(graph_t), intent(in) :: graph
  n = size (graph%el)
end function graph_get_n_elements

```

Retrieve a pointer to the drawing options of an element, so they can be modified. (The `target` attribute is not actually needed because the components are pointers.)

<Analysis: procedures>+≡

```

function graph_get_drawing_options_ptr (g, i) result (ptr)
  type(drawing_options_t), pointer :: ptr
  type(graph_t), intent(in), target :: g
  integer, intent(in) :: i
  ptr => graph_element_get_drawing_options_ptr (g%el(i))
end function graph_get_drawing_options_ptr

```

Output

The default output format just writes histogram and plot data.

<Analysis: procedures>+≡

```

subroutine graph_write (graph, unit)
  type(graph_t), intent(in) :: graph
  integer, intent(in), optional :: unit
  integer :: i
  do i = 1, size (graph%el)
    call graph_element_write (graph%el(i), unit)
  end do
end subroutine graph_write

```

The GAMELAN driver is not a simple wrapper, but it writes the plot/histogram contents embedded the complete graph. First, data are read in, global background commands next, then individual elements, then global foreground commands.

<Analysis: procedures>+≡

```

subroutine graph_write_gml_driver (g, filename, unit)

```

```

type(graph_t), intent(in) :: g
type(string_t), intent(in) :: filename
type(string_t) :: calc_cmd, bg_cmd, draw_cmd, err_cmd, symb_cmd, fg_cmd

  c // "number of graph elements: " &
  // int2char (graph_get_n_elements (graph)))
end subroutine graph_get_header

```

5.1.9 Analysis objects

This data structure holds all observables, histograms and such that are currently active. We have one global store; individual items are identified by their ID strings.

(This should rather be coded by type extension.)

<Analysis: parameters>≡

```

integer, parameter :: AN_UNDEFINED = 0
integer, parameter :: AN_OBSERVABLE = 1
integer, parameter :: AN_HISTOGRAM = 2
integer, parameter :: AN_PLOT = 3
integer, parameter :: AN_GRAPH = 4

```

<Analysis: public>+≡

```

public :: AN_UNDEFINED, AN_HISTOGRAM, AN_OBSERVABLE, AN_PLOT, AN_GRAPH

```

<Analysis: types>+≡

```

type :: analysis_object_t
  private
  type(string_t) :: id
  integer :: type = AN_UNDEFINED
  type(observable_t), pointer :: obs => null ()
  type(histogram_t), pointer :: h => null ()
  type(plot_t), pointer :: p => null ()
  type(graph_t), pointer :: g => null ()
  type(analysis_object_t), pointer :: next => null ()
end type analysis_object_t

```

Initializer/finalizer

Allocate with the correct type but do not fill initial values.

<Analysis: procedures>+≡

```

subroutine analysis_object_init (obj, id, type)
  type(analysis_object_t), intent(out) :: obj
  type(string_t), intent(in) :: id
  integer, intent(in) :: type
  obj%id = id
  obj%type = type
  select case (obj%type)
    case (AN_OBSERVABLE); allocate (obj%obs)

  case (AN_PLOT)
    call plot_get_header (obj%p, header, comment)
  end select
end subroutine analysis_object_get_header
```

5.1.10 Analysis object iterator

Analysis objects are containers which have iterable data structures: histograms/bins and plots/points. If they are to be treated on a common basis, it is useful to have an iterator which hides the implementation details.

The iterator is used only for elementary analysis objects that contain plot data: histograms or plots. It is invalid for meta-objects (graphs) and non-graphical objects (observables).

```
<Analysis: public>+≡
public :: analysis_iterator_t

<Analysis: types>+≡
type :: analysis_iterator_t
  private
  integer :: type = AN_UNDEFINED
  type(analysis_object_t), pointer :: object => null ()
  integer :: index = 1
```

```

    type(point_t), pointer :: point => null ()
end type

```

The initializer places the iterator at the beginning of the analysis object.

```

<Analysis: procedures>+≡
subroutine analysis_iterator_init (iterator, object)
    type(analysis_iterator_t), intent(out) :: iterator
    type(analysis_object_t), intent(in), target :: object
    iterator%object => object
    if (associated (iterator%object)) then
        iterator%type = iterator%object%type
        select case (iterator%type)
            case (AN_PLOT)
                iterator%point => iterator%object%p%first
        end select
    end if
end subroutine analysis_iterator_init

```

The iterator is valid as long as it points to an existing entry. An iterator for a data object without array data (observable) is always invalid.

```

<Analysis: public>+≡
public :: analysis_iterator_is_valid

<Analysis: procedures>+≡
function analysis_iterator_is_valid (iterator) result (valid)
    logical :: valid
    type(analysis_iterator_t), intent(in) :: iterator
    if (associated (iterator%object)) then
        select case (iterator%type)
            case (AN_HISTOGRAM)
                valid = iterator%index <= histogram_get_n_bins (iterator%object%h)
            case (AN_PLOT)
                valid = associated (iterator%point)
            case default
                valid = .false.
        end select
    else
        valid = .false.
    end if
end function analysis_iterator_is_valid

```

Advance the iterator.

```

<Analysis: public>+≡
public :: analysis_iterator_advance

<Analysis: procedures>+≡
subroutine analysis_iterator_advance (iterator)
    type(analysis_iterator_t), intent(inout) :: iterator
    if (associated (iterator%object)) then
        select case (iterator%type)
            case (AN_PLOT)
                iterator%point => iterator%point%next
        end select
    end if
end subroutine analysis_iterator_advance

```

```

        iterator%index = iterator%index + 1
    end if
end subroutine analysis_iterator_advance

```

Retrieve the object type:

```

<Analysis: public>+≡
    public :: analysis_iterator_get_type

<Analysis: procedures>+≡
    function analysis_iterator_get_type (iterator) result (type)
        integer :: type
        type(analysis_iterator_t), intent(in) :: iterator
        type = iterator%type
    end function analysis_iterator_get_type

```

Use the iterator to retrieve data. We implement a common routine which takes the data descriptors as optional arguments. Data which do not occur in the selected type trigger to an error condition.

The iterator must point to a valid entry.

```

<Analysis: public>+≡
    public :: analysis_iterator_get_data

<Analysis: procedures>+≡
    subroutine analysis_iterator_get_data (iterator, &
        x, y, yerr, xerr, width, excess, index, n_total)
        type(analysis_iterator_t), intent(in) :: iterator
        real(default), intent(out), optional :: x, y, yerr, xerr, width, excess
        integer, intent(out), optional :: index, n_total
        select case (iterator%type)
        case (AN_HISTOGRAM)
            if (present (x)) &
                x = bin_get_midpoint (iterator%object%h%bin(iterator%index))
            if (present (y)) &
                y = bin_get_sum (iterator%object%h%bin(iterator%index))
            if (present (yerr)) &
                yerr = bin_get_error (iterator%object%h%bin(iterator%index))
            if (present (xerr)) &
                call invalid ("histogram", "xerr")
            if (present (width)) &
                width = bin_get_width (iterator%object%h%bin(iterator%index))
            if (present (excess)) &
                excess = bin_get_excess (iterator%object%h%bin(iterator%index))
            if (present (index)) &
                index = iterator%index
            if (present (n_total)) &
                n_total = histogram_get_n_bins (iterator%object%h)
        case (AN_PLOT)
            if (present (x)) &
                x = point_get_x (iterator%point)
            if (present (y)) &
                y = point_get_y (iterator%point)
            if (present (yerr)) &
                yerr = point_get_yerr (iterator%point)
            if (present (xerr)) &

```

```

        xerr = point_get_xerr (iterator%point)
    if (present (width)) &
        call invalid ("plot", "width")
    if (present (excess)) &

```

5.1.11 Analysis store

This data structure holds all observables, histograms and such that are currently active. We have one global store; individual items are identified by their ID strings and types.

```

<Analysis: variables>≡
    type(analysis_store_t), save :: analysis_store

<Analysis: types>+≡
    type :: analysis_store_t
    private
        type(analysis_object_t), pointer :: first => null ()
        type(analysis_object_t), pointer :: last => null ()
    end type analysis_store_t

```

Delete the analysis store

```

<Analysis: public>+≡
    public :: analysis_final

<Analysis: procedures>+≡
    subroutine analysis_final ()
        type(analysis_object_t), pointer :: current
        do while (associated (analysis_store%first))
            current => analysis_store%first
            analysis_store%first => current%next
            call analysis_object_final (current)
        end do
        analysis_store%last => null ()
    end subroutine analysis_final

```

Append a new analysis object

```
<Analysis: procedures>+≡
subroutine analysis_store_append_object (id, type)
  type(string_t), intent(in) :: id
  integer, intent(in) :: type
  type(analysis_object_t), pointer :: obj
  allocate (obj)
  call analysis_object_init (obj, id, type)
  if (associated (analysis_store%last)) then
    analysis_store%last%next => obj
  else
    analysis_store%first => obj
  end if
  analysis_store%last => obj
end subroutine analysis_store_append_object
```

Return a pointer to the analysis object with given ID.

```
<Analysis: procedures>+≡
function analysis_store_get_object_ptr (id) result (obj)
  type(string_t), intent(in) :: id
  type(analysis_object_t), pointer :: obj
  obj => analysis_store%first
  do while (associated (obj))
    if (obj%id == id) return
    obj => obj%next
  end do
end function analysis_store_get_object_ptr
```

Initialize an analysis object: either reset it if present, or append a new entry.

```
<Analysis: procedures>+≡
subroutine analysis_store_init_object (id, type, obj)
  type(string_t), intent(in) :: id
  integer, intent(in) :: type
  type(analysis_object_t), pointer :: obj, next
  obj => analysis_store_get_object_ptr (id)
  if (associated (obj)) then
    next => analysis_object_get_next_ptr (obj)
    call analysis_object_final (obj)
    call analysis_object_init (obj, id, type)
    call analysis_object_set_next_ptr (obj, next)
  else
    call analysis_store_append_object (id, type)
    obj => analysis_store%last
  end if
end subroutine analysis_store_init_object
```

Get the type of a analysis object

```
<Analysis: public>+≡
public :: analysis_store_get_object_type

<Analysis: procedures>+≡
function analysis_store_get_object_type (id) result (type)
  type(string_t), intent(in) :: id
```

```

integer :: type
type(analysis_object_t), pointer :: object
object => analysis_store_get_object_ptr (id)
if (associated (object)) then
    type = object%type
else
    type = AN_UNDEFINED
end if
end function analysis_store_get_object_type

```

Return the number of objects in the store.

<Analysis: procedures>+≡

```

function analysis_store_get_n_objects () result (n)
    integer :: n
    type(analysis_object_t), pointer :: current
    n = 0
    current => analysis_store%first
    do while (associated (current))
        n = n + 1
        current => current%next
    end do
end function analysis_store_get_n_objects

```

Allocate an array and fill it with all existing IDs.

<Analysis: public>+≡

```

public :: analysis_store_get_ids

```

<Analysis: procedures>+≡

```

subroutine analysis_store_get_ids (id)
    type(string_t), dimension(:), allocatable, intent(out) :: id
    type(analysis_object_t), pointer :: current
    integer :: i
    allocate (id (analysis_store_get_n_objects()))
    i = 0
    current => analysis_store%first
    do while (associated (current))
        i = i + 1
        id(i) = current%id
        current => current%next
    end do
end subroutine analysis_store_get_ids

```

5.1.12 L^AT_EX driver file

Write a driver file for all objects in the store.

<Analysis: procedures>+≡

```

subroutine analysis_store_write_driver_all (filename_data, unit)
    type(string_t), intent(in) :: filename_data
    integer, intent(in), optional :: unit
    type(analysis_object_t), pointer :: obj
    call analysis_store_write_driver_header (unit)

```

```

obj => analysis_store%first
do while (associated (obj))
  call analysis_object_write_driver (obj, filename_data, unit)
  obj => obj%next
end do
call analysis_store_write_driver_footer (unit)
end subroutine analysis_store_write_driver_all

```

Write a driver file for an array of objects.

<Analysis: procedures>+≡

```

subroutine analysis_store_write_driver_obj (filename_data, id, unit)
  type(string_t), intent(in) :: filename_data
  type(string_t), dimension(:), intent(in) :: id
  integer, intent(in), optional :: unit
  type(analysis_object_t), pointer :: obj
  integer :: i
  call analysis_store_write_driver_header (unit)
  do i = 1, size (id)
    obj => analysis_store_get_object_ptr (id(i))
    if (associated (obj)) &
      call analysis_object_write_driver (obj, filename_data, unit)
  end do
  call analysis_store_write_driver_footer (unit)
end subroutine analysis_store_write_driver_obj

```

The beginning of the driver file.

<Analysis: procedures>+≡

```

subroutine analysis_store_write_driver_header (unit)
  integer, intent(in), optional :: unit
  integer :: u
  u = output_unit (unit); if (u < 0) return
  write(u, '(A)') "\documentclass[12pt]{article}"
  write(u, *)
  write(u, '(A)') "\usepackage{gamelan}"

    type(analysis_object_t), pointer :: obj
    obj => analysis_store_get_object_ptr (id)
    if (associated (obj)) then
      call analysis_object_clear (obj)
    end if
  end subroutine analysis_store_clear_obj

  subroutine analysis_store_clear_all ()
    type(analysis_object_t), pointer :: obj
    obj => analysis_store%first
    do while (associated (obj))
      call analysis_object_clear (obj)
      obj => obj%next
    end do
  end subroutine analysis_store_clear_all
```

There is one generic recording function whose behavior depends on the type of analysis object.

```
<Analysis: public>+≡
  public :: analysis_record_data

<Analysis: procedures>+≡
  subroutine analysis_record_data (id, x, y, yerr, xerr, &
    weight, excess, success, exist)
    type(string_t), intent(in) :: id
    real(default), intent(in) :: x
    real(default), intent(in), optional :: y, yerr, xerr, weight, excess
    logical, intent(out), optional :: success, exist
    type(analysis_object_t), pointer :: obj
    obj => analysis_store_get_object_ptr (id)
    if (associated (obj)) then
      call analysis_object_record_data (obj, x, y, yerr, xerr, &
        weight, excess, success)
      if (present (exist)) exist = .true.
    else
      if (present (success)) success = .false.
      if (present (exist)) exist = .false.
    end if
  end subroutine analysis_record_data
```

Build a graph

This routine sets up the array of graph elements by copying the graph elements given as input. The object must exist and already be initialized as a graph.

<Analysis: public>+≡

public :: analysis_fill_graph

<Analysis: procedures>+≡

```
subroutine analysis_fill_graph (id, i, id_in, drawing_options)
  type(string_t), intent(in) :: id
  integer, intent(in) :: i
  type(string_t), intent(in) :: id_in
  type(drawing_options_t), intent(in), optional :: drawing_options
  type(analysis_object_t), pointer :: obj
  type(graph_t), pointer :: g
  type(histogram_t), pointer :: h
  type(plot_t), pointer :: p
  obj => analysis_store_get_object_ptr (id)

5.2 PDG arrays

For defining aliases, we introduce a special type which holds a set of (integer) PDG codes.

```
<pdg_arrays.f90>≡  
  <File header>  
  
  module pdg_arrays  
  
    <Use file utils>  
    use sorting  
  
    <Standard module head>  
  
    <PDG arrays: public>  
  
    <PDG arrays: parameters>  
  
    <PDG arrays: types>  
  
    <PDG arrays: interfaces>  
  
    contains  
  
    <PDG arrays: procedures>  
  
  end module pdg_arrays
```

5.2.1 Type definition

Using an allocatable array eliminates the need for initializer and/or finalizer.

```
<PDG arrays: public>≡  
  public :: pdg_array_t  
  
<PDG arrays: types>≡  
  type :: pdg_array_t  
    private  
    integer, dimension(:), allocatable :: pdg  
  end type pdg_array_t
```

Output

```
<PDG arrays: public>+≡  
  public :: pdg_array_write  
  
<PDG arrays: procedures>≡  
  subroutine pdg_array_write (aval, unit)  
    type(pdg_array_t), intent(in) :: aval  
    integer, intent(in), optional :: unit  
    integer :: u, i  
    u = output_unit (unit); if (u < 0) return  
    write (u, "(A)", advance="no") "PDG("  
    if (allocated (aval%pdg)) then  
      do i = 1, size (aval%pdg)
```

```

        if (i > 1) write (u, "(A)", advance="no") " ", "
        write (u, "(IO)", advance="no")  aval%pdg(i)
    end do
end if
write (u, "(A)", advance="no") " )"
end subroutine pdg_array_write

```

5.2.2 Parameters

We need an UNDEFINED value:

```

⟨PDG arrays: parameters⟩≡
    integer, parameter, public :: UNDEFINED = 0

```

5.2.3 Basic operations

Assignment. We define assignment from and to an integer array. Note that the integer array, if it is the l.h.s., must be declared allocatable by the caller.

```

⟨PDG arrays: public⟩+=
    public :: assignment(=)

⟨PDG arrays: interfaces⟩≡
    interface assignment(=)
        module procedure pdg_array_from_int_array
        module procedure pdg_array_from_int
        module procedure int_array_from_pdg_array
    end interface

⟨PDG arrays: procedures⟩+=
    subroutine pdg_array_from_int_array (aval, iarray)
        type(pdg_array_t), intent(out) :: aval
        integer, dimension(:), intent(in) :: iarray
        allocate (aval%pdg (size (iarray)))
        aval%pdg = iarray
    end subroutine pdg_array_from_int_array

    elemental subroutine pdg_array_from_int (aval, int)
        type(pdg_array_t), intent(out) :: aval
        integer, intent(in) :: int
        allocate (aval%pdg (1))
        aval%pdg = int
    end subroutine pdg_array_from_int

    subroutine int_array_from_pdg_array (iarray, aval)
        integer, dimension(:), allocatable, intent(out) :: iarray
        type(pdg_array_t), intent(in) :: aval
        if (allocated (aval%pdg)) then
            allocate (iarray (size (aval%pdg)))
            iarray = aval%pdg
        else
            allocate (iarray (0))
        end if
    end subroutine int_array_from_pdg_array

```

Length of the array.

```
(PDG arrays: public)+≡  
  public :: pdg_array_get_length  
  
(PDG arrays: procedures)+≡  
  function pdg_array_get_length (aval) result (n)  
    type(pdg_array_t), intent(in) :: aval  
    integer :: n  
    if (allocated (aval%pdg)) then  
      n = size (aval%pdg)  
    else  
      n = 0  
    end if  
  end function pdg_array_get_length
```

Return the element with index i.

```
(PDG arrays: public)+≡  
  public :: pdg_array_get  
  
(PDG arrays: procedures)+≡  
  function pdg_array_get (aval, i) result (pdg)  
    type(pdg_array_t), intent(in) :: aval  
    integer, intent(in) :: i  
    integer :: pdg  
    pdg = aval%pdg(i)  
  end function pdg_array_get
```

Replace element with index i by a new array of elements.

```
(PDG arrays: public)+≡  
  public :: pdg_array_replace  
  
(PDG arrays: procedures)+≡  
  function pdg_array_replace (aval, i, pdg_new) result (aval_new)  
    type(pdg_array_t), intent(in) :: aval  
    integer, intent(in) :: i  
    integer, dimension(:), intent(in) :: pdg_new  
    type(pdg_array_t) :: aval_new  
    integer :: n, k, l  
    integer, dimension(:), allocatable :: tmp  
    n = size (aval%pdg)  
    l = size (pdg_new)  
    allocate (aval_new%pdg (n + l - 1))  
    aval_new%pdg(:i-1) = aval%pdg(:i-1)  
    aval_new%pdg(i:i+l-1) = pdg_new  
    aval_new%pdg(i+l:) = aval%pdg(i+1:)  
  end function pdg_array_replace
```

Concatenate two PDG arrays

```
(PDG arrays: public)+≡  
  public :: operator(//)
```

```

<PDG arrays: interfaces>+≡
  interface operator(//)
    module procedure concat_pdg_arrays
  end interface

<PDG arrays: procedures>+≡
  function concat_pdg_arrays (aval1, aval2) result (aval)
    type(pdg_array_t) :: aval
    type(pdg_array_t), intent(in) :: aval1, aval2
    integer :: n1, n2
    if (allocated (aval1%pdg) .and. allocated (aval2%pdg)) then
      n1 = size (aval1%pdg)
      n2 = size (aval2%pdg)
      allocate (aval%pdg (n1 + n2))
      aval%pdg(:n1) = aval1%pdg
      aval%pdg(n1+1:) = aval2%pdg
    else if (allocated (aval1%pdg)) then
      aval = aval1
    else if (allocated (aval2%pdg)) then
      aval = aval2
    end if
  end function concat_pdg_arrays

```

5.2.4 Matching

A PDG array matches a given PDG code if the code is present within the array. If either one is zero (UNDEFINED), the match also succeeds.

```

<PDG arrays: public>+≡
  public :: operator(.match.)

<PDG arrays: interfaces>+≡
  interface operator(.match.)
    module procedure pdg_array_match_integer
  end interface

<PDG arrays: procedures>+≡
  elemental function pdg_array_match_integer (aval, pdg) result (flag)
    logical :: flag
    type(pdg_array_t), intent(in) :: aval
    integer, intent(in) :: pdg
    if (allocated (aval%pdg)) then
      flag = pdg == UNDEFINED &
        .or. any (aval%pdg == UNDEFINED) &
        .or. any (aval%pdg == pdg)
    else
      flag = .false.
    end if
  end function pdg_array_match_integer

```

Comparison. Here, we take the PDG arrays as-is, assuming that they are sorted.

The ordering is a bit odd: first, we look only at the absolute values of the PDG codes. If they all match, the particle comes before the antiparticle, scanning from left to right.

```

(PDG arrays: public)+≡
public :: operator(<)
public :: operator(>)
public :: operator(<=)
public :: operator(>=)
public :: operator(==)
public :: operator(/=)

(PDG arrays: interfaces)+≡

  type(pdg_array_t), intent(in) :: aval1, aval2
  logical :: flag
  flag = .not. (aval1 == aval2)
end function pdg_array_ne

```

Equivalence. Two PDG arrays are equivalent if either both contain UNDEFINED or each element of array 1 is present in array 2, and vice versa.

```

<PDG arrays: public>+≡
  public :: operator(.eqv.)
  public :: operator(.neqv.)

<PDG arrays: interfaces>+≡
  interface operator(.eqv.)
    module procedure pdg_array_equivalent
  end interface
  interface operator(.neqv.)
    module procedure pdg_array_inequivalent
  end interface

<PDG arrays: procedures>+≡
  function pdg_array_equivalent (aval1, aval2) result (eq)
    logical :: eq
    type(pdg_array_t), intent(in) :: aval1, aval2
    logical, dimension(:), allocatable :: match1, match2

```

```

integer :: i
if (allocated (aval1%pdg) .and. allocated (aval2%pdg)) then
  eq = any (aval1%pdg == UNDEFINED) &
    .and. any (aval2%pdg == UNDEFINED)
  if (.not. eq) then
    allocate (match1 (size (aval1%pdg)))
    allocate (match2 (size (aval2%pdg)))
    match1 = .false.
    match2 = .false.
    do i = 1, size (aval1%pdg)
      match2 = match2 .or. aval1%pdg(i) == aval2%pdg
    end do
    do i = 1, size (aval2%pdg)
      match1 = match1 .or. aval2%pdg(i) == aval1%pdg
    end do
    eq = all (match1) .and. all (match2)
  end if
else
  eq = .false.
end if
end function pdg_array_equivalent

function pdg_array_inequivalent (aval1, aval2) result (neq)
  logical :: neq
  type(pdg_array_t), intent(in) :: aval1, aval2
  neq = .not. pdg_array_equivalent (aval1, aval2)
end function pdg_array_inequivalent

```

5.2.5 Sorting

Sort a PDG array by absolute value, particle before antiparticle.

```

(PDG arrays: public)+≡
  public :: sort_abs

(PDG arrays: interfaces)+≡
  interface sort_abs
    module procedure pdg_array_sort_abs
  end interface

(PDG arrays: procedures)+≡
  function pdg_array_sort_abs (aval1) result (aval2)
    type(pdg_array_t), intent(in) :: aval1
    type(pdg_array_t) :: aval2
    allocate (aval2%pdg (size (aval1%pdg)))
    aval2%pdg = sort_abs (aval1%pdg)
  end function pdg_array_sort_abs

```

5.3 subevents

The purpose of subevents is to store the relevant part of the physical event (either partonic or hadronic), and to hold particle selections and combinations which are constructed in cut or analysis expressions.

```
<subevents.f90>≡  
  <File header>  
  
  module subevents  
  
    use iso_c_binding !NODEP!  
    <Use kinds>  
    <Use file utils>  
    use c_particles !NODEP!  
    use lorentz !NODEP!  
    use sorting  
    use pdg_arrays  
  
    <Standard module head>  
  
    <Subevents: public>  
  
    <Subevents: parameters>  
  
    <Subevents: types>  
  
    <Subevents: interfaces>  
  
    contains  
  
    <Subevents: procedures>  
  
  end module subevents
```

5.3.1 Particles

For the purpose of this module, a particle has a type which can indicate a beam, incoming, outgoing, or composite particle, flavor and helicity codes (integer, undefined for composite), four-momentum and invariant mass squared. (Other particles types are used in extended event types, but also defined here.) Furthermore, each particle has an allocatable array of ancestors – particle indices which indicate the building blocks of a composite particle. For an incoming/outgoing particle, the array contains only the index of the particle itself.

For incoming particles, the momentum is inverted before storing it in the particle object.

```
<Subevents: parameters>≡  
  integer, parameter, public :: PRT_UNDEFINED = 0  
  integer, parameter, public :: PRT_BEAM = -9  
  integer, parameter, public :: PRT_INCOMING = 1  
  integer, parameter, public :: PRT_OUTGOING = 2  
  integer, parameter, public :: PRT_COMPOSITE = 3  
  integer, parameter, public :: PRT_VIRTUAL = 4
```

```

integer, parameter, public :: PRT_RESONANT = 5
integer, parameter, public :: PRT_BEAM_REMNANT = 9

```

The type

We initialize only the type here and mark as unpolarized. The initializers below do the rest.

```

<Subevents: public>≡
    public :: prt_t

<Subevents: types>≡
    type :: prt_t
        private
        integer :: type = PRT_UNDEFINED
        integer :: pdg
        logical :: polarized = .false.
        integer :: h
        type(vector4_t) :: p
        real(default) :: p2
        integer, dimension(:), allocatable :: src
    end type prt_t

```

Initializers. Polarization is set separately. Finalizers are not needed.

```

<Subevents: procedures>≡
    subroutine prt_init_beam (prt, pdg, p, p2, src)
        type(prt_t), intent(out) :: prt
        integer, intent(in) :: pdg
        type(vector4_t), intent(in) :: p
        real(default), intent(in) :: p2
        integer, dimension(:), intent(in) :: src
        prt%type = PRT_BEAM
        call prt_set (prt, pdg, - p, p2, src)
    end subroutine prt_init_beam

    subroutine prt_init_incoming (prt, pdg, p, p2, src)
        type(prt_t), intent(out) :: prt
        integer, intent(in) :: pdg
        type(vector4_t), intent(in) :: p
        real(default), intent(in) :: p2
        integer, dimension(:), intent(in) :: src
        prt%type = PRT_INCOMING
        call prt_set (prt, pdg, - p, p2, src)
    end subroutine prt_init_incoming

    subroutine prt_init_outgoing (prt, pdg, p, p2, src)
        type(prt_t), intent(out) :: prt
        integer, intent(in) :: pdg
        type(vector4_t), intent(in) :: p
        real(default), intent(in) :: p2
        integer, dimension(:), intent(in) :: src
        prt%type = PRT_OUTGOING
        call prt_set (prt, pdg, p, p2, src)
    end subroutine prt_init_outgoing

```

```

end subroutine prt_init_outgoing

subroutine prt_init_composite (prt, p, src)
  type(prt_t), intent(out) :: prt
  type(vector4_t), intent(in) :: p
  integer, dimension(:), intent(in) :: src
  prt%type = PRT_COMPOSITE
  call prt_set (prt, 0, p, p**2, src)
end subroutine prt_init_composite

```

This version is for temporary particle objects, so the `src` array is not set.

```

<Subevents: public>+≡
  public :: prt_init_combine

<Subevents: procedures>+≡

    do i = 1, size (prt%src)
      write (u, "(1x,I0)", advance="no") prt%src(i)
    end do
  end if
  write (u, "(A)" ) " "
end subroutine prt_write

```

Tools

Two particles match if their `src` arrays are the same.

```
<Subevents: interfaces>+≡
  interface operator(.match.)
    module procedure prt_match
  end interface

<Subevents: procedures>+≡
  elemental function prt_match (prt1, prt2) result (match)
    logical :: match
    type(prt_t), intent(in) :: prt1, prt2
    if (size (prt1%src) == size (prt2%src)) then
      match = all (prt1%src == prt2%src)
    else
      match = .false.
    end if
  end function prt_match
```

The combine operation makes a pseudoparticle whose momentum is the result of adding (the momenta of) the pair of input particles. We trace the particles from which a particle is built by storing a `src` array. Each particle entry in the `src` list contains a list of indices which indicates its building blocks. The indices refer to an original list of particles. Index lists are sorted, and they contain no element more than once.

We thus require that in a given pseudoparticle, each original particle occurs at most once.

The result is intent(inout), so it will not be initialized when the subroutine is entered.

```
<Subevents: procedures>+≡
  subroutine prt_combine (prt, prt_in1, prt_in2, ok)
    type(prt_t), intent(inout) :: prt
    type(prt_t), intent(in) :: prt_in1, prt_in2
    logical :: ok
    integer, dimension(:), allocatable :: src
    call combine_index_lists (src, prt_in1%src, prt_in2%src)
    ok = allocated (src)
    if (ok) call prt_init_composite (prt, prt_in1%p + prt_in2%p, src)
  end subroutine prt_combine
```

This variant does not produce the combined particle, it just checks whether the combination is valid (no common `src` entry).

```
<Subevents: public>+≡
  public :: are_disjoint

<Subevents: procedures>+≡
  function are_disjoint (prt_in1, prt_in2) result (flag)
    logical :: flag
    type(prt_t), intent(in) :: prt_in1, prt_in2
    flag = index_lists_are_disjoint (prt_in1%src, prt_in2%src)
  end function are_disjoint
```

`src` Lists with length > 1 are built by a `combine` operation which merges the lists in a sorted manner. If the result would have a duplicate entry, it is discarded, and the result is unallocated.

(Subevents: procedures)+≡

```
subroutine combine_index_lists (res, src1, src2)
  integer, dimension(:), intent(in) :: src1, src2
  integer, dimension(:), allocatable :: res
  integer :: i1, i2, i
  allocate (res (size (src1) + size (src2)))
  i1 = 1
  i2 = 1
  LOOP: do i = 1, size (res)
    if (src1(i1) < src2(i2)) then
      res(i) = src1(i1); i1 = i1 + 1
      if (i1 > size (src1)) then
        res(i+1:) = src2(i2:)
        exit LOOP
      end if
    else if (src1(i1) > src2(i2)) then
      res(i) = src2(i2); i2 = i2 + 1
      if (i2 > size (src2)) then
        res(i+1:) = src1(i1:)
        exit LOOP
      end if
    else
      deallocate (res)
      exit LOOP
    end if
  end do LOOP
end subroutine combine_index_lists
```

This function is similar, but it does not actually merge the list, it just checks whether they are disjoint (no common `src` entry).

(Subevents: procedures)+≡

```
function index_lists_are_disjoint (src1, src2) result (flag)
  logical :: flag
  integer, dimension(:), intent(in) :: src1, src2
  integer :: i1, i2, i
  flag = .true.
  i1 = 1
  i2 = 1
  LOOP: do i = 1, size (src1) + size (src2)
    if (src1(i1) < src2(i2)) then
      i1 = i1 + 1
      if (i1 > size (src1)) then
        exit LOOP
      end if
    else if (src1(i1) > src2(i2)) then
      i2 = i2 + 1
      if (i2 > size (src2)) then
        exit LOOP
      end if
    else
      exit LOOP
    end if
  end do LOOP
end function index_lists_are_disjoint
```

```

        flag = .false.
        exit LOOP
    end if
end do LOOP
end function index_lists_are_disjoint

```

5.3.2 C-compatible particle type

5.3.3 subevents

Particles are collected in subevents. This type is implemented as a dynamically allocated array, which need not be completely filled. The value `n_active` determines the number of meaningful entries.

Type definition

```

<Subevents: public>+≡
    public :: subevt_t

<Subevents: types>+≡
    type :: subevt_t
        private
        integer :: n_active = 0
        type(prt_t), dimension(:), allocatable :: prt
    contains
        <Subevents: subevt: TBP>
    end type subevt_t

```

Initialize, allocating with size zero (default) or given size. The number of contained particles is set equal to the size.

```

<Subevents: public>+≡
    public :: subevt_init

<Subevents: procedures>+≡
    subroutine subevt_init (subevt, n_active)
        type(subevt_t), intent(out) :: subevt
        integer, intent(in), optional :: n_active
        if (present (n_active)) subevt%n_active = n_active
        allocate (subevt%prt (subevt%n_active))
    end subroutine subevt_init

```

(Re-)allocate the subevent with some given size. If the size is greater than the previous one, do a real reallocation. Otherwise, just reset the recorded size. Contents are untouched, but become invalid.

```

<Subevents: public>+≡
    public :: subevt_reset

```

```

<Subevents: procedures>+≡
  subroutine subevt_reset (subevt, n_active)
    type(subevt_t), intent(inout) :: subevt
    integer, intent(in) :: n_active
    subevt%n_active = n_active
    if (subevt%n_active > size (subevt%prt)) then
      deallocate (subevt%prt)
      allocate (subevt%prt (subevt%n_active))
    end if
  end subroutine subevt_reset

```

Output. No prefix for the headline 'subevt', because this will usually be printed appending to a previous line.

```

<Subevents: public>+≡
  public :: subevt_write

<Subevents: subevt: TBP>≡
  procedure :: write => subevt_write

<Subevents: procedures>+≡
  subroutine subevt_write (object, unit, prefix)
    class(subevt_t), intent(in) :: object
    integer, intent(in), optional :: unit
    character(*), intent(in), optional :: prefix
    integer :: u, i
    u = output_unit (unit); if (u < 0) return
    write (u, "(1x,A)") "subevent:"
    do i = 1, object%n_active
      if (present (prefix)) write (u, "(A)", advance="no") prefix
      write (u, "(1x,I0)", advance="no") i
      call prt_write (object%prt(i), unit)
    end do
  end subroutine subevt_write

```

Defined assignment: transfer only meaningful entries. This is a deep copy (as would be default assignment).

```

<Subevents: interfaces>+≡
  interface assignment(=)
    module procedure subevt_assign
  end interface

<Subevents: procedures>+≡
  subroutine subevt_assign (subevt, subevt_in)
    type(subevt_t), intent(inout) :: subevt
    type(subevt_t), intent(in) :: subevt_in
    if (.not. allocated (subevt%prt)) then
      call subevt_init (subevt, subevt_in%n_active)
    else

Operations with subevents

The join operation joins two subevents. When appending the elements of the second list, we check for each particle whether it is already in the first list. If yes, it is discarded. The result list should be initialized already.

If a mask is present, it refers to the second subevent. Particles where the mask is not set are discarded.

<Subevents: public>+≡

```

public :: subevt_join

```

<Subevents: procedures>+≡

```

subroutine subevt_join (subevt, pl1, pl2, mask2)
  type(subevt_t), intent(inout) :: subevt
  type(subevt_t), intent(in) :: pl1, pl2
  logical, dimension(:), intent(in), optional :: mask2
  integer :: n1, n2, i, n
  n1 = pl1%n_active

            return
        end if
    end do
    flag = .true.
end function disjoint
end subroutine subevt_join

```

The combine operation makes a subevent whose entries are the result of adding (the momenta of) each pair of particles in the input lists. We trace the particles from which a particle is built by storing a `src` array. Each particle entry in the `src` list contains a list of indices which indicates its building blocks. The indices refer to an original list of particles. Index lists are sorted, and they contain no element more than once.

We thus require that in a given pseudoparticle, each original particle occurs at most once.

<Subevents: public>+≡

```
public :: subevt_combine
```

<Subevents: procedures>+≡

```

subroutine subevt_combine (subevt, pl1, pl2, mask12)
    type(subevt_t), intent(inout) :: subevt
    type(subevt_t), intent(in) :: pl1, pl2
    logical, dimension(:,,:), intent(in), optional :: mask12
    integer :: n1, n2, i1, i2, n, j
    logical :: ok
    n1 = pl1%n_active
    n2 = pl2%n_active
    call subevt_reset (subevt, n1 * n2)
    n = 1
    do i1 = 1, n1
        do i2 = 1, n2
            if (present (mask12)) then
                ok = mask12(i1,i2)
            else

```

```

        ok = .true.
    end if

    if (ok) then
        CHECK_DOUBLES: do j = 1, n - 1
            if (subevt%prt(n) .match. subevt%prt(j)) then
                ok = .false.; exit CHECK_DOUBLES
            end if
        end do CHECK_DOUBLES
        if (ok) n = n + 1
    end if
end do
subevt%n_active = n - 1
end subroutine subevt_combine

```

The collect operation makes a single-entry subevent which results from combining (the momenta of) all particles in the input list. As above, the result does not contain an original particle more than once; this is checked for each particle when it is collected. Furthermore, each entry has a mask; where the mask is false, the entry is dropped.

(Thus, if the input particles are already composite, there is some chance that the result depends on the order of the input list and is not as expected. This situation should be avoided.)

```

```

5.3.4 Eliminate numerical noise

This is useful for testing purposes: set entries to zero that are smaller in absolute values than a given tolerance parameter.

```

<Subevents: public>+≡
    public :: pacify

<Subevents: interfaces>+≡
    interface pacify
        module procedure pacify_prt
        module procedure pacify_subevt
    end interface pacify

<Subevents: procedures>+≡
    subroutine pacify_prt (prt)
        class(prt_t), intent(inout) :: prt
        real(default) :: e
        e = epsilon (1._default) * energy (prt%p)
        call pacify (prt%p, 10 * e)
        call pacify (prt%p2, 1e4 * e)
    end subroutine pacify_prt

    subroutine pacify_subevt (subevt)
        class(subevt_t), intent(inout) :: subevt
        integer :: i
        do i = 1, subevt%n_active
            call pacify (subevt%prt(i))
        end do
    end subroutine pacify_subevt

```

5.4 User Code Interface

Here we collect interface code that enables the user to inject his own code into the WHIZARD workflow. The code uses data types defined above, and is

referenced in the `expressions` module.

```

<user_code_interface.f90>≡
  <File header>

  module user_code_interface

    use iso_c_binding !NODEP!
    <Use kinds>
    <Use strings>
    use diagnostics !NODEP!
    use c_particles !NODEP!
    use os_interface

    <Standard module head>

    <User Code: public>

    <User Code: variables>

    <User Code: interfaces>

    contains

    <User Code: procedures>

  end module user_code_interface

```

5.4.1 User Code Management

This data structure globally holds the filehandle of the user-code library:

```

<User Code: public>≡
  public :: has_user_lib

<User Code: variables>≡
  type(dlaccess_t), save :: user_lib_handle
  logical, save :: has_user_lib = .false.
  type(string_t), save :: user

```

Compile, link and load user code files. Dlopen all user-provided libraries, included the one just compiled (if any).

By default, we are looking for a library `user.so`. If this is not present, try `user.f90` and compile it. This can be overridden.

In detail: First, compile all sources explicitly specified on the command line. Then collect all libraries specified on the command line, including `user.so` if it was generated. If there is still no code, check for an existing `user.f90` and compile this. Link everything into a `user.la` libtool library. When done, dlopen all libraries that we have so far.

```

<User Code: public>+≡
  public :: user_code_init

```

{User Code: procedures}≡

```
subroutine user_code_init (user_src, user_lib, user_target, rebuild, os_data)
  type(string_t), dimension(:), intent(in) :: user_src, user_lib
  type(string_t), intent(in) :: user_target
  logical, intent(in) :: rebuild
  type(os_data_t), intent(in) :: os_data
  type(string_t) :: user_src_file, user_obj_files, user_lib_file
  logical :: exist
  type(c_funptr) :: fptr
  integer :: i
  call msg_message ("Initializing user code")
  user = user_target; if (user == "") user = "user"
  user_obj_files = ""
  inquire (file = char (user) // ".la", exist = exist)

```

5.4.2 Interfaces for user-defined functions

The following functions represent user-defined real observables. There may be one or two particles as argument, the result is a real value.

```

<User Code: public>+≡
    public :: user_obs_int_unary
    public :: user_obs_int_binary
    public :: user_obs_real_unary
    public :: user_obs_real_binary

<User Code: interfaces>≡
    abstract interface
        function user_obs_int_unary (prt1) result (ival) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!

```

```

        type(c_prt_t), intent(in) :: prt1
        integer(c_int) :: ival
    end function user_obs_int_unary
end interface

abstract interface
    function user_obs_int_binary (prt1, prt2) result (ival) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        integer(c_int) :: ival
    end function user_obs_int_binary
end interface

abstract interface
    function user_obs_real_unary (prt1) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1
        real(c_double) :: rval
    end function user_obs_real_unary
end interface

abstract interface
    function user_obs_real_binary (prt1, prt2) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        real(c_double) :: rval
    end function user_obs_real_binary
end interface

```

The following function takes an array of C-compatible particles and return a single value. The particle array represents a subevent. For C interoperability, we have to use an assumed-size array, hence the array size has to be transferred explicitly.

The cut function returns an `int`, which we should interpret as a logical value (nonzero=true).

```

<User Code: public>+≡
    public :: user_cut_fun

<User Code: interfaces>+≡
    abstract interface
        function user_cut_fun (prt, n_prt) result (iflag) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt
            integer(c_int), intent(in) :: n_prt
            integer(c_int) :: iflag
        end function user_cut_fun
    end interface

```

The event-shape function returns a real value.

```

<User Code: public>+≡
  public :: user_event_shape_fun

<User Code: interfaces>+≡
  abstract interface
    function user_event_shape_fun (prt, n_prt) result (rval) bind(C)
      use iso_c_binding !NODEP!
      use c_particles !NODEP!
      type(c_prt_t), dimension(*), intent(in) :: prt
      integer(c_int), intent(in) :: n_prt
      real(c_double) :: rval
    end function user_event_shape_fun
  end interface

```

5.4.3 Interfaces for user-defined interactions

The following procedure interfaces pertain to user-defined interactions, e.g., spectra or structure functions.

This subroutine retrieves the basic information for setting up the interaction and event generation. All parameters are `intent(inout)`, so we can provide default values. `n_in` and `n_out` are the number of incoming and outgoing particles, respectively. `n_states` is the total number of distinct states that should be generated (counting all states of the incoming particles). `n_col` is the maximal number of color entries a particle can have. `n_dim` is the number of input parameters, i.e., integration dimensions, that the structure function call requires for computing kinematics and matrix elements. `n_var` is the number of variables (e.g., momentum fractions) that the structure function call has to transfer from the kinematics to the dynamics evaluation.

