            endif
c Delta-part of potential is absorbed by subtracting vzero from the
c original energy (shift from the potential to the free Hamiltonian):
            vzero = consde / (2.d0*pi)**3
c
            write (*,*) 'vzero=', vzero
c
c Find x-values pp(i) and weights w1(i) for the gaussian quadrature;
c care about large number of points in the important intervals:
c
            if (energy-vzero.le.0.d0) then
cc                call gauleg(0.d0, 1.d0, pp, w1, n/3)
cc                call gauleg(1.d0, 5.d0, pp(n/3+1), w1(n/3+1), n/3)
cc                call gauleg(0.d0, 0.2d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c                call gauleg(0.d0, 5.d0, pp, w1, n/3)
c                call gauleg(5.d0, 20.d0, pp(n/3+1), w1(n/3+1), n/3)
c                call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c            else

```

```

cc Avoid numerical singular points in the inner of the intervals:
c      critp = dsqrt((energy-vzero)*tmass)
c      if (critp.le.1.d0) then
cc Gauss-Legendre is symmetric => automatically principal-value prescription:
c          call gauleg(0.d0, 2.d0*critp, pp, w1, n/3)
c          call gauleg(2.d0*critp, 20.d0, pp(n/3+1),
c      u          w1(n/3+1), n/3)
c          call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c      else
cc Better behaviour at the border of the intervals:
c          call gauleg(0.d0, critp, pp, w1, n/3)
c          call gauleg(critp, 2.d0*critp, pp(n/3+1),
c      u          w1(n/3+1), n/3)
c          call gauleg(0.d0, 1.d0/(2.d0*critp), pp(2*n/3+1),
c      u          w1(2*n/3+1), n/3)
c      endif
c      endif
c
c Or different (simpler) method, good for V_JKT:
c      if (energy.le.0.d0) then
c          critp=tmass/3.d0
c      else
c          critp=max(tmass/3.d0,2.d0*dsqrt(energy*tmass))
c      endif
c      call gauleg(0.d0, critp, pp, w1, 2*n/3)
c      call gauleg(1.d0/xpmax, 1.d0/critp, pp(2*n/3+1),
c      u          w1(2*n/3+1), n/3)
c
c Do substitution p => 1/p for the last interval explicitly:
c      do 10 i=2*n/3+1,n
c          pp(i) = 1.d0/pp(i)
10      continue
c
c Reorder the arrays for the third interval:
c      do 20 i=1,n/3
c          xx(i) = pp(2*n/3+i)
c          w2(i) = w1(2*n/3+i)
20      continue
c      do 30 i=1,n/3
c          pp(n-i+1) = xx(i)
c          w1(n-i+1) = w2(i)
30      continue
c
c Calculate the integrals a(p) for the given momenta pp(i)
c and store weights and momenta for the output arrays:
c      do 40 i=1,n
c          a1(i) = a(pp(i)) !!! FB: can get stuck in original Toppik!
c          !!! FB: abuse 'np' as a flag to communicate unstable runs
c          if ( abs(a1(i)) .gt. 1d10 ) then
c              np = -1
c              return
c          endif
c          xpp(i)=pp(i)
c          xww(i)=w1(i)

```

```

40      continue
      do 41 i=n+1,nmax
          xpp(i)=0.d0
          xww(i)=0.d0
41      continue
c
c
c Solve the integral-equation by solving a system of algebraic equations:
      call sae(pp, w1, bb, a1, n)
c
c (The substitution for the integration to infinity pp => 1/pp
c is done already.)
      do 50 i=1,n
          zvfct(i)=bb(i)
          gg(i) = bb(i)*g0c(pp(i))
cc      gg(i) = (1.d0 + bb(i))*g0c(pp(i))
cc Urspruenglich anderes (Minus) VZ hier, dafuer kein Minus mehr bei der
cc Definition des WQs ueber Im G, 2.6.1998, tt.

c
c   Correction function for non-constant (energy and momentum dependent) width:
      FUNCTION GTPCOR1(TOPP,ETOT)
c
c      TOPP - momentum of t quark = - momentum of tbar
c      ETOT - total energy of t-tbar system
c      calls: GENWDS, RAN2
c
c      Evaluates a correction factor to the width of t-tbar system.
c      in future has to be replaced by a function evaluating
c      width including radiative corrections and GTPCOR.
c      I include two factors reducing the width:
c      a - time dilatation: for decay in flight lifetime
c          increased accordingly to relativistic kinematics
c      b - overall energy-momentum conservation: I assume that
c          t and tbar decay in flight and in this decays energies
c          of Ws follow from 2-body kinematics. Then I calculate
c          effective mass squared of b-bar system (it may be
c          negative!) from en-momentum conservation.
c          If effective mass is < 2*Mb + 2 GeV configuration
c          is rejected. The weight is acceptance.

c    * Based on TOPPIK Version 1.1
c      from M. Jezabek and TT, Karlsruhe, June 1992
c    * Version originally for non-constant top-width
c    * Constant width supplied here
c    * No generator included
c
c -- Use of double precision everywhere
c
c -- All masses, momenta, energies, widths in GeV
c

```

```

c -- Input parameters:
c
c   xenergy   : E=Sqrt[s]-2*topmass
c   xtm       : topmass (in the Pole scheme)
c   xtg       : top-width
c   xalphas   : alpha_s^{MSbar,n_f=5}(xscale)
c   xscale    : soft scale mu_{soft}
c   xcutn     : numerical UV cutoff on all momenta
c               (UV cutoff of the Gauss-Legendre grid)
c   xcutv     : renormalization cutoff on the
c               delta-, the (p^2+q^2)/(p-q)^2-, and the
c               1/r^2-[1/|p-q|]-potential:
c               if (max(p,q).ge.xcutv) then the three potentials
c               are set to zero in the Lippmann-Schwinger equation
c   xc0       : 0th order coefficient for the Coulomb potential,
c               see calling example above
c   xc1       : 1st order coefficient for the Coulomb potential
c   xc2       : 2nd order coefficient for the Coulomb potential
c   xcdeltc   : constant of the delta(r)-
c               [= constant in momentum space-] potential
c   xcdeletl  : constant for the additional log(q^2/mu^2)-part of the
c               delta-potential:
c               xcdeletc*1 + xcdeletl*log(q^2/mu^2)
c   xcfullc   : constant of the (p^2+q^2)/(p-q)^2-potential
c   xcfulll   : constant for the additional log(q^2/mu^2)-part of the
c               (p^2+q^2)/(p-q)^2-potential
c   xcrm2     : constant of the 1/r^2-[1/|p-q|]-potential
c   xkincm    : } kinetic corrections in the 0th order Green function:
c   xkinca    : } G_0(p):=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c               !!! WATCH THE SIGN IN G_0 !!!
c   jknflg    : flag for these kinetic corrections:
c               0 : no kinetic corrections applied
c               1 : kinetic corrections applied with cutoff xcutv
c                   for xkinca only
c               2 : kinetic corrections applied with cutoff xcutv
c                   for xkinca AND xkincm
c   jgcflg    : flag for G_0(p) in the LS equation:
c               0 (standard choice) : G_0(p) as given above
c               1 (for TIPT)         : G_0(p) = G_c^{0}(p) the 0th
c                                       order Coulomb Green function
c                                       in analytical form; not for
c                                       momenta p > 1000*topmass
c   xkincv    : additional kinematic vertexcorrection in G_0, see below:
c   jvflg     : flag for the additional vertexcorrection xkincv in the
c               "zeroth order" G_0(p) in the LS-equation:
c               0 : no correction, means G = G_0 + G_0 int V G
c                   with G_0=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c               1 : apply the correction in the LS equation as
c                   G = G_0 + xkincv*p^2/m_t^2/[E+iGamma_t-p^2/m_t] +
c                   G_0 int V G
c               and correct the integral over Im[G(p)] to get sigma_tot
c               from the optical theorem by the same factor.
c               The cutoff xcutv is applied for these corrections.
c

```

```

c -- Output:
c
c   xim      : R^{P wave}_{ttbar} from the imaginary part of the Green
c              function
c   xdi      : R^{P wave}_{ttbar} from the integral over the momentum
c              distribution:  $\int_0^{\text{xcutv}} dp \, p^3/m_t * |F(p,E)|^2$ 
c   np       : number of points used for the grid; fixed in tttoppik
c   xpp      : 1-dim array (max. 400 elements) giving the momenta of
c              the Gauss-Legendre grid (pp(i) in the code)
c   xww      : 1-dim array (max. 400 elements) giving the corresponding
c              Gauss-Legendre weights for the grid
c   xdsdp    : 1-dim array (max. 400 elements) giving the
c              momentum distribution of top:  $d\sigma^{\text{P wave}}/dp$ ,
c              normalized to R,
c              at the momenta of the Gauss-Legendre grid xpp(i)
c   zftild   : 1-dim array (max. 400 elements) of COMPLEX*16 numbers
c              giving the vertex function K_A for the P-wave
c              at the momenta of the grid.
c              Then  $F(p)=K_A(p)*G_0(p)$  corresponding to  $G=K_V*G_0$ .

c Delta-part of potential is absorbed by subtracting vzero from the
c original energy (shift from the potential to the free Hamiltonian):
        vzero = consde / (2.d0*pi)**3
        write (*,*) 'vzero=', vzero
c
c Find x-values pp(i) and weights w1(i) for the gaussian quadrature;
c care about large number of points in the important intervals:
        if (energy-vzero.le.0.d0) then
cc        call gauleg(0.d0, 1.d0, pp, w1, n/3)
cc        call gauleg(1.d0, 5.d0, pp(n/3+1), w1(n/3+1), n/3)
cc        call gauleg(0.d0, 0.2d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c        call gauleg(0.d0, 5.d0, pp, w1, n/3)
c        call gauleg(5.d0, 20.d0, pp(n/3+1), w1(n/3+1), n/3)
c        call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
        else
cc Avoid numerical singular points in the inner of the intervals:
c        critp = sqrt((energy-vzero)*tmass)
c        if (critp.le.1.d0) then
cc Gauss-Legendre is symmetric => automatically principal-value prescription:
c            call gauleg(0.d0, 2.d0*critp, pp, w1, n/3)
c            call gauleg(2.d0*critp, 20.d0, pp(n/3+1),
c                u      w1(n/3+1), n/3)
c            call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c        else

```

```

cc Better behaviour at the border of the intervals:
c      call gauleg(0.d0, critp, pp, w1, n/3)
c      call gauleg(critp, 2.d0*critp, pp(n/3+1),
c      u      w1(n/3+1), n/3)
c      call gauleg(0.d0, 1.d0/(2.d0*critp), pp(2*n/3+1),
c      u      w1(2*n/3+1), n/3)
c      endif
c      endif
c
c Or different (simpler) method, good for V_JKT:
c      if (energy.le.0.d0) then
c          critp=tmass/3.d0
c      else
c          critp=max(tmass/3.d0,2.d0*sqrt(energy*tmass))
c      endif
c      call gauleg(0.d0, critp, pp, w1, 2*n/3)
c      call gauleg(1.d0/xpmax, 1.d0/critp, pp(2*n/3+1),
c      u      w1(2*n/3+1), n/3)
c
c Do substitution  $p \Rightarrow 1/p$  for the last interval explicitly:
c      do 10 i=2*n/3+1,n
c          pp(i) = 1.d0/pp(i)
10      continue
c
c Reorder the arrays for the third interval:
c      do 20 i=1,n/3
c          xx(i) = pp(2*n/3+i)
c          w2(i) = w1(2*n/3+i)
20      continue
c      do 30 i=1,n/3
c          pp(n-i+1) = xx(i)
c          w1(n-i+1) = w2(i)
30      continue
c
c Calculate the integrals aax(p) for the given momenta pp(i)
c and store weights and momenta for the output arrays:
c      do 40 i=1,n
c          a1(i) = aax(pp(i)) !!! FB: can get stuck in original Toppik!
c          !!! FB: abuse 'np' as a flag to communicate unstable runs
c          if ( abs(a1(i)) .gt. 1d10 ) then
c              np = -1
c              return
c          endif
c          xpp(i)=pp(i)
c          xww(i)=w1(i)
40      continue
c      do 41 i=n+1,nmax
c          xpp(i)=0.d0
c          xww(i)=0.d0
41      continue
c
c Solve the integral-equation by solving a system of algebraic equations:
c      call saeax(pp, w1, bb, vec, a1, n)
c

```

```

c (The substitution for the integration to infinity pp => 1/pp
c is done already.)
      do 50 i=1,n
          zvfct(i)=bb(i)
          zftild(i)=vec(i)
          gg(i) = bb(i)*g0c(pp(i))
cc      gg(i) = (1.d0 + bb(i))*g0c(pp(i))

## Chapter 29

# Integration and Process Objects

This is the central part of the WHIZARD package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

**subevt\_expr** This enables process observables as (abstract) expressions, to be evaluated for each process call.

**parton\_states** A `parton_state_t` object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

**processes** Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: `prc_core` for matrix-element evaluation, `prc_core_def` for the associated configuration and driver, `sf_base` for beams and structure-functions, `phs_base` for phase space, and `mci_base` for integration and event generation.

**process\_stacks** Process stacks collect process objects.

### 29.1 Process observables

We define an abstract `subevt_expr_t` object as an extension of the `subevt_t` type. The object contains a local variable list, variable instances (as targets for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the `subevt`.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression `selection` which determines whether the object passes user-defined cuts.

The intention is that we fill the `subevt_t` base object and compute the variables once we have evaluated a kinematical phase space point (or a complete

event). We then evaluate the expressions and can use the results in further calculations.

The `process_expr_t` extension contains furthermore scale and weight expressions. The `event_expr_t` extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

Note that there are unit tests, but they are deferred to the `expr_tests` module.

```

            call object%selection%final ()
        end if
    end subroutine subvt_expr_final

```

## 29.1.2 Initialization

Initialization: define local variables and establish pointers.

The common variables are `sqrts` (the nominal beam energy, fixed), `sqrts_hat` (the actual energy), `n_in`, `n_out`, and `n_tot` for the subevt. With the exception of `sqrts`, all are implemented as pointers to subobjects.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure (subevt_expr_setup_vars), deferred :: setup_vars
  procedure :: base_setup_vars => subevt_expr_setup_vars
<Subevt expr: procedures>+≡
  subroutine subevt_expr_setup_vars (expr, sqrts)
    class(subevt_expr_t), intent(inout), target :: expr
    real(default), intent(in) :: sqrts
    call expr%var_list%final ()
    call var_list_append_real (expr%var_list, &
      var_str ("sqrts"), sqrts, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_real_ptr (expr%var_list, &
      var_str ("sqrts_hat"), expr%sqrts_hat, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_in"), expr%n_in, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_out"), expr%n_out, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_tot"), expr%n_tot, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
  end subroutine subevt_expr_setup_vars

```

Append the subevent expr (its base-type core) itself to the variable list, if it is not yet present.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure :: setup_var_self => subevt_expr_setup_var_self
<Subevt expr: procedures>+≡
  subroutine subevt_expr_setup_var_self (expr)
    class(subevt_expr_t), intent(inout), target :: expr
    if (.not. expr%var_list%contains (var_str ("@evt"))) then
      call var_list_append_subevt_ptr &
        (expr%var_list, &
        var_str ("@evt"), expr%subevt_t, &

        locked = .true., verbose = .false., intrinsic=.true.)
    end if
  end subroutine subevt_expr_setup_var_self

```

Link a variable list to the local one. This could be done event by event, but before evaluating expressions.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure :: link_var_list => subevt_expr_link_var_list

```

```

<Subvt expr: procedures>+≡
  subroutine subvt_expr_link_var_list (expr, var_list)
    class(subvt_expr_t), intent(inout) :: expr
    type(var_list_t), intent(in), target :: var_list
    call expr%var_list%link (var_list)
  end subroutine subvt_expr_link_var_list

```

Compile the selection expression. If there is no expression, the build method won't allocate the expression object.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: setup_selection => subvt_expr_setup_selection

<Subvt expr: procedures>+≡
  subroutine subvt_expr_setup_selection (expr, ef_cuts)
    class(subvt_expr_t), intent(inout), target :: expr
    class(expr_factory_t), intent(in) :: ef_cuts
    call ef_cuts%build (expr%selection)
    if (allocated (expr%selection)) then
      call expr%setup_var_self ()
      call expr%selection%setup_lexpr (expr%var_list)
      expr%has_selection = .true.
    end if
  end subroutine subvt_expr_setup_selection

```

### 29.1.3 Evaluation

Reset to initial state, i.e., mark the subvt as invalid.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: reset => subvt_expr_reset
  procedure :: base_reset => subvt_expr_reset

<Subvt expr: procedures>+≡
  subroutine subvt_expr_reset (expr)
    class(subvt_expr_t), intent(inout) :: expr
    expr%subvt_filled = .false.
  end subroutine subvt_expr_reset

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: base_evaluate => subvt_expr_evaluate

<Subvt expr: procedures>+≡
  subroutine subvt_expr_evaluate (expr, passed)
    class(subvt_expr_t), intent(inout) :: expr
    logical, intent(out) :: passed
    if (expr%has_selection) then
      call expr%selection%evaluate ()
      if (expr%selection%is_known ()) then
        passed = expr%selection%get_log ()
      else
        call msg_error ("Evaluate selection expression: result undefined")
      end if
    end if
  end subroutine subvt_expr_evaluate

```

```

        passed = .false.
    end if
else
    passed = .true.
end if
end subroutine subevt_expr_evaluate

```

#### 29.1.4 Implementation for partonic events

This implementation contains the expressions that we can evaluate for the partonic process during integration.

