        call evt%reset ()
    end subroutine evt_shower_prepare_new_event

```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations might be useful. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid.

```

<Shower: evt shower: TBP>+≡

```

## Matching and hadronization functions

The HEPRUP (event) common block is needed for the interface to the shower. Filling of it is triggered by some output file formats. If these are not present, the common block is filled with some dummy information. Be generous with

the number of processes in HEPUP so that PYTHIA only rarely needs to be reinitialized in case events with higher process ids are generated.

    <Events: procedures>

    <Events: tests>

end module events

```

### 28.4.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The **safety\_factor** reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The **sigma** and **n** values, if nontrivial, allow for reweighting the events according to the requested **norm\_mode**.

Various **parse\_node\_t** objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the **event\_expr\_t** objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

```

<Events: types>≡
    type :: event_config_t
        logical :: unweighted = .false.
        integer :: norm_mode = NORM_UNDEFINED
        integer :: factorization_mode = FM_IGNORE_HELICITY
        logical :: keep_correlations = .false.
        real(default) :: sigma = 1

```

## 28.4.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event_base` module. The core manages the main (dressed) particle set pointer and the current values for weights and sqme. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the **ref** value is the number in the file, while the **prc** value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of **alt** values is copied from an array of alternative event records. These values should represent calculated values.

The **sqme** and **weight** values mirror corresponding values in the **expr** sub-object. The idea is that when generating or reading events, the event record is filled first, then the **expr** object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the **expr** subobject. In particular, evaluating the event-selection expression sets the **passed** flag. Furthermore, the **expr** subobject collects data that can be used in the analysis and should be written to file, including copies of **sqme** and **weight**.

```

<Events: public>≡
    public :: event_t

```

### 28.4.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```
<Events: event: TBP>+≡
  procedure :: basic_init => event_init

<Events: procedures>+≡
  subroutine event_init (event, var_list, n_alt)
    class(event_t), intent(out) :: event
    type(var_list_t), intent(in), optional :: var_list
    integer, intent(in), optional :: n_alt
    type(string_t) :: norm_string
    logical :: polarized_events
    if (present (n_alt)) then
      call event%base_init (n_alt)
      call event%expr%init (n_alt)
    else
      call event%base_init (0)
    end if
    if (present (var_list)) then
      event%config%unweighted = var_list%get_lval (&
        var_str ("?unweighted"))
      norm_string = var_list%get_sval (&
        var_str ("sample_normalization"))
      event%config%norm_mode = &
        event_normalization_mode (norm_string, event%config%unweighted)
      polarized_events = &
        var_list%get_lval (var_str ("?polarized_events"))
      if (polarized_events) then
        event%config%factorization_mode = FM_SELECT_HELICITY
      else
        event%config%factorization_mode = FM_IGNORE_HELICITY
      end if
      if (event%config%unweighted) then
        event%config%safety_factor = var_list%get_rval (&
          var_str ("safety_factor"))
      end if
    else
      event%config%norm_mode = NORM_SIGMA
    end if
    allocate (evt_trivial_t :: event%transform_first)
    event%transform_last => event%transform_first
  end subroutine event_init
```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

```

<Events: event: TBP>+≡
  procedure :: set_sigma => event_set_sigma
  procedure :: set_n => event_set_n

<Events: procedures>+≡
  elemental subroutine event_set_sigma (event, sigma)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: sigma
    event%config%sigma = sigma
  end subroutine event_set_sigma

  elemental subroutine event_set_n (event, n)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: n
    event%config%n = n
  end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
  procedure :: import_transform => event_import_transform

<Events: procedures>+≡
  subroutine event_import_transform (event, evt)
    class(event_t), intent(inout) :: event
    class(evt_t), intent(inout), pointer :: evt
    event%transform_last%next => evt
    evt%previous => event%transform_last
    event%transform_last => evt
    evt => null ()
  end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡

  end subroutine event_setup_expressions

```

#### 28.4.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

<Events: event: TBP>+≡
  procedure :: evaluate_transforms => event_evaluate_transforms

<Events: procedures>+≡
  subroutine event_evaluate_transforms (event, r)
    class(event_t), intent(inout) :: event
    real(default), dimension(:), intent(in), optional :: r
    class(evt_t), pointer :: evt
    integer :: i_term
    call event%discard_particle_set ()
    call event%check ()
    if (event%instance%is_complete_event ()) then
      call event%instance%select_i_term (i_term)
      event%selected_i_term = i_term
      evt => event%transform_first
      do while (associated (evt))
        call evt%prepare_new_event &
          (event%selected_i_mci, event%selected_i_term)
        evt => evt%next
      end do
      evt => event%transform_first
      do while (associated (evt))
        call evt%generate_unweighted ()
        if (signal_is_pending ()) return
        call evt%make_particle_set (event%config%factorization_mode, &
          event%config%keep_correlations)
        if (signal_is_pending ()) return
      end do
    end if
  end subroutine event_evaluate_transforms

```

```

        if (.not. evt%particle_set_exists) exit
        evt => evt%next
    end do
    evt => event%transform_last
    if (associated (evt) .and. evt%particle_set_exists) then
        call event%link_particle_set (evt%particle_set)
    end if
end if
end if
end subroutine event_evaluate_transforms

```

Evaluate the event-related expressions, given a valid `particle_set`. If `update_sqme` is set, we use the process instance for the `sqme_prc` value. The `sqme_ref` value is always taken from the event record.

Note: without the explicit `particle_set` pointer, some gfortran 4.8 version corrupts its memory.

*(Events: event: TBP)+≡*

```

    procedure :: evaluate_expressions => event_evaluate_expressions

      evt => evt%next
    end do
  end subroutine event_reset

```

### 28.4.6 Squared Matrix Element and Weight

Transfer the result of the process instance calculation to the event record header.

```

<Events: event: TBP>+≡
  procedure :: import_instance_results => event_import_instance_results

<Events: procedures>+≡
  subroutine event_import_instance_results (event)
    class(event_t), intent(inout) :: event
    if (associated (event%instance)) then

```

```

        if (event%instance%has_evaluated_trace ()) then
            call event%set ( &
                sqme_prc = event%instance%get_sqme (), &
                weight_prc = event%instance%get_weight (), &
                excess_prc = event%instance%get_excess () &
            )
        end if
    end if
end subroutine event_import_instance_results

```

Duplicate the instance result / the reference result in the event record.

*(Events: event: TBP)+≡*

```

    procedure :: accept_sqme_ref => event_accept_sqme_ref
    procedure :: accept_sqme_prc => event_accept_sqme_prc
    procedure :: accept_weight_ref => event_accept_weight_ref
    procedure :: accept_weight_prc => event_accept_weight_prc

```

*(Events: procedures)+≡*

```

subroutine event_accept_sqme_ref (event)
    class(event_t), intent(inout) :: event
    if (event%sqme_ref_is_known ()) then
        call event%set (sqme_prc = event%get_sqme_ref ())
    end if
end subroutine event_accept_sqme_ref

subroutine event_accept_sqme_prc (event)
    class(event_t), intent(inout) :: event
    if (event%sqme_prc_is_known ()) then
        call event%set (sqme_ref = event%get_sqme_prc ())
    end if
end subroutine event_accept_sqme_prc

subroutine event_accept_weight_ref (event)
    class(event_t), intent(inout) :: event
    if (event%weight_ref_is_known ()) then
        call event%set (weight_prc = event%get_weight_ref ())
    end if
end subroutine event_accept_weight_ref

subroutine event_accept_weight_prc (event)
    class(event_t), intent(inout) :: event
    if (event%weight_prc_is_known ()) then
        call event%set (weight_ref = event%get_weight_prc ())
    end if
end subroutine event_accept_weight_prc

```

Update the weight normalization, just after generation. Unweighted and weighted events are generated with a different default normalization. The intended normalization is stored in the configuration record.

*(Events: event: TBP)+≡*

```

    procedure :: update_normalization => event_update_normalization

```

*(Events: procedures)+≡*

```

    subroutine event_update_normalization (event, mode_ref)

```

```

class(event_t), intent(inout) :: event
integer, intent(in), optional :: mode_ref
integer :: mode_old
real(default) :: weight, excess
if (present (mode_ref)) then
    mode_old = mode_ref
else if (event%config%unweighted) then
    mode_old = NORM_UNIT
else
    mode_old = NORM_SIGMA
end if
weight = event%get_weight_prc ()
call event_normalization_update (weight, &
    event%config%sigma, event%config%n, &
    mode_new = event%config%norm_mode, &
    mode_old = mode_old)
call event%set_weight_prc (weight)
excess = event%get_excess_prc ()
call event_normalization_update (excess, &
    event%config%sigma, event%config%n, &
    mode_new = event%config%norm_mode, &
    mode_old = mode_old)
call event%set_excess_prc (excess)
end subroutine event_update_normalization

```

The event is complete if it has a particle set plus valid entries for the sqme and weight values.

```

<Events: event: TBP>+≡
    procedure :: check => event_check

<Events: procedures>+≡
    subroutine event_check (event)
        class(event_t), intent(inout) :: event
        event%is_complete = event%has_valid_particle_set () &
            .and. event%sqme_ref_is_known () &
            .and. event%sqme_prc_is_known () &
            .and. event%weight_ref_is_known () &
            .and. event%weight_prc_is_known ()
        if (event%get_n_alt () /= 0) then
            event%is_complete = event%is_complete &
                .and. event%sqme_alt_is_known () &
                .and. event%weight_alt_is_known ()
        end if
    end subroutine event_check

```

## 28.4.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we

accept the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
  procedure :: generate => event_generate

<Events: procedures>+≡
  subroutine event_generate (event, i_mci, r)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci
    real(default), dimension(:), intent(in), optional :: r
    call event%reset ()
    event%selected_i_mci = i_mci
    if (event%config%unweighted) then
      call event%process%generate_unweighted_event (event%instance, i_mci)
      if (signal_is_pending ()) return
      call event%instance%evaluate_event_data ()
      call event%instance%normalize_weight ()
    else
      call event%process%generate_weighted_event (event%instance, i_mci)
      if (signal_is_pending ()) return
      call event%instance%evaluate_event_data ()
    end if
    event%selected_channel = event%instance%get_channel ()
    call event%import_instance_results ()
    call event%accept_sqme_prc ()
    call event%update_normalization ()
    call event%accept_weight_prc ()
    call event%evaluate_transforms (r)
    if (signal_is_pending ()) return
    call event%check ()
  end subroutine event_generate

```

Get a copy of the particle set belonging to the hard process.

```

<Events: event: TBP>+≡
  procedure :: get_hard_particle_set => event_get_hard_particle_set

<Events: procedures>+≡
  subroutine event_get_hard_particle_set (event, pset)
    class(event_t), intent(in) :: event
    type(particle_set_t), intent(out) :: pset
    class(evt_t), pointer :: evt
    evt => event%transform_first
    pset = evt%particle_set
  end subroutine event_get_hard_particle_set

```

## 28.4.8 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
  procedure :: select => event_select

```

```

<Events: procedures>+≡
  subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
    if (associated (event%instance)) then
      event%selected_i_mci = i_mci
      event%selected_i_term = i_term
      event%selected_channel = channel
    else
      call msg_bug ("Event: select term: process instance undefined")
    end if
  end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. The event reader may either read in the transformed event separately, or apply all event transforms to the hard particle set to (re)generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call **reset** on them.

```

<Events: event: TBP>+≡
  procedure :: set_hard_particle_set => event_set_hard_particle_set

<Events: procedures>+≡
  subroutine event_set_hard_particle_set (event, particle_set)
    class(event_t), intent(inout) :: event
    type(particle_set_t), intent(in) :: particle_set
    class(evt_t), pointer :: evt
    evt => event%transform_first
    call evt%set_particle_set (particle_set, &
      event%selected_i_mci, event%selected_i_term)
    call event%link_particle_set (evt%particle_set)
    evt => evt%next
    do while (associated (evt))
      call evt%reset ()
      evt => evt%next
    end do
  end subroutine event_set_hard_particle_set

```

Here we try to recover an event from the **particle\_set** subobject and recalculate the structure functions and matrix elements. We have the appropriate **process** object and an initialized **process\_instance** at hand, so beam and configuration data are known. From the **particle\_set**, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event **weight** may also be known already. If yes, we pass it to the **evaluate\_event\_data** procedure. It should already be normalized. If we have

an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

<Events: event: TBP>+≡
  procedure :: recalculate => event_recalculate

<Events: procedures>+≡
  subroutine event_recalculate &
    (event, update_sqme, weight_factor, recover_beams)
    class(event_t), intent(inout) :: event

## 28.5 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the `events` module which provides the concrete implementation of `event_base`. The other I/O formats access only the methods that are defined in `event_base`.

```

<eio_raw.f90>≡
  <File header>

  module eio_raw

    use kinds
    use io_units
    <Use strings>
    use unit_tests
    use diagnostics

    use lorentz
    use variables
    use model_data
    use particles
    use event_base
    use eio_data
    use eio_base
    use events

    <Standard module head>

```

```

    <EIO raw: public>

    <EIO raw: parameters>

    <EIO raw: types>

contains

    <EIO raw: procedures>

    <EIO raw: tests>

end module eio_raw

```

### 28.5.1 File Format Version

This is the current default file version.

```

<EIO raw: parameters>≡
    integer, parameter :: CURRENT_FILE_VERSION = 2

```

The user may change this number; this should force some compatibility mode for reading and writing. In any case, the file version stored in a event file that we read has to match the expected file version.

History of version numbers:

1. Format for WHIZARD 2.2.0 to 2.2.3. No version number stored in the raw file.
2. Format from 2.2.4 on. File contains version number. The file contains the transformed particle set (if applicable) after the hard-process particle set.

### 28.5.2 Type

Note the file version number. The default may be reset during initialization, which should enforce some compatibility mode.

```

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

## Chapter 29

# Integration and simulation

This layer of modules is just below the top-level API. We lay out specific data types for integration and simulation and implement the corresponding algorithms as methods acting on them. This helps to keep the command-level implementation concise and simple.

Generic modules for connecting Sindarin with WHIZARD:

**user\_files** Manage files that are accessed by user-written Sindarin code.

**rt\_data** The main runtime data block, giving access to all features of WHIZARD via contained data structures or pointers.

**dispatch** Dynamic dispatch for various WHIZARD objects that have multiple implementations. The dispatcher uses data from the **rt\_data** block to decide which path to follow.

More specific modules, the workhorses of WHIZARD. These modules use **rt\_data** components and the dispatcher. They define dedicated object types for bundling lower-level data and procedures that together provide the desired functionality.

**process\_configurations** Interpret process definitions to generate matrix-element objects and external code.

**compilations** Compile, link and access external matrix-element code.

**integrations** Manage integration runs.

**event\_streams** Manage external event I/O.

**simulations** Manage simulation runs.

## 29.1 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```
<user_files.f90>≡  
  <File header>  
  
  module user_files  
  
    <Use strings>  
    use io_units  
    use diagnostics  
    use ifiles  
    use analysis  
  
    <Standard module head>  
  
    <User files: public>  
  
    <User files: types>  
  
    <User files: interfaces>  
  
    contains  
  
    <User files: procedures>  
  
  end module user_files
```

### 29.1.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡  
  type :: file_t  
    private  
    type(string_t) :: name  
    integer :: unit = -1  
    logical :: reading = .false.  
    logical :: writing = .false.  
    type(file_t), pointer :: prev => null ()  
    type(file_t), pointer :: next => null ()  
  end type file_t
```

The initializer opens the file.

```
<User files: procedures>≡  
  subroutine file_init (file, name, action, status, position)  
    type(file_t), intent(out) :: file  
    type(string_t), intent(in) :: name  
    character(len=*), intent(in) :: action, status, position  
    file%unit = free_unit ()
```

```

file%name = name
open (unit = file%unit, file = char (file%name), &
      action = action, status = status, position = position)
select case (action)
case ("read")
  file%reading = .true.
case ("write")
  file%writing = .true.
case ("readwrite")
  file%reading = .true.
  file%writing = .true.
end select
end subroutine file_init

```

The finalizer closes it.

```

<User files: procedures>+≡
subroutine file_final (file)
  type(file_t), intent(inout) :: file
  close (unit = file%unit)
  file%unit = -1
end subroutine file_final

```

Check if a file is open with correct status.

```

<User files: procedures>+≡
function file_is_open (file, action) result (flag)
  logical :: flag
  type(file_t), intent(in) :: file
  character(*), intent(in) :: action
  select case (action)
case ("read")
  flag = file%reading
case ("write")
  flag = file%writing
case ("readwrite")
  flag = file%reading .and. file%writing
case default
  call msg_bug ("Checking file '" // char (file%name) &
               // "': illegal action specifier")
  end select
end function file_is_open

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the **advancing** option.

```

<User files: procedures>+≡
subroutine file_write_string (file, string, advancing)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: string
  logical, intent(in), optional :: advancing
  if (file%writing) then
    if (present (string)) then
      if (present (advancing)) then
        if (advancing) then

```

```

        write (file%unit, "(A)" char (string))
    else
        write (file%unit, "(A)", advance="no") char (string)
    end if
else
    write (file%unit, "(A)" char (string))
end if
else
    write (file%unit, *)
end if
else
    call msg_error ("Writing to file: File '" // char (file%name) &
        // "' is not open for writing.")
end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
subroutine file_write_ifile (file, ifile)
    type(file_t), intent(in) :: file
    type(ifile_t), intent(in) :: ifile
    type(line_p) :: line
    call line_init (line, ifile)
    do while (line_is_associated (line))
        call file_write_string (file, line_get_string_advance (line))
    end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
subroutine file_write_analysis (file, tag)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: tag
    if (file%writing) then
        if (present (tag)) then
            call analysis_write (tag, unit = file%unit)
        else
            call analysis_write (unit = file%unit)
        end if
    else
        call msg_error ("Writing analysis to file: File '" // char (file%name) &
            // "' is not open for writing.")
    end if
end subroutine file_write_analysis

```

### 29.1.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
public :: file_list_t

```

```

<User files: types>+≡
  type :: file_list_t
    type(file_t), pointer :: first => null ()
    type(file_t), pointer :: last => null ()
  end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
  public :: file_list_final

<User files: procedures>+≡
  subroutine file_list_final (file_list)
    type(file_list_t), intent(inout) :: file_list
    type(file_t), pointer :: current
    do while (associated (file_list%first))
      current => file_list%first
      file_list%first => current%next
      call file_final (current)
      deallocate (current)
    end do
    file_list%last => null ()
  end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```

<User files: procedures>+≡
  function file_list_get_file_ptr (file_list, name) result (current)
    type(file_t), pointer :: current
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    current => file_list%first
    do while (associated (current))
      if (current%name == name) return
      current => current%next
    end do
  end function file_list_get_file_ptr

```

Check if a file is open, public version:

```

<User files: public>+≡
  public :: file_list_is_open

<User files: procedures>+≡
  function file_list_is_open (file_list, name, action) result (flag)
    logical :: flag
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action
    type(file_t), pointer :: current
    current => file_list_get_file_ptr (file_list, name)
    if (associated (current)) then
      flag = file_is_open (current, action)
    else
      flag = .false.
    end if
  end function

```

```
end function file_list_is_open
```

Append a new file entry, i.e., open this file. Error if it is already open.

```
<User files: public>+≡
public :: file_list_open

<User files: procedures>+≡
subroutine file_list_open (file_list, name, action, status, position)
  type(file_list_t), intent(inout) :: file_list
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position
  type(file_t), pointer :: current
  if (.not. associated (file_list_get_file_ptr (file_list, name))) then
    allocate (current)
    call msg_message ("Opening file '" // char (name) // "' for output")
    call file_init (current, name, action, status, position)
    if (associated (file_list%last)) then
      file_list%last%next => current
      current%prev => file_list%last
    else
      file_list%first => current
    end if
    file_list%last => current
  else
    call msg_error ("Opening file: File '" // char (name) &
      // "' is already open.")
  end if
end subroutine file_list_open
```