```

<User Code: public>+≡
  public :: user_int_info

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_info (n_in, n_out, n_states, n_col, n_dim, n_var) &
      bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(inout) :: n_in, n_out, n_states, n_col
      integer(c_int), intent(inout) :: n_dim, n_var
    end subroutine user_int_info
  end interface

```

This subroutine retrieves the settings for the quantum number mask of a given particle index in the interaction. A nonzero value indicates that the corresponding quantum number is to be ignored. The lock index is the index of a particle that the current particle is related to. The relation applies if quantum numbers of one of the locked particles are summed over. (This is intended for helicity.)

```

<User Code: public>+≡
  public :: user_int_mask

<User Code: interfaces>+≡
  abstract interface
    subroutine user_int_mask (i_prt, m_flv, m_hel, m_col, i_lock) bind(C)

```

```

        use iso_c_binding !NODEP!
        integer(c_int), intent(in) :: i_prt
        integer(c_int), intent(inout) :: m_flv, m_hel, m_col, i_lock
    end subroutine user_int_mask
end interface

```

This subroutine retrieves the quantum numbers for the particle index `i_prt` in state `i_state`. The `flv` value is a PDG code. The `hel` value is an integer helicity (twice the helicity for fermions). The `col` array is an array which has at most `n_col` entries (see above). All parameters are `intent(inout)` since default values exist. In particular, if a mask entry is set by the previous procedure, the corresponding quantum number is ignored anyway.

```

<User Code: public>+≡
    public :: user_int_state
<User Code: interfaces>+≡
    abstract interface
        subroutine user_int_state (i_state, i_prt, flv, hel, col) bind(C)
            use iso_c_binding !NODEP!
            integer(c_int), intent(in) :: i_state, i_prt
            integer(c_int), intent(inout) :: flv, hel
            integer(c_int), dimension(*), intent(inout) :: col
        end subroutine user_int_state
    end interface

```

This subroutine takes an array of particle objects with array length `n_in` and an array of input parameters between 0 and 1 with array length `n_dim`. It returns an array of particle objects with array length `n_out`. In addition, it returns an array of internal variables (e.g., momentum fractions, Jacobian) with array length `n_var` that is used by the following subroutine for evaluating the dynamics, i.e., the matrix elements.

```

<User Code: public>+≡
    public :: user_int_kinematics
<User Code: interfaces>+≡
    abstract interface
        subroutine user_int_kinematics (prt_in, rval, prt_out, xval) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt_in
            real(c_double), dimension(*), intent(in) :: rval
            type(c_prt_t), dimension(*), intent(inout) :: prt_out
            real(c_double), dimension(*), intent(out) :: xval
        end subroutine user_int_kinematics
    end interface

```

This subroutine takes the array of variables (e.g., momentum fractions) with length `n_var` which has been generated by the previous subroutine and a real variable, the energy scale of the event. It returns an array of matrix-element values, one entry for each quantum state `n_states`. The ordering of matrix elements must correspond to the ordering of states.

```

<User Code: public>+≡
    public :: user_int_evaluate

```

```

⟨User Code: interfaces⟩+≡
  abstract interface
    subroutine user_int_evaluate (xval, scale, fval) bind(C)
      use iso_c_binding !NODEP!
      real(c_double), dimension(*), intent(in) :: xval
      real(c_double), intent(in) :: scale
      real(c_double), dimension(*), intent(out) :: fval
    end subroutine user_int_evaluate
  end interface

```

5.5 Variables

The user interface deals with variables that are handled similar to full-fledged programming languages. The system will add a lot of predefined variables (model parameters, flags, etc.) that are accessible to the user by the same methods.

Variables can be of various type: logical (boolean/flag), integer, real (default precision), subevents (used in cut expressions), arrays of PDG codes (aliases for particles), strings. Furthermore, in cut expressions we have unary and binary observables, which are used like real parameters but behave like functions.

```

⟨variables.f90⟩≡
  ⟨File header⟩

  module variables

    ⟨Use kinds⟩
    ⟨Use strings⟩
    ⟨Use file utils⟩
    use diagnostics !NODEP!
    use lorentz !NODEP!
    use pdg_arrays
    use subevents

    ⟨Standard module head⟩

    ⟨Variables: public⟩

    ⟨Variables: parameters⟩

    ⟨Variables: types⟩

    ⟨Variables: interfaces⟩

    contains

    ⟨Variables: procedures⟩

  end module variables

```

5.5.1 Variable list entries

Variable (and constant) values can be of one of the following types:

```
<Variables: parameters>≡
    integer, parameter, public :: V_NONE = 0, V_LOG = 1, V_INT = 2, V_REAL = 3
    integer, parameter, public :: V_CMPLX = 4, V_SEV = 5, V_PDG = 6, V_STR = 7
    integer, parameter, public :: V_OBS1_INT = 11, V_OBS2_INT = 12
    integer, parameter, public :: V_OBS1_REAL = 21, V_OBS2_REAL = 22
    integer, parameter, public :: V_UOBS1_INT = 31, V_UOBS2_INT = 32
    integer, parameter, public :: V_UOBS1_REAL = 41, V_UOBS2_REAL = 42
```

The type

This is an entry in the variable list. It can be of any type; in each case only one value is allocated. It may be physically allocated upon creation, in which case `is_allocated` is true, or it may contain just a pointer to a value somewhere else, in which case `is_allocated` is false.

The flag `is_defined` is set when the variable is given a value, even the undefined value. (Therefore it is distinct from `is_known`.) This matters for variable declaration in the SINDARIN language. The variable is set up in the compilation step and initially marked as defined, but after compilation all variables are set undefined. Each variable becomes defined when it is explicitly set. The difference matters in loops.

`is_locked` means that it cannot be given a value using the interface routines `var_list_set_XXX` below. It can only be initialized, or change automatically due to a side effect.

`is_copy` means that this is a local copy of a global variable. The copy has a pointer to the original, which can be used to restore a previous value.

`is_intrinsic` means that this variable is defined by the program, not by the user. Intrinsic variables cannot be (re)declared, but their values can be reset unless they are locked. `is_user_var` means that the variable has been declared by the user. It could be a new variable, or a local copy of an intrinsic variable.

The flag `is_known` is a pointer which parallels the use of the value pointer. For pointer variables, it is set if the value should point to a known value. For ordinary variables, it should be true.

The value is implemented as a set of alternative type-specific pointers. This emulates polymorphism, and it allows for actual pointer variables. Observable-type variables have function pointers as values, so they behave like macros. The functions make use of the particle objects accessible via the pointers `prt1` and `prt2`.

Finally, the `next` pointer indicates that we are making lists of variables. A more efficient implementation might switch to hashes or similar; the current implementation has $O(N)$ lookup.

```
<Variables: public>≡
    public :: var_entry_t

<Variables: types>≡
    type :: var_entry_t
        private
        integer :: type = V_NONE
        type(string_t) :: name
```

```

5.5.3 Copies and pointer variables

Initialize an entry with a copy of an existing variable entry. The copy is physically allocated with the same type as the original.

(Variables: procedures)+≡

```

subroutine var_entry_init_copy (var, original, user)
    type(var_entry_t), intent(out) :: var
    type(var_entry_t), intent(in), target :: original
    logical, intent(in), optional :: user
    type(string_t) :: name
    logical :: intrinsic
    name = var_entry_get_name (original)
    intrinsic = original%is_intrinsic
    select case (original%type)
    case (V_LOG)
        call var_entry_init_log (var, name, intrinsic=intrinsic, user=user)
    case (V_INT)
        call var_entry_init_int (var, name, intrinsic=intrinsic, user=user)
    case (V_REAL)
        call var_entry_init_real (var, name, intrinsic=intrinsic, user=user)
    case (V_CMPLX)

```

```

        call var_entry_init_cmplx (var, name, intrinsic=intrinsic, user=user)
    case (V_SEV)
        call var_entry_init_subevt (var, name, intrinsic=intrinsic, user=user)
    case (V_PDG)
        call var_entry_init_pdg_array (var, name, intrinsic=intrinsic, user=user)
    case (V_STR)
        call var_entry_init_string (var, name, intrinsic=intrinsic, user=user)
    end select
    var%is_copy = .true.
end subroutine var_entry_init_copy

```

Clear the pointer to the original.

(Variables: procedures)+≡

```

subroutine var_entry_clear_original_pointer (var)
    type(var_entry_t), intent(inout) :: var
    var%original => null ()
end subroutine var_entry_clear_original_pointer

```

Set the pointer to the original. For a free parameter, the variable holds both the value and the pointer. For a derived parameter, we associate the pointer directly. Derived parameters thus need not be synchronized explicitly.

Update: this does not work. If locked parameters are accessed in expressions and the model is non-default, the pointers in the expression may be undefined at compile time. Reassigning the variables at runtime does not help, since the pointers in the expression are dereferenced before assignment. Hence, no special treatment for derived parameters.

(Variables: procedures)+≡

```

subroutine var_entry_set_original_pointer (var, original)
    type(var_entry_t), intent(inout) :: var
    type(var_entry_t), intent(in), target :: original
    type(string_t) :: name
    type(var_entry_t), pointer :: next
    if (var_entry_is_locked (original)) then
!       next => var%next
!       name = var_entry_get_name (original)
!       select case (original%type)
!       case (V_LOG); call var_entry_init_log_ptr (var, name, &
!           original%lval, original%is_known)
!       case (V_INT); call var_entry_init_int_ptr (var, name, &
!           original%ival, original%is_known)
!       case (V_REAL); call var_entry_init_real_ptr (var, name, &
!           original%rval, original%is_known)
!       case (V_CMPLX); call var_entry_init_cmplx_ptr (var, name, &
!           original%cval, original%is_known)
!       case (V_SEV); call var_entry_init_subevt_ptr (var, name, &
!           original%pval, original%is_known)
!       case (V_PDG); call var_entry_init_pdg_array_ptr (var, name, &
!           original%aval, original%is_known)
!       case (V_STR); call var_entry_init_string_ptr (var, name, &
!           original%sval, original%is_known)
!       end select
!       var%next => next
    end if
end subroutine var_entry_set_original_pointer

```

```

        call var_entry_lock (var)
!      else
!        var%original => original
      end if
      var%original => original
end subroutine var_entry_set_original_pointer

```

Synchronize a variable with its original: if a pointer exists, set the value to be equal to value pointed to.

(Variables: procedures)+≡

```

subroutine var_entry_synchronize (var)
  type(var_entry_t), intent(inout) :: var
  if (associated (var%original)) then
    var%is_defined = var%original%is_defined
    var%is_known = var%original%is_known
    if (var%original%is_known) then
      select case (var%type)
        case (V_LOG); var%lval = var%original%lval
        case (V_INT); var%ival = var%original%ival
        case (V_REAL); var%rval = var%original%rval
        case (V_CMPLX); var%cval = var%original%cval
        case (V_SEV); var%pval = var%original%pval
        case (V_PDG); var%aval = var%original%aval
        case (V_STR); var%sval = var%original%sval
      end select
    end if
  end if
end subroutine var_entry_synchronize

```

Restore the previous value of the original, using the value stored in the variable. This is a side-effect operation.

(Variables: procedures)+≡

```

subroutine var_entry_restore (var)
  type(var_entry_t), intent(inout) :: var
  !!! ifort 11.1 rev5 chokes over the intent(in)
  !!! type(var_entry_t), intent(in) :: var
  if (associated (var%original)) then
    if (var%is_known) then
      select case (var%type)
        case (V_LOG); var%original%lval = var%lval
        case (V_INT); var%original%ival = var%ival
        case (V_REAL); var%original%rval = var%rval
        case (V_CMPLX); var%original%cval = var%cval
        case (V_SEV); var%original%pval = var%pval
        case (V_PDG); var%original%aval = var%aval
        case (V_STR); var%original%sval = var%sval
      end select
    end if
  end if
end subroutine var_entry_restore

```

5.5.4 Variable lists

The type

Variable lists can be linked together. No initializer needed. They are deleted separately.

```
<Variables: public>+≡
    public :: var_list_t
<Variables: types>+≡
    type :: var_list_t
        private
            type(var_entry_t), pointer :: first => null ()

5.5.5 Tools

Return a pointer to the variable list linked to by the current one.

<Variables: public>+≡

```

    public :: var_list_get_next_ptr

```

<Variables: procedures>+≡

```

    function var_list_get_next_ptr (var_list) result (next_ptr)
    type(var_list_t), pointer :: next_ptr
    type(var_list_t), intent(in) :: var_list
    next_ptr => var_list%next
end function var_list_get_next_ptr

```

Return a pointer to the variable with the requested name. If no such name exists, return a null pointer. In that case, try the next list if present, unless `follow_link` is unset. If `defined` is set, ignore entries that exist but are undefined.

<Variables: public>+≡

```

    public :: var_list_get_var_ptr

```

<Variables: procedures>+≡

```

recursive function var_list_get_var_ptr &

    end if
end function var_has_value

```

5.5.6 Process-specific variables

We allow the user to set a numeric process ID for each declared process.

```

<Variables: public>+=
    public :: var_list_init_num_id

<Variables: procedures>+=
    subroutine var_list_init_num_id (var_list, proc_id, num_id)
        type(var_list_t), intent(inout) :: var_list
        type(string_t), intent(in) :: proc_id
        integer, intent(in), optional :: num_id
        call var_list_set_procvar_int (var_list, proc_id, &
            var_str ("num_id"), num_id)
    end subroutine var_list_init_num_id

```

Integration results are stored in special variables. They are initialized by this subroutine. The values may or may not already known.

Note: the values which are not necessarily unique for a process with multiple MCI records, are disabled.

```

<Variables: public>+=
    public :: var_list_init_process_results

<Variables: procedures>+=
    subroutine var_list_init_process_results (var_list, proc_id, &

  end if
end subroutine var_list_set_procvar_real

```

5.5.7 Observable initialization

Observables are formally treated as variables, which however are evaluated each time the observable is used. The arguments (pointers) to evaluate and the function are part of the variable-list entry.

The procedure pointer should be set by this subroutine. This, however, triggers a bug in nagfor 5.2(649). As a workaround, we return the variable pointer, so the pointer can be set directly.

```

{Variables: procedures}+=
subroutine var_list_set_obs (var_list, name, type, var, prt1, prt2)
  type(var_list_t), intent(inout) :: var_list
  type(string_t), intent(in) :: name
  integer, intent(in) :: type
  type(var_entry_t), pointer :: var
  type(prt_t), intent(in), target :: prt1
  type(prt_t), intent(in), optional, target :: prt2
  allocate (var)
  call var_entry_init_obs (var, name, type, prt1, prt2)
  call var_list_append (var_list, var)

```

```
end subroutine var_list_set_obs
```

Unary and binary observables are different. Most unary observables can be equally well evaluated for particle pairs. Binary observables cannot be evaluated for single particles.

```

Check if a variable name is defined as an observable:

```

<Variables: procedures>+≡
function string_is_observable_id (string) result (flag)
    logical :: flag
    type(string_t), intent(in) :: string
    select case (char (string))
    case ("PDG", "Hel", "M", "M2", "E", "Px", "Py", "Pz", "P", "Pl", "Pt", &
        "Theta", "Phi", "Rap", "Eta", "Theta_RF", "Dist", "kT")
        flag = .true.
    case default
        flag = .false.
    end select
end function string_is_observable_id

```

5.5.8 Observables

These are analogous to the unary and binary numeric functions listed above. An observable takes the `pval` component(s) of its one or two argument nodes and produces an integer or real value.

Integer-valued unary observables

The PDG code

```

<Variables: procedures>+≡

```

```

integer function obs_pdg1 (prt1) result (pdg)
  type(prt_t), intent(in) :: prt1
  pdg = prt_get_pdg (prt1)
end function obs_pdg1

```

The helicity. The return value is meaningful only if the particle is polarized, otherwise an invalid value is returned (-9).

```

<Variables: procedures>+≡
integer function obs_helicity1 (prt1) result (h)
  type(prt_t), intent(in) :: prt1
  if (prt_is_polarized (prt1)) then
    h = prt_get_helicity (prt1)
  else
    h = -9
  end if
end function obs_helicity1

```

Real-valued unary observables

The invariant mass squared, obtained from the separately stored value.

```

<Variables: procedures>+≡
real(default) function obs_mass_squared1 (prt1) result (p2)
  type(prt_t), intent(in) :: prt1
  p2 = prt_get_msq (prt1)
end function obs_mass_squared1

```

The signed invariant mass, which is the signed square root of the previous observable.

```

<Variables: procedures>+≡
real(default) function obs_signed_mass1 (prt1) result (m)
  type(prt_t), intent(in) :: prt1
  real(default) :: msq
  msq = prt_get_msq (prt1)
  m = sign (sqrt (abs (msq)), msq)
end function obs_signed_mass1

```

The particle energy

```

<Variables: procedures>+≡
real(default) function obs_energy1 (prt1) result (e)
  type(prt_t), intent(in) :: prt1
  e = energy (prt_get_momentum (prt1))
end function obs_energy1

```

Particle momentum (components)

```

<Variables: procedures>+≡
real(default) function obs_px1 (prt1) result (p)
  type(prt_t), intent(in) :: prt1
  p = vector4_get_component (prt_get_momentum (prt1), 1)
end function obs_px1

```

```

real(default) function obs_py1 (prt1) result (p)
  type(prt_t), intent(in) :: prt1
  p = vector4_get_component (prt_get_momentum (prt1), 2)
end function obs_py1

real(default) function obs_pz1 (prt1) result (p)
  type(prt_t), intent(in) :: prt1
  p = vector4_get_component (prt_get_momentum (prt1), 3)
end function obs_pz1

real(default) function obs_p1 (prt1) result (p)
  type(prt_t), intent(in) :: prt1
  p = space_part_norm (prt_get_momentum (prt1))
end function obs_p1

real(default) function obs_pl1 (prt1) result (p)
  type(prt_t), intent(in) :: prt1
  p = longitudinal_part (prt_get_momentum (prt1))
end function obs_pl1

real(default) function obs_pt1 (prt1) result (p)
  type(prt_t), intent(in) :: prt1
  p = transverse_part (prt_get_momentum (prt1))
end function obs_pt1

```

Polar and azimuthal angle (lab frame).

```

<Variables: procedures>+≡
real(default) function obs_theta1 (prt1) result (p)
  type(prt_t), intent(in) :: prt1

end subroutine event_vars_read_raw

```

5.5.10 API for variable lists

Set a new value. If the variable holds a pointer, this pointer is followed, e.g., a model parameter is actually set. If `ignore` is set, do nothing if the variable does not exist. If `verbose` is set, echo the new value.

The specific versions:

```

{Variables: public}+=
    public :: var_list_set_log
    public :: var_list_set_int
    public :: var_list_set_real
    public :: var_list_set_cmplx
    public :: var_list_set_subevt
    public :: var_list_set_pdg_array
    public :: var_list_set_string

{Variables: procedures}+=
    subroutine var_list_set_log &

5.5.11 Linking model variables

The variable list of a model can be linked to the global variable list, so the model variables become available. However, the model may change during the execution of the command list, and this is not known at compile time. So, we make a copy of all variables that can be modified by the user; this will include all variables that are present in any of the models. At runtime, the linked list and the pointers to it can be exchanged, but the global variables will stay.

Append a single model variable to the local variable list. The pointer to the original is not set (yet). Check first if it already exists; in that case, do nothing.

```

<Variables: public>+≡
  public :: var_list_init_copy

<Variables: procedures>+≡
  subroutine var_list_init_copy (var_list, model_var, user)
    type(var_list_t), intent(inout), target :: var_list
    type(var_entry_t), intent(in), target :: model_var
    logical, intent(in), optional :: user
    type(var_entry_t), pointer :: var
    if (.not. var_list_exists &
        (var_list, model_var%name, follow_link = .false.)) then
      allocate (var)
      call var_entry_init_copy (var, model_var, user)
      call var_list_append (var_list, var)
    end if
  end subroutine var_list_init_copy

```

Append all model variables, or reuse (unset) them if they already exist. If `derived_only` is set, copy only derived parameters; these are real parameters that are locked. How should we (should we at all?) generalize this to complex parameters?

```

<Variables: public>+≡

```

```

public :: var_list_init_copies
<Variables: procedures>+≡
subroutine var_list_init_copies (var_list, model_vars, derived_only)
  type(var_list_t), intent(inout), target :: var_list

```

Clear all previously allocated pointers to some model:

```

<Variables: procedures>+≡
subroutine var_list_clear_original_pointers (var_list)
  type(var_list_t), intent(inout) :: var_list
  type(var_entry_t), pointer :: var
  var => var_list%first
  do while (associated (var))
    call var_entry_clear_original_pointer (var)
    var => var%next
  end do
end subroutine var_list_clear_original_pointers

```

Assign the pointer to the original for a single variable.

```

<Variables: public>+≡
public :: var_list_set_original_pointer
<Variables: procedures>+≡
subroutine var_list_set_original_pointer (var_list, name, model_vars)
  type(var_list_t), intent(inout) :: var_list
  type(string_t), intent(in) :: name

```

```

type(var_list_t), intent(in), target :: model_vars
type(var_entry_t), pointer :: var, model_var
integer :: type
model_var => var_list_get_var_ptr (model_vars, name)
if (associated (model_var)) then
    type = var_entry_get_type (model_var)
    var => var_list_get_var_ptr (var_list, name, type, follow_link=.false.)
    if (associated (var)) then
        call var_entry_set_original_pointer (var, model_var)
    end if
end if
end subroutine var_list_set_original_pointer

```

Assign pointers to the originals for all variables in the model variable list.

```

<Variables: public>+≡
    public :: var_list_set_original_pointers

<Variables: procedures>+≡
    subroutine var_list_set_original_pointers (var_list, model_vars)
        type(var_list_t), intent(inout) :: var_list
        type(var_list_t), intent(in), target :: model_vars
        type(var_entry_t), pointer :: var, model_var
        type(string_t) :: name
        integer :: type
        model_var => model_vars%first
        do while (associated (model_var))
            name = var_entry_get_name (model_var)
            type = var_entry_get_type (model_var)
            var => var_list_get_var_ptr (var_list, name, type, follow_link=.false.)
            if (associated (var)) then
                call var_entry_set_original_pointer (var, model_var)
            end if
            model_var => model_var%next
        end do
    end subroutine var_list_set_original_pointers

```

Synchronize the local variable list with the model variable list (which is accessed by the pointers assigned in the previous subroutine).

If `reset_pointers` is unset, do not reset pointers but just update values where a variable is a copy. Resetting pointers is done only in the local variable list.

```

<Variables: public>+≡
    public :: var_list_synchronize

<Variables: procedures>+≡
    subroutine var_list_synchronize (var_list, model_vars, reset_pointers)
        type(var_list_t), intent(inout) :: var_list
        type(var_list_t), intent(in), target :: model_vars
        logical, intent(in), optional :: reset_pointers
        type(var_entry_t), pointer :: var
        if (present (reset_pointers)) then
            if (reset_pointers) then
                call var_list_clear_original_pointers (var_list)
            end if
        end if
    end subroutine var_list_synchronize

```

```

        call var_list_set_original_pointers (var_list, model_vars)
    end if
end if
var => var_list%first
do while (associated (var))
    call var_entry_synchronize (var)
    var => var%next
end do
end subroutine var_list_synchronize

```

This is the inverse operation: synchronize the model variable list with the current variable list. This is necessary after discarding a local variable list.

For accessing all model variables, we should follow the links first, then scan the current list.

```

<Variables: public>+≡
    public :: var_list_restore

<Variables: procedures>+≡
    recursive subroutine var_list_restore (var_list, follow_link)
        type(var_list_t), intent(inout) :: var_list
        type(var_entry_t), pointer :: var

        flag = .true.
      case default
        flag = .false.
    end select
  else
    flag = .false.
  end if
end function

```

```
end function string_is_num_id
```

5.6 Expressions

In this module we define the structures needed to parse a user-defined expression, to compile it into an evaluation tree, and to evaluate it.

We have two flavors of expressions: one with particles and one without particles. The latter version is used for defining cut/selection criteria and for online analysis.

```
(expressions.f90)≡
  <File header>
```

```
module expressions
```

```
    use iso_c_binding !NODEP!
  <Use kinds>
  <Use strings>
    use constants !NODEP!
  <Use file utils>
    use diagnostics !NODEP!
    use lorentz !NODEP!
    use unit_tests
    use md5
    use formats
    use sorting
    use ifiles
    use lexers
    use syntax_rules
    use parser
    use analysis
    use pdg_arrays
    use subevents
    use user_code_interface
    use variables
```

```
  <Standard module head>
```

```
  <Expressions: public>
```

```
  <Expressions: types>
```

```
  <Expressions: interfaces>
```

```
  <Expressions: variables>
```

```
contains
```

```
  <Expressions: procedures>
```

```
  <Expressions: tests>
```

```
end module expressions
```

5.6.1 Tree nodes

The evaluation tree consists of branch nodes (unary and binary) and of leaf nodes, originating from a common root. The node object should be polymorphic. For the time being, polymorphism is emulated here. This means that we have to maintain all possibilities that the node may hold, including associated procedures as pointers.

The following parameter values characterize the node. Unary and binary operators have sub-nodes. The other are leaf nodes. Possible leafs are literal constants or named-parameter references.

(Expressions: types)≡

```
integer, parameter :: EN_UNKNOWN = 0, EN_UNARY = 1, EN_BINARY = 2
integer, parameter :: EN_CONSTANT = 3, EN_VARIABLE = 4
integer, parameter :: EN_CONDITIONAL = 5, EN_BLOCK = 6
integer, parameter :: EN_RECORD_CMD = 7
integer, parameter :: EN_OBS1_INT = 11, EN_OBS2_INT = 12
integer, parameter :: EN_OBS1_REAL = 21, EN_OBS2_REAL = 22
integer, parameter :: EN_UOBS1_INT = 31, EN_UOBS2_INT = 32
integer, parameter :: EN_UOBS1_REAL = 41, EN_UOBS2_REAL = 42
integer, parameter :: EN_PRT_FUN_UNARY = 101, EN_PRT_FUN_BINARY = 102
integer, parameter :: EN_EVAL_FUN_UNARY = 111, EN_EVAL_FUN_BINARY = 112
integer, parameter :: EN_LOG_FUN_UNARY = 121, EN_LOG_FUN_BINARY = 122
integer, parameter :: EN_INT_FUN_UNARY = 131, EN_INT_FUN_BINARY = 132
integer, parameter :: EN_REAL_FUN_UNARY = 141, EN_REAL_FUN_BINARY = 142
integer, parameter :: EN_FORMAT_STR = 161
```

    end select
end subroutine eval_node_init_obs

```

Initialize a block node which contains, in addition to the expression to be evaluated, a variable definition. The result type is not yet assigned, because we can compile the enclosed expression only after the var list is set up.

Note that the node always allocates a new variable list and appends it to the current one. Thus, if the variable redefines an existing one, it only shadows it but does not reset it. Any side-effects are therefore absent and need not be undone outside the block.

If the flag `new` is set, a variable is (re)declared. This must not be done for intrinsic variables. Vice versa, if the variable is not existent, the `new` flag is required.

(Expressions: procedures)+≡

```

subroutine eval_node_init_block (node, name, type, var_def, var_list)

5.6.2 Operation types

For the operations associated to evaluation tree nodes, we define abstract interfaces for all cases.

Particles/subevents are transferred by-reference, to avoid unnecessary copying. Therefore, subroutines instead of functions. (Furthermore, the function version of `unary_prt` triggers an obscure bug in nagfor 5.2(649) [invalid C code].)

(Expressions: interfaces)≡

```

abstract interface
    logical function unary_log (arg)
        import eval_node_t
        type(eval_node_t), intent(in) :: arg
    end function unary_log
end interface
abstract interface
    integer function unary_int (arg)
        import eval_node_t

```

```

        type(eval_node_t), intent(in) :: arg
    end function unary_int
end interface
abstract interface
    real(default) function unary_real (arg)
        import default
        import eval_node_t
        type(eval_node_t), intent(in) :: arg
    end function unary_real
end interface
abstract interface
    complex(default) function unary_cmplx (arg)

5.6.3 Specific operators

Our expression syntax contains all Fortran functions that make sense. These functions have to be provided in a form that they can be used in procedures pointers, and have the abstract interfaces above. For some intrinsic functions, we could use specific versions provided by Fortran directly. However, this has two drawbacks: (i) We should work with the values instead of the eval-nodes as argument, which complicates the interface; (ii) more importantly, the **default** real type need not be equivalent to double precision. This would, at least, introduce system dependencies. Finally, for operators there are no specific versions.

Therefore, we write wrappers for all possible functions, at the expense of some overhead.

Binary numerical functions

(*Expressions: procedures*) +=

```

integer function add_ii (en1, en2) result (y)

                is_known = .true.
                exit LOOP1
            end if
        end do
    end do LOOP1
end subroutine eval_pp

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

(Expressions: procedures)+≡

```

function user_obs_int_pp (en0, prt1, prt2) result (ival)
    integer :: ival
    type(eval_node_t), intent(inout) :: en0

```

Real, complex and integer values are numeric literals with an optional unit attached. In case of an integer, the unit actually makes it a real value in disguise. The signed version of real values is not possible in generic expressions; it is a special case for numeric constants in model files (see below). We do not introduce signed versions of complex values.

```

Compile a variable, with or without a specified type. Take the list of variables, look for the name and make a node with a pointer to the value. If no type is provided, the variable is numeric, and the stored value determines whether it is real or integer.

We explicitly demand that the variable is defined, so we do not accidentally point to variables that are declared only later in the script but have come into existence in a previous compilation pass.

Variables may actually be anonymous, these are expressions in disguise. In that case, the expression replaces the variable name in the parse tree, and we allocate an ordinary expression node in the eval tree.

Variables of type `V_PDG` (pdg-code array) are not treated here. They are handled by `eval_node_compile_cvariable`.

Retrieve the result of an integration. If the requested process has been integrated, the results are available as special variables. (The variables cannot be accessed in the usual way since they contain brackets in their names.)

Since this compilation step may occur before the processes have been loaded, we have to initialize the required variables before they are used.

This user observable behaves like a variable. We link the node to the generic user-observable entry in the variable list. The syntax element has an argument which provides the name of the user variable, this is stored as an eval-node alongside with the variable. When the variable value is used, the user-supplied external function is called and provides the (real) result value.

Variable definition

A block expression contains a variable definition (first argument) and an expression where the definition can be used (second argument). The `result_type` decides which type of expression is expected for the second argument. For numeric variables, if there is a mismatch between real and integer type, insert an extra node for type conversion.

Conditionals

A conditional has the structure if lexpr then expr else expr. So we first evaluate the logical expression, then depending on the result the first or second expression. Note that the second expression is mandatory.

The `result_type`, if present, defines the requested type of the `then` and `else` clauses. Default is numeric (int/real). If there is a mismatch between real and integer result types, insert conversion nodes.

Comparisons

Up to the loop, this is easy. There is always at least one comparison. This is evaluated, and the result is the logical node `en`. If it is constant, we keep its second sub-node as `en2`. (Thus, at the very end `en2` has to be deleted if `en` is (still) constant.)

If there is another comparison, we first check if the first comparison was constant. In that case, there are two possibilities: (i) it was true. Then, its right-hand side is compared with the new right-hand side, and the result replaces the previous one which is deleted. (ii) it was false. In this case, the result of the whole comparison is false, and we can exit the loop without evaluating anything else.

Now assume that the first comparison results in a valid branch, its second sub-node kept as `en2`. We first need a copy of this, which becomes the new left-hand side. If `en2` is constant, we make an identical constant node `en1`. Otherwise, we make `en1` an appropriate pointer node. Next, the first branch is saved as `en0` and we evaluate the comparison between `en1` and the a right-hand side. If this turns out to be constant, there are again two possibilities: (i) true, then we revert to the previous result. (ii) false, then the wh

end if
end subroutine eval_node_compile_compared_expr

```

This takes two extra arguments: **en1**, the left-hand-side of the comparison, is already allocated and evaluated. **en2** (the right-hand side) and **en** (the result) are allocated by the routine. **pn** is the parse node which contains the operator and the right-hand side as subnodes.

If the result of the comparison is constant, **en1** is deleted but **en2** is kept, because it may be used in a subsequent comparison. **en** then becomes a constant. If the result is variable, **en** becomes a branch node which refers to **en1** and **en2**.

```

A particle-list value is a PDG-code array, a particle identifier, a variable, a (grouped) pexpr, a block pexpr, a conditional, or a particle-list function.

The `cexpr` node is responsible for transforming a constant PDG-code array into a subevent. It takes the code array as its first argument, the event subevent as its second argument, and the requested particle type (incoming/outgoing) as its zero-th argument. The result is the list of particles in the event that match the code array.

Particle functions

This combines the treatment of 'join', 'combine', 'collect', 'select', and 'extract' which all have the same syntax. The one or two argument nodes are allocated. If there is a condition, the condition node is also allocated as a logical expression, for which the variable list is augmented by the appropriate (unary/binary) observables.

5.6.5 Auxiliary functions for the compiler

Issue an error that the current node could not be compiled because of type mismatch:

```

(Expressions: procedures) +=
subroutine eval_type_error (pn, string, t)
    type(parse_node_t), intent(in) :: pn

```

```

character(*), intent(in) :: string
integer, intent(in) :: t
type(string_t) :: type
select case (t)
case (V_NONE); type = "(none)"
case (V_LOG); type = "'logical'"
case (V_INT); type = "'integer'"
case (V_REAL); type = "'real'"
case (V_CMPLX); type = "'complex'"
case default; type = "(unknown)"
end select
call parse_node_write (pn)
call msg_fatal (" The " // string // &
               " operation is not defined for the given argument type " // &
               char (type))
end subroutine eval_type_error

```

If two numerics are combined, the result is integer if both arguments are integer, if one is integer and the other real or both are real, than its argument is real, otherwise complex.

(Expressions: procedures)+≡

```

function numeric_result_type (t1, t2) result (t)
integer, intent(in) :: t1, t2
integer :: t
if (t1 == V_INT .and. t2 == V_INT) then
t = V_INT
else if (t1 == V_INT .and. t2 == V_REAL) then
t = V_REAL
else if (t1 == V_REAL .and. t2 == V_INT) then
t = V_REAL
else if (t1 == V_REAL .and. t2 == V_REAL) then
t = V_REAL
else
t = V_CMPLX
end if
end function numeric_result_type

```

5.6.6 Evaluation

Evaluation is done recursively. For leaf nodes nothing is to be done.

Evaluating particle-list functions: First, we evaluate the particle lists. If a condition is present, we assign the particle pointers of the condition node to the allocated particle entries in the parent node, keeping in mind that the observables in the variable stack used for the evaluation of the condition also contain pointers to these entries. Then, the assigned procedure is evaluated, which sets the subevent in the parent node. If required, the procedure evaluates the condition node once for each (pair of) particles to determine the result.

(Expressions: procedures)+≡

```

5.6.7 Evaluation syntax

We have two different flavors of the syntax: with and without particles.

(Expressions: variables)+≡
 type(syntax_t), target, save :: syntax_expr

```
type(syntax_t), target, save :: syntax_pexpr
```

These are for testing only and may be removed:

<Expressions: public>≡

```
public :: syntax_expr_init
public :: syntax_pexpr_init
```

<Expressions: procedures>+≡

```
subroutine syntax_expr_init ()
  type(ifile_t) :: ifile
  call define_expr_syntax (ifile, particles=.false., analysis=.false.)
  call syntax_init (syntax_expr, ifile)
  call ifile_final (ifile)
end subroutine syntax_expr_init

subroutine syntax_pexpr_init ()
  type(ifile_t) :: ifile
  call define_expr_syntax (ifile, particles=.true., analysis=.false.)
  call syntax_init (syntax_pexpr, ifile)
  call ifile_final (ifile)
end subroutine syntax_pexpr_init
```

<Expressions: public>+≡

```
public :: syntax_expr_final
public :: syntax_pexpr_final
```

<Expressions: procedures>+≡

```
subroutine syntax_expr_final ()
  call syntax_final (syntax_expr)
end subroutine syntax_expr_final

subroutine syntax_pexpr_final ()
  call syntax_final (syntax_pexpr)
end subroutine syntax_pexpr_final
```

<Expressions: public>+≡

```
public :: syntax_pexpr_write
```

<Expressions: procedures>+≡

```
subroutine syntax_pexpr_write (unit)
  integer, intent(in), optional :: unit
  call syntax_write (syntax_pexpr, unit)
end subroutine syntax_pexpr_write
```

<Expressions: public>+≡

```
public :: define_expr_syntax
```

Numeric expressions.

<Expressions: procedures>+≡

```
subroutine define_expr_syntax (ifile, particles, analysis)
  type(ifile_t), intent(inout) :: ifile
  logical, intent(in) :: particles, analysis
  type(string_t) :: numeric_pexpr
  type(string_t) :: var_plist, var_alias
```

```

    end function eval_tree_get_md5sum

```

5.6.10 Direct evaluation

These procedures create an eval tree and evaluate it on-the-fly, returning only the final value. The evaluation must yield a well-defined value, unless the `is_known` flag is present, which will be set accordingly.

Chapter 6

Physics Models

A model object represents a physics model. It contains a table of particle data, a list of parameters, and a vertex table. The list of parameters is a variable list which includes the real parameters (which are pointers to the particle data table) and PDG array variables for the particles themselves. The vertex list is used for phase-space generation, not for calculating the matrix element.

Model definitions are read from model files. Therefore, this module contains a parser for model files. The parameter definitions (derived parameters) are Sindarin expressions.

The models, as read from file, are stored in a model library which is a simple list of model definitions. For setting up a process object we should make a copy (an instance) of a model, which gets the current parameter values from the global variable list.

6.1 Model module

```
<models.f90>≡  
  <File header>  
  
  module models  
  
    use iso_c_binding !NODEP!  
    <Use kinds>  
    use kinds, only: i8, i32 !NODEP!  
    use kinds, only: c_default_float !NODEP!  
    <Use strings>  
    use limits, only: VERTEX_TABLE_SCALE_FACTOR !NODEP!  
    <Use file utils>  
    use unit_tests  
    use md5  
    use os_interface  
    use hashes, only: hash  
    use diagnostics !NODEP!  
    use ifiles  
    use syntax_rules  
    use lexers  
    use parser
```

```

    use pdg_arrays
    use variables
    use expressions

    <Standard module head>

    <Models: public>

    <Models: parameters>

    <Models: types>

    <Models: interfaces>

    <Models: variables>

contains

    <Models: procedures>

    <Models: tests>

end module models

```

6.1.1 Physics Parameters

A parameter has a name, a value. Derived parameters also have a definition in terms of other parameters, which is stored as an `eval_tree`. External parameters are set by an external program.

The `pn` component is a pointer to the parameter definition inside the model parse tree. It allows us to recreate the `eval_tree` when making copies (instances) of the parameter object.

```

<Models: parameters>≡
    integer, parameter :: PAR_NONE = 0
    integer, parameter :: PAR_INDEPENDENT = 1, PAR_DERIVED = 2
    integer, parameter :: PAR_EXTERNAL = 3

<Models: public>≡
    public :: parameter_t

<Models: types>≡
    type :: parameter_t
    private
    integer :: type = PAR_NONE
    type(string_t) :: name
    real(default) :: value = 0
    type(parse_node_t), pointer :: pn => null ()
    type(eval_tree_t) :: eval_tree
end type parameter_t

```

Initialization depends on parameter type. Independent parameters are initialized by a constant value or a constant numerical expression (which may contain

a unit). Derived parameters are initialized by an arbitrary numerical expression, which makes use of the current variable list. The expression is evaluated by the function `parameter_reset`.

```

<Models: procedures>≡
  subroutine parameter_init_independent_value (par, name, value)
    type(parameter_t), intent(out) :: par
    type(string_t), intent(in) :: name
    real(default), intent(in) :: value
    par%type = PAR_INDEPENDENT
    par%name = name
    par%value = value
  end subroutine parameter_init_independent_value

  subroutine parameter_init_independent (par, name, pn)
    type(parameter_t), intent(out) :: par
    type(string_t), intent(in) :: name
    type(parse_node_t), intent(in), target :: pn
    par%type = PAR_INDEPENDENT
    par%name = name
    par%pn => pn
    call eval_tree_init_numeric_value (par%eval_tree, pn)
    par%value = eval_tree_get_real (par%eval_tree)
  end subroutine parameter_init_independent

  subroutine parameter_init_derived (par, name, pn, var_list)
    type(parameter_t), intent(out) :: par
    type(string_t), intent(in) :: name
    type(parse_node_t), intent(in), target :: pn
    type(var_list_t), intent(in), target :: var_list
    par%type = PAR_DERIVED
    par%name = name
    par%pn => pn
    call eval_tree_init_expr (par%eval_tree, pn, var_list=var_list)
    call parameter_reset_derived (par)
  end subroutine parameter_init_derived

  subroutine parameter_init_external (par, name)
    type(parameter_t), intent(out) :: par
    type(string_t), intent(in) :: name
    par%type = PAR_EXTERNAL
    par%name = name
  end subroutine parameter_init_external

```

The finalizer is needed for the evaluation tree in the definition.