```

⟨Subevt expr: public⟩≡
    public :: parton_expr_t

⟨Subevt expr: types⟩+≡
    type, extends (subevt_expr_t) :: parton_expr_t

```

```

        expr%has_weight = .true.
    end if
end subroutine parton_expr_setup_weight

```

Filling the partonic state consists of two parts. The first routine prepares the subevt without assigning momenta. It takes the particles from an `interaction_t`. It needs the indices and flavors for the beam, incoming, and outgoing particles.

We can assume that the particle content of the subevt does not change. Therefore, we set the event variables `n_in`, `n_out`, `n_tot` already in this initialization step.

```

<Subevt expr: parton expr: TBP>+≡

### 29.1.5 Implementation for full events

This implementation contains the expressions that we can evaluate for the full event. It also contains data that pertain to the event, suitable for communication with external event formats. These data simultaneously serve as pointer targets for the variable lists hidden in the expressions (eval trees).

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

```

⟨Subvt expr: public⟩+≡
    public :: event_expr_t

```

## 29.2 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states, depending on the the beam setup allows. The result is used for integration.

The `matrix` evaluator is the counterpart of `trace` which is kept exclusive in all observable quantum numbers. The `flows` evaluator is furthermore exclusive in colors, but neglecting all color interference. The `matrix` and `flows` evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. However, this causes memory corruption in gfortran 4.6.3. The extra `has_XXX` flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the `processes` module below.

```

⟨Parton states: procedures⟩

end module parton_states

```

### 29.2.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

⟨Parton states: types⟩≡
  type, abstract :: parton_state_t
    logical :: has_trace = .false.
    logical :: has_matrix = .false.
    logical :: has_flows = .false.
    type(evaluator_t) :: trace
    type(evaluator_t) :: matrix
    type(evaluator_t) :: flows
  contains
    ⟨Parton states: parton state: TBP⟩
  end type parton_state_t

```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both implemented as a pointer. The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```

(Parton states: public)≡
  public :: isolated_state_t

(Parton states: types)+≡
  type, extends (parton_state_t) :: isolated_state_t
    logical :: sf_chain_is_allocated = .false.
    type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()
    logical :: int_is_allocated = .false.
    type(interaction_t), pointer :: int_eff => null ()
  contains
    (Parton states: isolated state: TBP)
  end type isolated_state_t

```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

```

(Parton states: types)+≡
  public :: connected_state_t

(Parton states: types)+≡
  type, extends (parton_state_t) :: connected_state_t
    type(state_flv_content_t) :: state_flv
    logical :: has_flows_sf = .false.
    type(evaluator_t) :: flows_sf
    logical :: has_expr = .false.
    type(parton_expr_t) :: expr
  contains
    (Parton states: connected state: TBP)
  end type connected_state_t

```

Output: each evaluator is written only when it is active. The `sf_chain` is only written if it is explicitly allocated.

### 29.2.2 Common Initialization

Initialize the isolated parton state. In this version, the effective structure-function chain `sf_chain_eff` and the effective interaction `int_eff` both are trivial pointers to the seed structure-function chain and to the hard interaction, respectively.

```

(Parton states: isolated state: TBP) =
  procedure :: init => isolated_state_init_pointers

(Parton states: procedures) +=
  subroutine isolated_state_init_pointers (state, sf_chain, int)
    class(isolated_state_t), intent(out) :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(interaction_t), intent(in), target :: int
    state%sf_chain_eff => sf_chain
    state%int_eff => int
  end subroutine isolated_state_init_pointers

```

### 29.2.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask_in`.

There are two options: explicitly computing the color factor table (`use_cf` false; `nc` defined), or taking the color factor table from the hard matrix element data.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_square_trace => isolated_state_setup_square_trace

(Parton states: procedures)+≡
  subroutine isolated_state_setup_square_trace (state, core, qn_mask_in, &
    col)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), dimension(:), intent(in) :: qn_mask_in
    integer, dimension(:), intent(in) :: col
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    associate (data => core%data)
      allocate (qn_mask (data%n_in + data%n_out))
      qn_mask(:data%n_in) = &
        quantum_numbers_mask (.false., .true., .false.) &
        .or. qn_mask_in
      qn_mask(data%n_in+1:) = &
        quantum_numbers_mask (.true., .true., .true.)
    if (core%use_color_factors) then
      call state%trace%init_square (state%int_eff, qn_mask, &
        col_flow_index = data%cf_index, &
        col_factor = data%color_factors, &
        col_index_hi = col, &
        nc = core%nc)
    else
      call state%trace%init_square (state%int_eff, qn_mask, nc = core%nc)
    end if
    end associate
    state%has_trace = .true.
  end subroutine isolated_state_setup_square_trace

```

Setup the evaluator for the transition matrix, exclusive in helicities where this is requested.

For all unstable final-state particles we keep polarization according to the applicable decay options. If the process is a decay itself, this applies also to the initial state.

For all polarized final-state particles, we keep polarization including off-diagonal entries. We drop helicity completely for unpolarized final-state particles.

For the initial state, if the particle has not been handled yet, we apply the provided `qn_mask_in` which communicates the beam properties.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_square_matrix => isolated_state_setup_square_matrix

```

```

(Parton states: procedures)+≡
subroutine isolated_state_setup_square_matrix &

end subroutine isolated_state_setup_square_flows

```

## 29.2.4 Evaluator initialization: connected state

Setup a trace evaluator as a product of two evaluators (incoming state, effective interaction). In the result, all quantum numbers are summed over.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`.

The `resonant` flag applies if we want to construct a decay chain. The resonance property can propagate to the final event output.

*(Parton states: connected state: TBP)*≡

```

  procedure :: setup_connected_trace => connected_state_setup_connected_trace

```

*(Parton states: procedures)*+≡

```

  subroutine connected_state_setup_connected_trace &
    (state, isolated, int, resonant)
    class(connected_state_t), intent(inout), target :: state
    type(isolated_state_t), intent(in), target :: isolated
    type(interaction_t), intent(in), optional, target :: int
    logical, intent(in), optional :: resonant

```

```

type(quantum_numbers_mask_t) :: mask
type(interaction_t), pointer :: src_int
mask = quantum_numbers_mask (.true., .true., .true.)
if (present (int)) then
    src_int => int
else
    src_int => isolated%sf_chain_eff%get_out_int_ptr ()
end if
call state%trace%init_product (src_int, isolated%trace, &
    qn_mask_conn = mask, &
    qn_mask_rest = mask, &
    connections_are_resonant = resonant)
state%has_trace = .true.
end subroutine connected_state_setup_connected_trace

```

Setup a matrix evaluator as a product of two evaluators (incoming state, effective interaction). In the intermediate state, color and helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

```

(Parton states: connected state: TBP)+≡
    procedure :: setup_connected_matrix => connected_state_setup_connected_matrix
(Parton states: procedures)+≡
    subroutine connected_state_setup_connected_matrix &
        (state, isolated, int, resonant, qn_filter_conn)
    class(connected_state_t), intent(inout), target :: state
    type(isolated_state_t), intent(in), target :: isolated
    type(interaction_t), intent(in), optional, target :: int
    logical, intent(in), optional :: resonant
    type(quantum_numbers_t), intent(in), optional :: qn_filter_conn
    type(quantum_numbers_mask_t) :: mask
    type(interaction_t), pointer :: src_int
    mask = quantum_numbers_mask (.false., .true., .true.)
    if (present (int)) then
        src_int => int
    else
        src_int => isolated%sf_chain_eff%get_out_int_ptr ()
    end if
    call state%matrix%init_product &
        (src_int, isolated%matrix, mask, &
        qn_filter_conn = qn_filter_conn, &
        connections_are_resonant = resonant)
    state%has_matrix = .true.
end subroutine connected_state_setup_connected_matrix

```

Setup a matrix evaluator as a product of two evaluators (incoming state, effective interaction). In the intermediate state, only helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`, after creating an intermediate interaction that includes a correlated color state. We assume that for a caller-provided `int`, this is not necessary.

```

(Parton states: connected state: TBP)+≡

```

```

    procedure :: setup_connected_flows => connected_state_setup_connected_flows
  (Parton states: procedures)+≡
    subroutine connected_state_setup_connected_flows &
      (state, isolated, int, resonant, qn_filter_conn)
      class(connected_state_t), intent(inout), target :: state
      type(isolated_state_t), intent(in), target :: isolated
      type(interaction_t), intent(in), optional, target :: int
      logical, intent(in), optional :: resonant

      type(state_flv_content_t) :: state_flv
      state_flv = state%state_flv
    end function connected_state_get_state_flv

```

### 29.2.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

```

(Parton states: connected state: TBP)+≡
  procedure :: setup_subevt => connected_state_setup_subevt

(Parton states: procedures)+≡
  subroutine connected_state_setup_subevt (state, sf_chain, f_beam, f_in, f_out)
    class(connected_state_t), intent(inout), target :: state

    class(expr_factory_t), intent(in) :: ef_weight
    call state%expr%setup_weight (ef_weight)
  end subroutine connected_state_setup_weight

```

Reset the expression object: invalidate the subevt.

```

(Parton states: connected state: TBP)+≡
  procedure :: reset_expressions => connected_state_reset_expressions

(Parton states: procedures)+≡
  subroutine connected_state_reset_expressions (state)
    class(connected_state_t), intent(inout) :: state
    if (state%has_expr) call state%expr%reset ()
  end subroutine connected_state_reset_expressions

```

## 29.2.6 Evaluation

Transfer momenta to the trace evaluator and fill the `subevt` with this effective kinematics, if applicable.

Note: we may want to apply a boost for the `subevt`.

```

(Parton states: parton state: TBP)+≡
  procedure :: receive_kinematics => parton_state_receive_kinematics

(Parton states: procedures)+≡
  subroutine parton_state_receive_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
    if (state%has_trace) then
      call state%trace%receive_momenta ()
      select type (state)
        class is (connected_state_t)
          if (state%has_expr) then
            call state%expr%fill_subevt (state%trace%interaction_t)
          end if
        end select
      end if
    end subroutine parton_state_receive_kinematics

```

Recover kinematics: We assume that the trace evaluator is filled with momenta. Send those momenta back to the sources, then fill the variables and subevent as above.

The incoming momenta of the connected state are not connected to the isolated state but to the beam interaction. Therefore, the incoming momenta within the isolated state do not become defined, yet. Instead, we reconstruct the beam (and ISR) momentum configuration.

```

(Parton states: parton state: TBP)+≡
  procedure :: send_kinematics => parton_state_send_kinematics

(Parton states: procedures)+≡
  subroutine parton_state_send_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
    if (state%has_trace) then
      call interaction_send_momenta (state%trace%interaction_t)
      select type (state)
        class is (connected_state_t)
          call state%expr%fill_subevt (state%trace%interaction_t)
        end select
      end if
    end subroutine parton_state_send_kinematics

```

Evaluate the expressions. The routine evaluates first the cut expression. If the event passes, it evaluates the other expressions. Where no expressions are defined, default values are inserted.

```

(Parton states: connected state: TBP)+≡
  procedure :: evaluate_expressions => connected_state_evaluate_expressions

(Parton states: procedures)+≡
  subroutine connected_state_evaluate_expressions (state, passed, &
    scale, fac_scale, ren_scale, weight, scale_forced)

```

Evaluate the trace.

```

(Parton states: parton state: TBP) +=
    procedure :: evaluate_trace => parton_state_evaluate_trace

(Parton states: procedures) +=
    subroutine parton_state_evaluate_trace (state)
        class(parton_state_t), intent(inout) :: state
        if (state%has_trace) then
            call state%trace%evaluate ()
        end if
    end subroutine parton_state_evaluate_trace

```

Evaluate the extra evaluators that we need for physical events.

```

(Parton states: parton state: TBP) +=
    procedure :: evaluate_event_data => parton_state_evaluate_event_data

(Parton states: procedures) +=
    subroutine parton_state_evaluate_event_data (state)
        class(parton_state_t), intent(inout) :: state
        select type (state)
            type is (connected_state_t)
                if (state%has_flows_sf) then
                    call state%flows_sf%receive_momenta ()
                    call state%flows_sf%evaluate ()
                end if
        end select
        if (state%has_matrix) then

```

```

        call state%matrix%receive_momenta ()
        call state%matrix%evaluate ()
    end if
    if (state%has_flows) then
        call state%flows%receive_momenta ()
        call state%flows%evaluate ()
    end if
end subroutine parton_state_evaluate_event_data

```

Normalize the helicity density matrix by its trace, i.e., factor out the trace and put it into an overall normalization factor. The trace and flow evaluators are unchanged.

```

<Parton states: parton state: TBP>+≡
    procedure :: normalize_matrix_by_trace => &
        parton_state_normalize_matrix_by_trace

<Parton states: procedures>+≡
    subroutine parton_state_normalize_matrix_by_trace (state)
        class(parton_state_t), intent(inout) :: state
        if (state%has_matrix) then
            call state%matrix%normalize_by_trace ()
        end if
    end subroutine parton_state_normalize_matrix_by_trace

```

## 29.2.7 Accessing the state

Three functions return a pointer to the event-relevant interactions.

```

<Parton states: parton state: TBP>+≡
    procedure :: get_trace_int_ptr => parton_state_get_trace_int_ptr
    procedure :: get_matrix_int_ptr => parton_state_get_matrix_int_ptr
    procedure :: get_flows_int_ptr => parton_state_get_flows_int_ptr

<Parton states: procedures>+≡
    function parton_state_get_trace_int_ptr (state) result (ptr)
        class(parton_state_t), intent(in), target :: state
        type(interaction_t), pointer :: ptr
        if (state%has_trace) then
            ptr => state%trace%interaction_t
        else
            ptr => null ()
        end if
    end function parton_state_get_trace_int_ptr

    function parton_state_get_matrix_int_ptr (state) result (ptr)
        class(parton_state_t), intent(in), target :: state
        type(interaction_t), pointer :: ptr
        if (state%has_matrix) then
            ptr => state%matrix%interaction_t
        else
            ptr => null ()
        end if
    end function parton_state_get_matrix_int_ptr

```

```

function parton_state_get_flows_int_ptr (state) result (ptr)
  class(parton_state_t), intent(in), target :: state
  type(interaction_t), pointer :: ptr
  if (state%has_flows) then
    ptr => state%flows%interaction_t
  else
    ptr => null ()
  end if
end function parton_state_get_flows_int_ptr

```

Return the indices of the beam particles and the outgoing particles within the trace (and thus, matrix and flows) evaluator, respectively.

```

⟨Parton states: connected state: TBP⟩+≡
  procedure :: get_beam_index => connected_state_get_beam_index
  procedure :: get_in_index => connected_state_get_in_index

⟨Parton states: procedures⟩+≡
  subroutine connected_state_get_beam_index (state, i_beam)
    class(connected_state_t), intent(in) :: state
    integer, dimension(:), intent(out) :: i_beam
    call state%expr%get_beam_index (i_beam)
  end subroutine connected_state_get_beam_index

  subroutine connected_state_get_in_index (state, i_in)
    class(connected_state_t), intent(in) :: state
    integer, dimension(:), intent(out) :: i_in
    call state%expr%get_in_index (i_in)
  end subroutine connected_state_get_in_index

```

Return the number of outgoing (hard) particles for the state.

```

⟨Parton states: parton state: TBP⟩+≡
  procedure :: get_n_out => parton_state_get_n_out

⟨Parton states: procedures⟩+≡
  function parton_state_get_n_out (state) result (n)
    class(parton_state_t), intent(in), target :: state
    integer :: n
    n = state%trace%get_n_out ()
  end function parton_state_get_n_out

```

## 29.3 Process Component Management

This module contains tools for managing and combining process components and matrix-element code and values, acting at a level below the actual process definition.

The types introduced here are abstract base types.

```

⟨pcm_base.f90⟩≡
  ⟨File header⟩

  module pcm_base

```

```

! use kinds
! use io_units
!Use strings

 $\langle$ Standard module head $\rangle$ 

 $\langle$ PCM base: public $\rangle$ 

 $\langle$ PCM base: types $\rangle$ 

 $\langle$ PCM base: interfaces $\rangle$ 

contains

 $\langle$ PCM base: procedures $\rangle$ 

end module pcm_base

```

### 29.3.1 Manager Configuration

This object may holds process and method-specific data, and it should allocate the corresponding manager instance.

```

 $\langle$ PCM base: public $\rangle$  $\equiv$ 
    public :: pcm_t

 $\langle$ PCM base: types $\rangle$  $\equiv$ 
    type, abstract :: pcm_t
    contains
         $\langle$ PCM base: pcm: TBP $\rangle$ 
    end type pcm_t

```

The factory method. We use the `inout` intent, so calling this again is an error.

```

 $\langle$ PCM base: pcm: TBP $\rangle$  $\equiv$ 
    procedure(pcm_allocate_instance), deferred :: allocate_instance

 $\langle$ PCM base: interfaces $\rangle$  $\equiv$ 
    abstract interface
        subroutine pcm_allocate_instance (pcm, instance)
            import
            class(pcm_t), intent(in) :: pcm
            class(pcm_instance_t), intent(inout), allocatable :: instance
        end subroutine pcm_allocate_instance
    end interface

```

### 29.3.2 Manager Instance

This object deals with the actual (squared) matrix element values.

```

 $\langle$ PCM base: public $\rangle$  $+\equiv$ 
    public :: pcm_instance_t

```

```

⟨PCM base: types⟩+=
  type, abstract :: pcm_instance_t
end type pcm_instance_t

```

## 29.4 Complete Elementary Processes

This module combines hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the **computed** state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the **observed** state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible subsequent decay processes on the parton level, which are full-fledged process objects themselves.

```

### 29.4.1 The Process Object

A process object is the workspace for creating process instances for event generation. After initialization, its contents are filled by integration passes which shape the integration grids and compute cross sections. Processes are set up initially from user-level configuration data. After calculating integrals and thus developing integration grid data, the program may use a process object or a copy of it for the purpose of generating events.

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The **type** determines whether we are considering a decay or a scattering process.

The **meta** object describes the process and its environment. All contents become fixed when the object is initialized.

The **config** object holds physical and technical configuration data that have been obtained during process initialization, and which are common to all process components.

The individual process components are configured in the **component** objects. These objects contain more configuration parameters and workspace, as needed for the specific process variant.

The **term** objects describe parton configurations which are technically used as phase-space points. Each process component may split into several terms with distinct kinematics and particle content. Furthermore, each term may project on a different physical state, e.g., by particle recombination. The **term** object provides the framework for this projection, for applying cuts, weight, and thus completing the process calculation.

The **beam\_config** object describes the incoming particles, either the decay mother or the scattering beams. It also contains the structure-function infor-

mation.

The `mci_entry` objects configure a MC input parameter set and integrator, each. The number of parameters depends on the process component and on the beam and structure-function setup.

The `pcm` component is the process-component manager. This polymorphic object manages and hides the details of dealing with NLO processes where several components have to be combined in a non-trivial way. It also acts as an abstract factory for the corresponding object in `process_instance`, which does the actual work for this matter.