Delete a file entry, i.e., close this file. Error if it is not open.

```
<User files: public>+≡
public :: file_list_close

<User files: procedures>+≡
subroutine file_list_close (file_list, name)
  type(file_list_t), intent(inout) :: file_list
  type(string_t), intent(in) :: name
  type(file_t), pointer :: current
  current => file_list_get_file_ptr (file_list, name)
  if (associated (current)) then
    if (associated (current%prev)) then
      current%prev%next => current%next
    else
      file_list%first => current%next
    end if
    if (associated (current%next)) then
      current%next%prev => current%prev
    else
      file_list%last => current%prev
    end if
    call msg_message ("Closing file '" // char (name) // "' for output")
    call file_final (current)
    deallocate (current)
  else
```

```

        call msg_error ("Closing file: File '" // char (name) &
            // "' is not open.")
    end if
end subroutine file_list_close

```

Write a string to file. Error if it is not open.

```

<User files: public>+≡
    public :: file_list_write

<User files: interfaces>≡
    interface file_list_write
        module procedure file_list_write_string
        module procedure file_list_write_ifile
    end interface

<User files: procedures>+≡
    subroutine file_list_write_string (file_list, name, string, advancing)
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        type(string_t), intent(in), optional :: string
        logical, intent(in), optional :: advancing
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            call file_write_string (current, string, advancing)
        else
            call msg_error ("Writing to file: File '" // char (name) &
                // "'is not open.")
        end if
    end subroutine file_list_write_string

    subroutine file_list_write_ifile (file_list, name, ifile)
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        type(ifile_t), intent(in) :: ifile
        type(line_p) :: line
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            call file_write_ifile (current, ifile)
        else
            call msg_error ("Writing to file: File '" // char (name) &
                // "'is not open.")
        end if
    end subroutine file_list_write_ifile

```

Write an analysis object or all objects to data file. Error if it is not open. If the file name is empty, write to standard output.

```

<User files: public>+≡
    public :: file_list_write_analysis

<User files: procedures>+≡
    subroutine file_list_write_analysis (file_list, name, tag)
        type(file_list_t), intent(in) :: file_list

```

```

type(string_t), intent(in) :: name
type(string_t), intent(in), optional :: tag
type(file_t), pointer :: current
if (name == "") then
    if (present (tag)) then
        call analysis_write (tag)
    else
        call analysis_write
    end if
else

```

### 29.2.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn, is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

### 29.2.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

$\langle RT\ data: types \rangle \equiv$

```
type :: rt_parse_nodes_t
  type(parse_node_t), pointer :: cuts_lexpr => null ()
  type(parse_node_t), pointer :: scale_expr => null ()
  type(parse_node_t), pointer :: fac_scale_expr => null ()
  type(parse_node_t), pointer :: ren_scale_expr => null ()
  type(parse_node_t), pointer :: weight_expr => null ()
  type(parse_node_t), pointer :: selection_lexpr => null ()
  type(parse_node_t), pointer :: reweight_expr => null ()
  type(parse_node_t), pointer :: analysis_lexpr => null ()
  type(parse_node_p), dimension(:), allocatable :: alt_setup
```

```

contains
  <RT data: rt parse nodes: TBP>
end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

<RT data: procedures>≡
  subroutine rt_parse_nodes_clear (rt_pn, name)
    class(rt_parse_nodes_t), intent(inout) :: rt_pn
    type(string_t), intent(in) :: name
    select case (char (name))
    case ("cuts")
      rt_pn%cuts_lexpr => null ()
    case ("scale")
      rt_pn%scale_expr => null ()
    case ("factorization_scale")
      rt_pn%fac_scale_expr => null ()
    case ("renormalization_scale")
      rt_pn%ren_scale_expr => null ()
    case ("weight")
      rt_pn%weight_expr => null ()
    case ("selection")
      rt_pn%selection_lexpr => null ()
    case ("reweight")
      rt_pn%reweight_expr => null ()
    case ("analysis")
      rt_pn%analysis_lexpr => null ()
    end select
  end subroutine rt_parse_nodes_clear

```

Output for the parse nodes.

```

<RT data: rt parse nodes: TBP>+≡
  procedure :: write => rt_parse_nodes_write

<RT data: procedures>+≡
  subroutine rt_parse_nodes_write (object, unit)

  case ("renormalization_scale")
    pn => rt_pn%ren_scale_expr
  case ("weight")
    pn => rt_pn%weight_expr
  case ("selection")
    pn => rt_pn%selection_lexpr
  case ("reweight")
    pn => rt_pn%reweight_expr

```

```

case ("analysis")
  pn => rt_pn%analysis_lexpr
end select
if (associated (pn)) then
  write (u, "(A,1x,A,1x,A)") "Expression:", char (name), "(parse tree):"
  call parse_node_write_rec (pn, u)
else
  write (u, "(A,1x,A,A)") "Expression:", char (name), ": [undefined]"
end if
end subroutine rt_parse_nodes_show

```

### 29.2.3 The data type

This is a big data container which contains everything that is used and modified during the command flow. A local copy of this can be used to temporarily override defaults. The data set is transparent.

```

<RT data: public>≡
  public :: rt_data_t
<RT data: types>+≡
  type :: rt_data_t
    type(lexer_t), pointer :: lexer => null ()
    type(rt_data_t), pointer :: context => null ()
    type(var_list_t) :: var_list
    type(iterations_list_t) :: it_list
    type(os_data_t) :: os_data
    type(model_list_t) :: model_list
    type(model_t), pointer :: model => null ()
    logical :: model_is_copy = .false.
    type(model_t), pointer :: preload_model => null ()
    type(model_t), pointer :: fallback_model => null ()
    type(model_t), pointer :: radiation_model => null ()
    type(prclib_stack_t) :: prclib_stack
    type(process_library_t), pointer :: prclib => null ()
    type(beam_structure_t) :: beam_structure
    type(rt_parse_nodes_t) :: pn
    type(process_stack_t) :: process_stack
    type(string_t), dimension(:), allocatable :: sample_fmt
    type(file_list_t), pointer :: out_files => null ()
    logical :: quit = .false.
    integer :: quit_code = 0
    type(string_t) :: logfile
    logical :: nlo_calculation = .false.
    logical, dimension(3) :: active_nlo_components
  contains
    <RT data: rt data: TBP>
  end type rt_data_t

```

### 29.2.4 Output

```

<RT data: rt data: TBP>≡
  procedure :: write => rt_data_write

```

*<RT data: procedures>+≡*

```

subroutine rt_data_write (object, unit, vars, pacify)
  class(rt_data_t), intent(in) :: object

    call global%beam_structure%final_pol ()
```

```

    call global%beam_structure%final_mom ()
end subroutine rt_data_clear_beams

```

## 29.2.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

```

<RT data: rt data: TBP>+≡
    procedure :: global_init => rt_data_global_init

<RT data: procedures>+≡

### 29.2.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their

targets.

```

<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init

<RT data: procedures>+≡
  subroutine rt_data_local_init (local, global, env)
    class(rt_data_t), intent(inout), target :: local
    type(rt_data_t), intent(in), target :: global
    integer, intent(in), optional :: env
    local%context => global
    call local%process_stack%link (global%process_stack)
    call local%process_stack%init_var_list (local%var_list)
    call local%process_stack%link_var_list (global%var_list)
    call var_list_append_string &
      (local%var_list, var_str ("model_name"), var_str (""), &
        intrinsic=.true.)
    call local%init_pointer_variables ()
    local%fallback_model => global%fallback_model
    local%radiation_model => global%radiation_model
    local%os_data = global%os_data
    local%logfile = global%logfile
    call local%model_list%link (global%model_list)
    local%model => global%model
    if (associated (local%model)) then
      call local%model%link_var_list (local%var_list)
    end if
  end subroutine rt_data_local_init

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
  procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: procedures>+≡
  subroutine rt_data_init_pointer_variables (local)
    class(rt_data_t), intent(inout), target :: local
    logical, target, save :: known = .true.
    call var_list_append_string_ptr &
      (local%var_list, var_str ("%fc"), local%os_data%fc, known, &
        intrinsic=.true.)
    call var_list_append_string_ptr &
      (local%var_list, var_str ("%fcflags"), local%os_data%fcflags, known, &
        intrinsic=.true.)
  end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local

environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: activate => rt_data_activate

<RT data: procedures>+≡
  subroutine rt_data_activate (local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), pointer :: global
    global => local%context
    if (associated (global)) then

      if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
      if (allocated (global%sample_fmt)) then
        allocate (local%sample_fmt (size (global%sample_fmt)), &
          source = global%sample_fmt)
      end if
      local%out_files => global%out_files
      local%model => global%model
      local%model_is_copy = .false.
    else if (.not. associated (local%model)) then
      local%model => local%preload_model
      local%model_is_copy = .false.
    end if
    if (associated (local%model)) then
      call local%model%link_var_list (local%var_list)
      call var_list_set_string (local%var_list, var_str ("model_name"), &
        local%model%get_name (), is_known = .true.)
    else
      call var_list_set_string (local%var_list, var_str ("model_name"), &
        var_str (""), is_known = .false.)
    end if
  end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model

(which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
  procedure :: deactivate => rt_data_deactivate

<RT data: procedures>+≡
  subroutine rt_data_deactivate (local, global, keep_local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), optional, target :: global
    logical, intent(in), optional :: keep_local
    type(string_t) :: global_model, local_model
    logical :: same_model, delete
    delete = .true.; if (present (keep_local)) delete = .not. keep_local
    if (present (global)) then
      if (associated (global%model) .and. associated (local%model)) then
        global_model = global%model%get_name ()
        local_model = local%model%get_name ()
        same_model = global_model == local_model
      else
        same_model = .false.
      end if
      if (delete) then
        call local%process_stack%clear ()
        call local%unselect_model ()
        call local%unset_values ()
      else if (associated (local%model)) then
        call local%ensure_model_copy ()
      end if
      if (.not. same_model .and. global_model /= "") then
        call msg_message ("Restoring model '" // char (global_model) // "'")
      end if
      if (associated (global%model)) then
        call global%model%link_var_list (global%var_list)
      end if
      call global%restore_globals (local)
    else
      call local%unselect_model ()
    end if
  end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
  procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
  subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
    local%prclib_stack = global%prclib_stack
  end subroutine rt_data_copy_globals

```

This restores global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡

```

```

    procedure :: restore_globals => rt_data_restore_globals
<RT data: procedures>+≡
    subroutine rt_data_restore_globals (global, local)
        class(rt_data_t), intent(inout) :: global
        class(rt_data_t), intent(in) :: local
        global%prclib_stack = local%prclib_stack
    end subroutine rt_data_restore_globals

```

### 29.2.8 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
    procedure :: final => rt_data_global_final
<RT data: procedures>+≡
    subroutine rt_data_global_final (global)
        class(rt_data_t), intent(inout) :: global
        call global%process_stack%final ()
        call global%prclib_stack%final ()
!       call global%delete_model_copy ()
        call global%model_list%final ()
        call global%var_list%final (follow_link=.false.)
        if (associated (global%out_files)) then
            call file_list_final (global%out_files)
            deallocate (global%out_files)
        end if
    end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡
    procedure :: local_final => rt_data_local_final
<RT data: procedures>+≡
    subroutine rt_data_local_final (local)
        class(rt_data_t), intent(inout) :: local
        call local%process_stack%clear ()
!       call local%delete_model_copy ()
        call local%model_list%final ()
        call local%var_list%final (follow_link=.false.)
    end subroutine rt_data_local_final

```

### 29.2.9 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
  procedure :: read_model => rt_data_read_model

<RT data: procedures>+≡
  subroutine rt_data_read_model (global, name, model)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(model_t), pointer, intent(out) :: model
    type(string_t) :: filename
    filename = name // ".mdl"
    call global%model_list%read_model &
      (name, filename, global%os_data, model)
  end subroutine rt_data_read_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
  procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: procedures>+≡
  subroutine rt_data_init_fallback_model (global, name, filename)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name, filename
    call global%model_list%read_model &
      (name, filename, global%os_data, global%fallback_model)
  end subroutine rt_data_init_fallback_model

```

Initialize the radiation model. This model is used by a radiation-generator algorithm which is part of the NLO machinery. It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
  procedure :: init_radiation_model => rt_data_init_radiation_model

<RT data: procedures>+≡
  subroutine rt_data_init_radiation_model (global, name, filename)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name, filename
    call global%model_list%read_model &
      (name, filename, global%os_data, global%radiation_model)
  end subroutine rt_data_init_radiation_model

```

Activate a model: assign the current-model pointer and set the model name in the variable list. If necessary, read the model from file. Link the global variable list to the model variable list.

```

<RT data: rt data: TBP>+≡
  procedure :: select_model => rt_data_select_model

<RT data: procedures>+≡
  subroutine rt_data_select_model (global, name)
    class(rt_data_t), intent(inout), target :: global

```

```

type(string_t), intent(in) :: name
logical :: same_model
if (associated (global%model)) then
    same_model = global%model%get_name () == name
else
    same_model = .false.
end if
if (.not. same_model) then
!    call global%delete_model_copy ()
    global%model => global%model_list%get_model_ptr (name)
    if (.not. associated (global%model)) then
        call global%read_model (name, global%model)
        global%model_is_copy = .false.
    else if (associated (global%context)) then
        global%model_is_copy = &
            global%model_list%model_exists (name, follow_link=.false.)
    else
        global%model_is_copy = .false.
    end if
end if
if (associated (global%model)) then
    call global%model%link_var_list (global%var_list)
    call var_list_set_string (global%var_list, var_str (" $model_name"), &
        name, is_known = .true.)
    call msg_message ("Switching to model '" // char (name) // "'")
else
    call var_list_set_string (global%var_list, var_str (" $model_name"), &
        var_str (""), is_known = .false.)
end if
end subroutine rt_data_select_model

```

Remove the model link and unset the model name variable.

```

<RT data: rt data: TBP>+≡
    procedure :: unselect_model => rt_data_unselect_model

<RT data: procedures>+≡
    subroutine rt_data_unselect_model (global)
        class(rt_data_t), intent(inout), target :: global
        if (associated (global%model)) then
!            call global%delete_model_copy ()
            global%model => null ()
            global%model_is_copy = .false.
            call var_list_set_string (global%var_list, var_str (" $model_name"), &
                var_str (""), is_known = .false.)
        end if
    end subroutine rt_data_unselect_model

```

Create a copy of the currently selected model and append it to the local model list. The model pointer is redirected to the copy. (Not applicable for the global model list, those models will be modified in-place.)

```

<RT data: rt data: TBP>+≡
    procedure :: ensure_model_copy => rt_data_ensure_model_copy
!    procedure :: delete_model_copy => rt_data_delete_model_copy

```

```

<RT data: procedures>+≡
subroutine rt_data_ensure_model_copy (global)
  class(rt_data_t), intent(inout), target :: global
  if (associated (global%context)) then
    if (.not. global%model_is_copy) then
      call global%model_list%append_copy (global%model, global%model)
      global%model_is_copy = .true.
      call global%model%link_var_list (global%var_list)
    end if
  end if
end subroutine rt_data_ensure_model_copy

!   subroutine rt_data_delete_model_copy (global)
!     class(rt_data_t), intent(inout), target :: global
!     if (global%model_is_copy) then
!       call model_pointer_delete_instance (global%model)
!       global%model_is_copy = .false.
!     else
!       global%model => null ()
!     end if
!   end subroutine rt_data_delete_model_copy

```

Modify a model variable. The update mechanism will ensure that the model parameter set remains consistent. This has to take place in a local copy of the current model. If there is none yet, create one.

```

<RT data: rt data: TBP>+≡
  procedure :: model_set_real => rt_data_model_set_real

<RT data: procedures>+≡
subroutine rt_data_model_set_real (global, name, rval, verbose, pacified)

  <RT data: execute tests>
  end subroutine rt_data_test

```

#### Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```

<RT data: rt data: TBP>+≡
  procedure :: fix_system_dependencies => rt_data_fix_system_dependencies

<RT data: tests>+≡
  subroutine rt_data_fix_system_dependencies (rt_data)

## 29.3 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

This module provides no new types, just procedures.

```
<dispatch.f90>≡
  <File header>

  module dispatch

    <Use kinds>
    use kinds, only: i16, double

### 29.3.1 Interfaces

*⟨Dispatch: interfaces⟩*≡

```

interface
  subroutine GetXminM (set, mem, xmin)
    integer, intent(in) :: set, mem
    double precision, intent(out) :: xmin
  end subroutine GetXminM

```

```

end interface

<Dispatch: interfaces>+≡
interface
  subroutine GetXmaxM (set, mem, xmax)
    integer, intent(in) :: set, mem
    double precision, intent(out) :: xmax
  end subroutine GetXmaxM
end interface

<Dispatch: interfaces>+≡
interface
  subroutine GetQ2minM (set, mem, q2min)
    integer, intent(in) :: set, mem
    double precision, intent(out) :: q2min
  end subroutine GetQ2minM
end interface

<Dispatch: interfaces>+≡
interface
  subroutine GetQ2maxM (set, mem, q2max)
    integer, intent(in) :: set, mem
    double precision, intent(out) :: q2max
  end subroutine GetQ2maxM
end interface

```

### 29.3.2 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable.

Note: `core_def` has `intent(inout)` because gfortran 4.7.1 crashes for `intent(out)`.

```

<Dispatch: public>≡
public :: dispatch_core_def

<Dispatch: procedures>≡
subroutine dispatch_core_def (core_def, prt_in, prt_out, &
                             global, id, nlo_type)
  class(prc_core_def_t), allocatable, intent(inout) :: core_def
  type(string_t), dimension(:), intent(in) :: prt_in
  type(string_t), dimension(:), intent(in) :: prt_out
  type(rt_data_t), intent(in) :: global
  type(string_t), intent(in), optional :: id
  type(string_t), intent(in), optional :: nlo_type
  type(string_t) :: method
  type(string_t) :: model_name
  type(string_t) :: restrictions
  logical :: openmp_support
  logical :: report_progress
  logical :: diags, diags_color
  type(string_t) :: extra_options

```

```

type(model_t), pointer :: model
model => global%model
associate (var_list => global%get_var_list_ptr ())
  method = var_list%get_sval (var_str ("method"))
  if (associated (model)) then
    model_name = model%get_name ()

end select
end associate
end subroutine dispatch_core_def

```

### 29.3.3 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```

<Dispatch: public>+≡
    public :: dispatch_core

<Dispatch: procedures>+≡
    subroutine dispatch_core (core, core_def, model, &
        helicity_selection, qcd, use_color_factors)
        class(prc_core_t), allocatable, intent(inout) :: core
        class(prc_core_def_t), intent(in) :: core_def
        class(model_data_t), intent(in), target, optional :: model
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        type(qcd_t), intent(in), optional :: qcd
        logical, intent(in), optional :: use_color_factors
        select type (core_def)
        type is (prc_test_def_t)
            allocate (test_t :: core)
        type is (template_me_def_t)

```

```

        allocate (prc_template_me_t :: core)
        select type (core)
        type is (prc_template_me_t)
            call core%set_parameters (model)
        end select
class is (omega_def_t)
    if (.not. allocated (core)) allocate (prc_omega_t :: core)
    select type (core)
    type is (prc_omega_t)
        call core%set_parameters (model, &
            helicity_selection, qcd, use_color_factors)
    end select
type is (gosam_def_t)
    if (.not. allocated (core)) allocate (prc_gosam_t :: core)
    select type (core)
    type is (prc_gosam_t)
        call core%set_parameters (qcd, use_color_factors)
    end select
class default
    call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

### 29.3.4 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

*(Dispatch: public)* +=

```

public :: dispatch_core_update
public :: dispatch_core_restore

```

*(Dispatch: procedures)* +=

```

subroutine dispatch_core_update (core, model, helicity_selection, qcd, &
    saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(model_data_t), intent(in), optional, target :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    class(prc_core_t), allocatable, intent(inout), optional :: saved_core
    if (present (saved_core)) then
        allocate (saved_core, source = core)
    end if
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
        call core%set_parameters (model, helicity_selection, qcd)
        call core%activate_parameters ()
    type is (prc_gosam_t)
        call msg_message ("dispatch core restore: Gosam implementation not present yet!")