```

<Models: procedures>+≡
  subroutine parameter_final (par)
    type(parameter_t), intent(inout) :: par
    call eval_tree_final (par%eval_tree)
  end subroutine parameter_final

```

All derived parameters should be recalculated if some independent parameters have changed:

```

<Models: procedures>+≡

```

```

subroutine parameter_reset_derived (par)
  type(parameter_t), intent(inout) :: par
  select case (par%type)
  case (PAR_DERIVED)
    call eval_tree_evaluate (par%eval_tree)
    par%value = eval_tree_get_real (par%eval_tree)
  end select
end subroutine parameter_reset_derived

```

Direct access to the parameter value:

(Models: procedures)+≡

```

function parameter_get_value_ptr (par) result (val)
  real(default), pointer :: val
  type(parameter_t), intent(in), target :: par
  val => par%value
end function parameter_get_value_ptr

```

Output. [We should have a formula format for the eval tree, suitable for input and output!]

(Models: procedures)+≡

```

subroutine parameter_write (par, unit, write_defs)
  type(parameter_t), intent(in) :: par
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: write_defs
  logical :: defs
  integer :: u
  u = output_unit (unit); if (u < 0) return
  defs = .false.; if (present (write_defs)) defs = write_defs

    if (defs) then
      call eval_tree_write (par%eval_tree, unit)
    else
      write (u, *)
    end if
  case default
    write (u, *)
  end select
end subroutine parameter_write

```

Screen output variant.

(Models: procedures)+≡

```

subroutine parameter_show_independent (par, l, u)
  type(parameter_t), intent(in) :: par
  integer, intent(in) :: l, u
  character(len=1) :: buffer
  select case (par%type)
  case (PAR_INDEPENDENT)
    buffer = par%name
    write (u, "(4x,A,1x,'=',1x,ES19.12)") buffer, par%value
  end select
end subroutine parameter_show_independent

subroutine parameter_show_derived (par, l, u)
  type(parameter_t), intent(in) :: par
  integer, intent(in) :: l, u
  character(len=1) :: buffer
  select case (par%type)
  case (PAR_DERIVED)
    buffer = par%name
    write (u, "(4x,A,1x,'=',1x,ES19.12)") buffer, par%value
  end select
end subroutine parameter_show_derived

subroutine parameter_show_external (par, l, u)
  type(parameter_t), intent(in) :: par
  integer, intent(in) :: l, u
  character(len=1) :: buffer
  select case (par%type)
  case (PAR_EXTERNAL)
    buffer = par%name
    write (u, "(4x,A,1x,'=',1x,ES19.12)") buffer, par%value
  end select
end subroutine parameter_show_external

```

6.1.2 Particle codes

Let us define a few particle codes independent of the model.

SM fermions:

```

<Models: types>+≡
  integer, parameter, public :: ELECTRON = 11

```

Gauge bosons:

```

<Models: types>+≡
  integer, parameter, public :: GLUON = 21
  integer, parameter, public :: PHOTON = 22
  integer, parameter, public :: Z_BOSON = 23
  integer, parameter, public :: W_BOSON = 24

```

Hadrons:

```

<Models: types>+≡
  integer, parameter, public :: PROTON = 2212

```

```

<Models: types>+=
    integer, parameter, public :: PION = 111
    integer, parameter, public :: PIPLUS = 211
    integer, parameter, public :: PIMINUS = - PIPLUS

```

Hadron remnants (internal)

```

<Models: types>+=
    integer, parameter, public :: HADRON_REMNANT = 90
    integer, parameter, public :: HADRON_REMNANT_SINGLET = 91
    integer, parameter, public :: HADRON_REMNANT_TRIPLET = 92
    integer, parameter, public :: HADRON_REMNANT_OCTET = 93

```

Generic particles for internal use in event analysis:

```

<Models: types>+=
    integer, parameter, public :: PRT_ANY = 81
    integer, parameter, public :: PRT_VISIBLE = 82
    integer, parameter, public :: PRT_CHARGED = 83
    integer, parameter, public :: PRT_COLORED = 84

```

Further particle codes for internal use:

```

<Models: types>+=
    integer, parameter, public :: INVALID = 97
    integer, parameter, public :: KEYSTONE = 98
    integer, parameter, public :: COMPOSITE = 99

```

6.1.3 Spin codes

Somewhat redundant, but for better readability we define named constants for spin types. If the mass is nonzero, this is equal to the number of degrees of freedom.

```

<Models: types>+=
    integer, parameter, public :: UNKNOWN=0
    integer, parameter, public :: SCALAR=1, SPINOR=2, VECTOR=3, &
        VECTORSPINOR=4, TENSOR=5

```

Isospin types and charge types are counted in an analogous way, where charge type 1 is charge 0, 2 is charge 1/3, and so on. Zero always means unknown. Note that charge and isospin types have an explicit sign.

Color types are defined as the dimension of the representation.

6.1.4 Particle data

The particle-data type holds all information that pertains to a particular particle within a particular model. Information such as spin type, particle code etc. is stored within the object itself, while mass and width are associated to parameters, otherwise assumed zero.

```

<Models: public>+=
    public :: particle_data_t

```

<Models: types>+≡

```

type :: particle_data_t
  private
    type(string_t) :: longname
    integer :: pdg = UNDEFINED
    logical :: is_visible = .true.
    logical :: is_parton = .false.
    logical :: is_gauge = .false.
    logical :: is_left_handed = .false.
    logical :: is_right_handed = .false.
    logical :: has_antiparticle = .false.

aval = aval_p // aval_a
end function particle_data_get_colored_pdg

```

6.1.5 Vertex data

The vertex object contains an array of particle-data pointers, for which we need a separate type. (We could use the flavor type defined in another module.)

The program does not (yet?) make use of vertex definitions, so they are not stored here.

<Models: types>+≡

```

type :: particle_p
type(particle_data_t), pointer :: p => null ()
end type particle_p

```

<Models: types>+≡

```

type :: vertex_t
logical :: trilinear
integer, dimension(:), allocatable :: pdg
type(particle_p), dimension(:), allocatable :: prt
end type vertex_t

```

Initialize using PDG codes. The model is used for finding particle data pointers associated with the pdg codes.

<Models: procedures>+≡

```

subroutine vertex_init (vtx, pdg, model)
type(vertex_t), intent(out) :: vtx
integer, dimension(:), intent(in) :: pdg
type(model_t), intent(in), target, optional :: model
integer :: i
allocate (vtx%pdg (size (pdg)))
allocate (vtx%prt (size (pdg)))
vtx%trilinear = size (pdg) == 3
vtx%pdg = pdg
if (present (model)) then

```

```

do i = 1, size (pdg)
  vtx%prt(i)%p => model_get_particle_ptr (model, pdg(i))
end do
end if
end subroutine vertex_init

```

<Models: procedures>+≡

```

subroutine vertex_write (vtx, unit)
  type(vertex_t), intent(in) :: vtx
  integer, intent(in), optional :: unit
  integer :: u, i
  u = output_unit (unit); if (u < 0) return
  write (u, "(3x,A)", advance="no") "vertex"
  do i = 1, size (vtx%prt)
    if (associated (vtx%prt(i)%p)) then
      write (u, "(1x,A)", advance="no") &
        '"" // char (particle_data_get_name &
          (vtx%prt(i)%p, vtx%pdg(i) < 0)) &
        // '""
    else
      write (u, "(1x,I7)", advance="no") vtx%pdg(i)
    end if
  end do
  write (u, *)
end subroutine vertex_write

```

Single-particle lookup: Given a particle code, we return matching codes if present, otherwise zero. Actually, we return the antiparticles of the matching codes, as appropriate for computing splittings.

If the **radiative** flag is not set, we eliminate radiative decays. These have the properties that the initial particle coincides with one of the outgoing particles.

<Models: procedures>+≡

```

subroutine vertex_get_match (vtx, pdg1, pdg2, radiative)
  type(vertex_t), intent(in) :: vtx
  integer, intent(in) :: pdg1
  integer, dimension(:), allocatable, intent(out) :: pdg2
  logical, intent(in) :: radiative
  integer :: i, j
  do i = 1, size (vtx%pdg)
    if (vtx%pdg(i) == pdg1) then
      allocate (pdg2 (size (vtx%pdg) - 1))
      do j = 1, i-1
        pdg2(j) = anti (j)
      end do
      do j = i, size (pdg2)
        pdg2(j) = anti (j+1)
      end do
      exit
    end if
  end do
  if (allocated (pdg2)) then
    if (.not. radiative .and. any (pdg2 == pdg1)) deallocate (pdg2)
  end if
end subroutine vertex_get_match

```

```

    end if
contains
    function anti (i) result (pdg)
        integer, intent(in) :: i
        integer :: pdg
        if (vtx%prt(i)%p%has_antiparticle) then
            pdg = - vtx%pdg(i)
        else
            pdg = vtx%pdg(i)
        end if
    end function anti
end subroutine vertex_get_match

```

6.1.6 Vertex lookup table

The vertex lookup table is a hash table: given two particle codes, we check which codes are allowed for the third one.

The size of the hash table should be large enough that collisions are rare. We first select a size based on the number of vertices (multiplied by six because all permutations count), with some margin, and then choose the smallest integer power of two larger than this.

```

<Limits: public parameters>+≡
    integer, parameter, public :: VERTEX_TABLE_SCALE_FACTOR = 60

<Models: procedures>+≡
    function vertex_table_size (n_vtx) result (n)
        integer(i32) :: n
        integer, intent(in) :: n_vtx
        integer :: i, s
        s = VERTEX_TABLE_SCALE_FACTOR * n_vtx
        n = 1
        do i = 1, 31
            n = ishft (n, 1)
            s = ishft (s,-1)
            if (s == 0) exit
        end do
    end function vertex_table_size

```

The specific hash function takes two particle codes (arbitrary integers) and returns a 32-bit integer. It makes use of the universal function `hash` which operates on a byte array.

```

<Models: procedures>+≡
    function hash2 (pdg1, pdg2)
        integer(i32) :: hash2
        integer, intent(in) :: pdg1, pdg2
        integer(i8), dimension(1) :: mold
        hash2 = hash (transfer ((/pdg1, pdg2/), mold))
    end function hash2

```

Each entry in the vertex table stores the two particle codes and an array of possibilities for the third code.

```

<Models: types>+≡
  type :: vertex_table_entry_t
    integer :: pdg1 = 0, pdg2 = 0
    integer :: n = 0
    integer, dimension(:), allocatable :: pdg3
  end type vertex_table_entry_t

```

The vertex table:

```

<Models: types>+≡
  type :: vertex_table_t
    type(vertex_table_entry_t), dimension(:), allocatable :: entry
    integer :: n_collisions = 0
    integer(i32) :: mask
  end type vertex_table_t

```

Initializing the vertex table: This is done in two passes. First, we scan all permutations for all vertices and count the number of entries in each bucket of the hashtable. Then, the buckets are allocated accordingly and filled.

Collision resolution is done by just incrementing the hash value until an empty bucket is found. The vertex table size is fixed, since we know from the beginning the number of entries.

```

<Models: procedures>+≡
  subroutine vertex_table_init (vt, prt, vtx)
    type(vertex_table_t), intent(out) :: vt
    type(particle_data_t), dimension(:), intent(in) :: prt

```

6.1.7 Model data

A model object holds all information about parameters, particles, and vertices. For models that require an external program for parameter calculation, there is the pointer to a function that does this calculation, given the set of independent and derived parameters.

When reading a model, we create a parse tree. Parameter definitions are available via parse nodes. Since we may need those later when making model instances, we keep the whole parse tree in the model definition (but not in the instances).

(Models: public)+≡

```

    public :: model_t

```

(Models: types)+≡

```

    type :: model_t

```

For a model instance, we do not attempt to load a DL library. This is the core of the full initializer above.

(Models: procedures)+≡

```

subroutine model_basic_init (model, name, n_par, n_prt, n_vtx)
    type(model_t), intent(out) :: model
    type(string_t), intent(in) :: name
    integer, intent(in) :: n_par, n_prt, n_vtx
    model%name = name
    allocate (model%par (n_par))
    allocate (model%prt (n_prt))
    allocate (model%vtx (n_vtx))
end subroutine model_basic_init

```

Finalization: The variable list contains allocated pointers, also the parse tree. We also close the DL access object, if any, that enables external parameter calculation.

(Models: public)+≡

```

    public :: model_final

```

(Models: procedures)+≡

```

subroutine model_final (model)
    type(model_t), intent(inout) :: model
    call var_list_final (model%var_list)
    if (model%dlname /= "") call dlaccess_final (model%dlaccess)
    call parse_tree_final (model%parse_tree)
end subroutine model_final

```

Output. By default, the output is in the form of an input file. If `verbose` is true, for each derived parameter the definition (eval tree) is displayed, and the

vertex hash table is shown.

6.1.10 Model instances

A model instance is a copy of a model object. The parameters are true copies. The particle data and the variable list pointers should point to the copy, so modifying the parameters has only a local effect. Hence, we build them up explicitly. The vertex array is also rebuilt, it contains particle pointers. Finally, the vertex hash table can be copied directly since it contains no pointers.

The **multiplicity** entry depends on the association of the **mass_src** entry and therefore has to be set at the end.

The instance must carry the **target** attribute.

```

<Models: public>+≡
    public :: model_init_instance

```

<Models: procedures>+≡

```

```

6.1.11 Inclusive Processes

Automatically generate a list of possible final states for a given initial state (currently: a single massive particle).

The current implementation is intended for simple 2- and 3-body decays and will perform badly if used for other purposes. We generate all final states recursively without caring about kinematics or doublers, sort each final state, then transfer them all to an array. In this array, we mark all kinematically forbidden channels and all doublers, to finally a packed version.

If the flag `radiative` is unset, we do look at kinematics for each branching: a branching is omitted if either (a) all three

For temporary storage we need a list.

```

<Models: types>+≡
  type, extends (pdg_array_t) :: fs_entry_t
    type(fs_entry_t), pointer :: previous => null ()
    type(fs_entry_t), pointer :: next => null ()
  end type fs_entry_t

```

This is the wrapper type for the decay tree for the list of final states and the final array.

```

<Models: public>+≡
  public :: fs_table_t

```

```

<Models: types>+=
  type :: fs_table_t
    type(model_t), pointer :: model => null ()

Chapter 7

Quantum Numbers

We introduce separate types and modules for particle quantum numbers and use them for defining independent particles and entangled states.

helicities Types and methods for spin density matrices.

colors Dealing with colored particles, using the color-flow representation.

flavors PDG codes and particle properties, depends on the model.

quantum_states Quantum numbers and density matrices for entangled particle systems.

7.1 Helicities

This module defines types and tools for dealing with helicity information.

```
<helicities.f90>≡  
  <File header>  
  
  module helicities  
  
    <Use file utils>  
  
    <Standard module head>  
  
    <Helicities: public>  
  
    <Helicities: types>  
  
    <Helicities: interfaces>  
  
  contains  
  
    <Helicities: procedures>  
  
  end module helicities
```

7.1.1 Helicity types

Helicities may be defined or undefined, corresponding to a polarized or unpolarized state. Each helicity is actually a pair of helicities, corresponding to an entry in the spin density matrix. Obviously, diagonal entries are distinguished. In addition, we have a ghost flag that would apply to FP ghosts in particular.

```
<Helicities: public>≡  
  public :: helicity_t  
  
<Helicities: types>≡  
  type :: helicity_t  
    private  
    logical :: defined = .false.  
    integer :: h1, h2  
    logical :: ghost = .false.  
  end type helicity_t
```

Initializers:

```
<Helicities: public>+≡  
  public :: helicity_init  
  
<Helicities: interfaces>≡  
  interface helicity_init  
    module procedure helicity_init0, helicity_init0g  
    module procedure helicity_init1, helicity_init1g  
    module procedure helicity_init2, helicity_init2g  
  end interface
```

```

<Helicities: procedures>+≡
  elemental subroutine helicity_init0 (hel)
    type(helicity_t), intent(out) :: hel
  end subroutine helicity_init0

  elemental subroutine helicity_init0g (hel, ghost)
    type(helicity_t), intent(out) :: hel
    logical, intent(in) :: ghost
    hel%ghost = ghost
  end subroutine helicity_init0g

  elemental subroutine helicity_init1 (hel, h)
    type(helicity_t), intent(out) :: hel
    integer, intent(in) :: h
    hel%defined = .true.
    hel%h1 = h
    hel%h2 = h
  end subroutine helicity_init1

  elemental subroutine helicity_init1g (hel, h, ghost)
    type(helicity_t), intent(out) :: hel
    integer, intent(in) :: h
    logical, intent(in) :: ghost
    call helicity_init1 (hel, h)
    hel%ghost = ghost
  end subroutine helicity_init1g

  elemental subroutine helicity_init2 (hel, h2, h1)
    type(helicity_t), intent(out) :: hel
    integer, intent(in) :: h1, h2
    hel%defined = .true.
    hel%h2 = h2
    hel%h1 = h1
  end subroutine helicity_init2

  elemental subroutine helicity_init2g (hel, h2, h1, ghost)
    type(helicity_t), intent(out) :: hel
    integer, intent(in) :: h1, h2
    logical, intent(in) :: ghost
    call helicity_init2 (hel, h2, h1)
    hel%ghost = ghost
  end subroutine helicity_init2g

```

Set the ghost property separately:

```

<Helicities: public>+≡
  public :: helicity_set_ghost

<Helicities: procedures>+≡
  elemental subroutine helicity_set_ghost (hel, ghost)
    type(helicity_t), intent(inout) :: hel
    logical, intent(in) :: ghost
    hel%ghost = ghost
  end subroutine helicity_set_ghost

```

Undefine:

```
<Helicities: public>+≡
    public :: helicity_undefine

<Helicities: procedures>+≡
    elemental subroutine helicity_undefine (hel)
        type(helicity_t), intent(inout) :: hel
        hel%defined = .false.
        hel%ghost = .false.
    end subroutine helicity_undefine
```

Diagonalize by removing the second entry (use with care!)

```
<Helicities: public>+≡
    public :: helicity_diagonalize

<Helicities: procedures>+≡
    elemental subroutine helicity_diagonalize (hel)
        type(helicity_t), intent(inout) :: hel
        hel%h2 = hel%h1
    end subroutine helicity_diagonalize
```

Output (no linebreak). No output if undefined.

```
<Helicities: public>+≡
    public :: helicity_write

<Helicities: procedures>+≡
    subroutine helicity_write (hel, unit)
        type(helicity_t), intent(in) :: hel
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit); if (u < 0) return
        if (hel%defined) then
            if (hel%ghost) then
                write (u, "(A)", advance="no") "h*"
            else
                write (u, "(A)", advance="no") "h("
            end if
            write (u, "(IO)", advance="no") hel%h1
            if (hel%h1 /= hel%h2) then
                write (u, "(A)", advance="no") "|"
                write (u, "(IO)", advance="no") hel%h2
            end if
            write (u, "(A)", advance="no") ")"
        else if (hel%ghost) then
            write (u, "(A)", advance="no") "h*"
        end if
    end subroutine helicity_write
```

Binary I/O. Write contents only if defined.

```
<Helicities: public>+≡
    public :: helicity_write_raw
    public :: helicity_read_raw
```

```

<Helicities: procedures>+≡
  subroutine helicity_write_raw (hel, u)
    type(helicity_t), intent(in) :: hel
    integer, intent(in) :: u
    write (u) hel%defined
    if (hel%defined) then
      write (u) hel%h1, hel%h2
      write (u) hel%ghost
    end if
  end subroutine helicity_write_raw

  subroutine helicity_read_raw (hel, u, iostat)
    type(helicity_t), intent(out) :: hel
    integer, intent(in) :: u
    integer, intent(out), optional :: iostat
    read (u, iostat=iostat) hel%defined
    if (hel%defined) then
      read (u, iostat=iostat) hel%h1, hel%h2
      read (u, iostat=iostat) hel%ghost
    end if
  end subroutine helicity_read_raw

```

7.1.2 Predicates

Check if the helicity is defined:

```

<Helicities: public>+≡
  public :: helicity_is_defined

<Helicities: procedures>+≡
  elemental function helicity_is_defined (hel) result (defined)
    logical :: defined
    type(helicity_t), intent(in) :: hel
    defined = hel%defined
  end function helicity_is_defined

```

Return true if the two helicities are equal or the particle is unpolarized:

```

<Helicities: public>+≡
  public :: helicity_is_diagonal

<Helicities: procedures>+≡
  elemental function helicity_is_diagonal (hel) result (diagonal)
    logical :: diagonal
    type(helicity_t), intent(in) :: hel
    if (hel%defined) then
      diagonal = hel%h1 == hel%h2
    else
      diagonal = .true.
    end if
  end function helicity_is_diagonal

```

Return the ghost flag

```

<Helicities: public>+≡
  public :: helicity_is_ghost

```

```

<Helicities: procedures>+≡
  elemental function helicity_is_ghost (hel) result (ghost)
    logical :: ghost
    type(helicity_t), intent(in) :: hel
    ghost = hel%ghost
  end function helicity_is_ghost

```

7.1.3 Accessing contents

This returns a two-element array and thus cannot be elemental. The result is unpredictable if the helicity is undefined.

```

<Helicities: public>+≡
  public :: helicity_get

<Helicities: procedures>+≡
  pure function helicity_get (hel) result (h)
    integer, dimension(2) :: h
    type(helicity_t), intent(in) :: hel
    h(1) = hel%h2
    h(2) = hel%h1
  end function helicity_get

```

7.1.4 Comparisons

When comparing helicities, if either one is undefined, they are considered to match. In other words, an unpolarized particle matches any polarization. In the `dmatch` variant, it matches only diagonal helicity.

The ghost flag is ignored when matching, but matters when testing for equality.

```

<Helicities: public>+≡
  public :: operator(.match.)
  public :: operator(.dmatch.)
  public :: operator(==)
  public :: operator(/=)

<Helicities: interfaces>+≡
  interface operator(.match.)
    module procedure helicity_match
  end interface
  interface operator(.dmatch.)
    module procedure helicity_match_diagonal
  end interface
  interface operator(==)
    module procedure helicity_eq
  end interface
  interface operator(/=)
    module procedure helicity_neq
  end interface

```

```

<Helicities: procedures>+=
  elemental function helicity_match (hel1, hel2) result (eq)
    logical :: eq
    type(helicity_t), intent(in) :: hel1, hel2
    if (hel1%defined .and. hel2%defined) then
      eq = (hel1%h1 == hel2%h1) .and. (hel1%h2 == hel2%h2)
    else
      eq = .true.
    end if
  end function helicity_match

  elemental function helicity_match_diagonal (hel1, hel2) result (eq)
    logical :: eq
    type(helicity_t), intent(in) :: hel1, hel2
    if (hel1%defined .and. hel2%defined) then
      eq = (hel1%h1 == hel2%h1) .and. (hel1%h2 == hel2%h2)
    else if (hel1%defined) then
      eq = hel1%h1 == hel1%h2
    else if (hel2%defined) then
      eq = hel2%h1 == hel2%h2
    else
      eq = .true.
    end if
  end function helicity_match_diagonal

<Helicities: procedures>+=
  elemental function helicity_eq (hel1, hel2) result (eq)
    logical :: eq
    type(helicity_t), intent(in) :: hel1, hel2
    if (hel1%defined .and. hel2%defined) then
      eq = (hel1%h1 == hel2%h1) .and. (hel1%h2 == hel2%h2) &
        .and. (hel1%ghost .eqv. hel2%ghost)
    else if (.not. hel1%defined .and. .not. hel2%defined) then
      eq = hel1%ghost .eqv. hel2%ghost
    else
      eq = .false.
    end if
  end function helicity_eq

<Helicities: procedures>+=
  elemental function helicity_neq (hel1, hel2) result (neq)
    logical :: neq
    type(helicity_t), intent(in) :: hel1, hel2
    if (hel1%defined .and. hel2%defined) then
      neq = (hel1%h1 /= hel2%h1) .or. (hel1%h2 /= hel2%h2) &
        .or. (hel1%ghost .neqv. hel2%ghost)
    else if (.not. hel1%defined .and. .not. hel2%defined) then
      neq = hel1%ghost .neqv. hel2%ghost
    else
      neq = .true.
    end if
  end function helicity_neq

```

7.1.5 Tools

Merge two helicity objects by taking the first entry from the first and the second entry from the second argument. Makes sense only if the input helicities were defined and diagonal. The handling of ghost flags is not well-defined; one should verify beforehand that they match.

```
<Helicities: public>+≡
    public :: operator(.merge.)

<Helicities: interfaces>+≡
    interface operator(.merge.)
        module procedure merge_helicities
    end interface

<Helicities: procedures>+≡
    elemental function merge_helicities (hel1, hel2) result (hel)
        type(helicity_t) :: hel
        type(helicity_t), intent(in) :: hel1, hel2
        if (helicity_is_defined (hel1) .and. helicity_is_defined (hel2)) then
            call helicity_init2g (hel, hel2%h1, hel1%h1, hel1%ghost)
        else if (helicity_is_defined (hel1)) then
            hel = hel1
        else if (helicity_is_defined (hel2)) then
            hel = hel2
        end if
    end function merge_helicities
```

7.2 Colors

This module defines a type and tools for dealing with color information.

Each particle can have zero or more (in practice, usually not more than two) color indices. Color indices are positive; flow direction can be determined from the particle nature.

While parton shower matrix elements are diagonal in color, some special applications (e.g., subtractions for NLO matrix elements) require non-diagonal color matrices.

```
<colors.f90>≡  
  <File header>  
  
  module colors  
  
    <Use kinds>  
    <Use file utils>  
    use diagnostics !NODEP!  
    use unit_tests  
  
    <Standard module head>  
  
    <Colors: public>  
  
    <Colors: types>  
  
    <Colors: interfaces>  
  
    contains  
  
    <Colors: procedures>  
  
    <Colors: tests>  
  
  end module colors
```

7.2.1 The color type

A particle may have an arbitrary number of color indices (in practice, from zero to two, but more are possible). This object acts as a container.

The fact that color comes as an array prohibits elemental procedures in some places. (May add interfaces and multi versions where necessary.)

The color may be undefined; this corresponds to unallocated arrays.

NOTE: Due to a compiler bug in nagfor 5.2, we do not use allocatable but fixed-size arrays with dimension 2. Only nonzero entries count. This may be more efficient anyway, but gives up some flexibility. However, the squaring algorithm currently works only for singlets, (anti)triplets and octets anyway, so two components are enough.

```
<Colors: public>≡  
  public :: color_t  
  
<Colors: types>≡  
  type :: color_t
```

```

        private
!       integer, dimension(:), allocatable :: c1, c2
        integer, dimension(2) :: c1 = 0, c2 = 0
        logical :: ghost = .false.
    end type color_t

```

Initializers:

```

<Colors: public>+≡
    public :: color_init

<Colors: interfaces>≡
    interface color_init
        module procedure color_init_undefined, color_init_undefined_ghost
        module procedure color_init_array, color_init_array_ghost
        module procedure color_init_arrays, color_init_arrays_ghost
    end interface

```

Undefined color: array remains unallocated

```

<Colors: procedures>≡
    pure subroutine color_init_undefined (col)
        type(color_t), intent(out) :: col
    end subroutine color_init_undefined

    pure subroutine color_init_undefined_ghost (col, ghost)
        type(color_t), intent(out) :: col
        logical, intent(in) :: ghost
        col%ghost = ghost
    end subroutine color_init_undefined_ghost

```

This defines color from an arbitrary length color array, suitable for any representation. We may have two color arrays (non-diagonal matrix elements). This cannot be elemental. The third version assigns an array of colors, using a two-dimensional array as input.

```

<Colors: procedures>+≡
    pure subroutine color_init_array (col, c1)
        type(color_t), intent(out) :: col
        integer, dimension(:), intent(in) :: c1
!       allocate (col%c1 (size (c1)))
!       allocate (col%c2 (size (c1)))
        col%c1 = pack (c1, c1 /= 0, col%c1)
        col%c2 = col%c1
    end subroutine color_init_array

    pure subroutine color_init_array_ghost (col, c1, ghost)
        type(color_t), intent(out) :: col
        integer, dimension(:), intent(in) :: c1
        logical, intent(in) :: ghost
        call color_init_array (col, c1)
        col%ghost = ghost
    end subroutine color_init_array_ghost

    pure subroutine color_init_arrays (col, c1, c2)

```

```

        type(color_t), intent(out) :: col
        integer, dimension(:), intent(in) :: c1, c2
        if (size (c1) == size (c2)) then
!           allocate (col%c1 (size (c1)))
!           allocate (col%c2 (size (c2)))
            col%c1 = pack (c1, c1 /= 0, col%c1)
            col%c2 = pack (c2, c2 /= 0, col%c2)
        else if (size (c1) /= 0) then
!           allocate (col%c1 (size (c1)))
!           allocate (col%c2 (size (c1)))
            col%c1 = pack (c1, c1 /= 0, col%c1)
            col%c2 = col%c1
        else if (size (c2) /= 0) then
!           allocate (col%c1 (size (c2)))
!           allocate (col%c2 (size (c2)))
            col%c1 = pack (c2, c2 /= 0, col%c2)
            col%c2 = col%c1
        end if
    end subroutine color_init_arrays

    pure subroutine color_init_arrays_ghost (col, c1, c2, ghost)
        type(color_t), intent(out) :: col
        integer, dimension(:), intent(in) :: c1, c2
        logical, intent(in) :: ghost
        call color_init_arrays (col, c1, c2)
        col%ghost = ghost
    end subroutine color_init_arrays_ghost

```

This version is restricted to singlets, triplets, antitriplets, and octets: The input contains the color and anticolor index, each of the may be zero.

<Colors: public>+≡

```
public :: color_init_col_acl
```

<Colors: procedures>+≡

```

    elemental subroutine color_init_col_acl (col, col_in, acl_in)
        type(color_t), intent(out) :: col
        integer, intent(in) :: col_in, acl_in
        integer, dimension(0) :: null_array
        select case (col_in)
        case (0)
            select case (acl_in)
            case (0)
                call color_init_array (col, null_array)
            case default
                call color_init_array (col, (/ -acl_in /))
            end select
        case default
            select case (acl_in)
            case (0)
                call color_init_array (col, (/ col_in /))
            case default
                call color_init_array (col, (/ col_in, -acl_in /))
            end select
        end select
    end subroutine

```

```
end subroutine color_init_col_acl
```

This version is used for the external interface. We convert a fixed-size array of colors (for each particle) to the internal form by packing only the nonzero entries.

```
<Colors: public>+≡
```

```
public :: color_init_from_array
```

```
<Colors: interfaces>+≡
```

```
interface color_init_from_array
```

```
module procedure color_init_from_array1, color_init_from_array1g
```

```
module procedure color_init_from_array2, color_init_from_array2g
```

```
end interface
```

```
<Colors: procedures>+≡
```

```
pure subroutine color_init_from_array1 (col, c1)
```

```
type(color_t), intent(out) :: col
```

```
integer, dimension(:), intent(in) :: c1
```

```
logical, dimension(size(c1)) :: mask
```

```
mask = c1 /= 0
```

```
! allocate (col%c1 (count (mask)))
```

```
! allocate (col%c2 (size (col%c1)))
```

```
col%c1 = pack (c1, mask, col%c1)
```

```
col%c2 = col%c1
```

```
end subroutine color_init_from_array1
```

```
pure subroutine color_init_from_array1g (col, c1, ghost)
```

```
type(color_t), intent(out) :: col
```

```
integer, dimension(:), intent(in) :: c1
```

```
logical, intent(in) :: ghost
```

```
call color_init_from_array1 (col, c1)
```

```
col%ghost = ghost
```

```
end subroutine color_init_from_array1g
```

```
pure subroutine color_init_from_array2 (col, c1)
```

```
integer, dimension(:, :), intent(in) :: c1
```

```
type(color_t), dimension(size(c1,2)), intent(out) :: col
```

```
integer :: i
```

```
do i = 1, size (c1,2)
```

```
call color_init_from_array1 (col(i), c1(:,i))
```

```
end do
```

```
end subroutine color_init_from_array2
```

```
pure subroutine color_init_from_array2g (col, c1, ghost)
```

```
integer, dimension(:, :), intent(in) :: c1
```

```
type(color_t), dimension(size(c1,2)), intent(out) :: col
```

```
logical, intent(in), dimension(:) :: ghost
```

```
call color_init_from_array2 (col, c1)
```

```
col%ghost = ghost
```

```
end subroutine color_init_from_array2g
```

Set the ghost property

```
<Colors: public>+≡
```

```

public :: color_set_ghost
<Colors: procedures>+≡
  elemental subroutine color_set_ghost (col, ghost)
    type(color_t), intent(inout) :: col
    logical, intent(in) :: ghost
    col%ghost = ghost
  end subroutine color_set_ghost

```

Undefine the color state:

```

<Colors: public>+≡
  public :: color_undefine
<Colors: procedures>+≡
  elemental subroutine color_undefine (col, undefine_ghost)
    type(color_t), intent(inout) :: col
    logical, intent(in), optional :: undefine_ghost
  !   if (allocated (col%c1)) deallocate (col%c1)
  !   if (allocated (col%c2)) deallocate (col%c2)
    col%c1 = 0
    col%c2 = 0
    if (present (undefine_ghost)) then
      if (undefine_ghost) col%ghost = .false.
    else
      col%ghost = .false.
    end if
  end subroutine color_undefine

```

Output. As dense as possible, no linebreak. If color is undefined, no output.

```

<Colors: public>+≡
  public :: color_write
<Colors: interfaces>+≡
  interface color_write
    module procedure color_write_single
    module procedure color_write_array
  end interface
<Colors: procedures>+≡
  subroutine color_write_single (col, unit)
    type(color_t), intent(in) :: col
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit); if (u < 0) return
    if (color_is_defined (col)) then
      write (u, "(A)", advance="no") "c("
      if (col%c1(1) /= 0) write (u, "(I0)", advance="no") col%c1(1)
      if (any (col%c1 /= 0)) write (u, "(1x)", advance="no")
      if (col%c1(2) /= 0) write (u, "(I0)", advance="no") col%c1(2)
      if (.not. color_is_diagonal (col)) then
        write (u, "(A)", advance="no") "|"
        if (col%c2(1) /= 0) write (u, "(I0)", advance="no") col%c2(1)
        if (any (col%c2 /= 0)) write (u, "(1x)", advance="no")
        if (col%c2(2) /= 0) write (u, "(I0)", advance="no") col%c2(2)
      end if
    end if
  end subroutine color_write_single

```

```

        write (u, "(A)", advance="no") ")"
    else if (col%ghost) then
        write (u, "(A)", advance="no") "c*"
    end if
end subroutine color_write_single

subroutine color_write_array (col, unit)
    type(color_t), dimension(:), intent(in) :: col
    integer, intent(in), optional :: unit
    integer :: u
    integer :: i
    u = output_unit (unit); if (u < 0) return
    write (u, "(A)", advance="no") "["
    do i = 1, size (col)
        if (i > 1) write (u, "(1x)", advance="no")

    end do
    write (u, "(A)", advance="no") "]"
end subroutine color_write_array

```

Binary I/O. For allocatable colors, this would have to be modified.

```

<Colors: public>+≡
    public :: color_write_raw
    public :: color_read_raw

<Colors: procedures>+≡
    subroutine color_write_raw (col, u)
        type(color_t), intent(in) :: col
        integer, intent(in) :: u
        logical :: defined
        defined = color_is_defined (col) .or. color_is_ghost (col)
        write (u) defined
        if (defined) then
            write (u) col%c1, col%c2
            write (u) col%ghost
        end if
    end subroutine color_write_raw

    subroutine color_read_raw (col, u, iostat)
        type(color_t), intent(out) :: col
        integer, intent(in) :: u
        integer, intent(out), optional :: iostat
        logical :: defined
        read (u, iostat=iostat) defined
        if (defined) then
            read (u, iostat=iostat) col%c1, col%c2
            read (u, iostat=iostat) col%ghost
        end if
    end subroutine color_read_raw

```

7.2.2 Predicates

Return the definition status

```

<Colors: public>+≡
    public :: color_is_defined

<Colors: procedures>+≡
    elemental function color_is_defined (col) result (defined)
        logical :: defined
        type(color_t), intent(in) :: col
        !    defined = allocated (col%c1)
        defined = any (col%c1 /= 0)
    end function color_is_defined

```

Diagonal color objects have only one array allocated:

```

<Colors: public>+≡
    public :: color_is_diagonal

<Colors: procedures>+≡
    elemental function color_is_diagonal (col) result (diagonal)
        logical :: diagonal
        type(color_t), intent(in) :: col
        if (color_is_defined (col)) then
            diagonal = all (col%c1 == col%c2)
        else
            diagonal = .true.
        end if
    end function color_is_diagonal

```

Return the ghost flag

```

<Colors: public>+≡
    public :: color_is_ghost

<Colors: procedures>+≡
    elemental function color_is_ghost (col) result (ghost)
        logical :: ghost
        type(color_t), intent(in) :: col
        ghost = col%ghost
    end function color_is_ghost

```

The ghost parity: true if the color-ghost flag is set.

```

<Colors: interfaces>+≡
    interface color_ghost_parity
        module procedure color_ghost_parity0
        module procedure color_ghost_parity1
    end interface

<Colors: procedures>+≡
    pure function color_ghost_parity0 (col) result (parity)
        type(color_t), intent(in) :: col
        logical :: parity
        parity = color_is_ghost (col)
    end function color_ghost_parity0

    pure function color_ghost_parity1 (col) result (parity)
        type(color_t), dimension(:), intent(in) :: col
        logical :: parity

```

```

logical, dimension(size(col)) :: p
integer :: i
forall (i = 1:size(col))
    p(i) = color_ghost_parity0 (col(i))
end forall
parity = mod (count (p), 2) == 1
end function color_ghost_parity1

```

7.2.3 Accessing contents

Return the number of color indices. We assume that it is identical for both arrays.

```

<Colors: procedures>+≡
    elemental function color_number (col) result (n)
        integer :: n
        type(color_t), intent(in) :: col
        !    n = size (col%c1)
        n = count (col%c1 /= 0)
    end function color_number

```

Return the (first) color/anticolor entry (assuming that color is diagonal). The result is a positive color index.

```

<Colors: public>+≡
    public :: color_get_col
    public :: color_get_acl

<Colors: procedures>+≡
    function color_get_col (col) result (c)
        integer :: c
        type(color_t), intent(in) :: col
        integer :: i
        do i = 1, size (col%c1)
            if (col%c1(i) > 0) then
                c = col%c1(i)
                return
            end if
        end do
        c = 0
    end function color_get_col

    function color_get_acl (col) result (c)

                col_pos(i)%c1(j) = n
            end if
        end do SCAN2
    end do SCAN1
    allocate (c_index (n))
    c_index = c_tmp(1:n)
end subroutine extract_color_line_indices

```

Given a color array, pairwise contract the color lines in all possible ways and return the resulting array of arrays. The input color array must be diagonal, and each color should occur exactly twice, once as color and once as anticolor.

Gluon entries with equal color and anticolor are explicitly excluded.

This algorithm is generic, but for long arrays it is neither efficient, nor does it avoid duplicates. It is intended for small arrays, in particular for the state matrix of a structure-function pair.

<Colors: public>+≡

```

We have a pair of color index arrays which corresponds to a squared matrix element. We want to determine the number of color loops in this square matrix element. So we first copy the colors (stored in a single color array with a pair of color lists in each entry) to a temporary where the color indices are shifted by some offset. We then recursively follow each loop, starting at the first color that has the offset, resetting the first color index to the loop index and each further index to zero as we go. We check that (a) each color index occurs twice within the left (right) color array, (b) the loops are closed, so we always come back to a line which has the loop index.

In order for the algorithm to work we have to conjugate the colors of initial state particles (one for decays, two for scatterings) into their corresponding anticolors of outgoing particles.

7.2.7 The Madgraph color model

This section describes the method for matrix element and color flow calculation within Madgraph.

For each Feynman diagram, the colorless amplitude for a specified helicity and momentum configuration (in- and out- combined) is computed:

$$A_d(p, h) \quad (7.1)$$

Inserting color, the squared matrix element for definite helicity and momentum is

$$M^2(p, h) = \sum_{dd'} A_d(p, h) C_{dd'} A_{d'}^*(p, h) \quad (7.2)$$

where $C_{dd'}$ describes the color interference of the two diagrams A_d and $A_{d'}$, which is independent of momentum and helicity and can be calculated for each Feynman diagram pair by reducing it to the corresponding color graph. Obviously, one could combine all diagrams with identical color structure, such that the index d runs only over different color graphs. For colorless diagrams all elements of $C_{dd'}$ are equal to unity.

The hermitian matrix $C_{dd'}$ is diagonalized once and for all, such that it can be written in the form

$$C_{dd'} = \sum_{\lambda} c_d^{\lambda} \lambda c_{d'}^{\lambda*}, \quad (7.3)$$

where the eigenvectors c_d are normalized,

$$\sum_d |c_d^{\lambda}|^2 = 1, \quad (7.4)$$

and the λ values are the corresponding eigenvalues. In the colorless case, this means $c_d = 1/\sqrt{N_d}$ for all diagrams (N_d = number of diagrams), and $\lambda = N_d$ is the only nonzero eigenvalue.

Consequently, the squared matrix element for definite helicity and momentum can also be written as

$$M^2(p, h) = \sum_{\lambda} A_{\lambda}(p, h) \lambda A_{\lambda}(p, h)^* \quad (7.5)$$

with

$$A_{\lambda}(p, h) = \sum_d c_d^{\lambda} A_d(p, h). \quad (7.6)$$

For generic spin density matrices, this is easily generalized to

$$M^2(p, h, h') = \sum_{\lambda} A_{\lambda}(p, h) \lambda A_{\lambda}(p, h')^* \quad (7.7)$$

To determine the color flow probabilities of a given momentum-helicity configuration, the color flow amplitudes are calculated as

$$a_f(p, h) = \sum_d \beta_d^f A_d(p, h), \quad (7.8)$$

where the coefficients β_d^f describe the amplitude for a given Feynman diagram (or color graph) d to correspond to a definite color flow f . They are computed from $C_{dd'}$ by transforming this matrix into the color flow basis and neglecting all off-diagonal elements. Again, these coefficients do not depend on momentum or helicity and can therefore be calculated in advance. This gives the color flow transition matrix

$$F^f(p, h, h') = a_f(p, h) a_f^*(p, h') \quad (7.9)$$

which is assumed diagonal in color flow space and is separate from the color-summed transition matrix M^2 . They are, however, equivalent (up to a factor) to

leading order in $1/N_c$, and using the color flow transition matrix is appropriate for matching to hadronization.

Note that the color flow transition matrix is not normalized at this stage. To make use of it, we have to fold it with the in-state density matrix to get a pseudo density matrix

$$\hat{\rho}_{\text{out}}^f(p, h_{\text{out}}, h'_{\text{out}}) = \sum_{h_{\text{in}} h'_{\text{in}}} F^f(p, h, h') \rho_{\text{in}}(p, h_{\text{in}}, h'_{\text{in}}) \quad (7.10)$$

which gets a meaning only after contracted with projections on the outgoing helicity states k_{out} , given as linear combinations of helicity states with the unitary coefficient matrix $c(k_{\text{out}}, h_{\text{out}})$. Then the probability of finding color flow f when the helicity state k_{out} is measured is given by

$$P^f(p, k_{\text{out}}) = Q^f(p, k_{\text{out}}) / \sum_f Q^f(p, k_{\text{out}}) \quad (7.11)$$

where

$$Q^f(p, k_{\text{out}}) = \sum_{h_{\text{out}} h'_{\text{out}}} c(k_{\text{out}}, h_{\text{out}}) \hat{\rho}_{\text{out}}^f(p, h_{\text{out}}, h'_{\text{out}}) c^*(k_{\text{out}}, h'_{\text{out}}) \quad (7.12)$$

However, if we can assume that the out-state helicity basis is the canonical one, we can throw away the off diagonal elements in the color flow density matrix and normalize the ones on the diagonal to obtain

$$P^f(p, h_{\text{out}}) = \hat{\rho}_{\text{out}}^f(p, h_{\text{out}}, h_{\text{out}}) / \sum_f \hat{\rho}_{\text{out}}^f(p, h_{\text{out}}, h_{\text{out}}) \quad (7.13)$$

Finally, the color-summed out-state density matrix is computed by the scattering formula

$$\rho_{\text{out}}(p, h_{\text{out}}, h'_{\text{out}}) = \sum_{h_{\text{in}} h'_{\text{in}}} M^2(p, h, h') \rho_{\text{in}}(p, h_{\text{in}}, h'_{\text{in}}) \quad (7.14)$$

$$= \sum_{h_{\text{in}} h'_{\text{in}} \lambda} A_\lambda(p, h) \lambda A_\lambda(p, h')^* \rho_{\text{in}}(p, h_{\text{in}}, h'_{\text{in}}), \quad (7.15)$$

The trace of ρ_{out} is the squared matrix element, summed over all internal degrees of freedom. To get the squared matrix element for a definite helicity k_{out} and color flow f , one has to project the density matrix onto the given helicity state and multiply with $P^f(p, k_{\text{out}})$.

For diagonal helicities the out-state density reduces to

$$\rho_{\text{out}}(p, h_{\text{out}}) = \sum_{h_{\text{in}} \lambda} \lambda |A_\lambda(p, h)|^2 \rho_{\text{in}}(p, h_{\text{in}}). \quad (7.16)$$

Since no basis transformation is involved, we can use the normalized color flow probability $P^f(p, h_{\text{out}})$ and express the result as

$$\rho_{\text{out}}^f(p, h_{\text{out}}) = \rho_{\text{out}}(p, h_{\text{out}}) P^f(p, h_{\text{out}}) \quad (7.17)$$

$$= \sum_{h_{\text{in}} \lambda} \frac{|a^f(p, h)|^2}{\sum_f |a^f(p, h)|^2} \lambda |A_\lambda(p, h)|^2 \rho_{\text{in}}(p, h_{\text{in}}). \quad (7.18)$$

From these considerations, the following calculation strategy can be derived:

- Before the first event is generated, the color interference matrix $C_{dd'}$ is computed and diagonalized, so the eigenvectors c_d^λ , eigenvalues λ and color flow coefficients β_d^f are obtained. In practice, these calculations are done when the matrix element code is generated, and the results are hardcoded in the matrix element subroutine as **DATA** statements.
- For each event, one loops over helicities once and stores the matrices $A_\lambda(p, h)$ and $a^f(p, h)$. The allowed color flows, helicity combinations and eigenvalues are each labeled by integer indices, so one has to store complex matrices of dimension $N_\lambda \times N_h$ and $N_f \times N_h$, respectively.
- The further strategy depends on the requested information.
 1. If colorless diagonal helicity amplitudes are required, the eigenvalues $A_\lambda(p, h)$ are squared, summed with weight λ , and the result contracted with the in-state probability vector $\rho_{\text{in}}(p, h_{\text{in}})$. The result is a probability vector $\rho_{\text{out}}(p, h_{\text{out}})$.
 2. For colored diagonal helicity amplitudes, the color coefficients $a^f(p, h)$ are also squared and used as weights to obtain the color-flow probability vector $\rho_{\text{out}}^f(p, h_{\text{out}})$.
 3. For colorless non-diagonal helicity amplitudes, we contract the tensor product of $A_\lambda(p, h)$ with $A_\lambda(p, h')$, weighted with λ , with the correlated in-state density matrix, to obtain a correlated out-state density matrix.
 4. In the general (colored, non-diagonal) case, we do the same as in the colorless case, but return the un-normalized color flow density matrix $\hat{\rho}_{\text{out}}^f(p, h_{\text{out}}, h'_{\text{out}})$ in addition. When the relevant helicity basis is known, the latter can be used by the caller program to determine flow probabilities. (In reality, we assume the canonical basis and reduce the correlated out-state density to its diagonal immediately.)

7.3 Flavors: Particle properties

This module contains a type for holding the flavor code, and all functions that depend on the model, i.e., that determine particle properties.

The PDG code is packed in a special **flavor** type. (This prohibits meaningless operations, and it allows for a different implementation, e.g., some non-PDG scheme internally, if appropriate at some point.) In addition, the flavor object holds a pointer to a **particle_data** object which is centrally stored (as part of a physics model). In this way, all particle data can be accessed using just the **flv** object without having to carry them around.

The pointer component imposes a technical restriction: Assignment of flavor objects cannot be used, directly or indirectly, in pure, and thus in elemental procedures.