```

<Processes: public>≡
    public :: process_t

<Processes: process type>≡
    type :: process_t
    private
    type(process_metadata_t) :: &
        meta
    type(process_config_data_t) :: &
        config
    type(process_counter_t) :: &
        counter
    type(process_component_t), dimension(:), allocatable :: &
        component
    type(process_term_t), dimension(:), allocatable :: &
        term
    type(process_beam_config_t) :: &
        beam_config
    type(process_mci_entry_t), dimension(:), allocatable :: &
        mci_entry
    class(pcm_t), allocatable :: &
        pcm
    contains
    <Processes: process: TBP>
    end type process_t

```

This procedure is an important debugging and inspection tool; it is not used during normal operation. The process object is written to a file (identified by unit, which may also be standard output). Optional flags determine whether we show everything or just the interesting parts.

```

<Processes: process: TBP>≡
    procedure :: write => process_write

```

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam.data.t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by extending the code in the `beams` module.

```

We complete the kinematics configuration after the beam setup, but before we configure the chain of structure functions. The reason is that we need the total energy `sqrts` for the kinematics, but the structure-function setup requires the number of channels, which depends on the kinematics configuration. For instance, the kinematics module may return the need for parameterizing an s-channel resonance.

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

    allocate (process%config%ef_weight, source = ef_weight)
  end subroutine process_set_weight

```

## MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

```

<Processes: process: TBP>+≡
  procedure :: compute_md5sum => process_compute_md5sum

<Processes: procedures>+≡
  subroutine process_compute_md5sum (process)
    class(process_t), intent(inout) :: process
    integer :: i
    call process%config%compute_md5sum ()
    do i = 1, process%config%n_components
      associate (component => process%component(i))
        if (component%active) then
          call component%compute_md5sum ()
        end if
      end associate
    end do
    call process%beam_config%compute_md5sum ()
    do i = 1, process%config%n_mci
      call process%mci_entry(i)%compute_md5sum &
        (process%config, process%component, process%beam_config)
    end do
  end subroutine process_compute_md5sum

```

## Integration and event generation

The sampler test should just evaluate the squared matrix element `n_calls` times, discarding the results, and return. This can be done before integration, e.g., for timing estimates.

```

<Processes: process: TBP>+≡
  procedure :: sampler_test => process_sampler_test

<Processes: procedures>+≡
  subroutine process_sampler_test (process, instance, i_mci, n_calls)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout), target :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_calls
    call process%mci_entry(i_mci)%sampler_test (instance, n_calls)
  end subroutine process_sampler_test

```

Integrate the process, using a previously initialized process instance. We select one of the available MCI integrators by its index `i_mci` and thus integrate over (structure functions and) phase space for the associated (group of) process component(s).

The finalizer should be called after all integration passes have been completed. It will, for instance, write a summary of the integration results.

`integrate_dummy` does a “dummy” integration in the sense that nothing is done but just empty integration results appended.

```

<Processes: process: TBP>+≡
  procedure :: integrate => process_integrate
  procedure :: final_integration => process_final_integration

```

```

procedure :: integrate_dummy => process_integrate_dummy
<Processes: procedures>+≡
  subroutine process_integrate (process, instance, i_mci, n_it, n_calls, &
    adapt_grids, adapt_weights, final, pacify)
    class(process_t), intent(inout) :: process

```

Prepare event generation for the specified MCI entry. This implies, in particular, checking the phase-space file.

```

<Processes: process: TBP>+≡
    procedure :: prepare_simulation => process_prepare_simulation

<Processes: procedures>+≡
    subroutine process_prepare_simulation (process, i_mci)
        class(process_t), intent(inout) :: process
        integer, intent(in) :: i_mci
        call process%mci_entry(i_mci)%prepare_simulation ()
    end subroutine process_prepare_simulation

```

Generate a weighted event. We select one of the available MCI integrators by its index `i_mci` and thus generate an event for the associated (group of) process component(s). The arguments exactly correspond to the initializer and finalizer above.

The resulting event is stored in the `process_instance` object, which also holds the workspace of the integrator.

Note: The `process` object is declared `intent(inout)` because it contains the random-number state, which changes for each event. Otherwise, all volatile data are inside the `instance` object.

```

(Processes: process: TBP)+≡
  procedure :: generate_weighted_event => process_generate_weighted_event
  procedure :: generate_unweighted_event => process_generate_unweighted_event

(Processes: procedures)+≡
  subroutine process_generate_weighted_event (process, instance, i_mci)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%generate_weighted_event (instance)
  end subroutine process_generate_weighted_event

  subroutine process_generate_unweighted_event (process, instance, i_mci)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    call process%mci_entry(i_mci)%generate_unweighted_event (instance)
  end subroutine process_generate_unweighted_event

```

This replaces the event generation methods for the situation that the process instance object has been filled by other means (i.e., reading and/or recalculating its contents). We just have to fill in missing MCI data, especially the event weight.

```

(Processes: process: TBP)+≡
  procedure :: recover_event => process_recover_event

    class(process_t), intent(in) :: process
    character(32) :: md5sum
    md5sum = process%config%md5sum
  end function process_get_md5sum_cfg

```

## 29.4.2 Metadata

This information describes the process and its environment. It is fixed upon initialization.

The `id` string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The `num_id` is meaningful if nonzero. It is used for communication with external programs or file standards which do not support string IDs.

The `run_id` string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The `var_list` is a snapshot of the variable list, taken at the point where the process was initialized.

The `lib` pointer accesses the process library where the process definition and the process driver are located.

The `lib_index` is the index of entry in the process library that corresponds to the current process.

The `component_id` array identifies the individual process components.

The `component_description` is an array of human-readable strings that characterize the process components, for instance `a, b => c, d`.

The `active` mask array marks those components which are active. The others are skipped.

```

### 29.4.3 Generic Configuration Data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the variable list.

The number `n_in` is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number `n_components` is the number of components that constitute the current process.

The number `n_terms` is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number `n_mci` is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The `model` pointer identifies the physics model and its parameters. This is a pointer to an external object.

The `rng_factory` component spawns independent random-number generators for use in integration, event generation, and event postprocessing.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the `effective_state` subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The `md5sum` is taken and used to verify the process configuration when re-reading data from file.

```

<Processes: process part types>+=
  type :: process_config_data_t
    private
      integer :: n_in = 0
      integer :: n_components = 0
      integer :: n_terms = 0

    write (u, "(3x,A,A,A)") "MD5 sum (config) = ', config%md5sum, '"
end if
end if
end subroutine process_config_data_write

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

The model that we import here should be an instance of the global model. If we create the instance outside, we can make it an extension of the basic `model_data_t`. This will allow us to synchronize the variable list with the model. Using a pointer instead of an allocatable, we can guarantee the `target` attribute.

The RNG factory object is imported by moving the allocation.

```

<Processes: process config data: TBP>+≡
    procedure :: init => process_config_data_init

<Processes: procedures>+≡
    subroutine process_config_data_init &
        (config, meta, os_data, qcd, rng_factory, model)
    class(process_config_data_t), intent(out) :: config
    type(process_metadata_t), intent(in) :: meta
    type(os_data_t), intent(in) :: os_data
    type(qcd_t), intent(in) :: qcd
    class(rng_factory_t), intent(inout), allocatable :: rng_factory
    class(model_data_t), intent(inout), pointer :: model
    config%n_in = meta%lib%get_n_in (meta%id)
    config%n_components = size (meta%component_id)
    config%os_data = os_data
    config%qcd = qcd
    call move_alloc (from = rng_factory, to = config%rng_factory)
    config%model_name = model%get_name ()
    config%model => model
    model => null ()
end subroutine process_config_data_init

```

Since the captured model is a separate object allocated via a pointer, we need a finalizer.

```

```

#### 29.4.4 Beam configuration

The object **data** holds all details about the initial beam configuration. The allocatable array **sf** holds the structure-function configuration blocks. There are **n\_strfun** entries in the structure-function chain (not counting the initial beam object). We maintain **n\_channel** independent parameterizations of this chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is **n\_sfpar**.

The flag **azimuthal\_dependence** tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag **lab\_is\_cm\_frame** is obvious.

```

<Processes: process part types>+≡

```

```

type :: process_beam_config_t
  private

end subroutine process_counter_record

```

### 29.4.5 Multi-channel integration

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly the values that apply to the current pass. Previous values are archived in the `results` object.

The `counter` receives the counter statistics from the associated process instance, for diagnostics.

The `results` object records results, broken down in passes and iterations.

```

end subroutine process_mci_entry_write_chain_weights

```

Initialize. From the existing configuration, we obtain the number of channels and the number of parameters, separately for the structure-function chain and for the associated process component. We assume that the phase-space object has already been configured.

The allocation of the MCI integrator with the appropriate concrete type is the duty of the process core.

We assume that there is only one component associated with a MCI entry. This restriction should be relaxed.

end subroutine process_mci_entry_sampler_test

```

Integrate. The instance should be initialized.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

Generate an event. The instance should be initialized, otherwise event generation is directed by the mci integrator subobject. The integrator instance is contained in a mci\_work subobject of the process instance, which simultaneously serves as the sampler object. (We avoid the anti-aliasing rules if we assume that the sampling itself does not involve the integrator instance contained in the process instance.)

Regarding weighted events, we only take events which are valid, which means that they have valid kinematics and have passed cuts. Therefore, we have a rejection loop. For unweighted events, the unweighting routine should already take care of this.

```

### 29.4.6 Process Components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components can have different types. In short, `process_component_t` is a wrapper for the actual process variants.

If the `active` flag is false, we should skip this component. This happens if the associated process has vanishing matrix element.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

<Processes: process part types>+≡
  type :: process_component_t
    private
    type(process_component_def_t), pointer :: config => null ()
    integer :: index = 0
    class(prc_core_t), allocatable :: core
    class(prc_core_t), pointer :: core_sub_born
    logical :: active = .false.
    class(mci_t), allocatable :: mci_template
    integer, dimension(:), allocatable :: i_term
    integer :: i_mci = 0
    class(phs_config_t), allocatable :: phs_config

### 29.4.7 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`. In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`. This is the total number of independent entries in the density matrix. For each combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

This type is public only for use in a unit test.

```

<Processes: public>+≡
  public :: process_term_t

<Processes: process part types>+≡
  type :: process_term_t
    integer :: i_term_global = 0
    integer :: i_component = 0
    integer :: i_term = 0

```

```

integer :: n_allowed = 0

```

Write an account of all quantum number states and their current status.

```

<Processes: process term: TBP>+≡
  procedure :: write_state_summary => process_term_write_state_summary
<Processes: procedures>+≡
  subroutine process_term_write_state_summary (term, core, unit)
    class(process_term_t), intent(in) :: term
    class(prc_core_t), intent(in) :: core
    integer, intent(in), optional :: unit
    integer :: u, i, f, h, c
    type(state_iterator_t) :: it
    character :: sgn

```

```

u = given_output_unit (unit)
write (u, "(1x,A,I0)") "Term #", term%i_term_global
call it%init (term%int%get_state_matrix_ptr ())
do while (it%is_valid ())
  i = it%get_me_index ()
  f = term%flv(i)
  h = term%hel(i)
  c = term%col(i)
  if (core%is_allowed (term%i_term, f, h, c)) then
    sgn = "+"
  else
    sgn = " "
  end if
  write (u, "(1x,A1,1x,I0,2x)", advance="no") sgn, i
  call quantum_numbers_write (it%get_quantum_numbers (), u)
  write (u, *)
  call it%advance ()
end do
end subroutine process_term_write_state_summary

```

Finalizer: the `int` and potentially `int.eff` components have a finalizer that we must call.

```

<Processes: process term: TBP>+=
  procedure :: final => process_term_final

<Processes: procedures>+=
  subroutine process_term_final (term)
    class(process_term_t), intent(inout) :: term
    call term%int%final ()
    if (term%rearrange) then
      call term%int_eff%final ()
      deallocate (term%int_eff)
    end if
  end subroutine process_term_final

```

Initialize the term. We copy the process constants from the `core` object and set up the `int` hard interaction accordingly.

The `alpha_s` value is useful for writing external event records. This is the constant value which may be overridden by a event-specific running value. If the model does not contain the strong coupling, the value is zero.

The `rearrange` part is commented out; this or something equivalent could become relevant for NLO algorithms.

```

<Processes: process term: TBP>+=
  procedure :: init => process_term_init

<Processes: procedures>+=
  subroutine process_term_init &
    (term, i_term_global, i_component, i_term, core, model)
    class(process_term_t), intent(inout), target :: term
    integer, intent(in) :: i_term_global
    integer, intent(in) :: i_component
    integer, intent(in) :: i_term
    class(prc_core_t), intent(in) :: core

```

```

class(model_data_t), intent(in), target :: model
class(modelpar_data_t), pointer :: alpha_s_ptr

!       term%alpha_s = var_list%get_rval (var_list, var_str ("alphas"))
!   else
!       term%alpha_s = -1
!   end if
alpha_s_ptr => model%get_par_data_ptr (var_str ("alphas"))
if (associated (alpha_s_ptr)) then
    term%alpha_s = alpha_s_ptr%get_real ()
else
    term%alpha_s = -1
end if

call term%setup_interaction (core, model)
!   if (term%rearrange) then
!       call term%setup_effective_interaction (core, term%int, term%int_eff)
!   end if
end subroutine process_term_init

```

We fetch the process constants which determine the quantum numbers and use those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

```

### 29.4.9 Default Iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

<Processes: process: TBP>+≡

#### 29.4.10 Constant process data

The following methods return basic process data that stay constant after initialization.

The process and IDs.

```

<Processes: process: TBP>+=
  procedure :: get_id => process_get_id
  procedure :: get_num_id => process_get_num_id
  procedure :: get_run_id => process_get_run_id
  procedure :: get_library_name => process_get_library_name

<Processes: procedures>+=
  function process_get_id (process) result (id)
    class(process_t), intent(in) :: process
    type(string_t) :: id
    id = process%meta%id
  end function process_get_id

  function process_get_num_id (process) result (id)
    class(process_t), intent(in) :: process
    integer :: id
    id = process%meta%num_id
  end function process_get_num_id

  function process_get_run_id (process) result (id)
    class(process_t), intent(in) :: process
    type(string_t) :: id
    id = process%meta%run_id
  end function process_get_run_id

  function process_get_library_name (process) result (id)
    class(process_t), intent(in) :: process
    type(string_t) :: id
    id = process%meta%lib%get_name ()
  end function process_get_library_name

```

The number of incoming particles.

```

<Processes: process: TBP>+=
  procedure :: get_n_in => process_get_n_in

<Processes: procedures>+=
  function process_get_n_in (process) result (n)
    class(process_t), intent(in) :: process
    integer :: n
    n = process%config%n_in
  end function process_get_n_in

```

The number of MCI data sets.

```

<Processes: process: TBP>+=
  procedure :: get_n_mci => process_get_n_mci

<Processes: procedures>+=
  function process_get_n_mci (process) result (n)
    class(process_t), intent(in) :: process
    integer :: n
    n = process%config%n_mci
  end function process_get_n_mci

```

The number of process components, total.

```
<Processes: process: TBP>+≡
  procedure :: get_n_components => process_get_n_components

<Processes: procedures>+≡
  function process_get_n_components (process) result (n)
    class(process_t), intent(in) :: process
    integer :: n
    n = process%meta%n_components
  end function process_get_n_components
```

The number of process terms, total.

```
<Processes: process: TBP>+≡
  procedure :: get_n_terms => process_get_n_terms

<Processes: procedures>+≡
  function process_get_n_terms (process) result (n)
    class(process_t), intent(in) :: process
    integer :: n
    n = process%config%n_terms
  end function process_get_n_terms
```

Return the indices of the components that belong to a specific MCI entry.

```
<Processes: process: TBP>+≡
  procedure :: get_i_component => process_get_i_component

<Processes: procedures>+≡
  subroutine process_get_i_component (process, i_mci, i_component)
    class(process_t), intent(in) :: process
    integer, intent(in) :: i_mci
    integer, dimension(:), intent(out), allocatable :: i_component
    associate (mci_entry => process%mci_entry(i_mci))
      allocate (i_component (size (mci_entry%i_component)))
      i_component = mci_entry%i_component
    end associate
  end subroutine process_get_i_component
```

Return the ID of a specific component.

```
<Processes: process: TBP>+≡
  procedure :: get_component_id => process_get_component_id

<Processes: procedures>+≡
  function process_get_component_id (process, i_component) result (id)
    class(process_t), intent(in) :: process
    integer, intent(in) :: i_component
    type(string_t) :: id
    id = process%meta%component_id(i_component)
  end function process_get_component_id
```

Return a pointer to the definition of a specific component.

```
<Processes: process: TBP>+≡
  procedure :: get_component_def_ptr => process_get_component_def_ptr
```

```

<Processes: procedures>+≡
function process_get_component_def_ptr (process, i_component) result (ptr)
  class(process_t), intent(in) :: process
  integer, intent(in) :: i_component
  type(process_component_def_t), pointer :: ptr
  ptr => process%meta%lib%get_component_def_ptr (process%meta%id, i_component)
end function process_get_component_def_ptr

```

These procedures extract and restore (by transferring the allocation) the process core. This is useful for changing process parameters from outside this module.

```

<Processes: process: TBP>+≡
  procedure :: extract_component_core => process_extract_component_core
  procedure :: restore_component_core => process_restore_component_core

<Processes: procedures>+≡
  subroutine process_extract_component_core (process, i_component, core)

    end if
  end subroutine process_make_rng

```

### 29.4.11 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```

<Processes: process: TBP>+=
  procedure :: compute_amplitude => process_compute_amplitude

<Processes: procedures>+=
  function process_compute_amplitude &
    (process, i, j, p, f, h, c, fac_scale, ren_scale, alpha_qcd_forced) &
    result (amp)
    class(process_t), intent(in) :: process

    integer, intent(in) :: n
    call process%beam_config%allocate_sf_channels (n)
  end subroutine test_allocate_sf_channels

  subroutine test_set_component_sf_channel (process, c)
    class(process_t), intent(inout) :: process
    integer, dimension(:), intent(in) :: c
    call process%component(1)%phs_config%set_sf_channel (c)
  end subroutine test_set_component_sf_channel

  subroutine test_get_mci_ptr (process, mci)
    class(process_t), intent(in), target :: process
    class(mci_t), intent(out), pointer :: mci
    mci => process%mci_entry(1)%mci
  end subroutine test_get_mci_ptr

```

### Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

**sf\_chain** is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

**phs** is an instance of the phase space for the elementary process.

The array **f** contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either **sf\_chain** or **phs** are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component ('owned' by the object) or as a pointer.