```

```

class default
    call msg_bug ("Process core update: unexpected process definition type")
end select
end subroutine dispatch_core_update

subroutine dispatch_core_restore (core, saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_t), allocatable, intent(inout) :: saved_core
    call move_alloc (from = saved_core, to = core)
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
        call core%activate_parameters ()
    class default
        call msg_bug ("Process core restore: unexpected process definition type")
    end select
end subroutine dispatch_core_restore

```

### 29.3.5 Integrator allocation

Allocate an integrator according to the variable `$integration_method`.

```

<Dispatch: public>+≡
    public :: dispatch_mci

<Dispatch: procedures>+≡
    subroutine dispatch_mci (mci, global, process_id)
        class(mci_t), allocatable, intent(inout) :: mci
        type(rt_data_t), intent(in) :: global

```

### 29.3.7 FKS parameter

Initialize parameters used to optimize FKS calculations.

```

<Dispatch: public>+≡
    public :: dispatch_fks

<Dispatch: procedures>+≡
    subroutine dispatch_fks (fks_template, global)
        type(fks_template_t), intent(inout) :: fks_template
        type(rt_data_t), intent(in) :: global
        real(default) :: fks_dij_exp1, fks_dij_exp2
        integer :: fks_mapping_type

        fks_dij_exp1 = &
            global%var_list%get_rval (var_str ("fks_dij_exp1"))
        fks_dij_exp2 = &
            global%var_list%get_rval (var_str ("fks_dij_exp2"))
        fks_mapping_type = &
            global%var_list%get_ival (var_str ("fks_mapping_type"))

        call fks_template%set_dij_exp (fks_dij_exp1, fks_dij_exp2)
        call fks_template%set_mapping_type (fks_mapping_type)

    end subroutine dispatch_fks

```

### 29.3.8 Random-number generator

Allocate a random-number generator factory according to the variable `$rng_method`, using the current seed in the global record. We take only the lower 15 bits of the seed, so the actual value fits into a positive 16-bit signed integer.

Since we want to guarantee that all random-number generators in a run are independent, we increment the global seed by one after creating the rng factory. If the user wants to have identical sequences, he can always set the seed manually, before it is used.

```

(Dispatch: public)+≡
    public :: dispatch_rng_factory

(Dispatch: procedures)+≡
    subroutine dispatch_rng_factory (rng_factory, global, local_input)
        class(rng_factory_t), allocatable, intent(inout) :: rng_factory
        type(rt_data_t), intent(inout), target :: global
        type(rt_data_t), intent(in), target, optional :: local_input
        type(rt_data_t), pointer :: local
        type(string_t) :: rng_method
        integer :: seed
        character(30) :: buffer
        integer(i16) :: s
        if (present (local_input)) then
            local => local_input
        else
            local => global
        end if
        rng_method = &
            local%var_list%get_sval (var_str ("rng_method"))
        seed = &
            local%var_list%get_ival (var_str ("seed"))
        s = mod (seed, 32768)
        select case (char (rng_method))
        case ("unit_test")
            allocate (rng_test_factory_t :: rng_factory)
            call msg_message ("RNG: Initializing Test random-number generator")
        case ("tao")
            allocate (rng_tao_factory_t :: rng_factory)
            call msg_message ("RNG: Initializing TAO random-number generator")
        case default
            call msg_fatal ("Random-number generator '" &
                // char (rng_method) // "' not implemented")
        end select
        write (buffer, "(I0)") s
        call msg_message ("RNG: Setting seed for random-number generator to " &
            // trim (buffer))
        call rng_factory%init (s)
        call var_list_set_int (global%var_list, var_str ("seed"), seed + 1, &
            is_known = .true.)
    end subroutine dispatch_rng_factory

```

### 29.3.9 Structure function configuration data

This data type is a container for transferring structure-function specific data from the `dispatch_sf_data` to the `dispatch_sf_channels` subroutine.

```

(Dispatch: public)+≡
    public :: sf_prop_t

```

```

<Dispatch: types>≡
  type :: sf_prop_t
    real(default), dimension(2) :: isr_eps = 1
  end type sf_prop_t

```

Allocate a structure-function configuration object according to the `sf_method` string.

The `sf_prop` object can be used to transfer structure-function specific data up and to the `dispatch_sf_channels` subroutine below, so they can be used for particular mappings.

The `global` object is intent(inout) because the RNG generator seed may change during initialization.

The `pdg_in` array is the array of incoming flavors, corresponding to the upstream structure function or the beam array. This will be checked for the structure function in question and replaced by the outgoing flavors. The `pdg_prc` array is the array of incoming flavors (beam index, component index) for the hard process.

This is an auxiliary procedure, used by the beam-structure expansion: tell for a given structure function name, whether it corresponds to a pair spectrum ( $n = 2$ ), a single-particle structure function ( $n = 1$ ), or nothing ( $n = 0$ ). Though `energy_scan` can in principle also be a pair spectrum, it always has only one parameter.

end function strfun_mode

```

Dispatch a whole structure-function chain, given beam data and beam structure data.

This could be done generically, but we should look at the specific combination of structure functions in order to select appropriate mappings.

The `beam_structure` argument gets copied because we want to expand it to canonical form (one valid structure-function entry per record) before proceeding further.

The `pdg_prc` argument is the array of incoming flavors. The first index is the beam index, the second one the process component index. Each element is itself a PDG array, nontrivial if there is a flavor sum for the incoming state of this component.

The dispatcher is divided in two parts. The first part configures the structure function data themselves. After this, we can configure the phase space for the elementary process.

```

<Dispatch: public>+≡
  public :: dispatch_sf_config

<Dispatch: procedures>+≡
  subroutine dispatch_sf_config (sf_config, sf_prop, global, pdg_prc)

    deallocate (sf_data)
end do
end subroutine dispatch_sf_config

```

The second part configures channel mappings, using some conditions from the phase space configuration. If there are no structure functions, we enable a default setup with a single (dummy) structure-function channel. Otherwise, we look at the channel collection that we got from the phase-space configuration step. Each entry should be translated into an independent structure-function channel, where typically there is one default entry, which could be mapped using a standard s-channel mapping if the structure function setup recommends this, and other entries with s-channel resonances. The latter need to be translated into global mappings from the structure-function chain.

### 29.3.11 QCD coupling

Allocate the `alpha` (running coupling) component of the `qcd` block with a concrete implementation, depending on the variable settings in the `global` record.

If a fixed  $\alpha_s$  is requested, we do not allocate the `qcd%alpha` object. In this case, the matrix element code will just take the model parameter as-is, which implies fixed  $\alpha_s$ . If the object is allocated, the  $\alpha_s$  value is computed and updated for each matrix-element call.

```

<Dispatch: public>+≡
    public :: dispatch_qcd

        write (u, "(A)")  "* Test output end: dispatch_14"
```

```
end subroutine dispatch_14
```

## 29.4 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

```
<process_configurations.f90>≡
  <File header>

  module process_configurations

    <Use strings>
    use unit_tests
    use diagnostics

    use variables
    use models
    use prc_core_def
    use particle_specifiers
    use process_libraries
    use prclib_stacks
    use prc_test
    use prc_omega
    use rt_data
    use dispatch

    use prc_gosam

    <Standard module head>

    <Process configurations: public>

    <Process configurations: types>

    contains

    <Process configurations: procedures>

    <Process configurations: tests>

  end module process_configurations
```

### 29.4.1 Data Type

```
<Process configurations: public>≡
  public :: process_configuration_t

<Process configurations: types>≡
  type :: process_configuration_t
    type(process_def_entry_t), pointer :: entry => null ()
    type(string_t) :: id
    integer :: num_id = 0
  contains
```

```

    <Process configurations: process configuration: TBP>
end type process_configuration_t

```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

```

<Process configurations: process configuration: TBP>≡
    procedure :: init => process_configuration_init

<Process configurations: procedures>≡
    subroutine process_configuration_init &
        (config, prc_name, n_in, n_components, global)
    class(process_configuration_t), intent(out) :: config
    type(string_t), intent(in) :: prc_name
    integer, intent(in) :: n_in
    integer, intent(in) :: n_components
    type(rt_data_t), intent(in) :: global
    type(model_t), pointer :: model
    model => global%model
    config%id = prc_name
    allocate (config%entry)
    if (global%var_list%is_known (var_str ("process_num_id"))) then
        config%num_id = &
            global%var_list%get_ival (var_str ("process_num_id"))
        call config%entry%init (prc_name, &
            model = model, n_in = n_in, n_components = n_components, &
            num_id = config%num_id, nlo_process = global%nlo_calculation)
    else
        call config%entry%init (prc_name, &
            model = model, n_in = n_in, n_components = n_components, &
            nlo_process = global%nlo_calculation)
    end if
end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

```

<Process configurations: process configuration: TBP>+≡
    procedure :: setup_component => process_configuration_setup_component

<Process configurations: procedures>+≡
    subroutine process_configuration_setup_component &
        (config, i_component, prt_in, prt_out, global, &

```

## 29.4.2 Test

This is the master for calling self-test procedures.

```

<Process configurations: public>+≡
public :: process_configurations_test

<Process configurations: tests>≡
subroutine process_configurations_test (u, results)
integer, intent(in) :: u
type(test_results_t), intent(inout) :: results
<Process configurations: execute tests>
end subroutine process_configurations_test

```

### Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

```

<Process configurations: public>+≡
public :: prepare_test_library

```

```

<Process configurations: tests>+≡
subroutine prepare_test_library (global, libname, mode, procname)
  type(rt_data_t), intent(inout), target :: global
  type(string_t), intent(in) :: libname
  integer, intent(in) :: mode
  type(string_t), intent(in), dimension(:), optional :: procname
  type(prclib_entry_t), pointer :: lib
  type(string_t) :: prc_name
  type(string_t), dimension(:), allocatable :: prt_in, prt_out
  integer :: n_components
  type(process_configuration_t) :: prc_config

## 29.5 Compilation

This module manages compilation and loading of process libraries. It is needed as a separate module because integration depends on it.

```
<compilations.f90>≡  
  <File header>  
  
  module compilations  
  
    <Use strings>  
    use io_units  
    use unit_tests  
    use system_defs, only: TAB  
    use diagnostics  
    use os_interface  
    use md5  
    use variables  
    use model_data  
    use models  
    use process_libraries  
    use prclib_stacks  
    use rt_data  
    use process_configurations  
  
    <Standard module head>  
  
    <Compilations: public>  
  
    <Compilations: types>  
  
    contains  
  
    <Compilations: procedures>  
  
    <Compilations: tests>  
  
  end module compilations
```

### 29.5.1 The data type

The compilation item handles the compilation and loading of a single process library.

```
<Compilations: types>≡  
  type :: compilation_item_t  
    type(string_t) :: libname  
    type(string_t) :: static_external_tag  
    type(process_library_t), pointer :: lib => null ()  
    logical :: recompile_library = .false.  
  contains  
    <Compilations: compilation item: TBP>  
  end type compilation_item_t
```

Initialize:

```
<Compilations: compilation item: TBP>≡
  procedure :: init => compilation_item_init

<Compilations: procedures>≡
  subroutine compilation_item_init (comp, libname, stack, var_list)
    class(compilation_item_t), intent(out) :: comp

        end if
    end subroutine compilation_item_success

```

## 29.5.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>≡
    public :: compile_library

<Compilations: procedures>+≡
    subroutine compile_library (libname, global)
        type(string_t), intent(in) :: libname
        type(rt_data_t), intent(inout), target :: global
        type(compilation_item_t) :: comp
        logical :: force, recompile
        force = &
            global%var_list%get_lval (var_str ("?rebuild_library"))
        recompile = &
            global%var_list%get_lval (var_str ("?recompile_library"))
        if (associated (global%model)) then
            call comp%init (libname, global%prclib_stack, global%var_list)
            call comp%compile (global%model, global%os_data, force, recompile)
            if (signal_is_pending ()) return
        end if
    end subroutine compile_library

```

```

        call comp%load (global%os_data)
        if (signal_is_pending ()) return
    else
        call msg_fatal ("Process library compilation: " &
            // " model is undefined.")
    end if
    call comp%success ()
end subroutine compile_library

```

### 29.5.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```

<Compilations: types>+≡
    type :: compilation_t
    private
        type(string_t) :: exe_name
        type(string_t), dimension(:), allocatable :: lib_name
    contains
        <Compilations: compilation: TBP>
    end type compilation_t

```

Output.

```

<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write

<Compilations: procedures>+≡
    subroutine compilation_write (object, unit)
        class(compilation_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Compilation object:"
        write (u, "(3x,3A)") "executable          = '", &
            char (object%exe_name), "'
        write (u, "(3x,A)", advance="no") "process libraries ="
        do i = 1, size (object%lib_name)
            write (u, "(1x,3A)", advance="no") "' ", char (object%lib_name(i)), "'
        end do
        write (u, *)
    end subroutine compilation_write

```

Initialize: we know the names of the executable and of the libraries.

```

<Compilations: compilation: TBP>+≡
    procedure :: init => compilation_init

<Compilations: procedures>+≡
    subroutine compilation_init (compilation, exe_name, lib_name)
        class(compilation_t), intent(out) :: compilation
        type(string_t), intent(in) :: exe_name
        type(string_t), dimension(:), intent(in) :: lib_name
        compilation%exe_name = exe_name

```

```

        allocate (compilation%lib_name (size (lib_name)))
        compilation%lib_name = lib_name
    end subroutine compilation_init

```

Write the dispatcher subroutine for the compiled libraries. Also write a subroutine which returns the names of the compiled libraries.

*<Compilations: compilation: TBP>+≡*

```

#### 29.5.4 API for executable compilation

This is a shorthand for compiling and loading an executable, including the enclosed libraries. The `compilation` object is used only internally.

The global data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
    public :: compile_executable

<Compilations: procedures>+≡
    subroutine compile_executable (exename, libname, global)
        type(string_t), intent(in) :: exename
        type(string_t), dimension(:), intent(in) :: libname
        type(rt_data_t), intent(inout), target :: global
        type(compilation_t) :: compilation

```

```

type(compilation_item_t) :: item
type(string_t) :: ext_libtag
logical :: force, recompile
integer :: i
ext_libtag = ""
force = &
    global%var_list%get_lval (var_str ("?rebuild_library"))
recompile = &
    global%var_list%get_lval (var_str ("?recompile_library"))
call compilation%init (exename, [libname])
if (signal_is_pending ()) return
call compilation%write_dispatcher ()
if (signal_is_pending ()) return
do i = 1, size (libname)
    call item%init (libname(i), global%prclib_stack, global%var_list)
    call item%compile (global%model, global%os_data, &
        force=force, recompile=recompile)
    ext_libtag = "" // item%lib%get_static_modelname (global%os_data)
    if (signal_is_pending ()) return
    call item%success ()
end do
call compilation%write_makefile (global%os_data, ext_libtag)
if (signal_is_pending ()) return
call compilation%make_compile (global%os_data)
if (signal_is_pending ()) return
call compilation%make_link (global%os_data)
end subroutine compile_executable

```

### 29.5.5 Test

This is the master for calling self-test procedures.

```

<Compilations: public>+≡
    public :: compilations_test

<Compilations: tests>≡
    subroutine compilations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Compilations: execute tests>
    end subroutine compilations_test

```

### Intrinsic Matrix Element

Compile an intrinsic test matrix element (`prc_test` type).

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```

<Compilations: execute tests>≡
    call test (compilations_1, "compilations_1", &
        "intrinsic test processes", &
        u, results)

```

```

<Compilations: tests>+≡
subroutine compilations_1 (u)
  integer, intent(in) :: u
  type(string_t) :: libname, procname
  type(rt_data_t), target :: global

  write (u, "(A)")  "* Test output: compilations_1"
  write (u, "(A)")  "* Purpose: configure and compile test process"
  write (u, "(A)")

  call syntax_model_file_init ()

  call global%global_init ()

  libname = "compilation_1"
  procname = "prc_comp_1"
  call prepare_test_library (global, libname, 1, [procname])

  call compile_library (libname, global)

  call global%write_libraries (u)

  call global%final ()
  call syntax_model_file_final ()

  write (u, "(A)")
  write (u, "(A)")  "* Test output end: compilations_1"

end subroutine compilations_1

```

## External Matrix Element

Compile an external test matrix element (omega type)

```

<Compilations: execute tests>+≡
  call test (compilations_2, "compilations_2", &
    "external process (omega)", &
    u, results)

<Compilations: tests>+≡
subroutine compilations_2 (u)
  integer, intent(in) :: u
  type(string_t) :: libname, procname
  type(rt_data_t), target :: global

  write (u, "(A)")  "* Test output: compilations_2"
  write (u, "(A)")  "* Purpose: configure and compile test process"
  write (u, "(A)")

  call syntax_model_file_init ()

  call global%global_init ()
  call var_list_set_log (global%var_list, var_str ("?omega_openmp"), &
    .false., is_known = .true.)

```

```

libname = "compilation_2"
procname = "prc_comp_2"
call prepare_test_library (global, libname, 2, [procname,procname])

call compile_library (libname, global)

call global%write_libraries (u, libpath = .false.)

call global%final ()
call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_2"

end subroutine compilations_2

```

## External Matrix Element

Compile an external test matrix element (omega type) and create driver files for a static executable.

```

<Compilations: execute tests>+≡
  call test (compilations_3, "compilations_3", &
    "static executable: driver", &
    u, results)

<Compilations: tests>+≡
  subroutine compilations_3 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    type(compilation_t) :: compilation
    integer :: u_file
    character(80) :: buffer

    write (u, "(A)")  "* Test output: compilations_3"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()
    call var_list_set_log (global%var_list, var_str ("?omega_omp"), &
      .false., is_known = .true.)

    libname = "compilations_3_lib"
    procname = "prc_comp_3"
    exename = "compilations_3"

    call prepare_test_library (global, libname, 2, [procname,procname])

```

```

call compilation%init (exename, [libname])
call compilation%write (u)

write (u, "(A)")
write (u, "(A)")  "* Write dispatcher"
write (u, "(A)")

call compilation%write_dispatcher ()

u_file = free_unit ()
open (u_file, file = char (exename) // "_prclib_dispatcher.f90", &
      status = "old", action = "read")

### 29.5.6 Test static build

The tests for building a static executable are separate, since they should be skipped if the WHIZARD build itself has static libraries disabled.

```
<Compilations: public>+≡
  public :: compilations_static_test

<Compilations: tests>+≡
  subroutine compilations_static_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Compilations: static tests>
  end subroutine compilations_static_test
```

### External Matrix Element

Compile an external test matrix element (omega type) and incorporate this in a new static WHIZARD executable.