```
<flavors.f90>≡  
  <File header>  
  
  module flavors  
  
    <Use kinds>  
    <Use strings>  
    <Use file utils>  
    use pdg_arrays  
    use colors, only: color_t, color_init  
    use models  
  
    <Standard module head>  
  
    <Flavors: public>  
  
    <Flavors: types>  
  
    <Flavors: interfaces>  
  
    contains  
  
    <Flavors: procedures>  
  
  end module flavors
```

7.3.1 The flavor type

The flavor type is an integer representing the PDG code, or undefined (zero). Negative codes represent ant flavors.

For full generality, and analogy with helicity and color, we allow for non-diagonal flavor indices in density matrices. This is probably academic; an obscure application is the definition of proper isospin states.

Further properties of the given flavor can be retrieved via the particle-data pointer, if it is associated.

```
<Flavors: public>≡  
  public :: flavor_t
```

```

<Flavors: types>≡
  type :: flavor_t
  private
  integer :: f = UNDEFINED
  type(particle_data_t), pointer :: prt => null ()
end type flavor_t

```

Initializer form. If the model is assigned, the procedure is impure, therefore we have to define a separate array version.

```

    end do
end subroutine flavor_init1_name_model

```

This version transforms a PDG array value into a flavor array. The flavor array must be allocatable.

```

<Flavors: procedures>+≡
subroutine flavor_init_aval_model (flv, aval, model)
    type(flavor_t), dimension(:), intent(out), allocatable :: flv
    type(pdg_array_t), intent(in) :: aval
    type(model_t), intent(in), target :: model
    integer, dimension(:), allocatable :: pdg
    pdg = aval
    allocate (flv (size (pdg)))
    call flavor_init (flv, pdg, model)
end subroutine flavor_init_aval_model

```

Undefine the flavor state:

```

<Flavors: public>+≡
public :: flavor_undefine

<Flavors: procedures>+≡
elemental subroutine flavor_undefine (flv)

```

```

    type(flavor_t), intent(inout) :: flv
    flv%f = UNDEFINED
    flv%prt => null ()
end subroutine flavor_undefine

```

Output: dense, no linebreak

<Flavors: public>+≡

```

public :: flavor_write

```

<Flavors: procedures>+≡

```

subroutine flavor_write (flv, unit)
    type(flavor_t), intent(in) :: flv
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit); if (u < 0) return
    if (associated (flv%prt)) then
        write (u, "(A)", advance="no") "f("
    else
        write (u, "(A)", advance="no") "p("
    end if
    write (u, "(I0)", advance="no") flv%f
    write (u, "(A)", advance="no") ")"
end subroutine flavor_write

```

Binary I/O. Currently, the model information is not written/read, so after reading the particle-data pointer is empty.

<Flavors: public>+≡

```

public :: flavor_write_raw
public :: flavor_read_raw

```

<Flavors: procedures>+≡

```

subroutine flavor_write_raw (flv, u)
    type(flavor_t), intent(in) :: flv
    integer, intent(in) :: u
    write (u) flv%f
end subroutine flavor_write_raw

subroutine flavor_read_raw (flv, u, iostat)
    type(flavor_t), intent(out) :: flv
    integer, intent(in) :: u
    integer, intent(out), optional :: iostat
    read (u, iostat=iostat) flv%f
end subroutine flavor_read_raw

```

Assignment

Default assignment of flavor objects is possible, but cannot be used in pure procedures, because a pointer assignment is involved.

Assign the particle pointer separately. This cannot be elemental, so we define a scalar and an array version explicitly. We refer to an array of flavors, not an array of models.

<Flavors: public>+≡

```

public :: flavor_set_model
<Flavors: interfaces>+≡
interface flavor_set_model
  module procedure flavor_set_model_single
  module procedure flavor_set_model_array
  module procedure flavor_set_model_array2
end interface
<Flavors: procedures>+≡
subroutine flavor_set_model_single (flv, model)
  type(flavor_t), intent(inout) :: flv
  type(model_t), intent(in), target :: model
  if (flv%f /= UNDEFINED) &
    flv%prt => model_get_particle_ptr (model, flv%f)
end subroutine flavor_set_model_single

subroutine flavor_set_model_array (flv, model)
  type(flavor_t), dimension(:), intent(inout) :: flv
  type(model_t), intent(in), target :: model
  integer :: i
  do i = 1, size (flv)
    if (flv(i)%f /= UNDEFINED) &
      flv(i)%prt => model_get_particle_ptr (model, flv(i)%f)
    end do
  end do
end subroutine flavor_set_model_array

subroutine flavor_set_model_array2 (flv, model)
  type(flavor_t), dimension(:, :), intent(inout) :: flv
  type(model_t), intent(in), target :: model
  integer :: i, j
  do i = 1, size (flv, 2)
    do j = 1, size (flv, 1)
      if (flv(j,i)%f /= UNDEFINED) &
        flv(j,i)%prt => model_get_particle_ptr (model, flv(j,i)%f)
      end do
    end do
  end do
end subroutine flavor_set_model_array2

```

Predicates

Return the definition status

```

<Flavors: public>+≡
public :: flavor_is_defined
<Flavors: procedures>+≡
elemental function flavor_is_defined (flv) result (defined)
  logical :: defined
  type(flavor_t), intent(in) :: flv
  defined = flv%f /= UNDEFINED
end function flavor_is_defined

```

Check for valid flavor (including undefined):

```
<Flavors: public>+≡
    public :: flavor_is_valid

<Flavors: procedures>+≡
    elemental function flavor_is_valid (flv) result (valid)
        logical :: valid
        type(flavor_t), intent(in) :: flv
        valid = flv%f /= INVALID
    end function flavor_is_valid
```

Return true if the particle-data pointer is associated. (Debugging aid)

```
<Flavors: public>+≡
    public :: flavor_is_associated

<Flavors: procedures>+≡
    elemental function flavor_is_associated (flv) result (flag)
        logical :: flag
        type(flavor_t), intent(in) :: flv
        flag = associated (flv%prt)
    end function flavor_is_associated
```

Accessing contents

With the exception of the PDG code, all particle properties are accessible only via the `prt` pointer. If this is unassigned, some access function will crash.

Return the flavor as an integer

```
<Flavors: public>+≡
    public :: flavor_get_pdg

<Flavors: procedures>+≡
    elemental function flavor_get_pdg (flv) result (f)
        integer :: f
        type(flavor_t), intent(in) :: flv
        f = flv%f
    end function flavor_get_pdg
```

Return the flavor of the antiparticle

```
<Flavors: public>+≡
    public :: flavor_get_pdg_anti

<Flavors: procedures>+≡
    elemental function flavor_get_pdg_anti (flv) result (f)
        integer :: f
        type(flavor_t), intent(in) :: flv
        if (associated (flv%prt)) then
            if (particle_data_has_antiparticle (flv%prt)) then
                f = -flv%f
            else
                f = flv%f
            end if
        else
            f = 0
        end if
    end function flavor_get_pdg_anti
```

```

        end if
    end function flavor_get_pdg_anti

```

Absolute value:

```

<Flavors: public>+≡
    public :: flavor_get_pdg_abs

<Flavors: procedures>+≡
    elemental function flavor_get_pdg_abs (flv) result (f)
        integer :: f
        type(flavor_t), intent(in) :: flv
        f = abs (flv%f)
    end function flavor_get_pdg_abs

```

Generic properties

    do i = 1, size (flv1)
      flv(i) = flv1(i) .merge. flv2(i)
    end do
  end function merge_flavors1

```

Generate consecutive color indices for a given flavor. The indices are counted starting with the stored value of `c`, so new indices are created each time this (impure) function is called. The counter can be reset by the optional argument `c_seed` if desired. The optional flag `reverse` is used only for octets. If set, the color and anticolor entries of the octet particle are exchanged.

```

    (qn1%h /= qn2%h)
end function quantum_numbers_neq

```

Two sets of quantum numbers are compatible if the individual quantum numbers are compatible, depending on the mask. Flavor has to match, regardless of the flavor mask.

If the color flag is set, color is compatible if the ghost property is identical. If the color flag is unset, color has to be identical. I.e., if the flag is set, the color amplitudes can interfere. If it is not set, they must be identical, and there must be no ghost. The latter property is used for expanding physical color flows.

Helicity is compatible if the mask is unset, otherwise it has to match. This determines if two amplitudes can be multiplied (no mask) or traced (mask).

```

<Quantum numbers: public>+≡
    public :: quantum_numbers_are_compatible

<Quantum numbers: procedures>+≡
    elemental function quantum_numbers_are_compatible (qn1, qn2, mask) &
        result (flag)
        logical :: flag
        type(quantum_numbers_t), intent(in) :: qn1, qn2

        qn3%h = qn1%h .merge. qn2%h
    end function merge_quantum_numbers1

```

7.4.7 The quantum number mask

The quantum numbers mask is true for quantum numbers that should be ignored or summed over. The three mandatory entries correspond to flavor, color, and helicity, respectively.

There is an additional entry `cg`: If false, the color-ghosts property should be kept even if color is ignored. This is relevant only if `c` is set, otherwise it is always false.

The flag `hd` tells that only diagonal entries in helicity should be kept. If `h` is set, `hd` is irrelevant and will be kept `.false.`

```

<Quantum numbers: public>+≡
    public :: quantum_numbers_mask_t

<Quantum numbers: types>+≡
    type :: quantum_numbers_mask_t
        private
        logical :: f = .false.
        logical :: c = .false.
        logical :: cg = .false.
        logical :: h = .false.
        logical :: hd = .false.
    end type quantum_numbers_mask_t

```

Define a quantum number mask: Constructor form

```

<Quantum numbers: public>+≡
    public :: new_quantum_numbers_mask

<Quantum numbers: procedures>+≡
    elemental function new_quantum_numbers_mask &
        (mask_f, mask_c, mask_h, mask_cg, mask_hd) result (mask)
        type(quantum_numbers_mask_t) :: mask
        logical, intent(in) :: mask_f, mask_c, mask_h
        logical, intent(in), optional :: mask_cg
        logical, intent(in), optional :: mask_hd
        call quantum_numbers_mask_init &
            (mask, mask_f, mask_c, mask_h, mask_cg, mask_hd)
    end function new_quantum_numbers_mask

```

Define quantum numbers: Initializer form

```

<Quantum numbers: public>+≡
    public :: quantum_numbers_mask_init

<Quantum numbers: procedures>+≡
    elemental subroutine quantum_numbers_mask_init &
        (mask, mask_f, mask_c, mask_h, mask_cg, mask_hd)

  if (present (mask_cg)) then
    if (mask%c) mask%cg = mask_cg
  else
    mask%cg = mask_c
  end if
end subroutine quantum_numbers_mask_set_color

elemental subroutine quantum_numbers_mask_set_helicity (mask, mask_h, mask_hd)
  type(quantum_numbers_mask_t), intent(inout) :: mask
  logical, intent(in) :: mask_h
  logical, intent(in), optional :: mask_hd
  mask%h = mask_h
  if (present (mask_hd)) then
    if (.not. mask%h) mask%hd = mask_hd
  end if
end subroutine quantum_numbers_mask_set_helicity

```

The following routines assign part of a mask, depending on the flags given.

```

<Quantum numbers: public>+≡
public :: quantum_numbers_mask_assign
<Quantum numbers: procedures>+≡
elemental subroutine quantum_numbers_mask_assign &
  (mask, mask_in, flavor, color, helicity)
  type(quantum_numbers_mask_t), intent(inout) :: mask
  type(quantum_numbers_mask_t), intent(in) :: mask_in
  logical, intent(in), optional :: flavor, color, helicity
  if (present (flavor)) then
    if (flavor) then
      mask%f = mask_in%f
    end if
  end if
  if (present (color)) then
    if (color) then
      mask%c = mask_in%c
      mask%cg = mask_in%cg
    end if
  end if
  if (present (helicity)) then
    if (helicity) then

```

```

        mask%h = mask_in%h
        mask%hd = mask_in%hd
    end if
end if
end subroutine quantum_numbers_mask_assign

```

7.4.9 Mask predicates

Return true if either one of the entries is set:

```

<Quantum numbers: public>+≡
    public :: any

<Quantum numbers: interfaces>+≡
    interface any
        module procedure quantum_numbers_mask_any
    end interface

<Quantum numbers: procedures>+≡
    function quantum_numbers_mask_any (mask) result (match)
        logical :: match
        type(quantum_numbers_mask_t), intent(in) :: mask
        match = mask%f .or. mask%c .or. mask%h .or. mask%hd
    end function quantum_numbers_mask_any

```

7.4.10 Operators

The OR operation is applied to all components.

```

<Quantum numbers: public>+≡
    public :: operator(.or.)

<Quantum numbers: interfaces>+≡
    interface operator(.or.)
        module procedure quantum_numbers_mask_or
    end interface

<Quantum numbers: procedures>+≡
    elemental function quantum_numbers_mask_or (mask1, mask2) result (mask)
        type(quantum_numbers_mask_t) :: mask
        type(quantum_numbers_mask_t), intent(in) :: mask1, mask2
        mask%f = mask1%f .or. mask2%f
        mask%c = mask1%c .or. mask2%c
        if (mask%c) mask%cg = mask1%cg .or. mask2%cg
        mask%h = mask1%h .or. mask2%h
        if (.not. mask%h) mask%hd = mask1%hd .or. mask2%hd
    end function quantum_numbers_mask_or

```

7.4.11 Mask comparisons

Return true if the two masks are equivalent / differ:

```

<Quantum numbers: public>+≡

```

```

public :: operator(.eqv.)
public :: operator(.neqv.)

<Quantum numbers: interfaces>+≡
interface operator(.eqv.)
  module procedure quantum_numbers_mask_eqv
end interface
interface operator(.neqv.)
  module procedure quantum_numbers_mask_neqv
end interface

<Quantum numbers: procedures>+≡
elemental function quantum_numbers_mask_eqv (mask1, mask2) result (eqv)
  logical :: eqv
  type(quantum_numbers_mask_t), intent(in) :: mask1, mask2
  eqv = (mask1%f .eqv. mask2%f) .and. &
        (mask1%c .eqv. mask2%c) .and. &
        (mask1%cg .eqv. mask2%cg) .and. &
        (mask1%h .eqv. mask2%h) .and. &
        (mask1%hd .eqv. mask2%hd)
end function quantum_numbers_mask_eqv

elemental function quantum_numbers_mask_neqv (mask1, mask2) result (neqv)
  logical :: neqv
  type(quantum_numbers_mask_t), intent(in) :: mask1, mask2
  neqv = (mask1%f .neqv. mask2%f) .or. &
        (mask1%c .neqv. mask2%c) .or. &
        (mask1%cg .neqv. mask2%cg) .or. &
        (mask1%h .neqv. mask2%h) .or. &
        (mask1%hd .neqv. mask2%hd)
end function quantum_numbers_mask_neqv

```

7.4.12 Apply a mask

Applying a mask to the quantum number object means undefining those entries where the mask is set. The others remain unaffected.

The `hd` mask has the special property that it “diagonalizes” helicity, i.e., the second helicity entry is dropped and the result is a diagonal helicity quantum number.

```

<Quantum numbers: public>+≡
public :: quantum_numbers_undefine
public :: quantum_numbers_undefined

<Quantum numbers: interfaces>+≡
interface quantum_numbers_undefined
  module procedure quantum_numbers_undefined0
  module procedure quantum_numbers_undefined1
  module procedure quantum_numbers_undefined11
end interface

<Quantum numbers: procedures>+≡
elemental subroutine quantum_numbers_undefine (qn, mask)
  type(quantum_numbers_t), intent(inout) :: qn

```

```

type(quantum_numbers_mask_t), intent(in) :: mask
if (mask%f) call flavor_undefine (qn%f)
if (mask%c) call color_undefine (qn%c, undefine_ghost=mask%cg)
if (mask%h) then
    call helicity_undefine (qn%h)
else if (mask%hd) then
    if (.not. helicity_is_diagonal (qn%h)) then
        call helicity_diagonalize (qn%h)
    end if
end if
end if
end subroutine quantum_numbers_undefine

function quantum_numbers_undefined0 (qn, mask) result (qn_new)
type(quantum_numbers_t), intent(in) :: qn
type(quantum_numbers_mask_t), intent(in) :: mask
type(quantum_numbers_t) :: qn_new
qn_new = qn
call quantum_numbers_undefine (qn_new, mask)
end function quantum_numbers_undefined0

function quantum_numbers_undefined1 (qn, mask) result (qn_new)
type(quantum_numbers_t), dimension(:), intent(in) :: qn
type(quantum_numbers_mask_t), intent(in) :: mask
type(quantum_numbers_t), dimension(size(qn)) :: qn_new
qn_new = qn
call quantum_numbers_undefine (qn_new, mask)
end function quantum_numbers_undefined1

function quantum_numbers_undefined11 (qn, mask) result (qn_new)
type(quantum_numbers_t), dimension(:), intent(in) :: qn
type(quantum_numbers_mask_t), dimension(:), intent(in) :: mask
type(quantum_numbers_t), dimension(size(qn)) :: qn_new
qn_new = qn
call quantum_numbers_undefine (qn_new, mask)
end function quantum_numbers_undefined11

```

Return true if the input quantum number set has entries that would be removed by the applied mask, e.g., if polarization is defined but `mask%h` is set:

```

<Quantum numbers: public>+≡
public :: quantum_numbers_are_redundant

<Quantum numbers: procedures>+≡
elemental function quantum_numbers_are_redundant (qn, mask) &
    result (redundant)
logical :: redundant
type(quantum_numbers_t), intent(in) :: qn
type(quantum_numbers_mask_t), intent(in) :: mask
redundant = .false.
if (mask%f) then
    redundant = flavor_is_defined (qn%f)
end if
if (mask%c) then
    redundant = color_is_defined (qn%c)
end if

```

```

    if (mask%h) then
        redundant = helicity_is_defined (qn%h)
    else if (mask%hd) then
        redundant = .not. helicity_is_diagonal (qn%h)
    end if
end function quantum_numbers_are_redundant

```

Return true if the helicity flag is set or the diagonal-helicity flag is set.

```

<Quantum numbers: public>+≡
    public :: quantum_numbers_mask_diagonal_helicity

<Quantum numbers: procedures>+≡
    elemental function quantum_numbers_mask_diagonal_helicity (mask) &
        result (flag)
        logical :: flag

  <State matrices: tests>  
  
end module state_matrices
```

7.5.1 Nodes of the quantum state trie

A quantum state object represents an unnormalized density matrix, i.e., an array of possibilities for flavor, color, and helicity indices with associated complex values. Physically, the trace of this matrix is the summed squared matrix element for an interaction, and the matrix elements divided by this value correspond to the flavor-color-helicity density matrix. (Flavor and color are diagonal.)

We store density matrices as tries, that is, as trees where each branching represents the possible quantum numbers of a particle. The first branching is the first particle in the system. A leaf (the node corresponding to the last particle) contains the value of the matrix element.

Each node contains a flavor, color, and helicity entry. Note that each of those entries may be actually undefined, so we can also represent, e.g., unpolarized particles.

The value is meaningful only for leaves, which have no child nodes. There is a pointer to the parent node which allows for following the trie downwards from a leaf, it is null for a root node. The child nodes are implemented as a list, so there is a pointer to the first and last child, and each node also has a **next** pointer to the next sibling.

The root node does not correspond to a particle, only its children do. The quantum numbers of the root node are irrelevant and will not be set. However, we use a common type for the three classes (root, branch, leaf); they may easily be distinguished by the association status of parent and child.

Node type

The node is linked in all directions: the parent, the first and last in the list of children, and the previous and next sibling. This allows us for adding and removing nodes and whole branches anywhere in the trie. (Circular links are not allowed, however.). The node holds its associated set of quantum numbers. The integer index, which is set only for leaf nodes, is the index of the corresponding matrix element value within the state matrix.

Temporarily, matrix-element values may be stored within a leaf node. This is used during state-matrix factorization. When the state matrix is **frozen**, these values are transferred to the matrix-element array within the host state matrix.

```

<State matrices: types>≡
  type :: node_t
  private
  type(quantum_numbers_t) :: qn
  type(node_t), pointer :: parent => null ()
  type(node_t), pointer :: child_first => null ()
  type(node_t), pointer :: child_last => null ()
  type(node_t), pointer :: next => null ()
  type(node_t), pointer :: previous => null ()
  integer :: me_index = 0
  integer, dimension(:), allocatable :: me_count
  complex(default) :: me = 0
end type node_t

```

Operations on nodes

Recursively deallocate all children of the current node. This includes any values associated with the children.

```

<State matrices: procedures>≡
  pure recursive subroutine node_delete_offspring (node)
  type(node_t), pointer :: node
  type(node_t), pointer :: child
  child => node%child_first
  do while (associated (child))
    node%child_first => node%child_first%next
    call node_delete_offspring (child)
    deallocate (child)
  end do
  node%child_last => null ()

```

```
end subroutine node_delete_offspring
```

Remove a node including its offspring. Adjust the pointers of parent and siblings, if necessary.

(State matrices: procedures)+≡

```
pure subroutine node_delete (node)
  type(node_t), pointer :: node
  call node_delete_offspring (node)
  if (associated (node%previous)) then
    node%previous%next => node%next
  else if (associated (node%parent)) then
    node%parent%child_first => node%next
  end if
  if (associated (node%next)) then
    node%next%previous => node%previous
  else if (associated (node%parent)) then
    node%parent%child_last => node%previous
  end if
  deallocate (node)
end subroutine node_delete
```

Append a child node

(State matrices: procedures)+≡

```
subroutine node_append_child (node, child)
  type(node_t), target, intent(inout) :: node
  type(node_t), pointer :: child
  allocate (child)
  if (associated (node%child_last)) then
    node%child_last%next => child
    child%previous => node%child_last
  else
    node%child_first => child
  end if
  node%child_last => child
  child%parent => node
end subroutine node_append_child
```

I/O

Output of a single node, no recursion. We print the quantum numbers in square brackets, then the value (if any).

(State matrices: procedures)+≡

```
subroutine node_write (node, me_array, verbose, unit)
  type(node_t), intent(in) :: node
  complex(default), dimension(:), intent(in), optional :: me_array
  logical, intent(in), optional :: verbose
  integer, intent(in), optional :: unit
  logical :: verb
  integer :: u
  verb = .false.; if (present (verbose)) verb = verbose
  u = output_unit (unit); if (u < 0) return
```

```

call quantum_numbers_write (node%qn, u)
if (node%me_index /= 0) then
  write (u, "(A,I0,A)", advance="no") " => ME(", node%me_index, ")"
  if (present (me_array)) then
    write (u, "(A)", advance="no") " = "
    write (u, "('(',ES19.12,',',',ES19.12,')')'", advance="no") &
      pacify_complex (me_array(node%me_index))
  end if
end if
write (u, *)
if (verb) then
  call ptr_write ("parent      ", node%parent)
  call ptr_write ("child_first", node%child_first)
  call ptr_write ("child_last ", node%child_last)
  call ptr_write ("next       ", node%next)
  call ptr_write ("previous   ", node%previous)
end if
contains
subroutine ptr_write (label, node)
character(*), intent(in) :: label
type(node_t), pointer :: node
if (associated (node)) then
  write (u, "(10x,A,1x,'->',1x)", advance="no") label
  call quantum_numbers_write (node%qn, u)
  write (u, *)
end if
end subroutine ptr_write
end subroutine node_write

```

Recursive output of a node:

(State matrices: procedures)+≡

```

recursive subroutine node_write_rec (node, me_array, verbose, indent, unit)
type(node_t), intent(in), target :: node
complex(default), dimension(:), intent(in), optional :: me_array
logical, intent(in), optional :: verbose
integer, intent(in), optional :: indent
integer, intent(in), optional :: unit
type(node_t), pointer :: current
logical :: verb
integer :: i, u
verb = .false.; if (present (verbose)) verb = verbose
i = 0; if (present (indent)) i = indent
u = output_unit (unit); if (u < 0) return
current => node%child_first
do while (associated (current))
  write (u, "(A)", advance="no") repeat (" ", i)
  call node_write (current, me_array, verb, u)
  call node_write_rec (current, me_array, verb, i+2, u)
  current => current%next
end do
end subroutine node_write_rec

```

Binary I/O. Matrix elements are written only for leaf nodes.

<State matrices: procedures>+≡

```

recursive subroutine node_write_raw_rec (node, u)
  type(node_t), intent(in), target :: node
  integer, intent(in) :: u
  logical :: associated_child_first, associated_next
  call quantum_numbers_write_raw (node%qn, u)
  associated_child_first = associated (node%child_first)
  write (u) associated_child_first
  associated_next = associated (node%next)
  write (u) associated_next
  if (associated_child_first) then
    call node_write_raw_rec (node%child_first, u)
  else
    write (u) node%me_index
  end if
  if (associated_next) then
    call node_write_raw_rec (node%next, u)
  end if
end subroutine node_write_raw_rec

    node%child_first => child
    node%child_last => null ()
    call node_read_raw_rec (child, u, node, iostat=iostat)
    do while (associated (child))
      child%previous => node%child_last
      node%child_last => child
      child => child%next
    end do
  else
    read (u, iostat=iostat) node%me_index
  end if
  if (associated_next) then
    allocate (node%next)
    call node_read_raw_rec (node%next, u, parent, iostat=iostat)
  end if
end subroutine node_read_raw_rec

```

7.5.2 State matrix

Definition

The quantum state object is a container that keeps and hides the root node. For direct accessibility of values, they are stored in a separate array. The leaf nodes of the quantum-number tree point to those values, once the state matrix is finalized.

The `norm` component is redefined if a common factor is extracted from all nodes.

```

<State matrices: public>≡
    public :: state_matrix_t

<State matrices: types>+≡
    type :: state_matrix_t
    private
        type(node_t), pointer :: root => null ()
        integer :: depth = 0
        integer :: n_matrix_elements = 0
        logical :: leaf_nodes_store_values = .false.
        integer :: n_counters = 0
        complex(default), dimension(:), allocatable :: me
        real(default) :: norm = 1
    end type state_matrix_t

```

This initializer allocates the root node but does not fill anything. We declare whether values are stored within the nodes during state-matrix construction, and how many counters should be maintained (default: none).

```

<State matrices: public>+≡
    public :: state_matrix_init

<State matrices: procedures>+≡
    elemental subroutine state_matrix_init (state, store_values, n_counters)
        type(state_matrix_t), intent(out) :: state
        logical, intent(in), optional :: store_values
        integer, intent(in), optional :: n_counters
        allocate (state%root)
        if (present (store_values)) &
            state%leaf_nodes_store_values = store_values
        if (present (n_counters)) state%n_counters = n_counters
    end subroutine state_matrix_init

```

This recursively deletes all children of the root node, restoring the initial state. The matrix element array is not finalized, since it does not contain physical entries, just pointers.

```

<State matrices: public>+≡
    public :: state_matrix_final

<State matrices: procedures>+≡
    elemental subroutine state_matrix_final (state)
        type(state_matrix_t), intent(inout) :: state
        if (allocated (state%me)) deallocate (state%me)
        if (associated (state%root)) call node_delete (state%root)
        state%depth = 0
    end subroutine state_matrix_final

```

```

state%n_matrix_elements = 0
end subroutine state_matrix_final

```

Output: Present the tree as a nested list with appropriate indentation.

```

<State matrices: public>+≡
public :: state_matrix_write

<State matrices: procedures>+≡
subroutine state_matrix_write (state, unit, write_value_list, verbose)
  type(state_matrix_t), intent(in) :: state
  logical, intent(in), optional :: write_value_list, verbose
  integer, intent(in), optional :: unit
  complex(default) :: me_dum
  integer :: u
  integer :: i
  u = output_unit (unit); if (u < 0) return
  write (u, "(1x,A,ES19.12)") "State matrix: norm = ", state%norm
  if (associated (state%root)) then
    if (allocated (state%me)) then
      call node_write_rec (state%root, state%me, verbose, 1, u)
    else
      call node_write_rec (state%root, verbose=verbose, indent=1, unit=u)
    end if
  end if
  if (present (write_value_list)) then
    if (write_value_list .and. allocated (state%me)) then
      do i = 1, size (state%me)
        write (u, "(1x,I0,A)", advance="no") i, ":"
        me_dum = state%me(i)
        if (real(state%me(i)) == -real(state%me(i))) then
          me_dum = &
            cmplx (0._default, aimag(me_dum), kind=default)
        end if
        if (aimag(me_dum) == -aimag(me_dum)) then
          me_dum = &
            cmplx (real(me_dum), 0._default, kind=default)
        end if
        write (u, "('(',ES19.12,',',',ES19.12,')')") me_dum
      end do
    end if
  end if
end subroutine state_matrix_write

```

Binary I/O. The auxiliary matrix-element array is not written, but reconstructed after reading the tree.

```

<State matrices: public>+≡
public :: state_matrix_write_raw
public :: state_matrix_read_raw

<State matrices: procedures>+≡
subroutine state_matrix_write_raw (state, u)
  type(state_matrix_t), intent(in) :: state
  integer, intent(in) :: u
  logical :: associated_root

```

```

    associated_root = associated (state%root)
    write (u) associated_root
    if (associated_root) then
        write (u) state%depth
        write (u) state%norm
        call node_write_raw_rec (state%root, u)
    end if
end subroutine state_matrix_write_raw

subroutine state_matrix_read_raw (state, u, iostat)
    type(state_matrix_t), intent(out) :: state
    integer, intent(in) :: u
    integer, intent(out), optional :: iostat
    logical :: associated_root
    read (u, iostat=iostat) associated_root
    if (associated_root) then
        read (u, iostat=iostat) state%depth
        read (u, iostat=iostat) state%norm
        call state_matrix_init (state)
        call node_read_raw_rec (state%root, u, iostat=iostat)
        call state_matrix_freeze (state)
    end if
end subroutine state_matrix_read_raw

```

Properties of the quantum state

A state is defined if its root is allocated:

```

<State matrices: public>+≡
    public :: state_matrix_is_defined

<State matrices: procedures>+≡
    elemental function state_matrix_is_defined (state) result (defined)
        logical :: defined
        type(state_matrix_t), intent(in) :: state
        defined = associated (state%root)
    end function state_matrix_is_defined

```

A state is empty if its depth is zero:

```

<State matrices: public>+≡
    public :: state_matrix_is_empty

<State matrices: procedures>+≡
    elemental function state_matrix_is_empty (state) result (flag)
        logical :: flag
        type(state_matrix_t), intent(in) :: state
        flag = state%depth == 0
    end function state_matrix_is_empty

```

Return the number of matrix-element values.

```

<State matrices: public>+≡
    public :: state_matrix_get_n_matrix_elements

```

```

<State matrices: procedures>+≡
function state_matrix_get_n_matrix_elements (state) result (n)
  integer :: n
  type(state_matrix_t), intent(in) :: state
  n = state%n_matrix_elements
end function state_matrix_get_n_matrix_elements

```

Return the number of leaves. This can be larger than the number of independent matrix elements.

```

<State matrices: public>+≡
public :: state_matrix_get_n_leaves

<State matrices: procedures>+≡
function state_matrix_get_n_leaves (state) result (n)
  integer :: n
  type(state_matrix_t), intent(in) :: state
  type(state_iterator_t) :: it
  n = 0
  call state_iterator_init (it, state)
  do while (state_iterator_is_valid (it))
    n = n + 1
    call state_iterator_advance (it)
  end do
end function state_matrix_get_n_leaves

```

Return the depth:

```

<State matrices: public>+≡
public :: state_matrix_get_depth

<State matrices: procedures>+≡
function state_matrix_get_depth (state) result (depth)
  integer :: depth
  type(state_matrix_t), intent(in) :: state
  depth = state%depth
end function state_matrix_get_depth

```

Return the norm:

```

<State matrices: public>+≡
public :: state_matrix_get_norm

<State matrices: procedures>+≡
function state_matrix_get_norm (state) result (norm)
  real(default) :: norm
  type(state_matrix_t), intent(in) :: state
  norm = state%norm
end function state_matrix_get_norm

```

Retrieving contents

Return the quantum number array, using an index. We have to scan the state matrix since there is no shortcut.

```

<State matrices: public>+≡
public :: state_matrix_get_quantum_numbers

```

```

<State matrices: procedures>+≡
function state_matrix_get_quantum_numbers (state, i) result (qn)
  type(state_matrix_t), intent(in), target :: state
  integer, intent(in) :: i
  type(quantum_numbers_t), dimension(state%depth) :: qn
  type(state_iterator_t) :: it
  integer :: k
  k = 0
  call state_iterator_init (it, state)
  do while (state_iterator_is_valid (it))
    k = k + 1
    if (k == i) then
      qn = state_iterator_get_quantum_numbers (it)
      return
    end if
    call state_iterator_advance (it)
  end do
end function state_matrix_get_quantum_numbers

```

Return a single matrix element using its index. Works only if the shortcut array is allocated.

```

<State matrices: public>+≡
public :: state_matrix_get_matrix_element

<State matrices: procedures>+≡
function state_matrix_get_matrix_element (state, i) result (me)
  complex(default) :: me
  type(state_matrix_t), intent(in) :: state
  integer, intent(in) :: i
  if (allocated (state%me)) then
    me = state%me(i)
  else
    me = 0
  end if
end function state_matrix_get_matrix_element

```

Return the color index with maximum absolute value that is present within the state matrix.

```

<State matrices: public>+≡
public :: state_matrix_get_max_color_value

<State matrices: procedures>+≡
function state_matrix_get_max_color_value (state) result (cmax)
  integer :: cmax
  type(state_matrix_t), intent(in) :: state
  if (associated (state%root)) then
    cmax = node_get_max_color_value (state%root)
  else
    cmax = 0
  end if
contains
  recursive function node_get_max_color_value (node) result (cmax)
    integer :: cmax
    type(node_t), intent(in), target :: node

```

```

type(node_t), pointer :: current
cmax = quantum_numbers_get_max_color_value (node%qn)
current => node%child_first
do while (associated (current))
    cmax = max (cmax, node_get_max_color_value (current))
    current => current%next
end do
end function node_get_max_color_value
end function state_matrix_get_max_color_value

```

Building the quantum state

The procedure generates a branch associated to the input array of quantum numbers. If the branch exists already, it is used.

Optionally, we set the matrix-element index, a value (which may be added to the previous one), and increment one of the possible counters. We may also return the matrix element index of the current node.

```

<State matrices: public>+≡
public :: state_matrix_add_state

<State matrices: procedures>+≡
subroutine state_matrix_add_state &
    (state, qn, index, value, sum_values, counter_index, me_index)

    end if
  end if
case (2:)
  call node_make_branch (child, qn(2:))
end select
end subroutine node_make_branch
end subroutine state_matrix_add_state

```

Remove irrelevant flavor/color/helicity labels and the corresponding branchings. The masks indicate which particles are affected; the masks length should coincide with the depth of the trie (without the root node). Recursively scan the whole tree, starting from the leaf nodes and working up to the root node. If a mask entry is set for the current tree level, scan the children there. For each child within that level make a new empty branch where the masked quantum number is undefined. Then recursively combine all following children with matching quantum number into this new node and move on.

<State matrices: public>+≡

```
public :: state_matrix_collapse
```

<State matrices: procedures>+≡

```

subroutine state_matrix_collapse (state, mask)
  type(state_matrix_t), intent(inout) :: state
  type(quantum_numbers_mask_t), dimension(:), intent(in) :: mask
  type(state_matrix_t) :: red_state

```

```

    if (state_matrix_is_defined (state)) then
        call state_matrix_reduce (state, mask, red_state)
        call state_matrix_final (state)
        state = red_state
    end if
end subroutine state_matrix_collapse

```

Transform the given state matrix into a reduced state matrix where some quantum numbers are removed, as indicated by the mask. The procedure creates a new state matrix, so the old one can be deleted after this if it is no longer used.

```

<State matrices: public>+≡
    public :: state_matrix_reduce

<State matrices: procedures>+≡
    subroutine state_matrix_reduce (state, mask, red_state)
        type(state_matrix_t), intent(in), target :: state

        call state_iterator_init (it, state)
        do while (state_iterator_is_valid (it))
            qn = state_iterator_get_quantum_numbers (it)
            call quantum_numbers_undefine (qn, mask)
            call state_matrix_add_state (red_state, qn)
            call state_iterator_advance (it)
        end do
    end subroutine state_matrix_reduce

```

This subroutine sets up the matrix-element array. The leaf nodes acquire the index values that point to the appropriate matrix-element entry.

We recursively scan the trie. Once we arrive at a leaf node, the index is increased and associated to that node. Finally, we allocate the matrix-element array with the appropriate size.

If matrix element values are temporarily stored within the leaf nodes, we scan the state again and transfer them to the matrix-element array.

```

<State matrices: public>+≡
    public :: state_matrix_freeze

<State matrices: interfaces>≡
    interface state_matrix_freeze
        module procedure state_matrix_freeze1
        module procedure state_matrix_freeze2
    end interface

<State matrices: procedures>+≡
    subroutine state_matrix_freeze1 (state)
        type(state_matrix_t), intent(inout), target :: state
        type(state_iterator_t) :: it
        if (associated (state%root)) then
            if (allocated (state%me)) deallocate (state%me)
            allocate (state%me (state%n_matrix_elements))
            state%me = 0
        end if
    end subroutine state_matrix_freeze1

```

```

end if
if (state%leaf_nodes_store_values) then
  call state_iterator_init (it, state)
  do while (state_iterator_is_valid (it))
    state%me(state_iterator_get_me_index (it)) &
      = state_iterator_get_matrix_element (it)
    call state_iterator_advance (it)
  end do
  state%leaf_nodes_store_values = .false.
end if
end subroutine state_matrix_freeze1

subroutine state_matrix_freeze2 (state)
  type(state_matrix_t), dimension(:), intent(inout), target :: state
  integer :: i
  do i = 1, size (state)
    call state_matrix_freeze1 (state(i))
  end do
end subroutine state_matrix_freeze2

```

Direct access to the value array

Several methods for setting a value directly are summarized in this generic:

```

<State matrices: public>+≡
  public :: state_matrix_set_matrix_element

<State matrices: interfaces>+≡
  interface state_matrix_set_matrix_element
    module procedure state_matrix_set_matrix_element_qn
    module procedure state_matrix_set_matrix_element_all
    module procedure state_matrix_set_matrix_element_array
    module procedure state_matrix_set_matrix_element_single
    module procedure state_matrix_set_matrix_element_clone
  end interface

```

Set a value that corresponds to a quantum number array:

```

<State matrices: procedures>+≡
  subroutine state_matrix_set_matrix_element_qn (state, qn, value)
    type(state_matrix_t), intent(inout) :: state
    type(quantum_numbers_t), dimension(:), intent(in) :: qn
    complex(default), intent(in) :: value
    type(state_iterator_t) :: it
    if (.not. allocated (it%state%me)) then
      allocate (it%state%me (size(qn)))
    end if
    call state_iterator_init (it, state)
    do while (state_iterator_is_valid (it))
      if (all (qn == state_iterator_get_quantum_numbers (it))) then
        call state_iterator_set_matrix_element (it, value)
        return
      end if
      call state_iterator_advance (it)
    end do
  end subroutine

```

```
end subroutine state_matrix_set_matrix_element_qn
```

Set all matrix elements to a single value

```
<State matrices: procedures>+≡
subroutine state_matrix_set_matrix_element_all (state, value)
  type(state_matrix_t), intent(inout) :: state
  complex(default), intent(in) :: value
  if (.not. allocated (state%me)) then
    allocate (state%me (state%n_matrix_elements))
  end if
  state%me = value
end subroutine state_matrix_set_matrix_element_all
```

Set the matrix-element array directly.

```
<State matrices: procedures>+≡
subroutine state_matrix_set_matrix_element_array (state, value)
  type(state_matrix_t), intent(inout) :: state
  complex(default), dimension(:), intent(in) :: value
  if (.not. allocated (state%me)) then
    allocate (state%me (size (value)))
  end if
  state%me = value
end subroutine state_matrix_set_matrix_element_array

pure subroutine state_matrix_set_matrix_element_single (state, i, value)
  type(state_matrix_t), intent(inout) :: state
  integer, intent(in) :: i
  complex(default), intent(in) :: value
  if (.not. allocated (state%me)) then
    allocate (state%me (state%n_matrix_elements))
  end if
  state%me(i) = value
end subroutine state_matrix_set_matrix_element_single
```

Clone the matrix elements from another (matching) state matrix.

```
<State matrices: procedures>+≡
subroutine state_matrix_set_matrix_element_clone (state, state1)
  type(state_matrix_t), intent(inout) :: state
  type(state_matrix_t), intent(in) :: state1
  if (.not. allocated (state1%me)) return
  if (.not. allocated (state%me)) allocate (state%me (size (state1%me)))
  state%me = state1%me
end subroutine state_matrix_set_matrix_element_clone
```

Add a value to a matrix element

```
<State matrices: public>+≡
public :: state_matrix_add_to_matrix_element

<State matrices: procedures>+≡
subroutine state_matrix_add_to_matrix_element (state, i, value)
  type(state_matrix_t), intent(inout) :: state
  integer, intent(in) :: i
```

```

        complex(default), intent(in) :: value
        state%me(i) = state%me(i) + value
    end subroutine state_matrix_add_to_matrix_element

```

7.5.3 State iterators

Accessing the quantum state from outside is best done using a specialized iterator, i.e., a pointer to a particular branch of the quantum state trie. Technically, the iterator contains a pointer to a leaf node, but via parent pointers it allows to access the whole branch where the leaf is attached. For quick access, we also keep the branch depth (which is assumed to be universal for a quantum state).

```

<State matrices: public>+≡
    public :: state_iterator_t

<State matrices: types>+≡
    type :: state_iterator_t
        private
        integer :: depth = 0
        type(state_matrix_t), pointer :: state => null ()
        type(node_t), pointer :: node => null ()
    end type state_iterator_t

```

The initializer: Point at the first branch. Note that this cannot be pure, thus not be elemental, because the iterator can be used to manipulate data in the state matrix.

```

<State matrices: public>+≡
    public :: state_iterator_init

<State matrices: procedures>+≡
    subroutine state_iterator_init (it, state)
        type(state_iterator_t), intent(out) :: it
        type(state_matrix_t), intent(in), target :: state
        it%state => state
        it%depth = state%depth
        if (state_matrix_is_defined (state)) then
            it%node => state%root
            do while (associated (it%node%child_first))
                it%node => it%node%child_first
            end do
        else
            it%node => null ()
        end if
    end subroutine state_iterator_init

```

Go forward. Recursively programmed: if the next node does not exist, go back to the parent node and look at its successor (if present), etc.