```

<Processes: types>+≡
  type :: kinematics_t
    integer :: n_in = 0
    integer :: n_channel = 0
    integer :: selected_channel = 0
    type(sf_chain_instance_t), pointer :: sf_chain => null ()

end do
end subroutine kinematics_compute_other_channels

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

```

(Processes: kinematics: TBP)+≡
  procedure :: get_incoming_momenta => kinematics_get_incoming_momenta

(Processes: procedures)+≡
  subroutine kinematics_get_incoming_momenta (k, p)
    class(kinematics_t), intent(in) :: k

```

## Process component instance

The actual calculation of a sampling point is done from here.

The `config` pointer accesses the corresponding configuration in the `process` object.

The `active` flag indicates that we are currently computing this component, together with all other components that share the same MC parameter set. Inactive components are using a different MC parameter set and are not in use for this sampling point.

The `k_seed` subobject contains the kinematics (structure-function chain, phase space, etc.) that implements the ‘seed’ configuration of momenta. This version of the process kinematics is accessed by the MCI setup.

`p_seed` is the array of momenta that we compute from the MC input parameters, via the `k_seed` subobject. Depending on the process variant, these may or may not coincide with the momenta that enter the process terms associated to this component.

The `core_state` object can be used for storing intermediate results. Its precise type and contents depend on the process variant.

```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

```

## Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The `k_term` object is the instance of the kinematics setup (structure-function chain, phase space, etc.) that applies specifically to this term. In ordinary cases, it consists of straight pointers to the seed kinematics.

The `amp` array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The `int_hard` interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The `isolated` object holds the effective parton state for the elementary interaction. The amplitude entries are computed from `int_hard`.

The `connected` evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The `checked` flag is set once we have applied cuts on this term. The result of this is stored in the `passed` flag. Once the term has passed cuts, we calculate the various scale and weight expressions.

```

        end select
    end subroutine term_instance_final

```

For initialization, we make use of defined assignment for the `interaction_t` type. This creates a deep copy.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create mod-

ified copies (**rearrange**) as effective structure-function chain and interaction, respectively.

Finally, we set up the **subevt** component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

The **rearrange** parts are still commented out; they could become relevant for a NLO algorithm.

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain. (If we have an algorithm that uses rearrangement, it should evaluate `k_term` explicitly.)

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

        term%fac_scale = fac_scale
    end subroutine term_instance_set_fac_scale

```

Return data that might be useful for external processing. The factorization scale:

```

<Processes: term instance: TBP>+≡
    procedure :: get_fac_scale => term_instance_get_fac_scale

<Processes: procedures>+≡
    function term_instance_get_fac_scale (term) result (fac_scale)
        class(term_instance_t), intent(in) :: term
        real(default) :: fac_scale
        fac_scale = term%fac_scale
    end function term_instance_get_fac_scale

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

<Processes: term instance: TBP>+≡
    procedure :: get_alpha_s => term_instance_get_alpha_s

<Processes: procedures>+≡
    function term_instance_get_alpha_s (term, component) result (alpha_s)

    end function term_instance_get_alpha_s

```

## MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

```
<Processes: types>+≡
  type :: mci_work_t
    type(process_mci_entry_t), pointer :: config => null ()
    real(default), dimension(:), allocatable :: x
    class(mci_instance_t), pointer :: mci => null ()
    type(process_counter_t) :: counter
  contains
    <Processes: mci work: TBP>
  end type mci_work_t
```

First write configuration data, then the current values.

```
<Processes: mci work: TBP>≡
  procedure :: write => mci_work_write

<Processes: procedures>+≡
  subroutine mci_work_write (mci_work, unit, testflag)
    class(mci_work_t), intent(in) :: mci_work
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A,I0,A)") "Active MCI instance #", &
      mci_work%config%i_mci, " ="
    write (u, "(2x)", advance="no")
    do i = 1, mci_work%config%n_par
      write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
      if (i == mci_work%config%n_par_sf) &
        write (u, "(1x,'|')", advance="no")
    end do
    write (u, *)
    if (associated (mci_work%mci)) then
      call mci_work%mci%write (u, pacify = testflag)
      call mci_work%counter%write (u)
    end if
  end subroutine mci_work_write
```

The `mci` component may require finalization.

```
<Processes: mci work: TBP>+≡
  procedure :: final => mci_work_final

<Processes: procedures>+≡
  subroutine mci_work_final (mci_work)
    class(mci_work_t), intent(inout) :: mci_work
    if (associated (mci_work%mci)) then
      call mci_work%mci%final ()
      deallocate (mci_work%mci)
    end if
  end subroutine mci_work_final
```

Initialize with the maximum length that we will need. Contents are not initialized.

The integrator inside the `mci_entry` object is responsible for allocating and initializing its own instance, which is referred to by a pointer in the `mci_work` object.

```

(Processes: mci work: TBP)+≡
  procedure :: init => mci_work_init

(Processes: procedures)+≡
  subroutine mci_work_init (mci_work, mci_entry)
    class(mci_work_t), intent(out) :: mci_work

    counter = mci_work%counter
  end function mci_work_get_counter

```

### The process instance

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `count` object records process evaluations, broken down according to status.

The `sqme` value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The `weight` value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the `sqme` value times Jacobian weights from the integration, or unity, respectively.

The `i_mci` index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The `sf_chain` subobject is a realization of the beam and structure-function configuration in the `process` object. It is not used for calculation directly

but serves as the template for the sf-chain instances that are contained in the component objects.

The `component` subobjects determine the state of each component.

The `term` subobjects are workspace for evaluating kinematics, matrix elements, cuts etc.

The `mci_work` subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the `mci_work` array is selected by the `i_mci` index above.

```

<Processes: public>+≡
    public :: process_instance_t

<Processes: types>+≡
    type, extends (mci_sampler_t) :: process_instance_t
        type(process_t), pointer :: process => null ()
        integer :: evaluation_status = STAT_UNDEFINED
        real(default) :: sqme = 0
        real(default), dimension(:,:), allocatable :: sqme_real
        real(default) :: weight = 0

```

Initialization connects the instance with a process. All initial information is transferred from the process object. The process object contains templates for the interaction subobjects (beam and term), but no evaluators. The initialization routine creates evaluators for the matrix element trace, other evaluators are left untouched.

The **instance** object must have the **target** attribute (also in any caller) since the initialization routine assigns various pointers to subobject of **instance**.

Subroutine of the initialization above: initialize the beam and structure-function chain template. We establish pointers to the configuration data, so `beam_config` must have a `target` attribute.

The resulting chain is not used directly for calculation. It will acquire instances which are stored in the process-component instance objects.

```

<Processes: process instance: TBP>+≡
    procedure :: setup_sf_chain => process_instance_setup_sf_chain

<Processes: procedures>+≡
    subroutine process_instance_setup_sf_chain (instance, config)

            call instance%sf_chain%setup_tracing (config%sf_trace_file)
        end if
    end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and

the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

<Processes: process instance: TBP>+≡
  procedure :: setup_event_data => process_instance_setup_event_data

<Processes: procedures>+≡
  subroutine process_instance_setup_event_data (instance, model)

    end do
  end subroutine process_instance_setup_event_data

```

Choose a MC parameter set and the corresponding integrator. The choice persists beyond calls of the `reset` method above. This method is automatically called here.

```

<Processes: process instance: TBP>+≡
  procedure :: choose_mci => process_instance_choose_mci

<Processes: procedures>+≡
  subroutine process_instance_choose_mci (instance, i_mci)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    instance%i_mci = i_mci
    call instance%reset ()
  end subroutine process_instance_choose_mci

```

Explicitly set a MC parameter set. Works only if we are in initial state. We assume that the length of the parameter set is correct.

After setting the parameters, activate the components and terms that correspond to the chosen MC parameter set.

```

<Processes: process instance: TBP>+≡
  procedure :: set_mcpair => process_instance_set_mcpair

```

```

<Processes: procedures>+≡
  subroutine process_instance_set_mcpair (instance, x)
    class(process_instance_t), intent(inout) :: instance
    real(default), dimension(:), intent(in) :: x
    if (instance%evaluation_status == STAT_INITIAL) then
      associate (mci_work => instance%mci_work(instance%i_mci))
        call mci_work%set (x)
      end associate
      call instance%activate ()
    end if
  end subroutine process_instance_set_mcpair

```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The sf-chain instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```

<Processes: process instance: TBP>+≡
  procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

<Processes: procedures>+≡
  subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%receive_beam_momenta ()
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_receive_beam_momenta

```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```

<Processes: process instance: TBP>+≡
  procedure :: set_beam_momenta => process_instance_set_beam_momenta

<Processes: procedures>+≡
  subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%set_beam_momenta (p)
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_set_beam_momenta

```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```

<Processes: process instance: TBP>+≡
  procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

```

```

<Processes: procedures>+≡
subroutine process_instance_recover_beam_momenta (instance, i_term)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_term
  integer :: i
  if (.not. instance%process%beam_config%lab_is_cm_frame) then
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then

      associate (i_component => instance%term(i_term)%config%i_component)
        call instance%component(i_component)% &
          recover_seed_kinematics (instance%term(i_term))
      end associate
    end if
  end subroutine process_instance_recover_seed_kinematics

```

Third step of process evaluation: compute the effective momentum configurations, for all active terms, from the hard kinematics.

```

<Processes: process instance: TBP>+≡
  procedure :: compute_eff_kinematics => &
    process_instance_compute_eff_kinematics

<Processes: procedures>+≡
  subroutine process_instance_compute_eff_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: i
    if (instance%evaluation_status >= STAT_HARD_KINEMATICS) then
      do i = 1, size (instance%term)
        if (present (skip_term)) then
          if (i == skip_term) cycle
        end if

```

```

        if (instance%term(i)%active) then
            call instance%term(i)% &
                compute_eff_kinematics (instance%component)
        end if
    end do
    instance%evaluation_status = STAT_EFF_KINEMATICS
end if
end subroutine process_instance_compute_eff_kinematics

```

Inverse: recover the hard kinematics from effective kinematics for one term, then compute effective kinematics for the other terms.

*(Processes: process instance: TBP)+≡*

```

    procedure :: recover_hard_kinematics => &
        process_instance_recover_hard_kinematics

```

*(Processes: procedures)+≡*

```

    subroutine process_instance_recover_hard_kinematics (instance, i_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_term
        integer :: i
        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
            call instance%term(i_term)%recover_hard_kinematics (instance%component)
            do i = 1, size (instance%term)
                if (i /= i_term) then
                    if (instance%term(i)%active) then
                        call instance%term(i)% &
                            compute_eff_kinematics (instance%component)
                    end if
                end if
            end do
            instance%evaluation_status = STAT_EFF_KINEMATICS
        end if
    end subroutine process_instance_recover_hard_kinematics

```

Fourth step of process evaluation: check cuts for all terms. Where successful, compute any scales and weights. Otherwise, deactivate the term. If any of the terms has passed, set the state to STAT\_PASSED\_CUTS.

The argument `scale_forced`, if present, will override the scale calculation in the term expressions.

*(Processes: process instance: TBP)+≡*

```

    procedure :: evaluate_expressions => &
        process_instance_evaluate_expressions

```

*(Processes: procedures)+≡*

```

    subroutine process_instance_evaluate_expressions (instance, scale_forced)
        class(process_instance_t), intent(inout) :: instance
        real(default), intent(in), allocatable, optional :: scale_forced
        integer :: i
        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
            do i = 1, size (instance%term)
                if (instance%term(i)%active) then
                    call instance%term(i)%evaluate_expressions (scale_forced)
                end if
            end do
        end if
    end subroutine process_instance_evaluate_expressions

```

```

    end do
    if (any (instance%term%passed)) then
        instance%evaluation_status = STAT_PASSED_CUTS
    else
        instance%evaluation_status = STAT_FAILED_CUTS
    end if
end if
end subroutine process_instance_evaluate_expressions

```

Fifth step of process evaluation: fill the parameters for the non-selected channels, that have not been used for seeding. We should do this after evaluating cuts, since we may save some expensive calculations if the phase space point fails the cuts.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Processes: process instance: TBP>+≡
    procedure :: compute_other_channels => &
        process_instance_compute_other_channels

<Processes: procedures>+≡
    subroutine process_instance_compute_other_channels (instance, skip_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in), optional :: skip_term
        integer :: channel, skip_component, i
        channel = instance%selected_channel
        if (channel == 0) then
            call msg_bug ("Compute other channels: undefined integration channel")
        end if
        if (present (skip_term)) then
            skip_component = instance%term(skip_term)%config%i_component
        else
            skip_component = 0
        end if
        if (instance%evaluation_status >= STAT_PASSED_CUTS) then
            do i = 1, size (instance%component)
                if (i == skip_component) cycle
                if (instance%component(i)%active) then
                    call instance%component(i)%compute_other_channels &
                        (instance%mci_work(instance%i_mci), channel)
                end if
            end do
        end if
    end subroutine process_instance_compute_other_channels

```

Sixth step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

```

<Processes: process instance: TBP>+≡
    procedure :: evaluate_trace => process_instance_evaluate_trace

<Processes: procedures>+≡
    subroutine process_instance_evaluate_trace (instance)

```

```

class(process_instance_t), intent(inout) :: instance

        end select
    else
      ! failed kinematics, failed cuts: set sqme to zero
      instance%sqme = 0
    end if
  end if
end subroutine process_instance_evaluate_trace

```

Final step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

If `weight` is provided, we already know the kinematical event weight (the MCI weight which depends on the kinematics sampling algorithm, but not on the matrix element), so we do not need to take it from the MCI record.