```
<Compilations: static tests>≡
  call test (compilations_static_1, "compilations_static_1", &
    "static executable: compilation", &
    u, results)

<Compilations: tests>+≡
  subroutine compilations_static_1 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    type(compilation_item_t) :: item
    type(compilation_t) :: compilation
    logical :: exist

    write (u, "(A)")  "* Test output: compilations_static_1"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library"

    call syntax_model_file_init ()

    call global%global_init ()
    call var_list_set_log (global%var_list, var_str ("?omega_openmp"), &
      .false., is_known = .true.)

    libname = "compilations_static_1_lib"
    procname = "prc_comp_stat_1"
    exename = "compilations_static_1"

    call prepare_test_library (global, libname, 2, [procname, procname])
```

```

call compilation%init (exename, [libname])

write (u, "(A)")
write (u, "(A)")  "* Write dispatcher"

call compilation%write_dispatcher ()

write (u, "(A)")
write (u, "(A)")  "* Write Makefile"

call compilation%write_makefile (global%os_data)

write (u, "(A)")
write (u, "(A)")  "* Build libraries"

write (u, "(A)")  "* Test output end: compilations_static_1"

end subroutine compilations_static_1

```

## External Matrix Element

Compile an external test matrix element (`omega` type) and incorporate this in a new static WHIZARD executable. In this version, we use the wrapper `compile_executable` procedure.

```
(Compilations: static tests)+≡
  call test (compilations_static_2, "compilations_static_2", &
    "static executable: shortcut", &
    u, results)

(Compilations: tests)+≡
  subroutine compilations_static_2 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    type(compilation_item_t) :: item
    type(compilation_t) :: compilation
    logical :: exist
    integer :: u_file

    write (u, "(A)")  "* Test output: compilations_static_2"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library and compile"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()
    call var_list_set_log (global%var_list, var_str ("?omega_omp"), &
      .false., is_known = .true.)

    libname = "compilations_static_2_lib"
    procname = "prc_comp_stat_2"
    exename = "compilations_static_2"

    call prepare_test_library (global, libname, 2, [procname,procname])

    call compile_executable (exename, [libname], global)

    write (u, "(A)")  "* Check executable (should be present)"
    write (u, "(A)")

    inquire (file = char (exename), exist = exist)
    write (u, "(A,A,L1)") char (exename), " exists = ", exist

    write (u, "(A)")
    write (u, "(A)")  "* Cleanup"

    u_file = free_unit ()
    open (u_file, file = char (exename), status = "old", action = "write")
```

```
close (u_file, status = "delete")

call global%final ()
call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_static_2"

end subroutine compilations_static_2
```

## 29.6 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

```
<integrations.f90>≡  
  <File header>  
  
  module integrations  
  
    <Use kinds>  
    <Use strings>

    <Integrations: public>

    <Integrations: types>

contains

    <Integrations: procedures>

    <Integrations: tests>

end module integrations

```

### 29.6.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

<Integrations: public>≡
    public :: integration_t

<Integrations: types>≡
    type :: integration_t
        private
            type(string_t) :: process_id
            type(string_t) :: run_id
            type(process_t), pointer :: process => null ()
            type(var_list_t), pointer :: model_vars => null ()
            type(qcd_t) :: qcd
            logical :: rebuild_phs = .false.
            logical :: ignore_phs_mismatch = .false.
            logical :: phs_only = .false.
            logical :: process_has_me = .true.
            integer :: n_calls_test = 0
            logical :: vis_history = .true.
            type(string_t) :: history_filename
            type(string_t) :: log_filename
            logical :: combined_integration = .false.
        contains
            <Integrations: integration: TBP>
        end type integration_t

```

### 29.6.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied.

```

<Integrations: integration: TBP>≡
    procedure :: create_process => integration_create_process

<Integrations: procedures>≡
    subroutine integration_create_process (intg, process_id, global)
        class(integration_t), intent(out) :: intg

```

```

type(rt_data_t), intent(inout), optional, target :: global
type(string_t), intent(in) :: process_id
type(process_entry_t), pointer :: process_entry
intg%process_id = process_id
if (present (global)) then
  allocate (process_entry)
  intg%process => process_entry%process_t
  call global%process_stack%push (process_entry)
else
  allocate (process_t :: intg%process)
end if
intg%model_vars => null ()
end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the local stack directly. The intent(inout) attribute for the local data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

*(Integrations: integration: TBP)+≡*

```

procedure :: init_process => integration_init_process

```

*(Integrations: procedures)+≡*

```

subroutine integration_init_process (intg, local)
  class(integration_t), intent(inout) :: intg
  type(rt_data_t), intent(inout), target :: local
  type(string_t) :: model_name
  type(model_t), pointer :: model
  class(model_data_t), pointer :: model_instance
  class(rng_factory_t), allocatable :: rng_factory
  if (.not. local%prclib%contains (intg%process_id)) then
    call msg_fatal ("Process '" // char (intg%process_id) // "' not found" &
      // " in library '" // char (local%prclib%get_name ()) // "'")
    return
  end if

### 29.6.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```
<Integrations: integration: TBP>+≡
  procedure :: evaluate => integration_evaluate

<Integrations: procedures>+≡
  subroutine integration_evaluate &
    (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
    integer :: n_calls, n_it
    logical :: adapt_grids, adapt_weights, final

    n_it = it_list%get_n_it (pass)
    n_calls = it_list%get_n_calls (pass)
    adapt_grids = it_list%adapt_grids (pass)
    adapt_weights = it_list%adapt_weights (pass)
    final = pass == it_list%get_n_pass ()

    call intg%process%integrate (process_instance, &
      i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
      final, pacify)

  end subroutine integration_evaluate
```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

```
<Integrations: integration: TBP>+≡
  procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: procedures>+≡
  subroutine integration_make_iterations_list (intg, it_list)
    class(integration_t), intent(in) :: intg
    type(iterations_list_t), intent(out) :: it_list
    integer :: pass, n_pass
    integer, dimension(:), allocatable :: n_it, n_calls
    logical, dimension(:), allocatable :: adapt_grids, adapt_weights
    n_pass = intg%process%get_n_pass_default ()
    allocate (n_it (n_pass), n_calls (n_pass))
    allocate (adapt_grids (n_pass), adapt_weights (n_pass))
    do pass = 1, n_pass
      n_it(pass) = intg%process%get_n_it_default (pass)
      n_calls(pass) = intg%process%get_n_calls_default (pass)
```

```

        adapt_grids(pass)    = intg%process%adapt_grids_default (pass)
        adapt_weights(pass) = intg%process%adapt_weights_default (pass)
    end do
    call it_list%init (n_it, n_calls, &
        adapt_grids = adapt_grids, adapt_weights = adapt_weights)
end subroutine integration_make_iterations_list

```

## 29.6.4 API for integration objects

This initializer does everything except assigning cuts/scale/weight expressions.

*<Integrations: integration: TBP>+≡*

```
procedure :: init => integration_init
```

*<Integrations: procedures>+≡*

```

subroutine integration_init (intg, process_id, local, global, local_stack)
    class(integration_t), intent(out) :: intg
    type(string_t), intent(in) :: process_id
    type(rt_data_t), intent(inout), target :: local
    type(rt_data_t), intent(inout), optional, target :: global
    logical, intent(in), optional :: local_stack
    logical :: use_local
    use_local = .false.; if (present (local_stack)) use_local = local_stack
    if (present (global)) then
        call intg%create_process (process_id, global)
    else if (use_local) then
        call intg%create_process (process_id, local)
    else
        call intg%create_process (process_id)
    end if
    call intg%init_process (local)
    call intg%setup_process (local)
end subroutine integration_init

```

Do the integration for a single process, both warmup and final evaluation. The `eff_reset` flag is to suppress numerical noise in the graphical output of the integration history.

*<Integrations: integration: TBP>+≡*

```
procedure :: integrate => integration_integrate
```

Return the process pointer (needed by simulate):

*(Integrations: integration: TBP)+≡*

```

    procedure :: get_process_ptr => integration_get_process_ptr

```

*(Integrations: procedures)+≡*

```

    function integration_get_process_ptr (intg) result (ptr)
        class(integration_t), intent(in) :: intg
        type(process_t), pointer :: ptr
        ptr => intg%process
    end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The **integration** object exists only internally.

If the **global** environment is provided, the process object is appended to the global stack. Otherwise, if **local\_stack** is set, we append to the local process stack. If this is unset, the **process** object is not recorded permanently.

The **init\_only** flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The **eff\_reset** flag is to suppress numerical noise in the visualization of the integration history.

*(Integrations: public)+≡*

```

    public :: integrate_process

### 29.6.5 Test

This is the master for calling self-test procedures.

```

<Integrations: public>+≡
  public :: integrations_test

<Integrations: tests>≡
  subroutine integrations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Integrations: execute tests>

```

```

end subroutine integrations_test

<Integrations: public>+≡
public :: integrations_history_test

<Integrations: tests>+≡
subroutine integrations_history_test (u, results)
integer, intent(in) :: u
type(test_results_t), intent(inout) :: results
<Integrations: execute history tests>
end subroutine integrations_history_test

```

### Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the  $2 \rightarrow 2$  process  $ss \rightarrow ss$  with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (29.1)$$

$c$  is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (29.2)$$

$f$  is the flux of the incoming particles with mass  $m = 125 \text{ GeV}$  and energy  $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (29.3)$$

$\Phi_2$  is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (29.4)$$

The squared matrix element  $|M|^2$  is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (29.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```

## Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function  $f(x) = x$  for both beams. Together with the  $1/x_1x_2$  factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the  $m_s$  mass which we set to zero here.

```

## 29.7 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
(event_streams.f90)≡  
  <File header>  
  
  module event_streams  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use unit_tests  
    use diagnostics  
    use variables  
    use model_data  
    use models  
    use processes  
    use events  
    use eio_data  
    use eio_base  
    use rt_data  
    use dispatch  
  
    <Standard module head>  
  
    <Event streams: public>  
  
    <Event streams: types>  
  
    contains  
  
    <Event streams: tests>  
  
    <Event streams: procedures>  
  
  end module event_streams
```

### 29.7.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡  
  type :: event_stream_entry_t  
    class(eio_t), allocatable :: eio  
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```
<Event streams: public>≡  
  public :: event_stream_array_t
```

```

<Event streams: types>+≡
  type :: event_stream_array_t
    type(event_stream_entry_t), dimension(:), allocatable :: entry
    integer :: i_in = 0
  contains
    <Event streams: event stream array: TBP>
  end type event_stream_array_t

```

Output.

```

<Event streams: event stream array: TBP>≡
  procedure :: write => event_stream_array_write

<Event streams: procedures>≡
  subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event stream array:"
    if (allocated (object%entry)) then
      select case (size (object%entry))
        case (0)
          write (u, "(3x,A)") "[empty]"
        case default
          do i = 1, size (object%entry)
            if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
            call object%entry(i)%eio%write (u)
          end do
        end select
      else
        write (u, "(3x,A)") "[undefined]"
      end if
    end subroutine event_stream_array_write

```

Finalize all streams.

```

<Event streams: event stream array: TBP>+≡
  procedure :: final => event_stream_array_final

<Event streams: procedures>+≡
  subroutine event_stream_array_final (es_array)
    class(event_stream_array_t), intent(inout) :: es_array
    integer :: i
    do i = 1, size (es_array%entry)
      call es_array%entry(i)%eio%final ()
    end do
  end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

*(Event streams: event stream array: TBP)+≡*

```
procedure :: init => event_stream_array_init
```

*(Event streams: procedures)+≡*

```
subroutine event_stream_array_init &

## 29.8 Simulation

This module manages simulation: event generation and reading/writing of event files. The `simulation` object is intended to be used (via a pointer) outside of WHIZARD, if events are generated individually by an external driver.

```

            object%has_integral = .true.
        end if
    end subroutine mci_set_init

```

### 29.8.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

```

<Simulations: types>+≡
    type :: core_safe_t
        class(prc_core_t), allocatable :: core
    end type core_safe_t

```

### 29.8.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

```

<Simulations: procedures>+≡
    subroutine prepare_process &
        (process, process_id, integrate, local, global)
        type(process_t), pointer, intent(out) :: process

```

```

type(string_t), intent(in) :: process_id
logical, intent(in) :: integrate
type(rt_data_t), intent(inout), target :: local
type(rt_data_t), intent(inout), optional, target :: global
if (present (global)) then
    process => global%process_stack%get_process_ptr (process_id)
else
    process => local%process_stack%get_process_ptr (process_id)
end if
if (.not. associated (process)) then
    if (integrate) then
        call msg_message ("Simulate: process '" &
            // char (process_id) // "' needs integration")
    else
        call msg_message ("Simulate: process '" &
            // char (process_id) // "' needs initialization")
    end if
    if (present (global)) then
        call integrate_process (process_id, local, global, &
            init_only = .not. integrate)
    else
        call integrate_process (process_id, local, local_stack=.true., &
            init_only = .not. integrate)
    end if
    if (signal_is_pending ()) return
    process => global%process_stack%get_process_ptr (process_id)
    if (associated (process)) then
        if (integrate) then
            call msg_message ("Simulate: integration done")
            call global%process_stack%fill_result_vars (process_id)
        else
            call msg_message ("Simulate: process initialization done")
        end if
    else
        call msg_fatal ("Simulate: process '" &
            // char (process_id) // "' could not be initialized: aborting")
    end if
end if
end subroutine prepare_process

```

### 29.8.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocates the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the qcd and/or model components are present.

```

<Simulations: types>+≡
type, extends (event_t) :: entry_t
private
type(string_t) :: process_id
type(string_t) :: library
type(string_t) :: run_id
logical :: has_integral = .false.
real(default) :: integral = 0
real(default) :: error = 0
real(default) :: process_weight = 0
logical :: valid = .false.
type(counter_t) :: counter
integer :: n_in = 0
integer :: n_mci = 0
type(mci_set_t), dimension(:), allocatable :: mci_set
type(selector_t) :: mci_selector
type(core_safe_t), dimension(:), allocatable :: core_safe
class(model_data_t), pointer :: model => null ()
type(qcd_t) :: qcd
logical :: nlo_event = .false.
contains
<Simulations: entry: TBP>
end type entry_t

```

Output. Write just the configuration, the event is written by a separate routine.

The verbose option is unused, it is required by the interface of the base-object method.

```

<Simulations: entry: TBP>≡
procedure :: write_config => entry_write_config

<Simulations: procedures>+≡
subroutine entry_write_config (object, unit)
class(entry_t), intent(in) :: object
integer, intent(in), optional :: unit
integer :: u, i
u = given_output_unit (unit)
write (u, "(3x,A,A,A)") "Process   = '", char (object%process_id), "'"
write (u, "(3x,A,A,A)") "Library   = '", char (object%library), "'"

            call object%core_safe(i)%core%write (u)
        end do
    end if
end subroutine entry_write_config

```

Finalizer. The *instance* pointer component of the *event\_t* base type points to a target which we did explicitly allocate in the *entry\_init* procedure. Therefore, we finalize and explicitly deallocate it here. Then we call the finalizer of the base type.

```

<Simulations: entry: TBP>+≡
    procedure :: final => entry_final

<Simulations: procedures>+≡
    subroutine entry_final (object)
        class(entry_t), intent(inout) :: object
        integer :: i
        if (associated (object%instance)) then
            do i = 1, object%n_mci
                call object%instance%final_simulation (i)
            end do
            call object%instance%final ()
            deallocate (object%instance)
        end if
        call object%event_t%final ()
    end subroutine entry_final

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the *process\_instance* pointer. Assign data by looking at the process object and at the environment.

If *n\_alt* is set, we prepare for additional alternate sqme and weight entries.

If the process object is not found initially: if *integrate* is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If *generate* is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the *instance* and *process* pointers of the base type by the *connect* method, so we can reference them later.

```

## 29.8.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

*<Simulations: types>+≡*

```

    type, extends (entry_t) :: alt_entry_t
    contains
        <Simulations: alt entry: TBP>
    end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

### 29.8.7 The simulation type

Each simulation object corresponds to an event sample, identified by the `sample_id`.

The simulation may cover several processes simultaneously. All process-specific data, including the event records, are stored in the `entry` subobjects. The `current` index indicates which record was selected last. `version` is foreseen to contain a tag on the WHIZARD event file version. It can be

```

<Simulations: public>≡
  public :: simulation_t

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the `luminosity` setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the `luminosity`, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

NB: When reading from file, event transforms can't be applied because the process instance will not be complete. This should be fixed.

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

## 29.8.8 Event Stream I/O

Write an event to a generic eio event stream. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+≡
    generic :: write_event => write_event_eio
    procedure :: write_event_eio => simulation_write_event_eio

<Simulations: procedures>+≡
    subroutine simulation_write_event_eio (object, eio, i_prc)
        class(simulation_t), intent(in) :: object
        class(eio_t), intent(inout) :: eio
        integer, intent(in), optional :: i_prc
        integer :: current
        if (present (i_prc)) then
            current = i_prc
        else
            current = object%i_prc
        end if
        if (current > 0) then
            if (object%split_n_evt > 0) then
                if (object%counter%total > 1 .and. &
                    mod (object%counter%total, object%split_n_evt) == 1) then
                    call eio%split_out ()
                end if
            end if
            call eio%output (object%entry(current)%event_t, current, pacify = object%pacify)
        else
            call msg_fatal ("Simulation: write event: no process selected")
        end if
    end subroutine simulation_write_event_eio

```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```

<Simulations: simulation: TBP>+≡
  generic :: read_event => read_event_eio
  procedure :: read_event_eio => simulation_read_event_eio

<Simulations: procedures>+≡
  subroutine simulation_read_event_eio (object, eio)
    class(simulation_t), intent(inout) :: object
    class(eio_t), intent(inout) :: eio
    integer :: iostat, current
    call eio%input_i_prc (current, iostat)
    select case (iostat)
    case (0)
      object%i_prc = current
      call eio%input_event (object%entry(current)%event_t, iostat)
    end select
    select case (iostat)
    case (:-1)
      object%i_prc = 0
      object%i_mci = 0
    case (1:)
      call msg_error ("Reading events: I/O error, aborting read")
      object%i_prc = 0
      object%i_mci = 0
    case default
      object%i_mci = object%entry(current)%get_i_mci ()
    end select
  end subroutine simulation_read_event_eio

```

## 29.8.9 Event Stream Array

Write an event using an array of event I/O streams. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+≡
  generic :: write_event => write_event_es_array
  procedure :: write_event_es_array => simulation_write_event_es_array

<Simulations: procedures>+≡
  subroutine simulation_write_event_es_array (object, es_array)
    class(simulation_t), intent(in) :: object
    class(event_stream_array_t), intent(inout) :: es_array
    integer :: i_prc, event_index
    i_prc = object%i_prc
    if (i_prc > 0) then
      event_index = object%counter%total
      call es_array%output (object%entry(i_prc)%event_t, i_prc, &
        event_index, pacify = object%pacify)
    else

```

```

        call msg_fatal ("Simulation: write event: no process selected")
    end if
end subroutine simulation_write_event_es_array

```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

```

<Simulations: simulation: TBP>+=
    generic :: read_event => read_event_es_array
    procedure :: read_event_es_array => simulation_read_event_es_array

<Simulations: procedures>+=
    subroutine simulation_read_event_es_array (object, es_array, enable_switch, &
        fail)
        class(simulation_t), intent(inout) :: object

            object%i_mci = object%entry(i_prc)%get_i_mci ()
        case default
            write (msg_buffer, "(A,1x,I0,1x,A)" ) &
                "Reading events: I/O error, aborting read after", &
                object%counter%read, "events."
            call msg_error ()
            object%i_prc = 0
            object%i_mci = 0
            fail = .true.
        end select
    end subroutine

```

```

        end select
    else
        fail = .true.
    end if
end subroutine simulation_read_event_es_array

```

### 29.8.10 Recover event

Recalculate the process instance contents, given an event with known particle set. The indices for MC, term, and channel must be already set. The `recalculate` method of the selected entry will import the result into `sqme_prc` and `weight_prc`.