There is a possible pitfall in the implementation: If the dummy pointer argument to the `find_next` routine is used directly, we still get the correct result for the iterator, but calling the recursion on `node%parent` means that we manipulate a parent pointer in the original state in addition to the iterator.

Making a local copy of the pointer avoids this. Using pointer intent would be helpful, but we do not yet rely on this F2003 feature.

```

<State matrices: public>+≡
    public :: state_iterator_advance

<State matrices: procedures>+≡
    subroutine state_iterator_advance (it)
        type(state_iterator_t), intent(inout) :: it
        call find_next (it%node)
    contains
        recursive subroutine find_next (node_in)
            type(node_t), intent(in), target :: node_in
            type(node_t), pointer :: node
            node => node_in
            if (associated (node%next)) then
                node => node%next
                do while (associated (node%child_first))
                    node => node%child_first
                end do
                it%node => node
            else if (associated (node%parent)) then
                call find_next (node%parent)
            else
                it%node => null ()
            end if
        end subroutine find_next
    end subroutine state_iterator_advance

```

If all has been scanned, the iterator is at an undefined state. Check for this:

```

<State matrices: public>+≡
    public :: state_iterator_is_valid

<State matrices: procedures>+≡
    function state_iterator_is_valid (it) result (defined)
        logical :: defined
        type(state_iterator_t), intent(in) :: it
        defined = associated (it%node)
    end function state_iterator_is_valid

```

Return the matrix-element index that corresponds to the current node

```

<State matrices: public>+≡
    public :: state_iterator_get_me_index

<State matrices: procedures>+≡
    function state_iterator_get_me_index (it) result (n)
        integer :: n
        type(state_iterator_t), intent(in) :: it
        n = it%node%me_index
    end function state_iterator_get_me_index

```

Return the number of times this quantum-number state has been added (noting that it is physically inserted only the first time). Note that for each state, there is an array of counters.

```

<State matrices: public>+≡

```

```

public :: state_iterator_get_me_count
<State matrices: procedures>+≡
function state_iterator_get_me_count (it) result (n)
  integer, dimension(:), allocatable :: n
  type(state_iterator_t), intent(in) :: it
  if (allocated (it%node%me_count)) then
    allocate (n (size (it%node%me_count)))
    n = it%node%me_count
  else
    allocate (n (0))
  end if
end function state_iterator_get_me_count

```

Use the iterator to retrieve quantum-number information:

```

<State matrices: public>+≡
public :: state_iterator_get_quantum_numbers
public :: state_iterator_get_flavor
public :: state_iterator_get_color
public :: state_iterator_get_helicity

<State matrices: interfaces>+≡
interface state_iterator_get_quantum_numbers
  module procedure state_iterator_get_qn_multi
  module procedure state_iterator_get_qn_slice
  module procedure state_iterator_get_qn_range
  module procedure state_iterator_get_qn_single
end interface

interface state_iterator_get_flavor
  module procedure state_iterator_get_flv_multi
  module procedure state_iterator_get_flv_slice
  module procedure state_iterator_get_flv_range
  module procedure state_iterator_get_flv_single
end interface

interface state_iterator_get_color
  module procedure state_iterator_get_col_multi
  module procedure state_iterator_get_col_slice
  module procedure state_iterator_get_col_range
  module procedure state_iterator_get_col_single
end interface

interface state_iterator_get_helicity
  module procedure state_iterator_get_hel_multi
  module procedure state_iterator_get_hel_slice
  module procedure state_iterator_get_hel_range
  module procedure state_iterator_get_hel_single
end interface

```

These versions return the whole quantum number array

```

<State matrices: procedures>+≡
function state_iterator_get_qn_multi (it) result (qn)
  type(state_iterator_t), intent(in) :: it

```

```

type(quantum_numbers_t), dimension(it%depth) :: qn
type(node_t), pointer :: node
integer :: i
node => it%node
do i = it%depth, 1, -1
    qn(i) = node%qn
    node => node%parent
end do
end function state_iterator_get_qn_multi

            state_out%me = state_in%me
        end if
    end subroutine state_matrix_assign

```

Determine the indices of all diagonal matrix elements.

```

<State matrices: public>+≡
    public :: state_matrix_get_diagonal_entries

<State matrices: procedures>+≡
    subroutine state_matrix_get_diagonal_entries (state, i)
        type(state_matrix_t), intent(in) :: state
        integer, dimension(:), allocatable, intent(out) :: i
        integer, dimension(state%n_matrix_elements) :: tmp
        integer :: n
        type(state_iterator_t) :: it
        n = 0
        call state_iterator_init (it, state)
        do while (state_iterator_is_valid (it))
            if (all (quantum_numbers_are_diagonal ( &
                state_iterator_get_quantum_numbers (it)))) then
                n = n + 1
                tmp(n) = state_iterator_get_me_index (it)
            end if
            call state_iterator_advance (it)
        end do
        allocate (i(n))
        if (n > 0) i = tmp(:n)
    end subroutine state_matrix_get_diagonal_entries

```

Normalize all matrix elements, i.e., multiply by a common factor. Assuming that the factor is nonzero, of course.

```

<State matrices: public>+≡
    public :: state_matrix_renormalize

<State matrices: procedures>+≡
    subroutine state_matrix_renormalize (state, factor)
        type(state_matrix_t), intent(inout) :: state
        complex(default), intent(in) :: factor
        state%me = state%me * factor
    end subroutine state_matrix_renormalize

```

Renormalize the state matrix by its trace, if nonzero. The renormalization is reflected in the state-matrix norm.

```

<State matrices: public>+≡
    public :: state_matrix_normalize_by_trace

<State matrices: procedures>+≡
    subroutine state_matrix_normalize_by_trace (state)
        type(state_matrix_t), intent(inout) :: state
        real(default) :: trace
        trace = state_matrix_trace (state)
        if (trace /= 0) then
            state%me = state%me / trace
            state%norm = state%norm * trace
        end if
    end subroutine state_matrix_normalize_by_trace

```

Analogous, but renormalize by maximal (absolute) value.

```

<State matrices: public>+≡
    public :: state_matrix_normalize_by_max

<State matrices: procedures>+≡
    subroutine state_matrix_normalize_by_max (state)
        type(state_matrix_t), intent(inout) :: state
        real(default) :: m
        m = maxval (abs (state%me))
        if (m /= 0) then
            state%me = state%me / m
            state%norm = state%norm * m
        end if
    end subroutine state_matrix_normalize_by_max

```

Explicitly set the norm of a state matrix.

```

<State matrices: public>+≡
    public :: state_matrix_set_norm

<State matrices: procedures>+≡
    subroutine state_matrix_set_norm (state, norm)
        type(state_matrix_t), intent(inout) :: state
        real(default), intent(in) :: norm
        state%norm = norm
    end subroutine state_matrix_set_norm

```

Return the sum of all matrix element values.

```

<State matrices: public>+≡
    public :: state_matrix_sum

<State matrices: procedures>+≡
    function state_matrix_sum (state) result (value)
        complex(default) :: value
        type(state_matrix_t), intent(in) :: state
        value = sum (state%me)
    end function state_matrix_sum

```

Return the trace of a state matrix, i.e., the sum over all diagonal values. If `qn_in` is provided, only branches that match this quantum-numbers array are considered.

```

<State matrices: public>+≡
    public :: state_matrix_trace

<State matrices: procedures>+≡
    function state_matrix_trace (state, qn_in) result (trace)

      end do
    end do
  end subroutine state_matrix_add_color_contractions

```

This procedure merges two state matrices of equal depth. For each quantum number (flavor, color, helicity), we take the entry from the first argument where defined, otherwise the second one. (If both are defined, we get an off-diagonal matrix.) The resulting trie combines the information of the input tries in all

possible ways. Note that values are ignored, all values in the result are zero.

```

<State matrices: public>+≡

        end do
        call state_matrix_freeze (state3)
    end subroutine merge_state_matrices

```

Multiply matrix elements from two state matrices. Choose the elements as given by the integer index arrays, multiply them and store the sum of products in the indicated matrix element. The suffixes mean: c=conjugate first factor; f=include weighting factor.

Note that the `dot_product` intrinsic function conjugates its first complex argument. This is intended for the `c` suffix case, but must be reverted for the plain-product case.

We provide analogous subroutines for just summing over state matrix entries. The `evaluate_sum` variant includes the state-matrix norm in the evaluation, the `evaluate_me_sum` takes into account just the matrix elements proper.

```

<State matrices: public>+≡

        call state_matrix_final (state_tmp)
    end select
end subroutine outer_multiply_array

```

7.5.5 Factorization

In physical events, the state matrix is factorized into single-particle state matrices. This is essentially a measurement.

In a simulation, we select one particular branch of the state matrix with a probability that is determined by the matrix elements at the leaves. (This makes sense only if the state matrix represents a squared amplitude.) The selection is based on a (random) value `x` between 0 and one that is provided as the third argument.

For flavor and color, we select a unique value for each particle. For polarization, we have three options (modes). Option 1 is to drop helicity information altogether and sum over all diagonal helicities. Option 2 is to select a unique diagonal helicity in the same way as flavor and color. Option 3 is, for each particle, to trace over all remaining helicities in order to obtain an array of independent single-particle helicity matrices.

Only branches that match the given quantum-number array `qn_in`, if present, are considered. For this array, color is ignored.

If the optional `correlated_state` is provided, it is assigned the correlated density matrix for the selected flavor-color branch, so multi-particle spin correlations remain available even if they are dropped in the single-particle density matrices.

The algorithm is as follows: First, we determine the normalization by summing over all diagonal matrix elements. In a second scan, we select one of the diagonal matrix elements by a cumulative comparison with the normalized random number. In the corresponding quantum number array, we undefine the helicity entries. Then, we scan the third time. For each branch that matches the selected quantum number array (i.e., definite flavor and color, arbitrary helicity), we determine its contribution to any of the single-particle state matrices. The matrix-element value is added if all other quantum numbers are diagonal, while the helicity of the chosen particle may be arbitrary; this helicity determines the branch in the single-particle state.

As a result, flavor and color quantum numbers are selected with the correct probability. Within this subset of states, each single-particle state matrix results from tracing over all other particles. Note that the single-particle state matrices are not normalized.

The flag `ok` is set to false if the matrix element sum is zero, so factorization is not possible. This can happen if an event did not pass cuts.

7.6 Interactions

This module defines the `interaction_t` type. It is an extension of the `state_matrix_t` type.

The state matrix is a representation of a multi-particle density matrix. It implements all possible flavor, color, and quantum-number assignments of the entries in a generic density matrix, and it can hold a complex matrix element for each entry. (Note that this matrix can hold non-diagonal entries in color and helicity space.) The `interaction_t` object associates this with a list of momenta, such that the whole object represents a multi-particle state.

The `interaction_t` holds information about which particles are incoming, virtual (i.e., kept for the records), or outgoing. Each particle can be associated to a source within another interaction. This allows us to automatically fill those interaction momenta which have been computed or defined elsewhere. It also contains internal parent-child relations and flags for (virtual) particles which are to be treated as resonances.

A quantum-number mask array summarizes, for each particle within the interaction, the treatment of flavor, color, or helicity (expose or ignore). A list of locks states which particles are bound to have an identical quantum-number mask. This is useful when the mask is changed at one place.

```

  end module interactions

```

7.6.1 External interaction links

Each particle in an interaction can have a link to a corresponding particle in another interaction. This allows to fetch the momenta of incoming or virtual particles from the interaction where they are defined. The link object consists of a pointer to the interaction and an index.

```
<Interactions: types>≡
  type :: external_link_t
  private
    type(interaction_t), pointer :: int => null ()
    integer :: i
  end type external_link_t
```

Set an external link.

```
<Interactions: procedures>≡
  subroutine external_link_set (link, int, i)
    type(external_link_t), intent(out) :: link
    type(interaction_t), target, intent(in) :: int
    integer, intent(in) :: i
    if (i /= 0) then
      link%int => int
      link%i = i
    end if
  end subroutine external_link_set
```

Reassign an external link to a new interaction (which should be an image of the original target).

```
<Interactions: procedures>+≡
  subroutine external_link_reassign (link, int_src, int_target)
    type(external_link_t), intent(inout) :: link
    type(interaction_t), intent(in) :: int_src
    type(interaction_t), intent(in), target :: int_target
    if (associated (link%int)) then
      if (link%int%tag == int_src%tag) link%int => int_target
    end if
  end subroutine external_link_reassign
```

Return true if the link is set

```
<Interactions: procedures>+≡
  function external_link_is_set (link) result (flag)
    logical :: flag
    type(external_link_t), intent(in) :: link
    flag = associated (link%int)
  end function external_link_is_set
```

Return the interaction pointer.

```
<Interactions: public>≡
  public :: external_link_get_ptr

<Interactions: procedures>+≡
  function external_link_get_ptr (link) result (int)
    type(interaction_t), pointer :: int
```

```

    type(external_link_t), intent(in) :: link
    int => link%i
end function external_link_get_ptr

```

Return the index within that interaction

```

<Interactions: public>+≡
    public :: external_link_get_index

<Interactions: procedures>+≡
    function external_link_get_index (link) result (i)
        integer :: i
        type(external_link_t), intent(in) :: link
        i = link%i
    end function external_link_get_index

```

Return a pointer to the momentum of the corresponding particle. If there is no association, return a null pointer.

```

<Interactions: procedures>+≡
    function external_link_get_momentum_ptr (link) result (p)
        type(vector4_t), pointer :: p
        type(external_link_t), intent(in) :: link
        if (associated (link%i)) then
            p => link%i%p(link%i)
        else
            p => null ()
        end if
    end function external_link_get_momentum_ptr

```

7.6.2 Internal relations

In addition to the external links, particles within the interaction have parent-child relations. Here, more than one link is possible, and we set up a list.

```

<Interactions: types>+≡
    type :: internal_link_t
        private
        integer :: i
        type(internal_link_t), pointer :: next => null ()
    end type internal_link_t

    type :: internal_link_list_t
        private
        integer :: length = 0
        type(internal_link_t), pointer :: first => null ()
        type(internal_link_t), pointer :: last => null ()
    end type internal_link_list_t

```

Add an internal link.

```

<Interactions: procedures>+≡
    subroutine internal_link_list_append (link_list, i)
        type(internal_link_list_t), intent(inout) :: link_list
        integer, intent(in) :: i
    end subroutine internal_link_list_append

```

```

type(internal_link_t), pointer :: current
allocate (current)
current%i = i
if (associated (link_list%first)) then
    link_list%last%next => current
else
    link_list%first => current
end if
link_list%last => current
link_list%length = link_list%length + 1
end subroutine internal_link_list_append

```

Finalize the list of internal links.

(Interactions: procedures)+≡

```

subroutine internal_link_list_final (link_list)
type(internal_link_list_t), intent(inout) :: link_list
type(internal_link_t), pointer :: current
do while (associated (link_list%first))
    current => link_list%first
    link_list%first => current%next
    deallocate (current)
end do
link_list%last => null ()
link_list%length = 0
end subroutine internal_link_list_final

```

We need a deep copy of this list when we assign interaction objects.

(Interactions: interfaces)≡

```

interface assignment(=)
    module procedure internal_link_list_assign
end interface

```

(Interactions: procedures)+≡

```

subroutine internal_link_list_assign (link_list_out, link_list_in)
type(internal_link_list_t), intent(in) :: link_list_in
type(internal_link_list_t), intent(out) :: link_list_out
type(internal_link_t), pointer :: current, copy
current => link_list_in%first
do while (associated (current))
    allocate (copy)
    copy%i = current%i
    if (associated (link_list_out%first)) then
        link_list_out%last%next => copy
    else
        link_list_out%first => copy
    end if
    link_list_out%last => copy
    current => current%next
end do
end subroutine internal_link_list_assign

```

Return true if the link list is nonempty:

```

<Interactions: procedures>+=
function internal_link_list_has_entries (link_list) result (flag)
    logical :: flag
    type(internal_link_list_t), intent(in) :: link_list
    flag = associated (link_list%first)
end function internal_link_list_has_entries

```

Return a pointer to the first entry:

```

<Interactions: procedures>+=
function internal_link_list_get_first_ptr (link_list) result (link)
    type(internal_link_list_t), intent(in) :: link_list
    type(internal_link_t), pointer :: link
    link => link_list%first
end function internal_link_list_get_first_ptr

```

Advance this pointer.

```

<Interactions: procedures>+=
subroutine internal_link_advance (link)
    type(internal_link_t), pointer :: link
    link => link%next
end subroutine internal_link_advance

```

Return the index.

```

<Interactions: procedures>+=
function internal_link_get_index (link) result (i)
    integer :: i
    type(internal_link_t), intent(in) :: link
    i = link%i
end function internal_link_get_index

```

Return the list length

```

<Interactions: procedures>+=
function internal_link_list_get_length (link_list) result (length)
    integer :: length
    type(internal_link_list_t), intent(in) :: link_list
    length = link_list%length
end function internal_link_list_get_length

```

7.6.3 The interaction type

An interaction is an entangled system of particles. Thus, the interaction object consists of two parts: the subevent, and the quantum state which technically is a trie. The subnode levels beyond the trie root node are in correspondence to the subevent, so both should be traversed in parallel.

The subevent is implemented as an allocatable array of four-momenta. The first `n_in` particles are incoming, `n_vir` particles in-between can be kept for bookkeeping, and the last `n_out` particles are outgoing.

Distinct interactions are linked by their particles: for each particle, we have the possibility of links to corresponding particles in other interactions. Furthermore, for bookkeeping purposes we have a self-link array **relations** where the parent-child relations are kept, and a flag array **resonant** which is set for an intermediate resonance.

Each momentum is associated with masks for flavor, color, and helicity. If a mask entry is set, the associated quantum number is to be ignored for that particle. If any mask has changed, the flag **update** is set.

We can have particle pairs locked together. If this is the case, the corresponding mask entries are bound to be equal. This is useful for particles that go through the interaction.

The interaction tag serves bookkeeping purposes. In particular, it identifies links in printout.

```

<Interactions: public>+≡
    public :: interaction_t

<Interactions: types>+≡
    type :: interaction_t
        private
            integer :: tag = 0
            type(state_matrix_t) :: state_matrix
            integer :: n_in = 0
            integer :: n_vir = 0
            integer :: n_out = 0
            integer :: n_tot = 0
            logical, dimension(:), allocatable :: p_is_known
            type(vector4_t), dimension(:), allocatable :: p
            type(external_link_t), dimension(:), allocatable :: source
            type(internal_link_list_t), dimension(:), allocatable :: parents
            type(internal_link_list_t), dimension(:), allocatable :: children
            logical, dimension(:), allocatable :: resonant
            type(quantum_numbers_mask_t), dimension(:), allocatable :: mask
            integer, dimension(:), allocatable :: hel_lock
            logical :: update_state_matrix = .false.
            logical :: update_values = .false.
        end type interaction_t

```

Initialize the particle array with a fixed size. The first **n_in** particles are incoming, the rest outgoing. Masks are optional. There is also an optional tag. The interaction still needs fixing the values, but that is to be done after all branches have been added.

Interaction tags are assigned consecutively, using a **saved** variable local to this procedure. If desired, we can provide a seed for the interaction tags. Such a seed should be positive. The default seed is one. **tag=0** indicates an empty interaction.

If **set_relations** is set and true, we establish parent-child relations for all incoming and outgoing particles. Virtual particles are skipped; this option is normally used only for interactions without virtual particles.

```

<Interactions: public>+≡
    public :: interaction_init

```

<Interactions: procedures>+≡

```

```

7.6.4 Methods inherited from the state matrix member

Until F2003 is standard, we cannot implement inheritance directly. Therefore, we need wrappers for “inherited” methods.

Make a new branch in the state matrix if it does not yet exist. This is not just a wrapper but it introduces the interaction mask: where a quantum number

is masked, it is not transferred but set undefined. After this, the value array has to be updated.

```

<Interactions: public>+≡
    public :: interaction_add_state

<Interactions: procedures>+≡
    subroutine interaction_add_state &
        (int, qn, index, value, sum_values, counter_index, me_index)
        type(interaction_t), intent(inout) :: int
        type(quantum_numbers_t), dimension(:), intent(in) :: qn
        integer, intent(in), optional :: index
        complex(default), intent(in), optional :: value
        logical, intent(in), optional :: sum_values
        integer, intent(in), optional :: counter_index
        integer, intent(out), optional :: me_index
        type(quantum_numbers_t), dimension(size(qn)) :: qn_tmp
        qn_tmp = qn
        call quantum_numbers_undefine (qn_tmp, int%mask)
        call state_matrix_add_state &
            (int%state_matrix, qn_tmp, index, value, sum_values, &
             counter_index, me_index)
        int%update_values = .true.
    end subroutine interaction_add_state

```

Freeze the quantum state: First collapse the quantum state, i.e., remove quantum numbers if any mask has changed, then fix the array of value pointers.

```

<Interactions: public>+≡
    public :: interaction_freeze

<Interactions: procedures>+≡
    subroutine interaction_freeze (int)
        type(interaction_t), intent(inout) :: int
        if (int%update_state_matrix) then
            call state_matrix_collapse (int%state_matrix, int%mask)
            int%update_state_matrix = .false.
            int%update_values = .true.
        end if
        if (int%update_values) then
            call state_matrix_freeze (int%state_matrix)
            int%update_values = .false.
        end if
    end subroutine interaction_freeze

```

Return true if the state matrix is empty.

```

<Interactions: public>+≡
    public :: interaction_is_empty

<Interactions: procedures>+≡
    function interaction_is_empty (int) result (flag)
        logical :: flag
        type(interaction_t), intent(in) :: int
        flag = state_matrix_is_empty (int%state_matrix)
    end function interaction_is_empty

```

Get the number of values stored in the state matrix:

```
<Interactions: public>+≡
    public :: interaction_get_n_matrix_elements

<Interactions: procedures>+≡
    function interaction_get_n_matrix_elements (int) result (n)
        integer :: n
        type(interaction_t), intent(in) :: int
        n = state_matrix_get_n_matrix_elements (int%state_matrix)
    end function interaction_get_n_matrix_elements
```

Get the norm of the state matrix (if the norm has been taken out, otherwise this would be unity).

```
<Interactions: public>+≡
    public :: interaction_get_norm

<Interactions: procedures>+≡
    function interaction_get_norm (int) result (norm)
        real(default) :: norm
        type(interaction_t), intent(in) :: int
        norm = state_matrix_get_norm (int%state_matrix)
    end function interaction_get_norm
```

Get the quantum number array that corresponds to a given index.

```
<Interactions: public>+≡
    public :: interaction_get_quantum_numbers

<Interactions: procedures>+≡
    function interaction_get_quantum_numbers (int, i) result (qn)
        type(quantum_numbers_t), dimension(:), allocatable :: qn
        type(interaction_t), intent(in), target :: int
        integer, intent(in) :: i
        allocate (qn (state_matrix_get_depth (int%state_matrix)))
        qn = state_matrix_get_quantum_numbers (int%state_matrix, i)
    end function interaction_get_quantum_numbers
```

Get the matrix element that corresponds to a set of quantum numbers, a given index, or return the whole array.

```
<Interactions: public>+≡
    public :: interaction_get_matrix_element

<Interactions: procedures>+≡
    function interaction_get_matrix_element (int, i) result (me)
        complex(default) :: me
        type(interaction_t), intent(in) :: int
        integer, intent(in) :: i
        me = state_matrix_get_matrix_element (int%state_matrix, i)
    end function interaction_get_matrix_element
```

Set the complex value(s) stored in the quantum state.

```
<Interactions: public>+≡
    public :: interaction_set_matrix_element
```

<Interactions: interfaces>+≡

```
interface interaction_set_matrix_element
  module procedure interaction_set_matrix_element_qn
  module procedure interaction_set_matrix_element_all
  module procedure interaction_set_matrix_element_array
  module procedure interaction_set_matrix_element_single
  module procedure interaction_set_matrix_element_clone
end interface
```

Indirect access via the quantum number array:

<Interactions: procedures>+≡

```
subroutine interaction_set_matrix_element_qn (int, qn, val)
  type(interaction_t), intent(inout) :: int
  type(quantum_numbers_t), dimension(:), intent(in) :: qn
  complex(default), intent(in) :: val
  call state_matrix_set_matrix_element (int%state_matrix, qn, val)
end subroutine interaction_set_matrix_element_qn
```

Set all entries of the matrix-element array to a given value.

<Interactions: procedures>+≡

```
subroutine interaction_set_matrix_element_all (int, value)
  type(interaction_t), intent(inout) :: int
  complex(default), intent(in) :: value
  call state_matrix_set_matrix_element (int%state_matrix, value)
end subroutine interaction_set_matrix_element_all
```

Set the matrix-element array directly.

<Interactions: procedures>+≡

```
subroutine interaction_set_matrix_element_array (int, value)
  type(interaction_t), intent(inout) :: int
  complex(default), dimension(:), intent(in) :: value
  call state_matrix_set_matrix_element (int%state_matrix, value)
end subroutine interaction_set_matrix_element_array

pure subroutine interaction_set_matrix_element_single (int, i, value)
  type(interaction_t), intent(inout) :: int
  integer, intent(in) :: i
  complex(default), intent(in) :: value
  call state_matrix_set_matrix_element (int%state_matrix, i, value)
end subroutine interaction_set_matrix_element_single
```

Clone from another (matching) interaction.

<Interactions: procedures>+≡

```
subroutine interaction_set_matrix_element_clone (int, int1)
  type(interaction_t), intent(inout) :: int
  type(interaction_t), intent(in) :: int1
  call state_matrix_set_matrix_element (int%state_matrix, int1%state_matrix)
end subroutine interaction_set_matrix_element_clone
```

Get the indices of any diagonal matrix elements.

<Interactions: public>+≡

```
public :: interaction_get_diagonal_entries
```

```

<Interactions: procedures>+≡
  subroutine interaction_get_diagonal_entries (int, i)
    type(interaction_t), intent(in) :: int
    integer, dimension(:), allocatable, intent(out) :: i
    call state_matrix_get_diagonal_entries (int%state_matrix, i)
  end subroutine interaction_get_diagonal_entries

```

Renormalize the state matrix by its trace, if nonzero. The renormalization is reflected in the state-matrix norm.

```

<Interactions: public>+≡
  public :: interaction_normalize_by_trace

<Interactions: procedures>+≡
  subroutine interaction_normalize_by_trace (int)
    type(interaction_t), intent(inout) :: int
    call state_matrix_normalize_by_trace (int%state_matrix)
  end subroutine interaction_normalize_by_trace

```

Analogous, but renormalize by maximal (absolute) value.

```

<Interactions: public>+≡
  public :: interaction_normalize_by_max

<Interactions: procedures>+≡
  subroutine interaction_normalize_by_max (int)
    type(interaction_t), intent(inout) :: int
    call state_matrix_normalize_by_max (int%state_matrix)
  end subroutine interaction_normalize_by_max

```

Explicitly set the norm value (of the state matrix).

```

<Interactions: public>+≡
  public :: interaction_set_norm

<Interactions: procedures>+≡
  subroutine interaction_set_norm (int, norm)
    type(interaction_t), intent(inout) :: int
    real(default), intent(in) :: norm
    call state_matrix_set_norm (int%state_matrix, norm)
  end subroutine interaction_set_norm

```

Return the maximum absolute value of color indices.

```

<Interactions: public>+≡
  public :: interaction_get_max_color_value

<Interactions: procedures>+≡
  function interaction_get_max_color_value (int) result (cmax)
    integer :: cmax
    type(interaction_t), intent(in) :: int
    cmax = state_matrix_get_max_color_value (int%state_matrix)
  end function interaction_get_max_color_value

```

Factorize the state matrix into single-particle state matrices, the branch selection depending on a (random) value between 0 and 1; optionally also return a correlated state matrix.

```

<Interactions: public>+=
  public :: interaction_factorize

<Interactions: procedures>+=
  subroutine interaction_factorize &
    (int, mode, x, ok, single_state, correlated_state, qn_in)
    type(interaction_t), intent(in), target :: int
    integer, intent(in) :: mode
    real(default), intent(in) :: x
    logical, intent(out) :: ok
    type(state_matrix_t), &
      dimension(:), allocatable, intent(out) :: single_state
    type(state_matrix_t), intent(out), optional :: correlated_state
    type(quantum_numbers_t), dimension(:), intent(in), optional :: qn_in
    call state_matrix_factorize &
      (int%state_matrix, mode, x, ok, single_state, correlated_state, qn_in)
  end subroutine interaction_factorize

```

Sum all matrix element values

```

<Interactions: public>+=
  public :: interaction_sum

<Interactions: procedures>+=
  function interaction_sum (int) result (value)
    complex(default) :: value
    type(interaction_t), intent(in) :: int
    value = state_matrix_sum (int%state_matrix)
  end function interaction_sum

```

Append new states which are color-contracted versions of the existing states. The matrix element index of each color contraction coincides with the index of its origin, so no new matrix elements are generated. After this operation, no **freeze** must be performed anymore.

```

<Interactions: public>+=
  public :: interaction_add_color_contractions

<Interactions: procedures>+=
  subroutine interaction_add_color_contractions (int)
    type(interaction_t), intent(inout) :: int
    call state_matrix_add_color_contractions (int%state_matrix)
  end subroutine interaction_add_color_contractions

```

Multiply matrix elements from two interactions. Choose the elements as given by the integer index arrays, multiply them and store the sum of products in the indicated matrix element. The suffixes mean: c=conjugate first factor; f=include weighting factor.

```

<Interactions: public>+=
  public :: interaction_evaluate_product

    end do
  end if
end subroutine interaction_set_flavored_values

```

7.6.7 Handling Linked interactions

Store relations between corresponding particles within one interaction. The first particle is the parent, the second one the child. Links are established in both directions.

These relations have no effect on the propagation of momenta etc., they are rather used for mother-daughter relations in event output.

```

<Interactions: public>+≡
public :: interaction_relate
<Interactions: procedures>+≡
subroutine interaction_relate (int, i1, i2)
  type(interaction_t), intent(inout), target :: int
  integer, intent(in) :: i1, i2
  if (i1 /= 0 .and. i2 /= 0) then
    call internal_link_list_append (int%children(i1), i2)
    call internal_link_list_append (int%parents(i2), i1)
  end if
end subroutine interaction_relate

```

Transfer internal parent-child relations defined within interaction `int1` to a new interaction `int` where the particle indices are mapped to. Some particles in `int1` may have no image in `int`. In that case, a child entry maps to zero, and we skip this relation.

Also transfer resonance flags.

```

<Interactions: public>+≡
  public :: interaction_transfer_relations

<Interactions: procedures>+≡
  subroutine interaction_transfer_relations (int1, int2, map)
    type(interaction_t), intent(in) :: int1
    type(interaction_t), intent(inout), target :: int2
    integer, dimension(:), intent(in) :: map
    type(internal_link_t), pointer :: link
    integer :: i, k
    do i = 1, size (map)
      link => internal_link_list_get_first_ptr (int1%parents(i))
      do while (associated (link))
        k = internal_link_get_index (link)
        call interaction_relate (int2, map(k), map(i))
        call internal_link_advance (link)
      end do
      if (map(i) /= 0) then
        int2%resonant(map(i)) = int1%resonant(i)
      end if
    end do
  end subroutine interaction_transfer_relations

```

Make up internal parent-child relations for the particle(s) that are connected to a new interaction `int`.

If `resonant` is defined and true, the connections are marked as resonant in the result interaction

```

<Interactions: public>+≡
  public :: interaction_relate_connections

<Interactions: procedures>+≡
  subroutine interaction_relate_connections &
    (int, int_in, connection_index, &
     map, map_connections, resonant)
    type(interaction_t), intent(inout), target :: int
    type(interaction_t), intent(in) :: int_in
    integer, dimension(:), intent(in) :: connection_index
    integer, dimension(:), intent(in) :: map, map_connections
    logical, intent(in), optional :: resonant
    logical :: reson
    integer :: i, i2, k2
    type(internal_link_t), pointer :: link
    reson = .false.; if (present (resonant)) reson = resonant
    do i = 1, size (map_connections)
      k2 = connection_index(i)
      link => internal_link_list_get_first_ptr (int_in%children(k2))
      do while (associated (link))
        i2 = internal_link_get_index (link)
        call interaction_relate (int, map_connections(i), map(i2))
        call internal_link_advance (link)
      end do
      int%resonant(map_connections(i)) = reson
    end do
  end subroutine interaction_relate_connections

```

```
end subroutine interaction_relate_connections
```

Return the number of source/target links of the internal connections of particle i.

(Interactions: public)+≡

```
public :: interaction_get_n_children
public :: interaction_get_n_parents
```

(Interactions: procedures)+≡

```
function interaction_get_n_children (int, i) result (n)

  do while (associated (link))
    k = k + 1
    idx(k) = internal_link_get_index (link)
    call internal_link_advance (link)
  end do
end function interaction_get_children
```

```
function interaction_get_parents (int, i) result (idx)
  integer, dimension(:), allocatable :: idx
  type(interaction_t), intent(in) :: int
  integer, intent(in) :: i
  integer :: k
  type(internal_link_t), pointer :: link
  allocate (idx (internal_link_list_get_length (int%parents(i))))
  k = 0
```

```

link => internal_link_list_get_first_ptr (int%parents(i))
do while (associated (link))
  k = k + 1
  idx(k) = internal_link_get_index (link)
  call internal_link_advance (link)
end do
end function interaction_get_parents

```

Add a source link from an interaction to a corresponding particle within another interaction. These links affect the propagation of particles: the two linked particles are considered as the same particle, outgoing and incoming.

```

<Interactions: public>+≡
  public :: interaction_set_source_link

<Interactions: interfaces>+≡
  interface interaction_set_source_link
    module procedure interaction_set_source_link_int
  end interface

<Interactions: procedures>+≡
  subroutine interaction_set_source_link_int (int, i, int1, i1)
    type(interaction_t), intent(inout) :: int
    integer, intent(in) :: i
    type(interaction_t), intent(in), target :: int1
    integer, intent(in) :: i1
    if (i /= 0) call external_link_set (int%source(i), int1, i1)
  end subroutine interaction_set_source_link_int

```

Reassign links to a new interaction (which is an image of the current interaction).

```

<Interactions: public>+≡
  public :: interaction_reassign_links

<Interactions: procedures>+≡
  subroutine interaction_reassign_links (int, int_src, int_target)
    type(interaction_t), intent(inout) :: int
    type(interaction_t), intent(in) :: int_src
    type(interaction_t), intent(in), target :: int_target
    integer :: i
    if (allocated (int%source)) then
      do i = 1, size (int%source)
        call external_link_reassign (int%source(i), int_src, int_target)
      end do
    end if
  end subroutine interaction_reassign_links

```

Since links are one-directional, if we want to follow them backwards we have to scan all possibilities. This procedure returns the index of the particle within `int` which points to the particle `i1` within interaction `int1`. If unsuccessful, return zero.

```

<Interactions: public>+≡
  public :: interaction_find_link

```

<Interactions: procedures>+≡

```
function interaction_find_link (int, int1, i1) result (i)
  integer :: i
  type(interaction_t), intent(in) :: int, int1
  integer, intent(in) :: i1
  type(interaction_t), pointer :: int_tmp
  do i = 1, int%n_tot
    int_tmp => external_link_get_ptr (int%source(i))
    if (int_tmp%tag == int1%tag) then
      if (external_link_get_index (int%source(i)) == i1) return
    end if
  end do
  i = 0
end function interaction_find_link
```

The inverse: return interaction pointer and index for the ultimate source of i within int.

<Interactions: public>+≡

```
public :: interaction_find_source
```

<Interactions: procedures>+≡

```
subroutine interaction_find_source (int, i, int1, i1)
  type(interaction_t), intent(in) :: int
  integer, intent(in) :: i
  type(interaction_t), intent(out), pointer :: int1
  integer, intent(out) :: i1
  type(external_link_t) :: link
  link = interaction_get_ultimate_source (int, i)
  int1 => external_link_get_ptr (link)
  i1 = external_link_get_index (link)
end subroutine interaction_find_source
```

Follow source links recursively to return the ultimate source of a particle.

<Interactions: procedures>+≡

```
function interaction_get_ultimate_source (int, i) result (link)
  type(external_link_t) :: link
  type(interaction_t), intent(in) :: int
  integer, intent(in) :: i
  type(interaction_t), pointer :: int_src
  integer :: i_src
  link = int%source(i)
  if (external_link_is_set (link)) then
    do
      int_src => external_link_get_ptr (link)
      i_src = external_link_get_index (link)
      if (external_link_is_set (int_src%source(i_src))) then
        link = int_src%source(i_src)
      else
        exit
      end if
    end do
  end if
end function interaction_get_ultimate_source
```

Update mask entries by merging them with corresponding masks in interactions linked to the current one. The mask determines quantum numbers which are summed over.

Note that both the mask of the current interaction and the mask of the linked interaction are updated (side effect!). This ensures that both agree for the linked particle.

```

<Interactions: public>+≡
    public :: interaction_exchange_mask

<Interactions: procedures>+≡
    subroutine interaction_exchange_mask (int)
        type(interaction_t), intent(inout) :: int
        integer :: i, index_link

                call interaction_merge_mask_entry &
                    (int, i, int_link%mask(index_link))
                call interaction_merge_mask_entry &
                    (int_link, index_link, int%mask(i))
            end if
        end do
        call interaction_freeze (int)
    end subroutine interaction_exchange_mask

```

Copy momenta from interactions linked to the current one.

```

<Interactions: public>+≡
    public :: interaction_receive_momenta

<Interactions: procedures>+≡
    subroutine interaction_receive_momenta (int)
        type(interaction_t), intent(inout) :: int
        integer :: i, index_link
        type(interaction_t), pointer :: int_link
        do i = 1, int%n_tot
            if (external_link_is_set (int%source(i))) then
                int_link => external_link_get_ptr (int%source(i))
                index_link = external_link_get_index (int%source(i))
                call interaction_set_momentum (int, int_link%p(index_link), i)
            end if
        end do
    end subroutine interaction_receive_momenta

```

The inverse operation: Copy momenta back to the interactions linked to the current one.

```

<Interactions: public>+≡
    public :: interaction_send_momenta

<Interactions: procedures>+≡
    subroutine interaction_send_momenta (int)
        type(interaction_t), intent(in) :: int
        integer :: i, index_link

```

```

type(interaction_t), pointer :: int_link
do i = 1, int%n_tot
  if (external_link_is_set (int%source(i))) then
    int_link => external_link_get_ptr (int%source(i))
    index_link = external_link_get_index (int%source(i))
    call interaction_set_momentum (int_link, int%p(i), index_link)
  end if
end do
end subroutine interaction_send_momenta

```

For numerical comparisons: pacify all momenta in an interaction.

```

<Interactions: public>+≡
  public :: interaction_pacify_momenta

<Interactions: procedures>+≡
  subroutine interaction_pacify_momenta (int, acc)
    type(interaction_t), intent(inout) :: int
    real(default), intent(in) :: acc
    integer :: i
    do i = 1, int%n_tot
      call pacify (int%p(i), acc)
    end do
  end subroutine interaction_pacify_momenta

```

7.6.8 Recovering connections

When creating an evaluator for two interactions, we have to know by which particles they are connected. The connection indices can be determined if we have two linked interactions. We assume that `int1` is the source and `int2` the target, so the connections of interest are stored within `int2`. A connection is found if either the source is `int1`, or the (ultimate) source of a particle within `int2` coincides with the (ultimate) source of a particle within `int1`. The result is an array of index pairs.

To make things simple, we scan the interaction twice, once for counting hits, then allocate the array, then scan again and store the connections.

The connections are scanned for `int2`, which has sources in `int1`. It may happen that the order of connections is interchanged (crossed). We require the indices in `int1` to be sorted, so we reorder both index arrays correspondingly before returning them. (After this, the indices in `int2` may be out of order.)

```

<Interactions: public>+≡
  public :: find_connections

<Interactions: procedures>+≡
  subroutine find_connections (int1, int2, n, connection_index)
    type(interaction_t), intent(in) :: int1, int2
    integer, intent(out) :: n
    integer, dimension(:,:), intent(out), allocatable :: connection_index
    integer, dimension(:,:), allocatable :: conn_index_tmp
    integer, dimension(:), allocatable :: ordering
    integer :: i, j, k

        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Interactions: execute tests>
    end subroutine interaction_test

```

Generate an interaction of a polarized virtual photon and a colored quark which may be either up or down. Remove the quark polarization. Generate another interaction for the quark radiating a photon and link this to the first interaction. The radiation ignores polarization; transfer this information to the first interaction to simplify it. Then, transfer the momentum to the radiating quark and perform a splitting.