```

(Processes: process instance: TBP)+≡
  procedure :: evaluate_event_data => process_instance_evaluate_event_data

(Processes: procedures)+≡
  subroutine process_instance_evaluate_event_data (instance, weight)
    class(process_instance_t), intent(inout) :: instance
    real(default), intent(in), optional :: weight
    integer :: i
    if (instance%evaluation_status >= STAT_EVALUATED_TRACE) then
      do i = 1, size (instance%term)
        associate (term => instance%term(i))
          if (term%active .and. term%passed) then
            call term%evaluate_event_data ()
          end if
        end associate
      end do
      if (present (weight)) then
        instance%weight = weight
      else
        instance%weight = &
          instance%mci_work(instance%i_mci)%mci%get_event_weight ()
        instance%excess = &
          instance%mci_work(instance%i_mci)%mci%get_event_excess ()
      end if

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

    call instance%compute_seed_kinematics (i_term)
    call instance%compute_hard_kinematics (i_term)
    call instance%compute_eff_kinematics (i_term)
    call instance%compute_other_channels (i_term)
    call instance%evaluate_expressions (scale_forced)
    if (update_sqme) call instance%evaluate_trace ()
  end subroutine process_instance_recover

```

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the  $x$  array, and the  $f$  Jacobian array are exposed by the `sampler_t` object.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate => process_instance_evaluate

<Processes: procedures>+≡
  subroutine process_instance_evaluate (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call sampler%evaluate_sqme (c, x_in)
    if (sampler%is_valid ()) call sampler%fetch (val, x, f)
    call sampler%record_call ()
  end subroutine process_instance_evaluate

```

The phase-space point is valid if the event has valid kinematics and has passed the cuts.

```

<Processes: process instance: TBP>+≡
  procedure :: is_valid => process_instance_is_valid

```

```

<Processes: procedures>+≡
function process_instance_is_valid (sampler) result (valid)
  class(process_instance_t), intent(in) :: sampler
  logical :: valid
  valid = sampler%evaluation_status >= STAT_PASSED_CUTS
end function process_instance_is_valid

```

The `rebuild` method should rebuild the kinematics section out of the `x_in` parameter set. The integrand value `val` should not be computed, but is provided as input.

```

<Processes: process instance: TBP>+≡
  procedure :: rebuild => process_instance_rebuild

<Processes: procedures>+≡
  subroutine process_instance_rebuild (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(in) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call msg_bug ("process_instance_rebuild not implemented yet")
    x = 0
    f = 0
  end subroutine process_instance_rebuild

```

This is another method required by the `sampler_t` base type: fetch the data that are relevant for the MCI record.

```

<Processes: process instance: TBP>+≡
  procedure :: fetch => process_instance_fetch

<Processes: procedures>+≡
  subroutine process_instance_fetch (sampler, val, x, f)
    class(process_instance_t), intent(in) :: sampler
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    integer :: i, cc
    integer :: n_channel
    val = 0
    FIND_COMPONENT: do i = 1, size (sampler%component)
      associate (component => sampler%component(i))
        if (component%active) then
          associate (k => component%k_seed)
            n_channel = k%n_channel
            do cc = 1, n_channel
              call k%get_mcpair (cc, x(:,cc))
            end do
            f = k%f
            val = sampler%sqme * k%phs_factor
          end associate
        end if
      exit FIND_COMPONENT
    end associate
  end subroutine process_instance_fetch

```

```

        end do FIND_COMPONENT
    end subroutine process_instance_fetch

```

Initialize and finalize event generation for the specified MCI entry.

```

<Processes: process instance: TBP>+≡
    procedure :: init_simulation => process_instance_init_simulation
    procedure :: final_simulation => process_instance_final_simulation

<Processes: procedures>+≡
    subroutine process_instance_init_simulation (instance, i_mci, safety_factor)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci
        real(default), intent(in), optional :: safety_factor
        call instance%mci_work(i_mci)%init_simulation (safety_factor)
    end subroutine process_instance_init_simulation

    subroutine process_instance_final_simulation (instance, i_mci)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci
        call instance%mci_work(i_mci)%final_simulation ()
    end subroutine process_instance_final_simulation

```

### 29.4.13 Accessing the process instance

Once the seed kinematics is complete, we can retrieve the MC input parameters for all channels, not just the seed channel.

Note: We choose the first active component. This makes sense only if the seed kinematics is identical for all active components.

```

<Processes: process instance: TBP>+≡
    procedure :: get_mcpair => process_instance_get_mcpair

<Processes: procedures>+≡
    subroutine process_instance_get_mcpair (instance, channel, x)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
        real(default), dimension(:), intent(out) :: x
        integer :: i
        if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
            do i = 1, size (instance%component)
                if (instance%component(i)%active) then
                    call instance%component(i)%k_seed%get_mcpair (channel, x)
                    return
                end if
            end do
            call msg_bug ("Process instance: get_mcpair: no active channels")
        else
            call msg_bug ("Process instance: get_mcpair: no seed kinematics")
        end if
    end subroutine process_instance_get_mcpair

```

Return true if the `sqme` value is known. This also implies that the event is kinematically valid and has passed all cuts.

```

(Processes: process instance: TBP)+≡
  procedure :: has_evaluated_trace => process_instance_has_evaluated_trace

(Processes: procedures)+≡
  function process_instance_has_evaluated_trace (instance) result (flag)
    class(process_instance_t), intent(in) :: instance
    logical :: flag
    flag = instance%evaluation_status >= STAT_EVALUATED_TRACE
  end function process_instance_has_evaluated_trace

```

Return true if the event is complete. In particular, the event must be kinematically valid, passed all cuts, and the event data have been computed.

```

(Processes: process instance: TBP)+≡
  procedure :: is_complete_event => process_instance_is_complete_event

(Processes: procedures)+≡
  function process_instance_is_complete_event (instance) result (flag)
    class(process_instance_t), intent(in) :: instance
    logical :: flag
    flag = instance%evaluation_status >= STAT_EVENT_COMPLETE
  end function process_instance_is_complete_event

```

Select a term for the process instance which is to provide the event record.

Note: this should be done using random numbers and applying probabilities for the various terms and components that belong to the selected MCI group. The current implementation simply selects the first term for the first active component.

```

(Processes: process instance: TBP)+≡
  procedure :: select_i_term => process_instance_select_i_term

```

#### 29.4.14 NLO Stuff

[This should eventually be moved to a separate module.]

The NLO-aware version of the process-component manager.

This is the configuration object, which has the duty of allocating the corresponding instance. This is the nontrivial NLO version.

```

<Processes: types>+≡
  type, extends (pcm_t) :: pcm_nlo_t
  contains
    <Processes: pcm nlo: TBP>
  end type pcm_nlo_t

<Processes: pcm nlo: TBP>≡
  procedure :: allocate_instance => pcm_nlo_allocate_instance

<Processes: procedures>+≡
  subroutine pcm_nlo_allocate_instance (pcm, instance)
    class(pcm_nlo_t), intent(in) :: pcm
    class(pcm_instance_t), intent(inout), allocatable :: instance
    allocate (pcm_instance_nlo_t :: instance)
  end subroutine pcm_nlo_allocate_instance

```

As a first implementation, it acts as a wrapper for the NLO controller object and the squared matrix-element collector.

```

<Processes: public>+≡
  public :: pcm_instance_nlo_t

<Processes: types>+≡
  type, extends (pcm_instance_t) :: pcm_instance_nlo_t
    type(nlo_controller_t) :: controller
    logical :: collect_matrix_elements = .false.
    type(sqme_collector_t) :: collector
    integer :: active_real_component = 1
  end type pcm_instance_nlo_t

```

#### 29.4.15 Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

NB: The `recover.beams` option should be used only when the particle set originates from an external event file, and the user has asked for it. It should be switched off when reading from raw event file.

```

(Processes: process instance: TBP)+≡
  procedure :: get_trace => process_instance_get_trace
  procedure :: set_trace => process_instance_set_trace

(Processes: procedures)+≡
  subroutine process_instance_get_trace (instance, pset, i_term)
    class(process_instance_t), intent(in), target :: instance
    type(particle_set_t), intent(out) :: pset
    integer, intent(in) :: i_term
    type(interaction_t), pointer :: int
    logical :: ok
    int => instance%get_trace_int_ptr (i_term)
    call pset%init (ok, int, int, FM_IGNORE_HELICITY, &
      [0._default, 0._default], .false., .true.)
  end subroutine process_instance_get_trace

  subroutine process_instance_set_trace &
    (instance, pset, i_term, recover_beams, check_match)
    class(process_instance_t), intent(inout), target :: instance
    type(particle_set_t), intent(in) :: pset
    integer, intent(in) :: i_term
    logical, intent(in), optional :: recover_beams, check_match
    type(interaction_t), pointer :: int
    integer :: n_in
    int => instance%get_trace_int_ptr (i_term)
    n_in = instance%process%get_n_in ()
    call pset%fill_interaction (int, n_in, &
      recover_beams = recover_beams, &
      check_match = check_match, &
      state_flg = instance%get_state_flg (i_term))
  end subroutine process_instance_set_trace

```

This procedure allows us to override any QCD setting of the WHIZARD process and directly set the coupling value that comes together with a particle set.

```

API: driver for the unit tests below.

```

⟨Processes: public test⟩≡
  public :: processes_test

```

```

<Processes: test driver>≡
  subroutine processes_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Processes: execute tests>
  end subroutine processes_test

```

## Test process type

For the following tests, we define a simple implementation of the abstract `prc_core_t`, designed such as to complement the `prc_test_t` process definition type.

Note that it is not given that the actual process is defined as `prc_test_t` type. We enforce this by calling `prc_test_create_library`. The driver component in the process core will then become of type `prc_test_t`.

```

<Processes: public>+≡
  public :: test_t

<Processes: test types>≡
  type, extends (prc_core_t) :: test_t
  contains
    procedure :: write => test_write
    procedure :: needs_mcset => test_needs_mcset
    procedure :: get_n_terms => test_get_n_terms
    procedure :: is_allowed => test_is_allowed
    procedure :: compute_hard_kinematics => test_compute_hard_kinematics
    procedure :: compute_eff_kinematics => test_compute_eff_kinematics
    procedure :: recover_kinematics => test_recover_kinematics
    procedure :: compute_amplitude => test_compute_amplitude
  end type test_t

<Processes: test type procedures>≡
  subroutine test_write (object, unit)
    class(test_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(3x,A)") "test type implementing prc_test"
  end subroutine test_write

```

This process type always needs a MC parameter set and a single term. This only state is always allowed.

```

<Processes: test type procedures>+≡
  function test_needs_mcset (object) result (flag)
    class(test_t), intent(in) :: object
    logical :: flag
    flag = .true.
  end function test_needs_mcset

  function test_get_n_terms (object) result (n)
    class(test_t), intent(in) :: object

```

```

integer :: n
n = 1
end function test_get_n_terms

function test_is_allowed (object, i_term, f, h, c) result (flag)
class(test_t), intent(in) :: object
integer, intent(in) :: i_term, f, h, c
logical :: flag
flag = .true.
end function test_is_allowed

```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

*(Processes: test type procedures)*+≡

```

subroutine test_compute_hard_kinematics &
(object, p_seed, i_term, int_hard, core_state)
class(test_t), intent(in) :: object
type(vector4_t), dimension(:), intent(in) :: p_seed
integer, intent(in) :: i_term
type(interaction_t), intent(inout) :: int_hard
class(prc_core_state_t), intent(inout), allocatable :: core_state
call int_hard%set_momenta (p_seed)
end subroutine test_compute_hard_kinematics

```

This procedure is not called for `test_t`, just a placeholder.

*(Processes: test type procedures)*+≡

```

subroutine test_compute_eff_kinematics &
(object, i_term, int_hard, int_eff, core_state)
class(test_t), intent(in) :: object
integer, intent(in) :: i_term
type(interaction_t), intent(in) :: int_hard
type(interaction_t), intent(inout) :: int_eff
class(prc_core_state_t), intent(inout), allocatable :: core_state
end subroutine test_compute_eff_kinematics

```

Transfer the incoming momenta of `p_seed` directly to the effective interaction, and vice versa for the outgoing momenta.

`int_hard` is left untouched since `int_eff` is an alias (via pointer) to it.

*(Processes: test type procedures)*+≡

```

subroutine test_recover_kinematics &
(object, p_seed, int_hard, int_eff, core_state)
class(test_t), intent(in) :: object
type(vector4_t), dimension(:), intent(inout) :: p_seed
type(interaction_t), intent(inout) :: int_hard
type(interaction_t), intent(inout) :: int_eff
class(prc_core_state_t), intent(inout), allocatable :: core_state
integer :: n_in
n_in = int_eff%get_n_in ()
call int_eff%set_momenta (p_seed(1:n_in), outgoing = .false.)
p_seed(n_in+1:) = int_eff%get_momenta (outgoing = .true.)
end subroutine test_recover_kinematics

```

Compute the amplitude. The driver ignores all quantum numbers and, in fact, returns a constant. Nevertheless, we properly transfer the momentum vectors.

*<Processes: test type procedures>+≡*

```
function test_compute_amplitude &
    (object, j, p, f, h, c, fac_scale, ren_scale, alpha_qcd_forced, core_state) &
    result (amp)
class(test_t), intent(in) :: object
integer, intent(in) :: j
type(vector4_t), dimension(:), intent(in) :: p
integer, intent(in) :: f, h, c
real(default), intent(in) :: fac_scale, ren_scale
real(default), intent(in), allocatable :: alpha_qcd_forced
class(prc_core_state_t), intent(inout), allocatable, optional :: core_state
complex(default) :: amp
real(default), dimension(:,:), allocatable :: parray
integer :: i, n_tot
select type (driver => object%driver)
type is (prc_test_t)
    if (driver%scattering) then
        n_tot = 4
    else
        n_tot = 3
    end if
    allocate (parray (0:3,n_tot))
    forall (i = 1:n_tot) parray(:,i) = vector4_get_components (p(i))
    amp = driver%get_amplitude (parray)
end select
end function test_compute_amplitude
```

## Write an empty process object

The most trivial test is to write an uninitialized process object.

*<Processes: execute tests>≡*

```
call test (processes_1, "processes_1", &
    "write an empty process object", &

### Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```

<Processes: execute tests>+≡
  call test (processes_8, "processes_8", &
    "process evaluation with structure functions", &
    u, results)

### Complete events

For the purpose of simplifying further tests, we implement a convenience routine that initializes a process and prepares a single event. This is a wrapup of the test `processes_10`.

The procedure is re-exported by the `processes_ut` module.

```

(Processes: public test auxiliary)≡
  public :: prepare_test_process

(Processes: test auxiliary)≡
  subroutine prepare_test_process (process, process_instance, model)
    type(process_t), intent(out), target :: process
    type(process_instance_t), intent(out), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_library_t), target :: lib
    type(string_t) :: libname
    type(string_t) :: procname
    type(string_t) :: run_id

### Colored interaction

This test specifically checks the transformation of process data (flavor, helicity, and color) into an interaction in a process term.

We use the `test_t` process core (which has no nontrivial particles), but call only the `is_allowed` method, which always returns true.

```

<Processes: execute tests>+=
  call test (processes_13, "processes_13", &
    "colored interaction", &
    u, results)

<Processes: test declarations>+=

## 29.5 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

```

<process_stacks.f90>≡
<File header>

module process_stacks

<Use strings>
  use io_units
  use format_utils, only: write_separator
  use diagnostics

```

```

    use os_interface
    use sm_qcd
    use model_data
    use rng_base
    use variables
    use observables
    use process_libraries
    use processes

    <Standard module head>

    <Process stacks: public>

    <Process stacks: types>

contains

    <Process stacks: procedures>

end module process_stacks

```

### 29.5.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```

    <Process stacks: public>≡
        public :: process_entry_t

    <Process stacks: types>≡
        type, extends (process_t) :: process_entry_t
        type(process_entry_t), pointer :: next => null ()
        end type process_entry_t

```

### 29.5.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

The process stack can be linked to another one. This allows us to work with stacks of local scope.

```

    <Process stacks: public>+≡
        public :: process_stack_t

    <Process stacks: types>+≡
        type :: process_stack_t
        integer :: n = 0
        type(process_entry_t), pointer :: first => null ()
        type(var_list_t), pointer :: var_list => null ()
        type(process_stack_t), pointer :: next => null ()
        contains

```

```

    <Process stacks: process stack: TBP>
end type process_stack_t

```

Finalize partly: deallocate the process stack and variable list entries, but keep the variable list as an empty object. This way, the variable list links are kept.

```

<Process stacks: process stack: TBP>≡
    procedure :: clear => process_stack_clear

<Process stacks: procedures>≡
    subroutine process_stack_clear (stack)
        class(process_stack_t), intent(inout) :: stack
        type(process_entry_t), pointer :: process
        if (associated (stack%var_list)) then
            call stack%var_list%final ()
        end if
        do while (associated (stack%first))
            process => stack%first
            stack%first => process%next
            call process%final ()
            deallocate (process)
        end do
        stack%n = 0
    end subroutine process_stack_clear

```

Finalizer. Clear and deallocate the variable list.

```

<Process stacks: process stack: TBP>+≡
    procedure :: final => process_stack_final

<Process stacks: procedures>+≡
    subroutine process_stack_final (object)
        class(process_stack_t), intent(inout) :: object
        call object%clear ()
        if (associated (object%var_list)) then
            deallocate (object%var_list)
        end if
    end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write => process_stack_write

<Process stacks: procedures>+≡
    recursive subroutine process_stack_write (object, unit, pacify)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: pacify
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)
        call write_separator (u, 2)
        select case (object%n)
        case (0)
            write (u, "(1x,A)" "Process stack: [empty]"

```

```

        call write_separator (u, 2)
    case default
        write (u, "(1x,A)") "Process stack:"
        process => object%first
        do while (associated (process))
            call process%write (.false., u, pacify = pacify)
            process => process%next
        end do
    end select
    if (associated (object%next)) then
        write (u, "(1x,A)") "[Processes from context environment:]"
        call object%next%write (u, pacify)
    end if
end subroutine process_stack_write

```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write_var_list => process_stack_write_var_list

<Process stacks: procedures>+≡
    subroutine process_stack_write_var_list (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        if (associated (object%var_list)) then
            call var_list_write (object%var_list, unit)
        end if
    end subroutine process_stack_write_var_list

```

Short output.

```

<Process stacks: process stack: TBP>+≡
    procedure :: show => process_stack_show

<Process stacks: procedures>+≡
    recursive subroutine process_stack_show (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)
        select case (object%n)
            case (0)
            case default
                process => object%first
                do while (associated (process))
                    call process%show (u, verbose=.false.)
                    process => process%next
                end do
            end select
            if (associated (object%next)) call object%next%show ()
        end subroutine process_stack_show

```

### 29.5.3 Link

Link the current process stack to a global one.

```
<Process stacks: process stack: TBP>+≡
  procedure :: link => process_stack_link

<Process stacks: procedures>+≡
  subroutine process_stack_link (local_stack, global_stack)
    class(process_stack_t), intent(inout) :: local_stack
    type(process_stack_t), intent(in), target :: global_stack
    local_stack%next => global_stack
  end subroutine process_stack_link
```

Initialize the process variable list and link the main variable list to it.

```
<Process stacks: process stack: TBP>+≡
  procedure :: init_var_list => process_stack_init_var_list

<Process stacks: procedures>+≡
  subroutine process_stack_init_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(inout), optional :: var_list
    allocate (stack%var_list)
    if (present (var_list)) call var_list%link (stack%var_list)
  end subroutine process_stack_init_var_list
```

Link the process variable list to a global variable list.

```
<Process stacks: process stack: TBP>+≡
  procedure :: link_var_list => process_stack_link_var_list

<Process stacks: procedures>+≡
  subroutine process_stack_link_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in), target :: var_list
    call stack%var_list%link (var_list)
  end subroutine process_stack_link_var_list
```

### 29.5.4 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```
<Process stacks: process stack: TBP>+≡
  procedure :: push => process_stack_push

<Process stacks: procedures>+≡
  subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    process%next => stack%first
    stack%first => process
    process => null ()
    stack%n = stack%n + 1
  end subroutine process_stack_push
```

Initialize process variables for a given process ID, without setting values.