```

<Simulations: simulation: TBP>+≡
    procedure :: recalculate => simulation_recalculate

<Simulations: procedures>+≡
    subroutine simulation_recalculate (simulation)
        class(simulation_t), intent(inout) :: simulation
        integer :: i_prc
        i_prc = simulation%i_prc
        associate (entry => simulation%entry(i_prc))
            if (simulation%update_weight) then
                call simulation%entry(i_prc)%recalculate &
                    (update_sqme = simulation%update_sqme, &
                     recover_beams = simulation%recover_beams, &
                     weight_factor = entry%get_kinematical_weight ())
            else
                call simulation%entry(i_prc)%recalculate &
                    (update_sqme = simulation%update_sqme, &
                     recover_beams = simulation%recover_beams)
            end if
        end associate
    end subroutine simulation_recalculate

```

### 29.8.11 Extract contents

Return the MD5 sum that summarizes configuration and integration (but not the event file). Used for initializing the event streams.

```

<Simulations: simulation: TBP>+≡
    procedure :: get_md5sum_prc => simulation_get_md5sum_prc

## Chapter 30

# More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in init/final hooks that we can set at runtime.)

### 30.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
(expr_tests.f90)≡  
  <File header>  
  module expr_tests  
  
    <Use kinds>  
    <Use strings>  
    use format_defs, only: FMT_12  
    use format_utils, only: write_separator  
    use unit_tests  
    use os_interface  
    use ifiles  
    use lexers  
    use parser  
    use lorentz  
    use sm_qcd  
    use model_data  
    use interactions, only: reset_interaction_counter  
    use variables  
    use expr_base  
    use eval_trees

*⟨Expr tests: tests⟩*

end module expr\_tests

### 30.1.1 Test

This is the master for calling self-test procedures.

*⟨Expr tests: public⟩*≡

```
public :: subevt_expr_test
```

*⟨Expr tests: tests⟩*≡

```

subroutine subevt_expr_test (u, results)
  integer, intent(in) :: u
  type(test_results_t), intent(inout) :: results
  ⟨Expr tests: execute tests⟩
end subroutine subevt_expr_test

```

### Parton-event expressions

*⟨Expr tests: execute tests⟩*≡

```

call test (subevt_expr_1, "subevt_expr_1", &
  "parton-event expressions", &
  u, results)

```

*⟨Expr tests: tests⟩*+≡

```

subroutine subevt_expr_1 (u)

```

## Chapter 31

# Top Level

The top level consists of

**commands** Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

**whizard** This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

**main** The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

**whizard\_c\_interface** Alternative top-level procedures, for use in the context of a C-compatible caller program.

## 31.1 Commands

This module defines the command language of the main input file.

```
<commands.f90>≡  
  <File header>  
  
  module commands  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use constants  
    use string_utils, only: lower_case  
    use format_utils, only: write_indent  
    use format_defs, only: FMT_14, FMT_19  
    use unit_tests  
    use diagnostics  
    use sm_qcd  
    use pdf_builtin !NODEP!  
    use sorting  
    use sf_lhapdf  
    use os_interface  
    use ifiles  
    use lexers

### 31.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as **options**, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```
⟨Commands: types⟩≡
  type, abstract :: command_t
    type(parse_node_t), pointer :: pn => null ()
    class(command_t), pointer :: next => null ()
    type(parse_node_t), pointer :: pn_opt => null ()
    type(command_list_t), pointer :: options => null ()
    type(rt_data_t), pointer :: local => null ()
  contains
    ⟨Commands: command: TBP⟩
  end type command_t
```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```
⟨Commands: command: TBP⟩≡
  procedure :: final => command_final

⟨Commands: procedures⟩≡
  recursive subroutine command_final (cmd)
    class(command_t), intent(inout) :: cmd
    if (associated (cmd%options)) then
      call cmd%options%final ()
      deallocate (cmd%options)
      call cmd%local%local_final ()
      deallocate (cmd%local)
```

```

else
    cmd%local => null ()
end if
end subroutine command_final

```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

*(Commands: procedures)*+≡

```

subroutine dispatch_command (command, pn)
    class(command_t), intent(inout), pointer :: command
    type(parse_node_t), intent(in), target :: pn
    select case (char (parse_node_get_rule_key (pn)))

    allocate (cmd_include_t :: command)
case ("cmd_quit")
    allocate (cmd_quit_t :: command)
case default
    print *, char (parse_node_get_rule_key (pn))
    call msg_bug ("Command not implemented")
end select
command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_write), deferred :: write
⟨Commands: interfaces⟩≡
    abstract interface
        subroutine command_write (cmd, unit, indent)
            import
            class(command_t), intent(in) :: cmd
            integer, intent(in), optional :: unit, indent
        end subroutine command_write
    end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_compile), deferred :: compile
⟨Commands: interfaces⟩+≡
    abstract interface
        subroutine command_compile (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_compile
    end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_execute), deferred :: execute
⟨Commands: interfaces⟩+≡
    abstract interface
        subroutine command_execute (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_execute
    end interface

```

### 31.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```
<Commands: command: TBP>+≡
  procedure :: write_options => command_write_options

<Commands: procedures>+≡
  recursive subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options
```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```
<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
  recursive subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call cmd%options%compile (cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
      call cmd%local%deactivate ()
    else
      cmd%local => global
    end if
  end subroutine command_compile_options
```

Execute options. First prepare the local environment, then execute the command list.

```
<Commands: command: TBP>+≡
  procedure :: execute_options => cmd_execute_options

<Commands: procedures>+≡
  recursive subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call cmd%local%activate ()
      call cmd%options%execute (cmd%local)
```

```

        end if
    end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

⟨Commands: command: TBP⟩+≡
    procedure :: reset_options => cmd_reset_options

⟨Commands: procedures⟩+≡
    subroutine cmd_reset_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call cmd%local%deactivate (global)
        end if
    end subroutine cmd_reset_options

```

### 31.1.3 Specific command types

#### Model configuration

The command declares a model, looks for the specified file and loads it.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_model_t
        private
        type(string_t) :: name
    contains
        ⟨Commands: cmd model: TBP⟩
    end type cmd_model_t

```

#### Output

```

⟨Commands: cmd model: TBP⟩≡
    procedure :: write => cmd_model_write

⟨Commands: procedures⟩+≡
    subroutine cmd_model_write (cmd, unit, indent)
        class(cmd_model_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,1x,'"',A,'\"') "model =", char (cmd%name)
    end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

```

⟨Commands: cmd model: TBP⟩+≡
    procedure :: compile => cmd_model_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_model_compile (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_name
  type(model_t), pointer :: model
  pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
  cmd%name = parse_node_get_string (pn_name)
  model => null ()
  if (associated (global%model)) then
    if (global%model%get_name () == cmd%name) model => global%model
  end if
  if (.not. associated (model)) then
    if (global%model_list%model_exists (cmd%name)) then
      model => global%model_list%get_model_ptr (cmd%name)
    else
      call global%read_model (cmd%name, model)
    end if
  end if
  global%model => model
  if (associated (global%model)) then
    call global%model%link_var_list (global%var_list)
  end if
end subroutine cmd_model_compile

```

Execute: Insert a pointer into the global data record and reassign the variable list.

```

⟨Commands: cmd model: TBP⟩+≡
  procedure :: execute => cmd_model_execute

⟨Commands: procedures⟩+≡
subroutine cmd_model_execute (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  call global%select_model (cmd%name)
  if (.not. associated (global%model)) &
    call msg_fatal ("Switching to model '" &
      // char (cmd%name) // "' : model not found")
end subroutine cmd_model_execute

```

## Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_library_t
  private
  type(string_t) :: name
contains
  ⟨Commands: cmd library: TBP⟩
end type cmd_library_t

```

Output.

```
<Commands: cmd library: TBP>≡
  procedure :: write => cmd_library_write

<Commands: procedures>+≡
  subroutine cmd_library_write (cmd, unit, indent)
    class(cmd_library_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit)
    call write_indent (u, indent)
    write (u, "(1x,A,1x,'"',A,'\"')") "library =", char (cmd%name)
  end subroutine cmd_library_write
```

Compile. Get the library name.

```
<Commands: cmd library: TBP>+≡
  procedure :: compile => cmd_library_compile

<Commands: procedures>+≡
  subroutine cmd_library_compile (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_name
    pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
    cmd%name = parse_node_get_string (pn_name)
  end subroutine cmd_library_compile
```

Execute: Initialize a new library and push it on the library stack (if it does not yet exist). Insert a pointer to the library into the global data record. Then, try to load the library unless the rebuild flag is set.

```
<Commands: cmd library: TBP>+≡
  procedure :: execute => cmd_library_execute

<Commands: procedures>+≡
  subroutine cmd_library_execute (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(prclib_entry_t), pointer :: lib_entry
    type(process_library_t), pointer :: lib
    logical :: rebuild_library
    lib => global%prclib_stack%get_library_ptr (cmd%name)
    rebuild_library = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    if (.not. (associated (lib))) then
      allocate (lib_entry)
      call lib_entry%init (cmd%name)
      lib => lib_entry%process_library_t
      call global%add_prclib (lib_entry)
    else
      call global%update_prclib (lib)
    end if
    if (associated (lib) .and. .not. rebuild_library) then
      call lib%update_status (global%os_data)
```

```

        end if
    end subroutine cmd_library_execute

```

## Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_process_t
    private
        type(string_t) :: id
        integer :: n_in = 0

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

            end if
        end if
    end subroutine cmd_exec_execute

```

## Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_var_t
    private
      type(string_t) :: name
      integer :: type = V_NONE
      type(parse_node_t), pointer :: pn_value => null ()
      logical :: is_intrinsic = .false.
      logical :: is_model_var = .false.
    contains
      ⟨Commands: cmd var: TBP⟩
    end type cmd_var_t

```

Output. We know name, type, and properties, but not the value.

```

⟨Commands: cmd var: TBP⟩≡
  procedure :: write => cmd_var_write

⟨Commands: procedures⟩+≡
  subroutine cmd_var_write (cmd, unit, indent)
    class(cmd_var_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A)", advance="no") "var: ", char (cmd%name), " ("
    select case (cmd%type)
    case (V_NONE)
      write (u, "(A)", advance="no") "[unknown]"
    case (V_LOG)
      write (u, "(A)", advance="no") "logical"
    case (V_INT)

```

```

        write (u, "(A)", advance="no") "int"
    case (V_REAL)
        write (u, "(A)", advance="no") "real"
    case (V_CMPLX)
        write (u, "(A)", advance="no") "complex"
    case (V_STR)
        write (u, "(A)", advance="no") "string"
    case (V_PDG)
        write (u, "(A)", advance="no") "alias"
    end select
    if (cmd%is_intrinsic) then
        write (u, "(A)", advance="no") ", intrinsic"
    end if
    if (cmd%is_model_var) then
        write (u, "(A)", advance="no") ", model"
    end if
    write (u, "(A)" ) ")"
end subroutine cmd_var_write

```

Compile the lhs and determine the variable name and type. Check whether this variable can be created or modified as requested, and append the value to the variable list, if appropriate. The value is initially undefined. The rhs is assigned to a pointer, to be compiled and evaluated when the command is executed.

## SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_slha_t
  private
  type(string_t) :: file
  logical :: write_mode = .false.
  contains
  <Commands: cmd slha: TBP>
end type cmd_slha_t

```

Output.

```

<Commands: cmd slha: TBP>≡
  procedure :: write => cmd_slha_write

<Commands: procedures>+≡
  subroutine cmd_slha_write (cmd, unit, indent)
    class(cmd_slha_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "slha: file name = ", char (cmd%file)
    write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
  end subroutine cmd_slha_write

```

Compile. Read the filename and store it.

```

<Commands: cmd slha: TBP>+≡
  procedure :: compile => cmd_slha_compile

<Commands: procedures>+≡
  subroutine cmd_slha_compile (cmd, global)
    class(cmd_slha_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_key, pn_arg, pn_file
    pn_key => parse_node_get_sub_ptr (cmd%pn)
    pn_arg => parse_node_get_next_ptr (pn_key)

## Clear values

This command clears the current values of variables or other objects, where this makes sense. It parallels the `show` command. The objects are cleared, but not deleted.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_clear_t
private
type(string_t), dimension(:), allocatable :: name
contains
<Commands: cmd clear: TBP>
end type cmd_clear_t

```

Output: list the names of the objects to be cleared.

```

<Commands: cmd clear: TBP>≡
procedure :: write => cmd_clear_write

<Commands: procedures>+≡
subroutine cmd_clear_write (cmd, unit, indent)
class(cmd_clear_t), intent(in) :: cmd

```

```

integer, intent(in), optional :: unit, indent
integer :: u, i
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)", advance="no") "clear: "
if (allocated (cmd%name)) then
  do i = 1, size (cmd%name)
    write (u, "(1x,A)", advance="no") char (cmd%name(i))
  end do
  write (u, *)
else
  write (u, "(5x,A)") "[undefined]"
end if
end subroutine cmd_clear_write

```

Compile. Allocate an array which is filled with the names of the objects to be cleared.

Note: there is currently no need to account for options, but we prepare for that possibility.

```

## Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

*(Commands: types)+≡*

```

type, extends (command_t) :: cmd_expect_t
    private
        type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
        (Commands: cmd expect: TBP)
    end type cmd_expect_t

```

Simply tell the status.

```

<Commands: cmd expect: TBP>≡
  procedure :: write => cmd_expect_write

<Commands: procedures>+≡
  subroutine cmd_expect_write (cmd, unit, indent)
    class(cmd_expect_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    if (associated (cmd%pn_lexpr)) then
      write (u, "(1x,A)") "expect: [expression associated]"
    else
      write (u, "(1x,A)") "expect: [undefined]"
    end if
  end subroutine cmd_expect_write

```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

```

<Commands: cmd expect: TBP>+≡
  procedure :: compile => cmd_expect_compile

<Commands: procedures>+≡
  subroutine cmd_expect_compile (cmd, global)
    class(cmd_expect_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_arg
    pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_arg)
    cmd%pn_lexpr => parse_node_get_sub_ptr (pn_arg)
    call cmd%compile_options (global)
  end subroutine cmd_expect_compile

```

Execute. Evaluate both arguments, print them and their difference (if numerical), and whether they agree. Record the result.

```

<Commands: cmd expect: TBP>+≡
  procedure :: execute => cmd_expect_execute

<Commands: procedures>+≡
  subroutine cmd_expect_execute (cmd, global)
    class(cmd_expect_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    logical :: success, is_known
    var_list => cmd%local%get_var_list_ptr ()
    success = eval_log (cmd%pn_lexpr, var_list, is_known=is_known)
    if (is_known) then
      if (success) then
        call msg_message ("expect: success")
      else

```

```

        call msg_error ("expect: failure")
    end if
else
    call msg_error ("expect: undefined result")
    success = .false.
end if
call expect_record (success)
end subroutine cmd_expect_execute

```

## Beams

The beam command includes both beam and structure-function definition.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_beams_t
    private
    integer :: n_in = 0
    type(parse_node_p), dimension(:), allocatable :: pn_pdg
    integer :: n_sf_record = 0
    integer, dimension(:), allocatable :: n_entry
    type(parse_node_p), dimension(:, :), allocatable :: pn_sf_entry
contains
    <Commands: cmd beams: TBP>
end type cmd_beams_t

```

Output. The particle expressions are not resolved.

```

<Commands: cmd beams: TBP>≡
    procedure :: write => cmd_beams_write

<Commands: procedures>+≡
    subroutine cmd_beams_write (cmd, unit, indent)

## Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by

evaluate, i.e., compiled just-in-time and evaluated immediately.

```

<Commands: types>+≡
  type :: sentry_expr_t
    type(parse_node_p), dimension(:), allocatable :: expr
    contains
    <Commands: sentry expr: TBP>
  end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

<Commands: sentry expr: TBP>≡
  procedure :: compile => sentry_expr_compile

<Commands: procedures>+≡
  subroutine sentry_expr_compile (sentry, pn)
    class(sentry_expr_t), intent(out) :: sentry
    type(parse_node_t), intent(in), target :: pn
    type(parse_node_t), pointer :: pn_expr, pn_extra
    integer :: n_expr, i
    n_expr = parse_node_get_n_sub (pn)
    allocate (sentry%expr (n_expr))
    if (n_expr > 0) then
      i = 0
      pn_expr => parse_node_get_sub_ptr (pn)
      pn_extra => parse_node_get_next_ptr (pn_expr)
      do i = 1, n_expr
        sentry%expr(i)%ptr => pn_expr
        if (associated (pn_extra)) then
          pn_expr => parse_node_get_sub_ptr (pn_extra, 2)
          pn_extra => parse_node_get_next_ptr (pn_extra)
        end if
      end do
    end if
  end subroutine sentry_expr_compile

```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

```

<Commands: sentry expr: TBP>+≡
  procedure :: evaluate => sentry_expr_evaluate

```

## Cuts

Define a cut expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the cut expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_cuts_t
  private
    type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
    ⟨Commands: cmd cuts: TBP⟩
  end type cmd_cuts_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```

⟨Commands: cmd cuts: TBP⟩≡
  procedure :: write => cmd_cuts_write

⟨Commands: procedures⟩+≡
  subroutine cmd_cuts_write (cmd, unit, indent)
    class(cmd_cuts_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "cuts: [defined]"
  end subroutine cmd_cuts_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd cuts: TBP⟩+≡
  procedure :: compile => cmd_cuts_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_cuts_compile (cmd, global)
    class(cmd_cuts_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_cuts_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd cuts: TBP⟩+≡
  procedure :: execute => cmd_cuts_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_cuts_execute (cmd, global)
    class(cmd_cuts_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%cuts_lexpr => cmd%pn_lexpr
  end subroutine cmd_cuts_execute

```

## General, Factorization and Renormalization Scales

Define a scale expression for either the renormalization or the factorization scale. We store the parse tree for the right-hand side instead of compiling

it. Compilation is deferred to the process environment where the expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd scale: TBP⟩
  end type cmd_scale_t

```

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_fac_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd fac scale: TBP⟩
  end type cmd_fac_scale_t

```

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_ren_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd ren scale: TBP⟩
  end type cmd_ren_scale_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

⟨Commands: cmd scale: TBP⟩≡
  procedure :: write => cmd_scale_write

⟨Commands: procedures⟩+≡
  subroutine cmd_scale_write (cmd, unit, indent)
    class(cmd_scale_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "scale: [defined]"
  end subroutine cmd_scale_write

⟨Commands: cmd fac scale: TBP⟩≡
  procedure :: write => cmd_fac_scale_write

⟨Commands: procedures⟩+≡
  subroutine cmd_fac_scale_write (cmd, unit, indent)
    class(cmd_fac_scale_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "factorization scale: [defined]"
  end subroutine cmd_fac_scale_write

```

```

⟨Commands: cmd ren scale: TBP⟩≡
  procedure :: write => cmd_ren_scale_write
⟨Commands: procedures⟩+≡
  subroutine cmd_ren_scale_write (cmd, unit, indent)
    class(cmd_ren_scale_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "renormalization scale: [defined]"
  end subroutine cmd_ren_scale_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd scale: TBP⟩+≡
  procedure :: compile => cmd_scale_compile
⟨Commands: procedures⟩+≡
  subroutine cmd_scale_compile (cmd, global)
    class(cmd_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_scale_compile

```

```

⟨Commands: cmd fac scale: TBP⟩+≡
  procedure :: compile => cmd_fac_scale_compile
⟨Commands: procedures⟩+≡
  subroutine cmd_fac_scale_compile (cmd, global)
    class(cmd_fac_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_fac_scale_compile

```

```

⟨Commands: cmd ren scale: TBP⟩+≡
  procedure :: compile => cmd_ren_scale_compile
⟨Commands: procedures⟩+≡
  subroutine cmd_ren_scale_compile (cmd, global)
    class(cmd_ren_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_ren_scale_compile