7.7 Matrix element evaluation

The `evaluator_t` type is an extension of the `interaction_t` type. It represents either a density matrix as the square of a transition matrix element, or the product of two density matrices. Usually, some quantum numbers are summed over in the result.

The `interaction_t` subobject represents a multi-particle interaction with incoming, virtual, and outgoing particles and the associated (not necessarily diagonal) density matrix of quantum state. When the evaluator is initialized, this interaction is constructed from the input `interaction(s)`.

In addition, the initialization process sets up a multiplication table. For each matrix element of the result, it states which matrix elements are to be taken from the input `interaction(s)`, multiplied (optionally, with an additional weight factor) and summed over.

Eventually, to a processes we associate a chain of evaluators which are to be evaluated sequentially. The physical event and its matrix element value(s) can be extracted from the last evaluator in such a chain.

Evaluators are constructed only once (as long as this is possible) during an initialization step. Then, for each event, momenta are computed and transferred among evaluators using the links within the interaction subobject. The multiplication tables enable fast evaluation of the result without looking at quantum numbers anymore.

```

    use models
    use flavors
    use colors
    use helicities
    use quantum_numbers
    use state_matrices
    use interactions

```

```

    <Standard module head>

```

```

    <Evaluators: public>

```

⟨Evaluators: parameters⟩

⟨Evaluators: types⟩

⟨Evaluators: interfaces⟩

contains

⟨Evaluators: procedures⟩

⟨Evaluators: tests⟩

end module evaluators

7.7.1 Array of pairings

The evaluator contains an array of `pairing_array` objects. This makes up the multiplication table.

Each pairing array contains two list of matrix element indices and a list of numerical factors. The matrix element indices correspond to the input interactions. The corresponding matrix elements are to be multiplied and optionally multiplied by a factor. The results are summed over to yield one specific matrix element of the result evaluator.

⟨Evaluators: types⟩≡

```
type :: pairing_array_t
  integer, dimension(:), allocatable :: i1, i2
  complex(default), dimension(:), allocatable :: factor
end type pairing_array_t
```

⟨Evaluators: procedures⟩≡

```
elemental subroutine pairing_array_init (pa, n, has_i2, has_factor)
  type(pairing_array_t), intent(out) :: pa
  integer, intent(in) :: n
  logical, intent(in) :: has_i2, has_factor
  allocate (pa%i1 (n))
  if (has_i2) allocate (pa%i2 (n))
  if (has_factor) allocate (pa%factor (n))
end subroutine pairing_array_init
```

7.7.2 The evaluator type

Possible variants of evaluators:

⟨Evaluators: parameters⟩≡

```
integer, parameter :: &
  EVAL_UNDEFINED = 0, &
  EVAL_PRODUCT = 1, &
  EVAL_SQUARED_FLOWS = 2, &
  EVAL_SQUARE_WITH_COLOR_FACTORS = 3, &
  EVAL_COLOR_CONTRACTION = 4, &
  EVAL_IDENTITY = 5, &
  EVAL_QN_SUM = 6
```

The evaluator type contains the result interaction and an array of pairing lists, one for each matrix element in the result interaction.

```

(Evaluators: public)≡
    public :: evaluator_t

(Evaluators: types)+≡
    type :: evaluator_t
        private
        integer :: type = EVAL_UNDEFINED
        type(interaction_t), pointer :: int_in1 => null ()
        type(interaction_t), pointer :: int_in2 => null ()
        type(interaction_t) :: int
        type(pairing_array_t), dimension(:), allocatable :: pairing_array
    contains
    (Evaluators: evaluator: TBP)
end type evaluator_t

```

Output.

```

    eval%int_in2 => int2
  end if
end subroutine evaluator_replace_interaction

```

7.7.3 Auxiliary structures for evaluator creation

Creating an evaluator that properly handles all quantum numbers requires some bookkeeping. In this section, we define several auxiliary types and methods that organize and simplify this task. More structures are defined within the specific initializers (as local types and internal subroutines).

These types are currently implemented in a partial object-oriented way: We define some basic methods for initialization etc. here, but the evaluator routines below do access their internals as well. This simplifies some things such as index addressing using array slices, at the expense of losing some clarity.

Index mapping

Index mapping are abundant when constructing an evaluator. To have arrays of index mappings, we define this:

```

(Evaluators: types)+≡
  type :: index_map_t
    integer, dimension(:), allocatable :: entry
  end type index_map_t

(Evaluators: procedures)+≡
  elemental subroutine index_map_init (map, n)
    type(index_map_t), intent(out) :: map
    integer, intent(in) :: n
    allocate (map%entry (n))
  end subroutine index_map_init

(Evaluators: procedures)+≡
  function index_map_exists (map) result (flag)
    logical :: flag
    type(index_map_t), intent(in) :: map
    flag = allocated (map%entry)
  end function index_map_exists

(Evaluators: interfaces)+≡
  interface size
    module procedure index_map_size
  end interface

(Evaluators: procedures)+≡
  function index_map_size (map) result (s)
    integer :: s
    type(index_map_t), intent(in) :: map
    if (allocated (map%entry)) then
      s = size (map%entry)
    else
      s = 0
    end if
  end function index_map_size

(Evaluators: interfaces)+≡
  interface assignment(=)
    module procedure index_map_assign_int
    module procedure index_map_assign_array
  end interface

(Evaluators: procedures)+≡
  elemental subroutine index_map_assign_int (map, ival)
    type(index_map_t), intent(inout) :: map
    integer, intent(in) :: ival
    map%entry = ival
  end subroutine index_map_assign_int

  subroutine index_map_assign_array (map, array)
    type(index_map_t), intent(inout) :: map
    integer, dimension(:), intent(in) :: array
    map%entry = array
  end subroutine index_map_assign_array

```

```
end subroutine index_map_assign_array
```

```
<Evaluators: procedures>+≡
  elemental subroutine index_map_set_entry (map, i, ival)
    type(index_map_t), intent(inout) :: map
    integer, intent(in) :: i
    integer, intent(in) :: ival
    map%entry(i) = ival
  end subroutine index_map_set_entry
```

```
<Evaluators: procedures>+≡
  elemental function index_map_get_entry (map, i) result (ival)
    integer :: ival
    type(index_map_t), intent(in) :: map
    integer, intent(in) :: i
    ival = map%entry(i)
  end function index_map_get_entry
```

Index mapping (two-dimensional)

This is a variant with a square matrix instead of an array.

```
<Evaluators: types>+≡
  type :: index_map2_t
    integer :: s = 0
    integer, dimension(:,:), allocatable :: entry
  end type index_map2_t
```

```
<Evaluators: procedures>+≡
  elemental subroutine index_map2_init (map, n)
    type(index_map2_t), intent(out) :: map
    integer, intent(in) :: n
    map%s = n
    allocate (map%entry (n, n))
  end subroutine index_map2_init
```

```
<Evaluators: procedures>+≡
  function index_map2_exists (map) result (flag)
    logical :: flag
    type(index_map2_t), intent(in) :: map
    flag = allocated (map%entry)
  end function index_map2_exists
```

```
<Evaluators: interfaces>+≡
  interface size
    module procedure index_map2_size
  end interface
```

```
<Evaluators: procedures>+≡
  function index_map2_size (map) result (s)
    integer :: s
```

```

    type(index_map2_t), intent(in) :: map
    s = map%s
end function index_map2_size

```

```

<Evaluators: interfaces>+≡
interface assignment(=)
    module procedure index_map2_assign_int
end interface

```

```

<Evaluators: procedures>+≡
elemental subroutine index_map2_assign_int (map, ival)
    type(index_map2_t), intent(inout) :: map
    integer, intent(in) :: ival
    map%entry = ival
end subroutine index_map2_assign_int

```

```

<Evaluators: procedures>+≡
elemental subroutine index_map2_set_entry (map, i, j, ival)
    type(index_map2_t), intent(inout) :: map
    integer, intent(in) :: i, j
    integer, intent(in) :: ival
    map%entry(i,j) = ival
end subroutine index_map2_set_entry

```

```

<Evaluators: procedures>+≡
elemental function index_map2_get_entry (map, i, j) result (ival)
    integer :: ival
    type(index_map2_t), intent(in) :: map
    integer, intent(in) :: i, j
    ival = map%entry(i,j)
end function index_map2_get_entry

```

Auxiliary structures: particle mask

This is a simple container of a logical array.

```

<Evaluators: types>+≡
type :: prt_mask_t
    logical, dimension(:), allocatable :: entry
end type prt_mask_t

```

```

<Evaluators: procedures>+≡
subroutine prt_mask_init (mask, n)
    type(prt_mask_t), intent(out) :: mask
    integer, intent(in) :: n
    allocate (mask%entry (n))
end subroutine prt_mask_init

```

```

<Evaluators: interfaces>+≡

  integer :: s
  type(prt_mask_t), intent(in) :: mask
  s = size (mask%entry)
end function prt_mask_size
```

Quantum number containers

Trivial transparent containers:

```
<Evaluators: types>+≡
type :: qn_list_t
  type(quantum_numbers_t), dimension(:,:), allocatable :: qn
end type qn_list_t

type :: qn_mask_array_t
  type(quantum_numbers_mask_t), dimension(:), allocatable :: mask
end type qn_mask_array_t
```

Auxiliary structures: connection entries

This type is used as intermediate storage when computing the product of two evaluators or the square of an evaluator. The quantum-number array `qn` corresponds to the particles common to both interactions, but irrelevant quantum numbers (color) masked out. The index arrays `index_in` determine the entries in the input interactions that contribute to this connection. `n_index` is the size of these arrays, and `count` is used while filling the entries. Finally, the quantum-number arrays `qn_in_list` are the actual entries in the input interaction that contribute. In the product case, they exclude the connected quantum numbers.

Each evaluator has its own `connection_table` which contains an array of `connection_entry` objects, but also has stuff that specifically applies to the evaluator type. Hence, we do not generalize the `connection_table_t` type.

The filling procedure `connection_entry_add_state` is specific to the various evaluator types.

```
<Evaluators: types>+≡
type :: connection_entry_t
  type(quantum_numbers_t), dimension(:), allocatable :: qn_conn
  integer, dimension(:), allocatable :: n_index
  integer, dimension(:), allocatable :: count
  type(index_map_t), dimension(:), allocatable :: index_in
  type(qn_list_t), dimension(:), allocatable :: qn_in_list
end type connection_entry_t
```

```
<Evaluators: procedures>+≡
subroutine connection_entry_init &

      write (u, *)
    end do
  end do
end subroutine connection_entry_write

```

Color handling

For managing color-factor computation, we introduce this local type. The `index` is the index in the color table that corresponds to a given matrix element index in the input interaction. The `col` array stores the color assignments in rows. The `factor` array associates a complex number with each pair of arrays in the color table. The `factor_is_known` array reveals whether a given factor is known already or still has to be computed.

(Evaluators: types)+≡

```
type :: color_table_t
  integer, dimension(:), allocatable :: index
  type(color_t), dimension(:, :), allocatable :: col
  logical, dimension(:, :), allocatable :: factor_is_known
  complex(default), dimension(:, :), allocatable :: factor
end type color_table_t
```

This is the initializer. We extract the color states from the given state matrices, establish index mappings between the two states (implemented by the array `me_index`), make an array of color states, and initialize the color-factor table. The latter is two-dimensional (includes interference) and not yet filled.

(Evaluators: procedures)+≡

```
subroutine color_table_init (color_table, state, n_tot)
  type(color_table_t), intent(out) :: color_table
  type(state_matrix_t), intent(in) :: state
  integer, intent(in) :: n_tot
  type(state_iterator_t) :: it
  type(quantum_numbers_t), dimension(:), allocatable :: qn
  type(state_matrix_t) :: state_col
  integer :: index, n_col_state
  allocate (color_table%index &
    (state_matrix_get_n_matrix_elements (state)))
  color_table%index = 0
  allocate (qn (n_tot))
  call state_matrix_init (state_col)
  call state_iterator_init (it, state)
  do while (state_iterator_is_valid (it))
    index = state_iterator_get_me_index (it)
    call quantum_numbers_init (qn, col = state_iterator_get_color (it))
    call state_matrix_add_state (state_col, qn, &
      me_index = color_table%index(index))
    call state_iterator_advance (it)
  end do
  n_col_state = state_matrix_get_n_matrix_elements (state_col)
  allocate (color_table%col (n_tot, n_col_state))
  call state_iterator_init (it, state_col)
  do while (state_iterator_is_valid (it))
    index = state_iterator_get_me_index (it)
    color_table%col(:, index) = state_iterator_get_color (it)
    call state_iterator_advance (it)
  end do
  call state_matrix_final (state_col)
  allocate (color_table%factor_is_known (n_col_state, n_col_state))
  allocate (color_table%factor (n_col_state, n_col_state))
```

```

        color_table%factor_is_known = .false.
    end subroutine color_table_init

```

Output (debugging use):

(Evaluators: procedures)+≡

```

subroutine color_table_write (color_table, unit)
    type(color_table_t), intent(in) :: color_table
    integer, intent(in), optional :: unit
    integer :: i, j
    integer :: u
    u = output_unit (unit)
    write (u, *) "Color table:"
    if (allocated (color_table%index)) then
        write (u, *) "  Index mapping state => color table:"

            do j = 1, size (color_table%factor, 2)
                if (color_table%factor_is_known(i,j)) then
                    write (u, *) i, j, color_table%factor(i,j)
                end if
            end do
        end do
    end if
end subroutine color_table_write

```

This subroutine sets color factors, based on information from the hard matrix element: the list of pairs of color-flow indices (in the basis of the matrix element code), the list of corresponding factors, and the list of mappings from the matrix element index in the input interaction to the color-flow index in the hard matrix element object.

We first determine the mapping of color-flow indices from the hard matrix element code to the current color table. The mapping could be nontrivial because the latter is derived from iterating over a state matrix, which may return states in non-canonical order. The translation table can be determined because we have, for the complete state matrix, both the mapping to the hard interaction (the input `col_index_hi`) and the mapping to the current color table (the component `color_table%index`).

Once this mapping is known, we scan the list of index pairs `color_flow_index` and translate them to valid color-table index pairs. For this pair, the color factor is set using the corresponding entry in the list `col_factor`.

(Evaluators: procedures)+≡

```

subroutine color_table_set_color_factors (color_table, &
    col_flow_index, col_factor, col_index_hi)

```

```

type(color_table_t), intent(inout) :: color_table

        col_factor(cf_index)
    color_table%factor_is_known(ct_index_pair(1), ct_index_pair(2)) = .true.
end do
end subroutine color_table_set_color_factors

```

This function returns a color factor, given two indices which point to the matrix elements of the initial state matrix. Internally, we can map them to the corresponding indices in the color table. As a side effect, we store the color factor in the color table for later lookup. (I.e., this function is impure.)

(*Evaluators: procedures*) +=

```

!       print *, "    computed : ", factor
    end if
end function color_table_get_color_factor

```

7.7.4 Creating an evaluator: Matrix multiplication

The evaluator for matrix multiplication is the most complicated variant.

The initializer takes two input interactions and constructs the result evaluator, which consists of the interaction and the multiplication table for the product (or convolution) of the two. Normally, the input interactions are connected by one or more common particles (e.g., decay, structure function convolution).

In the result interaction, quantum numbers of the connections can be summed over. This is determined by the `qn_mask_conn` argument. The `qn_mask_rest` argument is its analog for the other particles within the result interaction. (E.g., for the trace of the state matrix, all quantum numbers are summed over.) Finally, the `connections_are_resonant` argument tells whether the connecting particles should be marked as resonant in the final event record. This is useful for decays.

The algorithm consists of the following steps:

1. **find_connections**: Find the particles which are connected, i.e., common to both input interactions. Either they are directly linked, or both are linked to a common source.
2. **compute_index_bounds_and_mappings**: Compute the mappings of particle indices from the input interactions to the result interaction. There is a separate mapping for the connected particles.
3. **accumulate_connected_states**: Create an auxiliary state matrix which lists the possible quantum numbers for the connected particles. When building this matrix, count the number of times each assignment is contained in any of the input states and, for each of the input states, record the index of the matrix element within the new state matrix. For the connected particles, reassign color indices such that no color state is present twice in different color-index assignment. Note that helicity assignments of the connected state can be (and will be) off-diagonal, so no spin correlations are lost in decays.
Do this for both input interactions.
4. **allocate_connection_entries**: Allocate a table of connections. Each table row corresponds to one state in the auxiliary matrix, and to multiple states of the input interactions. It collects all states of the unconnected particles in the two input interactions that are associated with the particular state (quantum-number assignment) of the connected particles.
5. **fill_connection_table**: Fill the table of connections by scanning both input interactions. When copying states, reassign color indices for the unconnected particles such that they match between all involved particle sets (interaction 1, interaction 2, and connected particles).
6. **make_product_interaction**: Scan the table of connections we have just built. For each entry, construct all possible pairs of states of the unconnected particles and combine them with the specific connected-particle

state. This is a possible quantum-number assignment of the result interaction. Now mask all quantum numbers that should be summed over, and append this to the result state matrix. Record the matrix element index of the result. We now have the result interaction.

7. **make_pairing_array**: First allocate the pairing array with the number of entries of the result interaction. Then scan the table of connections again. For each entry, record the indices of the matrix elements which have to be multiplied and summed over in order to compute this particular matrix element. This makes up the multiplication table.
8. **record_links**: Transfer all source pointers from the input interactions to the result interaction. Do the same for the internal parent-child relations and resonance assignments. For the connected particles, make up appropriate additional parent-child relations. This allows for fetching momenta from other interactions when a new event is filled, and to reconstruct the event history when the event is analyzed.

After all this is done, for each event, we just have to evaluate the pairing arrays (multiplication tables) in order to compute the result matrix elements in their proper positions. The quantum-number assignments remain fixed from now on.

```

7.7.5 Creating an evaluator: square

The generic initializer for an evaluator that squares a matrix element. Depending on the provided mask, we select the appropriate specific initializer for either diagonal or non-diagonal helicity density matrices.

```

(Evaluators: public)+≡
    public :: evaluator_init_square

(Evaluators: procedures)+≡
    subroutine evaluator_init_square (eval, int_in, qn_mask, &
        col_flow_index, col_factor, col_index_hi, expand_color_flows, nc)
        type(evaluator_t), intent(out), target :: eval

                col_flow_index, col_factor, col_index_hi, expand_color_flows, nc)
        end if
    end subroutine evaluator_init_square

```

Color-summed squared matrix (diagonal helicities)

The initializer for an evaluator that squares a matrix element, including color factors. The mask must be such that off-diagonal matrix elements are excluded.

If `color_flows` is set, the evaluator keeps color-flow entries separate and drops all interfering color structures. The color factors are set to unity in this case.

There is only one input interaction. The quantum-number mask is an array, one entry for each particle, so they can be treated individually. For academic purposes, we allow for the number of colors being different from three (but 3 is the default).

The algorithm is analogous to multiplication, with a few notable differences:

1. The connected particles are known, the correspondence is one-to-one. All particles are connected, and the mapping of indices is trivial, which simplifies the following steps.

2. **accumulate_connected_states**: The matrix of connected states encompasses all particles, but color indices are removed. However, ghost states are still kept separate from physical color states. No color-index reassignment is necessary.
3. The table of connections contains single index and quantum-number arrays instead of pairs of them. They are paired with themselves in all possible ways.
4. **make_squared_interaction**: Now apply the predefined quantum-numbers mask, which usually collects all color states (physical and ghosts), and possibly a helicity sum.
5. **make_pairing_array**: For each pair of input states, compute the color factor (including a potential ghost-parity sign) and store this in the pairing array together with the matrix-element indices for multiplication.
6. **record_links**: This is again trivial due to the one-to-one correspondence.

```

end subroutine evaluator_init_square_diag

```

Color-summed squared matrix (support nodiagonal helicities)

The initializer for an evaluator that squares a matrix element, including color factors. Unless requested otherwise by the quantum-number mask, the result

contains off-diagonal matrix elements. (The input interaction must be diagonal since it represents an amplitude, not a density matrix.)

There is only one input interaction. The quantum-number mask is an array, one entry for each particle, so they can be treated individually. For academic purposes, we allow for the number of colors being different from three (but 3 is the default).

The algorithm is analogous to the previous one, with some additional complications due to the necessity to loop over two helicity indices.

Copy with additional contracted color states

This evaluator involves no square or multiplication, its matrix elements are just copies of the (single) input interaction. However, the state matrix of the interaction contains additional states that have color indices contracted. This is used for copies of the beam or structure-function interactions that need to match the hard interaction also in the case where its color indices coincide.

Auxiliary procedure for initialization

This will become a standard procedure in F2008. The result is true if the number of true values in the mask is odd. We use the function for determining

the ghost parity of a quantum-number array.

```
<Evaluators: procedures>+≡
function parity (mask)
  logical :: parity
  logical, dimension(:) :: mask
  integer :: i
  parity = .false.
  do i = 1, size (mask)
    if (mask(i)) parity = .not. parity
  end do
end function parity
```

7.7.6 Accessing contents

Return the interaction component, as a pointer to avoid any copying.

```
<Evaluators: public>+≡
public :: evaluator_get_int_ptr

<Evaluators: procedures>+≡
function evaluator_get_int_ptr (eval) result (int)
  type(interaction_t), pointer :: int
  type(evaluator_t), intent(in), target :: eval
  int => eval%int
end function evaluator_get_int_ptr
```

7.7.7 Inherited procedures

Return true if the state matrix within the interaction is empty.

```
<Evaluators: public>+≡
public :: evaluator_is_empty

<Evaluators: procedures>+≡
function evaluator_is_empty (eval) result (flag)
  logical :: flag
  type(evaluator_t), intent(in) :: eval

    end subroutine evaluator_final

```

7.7.9 Creating an evaluator: identity

The identity evaluator creates a copy of the first input evaluator; the second input is not used.

All particles link back to the input evaluator and the internal relations are copied. As evaluation does take a shortcut by cloning the matrix elements, the pairing array is not used and does not have to be set up.

```

(Evaluators: public)+≡
    public :: evaluator_init_identity

(Evaluators: interfaces)+≡
    interface evaluator_init_identity

7.7.10 Creating an evaluator: quantum number sum

This evaluator operates on the diagonal of a density matrix and sums over the quantum numbers specified by the mask. The optional argument **drop** allows to drop a particle from the resulting density matrix. The handling of virtuals is not completely sane, especially in connection with dropping particles.

When summing over matrix element entries, we keep the separation into entries and normalization (in the corresponding evaluation routine below).

```

<Evaluators: public>+≡
    public :: evaluator_init_qn_sum

<Evaluators: interfaces>+≡
    interface evaluator_init_qn_sum
        module procedure evaluator_init_qn_sum_i
        module procedure evaluator_init_qn_sum_e
    end interface

```

```

7.7.11 Evaluation

When the input interactions (which are pointed to in the pairings stored within the evaluator) are filled with values, we can activate the evaluator, i.e., calculate the result values which are stored in the interaction.

The evaluation of matrix elements can be done in parallel. A `forall` construct is not appropriate, however. We would need `do concurrent` here. Nevertheless, the evaluation functions are marked as `pure`.

```

<Evaluators: public>+≡
public :: evaluator_evaluate

<Evaluators: procedures>+≡
subroutine evaluator_evaluate (eval)
type(evaluator_t), intent(inout), target :: eval
integer :: i
select case (eval%type)

            (eval%int, interaction_get_norm (eval%int_in1))
    end do
end select
end subroutine evaluator_evaluate

```

7.7.12 Unit tests

Test: Create two interactions. The interactions are twofold connected. The first connection has a helicity index that is kept, the second connection has a helicity index that is summed over. Concatenate the interactions in an evaluator, which thus contains a result interaction. Fill the input interactions with values, activate the evaluator and print the result.

Chapter 8

Particles

In this chapter, we deal with particles which have well-defined quantum numbers. While within interactions, all correlations are manifest, a particle array is derived by selecting a particular quantum number set. This involves tracing over all other particles, as far as polarization is concerned. Thus, a particle has definite flavor, color, and a single-particle density matrix for polarization.

8.1 Polarization

Particle polarization is determined by a particular quantum state which has just helicity information. For defining polarizations, we adopt the phase convention for a spin-1/2 particle that

$$\rho = \frac{1}{2}(1 + \vec{\alpha} \cdot \vec{\sigma}) \quad (8.1)$$

with the polarization axis $\vec{\alpha}$. Using this, we define

1. Trivial polarization: $\vec{\alpha} = 0$. [This is unpolarized, but distinct from the particular undefined polarization matrix which has the same meaning.]
2. Circular polarization: $\vec{\alpha}$ points in $\pm z$ direction.
3. Transversal polarization: $\vec{\alpha}$ points orthogonal to the z direction, with a phase ϕ that is 0 for the x axis, and $\pi/2 = 90^\circ$ for the y axis. For antiparticles, the phase switches sign, corresponding to complex conjugation.
4. Axis polarization, where we explicitly give $\vec{\alpha}$.

For higher spin, we retain this definition, but apply it to the two components with maximum and minimum weight. For massless particles, this is sufficient. For massive particles, we add the possibilities:

5. Longitudinal polarization: Only the 0-component is set. This is possible only for bosons.
6. Diagonal polarization: Explicitly specify all components in the helicity basis.

Obviously, this does not exhaust the possible density matrices for higher spin, but it should cover all practical applications.

    <Polarizations: procedures>

    <Polarizations: tests>

  end module polarizations

```

8.1.1 The polarization type

This is not an extension, but rather a restriction of the quantum state. Flavor and color are ignored, there is just a one-particle helicity density matrix.

```

<Polarizations: public>≡
  public :: polarization_t

<Polarizations: types>≡
  type :: polarization_t
    logical :: polarized = .false.
    integer :: spin_type = 0
    integer :: multiplicity = 0
    type(state_matrix_t) :: state
  end type polarization_t

```

8.1.2 Basic initializer and finalizer

We need the particle flavor for determining the allowed helicity values. The density matrix is not set, but prepared to be filled later. This is private.

```

```

The following three modes are useful mainly for spin-1/2 particle and massless particles of any nonzero spin. Only the highest-weight components are filled.

Circular polarization: The density matrix of the two highest-weight states

is

$$\rho(f) = \frac{1 - |f|}{2} \mathbf{1} + |f| \times \begin{cases} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, & f > 0; \\ \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, & f < 0, \end{cases}$$

If the polarization fraction $|f|$ is unity, we need only one entry in the density matrix.

```

        end if
        call state_matrix_freeze (pol%state)
    end subroutine polarization_init_circular

```

Transversal polarization is analogous to circular, but we get a density matrix

$$\rho(f, \phi) = \frac{1 - |f|}{2} \mathbf{1} + \frac{|f|}{2} \begin{pmatrix} 1 & e^{-i\phi} \\ e^{i\phi} & 1 \end{pmatrix}.$$

The phase is $\phi = 0$ for the x -axis, $\phi = 90^\circ$ for the y axis as polarization vector. For an antiparticle, the phase switches sign, and for $f < 0$, the off-diagonal elements switch sign.

```

(Polarizations: public)+≡
    public :: polarization_init_transversal

```

```

(Polarizations: procedures)+≡
subroutine polarization_init_transversal (pol, flv, phi, fraction)

  call polarization_init_axis &
    (pol, flv, fraction * (/ cos (phi), sin (phi), 0._default/))
end subroutine polarization_init_transversal

```

For axis polarization, we again set only the entries with maximum weight.

$$\rho(f, \phi) = \frac{1}{2} \begin{pmatrix} 1 + \alpha_3 & \alpha_1 - i\alpha_2 \\ \alpha_1 + i\alpha_2 & 1 - \alpha_3 \end{pmatrix}.$$

For an antiparticle, α_2 switches sign (complex conjugate).

8.1.7 Operations

Combine polarization states by computing the outer product of the state matrices.

```

(Polarizations: public)+≡
    public :: combine_polarization_states

(Polarizations: procedures)+≡
    subroutine combine_polarization_states (pol, state)
        type(polarization_t), dimension(:), intent(in), target :: pol
        type(state_matrix_t), intent(out) :: state
        call outer_multiply (pol%state, state)
    end subroutine combine_polarization_states

```

Transform a polarization density matrix into a polarization vector. This is possible without information loss only for spin-1/2 and for massless particles. To get a unique answer in all cases, we consider only the components with highest weight. Obviously, this loses the longitudinal component of a massive vector, for instance.

This is the inverse operation of `polarization_init_axis` above, where the polarization fraction is set to unity.

```

(Polarizations: public)+≡
    public :: polarization_get_axis

(Polarizations: procedures)+≡
    function polarization_get_axis (pol) result (alpha)
        real(default), dimension(3) :: alpha
        type(polarization_t), intent(in), target :: pol
        type(state_iterator_t) :: it
        complex(default), dimension(2,2) :: value
        type(helicity_t), dimension(2,2) :: hel
        type(helicity_t), dimension(1) :: hel1
        integer :: hmax, i, j
        if (pol%polarized) then
            hmax = pol%spin_type / 2
            call helicity_init (hel(1,1), hmax, hmax)

```

```

call helicity_init (hel(1,2), hmax,-hmax)
call helicity_init (hel(2,1),-hmax, hmax)
call helicity_init (hel(2,2),-hmax,-hmax)

  SCAN_HEL: do i = 1, 2
    do j = 1, 2
      if (hel1(1) == hel(i,j)) then
        value(i,j) = state_iterator_get_matrix_element (it)
        exit SCAN_HEL
      end if
    end do
  end do SCAN_HEL
  call state_iterator_advance (it)
end do
alpha(1) = value(1,2) + value(2,1)
alpha(2) = imago * (value(1,2) - value(2,1))
alpha(3) = value(1,1) - value(2,2)
else
  alpha = 0
end if
end function polarization_get_axis

```

This function returns polarization degree and polar and azimuthal angles (θ, ϕ) of the polarization axis.

(Polarizations: public)+≡

public :: polarization_to_angles

(Polarizations: procedures)+≡

```

subroutine polarization_to_angles (pol, r, theta, phi)
  type(polarization_t), intent(in) :: pol
  real(default), intent(out) :: r, theta, phi
  real(default), dimension(3) :: alpha
  real(default) :: r12
  if (pol%polarized) then
    alpha = polarization_get_axis (pol)
    r = sqrt (sum (alpha**2))
    if (any (alpha /= 0)) then
      r12 = sqrt (alpha(1)**2 + alpha(2)**2)
      theta = atan2 (r12, alpha(3))
      if (any (alpha(1:2) /= 0)) then
        phi = atan2 (alpha(2), alpha(1))
      else
        phi = 0
      end if
    else
      theta = 0
    end if
  else
    r = 0
    theta = 0
    phi = 0
  end if
end subroutine polarization_to_angles

```

```

end if
end subroutine polarization_to_angles

```

8.1.8 Sparse Matrix

We introduce a simpler implementation of a sparse matrix that should represent polarization. It consists of an integer array that represents the index values, and a complex array that represents the nonvanishing entries. The number of nonvanishing entries must be known for initialization, but the entries are filled one at a time.

This should eventually replace the more baroque polarization definition above, but in the first stage we introduce it just as an intermediage storage container.

Here is a base type without the special properties of a spin-density matrix.

```

<Polarizations: public>+≡
  public :: smatrix_t

<Polarizations: types>+≡
  type :: smatrix_t
    private
    integer :: dim = 0
    integer :: n_entry = 0
    integer, dimension(:,:), allocatable :: index
    complex(default), dimension(:), allocatable :: value
  contains
    <Polarizations: smatrix: TBP>
  end type smatrix_t

```

Output.

```

<Polarizations: smatrix: TBP>≡
  procedure :: write => smatrix_write

<Polarizations: procedures>+≡
  subroutine smatrix_write (object, unit, indent)
    class(smatrix_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    integer :: u, i, ind
    u = output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    if (allocated (object%value)) then
      if (size (object%value) > 0) then
        do i = 1, object%n_entry
          write (u, "(1x,A,'@(')", advance="no") repeat (" ", ind)
          write (u, "(SP,9999(I2.1,':',1x))", advance="no") &
            object%index(:,i)
          write (u, "('(',ES19.12,',',ES19.12,')')'") object%value(i)
        end do
      else
        write (u, "(1x,A)", advance="no") repeat (" ", ind)
        write (u, "(A)" "[empty matrix]"
      end if
    else

```

```

        write (u, "(1x,A)", advance="no") repeat (" ", ind)
        write (u, "(A)") "[undefined matrix]"
    end if
end subroutine smatrix_write

```

Initialization: allocate arrays to the correct size. We specify both the dimension of the matrix (if different from two, this is rather a generic tensor) and the number of nonvanishing entries.

```

<Polarizations: smatrix: TBP>+≡
    procedure :: init => smatrix_init

<Polarizations: procedures>+≡
    subroutine smatrix_init (smatrix, dim, n_entry)
        class(smatrix_t), intent(out) :: smatrix
        integer, intent(in) :: dim
        integer, intent(in) :: n_entry
        smatrix%dim = dim
        smatrix%n_entry = n_entry
        allocate (smatrix%index (dim, n_entry))
        allocate (smatrix%value (n_entry))
    end subroutine smatrix_init

```

Fill: one entry at a time.

```

<Polarizations: smatrix: TBP>+≡
    procedure :: set_entry => smatrix_set_entry

<Polarizations: procedures>+≡
    subroutine smatrix_set_entry (smatrix, i, index, value)
        class(smatrix_t), intent(inout) :: smatrix
        integer, intent(in) :: i
        integer, dimension(:), intent(in) :: index
        complex(default), intent(in) :: value
        smatrix%index(:,i) = index
        smatrix%value(i) = value
    end subroutine smatrix_set_entry

```

8.1.9 Polarization Matrix

As an extension of the more generic `smatrix` type, we implement a proper spin-density matrix. After the matrix has been filled, we can fix spin type and multiplicity for a particle, check the matrix for consistency, and normalize it if necessary.

```

<Polarizations: public>+≡
    public :: pmatrix_t

<Polarizations: types>+≡
    type, extends (smatrix_t) :: pmatrix_t
        private
        integer :: spin_type = 0
        integer :: multiplicity = 0
        logical :: massive = .true.
        integer :: chirality = 0
    end type pmatrix_t

```

```

    real(default) :: degree = 1
    logical :: pure = .false.
contains
  <Polarizations: pmatrix: TBP>
end type pmatrix_t

```

Output, including extra data. (The `indent` argument is ignored.)

```

<Polarizations: pmatrix: TBP>≡
  procedure :: write => pmatrix_write
<Polarizations: procedures>+≡
  subroutine pmatrix_write (object, unit, indent)
    class(pmatrix_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = output_unit (unit)
    write (u, "(1x,A)") "Polarization: spin density matrix"
    write (u, "(3x,A,I0)") "spin type      = ", object%spin_type
    write (u, "(3x,A,I0)") "multiplicity = ", object%multiplicity
    write (u, "(3x,A,L1)") "massive      = ", object%massive
    write (u, "(3x,A,I0)") "chirality    = ", object%chirality
    write (u, "(3x,A,F10.7)") "pol.degree   = ", object%degree
    write (u, "(3x,A,L1)") "pure state   = ", object%pure
    call object%smatrix_t%write (u, 1)
  end subroutine pmatrix_write

```

This assignment is trivial, but must be coded explicitly.

```

<Polarizations: pmatrix: TBP>+≡
  generic :: assignment(=) => pmatrix_assign_from_smatrix
  procedure, private :: pmatrix_assign_from_smatrix
<Polarizations: procedures>+≡
  subroutine pmatrix_assign_from_smatrix (pmatrix, smatrix)
    class(pmatrix_t), intent(out) :: pmatrix
    type(smatrix_t), intent(in) :: smatrix
    pmatrix%smatrix_t = smatrix
  end subroutine pmatrix_assign_from_smatrix

```

Declare spin, multiplicity, and polarization degree. Check whether all entries fit, and whether this is a valid matrix.

The required properties are:

1. all entries apply to the given spin and mass type
2. the diagonal is real
3. only the upper of corresponding off-diagonal elements is specified, i.e., the row index is less than the column index
4. the trace is nonnegative and equal to the polarization degree (the remainder, proportional to the unit matrix, is understood to be present)
5. the trace of the matrix square is positive and less or equal to the trace of the matrix itself, which is the polarization degree. (If it is equal, we are dealing with a pure state).

```

    <Particles: parameters>

    <Particles: types>

    <Particles: interfaces>

    contains

    <Particles: procedures>

    <Particles: tests>

  end module particles

```

8.2.1 The particle type

Particle status codes

The overall status codes (incoming/outgoing etc.) are inherited from the module `subevents`.

Polarization status:

```
<Particles: parameters>≡  
  integer, parameter, public :: PRT_UNPOLARIZED = 0  
  integer, parameter, public :: PRT_DEFINITE_HELICITY = 1  
  integer, parameter, public :: PRT_GENERIC_POLARIZATION = 2
```

Definition

The quantum numbers are flavor (from which invariant particle properties can be derived), color, and polarization. The particle may be unpolarized. In this case, `hel` and `pol` are unspecified. If it has a definite helicity, the `hel` component is defined. If it has a generic polarization, the `pol` component is defined. For each particle we store the four-momentum and the invariant mass squared, i.e., the squared norm of the four-momentum. There is also an optional list of parent and child particles, for bookkeeping in physical events.

```
<Particles: public>≡  
  public :: particle_t  
  
<Particles: types>≡  
  type :: particle_t  
    private  
    integer :: status = PRT_UNDEFINED  
    integer :: polarization = PRT_UNPOLARIZED  
    type(flavor_t) :: flv  
    type(color_t) :: col  
    type(helicity_t) :: hel  
    type(polarization_t) :: pol  
    type(vector4_t) :: p = vector4_null  
    real(default) :: p2 = 0  
    integer, dimension(:), allocatable :: parent  
    integer, dimension(:), allocatable :: child  
  end type particle_t
```

Particle initializers:

```
<Particles: interfaces>≡  
  interface particle_init  
    module procedure particle_init_particle  
    module procedure particle_init_state  
  end interface
```

Copy a particle. (Deep copy) The excludes the parent-child relations.

```
<Particles: procedures>≡  
  subroutine particle_init_particle (prt_out, prt_in)  
    type(particle_t), intent(out) :: prt_out  
    type(particle_t), intent(in) :: prt_in
```

```

    prt_out%status = prt_in%status
    prt_out%polarization = prt_in%polarization
    prt_out%flv = prt_in%flv
    prt_out%col = prt_in%col
    prt_out%hel = prt_in%hel
    prt_out%pol = prt_in%pol
    prt_out%p = prt_in%p
    prt_out%p2 = prt_in%p2
end subroutine particle_init_particle

```

Initialize a particle using a single-particle state matrix which determines flavor, color, and polarization. The state matrix must have unique flavor and color. The factorization mode determines whether the particle is unpolarized, has definite helicity, or generic polarization. This mode is translated into the polarization status.

```

<Particles: procedures>+≡
subroutine particle_init_state (prt, state, status, mode)
    type(particle_t), intent(out) :: prt

```

8.2.2 Particle sets

A particle set is what is usually called an event: an array of particles. The individual particle entries carry momentum, quantum numbers, polarization, and optionally connections. There is (also optionally) a correlated state-density matrix that maintains spin correlations that are lost in the individual particle entries.

```

(Particles: public)+≡
    public :: particle_set_t

(Particles: types)+≡
    type :: particle_set_t
    !!! JRR: WK please check
    !     private
        integer :: n_beam = 0
        integer :: n_in  = 0
        integer :: n_vir = 0
        integer :: n_out = 0
        integer :: n_tot = 0
        type(particle_t), dimension(:), allocatable :: prt
        type(state_matrix_t) :: correlated_state
    end type particle_set_t

```

A particle set can be initialized from an interaction or from a HepMC event record.

```

(Particles: public)+≡
    public :: particle_set_init

(Particles: interfaces)+≡
    interface particle_set_init
        module procedure particle_set_init_interaction
    !     module procedure particle_set_init_hepmc
    end interface

```

When a particle set is initialized from a given interaction, we have to determine the branch within the original state matrix that fixes the particle quantum numbers. This is done with the appropriate probabilities, based on a random number `x`. The `mode` determines whether the individual particles become unpolarized, or take a definite (diagonal) helicity, or acquire single-particle polarization matrices. The flag `keep_correlations` tells whether the spin-correlation matrix is to be calculated and stored in addition to the particles. The flag `keep_virtual` tells whether virtual particles should be dropped. Note that if virtual particles are dropped, the spin-correlation matrix makes no sense, and parent-child relations are not set.

For a correct disentangling of color and flavor (in the presence of helicity), we consider two interactions. `int` has no color information, and is used to select a flavor state. Consequently, we trace over helicities here. `int_flows` contains color-flow and potentially helicity information, but is useful only after the flavor combination has been chosen. So this interaction is used to select helicity and color, but restricted to the selected flavor combination.

`int` and `int_flows` may be identical if there is only a single (or no) color flow. If there is just a single flavor combination, `x(1)` can be set to zero.

The current algorithm of evaluator convolution requires that the beam particles are assumed outgoing (in the beam interaction) and become virtual in all derived interactions. In the particle set they should be re-identified as incoming. The optional integer `n_incoming` can be used to perform this correction.

The flag `is_valid` is false if factorization of the state is not possible, in particular if the squared matrix element is zero.

(Particles: procedures)+≡

```

subroutine particle_set_init_interaction &

```

8.2.3 I/O formats

Here, we define input/output of particle sets in various formats. This is the right place since particle sets contain most of the event information.

All write/read routines take as first argument the object, as second argument the I/O unit which in this case is a mandatory argument. Then follow further event data.

Internal binary format

This format is supposed to contain the complete information, so the particle data set can be fully reconstructed. The exception is the model part of the particle flavors; this is unassigned for the flavor values read from file.

<Particles: public>+≡

```

    public :: particle_set_write_raw
    public :: particle_set_read_raw

```

```

<Particles: procedures>+≡

end subroutine particle_set_read_raw

```

HepMC format

The master output function fills a HepMC GenEvent object that is already initialized, but has no vertices in it.

We first set up the vertex lists and enter the vertices into the HepMC event. Then, we assign first all incoming particles and then all outgoing particles to their associated vertices. Particles which have neither parent nor children entries (this should not happen) are dropped.

Finally, we insert the beam particles. If there are none, use the incoming particles instead.

Reconstruct the momenta within an interaction object from a particle set. We start from the incoming particles, which should be stored at the beginning. (The number of incoming particles is provided separately, so we do not need to analyze the interaction or particle set for this.) We follow their children down the tree until the interaction is exhausted.

This implies that the particle set may contain a longer tree (e.g., decay chains) than the interaction. The remainder of the tree is simply ignored.