```

(Process stacks: process stack: TBP)+≡
  procedure :: init_result_vars => process_stack_init_result_vars

(Process stacks: procedures)+≡
  subroutine process_stack_init_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    call var_list_init_num_id (stack%var_list, id)
    call var_list_init_process_results (stack%var_list, id)
  end subroutine process_stack_init_result_vars

```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```

(Process stacks: process stack: TBP)+≡
  procedure :: fill_result_vars => process_stack_fill_result_vars

(Process stacks: procedures)+≡
  subroutine process_stack_fill_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    type(process_t), pointer :: process
    process => stack%get_process_ptr (id)
    if (associated (process)) then
      call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
      if (process%has_integral ()) then
        call var_list_init_process_results (stack%var_list, id, &
          integral = process%get_integral (), &
          error = process%get_error ())
      end if
    else
      call msg_bug ("process_stack_fill_result_vars: unknown process ID")
    end if
  end subroutine process_stack_fill_result_vars

```

### 29.5.5 Data Access

Tell if a process exists.

```

(Process stacks: process stack: TBP)+≡
  procedure :: exists => process_stack_exists

(Process stacks: procedures)+≡
  function process_stack_exists (stack, id) result (flag)
    class(process_stack_t), intent(in) :: stack
    type(string_t), intent(in) :: id
    logical :: flag
    type(process_t), pointer :: process
    process => stack%get_process_ptr (id)
    flag = associated (process)
  end function process_stack_exists

```

Return a pointer to a process with specific ID. Look also at a linked stack, if necessary.

```

<Process stacks: process stack: TBP>+≡
    procedure :: get_process_ptr => process_stack_get_process_ptr

<Process stacks: procedures>+≡
    recursive function process_stack_get_process_ptr (stack, id) result (ptr)
        class(process_stack_t), intent(in) :: stack
        type(string_t), intent(in) :: id
        type(process_t), pointer :: ptr
        type(process_entry_t), pointer :: entry
        ptr => null ()
        entry => stack%first
        do while (associated (entry))
            if (entry%get_id () == id) then
                ptr => entry%process_t
                return
            end if
            entry => entry%next
        end do
        if (associated (stack%next)) ptr => stack%next%get_process_ptr (id)
    end function process_stack_get_process_ptr

```

### 29.5.6 Unit tests

Test module, followed by the corresponding implementation module.

```

<process_stacks_ut.f90>≡
    <File header>

    module process_stacks_ut
        use unit_tests
        use process_stacks_ut

    <Standard module head>

    <Process stacks: public test>

    contains

    <Process stacks: test driver>

    end module process_stacks_ut

<process_stacks_uti.f90>≡
    <File header>

    module process_stacks_uti

    <Use strings>
        use os_interface
        use sm_qcd
        use model_data
        use process_libraries

```

```

use rng_base

## Chapter 30

# Matching

```
<matching_base.f90>≡  
  <File header>  
  
  module matching_base  
  
    <Use strings>  
    use diagnostics  
    use sm_qcd  
    use model_data  
    use particles  
    use variables  
    use shower_base  
    use processes  
    use rng_base  
  
    <Standard module head>  
  
    <Matching base: public>  
  
    <Matching base: parameters>  
  
    <Matching base: types>  
  
    <Matching base: interfaces>  
  
    contains  
  
    <Matching base: procedures>  
  
  end module matching_base
```

### 30.1 Abstract Matching Type

A matching will need access to the `shower` as well as matrix elements that we currently get over `process_instace`. The `model` is intended for the backup `model_hadrons`.

```

<Matching base: public>≡
  public :: matching_t

<Matching base: types>≡
  type, abstract :: matching_t
  logical :: is_hadron_collision = .false.
  type(qcd_t), pointer :: qcd => null ()
  class(shower_base_t), pointer :: shower => null ()
  type(process_instance_t), pointer :: process_instance => null ()
  class(model_data_t), pointer :: model => null ()
  class(rng_t), allocatable :: rng
  type(string_t) :: process_name
  contains
  <Matching base: matching: TBP>
  end type matching_t

<Matching base: matching: TBP>≡
  procedure (matching_init), deferred :: init

<Matching base: interfaces>≡
  abstract interface
    subroutine matching_init (matching, var_list, process_name)
      import
      class(matching_t), intent(out) :: matching
      type(var_list_t), intent(in) :: var_list
      type(string_t), intent(in) :: process_name
    end subroutine matching_init
  end interface

If we use a polymorphic settings type, this boilerplate wouldn't be necessary
but then we introduce select type statements all over the place.

<default matching init>≡
  type(var_list_t), intent(in) :: var_list
  type(string_t), intent(in) :: process_name
  call msg_debug (D_MATCHING, "matching_init")
  call matching%settings%init (var_list)
  matching%process_name = process_name

<Matching base: matching: TBP>+≡
  procedure (matching_write), deferred :: write

<Matching base: interfaces>+≡
  abstract interface
    subroutine matching_write (matching, unit)
      import
      class(matching_t), intent(in) :: matching
      integer, intent(in), optional :: unit
    end subroutine matching_write
  end interface

<Matching base: matching: TBP>+≡
  procedure :: import_rng => matching_import_rng

```

```

<Matching base: procedures>≡
  pure subroutine matching_import_rng (matching, rng)
    class(matching_t), intent(inout) :: matching
    class(rng_t), allocatable, intent(inout) :: rng
    call move_alloc (from = rng, to = matching%rng)
  end subroutine matching_import_rng

<Matching base: matching: TBP>+≡
  procedure :: connect => matching_connect
  procedure :: base_connect => matching_connect

<Matching base: procedures>+≡
  subroutine matching_connect (matching, process_instance, model, shower)
    class(matching_t), intent(inout) :: matching
    type(process_instance_t), intent(in), target :: process_instance

### 30.3 CKKW matching

This module contains the CKKW matching.

The type `ckkw_pseudo_shower_weights_t` gives the (relative) weights for different clusterings of the final particles, as given in Eq. (2.7) of hep-ph/0503281v1. Each particle has a binary labelling (power of 2) (first particle = 1, second particle = 2, third particle = 4, ...). Each recombination therefore corresponds to an integer, that is not a power of 2. For multiple subsequent recombinations, no different weights for different sequences of clustering are stored. It is assumed that the weight of a multiply recombined state is a combination of the states with one fewer recombination and that these states' contributions are proportional to their weights. For a  $2 > n$  event, the weights array thus has the size  $2^{(2+n)-1}$ . The `weights_by_type` array gives the weights depending on the type of the particle, the first index is the same as for weights, the second index gives the type of the new mother particle:

- 0: uncolored ( $\gamma$ ,  $Z$ ,  $W$ , Higgs)
- 1: colored (quark)
- 2: gluon
- 3: squark
- 4: gluino

`alphaS` gives the value for  $\alpha_{\text{ps}}$  used in the generation of the matrix element. This is needed for the reweighting using the values for a running  $\alpha_{\text{ps}}$  at the scales of the clusterings.

## 30.4 POWHEG

This module generates radiation according to the POWHEG Sudakov form factor

$$\Delta^{f_b}(\Phi_n, p_T) = \prod_{\alpha_r \in \{\alpha_r | f_b\}} \Delta_{\alpha_r}^{f_b}(\Phi_n, p_T), \quad (30.1)$$

with

$$\Delta_{\alpha_r}^{f_b}(\Phi_n, p_T) = \exp \left\{ - \left[ \int d\Phi_{\text{rad}} \frac{R(\Phi_{n+1})}{B^{f_b}(\Phi_n)} \theta(k_T(\Phi_{n+1}) - p_T) \right]_{\alpha_r}^{\Phi_n^{\alpha_r} = \Phi_n} \right\} \quad (30.2)$$

We expect that an underlying Born flavor structure  $f_b$  has been generated with a probability proportional to its contribution to the  $\tilde{B}$  at the given kinematic point.

```

We have to solve the equation

$$\frac{\log \Delta^{(U)}(p_T)}{\log \Delta^{(U)}(p_T^{\max})} = \log \Delta^{(U)}(p_T) = \log r_1$$

iteratively for  $p_T$ . If the current emission is not accepted, in the next step it is  $\log \Delta^{(U)}(p_T^{\max}) = \log r_1$ , so that we have to solve the equation

$$\log \Delta^{(U)}(p_T) = \log r_1 + \log r_2$$

using the second random number  $r_2$ .

## Simple FSR

This corresponds to Appendix C of 1002.2581

```

<POWHEG matching: public>+≡
    public :: sudakov_simple_fsr_t

<POWHEG matching: types>+≡
    type, extends (sudakov_t) :: sudakov_simple_fsr_t
    contains
        <POWHEG matching: sudakov simple fsr: TBP>
    end type sudakov_simple_fsr_t

```

The simplest upper bounding function for final-state radiation is

$$\text{upper\_bound\_func} = \frac{U(\xi, y)}{N} = \frac{\alpha_s}{\xi(1-y)} \quad (30.4)$$

```

<POWHEG matching: sudakov simple fsr: TBP>≡
  procedure :: upper_bound_func => sudakov_simple_fsr_upper_bound_func

<POWHEG matching: procedures>+≡
  pure function sudakov_simple_fsr_upper_bound_func (sudakov, xi, y, alpha_s) result (u)
    real(default) :: u
    class(sudakov_simple_fsr_t), intent(in) :: sudakov
    real(default), intent(in) :: xi, y, alpha_s
    u = alpha_s / (xi * (1 - y))
  end function sudakov_simple_fsr_upper_bound_func

```

The above upper bounding function corresponds to the transverse momentum scale

$$k_T^2 = \frac{s}{2} \xi^2 (1-y). \quad (30.5)$$

```

<POWHEG matching: sudakov simple fsr: TBP>+≡

end subroutine sudakov_massive_fsr_compute_xi_max_extended

```

For massive emitters, the radiation variable  $\xi$  is constructed as follows. First,

$$\xi_{\min}(k_T^2) = \frac{\sqrt{k_T^2(k_T^2 z_2^2 + 8\bar{p}^0 q(1 - z_2)) - k_T^2 z_2}}{2q^2(1 - z_2)} \quad (30.7)$$

is computed. Then  $\xi_1$  is computed according to the same equation with  $z_2 \leftrightarrow z_1$ . Finally,  $\xi$  is generated according to

$$\xi = \frac{1}{q^2} \exp \left[ \log(\xi_{\min} q^2 - k_T^2) + r \log \frac{\xi_m q^2 - k_T^2}{\xi_{\min} q^2 - k_T^2} + k_T^2 \right], \quad (30.8)$$

where  $\xi_m = \min(\xi_{\max}, \xi_1)$ .

```

## Generation algorithm and grid initialization

compute\_sqme\_real is the projected real matrix element  $R_{\alpha_r} = S_{\alpha_r} R$  whereby the current  $\alpha_r$  is implied by the emitter. Furthermore, it is multiplied by the Jacobian.

*(POWHEG matching: powheg matching: TBP)+≡*

For each underlying Born  $f_b$ , there is a number of radiation regions. A radiation region rr may correspond multiple  $\alpha_r$ s. The phase space only depends upon the radiation region kinematics rr and not on the specific  $\alpha_r$ .  $\alpha_r$  can be picked

in the set  $\{\alpha_r|f_b,rr\}$  proportional to their  $R_{\alpha_r}$ . For now, we simplify things though and just work with the  $\alpha_r$ .

The following is valid for one underlying Born.

```

#### 30.4.4 $\alpha_s$ and its reweighting

The main point to ensure here is that the simple fixed-flavor-1-loop expression  $\alpha_s^{\text{rad}}$  is larger than the more accurate  $\alpha_s$  such that we can use a reweighting veto and use  $\alpha_s^{\text{rad}}$  for the generation of the emission. This can be done by setting

$$\alpha_s^{\text{rad}}(\mu_0) = \alpha_s(\mu_0) \quad (30.13)$$

whereby  $\mu_0^2$  is the `scale_to_relate2` that is taken to be  $p_{T,\text{min}}^2$ .

## Chapter 31

# Event Implementation

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

**event\_transforms** Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

**decays** Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

**showers** Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

**hadrons** (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

**tau\_decays** (not implemented yet) Let  $\tau$  leptons decay taking full spin correlations into account.

**events** Combine all pieces to generate full events.

**eio\_raw** Raw I/O for complete events.

### 31.1 Abstract Event Transforms

*⟨Event transforms: public⟩*

*⟨Event transforms: types⟩*

*⟨Event transforms: interfaces⟩*

**contains**

*⟨Event transforms: procedures⟩*

**end module event\_transforms**

### 31.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified setting that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include **previous** and **next** pointers.

*⟨Event transforms: public⟩*≡

```
public :: evt_t
```

*⟨Event transforms: types⟩*≡

```

type, abstract :: evt_t
  type(process_t), pointer :: process => null ()
  type(process_instance_t), pointer :: process_instance => null ()
  class(model_data_t), pointer :: model => null ()
  class(rng_t), allocatable :: rng
  integer :: rejection_count = 0
  logical :: particle_set_exists = .false.
  type(particle_set_t) :: particle_set
  class(evt_t), pointer :: previous => null ()
  class(evt_t), pointer :: next => null ()
  real(default) :: weight = 0._default
  logical :: only_weighted_events = .false.

```

```

contains
  <Event transforms: evt: TBP>
end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡
  procedure :: final => evt_final
  procedure :: base_final => evt_final

<Event transforms: procedures>≡
  subroutine evt_final (evt)
    class(evt_t), intent(inout) :: evt
    if (allocated (evt%rng)) call evt%rng%final ()
    if (evt%particle_set_exists) &
      call evt%particle_set%final ()
  end subroutine evt_final

<Event transforms: evt: TBP>+≡
  procedure (evt_write), deferred :: write

<Event transforms: interfaces>≡
  abstract interface
    subroutine evt_write (evt, unit, verbose, more_verbose, testflag)
      import
      class(evt_t), intent(in) :: evt
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose, more_verbose, testflag
    end subroutine evt_write
  end interface

```

Output. We can print r.n.g. info.

```

<Event transforms: evt: TBP>+≡
  procedure :: base_write => evt_base_write

<Event transforms: procedures>+≡
  subroutine evt_base_write (evt, unit, testflag, show_set)
    class(evt_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag, show_set
    integer :: u
    logical :: show
    u = given_output_unit (unit)
    show = .true.; if (present (show_set)) show = show_set
    if (associated (evt%process)) then
      write (u, "(3x,A,A,A)") "Associated process: '", &
        char (evt%process%get_id ()), "'"
    end if
    if (allocated (evt%rng)) then
      call evt%rng%write (u, 1)
      write (u, "(3x,A,I0)") "Number of tries = ", evt%rejection_count
    end if
    if (show) then
      if (evt%particle_set_exists) then

```

```

        call write_separator (u)
        call evt%particle_set%write (u, testflag = testflag)
    end if
end if
end subroutine evt_base_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

```

<Event transforms: evt: TBP>+≡
    procedure :: connect => evt_connect
    procedure :: base_connect => evt_connect

<Event transforms: procedures>+≡
    subroutine evt_connect (evt, process_instance, model, process_stack)
        class(evt_t), intent(inout), target :: evt
        type(process_instance_t), intent(in), target :: process_instance
        class(model_data_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        evt%process => process_instance%process
        evt%process_instance => process_instance
        evt%model => model
        call evt%process%make_rng (evt%rng)
    end subroutine evt_connect

```

Reset internal state.

```

<Event transforms: evt: TBP>+≡
    procedure :: reset => evt_reset
    procedure :: base_reset => evt_reset

<Event transforms: procedures>+≡
    subroutine evt_reset (evt)
        class(evt_t), intent(inout) :: evt
        evt%rejection_count = 0
        evt%particle_set_exists = .false.
    end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

<Event transforms: evt: TBP>+≡
    procedure (evt_prepare_new_event), deferred :: prepare_new_event

<Event transforms: interfaces>+≡
    interface
        subroutine evt_prepare_new_event (evt, i_mci, i_term)
            import
            class(evt_t), intent(inout) :: evt
            integer, intent(in) :: i_mci, i_term
        end subroutine evt_prepare_new_event
    end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)
      import
      class(evt_t), intent(inout) :: evt
      real(default), intent(inout) :: probability
    end subroutine evt_generate_weighted
  end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted

(Event transforms: procedures)+≡
  subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set

(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
  end interface

```

```

        integer, intent(in) :: factorization_mode
        logical, intent(in) :: keep_correlations
        real(default), dimension(:), intent(in), optional :: r
    end subroutine evt_make_particle_set
end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

<Event transforms: evt: TBP>+≡
    procedure :: set_particle_set => evt_set_particle_set

<Event transforms: procedures>+≡
    subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
        class(evt_t), intent(inout) :: evt
        type(particle_set_t), intent(in) :: particle_set
        integer, intent(in) :: i_term, i_mci
        call evt%prepare_new_event (i_mci, i_term)
        evt%particle_set = particle_set
        evt%particle_set_exists = .true.
    end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. (We need two interactions, one with color summed over, and one with the probability distributed among flows.)

We use the two values from the random number generator for factorizing the state. For testing purposes, we can provide those numbers explicitly.