```

Instead of evaluating the scale expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd scale: TBP⟩+≡
  procedure :: execute => cmd_scale_execute
⟨Commands: procedures⟩+≡
  subroutine cmd_scale_execute (cmd, global)
    class(cmd_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%scale_expr => cmd%pn_expr
  end subroutine cmd_scale_execute

```

```

<Commands: cmd fac scale: TBP>+≡
  procedure :: execute => cmd_fac_scale_execute

<Commands: procedures>+≡
  subroutine cmd_fac_scale_execute (cmd, global)
    class(cmd_fac_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%fac_scale_expr => cmd%pn_expr
  end subroutine cmd_fac_scale_execute

<Commands: cmd ren scale: TBP>+≡
  procedure :: execute => cmd_ren_scale_execute

<Commands: procedures>+≡
  subroutine cmd_ren_scale_execute (cmd, global)
    class(cmd_ren_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%ren_scale_expr => cmd%pn_expr
  end subroutine cmd_ren_scale_execute

```

## Weight

Define a weight expression. The weight is applied to a process to be integrated, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_weight_t
    private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd weight: TBP>
  end type cmd_weight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd weight: TBP>≡
  procedure :: write => cmd_weight_write

<Commands: procedures>+≡
  subroutine cmd_weight_write (cmd, unit, indent)
    class(cmd_weight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "weight expression: [defined]"
  end subroutine cmd_weight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd weight: TBP>+≡
  procedure :: compile => cmd_weight_compile

```

```

⟨Commands: procedures⟩+≡
  subroutine cmd_weight_compile (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_weight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd weight: TBP⟩+≡
  procedure :: execute => cmd_weight_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_weight_execute (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%weight_expr => cmd%pn_expr
  end subroutine cmd_weight_execute

```

## Selection

Define a selection expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_selection_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd selection: TBP⟩
  end type cmd_selection_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

⟨Commands: cmd selection: TBP⟩≡
  procedure :: write => cmd_selection_write

⟨Commands: procedures⟩+≡
  subroutine cmd_selection_write (cmd, unit, indent)
    class(cmd_selection_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "selection expression: [defined]"
  end subroutine cmd_selection_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd selection: TBP⟩+≡
  procedure :: compile => cmd_selection_compile

```

```

<Commands: procedures>+≡
  subroutine cmd_selection_compile (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_selection_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd selection: TBP>+≡
  procedure :: execute => cmd_selection_execute

<Commands: procedures>+≡
  subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

## Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_reweight_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd reweight: TBP>
  end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd reweight: TBP>≡
  procedure :: write => cmd_reweight_write

<Commands: procedures>+≡
  subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: compile => cmd_reweight_compile

```

```

⟨Commands: procedures⟩+≡
  subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd reweight: TBP⟩+≡
  procedure :: execute => cmd_reweight_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_reweight_execute (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%reweight_expr => cmd%pn_expr
  end subroutine cmd_reweight_execute

```

## Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_alt_setup_t
  private
    type(parse_node_p), dimension(:), allocatable :: setup
  contains
    ⟨Commands: cmd alt setup: TBP⟩
  end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

⟨Commands: cmd alt setup: TBP⟩≡
  procedure :: write => cmd_alt_setup_write

⟨Commands: procedures⟩+≡
  subroutine cmd_alt_setup_write (cmd, unit, indent)
    class(cmd_alt_setup_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
  end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

⟨Commands: cmd alt setup: TBP⟩+≡
  procedure :: compile => cmd_alt_setup_compile

```

```

<Commands: procedures>+=
subroutine cmd_alt_setup_compile (cmd, global)
  class(cmd_alt_setup_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_list, pn_setup
  integer :: i
  pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
  if (associated (pn_list)) then
    allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
    i = 1
    pn_setup => parse_node_get_sub_ptr (pn_list)
    do while (associated (pn_setup))
      cmd%setup(i)%ptr => pn_setup
      i = i + 1
      pn_setup => parse_node_get_next_ptr (pn_setup)
    end do
  else
    allocate (cmd%setup (0))
  end if
end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

<Commands: cmd alt setup: TBP>+=
procedure :: execute => cmd_alt_setup_execute

<Commands: procedures>+=
subroutine cmd_alt_setup_execute (cmd, global)
  class(cmd_alt_setup_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  if (allocated (global%pn%alt_setup)) deallocate (global%pn%alt_setup)
  allocate (global%pn%alt_setup (size (cmd%setup)), source = cmd%setup)
end subroutine cmd_alt_setup_execute

```

## Integration

Integrate several processes, consecutively with identical parameters.

```

<Commands: types>+=
type, extends (command_t) :: cmd_integrate_t
  private
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id
contains
  <Commands: cmd integrate: TBP>
end type cmd_integrate_t

```

Output: we know the process IDs.

```

<Commands: cmd integrate: TBP>=
procedure :: write => cmd_integrate_write

<Commands: procedures>+=
subroutine cmd_integrate_write (cmd, unit, indent)
  class(cmd_integrate_t), intent(in) :: cmd

```

```

integer, intent(in), optional :: unit, indent
integer :: u, i
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)", advance="no") "integrate ("
do i = 1, cmd%n_proc
  if (i > 1) write (u, "(A,1x)", advance="no") ", "
  write (u, "(A)", advance="no") char (cmd%process_id(i))
end do
write (u, "(A)") ")"
end subroutine cmd_integrate_write

```

Compile.

*<Commands: cmd integrate: TBP>+≡*

```
procedure :: compile => cmd_integrate_compile
```

*<Commands: procedures>+≡*

```

subroutine cmd_integrate_compile (cmd, global)
  class(cmd_integrate_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_proclist, pn_proc
  integer :: i
  pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
  call cmd%compile_options (global)
  cmd%n_proc = parse_node_get_n_sub (pn_proclist)
  allocate (cmd%process_id (cmd%n_proc))
  pn_proc => parse_node_get_sub_ptr (pn_proclist)
  do i = 1, cmd%n_proc
    cmd%process_id(i) = parse_node_get_string (pn_proc)
    call global%process_stack%init_result_vars (cmd%process_id(i))
    pn_proc => parse_node_get_next_ptr (pn_proc)
  end do
end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

*<Commands: cmd integrate: TBP>+≡*

```
procedure :: execute => cmd_integrate_execute
```

*<Commands: procedures>+≡*

```

subroutine cmd_integrate_execute (cmd, global)
  class(cmd_integrate_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  integer :: i

```

```

do i = 1, cmd%n_proc
  call integrate_process (cmd%process_id(i), cmd%local, global)
  call global%process_stack%fill_result_vars (cmd%process_id(i))
  if (signal_is_pending ()) return
end do
end subroutine cmd_integrate_execute

```

## Observables

Declare an observable. After the declaration, it can be used to record data, and at the end one can retrieve average and error.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_observable_t
  private
  type(string_t) :: id
  contains
  ⟨Commands: cmd_observable: TBP⟩
end type cmd_observable_t

```

Output. We know the ID.

```

⟨Commands: cmd_observable: TBP⟩≡
  procedure :: write => cmd_observable_write

⟨Commands: procedures⟩+≡
  subroutine cmd_observable_write (cmd, unit, indent)
    class(cmd_observable_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "observable: ", char (cmd%id)
  end subroutine cmd_observable_write

```

Compile. Just record the observable ID.

```

⟨Commands: cmd_observable: TBP⟩+≡
  procedure :: compile => cmd_observable_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_observable_compile (cmd, global)
    class(cmd_observable_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_tag
    pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
    if (associated (pn_tag)) then
      cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    end if
    call cmd%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      cmd%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("observable: name expression not implemented (yet)")
    end select
  end subroutine cmd_observable_compile

```

```

        end select
    end subroutine cmd_observable_compile

```

Command execution. This declares the observable and allocates it in the analysis store.

```

<Commands: cmd observable: TBP>+≡
    procedure :: execute => cmd_observable_execute

<Commands: procedures>+≡
    subroutine cmd_observable_execute (cmd, global)
        class(cmd_observable_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(var_list_t), pointer :: var_list
        type(graph_options_t) :: graph_options
        type(string_t) :: label, unit
        var_list => cmd%local%get_var_list_ptr ()
        label = var_list%get_sval (var_str ("$_obs_label"))
        unit = var_list%get_sval (var_str ("$_obs_unit"))
        call graph_options_init (graph_options)
        call set_graph_options (graph_options, var_list)
        call analysis_init_observable (cmd%id, label, unit, graph_options)
    end subroutine cmd_observable_execute

```

## Histograms

Declare a histogram. At minimum, we have to set lower and upper bound and bin width.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_histogram_t
        private
        type(string_t) :: id
        type(parse_node_t), pointer :: pn_lower_bound => null ()
        type(parse_node_t), pointer :: pn_upper_bound => null ()
        type(parse_node_t), pointer :: pn_bin_width => null ()
    contains
        <Commands: cmd histogram: TBP>
    end type cmd_histogram_t

```

Output. Just print the ID.

```

<Commands: cmd histogram: TBP>≡
    procedure :: write => cmd_histogram_write

<Commands: procedures>+≡
    subroutine cmd_histogram_write (cmd, unit, indent)
        class(cmd_histogram_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A)") "histogram: ", char (cmd%id)
    end subroutine cmd_histogram_write

```

Compile. Record the histogram ID and initialize lower, upper bound and bin width.

```

<Commands: cmd histogram: TBP>+≡
  procedure :: compile => cmd_histogram_compile

<Commands: procedures>+≡
  subroutine cmd_histogram_compile (cmd, global)
    class(cmd_histogram_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_tag, pn_args, pn_arg1, pn_arg2, pn_arg3
    character(*), parameter :: e_illegal_use = &
      "illegal usage of 'histogram': insufficient number of arguments"
    pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_args => parse_node_get_next_ptr (pn_tag)
    if (associated (pn_args)) then
      pn_arg1 => parse_node_get_sub_ptr (pn_args)
      if (.not. associated (pn_arg1)) call msg_fatal (e_illegal_use)

```

## Plots

Declare a plot. No mandatory arguments, just options.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_plot_t
  private
  type(string_t) :: id
  contains
  <Commands: cmd plot: TBP>
end type cmd_plot_t
```

Output. Just print the ID.

```
<Commands: cmd plot: TBP>≡
  procedure :: write => cmd_plot_write

<Commands: procedures>+≡
  subroutine cmd_plot_write (cmd, unit, indent)
    class(cmd_plot_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "plot: ", char (cmd%id)
  end subroutine cmd_plot_write
```

Compile. Record the plot ID and initialize lower, upper bound and bin width.

```
<Commands: cmd plot: TBP>+≡
  procedure :: compile => cmd_plot_compile

<Commands: procedures>+≡
  subroutine cmd_plot_compile (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_tag
    pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%init (pn_tag, global)
  end subroutine cmd_plot_compile
```

This init routine is separated because it is reused below for graph initialization.

```
<Commands: cmd plot: TBP>+≡
  procedure :: init => cmd_plot_init

<Commands: procedures>+≡
  subroutine cmd_plot_init (plot, pn_tag, global)
    class(cmd_plot_t), intent(inout) :: plot
    type(parse_node_t), intent(in), pointer :: pn_tag
    type(rt_data_t), intent(inout), target :: global
    call plot%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      plot%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("plot: name expression not implemented (yet)")
```

```

    end select
end subroutine cmd_plot_init

```

Command execution. This declares the plot and allocates it in the analysis store.

```

⟨Commands: cmd plot: TBP⟩+≡
  procedure :: execute => cmd_plot_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_plot_execute (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call drawing_options_init_plot (drawing_options)
    call set_drawing_options (drawing_options, var_list)

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

## Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_graph_t
    private
    type(string_t) :: id
    integer :: n_elements = 0
    type(cmd_plot_t), dimension(:), allocatable :: el
    type(string_t), dimension(:), allocatable :: element_id
  contains
    ⟨Commands: cmd graph: TBP⟩
  end type cmd_graph_t

```

Output. Just print the ID.

```

⟨Commands: cmd graph: TBP⟩≡
  procedure :: write => cmd_graph_write

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return

```

```

    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)" "graph: ", char (cmd%id), &
           " (", cmd%n_elements, " entries)"
end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

⟨Commands: cmd graph: TBP⟩+≡
    procedure :: compile => cmd_graph_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_graph_compile (cmd, global)
        class(cmd_graph_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
        integer :: i

        pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
        pn_tag => parse_node_get_sub_ptr (pn_term)
        cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
        call cmd%compile_options (global)
        select case (char (parse_node_get_rule_key (pn_tag)))
        case ("analysis_id")
            cmd%id = parse_node_get_string (pn_tag)
        case default
            call msg_bug ("graph: name expression not implemented (yet)")
        end select
        pn_def => parse_node_get_next_ptr (pn_term, 2)
        cmd%n_elements = parse_node_get_n_sub (pn_def)
        allocate (cmd%element_id (cmd%n_elements))
        allocate (cmd%el (cmd%n_elements))
        pn_term => parse_node_get_sub_ptr (pn_def)
        pn_tag => parse_node_get_sub_ptr (pn_term)
        cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
        call cmd%el(1)%init (pn_tag, global)
        cmd%element_id(1) = parse_node_get_string (pn_tag)
        pn_app => parse_node_get_next_ptr (pn_term)
        do i = 2, cmd%n_elements
            pn_term => parse_node_get_sub_ptr (pn_app, 2)
            pn_tag => parse_node_get_sub_ptr (pn_term)
            cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
            call cmd%el(i)%init (pn_tag, global)
            cmd%element_id(i) = parse_node_get_string (pn_tag)
            pn_app => parse_node_get_next_ptr (pn_app)
        end do

    end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: execute => cmd_graph_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_execute (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options
    integer :: i, type

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

    do i = 1, cmd%n_elements
      if (associated (cmd%el(i)%options)) then
        call cmd%el(i)%options%execute (cmd%el(i)%local)
      end if
      type = analysis_store_get_object_type (cmd%element_id(i))
      select case (type)
        case (AN_HISTOGRAM)
          call drawing_options_init_histogram (drawing_options)
        case (AN_PLOT)
          call drawing_options_init_plot (drawing_options)
        end select
      call set_drawing_options (drawing_options, var_list)
      if (associated (cmd%el(i)%options)) then
        call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
      end if
      call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
    end do
  end subroutine cmd_graph_execute

```

## Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
  type :: analysis_id_t
    type(string_t) :: tag
    type(parse_node_t), pointer :: pn_sexpr => null ()
  end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_analysis_t
  private
    type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
    ⟨Commands: cmd analysis: TBP⟩
  end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

⟨Commands: cmd analysis: TBP⟩≡
  procedure :: write => cmd_analysis_write

⟨Commands: procedures⟩+≡
  subroutine cmd_analysis_write (cmd, unit, indent)
    class(cmd_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "analysis: [defined]"
  end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd analysis: TBP⟩+≡
  procedure :: compile => cmd_analysis_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd analysis: TBP⟩+≡
  procedure :: execute => cmd_analysis_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_analysis_execute (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%analysis_lexpr => cmd%pn_lexpr
  end subroutine cmd_analysis_execute

```

## Write histograms and plots

The data type encapsulating the command:

```

⟨Commands: types⟩+≡

```

```

type, extends (command_t) :: cmd_write_analysis_t
private
  type(analysis_id_t), dimension(:), allocatable :: id
  type(string_t), dimension(:), allocatable :: tag
contains
  <Commands: cmd write analysis: TBP>
end type cmd_write_analysis_t

```

Output. Just the keyword.

```

<Commands: cmd write analysis: TBP>≡
  procedure :: write => cmd_write_analysis_write

<Commands: procedures>+≡
  subroutine cmd_write_analysis_write (cmd, unit, indent)
    class(cmd_write_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "write_analysis"
  end subroutine cmd_write_analysis_write

```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: compile => cmd_write_analysis_compile

<Commands: procedures>+≡
  subroutine cmd_write_analysis_compile (cmd, global)
    class(cmd_write_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
    integer :: n, i
    pn_clause => parse_node_get_sub_ptr (cmd%pn)
    pn_args => parse_node_get_sub_ptr (pn_clause, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
    call cmd%compile_options (global)
    if (associated (pn_args)) then
      n = parse_node_get_n_sub (pn_args)
      allocate (cmd%id (n))
      do i = 1, n
        pn_id => parse_node_get_sub_ptr (pn_args, i)
        if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
          cmd%id(i)%tag = parse_node_get_string (pn_id)
        else
          cmd%id(i)%pn_sexpr => pn_id
        end if
      end do
    else
      allocate (cmd%id (0))
    end if
  end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```
(Commands: parameters)+≡
character(*), parameter, public :: &
    DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
    FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(5), parameter, public :: &
    FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "lo", "la" ]
character(len=3), dimension(14), parameter, public :: &
    FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
        "f95", "log", "ltp", "mpx", "pdf", "phs", "sin", "tex" ]
```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```
(Commands: cmd write analysis: TBP)+≡
    procedure :: execute => cmd_write_analysis_execute

(Commands: procedures)+≡
    subroutine cmd_write_analysis_execute (cmd, global)
        class(cmd_write_analysis_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(var_list_t), pointer :: var_list
        var_list => cmd%local%get_var_list_ptr ()
        call write_analysis_wrap (var_list, global%out_files, &
            cmd%id, tag = cmd%tag)
    end subroutine cmd_write_analysis_execute
```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

```
(Commands: procedures)+≡
    subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
        type(var_list_t), intent(inout), target :: var_list
        type(file_list_t), intent(inout), target :: out_files
        type(analysis_id_t), dimension(:), intent(in), target :: id

### 31.1.4 User-controlled output to data files

#### Open file (output)

Open a file for output.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_open_out_t
private
type(parse_node_t), pointer :: file_expr => null ()
contains
⟨Commands: cmd open out: TBP⟩
end type cmd_open_out_t

```

Finalizer for the embedded eval tree.

```

⟨Commands: procedures⟩+≡
subroutine cmd_open_out_final (object)
    class(cmd_open_out_t), intent(inout) :: object
end subroutine cmd_open_out_final

```

Output (trivial here).

```

⟨Commands: cmd open out: TBP⟩≡
procedure :: write => cmd_open_out_write

```

```

⟨Commands: procedures⟩+≡
  subroutine cmd_open_out_write (cmd, unit, indent)
    class(cmd_open_out_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)", advance="no") "open_out: <filename>"
  end subroutine cmd_open_out_write

```

Compile: create an eval tree for the filename expression.

```

⟨Commands: cmd open out: TBP⟩+≡
  procedure :: compile => cmd_open_out_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_open_out_compile (cmd, global)
    class(cmd_open_out_t), intent(inout) :: cmd

        action = "write", status = "replace", position = "asis")
    else
      call msg_fatal ("open_out: file name argument evaluates to unknown")
    end if
    call file_expr%final ()
  end subroutine cmd_open_out_execute

```

## Open file (output)

Close an output file. Except for the `execute` method, everything is analogous to the open command, so we can just inherit.

```

⟨Commands: types⟩+=
  type, extends (cmd_open_out_t) :: cmd_close_out_t
  private
  contains
    ⟨Commands: cmd close out: TBP⟩
  end type cmd_close_out_t

```

Execute: remove the file from the global list of output files.

```

⟨Commands: cmd close out: TBP⟩=
  procedure :: execute => cmd_close_out_execute

⟨Commands: procedures⟩+=
  subroutine cmd_close_out_execute (cmd, global)
    class(cmd_close_out_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(eval_tree_t) :: file_expr
    type(string_t) :: file
    var_list => cmd%local%var_list
    call file_expr%init_sexpr (cmd%file_expr, var_list)
    call file_expr%evaluate ()
    if (file_expr%is_known ()) then
      file = file_expr%get_string ()
      call file_list_close (global%out_files, file)
    else
      call msg_fatal ("close_out: file name argument evaluates to unknown")
    end if
    call file_expr%final ()
  end subroutine cmd_close_out_execute

```

### 31.1.5 Print custom-formatted values

```

⟨Commands: types⟩+=
  type, extends (command_t) :: cmd_printf_t
  private
    type(parse_node_t), pointer :: sexpr => null ()
    type(parse_node_t), pointer :: sprintf_fun => null ()
    type(parse_node_t), pointer :: sprintf_clause => null ()
    type(parse_node_t), pointer :: sprintf => null ()
  contains
    ⟨Commands: cmd printf: TBP⟩
  end type cmd_printf_t

```

Finalize.