The detailed ordering of the subsequent sub-interactions may differ between the interaction and the particle set. However, within each sub-interaction, the ordering of particles must match.

It may happen that the particle set lacks beam and remnant particles which are present in the interaction. In this case, the beam particles (the first two entries in the interaction) will not be filled. However, we can use the source link of the beam particles to recover their momenta from the actual beam interaction (which is stored somewhere else), and then recover the beam-remnant momenta as the difference of the beam and parton momenta.

This reconstructs the hard interaction from a particle set. First the particle set is reduced to the incoming partons, then we add the direct children of those. The interaction and particle set should match in their array sizes. If we find a permutation of the particle flavors that matches one of the given flavor states, the assignment of momenta is made accordingly.

end do
end subroutine particle_set_extract_interaction

```

Given a particle set with an arbitrary ordering of particles, we need the permutation that yields an ordering that is present in the state matrix. This can be found by examining the flavor table. The result is a permutation of the PDG array that matches a row in the flavor table. If ok is returned false, no match was found.

(Particles: procedures)+≡

```

subroutine find_flavor_ordering (flv_state, pdg, n_in, perm, ok)

end do SCAN_INPUT
ok = .true.
end if
end subroutine find_ordering_for_this_state
end subroutine find_flavor_ordering

```

This procedure reconstructs an array of vertex indices from the parent-child information in the particle entries, according to the HepMC scheme. For each particle, we determine which vertex it comes from and which vertex it goes to. We return the two arrays and the maximum vertex index.

For each particle in the list, we first check its parents. If for any parent the vertex where it goes to is already known, this vertex index is assigned as the current 'from' vertex. Otherwise, a new index is created, assigned as the current 'from' vertex, and as the 'to' vertex for all parents.

Then, the analogous procedure is done for the children.

```

(Particles: public) +=
    public :: particle_set_assign_vertices

(Particles: procedures) +=
    subroutine particle_set_assign_vertices &
        (particle_set, v_from, v_to, n_vertices)

end subroutine particle_set_assign_vertices

```

8.2.4 Expression interface

This converts a `particle_set` object as defined here to a more concise `subevt` object that can be used as the event root of an expression. In particular, the latter lacks virtual particles, spin correlations and parent-child relations.

```

(Particles: public) +=
  public :: particle_set_to_subevt

(Particles: procedures) +=
  subroutine particle_set_to_subevt (particle_set, subevt)
    type(particle_set_t), intent(in), target :: particle_set
    type(subevt_t), intent(out) :: subevt
    type(particle_t), pointer :: prt
    integer :: i, k
    integer, dimension(2) :: hel
    call subevt_init &
      (subevt, particle_set%n_beam + particle_set%n_in + particle_set%n_out)
    k = 0
    do i = 1, particle_set%n_tot
      prt => particle_set%prt(i)
      select case (particle_get_status (prt))
      case (PRT_BEAM)
        k = k + 1
        call subevt_set_beam (subevt, k, &
          particle_get_pdg (prt), &
          particle_get_momentum (prt), &
          particle_get_p2 (prt))
      case (PRT_INCOMING)
        k = k + 1
        call subevt_set_incoming (subevt, k, &
          particle_get_pdg (prt), &
          particle_get_momentum (prt), &
          particle_get_p2 (prt))
      end select
    end do
  end subroutine

```

```

      case (PRT_OUTGOING)
        k = k + 1
        call subevt_set_outgoing (subevt, k, &
          particle_get_pdg (prt), &
          particle_get_momentum (prt), &
          particle_get_p2 (prt))
      end select
    select case (particle_get_status (prt))
    case (PRT_BEAM, PRT_INCOMING, PRT_OUTGOING)
      if (prt%polarization == PRT_DEFINITE_HELICITY) then
        if (helicity_is_diagonal (prt%hel)) then
          hel = helicity_get (prt%hel)
          call subevt_polarize (subevt, k, hel(1))
        end if
      end if
    end select
  end do
end subroutine particle_set_to_subevt

```

This replaces the `particle_set`

```

<Particles: public>+≡
  public :: particle_set_replace

<Particles: procedures>+≡
  subroutine particle_set_replace (particle_set, newprt)

Chapter 9

Initial State

9.1 Beam structure

This module stores the beam structure definition as it is declared in the SIN-DARIN script. The structure definition is not analyzed, just recorded for later use.

We do not capture any numerical parameters, just names of particles and structure functions.

```
(beam_structures.f90)≡  
  <File header>  
  
  module beam_structures  
  
    <Use kinds>  
    <Use strings>  
    <Use file utils>  
    use diagnostics !NODEP!  
    use unit_tests  
  
    use variables  
    use polarizations  
  
    <Standard module head>  
  
    <Beam structures: public>  
  
    <Beam structures: types>  
  
    <Beam structures: interfaces>  
  
    contains  
  
    <Beam structures: procedures>  
  
    <Beam structures: tests>  
  
  end module beam_structures
```

9.1.1 Beam structure elements

An entry in a beam-structure record consists of a string that denotes a type of structure function.

```
<Beam structures: types>≡
    type :: beam_structure_entry_t
        logical :: is_valid = .false.
        type(string_t) :: name
    contains
        <Beam structures: beam structure entry: TBP>
    end type beam_structure_entry_t
```

Output.

```
<Beam structures: beam structure entry: TBP>≡
    procedure :: to_string => beam_structure_entry_to_string

<Beam structures: procedures>≡
    function beam_structure_entry_to_string (object) result (string)
        class (beam_structure_entry_t), intent(in) :: object
        type(string_t) :: string
        if (object%is_valid) then
            string = object%name
        else
            string = "none"
        end if
    end function beam_structure_entry_to_string
```

A record in the beam-structure sequence denotes either a structure-function entry, a pair of such entries, or a pair spectrum.

```
<Beam structures: types>+≡
    type :: beam_structure_record_t
        type (beam_structure_entry_t), dimension(:), allocatable :: entry
    end type beam_structure_record_t
```

9.1.2 Beam structure type

The beam-structure object contains the beam particle(s) as simple strings. The sequence of records indicates the structure functions by name. No numerical parameters are stored.

```
<Beam structures: public>≡
    public :: beam_structure_t

<Beam structures: types>+≡
    type :: beam_structure_t
        private
        integer :: n_beam = 0
        type(string_t), dimension(:), allocatable :: prt
        type (beam_structure_record_t), dimension(:), allocatable :: record
        type (smatrix_t), dimension(:), allocatable :: smatrix
        real(default), dimension(:), allocatable :: pol_f
    contains
        <Beam structures: beam structure: TBP>
```

```
end type beam_structure_t
```

The finalizer deletes all contents explicitly, so we can continue with an empty beam record. (It is not needed for deallocation.) We have distinct finalizers for the independent parts of the beam structure.

```
<Beam structures: beam structure: TBP>≡
  procedure :: final_sf => beam_structure_final_sf

<Beam structures: procedures>+≡
  subroutine beam_structure_final_sf (object)
    class(beam_structure_t), intent(inout) :: object
    if (allocated (object%prt)) deallocate (object%prt)
    if (allocated (object%record)) deallocate (object%record)
    object%n_beam = 0
  end subroutine beam_structure_final_sf
```

Output. The actual information fits in a single line, therefore we can provide a `to_string` method. The `show` method also lists the current values of relevant global variables.

```
<Beam structures: beam structure: TBP>+≡
  procedure :: write => beam_structure_write
  procedure :: to_string => beam_structure_to_string

<Beam structures: procedures>+≡
  subroutine beam_structure_write (object, unit)
    class(beam_structure_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit)
    write (u, "(1x,A,A)") "Beam structure: ", char (object%to_string ())
    if (allocated (object%smatrix)) then
      do i = 1, size (object%smatrix)
        write (u, "(3x,A,I0,A)") "polarization (beam ", i, "):"
        call object%smatrix(i)%write (u, indent=2)
      end do
    end if
    if (allocated (object%pol_f)) then

        end do
    else
        allocate (beam_structure%record (0))
    end if
end subroutine beam_structure_init_sf

```

Set an entry, specified by record number and entry number.

```

<Beam structures: beam structure: TBP>+=
  procedure :: set_sf => beam_structure_set_sf

<Beam structures: procedures>+=
  subroutine beam_structure_set_sf (beam_structure, i, j, name)
    class(beam_structure_t), intent(inout) :: beam_structure
    integer, intent(in) :: i, j
    type(string_t), intent(in) :: name
    associate (entry => beam_structure%record(i)%entry(j))
      entry%name = name
      entry%is_valid = .true.
    end associate
  end subroutine beam_structure_set_sf

```

Expand the beam-structure object. (i) For a pair spectrum, keep the entry. (ii) For a single-particle structure function written as a single entry, replace this by a record with two entries. (ii) For a record with two nontrivial entries, separate this into two records with one trivial entry each.

To achieve this, we need a function that tells us whether an entry is a spectrum or a structure function. It returns 0 for a trivial entry, 1 for a single-particle structure function, and 2 for a two-particle spectrum.

```

<Beam structures: interfaces>=
  abstract interface
    function strfun_mode_fun (name) result (n)
      import
      type(string_t), intent(in) :: name
      integer :: n
    end function strfun_mode_fun
  end interface

```

Algorithm: (1) Mark entries as invalid where necessary. (2) Count the number of entries that we will need. (3) Expand and copy entries to a new record array. (4) Replace the old array by the new one.

```

9.1.3 Polarization

To record polarization, we provide an allocatable array of `smatrix` objects, sparse matrices. The polarization structure is independent of the structure-function setup, they are combined only when an actual beam object is constructed.

```

<Beam structures: beam structure: TBP>+=
  procedure :: final_pol => beam_structure_final_pol
  procedure :: init_pol => beam_structure_init_pol

<Beam structures: procedures>+=
  subroutine beam_structure_final_pol (beam_structure)
    class(beam_structure_t), intent(inout) :: beam_structure
    if (allocated (beam_structure%smatrix)) deallocate (beam_structure%smatrix)
    if (allocated (beam_structure%pol_f)) deallocate (beam_structure%pol_f)
  end subroutine beam_structure_final_pol

  subroutine beam_structure_init_pol (beam_structure, n)
    class(beam_structure_t), intent(inout) :: beam_structure
    integer, intent(in) :: n
    if (allocated (beam_structure%smatrix)) deallocate (beam_structure%smatrix)
    allocate (beam_structure%smatrix (n))
    if (.not. allocated (beam_structure%pol_f)) &
      allocate (beam_structure%pol_f (n), source = 1._default)
  end subroutine beam_structure_init_pol

```

Directly copy the spin density matrices.

```

<Beam structures: beam structure: TBP>+=
  procedure :: set_smatrix => beam_structure_set_smatrix

<Beam structures: procedures>+=
  subroutine beam_structure_set_smatrix (beam_structure, i, smatrix)
    class(beam_structure_t), intent(inout) :: beam_structure
    integer, intent(in) :: i
    type(smatrix_t), intent(in) :: smatrix
    beam_structure%smatrix(i) = smatrix
  end subroutine beam_structure_set_smatrix

```

Initialize one of the spin density matrices manually.

```

<Beam structures: beam structure: TBP>+=
  procedure :: init_smatrix => beam_structure_init_smatrix

<Beam structures: procedures>+=
  subroutine beam_structure_init_smatrix (beam_structure, i, n_entry)
    class(beam_structure_t), intent(inout) :: beam_structure
    integer, intent(in) :: i

```

```

        integer, intent(in) :: n_entry
        call beam_structure%smatrix(i)%init (2, n_entry)
    end subroutine beam_structure_init_smatrix

```

Set a polarization entry.

```

<Beam structures: beam structure: TBP>+≡
    procedure :: set_sentry => beam_structure_set_sentry

<Beam structures: procedures>+≡
    subroutine beam_structure_set_sentry &
        (beam_structure, i, i_entry, index, value)
        class(beam_structure_t), intent(inout) :: beam_structure

9.2.1 Beam data

The beam data type contains beam data for one or two beams, depending on whether we are dealing with beam collisions or particle decay. In addition, it holds the c.m. energy `sqrts`, the Lorentz transformation `L` that transforms the c.m. system into the lab system, and the pair of c.m. momenta.

```

<Beams: public>≡
    public :: beam_data_t

<Beams: types>≡
    type :: beam_data_t
        logical :: initialized = .false.
        integer :: n = 0
        type(flavor_t), dimension(:), allocatable :: flv
        real(default), dimension(:), allocatable :: mass
        type(pmatrix_t), dimension(:), allocatable :: pmatrix
        logical :: lab_is_cm_frame = .true.
        type(vector4_t), dimension(:), allocatable :: p_cm
        type(vector4_t), dimension(:), allocatable :: p
        type(lorentz_transformation_t), pointer :: L_cm_to_lab => null ()
        real(default) :: sqrts = 0
        character(32) :: md5sum = ""
    contains
        <Beams: beam data: TBP>
    end type beam_data_t

```

Generic initializer. This is called by the specific initializers below. Initialize either for decay or for collision.

```

<Beams: procedures>≡
    subroutine beam_data_init (beam_data, n)
        type(beam_data_t), intent(out) :: beam_data
        integer, intent(in) :: n
        beam_data%n = n
        allocate (beam_data%flv (n))
        allocate (beam_data%mass (n))

```

```

        allocate (beam_data%pmatrix (n))
        allocate (beam_data%p_cm (n))
        allocate (beam_data%p (n))
        beam_data%initialized = .true.
    end subroutine beam_data_init

```

Finalizer: needed for the polarization components of the beams.

Note: The polarization finalizer causes memory corruption with gfortran 4.6.3. The implementation of polarization by a state matrix, at this place, is not really a good idea, in any case.

```

(Beams: public)+≡
    public :: beam_data_final

(Beams: procedures)+≡
    subroutine beam_data_final (beam_data)
        type(beam_data_t), intent(inout) :: beam_data

            call beam_data_init_sqrts &
                (beam_data, m(1), flv, smatrix, pol_f, p_cm, theta, phi)
        end if
    end subroutine beam_data_init_decay

```

9.2.5 Sanity check

After the beams have been set, the initial-particle masses may have been modified. This can be checked here.

```

<Beams: public>+≡
    public :: beam_data_masses_are_consistent

<Beams: procedures>+≡
    function beam_data_masses_are_consistent (beam_data) result (flag)
        logical :: flag
        type(beam_data_t), intent(in) :: beam_data
        flag = all (beam_data%mass == flavor_get_mass (beam_data%flv))
    end function beam_data_masses_are_consistent

```

9.2.6 The beams type

Beam objects are interaction objects that contain the actual beam data including polarization and density matrix. For collisions, the beam object actually contains two beams.

```

(Beams: public)+≡
    public :: beam_t

(Beams: types)+≡
    type :: beam_t
    private
        type(interaction_t) :: int
    end type beam_t

```

The constructor contains code that converts beam data into the (entangled) particle-pair quantum state. First, we set the number of particles and polarization mask. (The polarization mask is handed over to all later interactions, so if helicity is diagonal or absent, this fact is used when constructing the hard-interaction events.) Then, we construct the entangled state that combines helicity, flavor and color of the two particles (where flavor and color are unique, while several helicity states are possible). Then, we transfer this state together with the associated values from the spin density matrix into the `interaction_t` object.

```

(Beams: public)+≡
    public :: beam_init

(Beams: procedures)+≡
    subroutine beam_init (beam, beam_data)
        type(beam_t), intent(out) :: beam
        type(beam_data_t), intent(in), target :: beam_data
        type(quantum_numbers_mask_t), dimension(beam_data%n) :: mask
        type(state_matrix_t), target :: state_hel, state_fc, state_tmp

    contains  
  
    ⟨SF aux: procedures⟩  
  
    ⟨SF aux: tests⟩  
  
  end module sf_aux
```

10.1.1 Momentum splitting

Let us consider first an incoming parton with momentum k and invariant mass squared $s = k^2$ that splits into two partons with momenta q, p and invariant masses $t = q^2$ and $u = p^2$. (This is an abuse of the Mandelstam notation. t is actually the momentum transfer, assuming that p is radiated and q initiates the hard process.) The energy is split among the partons such that if $E = k^0$, we have $q^0 = xE$ and $p^0 = \bar{x}E$, where $\bar{x} \equiv 1 - x$.

We define the angle θ as the polar angle of p w.r.t. the momentum axis of the incoming momentum k . Ignoring azimuthal angle, we can write the four-momenta in the basis (E, p_T, p_L) as

$$k = \begin{pmatrix} E \\ 0 \\ p \end{pmatrix}, \quad p = \begin{pmatrix} \bar{x}E \\ \bar{x}\bar{p} \sin \theta \\ \bar{x}\bar{p} \cos \theta \end{pmatrix}, \quad q = \begin{pmatrix} xE \\ -\bar{x}\bar{p} \sin \theta \\ p - \bar{x}\bar{p} \cos \theta \end{pmatrix}, \quad (10.1)$$

where the first two mass-shell conditions are

$$p^2 = E^2 - s, \quad \bar{p}^2 = E^2 - \frac{u}{\bar{x}^2}. \quad (10.2)$$

The second condition implies that, for positive u , $\bar{x}^2 > u/E^2$, or equivalently

$$x < 1 - \sqrt{u}/E. \quad (10.3)$$

We are interested in the third mass-shell conditions: s and u are fixed, so we need t as a function of $\cos \theta$:

$$t = -2\bar{x}(E^2 - p\bar{p} \cos \theta) + s + u. \quad (10.4)$$

Solving for $\cos \theta$, we get

$$\cos \theta = \frac{2\bar{x}E^2 + t - s - u}{2\bar{x}p\bar{p}}. \quad (10.5)$$

We can compute $\sin^2 \theta$ numerically as $\sin^2 \theta = 1 - \cos^2 \theta$, but it is important to reexpress this in view of numerical stability. To this end, we first determine the bounds for t . The cosine must be between -1 and 1 , so the bounds are

$$t_0 = -2\bar{x}(E^2 + p\bar{p}) + s + u, \quad (10.6)$$

$$t_1 = -2\bar{x}(E^2 - p\bar{p}) + s + u. \quad (10.7)$$

Computing $\sin^2 \theta$ from $\cos \theta$ above, we observe that the numerator is a quadratic polynomial in t which has the zeros t_0 and t_1 , while the common denominator is given by $(2\bar{x}p\bar{p})^2$. Hence, we can write

$$\sin^2 \theta = -\frac{(t - t_0)(t - t_1)}{(2\bar{x}p\bar{p})^2} \quad \text{and} \quad \cos \theta = \frac{(t - t_0) + (t - t_1)}{4\bar{x}p\bar{p}}, \quad (10.8)$$

which is free of large cancellations near $t = t_0$ or $t = t_1$.

If all is massless, i.e., $s = u = 0$, this simplifies to

$$t_0 = -4\bar{x}E^2, \quad t_1 = 0, \quad (10.9)$$

$$\sin^2 \theta = -\frac{t}{\bar{x}E^2} \left(1 + \frac{t}{4\bar{x}E^2}\right), \quad \cos \theta = 1 + \frac{t}{2\bar{x}E^2}. \quad (10.10)$$

Here is the implementation. First, we define a container for the kinematical integration limits and some further data.

```

<SF aux: public>≡
  public :: splitting_data_t

<SF aux: types>≡
  type :: splitting_data_t
    private
    logical :: collinear = .false.

    write (u, 1) "E    =", d%E
    write (u, 1) "p    =", d%p
    write (u, 1) "pb   =", d%pb
    write (u, 1) "s    =", d%s
    write (u, 1) "u    =", d%u
    write (u, 1) "m2   =", d%m2
  end subroutine splitting_data_write

```

10.1.2 Constant data

This is the initializer for the data. The input consists of the incoming momentum, its invariant mass squared, and the invariant mass squared of the radiated particle. m_2 is the *physical* mass squared of the outgoing particle. The t bounds depend on the chosen x value and cannot be determined yet.

```

(SF aux: splitting data: TBP)+≡
  procedure :: init => splitting_data_init

(SF aux: procedures)+≡
  subroutine splitting_data_init (d, k, mk2, mr2, mo2, collinear)
    class(splitting_data_t), intent(out) :: d
    type(vector4_t), intent(in) :: k
    real(default), intent(in) :: mk2, mr2, mo2
    logical, intent(in), optional :: collinear
    if (present (collinear)) d%collinear = collinear
    d%E = energy (k)
    d%x1 = 1 - sqrt (max (mr2, 0._default)) / d%E
    d%p = sqrt (d%E**2 - mk2)
    d%s = mk2
    d%u = mr2
    d%m2 = mo2
  end subroutine splitting_data_init

```

Retrieve the x bounds, if needed for x sampling. Generating an x value is done by the caller, since this is the part that depends on the nature of the structure function.

```

(SF aux: splitting data: TBP)+≡
  procedure :: get_x_bounds => splitting_get_x_bounds

(SF aux: procedures)+≡
  function splitting_get_x_bounds (d) result (x)
    class(splitting_data_t), intent(in) :: d
    real(default), dimension(2) :: x
    x = (/ d%x0, d%x1 /)
  end function splitting_get_x_bounds

```

Now set the momentum fraction and compute t_0 and t_1 .

[The calculation of t_1 is subject to numerical problems. The exact formula is ($s = m_i^2$, $u = m_r^2$)

$$t_1 = -2\bar{x}E^2 + m_i^2 + m_r^2 + 2\bar{x}\sqrt{E^2 - m_i^2}\sqrt{E^2 - m_r^2/\bar{x}^2}. \quad (10.11)$$

The structure-function paradigm is useful only if $E \gg m_i, m_r$. In a Taylor expansion for large E , the leading term cancels. The expansion of the square roots (to subleading order) yields

$$t_1 = xm_i^2 - \frac{x}{\bar{x}}m_r^2. \quad (10.12)$$

There are two cases of interest: $m_i = m_o$ and $m_r = 0$,

$$t_1 = xm_o^2 \quad (10.13)$$

and $m_i = m_r$ and $m_o = 0$,

$$t_1 = -\frac{x^2}{\bar{x}} m_i^2. \quad (10.14)$$

In both cases, $t_1 \leq m_o^2$.]

That said, it turns out that taking the t_1 evaluation at face value leads to less problems than the approximation. We express the angles in terms of $t - t_0$ and $t - t_1$. Numerical noise in t_1 can then be tolerated.

```

<SF aux: splitting data: TBP>+≡
  procedure :: set_t_bounds => splitting_set_t_bounds

<SF aux: procedures>+≡
  elemental subroutine splitting_set_t_bounds (d, x, xb)
    class(splitting_data_t), intent(inout) :: d
    real(default), intent(in), optional :: x, xb
    real(default) :: tp, tm
    if (present (x)) d%x = x
    if (present (xb)) d%xb = xb
    if (d%xb /= 0) then
      d%pb = sqrt (max (d%E**2 - d%u / d%xb**2, 0._default))
    else
      d%pb = 0
    end if
    tp = -2 * d%xb * d%E**2 + d%s + d%u
    tm = -2 * d%xb * d%p * d%pb
    d%t0 = tp + tm
    d%t1 = tp - tm
    d%t = d%t1
  end subroutine splitting_set_t_bounds

```

10.1.3 Sampling recoil

Compute a value for the momentum transfer t , using a random number r . We assume a logarithmic distribution for $t - m^2$, corresponding to the propagator $1/(t - m^2)$ with the physical mass m for the outgoing particle. Optionally, we can narrow the kinematical bounds.

If all three masses in the splitting vanish, the upper limit for t is zero. In that case, the t value is set to zero and the splitting will be collinear.

```

<SF aux: splitting data: TBP>+≡
  procedure :: sample_t => splitting_sample_t

<SF aux: procedures>+≡
  subroutine splitting_sample_t (d, r, t0, t1)
    class(splitting_data_t), intent(inout) :: d
    real(default), intent(in) :: r
    real(default), intent(in), optional :: t0, t1
    real(default) :: tt0, tt1, tt0m, tt1m
    if (d%collinear) then
      d%t = d%t1
    else
      tt0 = d%t0; if (present (t0)) tt0 = max (t0, tt0)
      tt1 = d%t1; if (present (t1)) tt1 = min (t1, tt1)
      tt0m = tt0 - d%m2

```

```

        tt1m = tt1 - d%m2
        if (tt0m < 0 .and. tt1m < 0 .and. abs(tt0m) > &
            epsilon(tt0m) .and. abs(tt1m) > epsilon(tt0m)) then
            d%t = d%m2 + tt0m * exp (r * log (tt1m / tt0m))
        else
            d%t = tt1
        end if
    end if
end subroutine splitting_sample_t

```

The inverse operation: Given t , we recover the value of r that would have produced this value.

```

<SF aux: splitting data: TBP>+≡
    procedure :: inverse_t => splitting_inverse_t
<SF aux: procedures>+≡
    subroutine splitting_inverse_t (d, r, t0, t1)
        class(splitting_data_t), intent(in) :: d
        real(default), intent(out) :: r
        real(default), intent(in), optional :: t0, t1
        real(default) :: tt0, tt1, tt0m, tt1m
        if (d%collinear) then
            r = 0
        else
            tt0 = d%t0; if (present (t0)) tt0 = max (t0, tt0)
            tt1 = d%t1; if (present (t1)) tt1 = min (t1, tt1)
            tt0m = tt0 - d%m2
            tt1m = tt1 - d%m2
            if (tt0m < 0 .and. tt1m < 0) then
                r = log ((d%t - d%m2) / tt0m) / log (tt1m / tt0m)
            else
                r = 0
            end if
        end if
    end subroutine splitting_inverse_t

```

This is trivial, but provided for convenience:

```

<SF aux: splitting data: TBP>+≡
    procedure :: sample_phi => splitting_sample_phi
<SF aux: procedures>+≡
    subroutine splitting_sample_phi (d, r)
        class(splitting_data_t), intent(inout) :: d
        real(default), intent(in) :: r
        if (d%collinear) then
            d%phi = 0
        else
            d%phi = (1-r) * d%phi0 + r * d%phi1
        end if
    end subroutine splitting_sample_phi

```

Inverse:

```

<SF aux: splitting data: TBP>+≡
    procedure :: inverse_phi => splitting_inverse_phi

```

```

<SF aux: procedures>+≡
subroutine splitting_inverse_phi (d, r)
  class(splitting_data_t), intent(in) :: d
  real(default), intent(out) :: r
  if (d%collinear) then
    r = 0
  else
    r = (d%phi - d%phi0) / (d%phi1 - d%phi0)
  end if
end subroutine splitting_inverse_phi

```

10.1.4 Splitting

In this function, we actually perform the splitting. The incoming momentum k is split into (if no recoil) $q_1 = (1 - x)k$ and $q_2 = xk$.

Apart from the splitting data, we need the incoming momentum k , the momentum transfer t , and the azimuthal angle ϕ . The momentum fraction x is already known here.

Alternatively, we can split without recoil. The azimuthal angle is irrelevant, and the momentum transfer is always equal to the upper limit t_1 , so the polar angle is zero. Obviously, if there are nonzero masses it is not possible to keep both energy-momentum conservation and at the same time all particles on shell. We choose for dropping the on-shell condition here.

```

<SF aux: splitting data: TBP>+≡
procedure :: split_momentum => splitting_split_momentum

<SF aux: procedures>+≡
function splitting_split_momentum (d, k) result (q)
  class(splitting_data_t), intent(in) :: d
  type(vector4_t), dimension(2) :: q
  type(vector4_t), intent(in) :: k
  real(default) :: st2, ct2, st, ct, cp, sp
  type(lorentz_transformation_t) :: rot
  real(default) :: tt0, tt1, den
  type(vector3_t) :: kk, q1, q2
  if (d%collinear) then
    if (d%s == 0 .and. d%u == 0) then
      q(1) = d%xb * k
      q(2) = d%x * k
    else
      kk = space_part (k)
      q1 = d%xb * (d%pb / d%p) * kk
      q2 = kk - q1
      q(1) = vector4_moving (d%xb * d%E, q1)
      q(2) = vector4_moving (d%x * d%E, q2)
    end if
  else
    den = 2 * d%xb * d%p * d%pb
    tt0 = max (d%t - d%t0, 0._default)
    tt1 = min (d%t - d%t1, 0._default)
    if (den**2 <= epsilon(den)) then
      st2 = 1
    end if
  end if
end function splitting_split_momentum

```

```

else
  st2 = - (tt0 * tt1) / den ** 2
end if
if (st2 > 1) then
  st2 = 1
end if
ct2 = 1 - st2
st = sqrt (max (st2, 0._default))
ct = sqrt (max (ct2, 0._default))
sp = sin (d%phi)
cp = cos (d%phi)
rot = rotation_to_2nd (3, space_part (k))
q1 = vector3_moving (d%xb * d%pb * [st * cp, st * sp, ct])
q2 = vector3_moving (d%p, 3) - q1
q(1) = rot * vector4_moving (d%xb * d%E, q1)
q(2) = rot * vector4_moving (d%x * d%E, q2)
end if
end function splitting_split_momentum

```

Momenta generated by splitting will in general be off-shell. They are on-shell only if they are collinear and massless. This subroutine puts them on shell by brute force, violating either momentum or energy conservation. The direction of three-momentum is always retained.

If the energy is below mass shell, we return a zero momentum.

```

<SF aux: parameters>≡
  integer, parameter, public :: KEEP_ENERGY = 0, KEEP_MOMENTUM = 1

<SF aux: public>+≡
  public :: on_shell

<SF aux: procedures>+≡
  elemental subroutine on_shell (p, m2, keep)
    type(vector4_t), intent(inout) :: p
    real(default), intent(in) :: m2
    integer, intent(in) :: keep
    real(default) :: E, E2, pn
    select case (keep)
    case (KEEP_ENERGY)
      E = energy (p)
      E2 = E ** 2
      if (E2 >= m2) then
        pn = sqrt (E2 - m2)
        p = vector4_moving (E, pn * direction (space_part (p)))
      else
        p = vector4_null
      end if
    case (KEEP_MOMENTUM)
      E = sqrt (space_part (p) ** 2 + m2)
      p = vector4_moving (E, space_part (p))
    end select
  end subroutine on_shell

```

10.1.5 Recovering the splitting

This is the inverse problem. We have on-shell momenta and want to deduce the splitting parameters x , t , and ϕ .

```

(SF aux: splitting data: TBP)+≡

<SF aux: procedures>+≡
  function splitting_get_x (sd) result (x)
    class(splitting_data_t), intent(in) :: sd
    real(default) :: x
    x = sd%x
  end function splitting_get_x

```

10.1.7 Unit tests

```

<SF aux: public>+≡
  public :: sf_aux_test

<SF aux: tests>≡
  subroutine sf_aux_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <SF aux: execute tests>
  end subroutine sf_aux_test

```

Momentum splitting: massless radiation

Compute momentum splitting for generic kinematics. It turns out that for $x = 0.5$, where $t - m^2$ is the geometric mean between its upper and lower bounds (this can be directly seen from the logarithmic distribution in the function `sample_t` for $r \equiv x = 1 - x = 0.5$), we arrive at an exact number $t = -0.15$ for the given input values.

```

<SF aux: execute tests>≡

```

```

Momentum splitting: massless parton

Compute momentum splitting for generic kinematics. It turns out that for $x = 0.5$, where $t - m^2$ is the geometric mean between its upper and lower bounds, we arrive at an exact number $t = -0.36$ for the given input values.

```

10.2 Mappings for structure functions

In this module, we provide a wrapper for useful mappings of the unit square that we can apply to a pair of structure functions.

In some cases it is useful, or even mandatory, to map the MC input parameters nontrivially onto a pair of structure functions for the two beams. In all cases considered here, instead of x_1 and x_2 as parameters for the beams, we generate one parameter for the product $x_1 x_2$ (so it directly corresponds to \sqrt{s}) and one parameter related to the quotient.

```

  <File header>  
  
  module sf_mappings  
  
    <Use kinds>  
    <Use file utils>  
    use diagnostics !NODEP!  
    use unit_tests  
  
    <Standard module head>  
  
    <SF mappings: public>  
  
    <SF mappings: parameters>  
  
    <SF mappings: types>  
  
    <SF mappings: interfaces>  
  
    contains  
  
    <SF mappings: procedures>  
  
    <SF mappings: tests>  
  
  end module sf_mappings
```

10.2.1 Base type

First, we define an abstract base type for the mapping. In all cases we need to store the indices of the parameters on which the mapping applies. Additional parameters can be stored in the extensions of this type.

```
<SF mappings: public>≡  
  public :: sf_mapping_t  
  
<SF mappings: types>≡  
  type, abstract :: sf_mapping_t  
    integer, dimension(:), allocatable :: i  
    contains  
    <SF mappings: sf mapping: TBP>  
  end type sf_mapping_t
```

The output routine is deferred:

```

<SF mappings: sf mapping: TBP>≡
  procedure (sf_mapping_write), deferred :: write

<SF mappings: interfaces>≡
  abstract interface
    subroutine sf_mapping_write (object, unit)
      import
      class(sf_mapping_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine sf_mapping_write
  end interface

```

Initializer for the base type. The array of parameter indices is allocated but initialized to zero.

```

<SF mappings: sf mapping: TBP>+≡
  procedure :: base_init => sf_mapping_base_init

<SF mappings: procedures>≡
  subroutine sf_mapping_base_init (mapping, n_par)
    class(sf_mapping_t), intent(out) :: mapping
    integer, intent(in) :: n_par
    allocate (mapping%i (n_par))
    mapping%i = 0
  end subroutine sf_mapping_base_init

```

Computation: the values **p** are the input parameters, the values **r** are the output parameters. The Jacobian is **f**. We modify only the two parameters indicated by the indices **i**.

```

<SF mappings: sf mapping: TBP>+≡
  procedure (sf_mapping_compute), deferred :: compute

<SF mappings: interfaces>+≡
  abstract interface
    subroutine sf_mapping_compute (mapping, r, f, p)
      import
      class(sf_mapping_t), intent(in) :: mapping
      real(default), dimension(:), intent(out) :: r
      real(default), intent(out) :: f
      real(default), dimension(:), intent(in) :: p
    end subroutine sf_mapping_compute
  end interface

```

The inverse mapping. Use **r** to reconstruct **p** and also compute **f**.

```

<SF mappings: sf mapping: TBP>+≡
  procedure (sf_mapping_inverse), deferred :: inverse

<SF mappings: interfaces>+≡
  abstract interface
    subroutine sf_mapping_inverse (mapping, r, f, p)
      import
      class(sf_mapping_t), intent(in) :: mapping
      real(default), dimension(:), intent(in) :: r
      real(default), intent(out) :: f
    end subroutine sf_mapping_inverse
  end interface

```

```

        real(default), dimension(:), intent(out) :: p
    end subroutine sf_mapping_inverse
end interface

```

10.2.2 Integral

This is a consistency check for the self-tests: the integral over the unit square should be unity. We estimate this by a simple binning and adding up the values; this should be sufficient for a self-test.

The argument is the requested number of sampling points. We take the square root for binning in both dimensions, so the precise number might be different.

```

<SF mappings: sf mapping: TBP>+≡
    procedure :: integral => sf_mapping_integral

<SF mappings: procedures>+≡
    function sf_mapping_integral (mapping, n_calls) result (integral)
        class(sf_mapping_t), intent(in) :: mapping
        integer, intent(in) :: n_calls
        real(default) :: integral
        integer :: n_bin, i, j
        real(default), dimension(2) :: p, r
        real(default) :: dx, f, s
        n_bin = nint (sqrt (real (n_calls)))
        dx = 1._default / n_bin
        s = 0
        do i = 1, n_bin
            p(1) = i * dx - dx/2
            do j = 1, n_bin
                p(2) = j * dx - dx/2
                call mapping%compute (r, f, p)
                s = s + f
            end do
        end do
        integral = s / n_bin / n_bin
    end function sf_mapping_integral

```

10.2.3 Implementation: standard mapping

This maps the unit square (r_1, r_2) such that p_1 is the product $r_1 r_2$, while p_2 is related to the ratio.

```

<SF mappings: public>+≡
    public :: sf_s_mapping_t

<SF mappings: types>+≡
    type, extends (sf_mapping_t) :: sf_s_mapping_t
        logical :: power_set = .false.
        real(default) :: power = 1._default
    contains
        <SF mappings: sf standard mapping: TBP>
    end type sf_s_mapping_t

```

Output.

```
<SF mappings: sf standard mapping: TBP>≡
  procedure :: write => sf_s_mapping_write

<SF mappings: procedures>+≡
  subroutine sf_s_mapping_write (object, unit)
    class(sf_s_mapping_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = output_unit (unit)
    write (u, "(1x,A)", advance="no") "map"
    if (any (object%i /= 0)) then
      write (u, "('(',IO,',',IO,')')", advance="no") object%i
    end if
    write (u, "(A,F7.5,A)" ": standard (" , object%power, ")")
  end subroutine sf_s_mapping_write
```

Initialize: index pair and power parameter.

```
<SF mappings: sf standard mapping: TBP>+≡
  procedure :: init => sf_s_mapping_init

<SF mappings: procedures>+≡
  subroutine sf_s_mapping_init (mapping, power)
    class(sf_s_mapping_t), intent(out) :: mapping
    real(default), intent(in), optional :: power
    call mapping%base_init (2)
    if (present (power)) then
      mapping%power_set = .true.
      mapping%power = power
    end if
  end subroutine sf_s_mapping_init
```

Apply mapping.

```
<SF mappings: sf standard mapping: TBP>+≡
  procedure :: compute => sf_s_mapping_compute

<SF mappings: procedures>+≡
  subroutine sf_s_mapping_compute (mapping, r, f, p)
    class(sf_s_mapping_t), intent(in) :: mapping
    real(default), dimension(:), intent(out) :: r
    real(default), intent(out) :: f
    real(default), dimension(:), intent(in) :: p
    real(default), dimension(2) :: r2
    integer :: j
    if (mapping%power_set) then
      call map_unit_square (r2, f, p(mapping%i), mapping%power)
    else
      call map_unit_square (r2, f, p(mapping%i))
    end if
    do j = 1, 2
      r(mapping%i(j)) = r2(j)
    end do
  end subroutine sf_s_mapping_compute
```

Apply inverse.

```

<SF mappings: sf standard mapping: TBP>+≡
  procedure :: inverse => sf_s_mapping_inverse

<SF mappings: procedures>+≡
  subroutine sf_s_mapping_inverse (mapping, r, f, p)
    class(sf_s_mapping_t), intent(in) :: mapping
    real(default), dimension(:), intent(in) :: r
    real(default), intent(out) :: f
    real(default), dimension(:), intent(out) :: p
    real(default), dimension(2) :: p2
    integer :: j
    if (mapping%power_set) then
      call map_unit_square_inverse (r(mapping%i), f, p2, mapping%power)
    else
      call map_unit_square_inverse (r(mapping%i), f, p2)
    end if
    do j = 1, 2
      p(mapping%i(j)) = p2(j)
    end do
  end subroutine sf_s_mapping_inverse

```

10.2.4 Basic formulas

This mapping of the unit square is appropriate in particular for structure functions which are concentrated at the lower end. Instead of a rectangular grid, one set of grid lines corresponds to constant parton c.m. energy. The other set is chosen such that the jacobian is only mildly singular ($\ln x$ which is zero at $x = 1$), corresponding to an initial concentration of sampling points at the maximum energy. If **power** is greater than one (the default), points are also concentrated at the lower end.

The formula is (**power**= α):

$$r_1 = (p_1^{p_2})^\alpha \quad (10.15)$$

$$r_2 = (p_1^{1-p_2})^\alpha \quad (10.16)$$

$$f = \alpha^2 p_1^{\alpha-1} |\log p_1| \quad (10.17)$$

and for the default case $\alpha = 1$:

$$r_1 = p_1^{p_2} \quad (10.18)$$

$$r_2 = p_1^{1-p_2} \quad (10.19)$$

$$f = |\log p_1| \quad (10.20)$$

```

<SF mappings: procedures>+≡
  subroutine map_unit_square (r, factor, p, power)
    real(default), dimension(2), intent(out) :: r
    real(default), intent(out) :: factor
    real(default), dimension(2), intent(in) :: p
    real(default), intent(in), optional :: power
    real(default) :: xx, yy
    factor = 1

```

```

xx = p(1)
yy = p(2)
if (present(power)) then
  if (p(1) > 0 .and. power > 1) then
    xx = p(1)**power
    factor = factor * power * xx / p(1)
  end if
end if
if (xx /= 0) then
  r(1) = xx ** yy
  r(2) = xx / r(1)
  factor = factor * abs (log (xx))
else
  r = 0
end if
end subroutine map_unit_square

```

This is the inverse mapping.

(SF mappings: procedures)+≡

```

subroutine map_unit_square_inverse (r, factor, p, power)
  real(kind=default), dimension(2), intent(in) :: r
  real(kind=default), intent(out) :: factor
  real(kind=default), dimension(2), intent(out) :: p
  real(kind=default), intent(in), optional :: power
  real(kind=default) :: lg, xx, yy
  factor = 1
  xx = r(1) * r(2)
  if (xx /= 0) then
    lg = log (xx)
    yy = log (r(1)) / lg
    p(2) = yy
    factor = factor * abs (lg)
    if (present(power)) then
      p(1) = xx**(1._default/power)
      factor = factor * power * xx / p(1)
    else
      p(1) = xx
    end if
  else
    p = 0
  end if
end subroutine map_unit_square_inverse

```

Structure-function channels

A structure-function chain parameterization (channel) may contain a mapping that applies to multiple structure functions. This is described by an extension of the `sf_mapping_t` type. In addition, it may contain mappings that apply to (other) individual structure functions. The details of these mappings are implementation-specific.

The `sf_channel_t` type combines this information. It contains an array of map codes, one for each structure-function entry. The code values are:

none MC input parameters r directly become energy fractions x

single default mapping for a single structure-function entry

multi/s map $r \rightarrow x$ such that one MC input parameter is \hat{s}/s

multi/resonance as before, adapted to s-channel resonance (not implemented yet)

multi/on-shell as before, adapted to an on-shell particle in the s channel (not implemented yet)

```

⟨SF mappings: parameters⟩≡
  integer, parameter :: SFMAP_NONE = 0
  integer, parameter :: SFMAP_SINGLE = 1
  integer, parameter :: SFMAP_MULTI_S = 2
  integer, parameter :: SFMAP_MULTI_RES = 3
  integer, parameter :: SFMAP_MULTI_ONS = 4

```

Then, it contains an allocatable entry for the multi mapping. This entry holds the MC-parameter indices on which the mapping applies (there may be more than one MC parameter per structure-function entry) and any parameters associated with the mapping.