```

<Event transforms: evt: TBP>+≡
    procedure :: factorize_interactions => evt_factorize_interactions

<Event transforms: procedures>+≡
    subroutine evt_factorize_interactions &
        (evt, int_matrix, int_flows, factorization_mode, keep_correlations, r)
        class(evt_t), intent(inout) :: evt
        type(interaction_t), intent(in), target :: int_matrix, int_flows
        integer, intent(in) :: factorization_mode
        logical, intent(in) :: keep_correlations
        real(default), dimension(:), intent(in), optional :: r
        real(default), dimension(2) :: x
        if (present (r)) then
            if (size (r) == 2) then
                x = r
            else
                call msg_bug ("event factorization: size of r array must be 2")
            end if
        else
            call evt%rng%generate (x)
        end if
        call evt%particle_set%init (evt%particle_set_exists, &
            int_matrix, int_flows, factorization_mode, x, &
            keep_correlations, keep_virtual=.true.)
        evt%particle_set_exists = .true.
    end subroutine evt_factorize_interactions

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

```

<Event transforms: evt: TBP>+≡
  procedure :: tag_incoming => evt_tag_incoming

<Event transforms: procedures>+≡
  subroutine evt_tag_incoming (evt)
    class(evt_t), intent(inout) :: evt

    call evt%process_instance%get_beam_index (i_term, beam_index)
    call evt%particle_set%reset_status (beam_index, PRT_BEAM)
    allocate (in_index (n_in))
    call evt%process_instance%get_in_index (i_term, in_index)
    call evt%particle_set%reset_status (in_index, PRT_INCOMING)
  end subroutine evt_tag_incoming

```

### 31.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

<Event transforms: public>+≡
  public :: evt_trivial_t

<Event transforms: types>+≡
  type, extends (evt_t) :: evt_trivial_t
    contains
    <Event transforms: evt trivial: TBP>
  end type evt_trivial_t

```

The finalizer is trivial. Some output:

```

<Event transforms: evt trivial: TBP>≡
  procedure :: write => evt_trivial_write

<Event transforms: procedures>+≡
  subroutine evt_trivial_write (evt, unit, verbose, more_verbose, testflag)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, more_verbose, testflag
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    write (u, "(1x,A)") "Event transform: trivial (hard process)"
  end subroutine evt_trivial_write

```

```

        call write_separator (u)
        call evt%base_write (u, testflag = testflag)
    end subroutine evt_trivial_write

```

Nothing to do here:

```

<Event transforms: evt trivial: TBP>+≡
    procedure :: prepare_new_event => evt_trivial_prepare_new_event

<Event transforms: procedures>+≡
    subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
        class(evt_trivial_t), intent(inout) :: evt
        integer, intent(in) :: i_mci, i_term
        call evt%reset ()
    end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

<Event transforms: evt trivial: TBP>+≡
    procedure :: generate_weighted => evt_trivial_generate_weighted

<Event transforms: procedures>+≡
    subroutine evt_trivial_generate_weighted (evt, probability)
        class(evt_trivial_t), intent(inout) :: evt
        real(default), intent(inout) :: probability
        probability = 1
    end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is.

```

<Event transforms: evt trivial: TBP>+≡
    procedure :: make_particle_set => evt_trivial_make_particle_set

<Event transforms: procedures>+≡
    subroutine evt_trivial_make_particle_set &
        (evt, factorization_mode, keep_correlations, r)
        class(evt_trivial_t), intent(inout) :: evt
        integer, intent(in) :: factorization_mode
        logical, intent(in) :: keep_correlations
        real(default), dimension(:), intent(in), optional :: r
        integer :: i_term
        type(interaction_t), pointer :: int_matrix, int_flows
        if (evt%process_instance%is_complete_event ()) then
            call evt%process_instance%select_i_term (i_term)
            int_matrix => evt%process_instance%get_matrix_int_ptr (i_term)
            int_flows => evt%process_instance%get_flows_int_ptr (i_term)
            call evt%factorize_interactions (int_matrix, int_flows, &
                factorization_mode, keep_correlations, r)
            call evt%tag_incoming ()
        else
            call msg_bug ("Event factorization: event is incomplete")
        end if
    end subroutine evt_trivial_make_particle_set

```

### 31.1.3 Unit tests

Test module, followed by the corresponding implementation module.

```
<event_transforms_ut.f90>≡
  <File header>

  module event_transforms_ut
    use unit_tests
    use event_transforms_uti

    <Standard module head>

    <Event transforms: public test>

    contains

    <Event transforms: test driver>

  end module event_transforms_ut

<event_transforms_uti.f90>≡
  <File header>

  module event_transforms_uti

    <Use kinds>
    <Use strings>
    use format_utils, only: write_separator
    use os_interface
    use sm_qcd

### 31.2.5 Hadronization Event Transform

This is the type for the hadronization event transform. It does not depend on the specific hadronization implementation of `hadrons_t`.

*<Hadrons: public>+≡*

```

public :: evt_hadrons_t

```

*<Hadrons: types>+≡*

```

type, extends (evt_t) :: evt_hadrons_t
    class(hadrons_t), allocatable :: hadrons
    type(model_t), pointer :: model_hadrons => null()
    type(qcd_t), pointer :: qcd_t => null()
    logical :: is_first_event

```

```

contains
  <Hadrons: evt hadrons: TBP>≡
end type evt_hadrons_t

```

Initialize the parameters. The `model_hadrons` is supposed to be the SM variant that contains all hadrons that may be generated in the shower.

```

<Hadrons: evt hadrons: TBP>≡
  procedure :: init => evt_hadrons_init
<Hadrons: procedures>+≡
  subroutine evt_hadrons_init (evt, settings, model_hadrons, method)
    class(evt_hadrons_t), intent(out) :: evt
    type(shower_settings_t), intent(in) :: settings
    type(model_t), intent(in), target :: model_hadrons
    type(string_t), intent(in) :: method
    evt%model_hadrons => model_hadrons
    !!! TODO: (bcn 2015-03-27) method should be part of hadronization settings
    select case (char (method))
    case ("PYTHIA6")
      allocate (hadrons_pythia6_t :: evt%hadrons)
    case ("PYTHIA8")
      allocate (hadrons_pythia8_t :: evt%hadrons)
    case default
      call msg_fatal ("Hadronization method " // char (method) // &
        " not implemented.")
    end select
    call evt%hadrons%init (settings, model_hadrons)
    evt%is_first_event = .true.
  end subroutine evt_hadrons_init

```

Output.

```

<Hadrons: evt hadrons: TBP>+≡
  procedure :: write => evt_hadrons_write
<Hadrons: procedures>+≡
  subroutine evt_hadrons_write (evt, unit, verbose, more_verbose, testflag)

    end if
  end associate
  evt%is_first_event = .false.
end subroutine evt_hadrons_first_event

```

Here we take the particle set from the previous event transform and apply the hadronization. The result is stored in the `evt%hadrons` object. We always return a probability of unity as we don't have the analytic weight of the hadronization. Invalid events have to be discarded by the caller which is why we mark the particle set as invalid.

```

<Hadrons: evt hadrons: TBP>+≡
  procedure :: generate_weighted => evt_hadrons_generate_weighted

<Hadrons: procedures>+≡
subroutine evt_hadrons_generate_weighted (evt, probability)
  class(evt_hadrons_t), intent(inout) :: evt
  real(default), intent(inout) :: probability
  logical :: valid
  if (signal_is_pending ()) return
  evt%particle_set = evt%previous%particle_set
  if (evt%is_first_event) then
    call evt%first_event ()
  end if
  call evt%hadrons%hadronize (evt%particle_set, valid)
  probability = 1
  evt%particle_set_exists = valid
end subroutine evt_hadrons_generate_weighted

```

The factorization parameters are irrelevant.

```

<Hadrons: evt hadrons: TBP>+≡
  procedure :: make_particle_set => evt_hadrons_make_particle_set

        call evt%reset ()
    end subroutine evt_hadrons_prepare_new_event

```

### 31.3 Tau decays

```

⟨tau_decays.f90⟩≡
    ⟨File header⟩

    module tau_decays

        ⟨Use kinds⟩
        use io_units
        use format_utils, only: write_separator
        use sm_qcd
        use model_data
        use models
        use event_transforms

        ⟨Standard module head⟩

        ⟨Tau decays: public⟩

        ⟨Tau decays: types⟩

        contains

        ⟨Tau decays: procedures⟩

    end module tau_decays

```

#### 31.3.1 Tau Decays Event Transform

This is the type for the tau decay event transform.

```

⟨Tau decays: public⟩≡
    public :: evt_tau_decays_t

```

```

<Tau decays: types>≡
  type, extends (evt_t) :: evt_tau_decays_t
    type(model_t), pointer :: model_hadrons => null()
    type(qcd_t), pointer :: qcd_t => null()
  contains
    <Tau decays: evt tau decays: TBP>
  end type evt_tau_decays_t

```

Output.

```

<Tau decays: evt tau decays: TBP>≡
  procedure :: write => evt_tau_decays_write

<Tau decays: procedures>≡
  subroutine evt_tau_decays_write (evt, unit, verbose, more_verbose, testflag)
    class(evt_tau_decays_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, more_verbose, testflag
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    write (u, "(1x,A)") "Event transform: tau decays"
    call write_separator (u)
    call evt%base_write (u, testflag = testflag, show_set = .false.)
    if (evt%particle_set_exists) &
      call evt%particle_set%write &
        (u, summary = .true., compressed = .true., testflag = testflag)
    call write_separator (u)
  end subroutine evt_tau_decays_write

```

Here we take the particle set from the previous event transform and apply the tau decays. What probability should be given back, the product of branching ratios of the corresponding tau decays?

```

<Tau decays: evt tau decays: TBP>+≡
  procedure :: generate_weighted => evt_tau_decays_generate_weighted

<Tau decays: procedures>+≡
  subroutine evt_tau_decays_generate_weighted (evt, probability)

    real(default), intent(inout) :: probability
    logical :: valid
    evt%particle_set = evt%previous%particle_set
    !!! To be checked or expanded
    probability = 1
    valid = .true.
    evt%particle_set_exists = valid
  end subroutine evt_tau_decays_generate_weighted

```

The factorization parameters are irrelevant.

```

<Tau decays: evt tau decays: TBP>+≡
  procedure :: make_particle_set => evt_tau_decays_make_particle_set

```

```

<Tau decays: procedures>+≡
  subroutine evt_tau_decays_make_particle_set &
    (evt, factorization_mode, keep_correlations, r)
    class(evt_tau_decays_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    logical :: valid
    !!! to be checked and expanded
    valid = .true.
    evt%particle_set_exists = evt%particle_set_exists .and. valid
  end subroutine evt_tau_decays_make_particle_set

<Tau decays: evt tau decays: TBP>+≡
  procedure :: prepare_new_event => evt_tau_decays_prepare_new_event

<Tau decays: procedures>+≡
  subroutine evt_tau_decays_prepare_new_event (evt, i_mci, i_term)
    class(evt_tau_decays_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
  end subroutine evt_tau_decays_prepare_new_event

```

## 31.4 Decays

```

<decays.f90>≡
  <File header>

  module decays

    <Use kinds>
    <Use strings>
    use io_units
    use format_utils, only: write_indent, write_separator
    use format_defs, only: FMT_15
    use unit_tests, only: nearly_equal, vanishes
    use diagnostics
    use flavors
    use helicities
    use quantum_numbers
    use interactions
    use evaluators
    use model_data
    use rng_base
    use selectors
    use parton_states
    use processes
    use process_stacks
    use event_transforms

    <Standard module head>

```

```

    <Decays: public>

    <Decays: types>

    <Decays: interfaces>

contains

    <Decays: procedures>

end module decays

```

### 31.4.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

<Decays: types>≡
    type, abstract :: any_config_t
        private
        contains
        <Decays: any config: TBP>
    end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
    procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
    interface
        subroutine any_config_final (object)
            import
            class(any_config_t), intent(inout) :: object
        end subroutine any_config_final
    end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
    procedure (any_config_write), deferred :: write

<Decays: interfaces>+≡
    interface
        subroutine any_config_write (object, unit, indent, verbose)
            import
            class(any_config_t), intent(in) :: object
            integer, intent(in), optional :: unit, indent
            logical, intent(in), optional :: verbose
        end subroutine any_config_write
    end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_config_t
  private
    class(any_config_t), allocatable :: c
  end type particle_config_t

```

### 31.4.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above. This also works around a compiler bug in gfortran.

```

<Decays: types>+≡
  type, abstract :: any_t
  private
    contains
    <Decays: any: TBP>
  end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final

<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
        class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
      import
        class(any_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
    end subroutine any_write
  end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_out_t
  private

```

```

        class(any_t), allocatable :: c
    end type particle_out_t

```

### 31.4.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+≡
    type :: decay_term_config_t
    private
        type(particle_config_t), dimension(:), allocatable :: prt
    contains
        <Decays: decay term config: TBP>
    end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>≡
    procedure :: final => decay_term_config_final

<Decays: procedures>≡
    recursive subroutine decay_term_config_final (object)
        class(decay_term_config_t), intent(inout) :: object
        integer :: i
        if (allocated (object%prt)) then
            do i = 1, size (object%prt)
                if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
            end do
        end if
    end subroutine decay_term_config_final

```

Output, with optional indentation

```

<Decays: decay term config: TBP>+≡
    procedure :: write => decay_term_config_write

<Decays: procedures>+≡
    recursive subroutine decay_term_config_write (object, unit, indent, verbose)
        class(decay_term_config_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        logical, intent(in), optional :: verbose
        integer :: i, j, u, ind
        logical :: verb
        u = given_output_unit (unit)
        ind = 0; if (present (indent)) ind = indent
        verb = .true.; if (present (verbose)) verb = verbose
        call write_indent (u, ind)
        write (u, "(1x,A)", advance="no") "Final state:"
        do i = 1, size (object%prt)
            select type (prt_config => object%prt(i)%c)
                type is (stable_config_t)
                    write (u, "(1x,A)", advance="no") &
                        char (prt_config%flv(1)%get_name ())

```

```

        do j = 2, size (prt_config%flv)
            write (u, "(:',A)", advance="no") &
                char (prt_config%flv(j)%get_name ())
        end do
        type is (unstable_config_t)
            write (u, "(1x,A)", advance="no") &
                char (prt_config%flv%get_name ())
        end select
    end do
    write (u, *)
    if (verb) then
        do i = 1, size (object%prt)
            call object%prt(i)%c%write (u, ind)
        end do
    end if
end subroutine decay_term_config_write

```

Initialize, given a set of flavors. For each flavor, we must indicate whether the particle is stable. The second index of the flavor array runs over alternatives for each decay product; alternatives are allowed only if the decay product is itself stable.

*<Decays: decay term config: TBP>+≡*

```

    procedure :: init => decay_term_config_init

```

*<Decays: procedures>+≡*

```

    recursive subroutine decay_term_config_init &
        (term, flv, stable, model, process_stack)

      end select
    end do
  end do
end subroutine decay_term_generate

```

### 31.4.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```

<Decays: public>≡
  public :: decay_root_config_t

<Decays: types>+≡
  type :: decay_root_config_t
  private
    type(string_t) :: process_id
    type(process_t), pointer :: process => null ()
    class(model_data_t), pointer :: model => null ()
    type(decay_term_config_t), dimension(:), allocatable :: term_config
  contains
    <Decays: decay root config: TBP>
  end type decay_root_config_t

```

The finalizer is recursive since there may be cascade decays.

```

<Decays: decay root config: TBP>≡
  procedure :: final => decay_root_config_final

```

```

<Decays: procedures>+≡
recursive subroutine decay_root_config_final (object)
  class(decay_root_config_t), intent(inout) :: object
  integer :: i
  if (allocated (object%term_config)) then
    do i = 1, size (object%term_config)
      call object%term_config(i)%final ()
    end do
  end if
end subroutine decay_root_config_final

```

The output routine is also recursive, and it contains an adjustable indentation.

end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing

particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

For the unstable particles, we have to check whether their masses match between the production and the decay. Fortunately, both versions are available for comparison.

### 31.4.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```

<Decays: types>+≡
    type, abstract :: decay_gen_t
    private
        type(decay_term_t), dimension(:), allocatable :: term
        type(process_instance_t), pointer :: process_instance => null ()

```

```

        integer :: selected_mci = 0
        integer :: selected_term = 0
    contains
        <Decays: decay gen: TBP>
    end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

<Decays: public>+≡
    public :: decay_root_t

<Decays: types>+≡
    type, extends (decay_gen_t) :: decay_root_t
    private
        type(decay_root_config_t), pointer :: config => null ()
    contains
        <Decays: decay root: TBP>
    end type decay_root_t

```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```

<Decays: decay gen: TBP>≡
    procedure :: base_final => decay_gen_final

<Decays: procedures>+≡

### 31.4.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

The flavor component should be identical to the flavor component of the parent particle (`unstable` object).