```

⟨Commands: cmd printf: TBP⟩=
  procedure :: final => cmd_printf_final

⟨Commands: procedures⟩+=
  subroutine cmd_printf_final (cmd)
    class(cmd_printf_t), intent(inout) :: cmd
    call parse_node_final (cmd%sexpr, recursive = .false.)
    deallocate (cmd%sexpr)
  end subroutine cmd_printf_final

```

```

call parse_node_final (cmd%sprintf_fun, recursive = .false.)
deallocate (cmd%sprintf_fun)
call parse_node_final (cmd%sprintf_clause, recursive = .false.)
deallocate (cmd%sprintf_clause)
call parse_node_final (cmd%sprintf, recursive = .false.)
deallocate (cmd%sprintf)
end subroutine cmd_printf_final

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```

⟨Commands: cmd printf: TBP⟩+=
  procedure :: write => cmd_printf_write
⟨Commands: procedures⟩+=
  subroutine cmd_printf_write (cmd, unit, indent)
    class(cmd_printf_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "printf:"
  end subroutine cmd_printf_write

```

Compile. We create a fake parse node (subtree) with a `sprintf` command with identical arguments which can then be handled by the corresponding evaluation procedure.

```

⟨Commands: cmd printf: TBP⟩+=
  procedure :: compile => cmd_printf_compile
⟨Commands: procedures⟩+=
  subroutine cmd_printf_compile (cmd, global)
    class(cmd_printf_t), intent(inout) :: cmd

    call parse_node_create_branch (cmd%sprintf_clause, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf_clause")))
    allocate (cmd%sprintf)
    call parse_node_create_key (cmd%sprintf, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf")))
    call parse_node_append_sub (cmd%sprintf_clause, cmd%sprintf)
    call parse_node_append_sub (cmd%sprintf_clause, pn_format)
  end subroutine cmd_printf_compile

```

```

call parse_node_freeze_branch (cmd%sprintf_clause)
call parse_node_append_sub (cmd%sprintf_fun, cmd%sprintf_clause)
if (associated (pn_args)) then
    call parse_node_append_sub (cmd%sprintf_fun, pn_args)
end if
call parse_node_freeze_branch (cmd%sprintf_fun)
call parse_node_append_sub (cmd%sexpr, cmd%sprintf_fun)
call parse_node_freeze_branch (cmd%sexpr)
end subroutine cmd_printf_compile

```

Execute. Evaluate the string (pretending this is a `sprintf` expression) and print it.

*<Commands: cmd printf: TBP>+≡*

```

procedure :: execute => cmd_printf_execute

```

*<Commands: procedures>+≡*

```

subroutine cmd_printf_execute (cmd, global)
class(cmd_printf_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(var_list_t), pointer :: var_list
type(string_t) :: string, file
type(eval_tree_t) :: sprintf_expr
logical :: advance
var_list => cmd%local%get_var_list_ptr ()
advance = var_list%get_lval (&
    var_str ("?out_advance"))
file = var_list%get_sval (&
    var_str ("out_file"))
call sprintf_expr%init_sexpr (cmd%sexpr, var_list)
call sprintf_expr%evaluate ()
if (sprintf_expr%is_known ()) then
    string = sprintf_expr%get_string ()
    if (len (file) == 0) then
        call msg_result (char (string))
    else
        call file_list_write (global%out_files, file, string, advance)
    end if
end if
end if
end subroutine cmd_printf_execute

```

## Record data

The expression syntax already contains a `record` keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

*<Commands: types>+≡*

```

type, extends (command_t) :: cmd_record_t
private
type(parse_node_t), pointer :: pn_lexpr => null ()
contains
<Commands: cmd record: TBP>
end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

⟨Commands: cmd record: TBP⟩≡
  procedure :: write => cmd_record_write

⟨Commands: procedures⟩+≡
  subroutine cmd_record_write (cmd, unit, indent)
    class(cmd_record_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)" "record"
  end subroutine cmd_record_write

```

Compile. This is a hack which transforms the record command into a record expression, which we handle in the expressions module.

```

⟨Commands: cmd record: TBP⟩+≡
  procedure :: compile => cmd_record_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_record_compile (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
    call parse_node_create_branch (pn_lexpr, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))
    call parse_node_create_branch (pn_lsinglet, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lsinglet")))
    call parse_node_append_sub (pn_lexpr, pn_lsinglet)
    call parse_node_create_branch (pn_lterm, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lterm")))
    call parse_node_append_sub (pn_lsinglet, pn_lterm)
    pn_record => parse_node_get_sub_ptr (cmd%pn)
    call parse_node_append_sub (pn_lterm, pn_record)
    cmd%pn_lexpr => pn_lexpr
  end subroutine cmd_record_compile

```

Command execution. Again, transfer this to the embedded expression and just forget the logical result.

```

⟨Commands: cmd record: TBP⟩+≡
  procedure :: execute => cmd_record_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_record_execute (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    logical :: lval
    var_list => global%get_var_list_ptr ()
    lval = eval_log (cmd%pn_lexpr, var_list)
  end subroutine cmd_record_execute

```

## Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_unstable_t
  private
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id
  type(parse_node_t), pointer :: pn_prt_in => null ()
  contains
  <Commands: cmd unstable: TBP>
end type cmd_unstable_t
```

Output: we know the process IDs.

```
<Commands: cmd unstable: TBP>≡
  procedure :: write => cmd_unstable_write

<Commands: procedures>+≡
  subroutine cmd_unstable_write (cmd, unit, indent)
    class(cmd_unstable_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u, i
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,1x,I0,1x,A)", advance="no") &
      "unstable:", 1, "("
    do i = 1, cmd%n_proc
      if (i > 1) write (u, "(A,1x)", advance="no") ", "
      write (u, "(A)", advance="no") char (cmd%process_id(i))
    end do
    write (u, "(A)") ")"
  end subroutine cmd_unstable_write
```

Compile. Initiate an eval tree for the decaying particle and determine the decay channel process IDs.

```
<Commands: cmd unstable: TBP>+≡
  procedure :: compile => cmd_unstable_compile

<Commands: procedures>+≡
  subroutine cmd_unstable_compile (cmd, global)
    class(cmd_unstable_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_list, pn_proc
    integer :: i
    cmd%pn_prt_in => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_list => parse_node_get_next_ptr (cmd%pn_prt_in)
    if (associated (pn_list)) then
      select case (char (parse_node_get_rule_key (pn_list)))
      case ("unstable_arg")
        cmd%n_proc = parse_node_get_n_sub (pn_list)
        cmd%pn_opt => parse_node_get_next_ptr (pn_list)
      case default
        cmd%n_proc = 0
      end select
    end if
  end subroutine cmd_unstable_compile
```

```

        cmd%pn_opt => pn_list
        pn_list => null ()
    end select
end if
call cmd%compile_options (global)
if (associated (pn_list)) then
    allocate (cmd%process_id (cmd%n_proc))
    pn_proc => parse_node_get_sub_ptr (pn_list)
    do i = 1, cmd%n_proc
        cmd%process_id(i) = parse_node_get_string (pn_proc)
        call cmd%local%process_stack%init_result_vars (cmd%process_id(i))
        pn_proc => parse_node_get_next_ptr (pn_proc)
    end do
else
    allocate (cmd%process_id (0))
end if
end subroutine cmd_unstable_compile

```

Command execution. Evaluate the decaying particle and mark the decays in the current model object.

```

```

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

end subroutine cmd_sample_format_compile

```

Execute. Transfer the list of format specifications to the corresponding array in the runtime data set.

```

<Commands: cmd sample format: TBP>+≡
  procedure :: execute => cmd_sample_format_execute

<Commands: procedures>+≡
subroutine cmd_sample_format_execute (cmd, global)
  class(cmd_sample_format_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  if (allocated (global%sample_fmt)) deallocate (global%sample_fmt)
  allocate (global%sample_fmt (size (cmd%format)), source = cmd%format)
end subroutine cmd_sample_format_execute

```

## The simulate command

This is the actual SINDARIN command.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_simulate_t
    ! not private anymore as required by the whizard-c-interface
    integer :: n_proc = 0
    type(string_t), dimension(:), allocatable :: process_id
    contains
    <Commands: cmd simulate: TBP>≡
  end type cmd_simulate_t
```

Output: we know the process IDs.

```
<Commands: cmd simulate: TBP>≡
  procedure :: write => cmd_simulate_write

<Commands: procedures>+≡
  subroutine cmd_simulate_write (cmd, unit, indent)
    class(cmd_simulate_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u, i
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)", advance="no") "simulate ("
    do i = 1, cmd%n_proc
      if (i > 1) write (u, "(A,1x)", advance="no") ", "
      write (u, "(A)", advance="no") char (cmd%process_id(i))
    end do
    write (u, "(A)") ")"
  end subroutine cmd_simulate_write
```

Compile. In contrast to WHIZARD 1 the confusing option to give the number of unweighted events for weighted events as if unweighting were to take place has been abandoned. (We both use `n_events` for weighted and unweighted events, the variable `n_calls` from WHIZARD 1 has been discarded.

```
<Commands: cmd simulate: TBP>+≡
  procedure :: compile => cmd_simulate_compile

<Commands: procedures>+≡
  subroutine cmd_simulate_compile (cmd, global)

        pn_proc => parse_node_get_next_ptr (pn_proc)
    end do
end subroutine cmd_simulate_compile

```

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

```

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

```

```

## Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

Note: for the integer/real range array, the obvious implementation as a polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are apparently broken.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_scan_t
    private
    type(string_t) :: name
    integer :: n_values = 0
    type(parse_node_p), dimension(:), allocatable :: scan_cmd
    !!! !!! gfortran 4.7.x memory corruption
    !!! class(range_t), dimension(:), allocatable :: range
    type(range_int_t), dimension(:), allocatable :: range_int
    type(range_real_t), dimension(:), allocatable :: range_real
contains
    <Commands: cmd scan: TBP>
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

<Commands: cmd scan: TBP>≡
    procedure :: final => cmd_scan_final

<Commands: procedures>+≡
    recursive subroutine cmd_scan_final (cmd)
    class(cmd_scan_t), intent(inout) :: cmd
    type(parse_node_t), pointer :: pn_var_single, pn_decl_single
    type(string_t) :: key
    integer :: i
    if (allocated (cmd%scan_cmd)) then
        do i = 1, size (cmd%scan_cmd)
            pn_var_single => parse_node_get_sub_ptr (cmd%scan_cmd(i)%ptr)
            key = parse_node_get_rule_key (pn_var_single)
            select case (char (key))
            case ("scan_string_decl", "scan_log_decl")
                pn_decl_single => parse_node_get_sub_ptr (pn_var_single, 2)
                call parse_node_final (pn_decl_single, recursive=.false.)
                deallocate (pn_decl_single)
            end select
        end do
    end if
end subroutine cmd_scan_final

```

```

        call parse_node_final (pn_var_single, recursive=.false.)
        deallocate (pn_var_single)
    end do
    deallocate (cmd%scan_cmd)
end if
!!! !!! gfortran 4.7.x memory corruption
!!! if (allocated (cmd%range)) then
!!!     do i = 1, size (cmd%range)
!!!         call cmd%range(i)%final ()
!!!     end do
!!! end if
if (allocated (cmd%range_int)) then
    do i = 1, size (cmd%range_int)
        call cmd%range_int(i)%final ()
    end do
end if
if (allocated (cmd%range_real)) then
    do i = 1, size (cmd%range_real)
        call cmd%range_real(i)%final ()
    end do
end if
end subroutine cmd_scan_final

```

Output.

*<Commands: cmd scan: TBP>+≡*

```

    procedure :: write => cmd_scan_write

```

*<Commands: procedures>+≡*

```

subroutine cmd_scan_write (cmd, unit, indent)
    class(cmd_scan_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,1x,A,1x,'(',I0,')')") "scan:", char (cmd%name), &
        cmd%n_values
end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

```

⟨Commands: cmd_scan: TBP⟩+=
  procedure :: execute => cmd_scan_execute

⟨Commands: procedures⟩+=

```

## Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of `else if` constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```
(Commands: types)+≡
  type, extends (command_t) :: cmd_if_t
  private
    type(parse_node_t), pointer :: pn_if_lexpr => null ()
    type(command_list_t), pointer :: if_body => null ()
    type(cmd_if_t), dimension(:), pointer :: elsif_cmd => null ()
    type(command_list_t), pointer :: else_body => null ()
  contains
    (Commands: cmd if: TBP)
  end type cmd_if_t
```

Finalizer. There are no local options, therefore we can simply override the default finalizer.

```
(Commands: cmd if: TBP)≡
  procedure :: final => cmd_if_final

(Commands: procedures)+≡
  recursive subroutine cmd_if_final (cmd)
    class(cmd_if_t), intent(inout) :: cmd
    integer :: i
    if (associated (cmd%if_body)) then
      call command_list_final (cmd%if_body)
      deallocate (cmd%if_body)
    end if
    if (associated (cmd%elsif_cmd)) then
      do i = 1, size (cmd%elsif_cmd)
        call cmd_if_final (cmd%elsif_cmd(i))
      end do
      deallocate (cmd%elsif_cmd)
    end if
    if (associated (cmd%else_body)) then
      call command_list_final (cmd%else_body)
      deallocate (cmd%else_body)
    end if
  end subroutine cmd_if_final
```

Output. Recursively write the command lists.

```
(Commands: cmd if: TBP)+≡
  procedure :: write => cmd_if_write

(Commands: procedures)+≡
  subroutine cmd_if_write (cmd, unit, indent)
    class(cmd_if_t), intent(in) :: cmd

### Include another command-list file

The include command allocates a local parse tree. This must not be deleted before the command object itself is deleted, since pointers may point to subobjects of it.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_include_t
    private
        type(string_t) :: file
        type(command_list_t), pointer :: command_list => null ()
        type(parse_tree_t) :: parse_tree
    contains
        <Commands: cmd include: TBP>
    end type cmd_include_t

```

Finalizer: delete the command list. No options, so we can simply override the default finalizer.

```

<Commands: cmd include: TBP>≡
    procedure :: final => cmd_include_final

<Commands: procedures>+≡
    subroutine cmd_include_final (cmd)
        class(cmd_include_t), intent(inout) :: cmd
        call parse_tree_final (cmd%parse_tree)
        if (associated (cmd%command_list)) then
            call cmd%command_list%final ()
            deallocate (cmd%command_list)
        end if
    end subroutine cmd_include_final

```

Write: display the command list as-is, if allocated.

```

<Commands: cmd include: TBP>+≡
    procedure :: write => cmd_include_write

```

```

<Commands: procedures>+≡
subroutine cmd_include_write (cmd, unit, indent)
  class(cmd_include_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u, ind
  u = given_output_unit (unit)
  ind = 0; if (present (indent)) ind = indent
  call write_indent (u, indent)
  write (u, "(A,A,A,A)") "include ", "'", char (cmd%file), "'"
  if (associated (cmd%command_list)) then
    call cmd%command_list%write (u, ind + 1)
  end if
end subroutine cmd_include_write

```

Compile file contents: First parse the file, then immediately compile its contents.  
Use the global data set.

```

<Commands: cmd include: TBP>+≡
  procedure :: compile => cmd_include_compile

<Commands: procedures>+≡
subroutine cmd_include_compile (cmd, global)
  class(cmd_include_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_arg, pn_file
  type(string_t) :: file
  logical :: exist
  integer :: u
  type(stream_t), target :: stream
  type(lexer_t) :: lexer
  pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
  pn_file => parse_node_get_sub_ptr (pn_arg)
  file = parse_node_get_string (pn_file)
  inquire (file=char(file), exist=exist)
  if (exist) then
    cmd%file = file
  else
    cmd%file = global%os_data%whizard_cutspath // "/" // file
    inquire (file=char(cmd%file), exist=exist)
    if (.not. exist) then
      call msg_error ("Include file '" // char (file) // "' not found")
      return
    end if
  end if
  u = free_unit ()
  call lexer_init_cmd_list (lexer, global%lexer)
  call stream_init (stream, char (cmd%file))
  call lexer_assign_stream (lexer, stream)
  call parse_tree_init (cmd%parse_tree, syntax_cmd_list, lexer)
  call stream_final (stream)
  call lexer_final (lexer)
  close (u)
  allocate (cmd%command_list)
  call cmd%command_list%compile (parse_tree_get_root_ptr (cmd%parse_tree), &
    global)

```

```
end subroutine cmd_include_compile
```

Execute file contents in the global context.

```
<Commands: cmd include: TBP>+≡
  procedure :: execute => cmd_include_execute

<Commands: procedures>+≡
  subroutine cmd_include_execute (cmd, global)
    class(cmd_include_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%command_list)) then
      call msg_message &
        ("Including Sindarin from '" // char (cmd%file) // "'")
      call cmd%command_list%execute (global)
      call msg_message &
        ("End of included '" // char (cmd%file) // "'")
    end if
  end subroutine cmd_include_execute
```

## Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_quit_t
  private
  logical :: has_code = .false.
  type(parse_node_t), pointer :: pn_code_expr => null ()
  contains
  <Commands: cmd quit: TBP>
  end type cmd_quit_t
```

Output.

```
<Commands: cmd quit: TBP>≡
  procedure :: write => cmd_quit_write

<Commands: procedures>+≡
  subroutine cmd_quit_write (cmd, unit, indent)
    class(cmd_quit_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,L1)" "quit: has_code = ", cmd%has_code
  end subroutine cmd_quit_write
```

Compile: allocate a quit object which serves as a placeholder.