There can be only one multi-mapping per channel.

```

⟨SF mappings: public⟩+≡
  public :: sf_channel_t

⟨SF mappings: types⟩+≡
  type :: sf_channel_t
    integer, dimension(:), allocatable :: map_code
    class(sf_mapping_t), allocatable :: multi_mapping
    contains
    ⟨SF mappings: sf channel: TBP⟩
  end type sf_channel_t

```

The output format prints a single character for each structure-function entry and, if applicable, an account of the mapping parameters.

```

⟨SF mappings: sf channel: TBP⟩≡
  procedure :: write => sf_channel_write

⟨SF mappings: procedures⟩+≡
  subroutine sf_channel_write (object, unit)
    class(sf_channel_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = output_unit (unit)
    if (allocated (object%map_code)) then
      do i = 1, size (object%map_code)
        select case (object%map_code (i))
          case (SFMAP_NONE)
            write (u, "(1x,A)", advance="no") "-"

```

```

        case (SFMAP_SINGLE)
            write (u, "(1x,A)", advance="no") "+"
        case (SFMAP_MULTI_S)
            write (u, "(1x,A)", advance="no") "s"
        case (SFMAP_MULTI_RES)
            write (u, "(1x,A)", advance="no") "r"
        case (SFMAP_MULTI_ONS)
            write (u, "(1x,A)", advance="no") "o"
        end select
    end do
else
    write (u, "(1x,A)", advance="no") "-"
end if
if (allocated (object%multi_mapping)) then
    write (u, "(1x, '/')", advance="no")
    call object%multi_mapping%write (u)
else
    write (u, *)
end if
end subroutine sf_channel_write

```

Initializer for a single `sf_channel` object.

```

<SF mappings: sf channel: TBP>+≡
    procedure :: init => sf_channel_init

<SF mappings: procedures>+≡
    subroutine sf_channel_init (channel, n_strfun)
        class(sf_channel_t), intent(out) :: channel
        integer, intent(in) :: n_strfun
        allocate (channel%map_code (n_strfun))
        channel%map_code = SFMAP_NONE
    end subroutine sf_channel_init

```

Assignment. This merely copies intrinsic assignment, but apparently the latter is bugged in gfortran 4.6.3, causing memory corruption.

```

<SF mappings: sf channel: TBP>+≡
    generic :: assignment (=) => sf_channel_assign
    procedure :: sf_channel_assign

<SF mappings: procedures>+≡
    subroutine sf_channel_assign (copy, original)
        class(sf_channel_t), intent(out) :: copy
        type(sf_channel_t), intent(in) :: original
        allocate (copy%map_code (size (original%map_code)))
        copy%map_code = original%map_code
        if (allocated (original%multi_mapping)) then
            allocate (copy%multi_mapping, source = original%multi_mapping)
        end if
    end subroutine sf_channel_assign

```

This initializer allocates an array of channels with common number of structure-function entries, therefore it is not a type-bound procedure.

```

<SF mappings: public>+≡
    public :: allocate_sf_channels

```

```

<SF mappings: procedures>+≡
subroutine allocate_sf_channels (channel, n_channel, n_strfun)
  type(sf_channel_t), dimension(:), intent(out), allocatable :: channel
  integer, intent(in) :: n_channel
  integer, intent(in) :: n_strfun
  integer :: c
  allocate (channel (n_channel))
  do c = 1, n_channel
    call channel(c)%init (n_strfun)
  end do
end subroutine allocate_sf_channels

```

This marks a given subset of indices as single-mapping.

```

<SF mappings: sf channel: TBP>+≡
  procedure :: activate_mapping => sf_channel_activate_mapping

<SF mappings: procedures>+≡
subroutine sf_channel_activate_mapping (channel, i_sf)
  class(sf_channel_t), intent(inout) :: channel
  integer, dimension(:), intent(in) :: i_sf
  channel%map_code(i_sf) = SFMAP_SINGLE
end subroutine sf_channel_activate_mapping

```

This sets an s-channel multichannel mapping. The length of the `i_sf` array must be 2. The parameter indices are not yet set.

```

<SF mappings: sf channel: TBP>+≡
  procedure :: set_s_mapping => sf_channel_set_s_mapping

<SF mappings: procedures>+≡
subroutine sf_channel_set_s_mapping (channel, i_sf, power)
  class(sf_channel_t), intent(inout) :: channel
  integer, dimension(:), intent(in) :: i_sf
  real(default), intent(in), optional :: power
  channel%map_code(i_sf) = SFMAP_MULTI_S
  allocate (sf_s_mapping_t :: channel%multi_mapping)
  select type (mapping => channel%multi_mapping)
    type is (sf_s_mapping_t)
      call mapping%init (power)
    end select
end subroutine sf_channel_set_s_mapping

```

Return true if the mapping code at position `i_sf` is `SFMAP_SINGLE`.

```

<SF mappings: sf channel: TBP>+≡
  procedure :: is_single_mapping => sf_channel_is_single_mapping

<SF mappings: procedures>+≡
function sf_channel_is_single_mapping (channel, i_sf) result (flag)
  class(sf_channel_t), intent(in) :: channel
  integer, intent(in) :: i_sf
  logical :: flag
  flag = channel%map_code(i_sf) == SFMAP_SINGLE
end function sf_channel_is_single_mapping

```

Return true if the mapping code at position `i_sf` is any of the `SFMAP_MULTI` mappings.

```

<SF mappings: sf channel: TBP>+≡
  procedure :: is_multi_mapping => sf_channel_is_multi_mapping

<SF mappings: procedures>+≡
  function sf_channel_is_multi_mapping (channel, i_sf) result (flag)
    class(sf_channel_t), intent(in) :: channel
    integer, intent(in) :: i_sf
    logical :: flag
    select case (channel%map_code(i_sf))
    case (SFMAP_NONE, SFMAP_SINGLE)
      flag = .false.
    case default
      flag = .true.
    end select
  end function sf_channel_is_multi_mapping

```

Return true if there is any nontrivial mapping in any of the channels.

Note: we provide an explicit public function. gfortran 4.6.3 has problems with the alternative implementation as a type-bound procedure for an array base object.

```

<SF mappings: public>+≡
  public :: any_sf_channel_has_mapping

<SF mappings: procedures>+≡
  function any_sf_channel_has_mapping (channel) result (flag)
    type(sf_channel_t), dimension(:), intent(in) :: channel
    logical :: flag
    integer :: c
    flag = .false.
    do c = 1, size (channel)
      flag = flag .or. any (channel(c)%map_code /= SFMAP_NONE)
    end do
  end function any_sf_channel_has_mapping

```

Set a parameter index for an active multi mapping. We assume that the index array is allocated properly.

```

<SF mappings: sf channel: TBP>+≡
  procedure :: set_par_index => sf_channel_set_par_index

<SF mappings: procedures>+≡
  subroutine sf_channel_set_par_index (channel, j, i_par)
    class(sf_channel_t), intent(inout) :: channel
    integer, intent(in) :: j
    integer, intent(in) :: i_par
    channel%multi_mapping%i(j) = i_par
  end subroutine sf_channel_set_par_index

```

10.2.5 Unit tests

```

<SF mappings: public>+≡
  public :: sf_mappings_test

```

```

<SF mappings: tests>≡
  subroutine sf_mappings_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <SF mappings: execute tests>
  end subroutine sf_mappings_test

```

Check standard mapping

Probe the standard mapping of the unit square for different parameter values. Also calculates integrals. For a finite number of bins, they differ slightly from 1, but the result is well-defined because we are not using random points.

```

<SF mappings: execute tests>≡
  call test (sf_mappings_1, "sf_mappings_1", &
    "standard pair mapping", &
    u, results)

<SF mappings: tests>+≡
  subroutine sf_mappings_1 (u)
    integer, intent(in) :: u
    class(sf_mapping_t), allocatable :: mapping
    real(default), dimension(2) :: p, r
    real(default) :: f

10.3.1 Abstract structure-function data type

This type should hold all configuration data for a specific type of structure function. The base object is empty; the implementations will fill it.

⟨SF base: public⟩≡

```
public :: sf_data_t
```

⟨SF base: types⟩≡

```
type, abstract :: sf_data_t
```

```
contains
```

⟨SF base: sf data: TBP⟩

```
end type sf_data_t
```

Output.

⟨SF base: sf data: TBP⟩≡

```
procedure (sf_data_write), deferred :: write
```

⟨SF base: interfaces⟩≡

```
abstract interface
```

```
subroutine sf_data_write (data, unit, verbose)
```

```

import
class(sf_data_t), intent(in) :: data
integer, intent(in), optional :: unit
logical, intent(in), optional :: verbose
end subroutine sf_data_write
end interface

```

Return the number of input parameters that determine the structure function.

```

⟨SF base: sf data: TBP⟩+≡
  procedure (sf_data_get_int), deferred :: get_n_par

⟨SF base: interfaces⟩+≡
  abstract interface
    function sf_data_get_int (data) result (n)
      import
      class(sf_data_t), intent(in) :: data
      integer :: n
    end function sf_data_get_int
  end interface

```

Return the outgoing particle PDG codes for the current setup.

```

⟨SF base: sf data: TBP⟩+≡
  procedure (sf_data_get_pdg_out), deferred :: get_pdg_out

⟨SF base: interfaces⟩+≡
  abstract interface
    function sf_data_get_pdg_out (data) result (pdg_out)
      import
      class(sf_data_t), intent(in) :: data
      integer, dimension(:), allocatable :: pdg_out
    end function sf_data_get_pdg_out
  end interface

```

Allocate a matching structure function interaction object and properly initialize it.

Note: We should insist on `intent(out)` for the second argument, but gfortran 4.6.3 does not like it. In any case, the interaction should enter this deallocated.

```

⟨SF base: sf data: TBP⟩+≡
  procedure (sf_data_allocate_sf_int), deferred :: allocate_sf_int

⟨SF base: interfaces⟩+≡
  abstract interface
    subroutine sf_data_allocate_sf_int (data, sf_int)
      import
      class(sf_data_t), intent(in) :: data
      class(sf_int_t), intent(inout), allocatable :: sf_int
    end subroutine sf_data_allocate_sf_int
  end interface

```

10.3.2 Structure-function chain configuration

This is the data type that the `processes` module uses for setting up its structure-function chain. For each structure function described by the beam data, there is an entry. The `i` array indicates the beam(s) to which this structure function applies, and the `data` object contains the actual configuration data.

```

<SF base: public>+=
    public :: sf_config_t
<SF base: types>+=
    type :: sf_config_t
        integer, dimension(:), allocatable :: i
        class(sf_data_t), allocatable :: data
    contains
        <SF base: sf config: TBP>
    end type sf_config_t

```

Output:

```

<SF base: sf config: TBP>=
    procedure :: write => sf_config_write
<SF base: procedures>=
    subroutine sf_config_write (object, unit)
        class(sf_config_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = output_unit (unit)
        if (allocated (object%i)) then
            write (u, "(1x,A,2(1x,I0))") "Structure-function configuration: &
                &beam(s)", object%i
            if (allocated (object%data)) call object%data%write (u)
        else
            write (u, "(1x,A)") "Structure-function configuration: [undefined]"
        end if
    end subroutine sf_config_write

```

Initialize.

```

<SF base: sf config: TBP>+=
    procedure :: init => sf_config_init
<SF base: procedures>+=
    subroutine sf_config_init (sf_config, i_beam, sf_data)
        class(sf_config_t), intent(out) :: sf_config
        integer, dimension(:), intent(in) :: i_beam
        class(sf_data_t), intent(in) :: sf_data
        allocate (sf_config%i (size (i_beam)), source = i_beam)
        allocate (sf_config%data, source = sf_data)
    end subroutine sf_config_init

```

10.3.3 Structure-function instance

The `sf_int_t` data type contains an `interaction_t` object (it is an extension of this type) and a pointer to the `sf_data_t` configuration data. This interaction,

or copies of it, is used to implement structure-function kinematics and dynamics in the context of process evaluation.

The status code `status` tells whether the interaction is undefined, has defined kinematics (but matrix elements invalid), or is completely defined. There is also a status code for failure. The implementation is responsible for updating the status.

The entries `mi2`, `mr2`, and `mo2` hold the squared invariant masses of the incoming, radiated, and outgoing particle, respectively. They are supposed to be set upon initialization, but could also be varied event by event.

If the radiated or outgoing mass is nonzero, we may need to apply an on-shell projection. The projection mode is stored as `on_shell_mode`.

The array `beam_index` is the list of beams on which this structure function applies (1, 2, or both). The arrays `incoming`, `radiated`, and `outgoing` contain the indices of the respective particle sets within the interaction, for convenient lookup. The array `par_index` indicates the MC input parameters that this entry will use up in the structure-function chain.

In the abstract base type, we do not implement the data pointer. This allows us to restrict its type in the implementations.

```

<SF base: public>+≡
  public :: sf_int_t

<SF base: types>+≡
  type, abstract, extends (interaction_t) :: sf_int_t
    integer :: status = SF_UNDEFINED
    real(default), dimension(:), allocatable :: mi2
    real(default), dimension(:), allocatable :: mr2
    real(default), dimension(:), allocatable :: mo2
    integer :: on_shell_mode = KEEP_ENERGY
    logical :: qmin_defined = .false.
    logical :: qmax_defined = .false.
    real(default), dimension(:), allocatable :: qmin
    real(default), dimension(:), allocatable :: qmax
    integer, dimension(:), allocatable :: beam_index
    integer, dimension(:), allocatable :: incoming
    integer, dimension(:), allocatable :: radiated
    integer, dimension(:), allocatable :: outgoing
    integer, dimension(:), allocatable :: par_index
  contains
    <SF base: sf_int: TBP>
  end type sf_int_t

```

Status codes. The codes that refer to links, masks, and connections, apply to structure-function chains only.

The status codes are public.

```

<SF base: parameters>≡
  integer, parameter, public :: SF_UNDEFINED = 0
  integer, parameter, public :: SF_INITIAL = 1
  integer, parameter, public :: SF_DONE_LINKS = 2
  integer, parameter, public :: SF_FAILED_MASK = 3
  integer, parameter, public :: SF_DONE_MASK = 4
  integer, parameter, public :: SF_FAILED_CONNECTIONS = 5
  integer, parameter, public :: SF_DONE_CONNECTIONS = 6

```

```

integer, parameter, public :: SF_SEED_KINEMATICS = 10
integer, parameter, public :: SF_FAILED_KINEMATICS = 11
integer, parameter, public :: SF_DONE_KINEMATICS = 12
integer, parameter, public :: SF_FAILED_EVALUATION = 13
integer, parameter, public :: SF_EVALUATED = 20

```

Write a string version of the status code:

```

⟨SF base: procedures⟩+≡
  subroutine write_sf_status (status, u)
    integer, intent(in) :: status
    integer, intent(in) :: u
    select case (status)
    case (SF_UNDEFINED)
      write (u, "(1x,'[,A,']')") "undefined"
    case (SF_INITIAL)
      write (u, "(1x,'[,A,']')") "initialized"
    case (SF_DONE_LINKS)
      write (u, "(1x,'[,A,']')") "links set"
    case (SF_FAILED_MASK)
      write (u, "(1x,'[,A,']')") "mask mismatch"
    case (SF_DONE_MASK)
      write (u, "(1x,'[,A,']')") "mask set"
    case (SF_FAILED_CONNECTIONS)
      write (u, "(1x,'[,A,']')") "connections failed"
    case (SF_DONE_CONNECTIONS)
      write (u, "(1x,'[,A,']')") "connections set"
    case (SF_SEED_KINEMATICS)
      write (u, "(1x,'[,A,']')") "incoming momenta set"
    case (SF_FAILED_KINEMATICS)
      write (u, "(1x,'[,A,']')") "kinematics failed"
    case (SF_DONE_KINEMATICS)
      write (u, "(1x,'[,A,']')") "kinematics set"
    case (SF_FAILED_EVALUATION)
      write (u, "(1x,'[,A,']')") "evaluation failed"
    case (SF_EVALUATED)
      write (u, "(1x,'[,A,']')") "evaluated"
    end select
  end subroutine write_sf_status

```

Finalizer. Required because the base interaction needs a finalizer. We provide an implementation, which need not be overwritten if the implementation does not add finalizable subobjects.

```

⟨SF base: sf int: TBP⟩≡
  procedure :: final => sf_int_final

⟨SF base: procedures⟩+≡
  subroutine sf_int_final (object)
    class(sf_int_t), intent(inout) :: object
    call interaction_final (object%interaction_t)
  end subroutine sf_int_final

```

This is the basic output routine. Display status and interaction.

```

⟨SF base: sf int: TBP⟩+≡

```

```

    procedure :: base_write => sf_int_base_write
<SF base: procedures>+≡

            write (u, "(3x,A,1x,ES19.12)") "q_min      =", object%qmin
        if (object%qmax_defined) &
            write (u, "(3x,A,1x,ES19.12)") "q_max      =", object%qmax
        call interaction_write (object%interaction_t, u)
    end subroutine sf_int_base_write

```

The type string identifies the structure function class, and possibly more details about the structure function.

```

<SF base: sf_int: TBP>+≡
    procedure (sf_int_type_string), deferred :: type_string
<SF base: interfaces>+≡
    abstract interface
        function sf_int_type_string (object) result (string)
            import
            class(sf_int_t), intent(in) :: object
            type(string_t) :: string
        end function sf_int_type_string
    end interface

```

Output of the concrete object. We should not forget to call the output routine for the base type.

```

<SF base: sf_int: TBP>+≡
    procedure (sf_int_write), deferred :: write
<SF base: interfaces>+≡
    abstract interface
        subroutine sf_int_write (object, unit)
            import
            class(sf_int_t), intent(in) :: object
            integer, intent(in), optional :: unit
        end subroutine sf_int_write
    end interface

```

Basic initialization: set the invariant masses for the particles and initialize the interaction. The caller should then add states to the interaction and freeze it.

The dimension of the mask should be equal to the sum of the dimensions of the mass-squared arrays, which determine incoming, radiated, and outgoing particles, respectively.

Optionally, we can define minimum and maximum values for the momentum transfer to the outgoing particle(s). If all masses are zero, this is actually required for non-collinear splitting.

```

<SF base: sf_int: TBP>+≡
  procedure :: base_init => sf_int_base_init

  allocate (sf_int%outgoing (size (outgoing)))
  sf_int%outgoing = outgoing
end subroutine sf_int_set_outgoing

```

Initialization. This proceeds via an abstract data object, which for the actual implementation should have the matching concrete type. Since all implementations have the same signature, we can prepare a deferred procedure. The data object will become the target of a corresponding pointer within the `sf_int_t` implementation.

This should call the previous procedure.

```

⟨SF base: sf_int: TBP⟩+≡
  procedure (sf_int_init), deferred :: init

⟨SF base: interfaces⟩+≡
  abstract interface
    subroutine sf_int_init (sf_int, data)

            end if
        end if
    end subroutine sf_int_seed_energies

```

Complete the structure-function kinematics, derived from an input parameter (array) r between 0 and 1. The interaction momenta are calculated, and we return x (the momentum fraction), and f (the Jacobian factor for the map $r \rightarrow x$), if `map` is set.

If the `map` flag is unset, r and x values will coincide, and f will become unity. If it is set, the structure-function implementation chooses a convenient mapping from r to x with Jacobian f .

In the `inverse_kinematics` variant, we exchange the intent of `x` and `r`. The momenta are calculated only if the optional flag `set_momenta` is present and set.

```

```

Single splitting: compute momenta, given x input parameters. We assume that the incoming momentum is set. The status code is set to `SF_FAILED_KINEMATICS` if the x array does not correspond to a valid momentum configuration. Otherwise, it is updated to `SF_DONE_KINEMATICS`.

We force the outgoing particle on-shell. The on-shell projection is determined by the `on_shell_mode`. The radiated particle should already be on shell.

```

The inverse procedure: we compute the x array from the momentum configuration.

NOTE: Here and above, the single-particle case is treated in detail, allowing for non-collinearity and non-vanishing masses and nontrivial momentum-transfer bounds. For the pair case, we currently implement only collinear splitting and assume massless particles. This should be improved.

Apply the structure function, i.e., evaluate the interaction. For the calculation, we may use the stored momenta, any further information stored inside the `sf_int` implementation during kinematics setup, and the given energy scale. It may happen that for the given kinematics the value is not defined. This should be indicated by the status code.

(SF base: sf_int: TBP)+≡

```

        value = value_array(i_state)
    else
        value = 0
    end if
end subroutine sf_int_compute_value

```

10.3.6 Structure-function instance

This is a wrapper for `sf_int_t` objects, such that we can build an array with different structure-function types. The structure-function contains an array (a sequence) of `sf_int_t` objects.

The object, it holds the evaluator that connects the preceding part of the structure-function chain to the current interaction.

It also stores the input and output parameter values for the contained structure function. The `r` array has a second dimension, corresponding to the mapping channels in a multi-channel configuration. There is a Jacobian entry `f` for each channel. The corresponding logical array `mapping` tells whether we apply the mapping appropriate for the current structure function in this channel. The `x` parameter values (energy fractions) are common to all channels.

(SF base: types)+≡

```

    type :: sf_instance_t
        class(sf_int_t), allocatable :: int
        type(evaluator_t) :: eval
        real(default), dimension(:, :), allocatable :: r
        real(default), dimension(:), allocatable :: f

```

```

        logical, dimension(:), allocatable :: m
        real(default), dimension(:), allocatable :: x
    end type sf_instance_t

```

10.3.7 Structure-function chain

A chain is an array of structure functions `sf`, initiated by a beam setup. We do not use this directly for evaluation, but create instances with copies of the contained interactions.

`n_par` is the total number of MC input parameters that is necessary for completely determining the structure-function chain.

```

<SF base: public>+≡
    public :: sf_chain_t

<SF base: types>+≡
    type, extends (beam_t) :: sf_chain_t
        type(beam_data_t), pointer :: beam_data => null ()
        integer :: n_in = 0
        integer :: n_strfun = 0
        integer :: n_par = 0
        type(sf_instance_t), dimension(:), allocatable :: sf
    contains
        <SF base: sf chain: TBP>
    end type sf_chain_t

```

Finalizer.

```

<SF base: sf chain: TBP>≡
    procedure :: final => sf_chain_final

      end do
    end if
  else
    write (u, "(3x,A)") "[undefined]"
  end if
end subroutine sf_chain_write

```

Initialize: setup beams. The `beam_data` target must remain valid for the lifetime of the chain, since we just establish a pointer. The structure-function configuration array is used to initialize the individual structure-function entries. The target attribute is needed because the `sf_int` entries establish pointers to the configuration data.

  end subroutine write_separator_double

```

10.3.9 Chain instances

A structure-function chain instance contains copies of the interactions in the configuration chain, suitably linked to each other and connected by evaluators.

After initialization, `out_sf` should point, for each beam, to the last structure function that affects this beam. `out_sf_i` should indicate the index of the corresponding outgoing particle within that structure-function interaction.

Analogously, `out_eval` is the last evaluator in the structure-function chain, which contains the complete set of outgoing particles. `out_eval_i` should indicate the index of the outgoing particles, within that evaluator, which will initiate the collision.

When calculating actual kinematics, we fill the `p`, `r`, and `x` arrays and the `f` factor. The `p` array denotes the MC input parameters as they come from the random-number generator. The `r` array results from applying global mappings.

The **x** array results from applying structure-function local mappings. The *x* values can be interpreted directly as momentum fractions (or angle fractions, where recoil is involved). The **f** factor is the Jacobian that results from applying all mappings.

The **mapping** entry may store a global mapping that is applied to a combination of *x* values and structure functions, as opposed to mappings that affect only a single structure function. It is applied before the latter mappings, in the transformation from the **p** array to the **r** array. For parameters affected by this mapping, we should ensure that they are not involved in a local mapping.

```

Initialize. This creates a copy of the interactions in the configuration chain, assumed to be properly initialized. In the copy, we allocate the `p` etc. arrays.

The brute-force assignment of the `sf` component would be straightforward, but at least gfortran 4.6.3 would like a more fine-grained copy. In any case, the copy is deep as far as allocatables are concerned, but for the contained `interaction_t` objects the copy is shallow, as long as we do not bind defined assignment to the type. Therefore, we have to re-assign the `interaction_t` components explicitly, this time calling the proper defined assignment. Furthermore, we allocate the parameter arrays for each structure function.

```

Copy a channel-mapping object to the structure-function chain instance. We assume that assignment is sufficient, i.e., any non-static components of the `channel` object are allocatable und thus recursively copied.

After the copy, we extract the single-entry mappings and activate them for the individual structure functions. If there is a multi-entry mapping, we obtain the corresponding MC parameter indices and set them in the copy of the channel object.

```

<SF base: sf chain instance: TBP>+≡

end subroutine sf_chain_instance_set_channel

```

Link the interactions in the chain. First, link the beam instance to its template in the configuration chain, which should have the appropriate momenta fixed.

Then, we follow the chain via the arrays `out_sf` and `out_sf_i`. The arrays are (up to) two-dimensional, the entries correspond to the beam particle(s). For each beam, the entry `out_sf` points to the last interaction that affected this beam, and `out_sf_i` is the out-particle index within that interaction. For the initial beam, `out_sf` is zero by definition.

For each entry in the chain, we scan the affected beams (one or two). We look for `out_sf` and link the out-particle there to the corresponding in-particle in the current interaction. Then, we update the entry in `out_sf` and `out_sf_i` to point to the current interaction.

      chain%status = SF_DONE_CONNECTIONS
    end if
  contains
    <SF base: init evaluators: find outgoing particles>
    end subroutine sf_chain_instance_init_evaluators

```

This is an internal subroutine of the previous one: After evaluators are set, trace the outgoing particles to the last evaluator. We only need the first channel, all channels are equivalent for this purpose.

For each beam, the outgoing particle is located by `out_sf` (the structure-function object where it originates) and `out_sf_i` (the index within that object). This particle is referenced by the corresponding evaluator, which in turn is referenced by the next evaluator, until we are at the end of the chain. We can trace back references by `interaction_find_link`. Knowing that `out_eval` is the index of the last evaluator, we thus determine `out_eval_i`, the index of the outgoing particle within that evaluator.

```

<SF base: init evaluators: find outgoing particles>≡
  subroutine find_outgoing_particles ()

    int => int_next
  end do
  chain%out_eval_i(j) = out_i
end do
end subroutine find_outgoing_particles

```

Compute the kinematics in the chain instance. We can assume that the seed momenta are set in the configuration beams. Scanning the chain, we first transfer the incoming momenta. Then, the use up the MC input parameter array *p* to compute the radiated and outgoing momenta.

In the multi-channel case, *c_sel* is the channel which we use for computing the kinematics and the *x* values. In the other channels, we invert the kinematics in order to recover the corresponding rows in the *r* array, and the Jacobian *f*.

We first apply any global mapping to transform the input *p* into the array *r*. This is then given to the structure functions which compute the final array *x* and Jacobian factors *f*, which we multiply to obtain the overall Jacobian.

This is a variant of the previous procedure. We know the x parameters and reconstruct the momenta and the MC input parameters p . We do not need to

select a channel.

Note: this is probably redundant, since the method we actually want starts from the momenta, recovers all x parameters, and then inverts mappings. See below `recover_kinematics`.

```

```

    end if
end subroutine sf_chain_instance_inverse_kinematics

```

Recover the kinematics: assuming that the last evaluator has been filled with a valid set of momenta, we travel the momentum links backwards and fill the preceding evaluators and, as a side effect, interactions. We stop at the beam interaction.

After all momenta are set, apply the `inverse_kinematics` procedure above, suitably modified, to recover the x and p parameters and the Jacobian factors.

The `c_sel` (channel) argument is just used to mark a selected channel for the records, otherwise the recovery procedure is independent of this.

10.3.13 Test implementation: pair spectrum

Another template, this time for a incoming particle pair, splitting into two radiated and two outgoing particles.

Configuration data

For simplicity, the spectrum contains two mirror images of the previous structure-function configuration: the incoming and all outgoing particles are test scalars.

We have two versions, one with radiated particles, one without.

```
<SF base: test types>+≡
  type, extends (sf_data_t) :: sf_test_spectrum_data_t
    type(model_t), pointer :: model => null ()
    type(flavor_t) :: flv_in
    type(flavor_t) :: flv_out
    type(flavor_t) :: flv_rad
    logical :: with_radiation = .true.
    real(default) :: m = 0
  contains
    <SF base: sf test spectrum data: TBP>
  end type sf_test_spectrum_data_t
```

Output.

```
<SF base: sf test spectrum data: TBP>≡
  procedure :: write => sf_test_spectrum_data_write

<SF base: procedures>+≡
  subroutine sf_test_spectrum_data_write (data, unit, verbose)

Structure function instance configuration

We create a structure-function chain instance which implements a configured structure-function chain. We link the momentum entries in the interactions and compute kinematics.

We do not actually connect the interactions and create evaluators. We skip this step and manually advance the status of the chain instead.

```

Structure function chain evaluation

Here, we test the complete workflow for structure-function chains. First, we create the template chain, then initialize an instance. We set up links, mask, and evaluators. Finally, we set kinematics and evaluate the matrix elements and their products.

```

10.4.1 Physics

The ISR structure function is in the most crude approximation (LLA without α corrections, i.e. ϵ^0)

$$f_0(x) = \epsilon(1-x)^{-1+\epsilon} \quad \text{with} \quad \epsilon = \frac{\alpha}{\pi} q_e^2 \ln \frac{s}{m^2}, \quad (10.21)$$

where m is the mass of the incoming (and outgoing) particle, which is initially assumed on-shell.

Here, the form of ϵ results from the kinematical bounds for the momentum squared of the outgoing particle, which in the limit $m^2 \ll s$ are given by

$$t_0 = -2\bar{x}E(E+p) + m^2 \approx -\bar{x}s, \quad (10.22)$$

$$t_1 = -2\bar{x}E(E-p) + m^2 \approx xm^2, \quad (10.23)$$

so the integration over the propagator $1/(t-m^2)$ yields

$$\ln \frac{t_0 - m^2}{t_1 - m^2} = \ln \frac{s}{m^2}. \quad (10.24)$$

In $f_0(x)$, there is an integrable singularity at $x = 1$ which does not spoil the integration, but would lead to an unbounded f_{\max} . Therefore, we map this singularity like

$$x = 1 - (1-x')^{1/\epsilon} \quad (10.25)$$

such that

$$\int dx f_0(x) = \int dx' \quad (10.26)$$

The structure function has three parameters: α , m_{in} of the incoming particle and s , the hard scale. Internally, we store the exponent ϵ which is the relevant

parameter. (In conventional notation, $\epsilon = \beta/2$.) As defaults, we take the actual values of α (which is probably $\alpha(s)$), the actual mass m_{in} and the squared total c.m. energy s .

Including ϵ , ϵ^2 , and ϵ^3 corrections, the successive approximation of the ISR structure function read

$$f_0(x) = \epsilon(1-x)^{-1+\epsilon} \quad (10.27)$$

$$f_1(x) = g_1(\epsilon) f_0(x) - \frac{\epsilon}{2}(1+x) \quad (10.28)$$

$$f_2(x) = g_2(\epsilon) f_0(x) - \frac{\epsilon}{2}(1+x) - \frac{\epsilon^2}{8} \left(\frac{1+3x^2}{1-x} \ln x + 4(1+x) \ln(1-x) + 5+x \right) \quad (10.29)$$

$$f_3(x) = g_3(\epsilon) f_0(x) - \frac{\epsilon}{2}(1+x) - \frac{\epsilon^2}{8} \left(\frac{1+3x^2}{1-x} \ln x + 4(1+x) \ln(1-x) + 5+x \right) - \frac{\epsilon^3}{48} \left((1+x) [6 \text{Li}_2(x) + 12 \ln^2(1-x) - 3\pi^2] + 6(x+5) \ln(1-x) + \frac{1}{1-x} \left[\frac{3}{2}(1+8x+3x^2) \ln x + 12(1+x^2) \ln x \ln(1-x) - \frac{1}{2}(1+7x^2) \ln^2 x + \frac{1}{4}(39-24x-15x^2) \right] \right) \quad (10.30)$$

where the successive approximations to the prefactor of the leading singularity

$$g(\epsilon) = \frac{\exp\left(\epsilon(-\gamma_E + \frac{3}{4})\right)}{\Gamma(1+\epsilon)}, \quad (10.31)$$

are given by

$$g_0(\epsilon) = 1 \quad (10.32)$$

$$g_1(\epsilon) = 1 + \frac{3}{4}\epsilon \quad (10.33)$$

$$g_2(\epsilon) = 1 + \frac{3}{4}\epsilon + \frac{27-8\pi^2}{96}\epsilon^2 \quad (10.34)$$

$$g_3(\epsilon) = 1 + \frac{3}{4}\epsilon + \frac{27-8\pi^2}{96}\epsilon^2 + \frac{27-24\pi^2+128\zeta(3)}{384}\epsilon^3, \quad (10.35)$$

where, numerically

$$\zeta(3) = 1.20205690315959428539973816151 \dots \quad (10.36)$$

Although one could calculate the function $g(\epsilon)$ exactly, truncating its Taylor expansion ensures the exact normalization of the truncated structure function at each given order:

$$\int_0^1 dx f_i(x) = 1 \quad \text{for all } i. \quad (10.37)$$

Effectively, the $O(\epsilon)$ correction reduces the low- x tail of the structure function by 50% while increasing the coefficient of the singularity by $O(\epsilon)$. Relative

to this, the $O(\epsilon^2)$ correction slightly enhances $x > \frac{1}{2}$ compared to $x < \frac{1}{2}$. At $x = 0$, $f_2(x)$ introduces a logarithmic singularity which should be cut off at $x_0 = O(e^{-1/\epsilon})$: for lower x the perturbative series breaks down. The f_3 correction is slightly positive for low x values and negative near $x = 1$, where the Li_2 piece slightly softens the singularity at $x = 1$.

Instead of the definition for ϵ given above, it is customary to include a universal nonlogarithmic piece:

$$\epsilon = \frac{\alpha}{\pi} q_e^2 \left(\ln \frac{s}{m^2} - 1 \right) \quad (10.38)$$

10.4.2 Implementation

In the concrete implementation, the zeroth order mapping (10.25) is implemented, and the Jacobian is equal to $f_i(x)/f_0(x)$. This can be written as

$$\frac{f_0(x)}{f_0(x)} = 1 \quad (10.39)$$

$$\frac{f_1(x)}{f_0(x)} = 1 + \frac{3}{4}\epsilon - \frac{1-x^2}{2(1-x')} \quad (10.40)$$

$$\begin{aligned} \frac{f_2(x)}{f_0(x)} = 1 + \frac{3}{4}\epsilon + \frac{27-8\pi^2}{96}\epsilon^2 - \frac{1-x^2}{2(1-x')} \\ - \frac{(1+3x^2)\ln x + (1-x)(4(1+x)\ln(1-x) + 5+x)}{8(1-x')}\epsilon \end{aligned} \quad (10.41)$$

For $x = 1$ (i.e., numerically indistinguishable from 1), this reduces to

$$\frac{f_0(x)}{f_0(x)} = 1 \quad (10.42)$$

$$\frac{f_1(x)}{f_0(x)} = 1 + \frac{3}{4}\epsilon \quad (10.43)$$

$$\frac{f_2(x)}{f_0(x)} = 1 + \frac{3}{4}\epsilon + \frac{27-8\pi^2}{96}\epsilon^2 \quad (10.44)$$

The last line in (10.41) is zero for

$$x_{\min} = 0.00714053329734592839549879772019 \quad (10.45)$$

(Mathematica result), independent of ϵ . For x values less than this we ignore this correction because of the logarithmic singularity which should in principle be resummed.

10.4.4 The ISR object

The `isr_t` data type is a $1 \rightarrow 2$ interaction, i.e., we allow for single-photon emission only (but use the multi-photon resummed radiator function). The particles are ordered as (incoming, photon, outgoing).

There is no need to handle several flavors (and data blocks) in parallel, since ISR is always applied immediately after beam collision. (ISR for partons is accounted for by the PDFs themselves.) Polarization is carried through, i.e., we retain the polarization of the incoming particle and treat the emitted photon as unpolarized. Color is trivially carried through. This implies that particles 1 and 3 should be locked together. For ISR we don't need the `q` variable.

```

<SF isr: types>+≡
    type, extends (sf_int_t) :: isr_t
        type(isr_data_t), pointer :: data => null ()
        real(default) :: x = 0

      write (u, "(1x,A)") "ISR data: [undefined]"
    end if
  end subroutine isr_write

```

10.4.5 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ were trivial. The ISR structure function allows for a straightforward mapping of the unit interval. So, to leading order, the structure function value is unity, but the x value is transformed. Higher orders affect the function value.

The structure function implementation applies the above mapping to the input (random) number \mathbf{r} to generate the momentum fraction \mathbf{x} and the function value \mathbf{f} . For numerical stability reasons, we also output \mathbf{xb} , which is $\bar{x} = 1 - x$. The mapping ensures that $f = 1$ at leading order, and the higher-order corrections are well-behaved. So, the Jacobian for the kinematics is one if the mapping is applied as it is already defined within the value of the structure function. If the `no_map` flag is set, we do not apply this mapping.

```

<SF isr: isr: TBP>+≡
  procedure :: complete_kinematics => isr_complete_kinematics

<SF isr: procedures>+≡
  subroutine isr_complete_kinematics (sf_int, x, f, r, map)
    class(isr_t), intent(inout) :: sf_int
    real(default), dimension(:), intent(out) :: x
    real(default), intent(out) :: f
    real(default), dimension(:), intent(in) :: r
    logical, intent(in) :: map
    real(default) :: rb1, xb1, eps
    eps = sf_int%data%eps
    !!!
    rb1 = 1 - r(1)
    if (map) then
      if (rb1 < tiny(1._default)**eps) then
        xb1 = 0

```

```

        else
            xb1 = rb1**(1/eps)
        end if
        f = 1
    else
        xb1 = rb1
        f = xb1 ** (-1 + eps)
    end if
    x(1) = 1 - xb1
    if (size (x) == 3) x(2:3) = r(2:3)
    call sf_int%split_momentum (x, xb1)
    sf_int%data%map = map
    select case (sf_int%status)
    case (SF_DONE_KINEMATICS)

10.4.6 ISR application

For ISR, we could in principle compute kinematics and function value in a single step. In order to be able to reweight matrix elements including structure functions we split kinematics and structure function calculation. The structure function works on a single beam, assuming that the input momentum has been set.

After splitting momenta, we set the outgoing momenta on-shell. We choose to conserve momentum, so energy conservation may be violated.

```

10.5.1 Physics

The EPA structure function for a photon inside an (elementary) particle p with energy E , mass m and charge q_p (e.g., electron) is given by ($\bar{x} \equiv 1 - x$)

$$\begin{aligned}
 f(x) = \frac{\alpha}{\pi} q_p^2 \frac{1}{x} & \left[\left(\bar{x} + \frac{x^2}{2} \right) \ln \frac{Q_{\max}^2}{Q_{\min}^2} \right. \\
 & \left. - \left(1 - \frac{x}{2} \right)^2 \ln \frac{x^2 + \frac{Q_{\max}^2}{E^2}}{x^2 + \frac{Q_{\min}^2}{E^2}} - x^2 \frac{m^2}{Q_{\min}^2} \left(1 - \frac{Q_{\min}^2}{Q_{\max}^2} \right) \right]. \quad (10.46)
 \end{aligned}$$

If no explicit Q bounds are provided, the kinematical bounds are

$$-Q_{\max}^2 = t_0 = -2\bar{x}(E^2 + p\bar{p}) + 2m^2 \approx -4\bar{x}E^2, \quad (10.47)$$

$$-Q_{\min}^2 = t_1 = -2\bar{x}(E^2 - p\bar{p}) + 2m^2 \approx -\frac{x^2}{\bar{x}}m^2. \quad (10.48)$$

The second and third terms in (10.46) are negative definite (and subleading). Noting that $\bar{x} + x^2/2$ is bounded between $1/2$ and 1 , we derive that $f(x)$ is always smaller than

$$\bar{f}(x) = \frac{\alpha}{\pi} q_p^2 \frac{L - 2 \ln x}{x} \quad \text{where} \quad L = \ln \frac{\min(4E_{\max}^2, Q_{\max}^2)}{\max(m^2, Q_{\min}^2)}, \quad (10.49)$$

where we allow for explicit Q bounds that narrow the kinematical range. Therefore, we generate this distribution:

$$\int_{x_0}^{x_1} dx \bar{f}(x) = C(x_0, x_1) \int_0^1 dx' \quad (10.50)$$

We set

$$\ln x = \frac{1}{2} \left\{ L - \sqrt{L^2 - 4 [x' \ln x_1 (L - \ln x_1) + \bar{x}' \ln x_0 (L - \ln x_0)]} \right\} \quad (10.51)$$

such that $x(0) = x_0$ and $x(1) = x_1$ and

$$\frac{dx}{dx'} = \left(\frac{\alpha}{\pi} q_p^2 \right)^{-1} x \frac{C(x_0, x_1)}{L - 2 \ln x} \quad (10.52)$$

with

$$C(x_0, x_1) = \frac{\alpha}{\pi} q_p^2 [\ln x_1 (L - \ln x_1) - \ln x_0 (L - \ln x_0)] \quad (10.53)$$

such that (10.50) is satisfied. Finally, we have

$$\int_{x_0}^{x_1} dx f(x) = C(x_0, x_1) \int_0^1 dx' \frac{f(x(x'))}{\bar{f}(x(x'))} \quad (10.54)$$

where x' is calculated from x via (10.51).

The structure of the mapping is most obvious from:

$$x'(x) = \frac{\log x (L - \log x) - \log x_0 (L - \log x_0)}{\log x_1 (L - \log x_1) - \log x_0 (L - \log x_0)}. \quad (10.55)$$

10.5.2 The EPA data block

The EPA parameters are: α , E_{\max} , m , Q_{\min} , and x_{\min} . Instead of m we can use the incoming particle PDG code as input; from this we can deduce the mass and charge.

Internally we store in addition $C_{0/1} = \frac{\alpha}{\pi} q_e^2 \ln x_{0/1} (L - \ln x_{0/1})$, the c.m. energy squared and the incoming particle mass.

10.5.3 The EPA object

The `epa_t` data type is a $1 \rightarrow 2$ interaction. We should be able to handle several flavors in parallel, since EPA is not necessarily applied immediately after beam collision: Photons may be radiated from quarks. In that case, the partons are massless and q_{\min} applies instead, so we do not need to generate several kinematical configurations in parallel.

The particles are ordered as (incoming, radiated, photon), where the photon initiates the hard interaction.

We generate an unpolarized photon and transfer initial polarization to the radiated parton. Color is transferred in the same way. !!! JRR: WK please check For EPA we don't seem to need the `q` variable.

```

<SF epa: types>+≡
  !!! JRR: WK please check

10.5.4 Kinematics

Set kinematics. If `map` is unset, the r and x values coincide, and the Jacobian $f(r)$ is trivial.

If `map` is set (which is the default), we are asked to provide an efficient mapping. This has been written down above and uses the upper limit on the structure function.

```

<SF epa: epa: TBP>+≡
procedure :: complete_kinematics => epa_complete_kinematics

<SF epa: procedures>+≡

10.5.5 EPA structure function

The EPA structure function allows for a straightforward mapping of the unit interval. The x value is transformed, and the mapped structure function becomes unity at its upper boundary.

The structure function implementation applies the above mapping to the input (random) number r to generate the momentum fraction x and the function value f . For numerical stability reasons, we also output xb , which is $\bar{x} = 1 - x$.

If `map` is set, the mapping is applied, otherwise it is switched off.

(EPA: procedures)≡

```