```
<Commands: cmd quit: TBP>+≡
  procedure :: compile => cmd_quit_compile
```

```

⟨Commands: procedures⟩+≡
subroutine cmd_quit_compile (cmd, global)
  class(cmd_quit_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_arg
  pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
  if (associated (pn_arg)) then
    cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
    cmd%has_code = .true.
  end if
end subroutine cmd_quit_compile

```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```

⟨Commands: cmd quit: TBP⟩+≡
  procedure :: execute => cmd_quit_execute

⟨Commands: procedures⟩+≡
subroutine cmd_quit_execute (cmd, global)
  class(cmd_quit_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  logical :: is_known
  var_list => global%get_var_list_ptr ()
  if (cmd%has_code) then
    global%quit_code = eval_int (cmd%pn_code_expr, var_list, &
      is_known=is_known)
    if (.not. is_known) then
      call msg_error ("Undefined return code of quit/exit command")
    end if
  end if
  global%quit = .true.
end subroutine cmd_quit_execute

```

### 31.1.6 The command list

The command list holds a list of commands and relevant global data.

```

⟨Commands: public⟩+≡
  public :: command_list_t

⟨Commands: types⟩+≡
  type :: command_list_t
    ! not private anymore as required by the whizard-c-interface
    class(command_t), pointer :: first => null ()
    class(command_t), pointer :: last => null ()
  contains
    ⟨Commands: command list: TBP⟩
  end type command_list_t

```

Output.

```
<Commands: command list: TBP>+≡
  procedure :: write => command_list_write

<Commands: procedures>+≡
  recursive subroutine command_list_write (cmd_list, unit, indent)
    class(command_list_t), intent(in) :: cmd_list
    integer, intent(in), optional :: unit, indent
    class(command_t), pointer :: cmd
    cmd => cmd_list%first
    do while (associated (cmd))
      call cmd%write (unit, indent)
      cmd => cmd%next
    end do
  end subroutine command_list_write
```

Append a new command to the list and free the original pointer.

```
<Commands: command list: TBP>+≡
  procedure :: append => command_list_append

<Commands: procedures>+≡
  subroutine command_list_append (cmd_list, command)
    class(command_list_t), intent(inout) :: cmd_list
    class(command_t), intent(inout), pointer :: command
    if (associated (cmd_list%last)) then
      cmd_list%last%next => command
    else
      cmd_list%first => command
    end if
    cmd_list%last => command
    command => null ()
  end subroutine command_list_append
```

Finalize.

```
<Commands: command list: TBP>+≡
  procedure :: final => command_list_final

<Commands: procedures>+≡
  recursive subroutine command_list_final (cmd_list)
    class(command_list_t), intent(inout) :: cmd_list
    class(command_t), pointer :: command
    do while (associated (cmd_list%first))
      command => cmd_list%first
      cmd_list%first => cmd_list%first%next
      call command%final ()
      deallocate (command)
    end do
    cmd_list%last => null ()
  end subroutine command_list_final
```

### 31.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```
(Commands: command list: TBP)+≡
  procedure :: compile => command_list_compile

(Commands: procedures)+≡
  recursive subroutine command_list_compile (cmd_list, pn, global)
    class(command_list_t), intent(inout), target :: cmd_list
    type(parse_node_t), intent(in), target :: pn
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_cmd
    class(command_t), pointer :: command
    integer :: i
    pn_cmd => parse_node_get_sub_ptr (pn)
    do i = 1, parse_node_get_n_sub (pn)
      call dispatch_command (command, pn_cmd)
      call command%compile (global)
      call cmd_list%append (command)
      call terminate_now_if_signal ()
      pn_cmd => parse_node_get_next_ptr (pn_cmd)
    end do
  end subroutine command_list_compile
```

### 31.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```
(Commands: command list: TBP)+≡
  procedure :: execute => command_list_execute

(Commands: procedures)+≡
  recursive subroutine command_list_execute (cmd_list, global)
    class(command_list_t), intent(in) :: cmd_list
    type(rt_data_t), intent(inout), target :: global
    class(command_t), pointer :: command
    command => cmd_list%first
    COMMAND_COND: do while (associated (command))
      call command%execute_options (global)
      call command%execute (global)
      call command%reset_options (global)
      call terminate_now_if_signal ()
      if (global%quit) exit COMMAND_COND
      command => command%next
    end do COMMAND_COND
  end subroutine command_list_execute
```

### 31.1.9 Command list syntax

```
<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡
    public :: syntax_cmd_list_init

<Commands: procedures>+≡
    subroutine syntax_cmd_list_init ()
        type(ifile_t) :: ifile
        call define_cmd_list_syntax (ifile)
        call syntax_init (syntax_cmd_list, ifile)
        call ifile_final (ifile)
    end subroutine syntax_cmd_list_init

<Commands: public>+≡
    public :: syntax_cmd_list_final

<Commands: procedures>+≡
    subroutine syntax_cmd_list_final ()
        call syntax_final (syntax_cmd_list)
    end subroutine syntax_cmd_list_final

<Commands: public>+≡
    public :: syntax_cmd_list_write

<Commands: procedures>+≡
    subroutine syntax_cmd_list_write (unit)
        integer, intent(in), optional :: unit
        call syntax_write (syntax_cmd_list, unit)
    end subroutine syntax_cmd_list_write

<Commands: procedures>+≡
    subroutine define_cmd_list_syntax (ifile)
        type(ifile_t), intent(inout) :: ifile
        call ifile_append (ifile, "SEQ command_list = command*")

    <WHIZARD: public>

    <WHIZARD: types>

    save

contains

    <WHIZARD: procedures>

end module whizard

```

### 31.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```

<WHIZARD: public>≡
    public :: whizard_options_t

<WHIZARD: types>≡
    type :: whizard_options_t
        type(string_t) :: preload_model
        type(string_t) :: default_lib
        type(string_t) :: preload_libraries
        logical :: rebuild_library = .false.
        logical :: recompile_library = .false.
        logical :: rebuild_user
        logical :: rebuild_phs = .false.
        logical :: rebuild_grids = .false.
        logical :: rebuild_events = .false.
    end type whizard_options_t

```

### 31.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

<WHIZARD: types>+≡
    type, extends (parse_tree_t) :: pt_entry_t
        type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the `last` pointer.

```

<WHIZARD: types>+=
  type :: pt_stack_t
    type(pt_entry_t), pointer :: last => null ()
    contains
      <WHIZARD: pt_stack: TBP>
    end type pt_stack_t

```

The finalizer is called at the very end.

```

<WHIZARD: pt_stack: TBP>=
  procedure :: final => pt_stack_final

<WHIZARD: procedures>=
  subroutine pt_stack_final (pt_stack)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(pt_entry_t), pointer :: current
    do while (associated (pt_stack%last))
      current => pt_stack%last
      pt_stack%last => current%previous
      call parse_tree_final (current%parse_tree_t)
      deallocate (current)
    end do
  end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt_stack: TBP>+=
  procedure :: push => pt_stack_push

<WHIZARD: procedures>+=
  subroutine pt_stack_push (pt_stack, parse_tree)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(parse_tree_t), intent(out), pointer :: parse_tree
    type(pt_entry_t), pointer :: current
    allocate (current)
    parse_tree => current%parse_tree_t
    current%previous => pt_stack%last
    pt_stack%last => current
  end subroutine pt_stack_push

```

### 31.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a `WHIZARD` instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the

syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+≡
    public :: whizard_t

<WHIZARD: types>+≡
    type :: whizard_t
        type(whizard_options_t) :: options
        type(rt_data_t) :: global
        type(pt_stack_t) :: pt_stack
    contains
        <WHIZARD: whizard: TBP>
    end type whizard_t

```

### 31.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>≡
    procedure :: init => whizard_init

<WHIZARD: procedures>+≡
    subroutine whizard_init (whizard, options, paths, logfile)
        class(whizard_t), intent(out), target :: whizard
        type(whizard_options_t), intent(in) :: options
        type(paths_t), intent(in), optional :: paths
        type(string_t), intent(in), optional :: logfile
        call init_syntax_tables ()
        whizard%options = options
        call whizard%global%global_init (paths, logfile)
        call whizard%init_rebuild_flags ()
        call whizard%preload_model ()
        call whizard%preload_library ()
        call whizard%global%init_fallback_model &
            (var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))
        call whizard%global%init_radiation_model &
            (var_str ("SM_rad"), var_str ("SM_rad.mdl"))
    end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: final => whizard_final

<WHIZARD: procedures>+≡
    subroutine whizard_final (whizard)
        class(whizard_t), intent(inout), target :: whizard
        call whizard%global%final ()
        call whizard%pt_stack%final ()
        !!! JRR: WK please check (#529)
        !    call user_code_final ()
        call final_syntax_tables ()
    end subroutine whizard_final

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: procedures>+≡
    subroutine whizard_init_rebuild_flags (whizard)
        class(whizard_t), intent(inout), target :: whizard
        associate (var_list => whizard%global%var_list, options => whizard%options)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_library"), options%rebuild_library, &
                intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?recompile_library"), &
                options%recompile_library, &
                intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_phase_space"), options%rebuild_phs, &
                intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_grids"), options%rebuild_grids, &
                intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_events"), options%rebuild_events, &
                intrinsic=.true.)
        end associate
    end subroutine whizard_init_rebuild_flags

```

This procedure preloads a model, if a model name is given.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: preload_model => whizard_preload_model

<WHIZARD: procedures>+≡
    subroutine whizard_preload_model (whizard)
        class(whizard_t), intent(inout), target :: whizard
        type(string_t) :: model_name
        model_name = whizard%options%preload_model
        if (model_name /= "") then
            call whizard%global%read_model (model_name, whizard%global%preload_model)
            whizard%global%model => whizard%global%preload_model
            if (associated (whizard%global%model)) then
                call whizard%global%model%link_var_list (whizard%global%var_list)
                call msg_message ("Preloaded model: " &
                    // char (model_name))
            else
                call msg_fatal ("Preloading model " // char (model_name) &
                    // " failed")
            end if
        else
            call msg_message ("No model preloaded")
        end if
    end subroutine whizard_preload_model

```

This procedure preloads a library, if a library name is given.

Note: This version just opens a new library with that name. It does not load (yet) an existing library on file, as previous WHIZARD versions would do.

```

<WHIZARD: whizard: TBP>+=
  procedure :: preload_library => whizard_preload_library
<WHIZARD: procedures>+=
  subroutine whizard_preload_library (whizard)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t) :: library_name, libs
    type(string_t), dimension(:), allocatable :: libname_static
    type(prclib_entry_t), pointer :: lib_entry
    integer :: i
    call get_prclib_static (libname_static)
    do i = 1, size (libname_static)
      allocate (lib_entry)
      call lib_entry%init_static (libname_static(i))
      call whizard%global%add_prclib (lib_entry)
    end do
    libs = adjustl (whizard%options%preload_libraries)
    if (libs == "" .and. whizard%options%default_lib /= "") then
      allocate (lib_entry)
      call lib_entry%init (whizard%options%default_lib)
      call whizard%global%add_prclib (lib_entry)
      call msg_message ("Preloaded library: " // &
        char (whizard%options%default_lib))
    end if
    SCAN_LIBS: do while (libs /= "")
      call split (libs, library_name, " ")
      if (library_name /= "") then
        allocate (lib_entry)
        call lib_entry%init (library_name)
        call whizard%global%add_prclib (lib_entry)
        call msg_message ("Preloaded library: " // char (library_name))
      end if
    end do SCAN_LIBS
  end subroutine whizard_preload_library

```

### 31.2.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

```

<WHIZARD: public>+=
  public :: init_syntax_tables
  public :: final_syntax_tables

```

```

<WHIZARD: procedures>+≡
subroutine init_syntax_tables ()
  call syntax_model_file_init ()
  call syntax_phs_forest_init ()
  call syntax_pexpr_init ()
  call syntax_slha_init ()
  call syntax_blha_contract_init ()
  call syntax_cmd_list_init ()
end subroutine init_syntax_tables

subroutine final_syntax_tables ()
  call syntax_model_file_final ()
  call syntax_phs_forest_final ()
  call syntax_pexpr_final ()
  call syntax_slha_final ()
  call syntax_blha_contract_final ()
  call syntax_cmd_list_final ()
end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡

```

### 31.2.6 Execute command lists

Process commands given on the command line, stored as an ifile. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: process_ifile => whizard_process_ifile
<WHIZARD: procedures>+≡
  subroutine whizard_process_ifile (whizard, ifile, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    type(ifile_t), intent(in) :: ifile
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    call msg_message ("Reading commands given on the command line")
    call lexer_init_cmd_list (lexer)
    call stream_init (stream, ifile)
    call whizard%process_stream (stream, lexer, quit, quit_code)
    call stream_final (stream)
    call lexer_final (lexer)
  end subroutine whizard_process_ifile

```

Process standard input as a command list. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: process_stdin => whizard_process_stdin
<WHIZARD: procedures>+≡
  subroutine whizard_process_stdin (whizard, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    call msg_message ("Reading commands from standard input")
    call lexer_init_cmd_list (lexer)
    call stream_init (stream, 5)
    call whizard%process_stream (stream, lexer, quit, quit_code)
    call stream_final (stream)
    call lexer_final (lexer)
  end subroutine whizard_process_stdin

```

Process a file as a command list.

*<WHIZARD: whizard: TBP>+≡*

```
procedure :: process_file => whizard_process_file
```

*<WHIZARD: procedures>+≡*

```
subroutine whizard_process_file (whizard, file, quit, quit_code)
  class(whizard_t), intent(inout), target :: whizard
  type(string_t), intent(in) :: file
  logical, intent(out) :: quit
  integer, intent(out) :: quit_code
  type(lexer_t), target :: lexer
  type(stream_t), target :: stream
  logical :: exist
  call msg_message ("Reading commands from file '" // char (file) // "'")
  inquire (file=char(file), exist=exist)
  if (exist) then
    call lexer_init_cmd_list (lexer)
    call stream_init (stream, char (file))
    call whizard%process_stream (stream, lexer, quit, quit_code)
    call stream_final (stream)
    call lexer_final (lexer)
  else
    call msg_error ("File '" // char (file) // "' not found")
  end if
end subroutine whizard_process_file
```

*<WHIZARD: whizard: TBP>+≡*

```
procedure :: process_stream => whizard_process_stream
```

*<WHIZARD: procedures>+≡*

```
subroutine whizard_process_stream (whizard, stream, lexer, quit, quit_code)
  class(whizard_t), intent(inout), target :: whizard
  type(stream_t), intent(inout), target :: stream
  type(lexer_t), intent(inout), target :: lexer
  logical, intent(out) :: quit

    type(stream_t), target :: stream
    type(string_t) :: prompt1
    type(string_t) :: prompt2
    type(string_t) :: input
    type(string_t) :: extra
    integer :: last
    integer :: iostat
    logical :: mask_tmp
    logical :: quit
    call msg_message ("Launching interactive shell")
    call lexer_init_cmd_list (lexer)
    prompt1 = "whish? "
    prompt2 = "      > "
    COMMAND_LOOP: do
      call put (6, prompt1)
      call get (5, input, iostat=iostat)
      if (iostat > 0 .or. iostat == EOF) exit COMMAND_LOOP
      CONTINUE_INPUT: do
        last = len_trim (input)
        if (extract (input, last, last) /= BACKSLASH) exit CONTINUE_INPUT
        call put (6, prompt2)
        call get (5, extra, iostat=iostat)
        if (iostat > 0) exit COMMAND_LOOP
        input = replace (input, last, extra)
      end do CONTINUE_INPUT
      call stream_init (stream, input)
      mask_tmp = mask_fatal_errors
      mask_fatal_errors = .true.
      call whizard%process_stream (stream, lexer, quit, quit_code)
      msg_count = 0
      mask_fatal_errors = mask_tmp
      call stream_final (stream)
      if (quit) exit COMMAND_LOOP
    end do COMMAND_LOOP
    print *
    call lexer_final (lexer)
  end subroutine whizard_shell
```

### 31.2.8 Self-tests

For those self-tests, we need some auxiliary routines that provide an environment. The environment depends on things that are not available at the level of the

module that we want to test.

### Testbed for event I/O

This subroutine prepares a test process with a single event. All objects are allocated via anonymous pointers, because we want to recover the pointers and delete the objects in a separate procedure.

(*WHIZARD: procedures*) $\equiv$

```
subroutine prepare_eio_test (event, unweighted, n_alt)
  use variables
  use model_data
  use event_base
  class(generic_event_t), intent(inout), pointer :: event
  logical, intent(in), optional :: unweighted
  integer, intent(in), optional :: n_alt
  type(model_data_t), pointer :: model
  type(var_list_t) :: var_list
  type(process_t), pointer :: process
  type(process_instance_t), pointer :: process_instance

  allocate (model)
  call model%init_test ()

  allocate (process)
  allocate (process_instance)

  call prepare_test_process (process, process_instance, model)
  call process_instance%setup_event_data ()

  call model%final ()
  deallocate (model)

  allocate (event_t :: event)
  select type (event)
  type is (event_t)
    if (present (unweighted)) then
      call var_list_append_log (var_list, &
        var_str ("?unweighted"), unweighted, &
        intrinsic = .true.)
    else
      call var_list_append_log (var_list, &
        var_str ("?unweighted"), .true., &
        intrinsic = .true.)
    end if
    call var_list_append_string (var_list, &
      var_str ("sample_normalization"), &
      var_str ("auto"), intrinsic = .true.)
    call event%basic_init (var_list, n_alt)
    call event%connect (process_instance, process%get_model_ptr ())
    call var_list%final ()
  end select
end subroutine prepare_eio_test
```

Recover those pointers, finalize the objects and deallocate.

```

<WHIZARD: procedures>+≡
  subroutine cleanup_eio_test (event)
    use model_data
    use event_base
    class(generic_event_t), intent(inout), pointer :: event
    type(process_t), pointer :: process
    type(process_instance_t), pointer :: process_instance
    select type (event)
    type is (event_t)
      process => event%get_process_ptr ()
      process_instance => event%get_process_instance_ptr ()
      call cleanup_test_process (process, process_instance)
      deallocate (process_instance)
      deallocate (process)
      call event%final ()
    end select
    deallocate (event)
  end subroutine cleanup_eio_test

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

<WHIZARD: prepare testbed>≡
  eio_prepare_test => prepare_eio_test
  eio_cleanup_test => cleanup_eio_test

```

## Any Model

This procedure reads any model from file and, optionally, assigns a var-list pointer.

```

<WHIZARD: procedures>+≡
  subroutine prepare_whizard_model (model, name, vars)
    <Use strings>
    use os_interface
    use model_data
    use var_base
    use models
    class(model_data_t), intent(inout), pointer :: model
    type(string_t), intent(in) :: name
    class(vars_t), pointer, intent(out), optional :: vars
    type(os_data_t) :: os_data
    call syntax_model_file_init ()
    call os_data_init (os_data)
    allocate (model_t :: model)
    select type (model)
    type is (model_t)
      call model%read (name // ".mdl", os_data)
      if (present (vars)) then
        vars => model%get_var_list_ptr ()
      end if
    end select
  end subroutine prepare_whizard_model

```

Cleanup after use. Includes deletion of the model-file syntax.

```

<WHIZARD: procedures>+≡
  subroutine cleanup_whizard_model (model)
    use model_data
    use models
    class(model_data_t), intent(inout), pointer :: model
    call model%final ()
    deallocate (model)
    call syntax_model_file_final ()
  end subroutine cleanup_whizard_model

```

Assign those procedures to appropriate pointers (module variables) in the `model_testbed` module, so they can be called as if they were module procedures.

```

<WHIZARD: prepare testbed>+≡
  prepare_model => prepare_whizard_model
  cleanup_model => cleanup_whizard_model

```

### Fallback model: hadrons

Some event format tests require the hadronic SM implementation, which has to be read from file. We provide the functionality here, so the tests do not depend on model I/O.

```

<WHIZARD: procedures>+≡
  subroutine prepare_fallback_model (model)
    use model_data
    class(model_data_t), intent(inout), pointer :: model
    call prepare_whizard_model (model, var_str ("SM_hadrons"))
  end subroutine prepare_fallback_model

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

<WHIZARD: prepare testbed>+≡
  eio_prepare_fallback_model => prepare_fallback_model
  eio_cleanup_fallback_model => cleanup_model

```

### Procedure for Checking

This is for developers only, but needs a well-defined interface.

```

<WHIZARD: public>+≡
  public :: whizard_check

<WHIZARD: procedures>+≡

### 31.3 Driver program

The main program handles command options, initializes the environment, and runs WHIZARD in a particular mode (interactive, file, standard input).

This is also used in the C interface:

```
<Main: cmdline arg len declaration>≡  
    integer, parameter :: CMDLINE_ARG_LEN = 1000
```

The actual main program:

```
<main.f90>≡  
<File header>  
  
program main  
  
<Use strings>  
    use unit_tests  
    use system_dependencies  
    use diagnostics  
    use ifiles  
    use os_interface  
    use whizard  
  
    implicit none  
  
<Main: cmdline arg len declaration>  
  
    ! Main program variable declarations  
    character(CMDLINE_ARG_LEN) :: arg  
    character(2) :: option  
    type(string_t) :: long_option, value  
    integer :: i, j, arg_len, arg_status  
    logical :: look_for_options  
    logical :: interactive  
    logical :: banner  
    type(string_t) :: files, this, model, default_lib, library, libraries  
    type(string_t) :: check, checks, logfile  
    type(test_results_t) :: test_results  
    logical :: success  
    logical :: user_code_enable = .false.