```

⟨Decays: types⟩+≡
    type, extends (decay_root_config_t) :: decay_config_t
    private
        type(flavor_t) :: flv
        real(default) :: weight = 0
        real(default) :: integral = 0
        real(default) :: abs_error = 0
        real(default) :: rel_error = 0
        type(selector_t) :: mci_selector
    contains
        ⟨Decays: decay config: TBP⟩
    end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
  procedure :: write => decay_config_write

<Decays: procedures>+≡
  recursive subroutine decay_config_write (object, unit, indent, verbose)
    class(decay_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose

        class(decay_config_t), intent(inout) :: decay
        call decay%decay_root_config_t%compute ()
        if (.not. vanishes (decay%integral)) then
            decay%rel_error = decay%abs_error / decay%integral
        else
            decay%rel_error = 0
        end if
    end subroutine decay_config_compute

```

### 31.4.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

⟨Decays: types⟩+≡
    type, extends (decay_gen_t) :: decay_t
    private
        type(decay_config_t), pointer :: config => null ()
        class(rng_t), allocatable :: rng
    contains
        ⟨Decays: decay: TBP⟩
    end type decay_t

```

The finalizer is recursive.

```

<Decays: decay: TBP>≡
  procedure :: final => decay_final

<Decays: procedures>+≡
  recursive subroutine decay_final (object)
    class(decay_t), intent(inout) :: object
    integer :: i
    call object%base_final ()
    do i = 1, object%config%process%get_n_mci ()
      call object%process_instance%final_simulation (i)
    end do
    call object%process_instance%final ()
    deallocate (object%process_instance)
  end subroutine decay_final

```

Output.

```

<Decays: decay: TBP>+≡
  procedure :: write => decay_write

<Decays: procedures>+≡
  recursive subroutine decay_write (object, unit, indent, recursive)
    class(decay_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent, recursive
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call object%config%write (unit, indent, verbose = .false.)
    if (allocated (object%rng)) then
      call object%rng%write (u, ind + 1)
    end if
    call write_indent (u, ind)
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI    = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI    = [undefined]"
    end if
    call write_indent (u, ind)
    if (object%selected_term > 0) then
      write (u, "(3x,A,I0)") "Selected term  = ", object%selected_term
      call object%term(object%selected_term)%write (u, ind + 1)
    else
      write (u, "(3x,A)") "Selected term  = [undefined]"
    end if
  end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
  procedure :: init => decay_init

```

```

<Decays: procedures>+≡
recursive subroutine decay_init (decay, config)
  class(decay_t), intent(out) :: decay
  type(decay_config_t), intent(in), target :: config
  integer :: i
  call decay%base_init (config%term_config)
  decay%config => config
  allocate (decay%process_instance)
  call decay%process_instance%init (decay%config%process)
  call decay%process_instance%setup_event_data (decay%config%model)
  do i = 1, decay%config%process%get_n_mci ()
    call decay%process_instance%init_simulation (i)
  end do
  call decay%config%process%make_rng (decay%rng)
  call decay%make_term_rng (decay%config%process)
end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
  procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
recursive subroutine decay_link_interactions (decay, i_prt, trace)
  class(decay_t), intent(inout) :: decay
  integer, intent(in) :: i_prt
  type(interaction_t), intent(in), target :: trace
  type(interaction_t), pointer :: beam_int
  integer :: n_in, n_vir
  beam_int => decay%process_instance%get_beam_int_ptr ()
  n_in = trace%get_n_in ()
  n_vir = trace%get_n_vir ()
  call beam_int%set_source_link (1, trace, &
    n_in + n_vir + i_prt)
  call decay%link_term_interactions ()
end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
  procedure :: select_chain => decay_select_chain

<Decays: procedures>+≡
recursive subroutine decay_select_chain (decay)
  class(decay_t), intent(inout) :: decay
  real(default) :: x
  integer :: i
  call decay%rng%generate (x)
  decay%selected_mci = decay%config%mc_selector%select (x)

```

```

    call decay%process_instance%choose_mci (decay%selected_mci)
    call decay%process_instance%select_i_term (decay%selected_term)
    do i = 1, size (decay%term)
        call decay%term(i)%select_chain ()
    end do
end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

<Decays: decay: TBP>+≡
    procedure :: generate => decay_generate

<Decays: procedures>+≡
    recursive subroutine decay_generate (decay)
        class(decay_t), intent(inout) :: decay
        type(isolated_state_t), pointer :: isolated_state
        integer :: i
        call decay%process_instance%receive_beam_momenta ()
        call decay%config%process%generate_unweighted_event &
            (decay%process_instance, decay%selected_mci)
        if (signal_is_pending ()) return
        call decay%process_instance%evaluate_event_data ()
        isolated_state => &
            decay%process_instance%get_isolated_state_ptr (decay%selected_term)
        call isolated_state%normalize_matrix_by_trace ()
        do i = 1, size (decay%term)
            call decay%term(i)%generate ()
            if (signal_is_pending ()) return
        end do
    end subroutine decay_generate

```

### 31.4.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```

<Decays: types>+≡
    type, extends (any_config_t) :: stable_config_t
    private
        type(flavor_t), dimension(:), allocatable :: flv
    contains
        <Decays: stable config: TBP>
    end type stable_config_t

```

The finalizer is empty:

```

<Decays: stable config: TBP>≡
    procedure :: final => stable_config_final

```

```

<Decays: procedures>+≡
  subroutine stable_config_final (object)
    class(stable_config_t), intent(inout) :: object
  end subroutine stable_config_final

```

Output.

```

<Decays: stable config: TBP>+≡
  procedure :: write => stable_config_write

<Decays: procedures>+≡
  recursive subroutine stable_config_write (object, unit, indent, verbose)
    class(stable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"
    write (u, "(1x,A)", advance = "no") char (object%flv(1)%get_name ())
    do i = 2, size (object%flv)
      write (u, "(':',A)", advance = "no") &
        char (object%flv(i)%get_name ())
    end do
    write (u, *)
  end subroutine stable_config_write

```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```

<Decays: stable config: TBP>+≡
  procedure :: init => stable_config_init

<Decays: procedures>+≡
  subroutine stable_config_init (config, flv)
    class(stable_config_t), intent(out) :: config
    type(flavor_t), dimension(:), intent(in) :: flv
    integer, dimension (size (flv)) :: pdg
    logical, dimension (size (flv)) :: mask
    integer :: i
    pdg = flv%get_pdg ()
    mask(1) = .true.
    forall (i = 2 : size (pdg))
      mask(i) = all (pdg(i) /= pdg(1:i-1))
    end forall
    allocate (config%flv (count (mask)))
    config%flv = pack (flv, mask)
  end subroutine stable_config_init

```

Here is the corresponding object instance. Except for the pointer to the configuration, there is no content.

```

<Decays: types>+≡
  type, extends (any_t) :: stable_t
  private

```

```

        type(stable_config_t), pointer :: config => null ()
contains
    <Decays: stable: TBP>≡
end type stable_t

```

The finalizer does nothing.

```

<Decays: stable: TBP>≡
    procedure :: final => stable_final

<Decays: procedures>+≡
    subroutine stable_final (object)
        class(stable_t), intent(inout) :: object
    end subroutine stable_final

```

We can delegate output to the configuration object.

```

<Decays: stable: TBP>+≡
    procedure :: write => stable_write

<Decays: procedures>+≡
    subroutine stable_write (object, unit, indent)
        class(stable_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        call object%config%write (unit, indent)
    end subroutine stable_write

```

Initializer: just assign the configuration.

```

<Decays: stable: TBP>+≡
    procedure :: init => stable_init

<Decays: procedures>+≡
    subroutine stable_init (stable, config)
        class(stable_t), intent(out) :: stable
        type(stable_config_t), intent(in), target :: config
        stable%config => config
    end subroutine stable_init

```

### 31.4.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: public>+≡
    public :: unstable_config_t

<Decays: types>+≡
    type, extends (any_config_t) :: unstable_config_t
    private
    type(flavor_t) :: flv
    real(default) :: integral = 0

```

```

    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: selector
    type(decay_config_t), dimension(:), allocatable :: decay_config
contains
  <Decays: unstable config: TBP>
end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
  procedure :: final => unstable_config_final
<Decays: procedures>+≡
  recursive subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%final ()
      end do
    end if
  end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
  procedure :: write => unstable_config_write
<Decays: procedures>+≡
  recursive subroutine unstable_config_write (object, unit, indent, verbose)
    class(unstable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    logical :: verb
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
      char (object%flv%get_name ())
    call write_indent (u, ind)
    write (u, 1) "total width =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs) =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel) =", object%rel_error
1  format (5x,A,ES19.12)
    if (verb .and. allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%write (u, ind + 1)
      end do
    end if
  end subroutine unstable_config_write

```

Initializer. For the unstable particle, the flavor is unique.

```

<Decays: unstable config: TBP>+≡
  procedure :: init => unstable_config_init

<Decays: procedures>+≡
  subroutine unstable_config_init (unstable, flv, set_decays, model)
    class(unstable_config_t), intent(out) :: unstable
    type(flavor_t), intent(in) :: flv
    logical, intent(in), optional :: set_decays
    class(model_data_t), intent(in), optional, target :: model
    type(string_t), dimension(:), allocatable :: decay
    unstable%flv = flv
    if (present (set_decays)) then
      call unstable%flv%get_decays (decay)
      call unstable%init_decays (decay, model)
    end if
  end subroutine unstable_config_init

```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```

<Decays: unstable config: TBP>+≡
  procedure :: init_decays => unstable_config_init_decays

<Decays: procedures>+≡
  recursive subroutine unstable_config_init_decays &
    (unstable, decay_id, model, process_stack)
    class(unstable_config_t), intent(inout) :: unstable
    type(string_t), dimension(:), intent(in) :: decay_id
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    integer :: i
    allocate (unstable%decay_config (size (decay_id)))
    do i = 1, size (decay_id)
      associate (decay => unstable%decay_config(i))
        if (present (process_stack)) then
          call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
            model, process_stack)
        else
          call decay%init (model, decay_id(i))
        end if
        call decay%set_flv (unstable%flv)
      end associate
    end do
  end subroutine unstable_config_init_decays

```

Explicitly connect a specific decay with a process. This is used only in unit tests.

```

<Decays: unstable config: TBP>+≡
  procedure :: connect_decay => unstable_config_connect_decay

```

```

<Decays: procedures>+≡
  subroutine unstable_config_connect_decay (unstable, i, process, model)
    class(unstable_config_t), intent(inout) :: unstable
    integer, intent(in) :: i
    type(process_t), intent(in), target :: process
    class(model_data_t), intent(in), target :: model
    associate (decay => unstable%decay_config(i))
      call decay%connect (process, model)
    end associate
  end subroutine unstable_config_connect_decay

```

Compute the total width and branching ratios, initializing the decay selector.

```

<Decays: unstable config: TBP>+≡
  procedure :: compute => unstable_config_compute

<Decays: procedures>+≡
  recursive subroutine unstable_config_compute (unstable)
    class(unstable_config_t), intent(inout) :: unstable
    integer :: i
    do i = 1, size (unstable%decay_config)
      call unstable%decay_config(i)%compute ()
    end do
    unstable%integral = sum (unstable%decay_config%integral)
    if (unstable%integral <= 0) then
      call unstable%write ()
      call msg_fatal ("Decay configuration: computed total width is zero")
    end if
    unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
    unstable%rel_error = unstable%abs_error / unstable%integral
    call unstable%selector%init (unstable%decay_config%integral)
    do i = 1, size (unstable%decay_config)
      unstable%decay_config(i)%weight &
        = unstable%selector%get_weight (i)
    end do
  end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: public>+≡
  public :: unstable_t

<Decays: types>+≡
  type, extends (any_t) :: unstable_t
    private
    type(unstable_config_t), pointer :: config => null ()
    class(rng_t), allocatable :: rng
    integer :: selected_decay = 0
    type(decay_t), dimension(:), allocatable :: decay
  contains

  unstable%selected_decay = unstable%config%selector%select (x)
  call unstable%decay(unstable%selected_decay)%select_chain ()
end subroutine unstable_select_chain

```

Generate a decay event.

```

<Decays: unstable: TBP>+≡
  procedure :: generate => unstable_generate

<Decays: procedures>+≡
  recursive subroutine unstable_generate (unstable)
    class(unstable_t), intent(inout) :: unstable
    call unstable%decay(unstable%selected_decay)%generate ()
  end subroutine unstable_generate

```

### 31.4.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+≡
  type, extends (connected_state_t) :: decay_chain_entry_t
  private
    integer :: index = 0
    type(decay_config_t), pointer :: config => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
    type(decay_chain_entry_t), pointer :: previous => null ()
  end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: public>+≡

```

```

public :: decay_chain_t
<Decays: types>+≡
type :: decay_chain_t
private
type(process_instance_t), pointer :: process_instance => null ()
integer :: selected_term = 0
type(evaluator_t) :: correlated_trace
type(decay_chain_entry_t), pointer :: last => null ()
contains
<Decays: decay chain: TBP>
end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay chain: TBP>≡
procedure :: final => decay_chain_final

<Decays: procedures>+≡
subroutine decay_chain_final (object)
class(decay_chain_t), intent(inout) :: object
type(decay_chain_entry_t), pointer :: entry
do while (associated (object%last))
entry => object%last
object%last => entry%previous
call entry%final ()

                end if
            end select
        end do
    end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

<Decays: decay chain: TBP>+≡

end associate
evt%is_first_event = .false.
end subroutine evt_shower_first_event

```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations is under construction. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid. This procedure directly takes the (MLM) matching into account.

## 31.6 Fixed Order NLO Events

This section deals with the generation of weighted event samples which take into account next-to-leading order corrections. An approach generating unweighted events is not possible here, because negative weights might occur due to subtraction. Note that the events produced this way are not physical in the sense that they will not keep NLO-accuracy when interfaced to a parton shower. They

are rather useful for theoretical consistency checks and a fast estimate of NLO effects.

We generate NLO events in the following way: First, the integration is carried out using the complete divergence-subtracted NLO matrix element. In the subsequent simulation,  $N$ -particle kinematics are generated using  $\mathcal{B} + \mathcal{V} + \mathcal{C}$  as weight. After that, the program loops over all singular regions and for each of them generates an event with  $N + 1$ -particle kinematics. The weight for those events corresponds to the real matrix element  $\mathcal{R}^\alpha$  evaluated at the  $\alpha$ -region's emitter's phase space point, multiplied with  $S_\alpha$ . This procedure is implemented using the `evt_nlo` transform.

```

<evt_nlo.f90>≡
  <File header>

  module evt_nlo

    <Use kinds>
    use constants
    use lorentz
    use diagnostics
    use sm_qcd
    use model_data
    use particles
    use processes
    use process_stacks
    use event_transforms

    use nlo_data, only: sqme_collector_t
    use phs_fks

    <Standard module head>

    <Evt Nlo: public>

    <Evt Nlo: types>

    contains

    <Evt Nlo: procedures>

  end module evt_nlo

```

This event transformation is for the generation of fixed-order NLO events. It takes an event with Born kinematics and creates  $N_\alpha + 1$  modified weighted events. The first one has Born kinematics and its weight is the sum of Born, Real and subtraction matrix elements. The other  $N_\alpha$  events have a weight which is equal to the real matrix element, evaluated with the phase space corresponding to the emitter of the  $\alpha$ -region. All NLO event objects share the same event transformation. For this reason, we save the particle set of the current  $\alpha$ -region in the array `particle_set_radiated`. Otherwise it would be unretrievable if the usual particle set of the event object was used. @

  end subroutine evt_nlo_prepare_new_event

```

The event transform has a variable which counts the number of times it has already been called for one generation point. If `i_evaluation` is zero, this means that `evt_nlo_generate` is called for the first time, so that the generation of an  $N$ -particle event is required. In all other cases, emission events are generated. Note that for the first event, the computed weights are added to `probability`, which at this point is equal to  $\mathcal{B} + \mathcal{V}$ , whereas for all other runs `probability` is replaced. To keep  $\langle \sum w_i \rangle = N \times \sigma$  as it is for weighted LO events, we have to multiply by  $N_{\alpha_r} + 1$  since the cross section is distributed over the real and Born subevents.

### 31.7.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The `safety_factor` reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The `sigma` and `n` values, if nontrivial, allow for reweighting the events according to the requested `norm_mode`.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the `event_expr_t` objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

*(Events: types)*≡

```
type :: event_config_t
  logical :: unweighted = .false.
  integer :: norm_mode = NORM_UNDEFINED
  integer :: factorization_mode = FM_IGNORE_HELICITY

```

### 31.7.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event.base` module. The core manages the main (dressed) particle set pointer and the current values for weights and `sqme`. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

The `sqme` and `weight` values mirror corresponding values in the `expr` sub-object. The idea is that when generating or reading events, the event record is filled first, then the `expr` object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the `expr` subobject. In particular, evaluating the event-selection expression sets the `passed` flag. Furthermore, the `expr` subobject collects data that can be used in the analysis and should be written to file, including copies of `sqme` and `weight`.

```

                class default
                    call evt%write (u, verbose = verb, testflag = testflag)
                end select
                call write_separator (u, 2)
                evt => evt%next
            end do
        else
            call write_separator (u, 2)
        end if
        if (object%expr%subevt_filled) then
            call object%expr%write (u, pacified = testflag)
            call write_separator (u, 2)
        end if
    else
        call write_separator (u, 2)
        write (u, "(1x,A)") "Process instance: [undefined]"
        call write_separator (u, 2)
    end if
end subroutine event_write

```

### 31.7.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode

is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```

<Events: event: TBP>+≡
  procedure :: basic_init => event_init

<Events: procedures>+≡
  subroutine event_init (event, var_list, n_alt)
    class(event_t), intent(out) :: event
    type(var_list_t), intent(in), optional :: var_list
    integer, intent(in), optional :: n_alt
    type(string_t) :: norm_string
    logical :: polarized_events
    if (present (n_alt)) then
      call event%base_init (n_alt)
      call event%expr%init (n_alt)
    else
      call event%base_init (0)
    end if
    if (present (var_list)) then
      event%config%unweighted = var_list%get_lval (&
        var_str ("?unweighted"))
      norm_string = var_list%get_sval (&
        var_str ("sample_normalization"))
      event%config%norm_mode = &
        event_normalization_mode (norm_string, event%config%unweighted)
      polarized_events = &
        var_list%get_lval (var_str ("?polarized_events"))
      if (polarized_events) then
        event%config%factorization_mode = FM_SELECT_HELICITY
      else
        event%config%factorization_mode = FM_IGNORE_HELICITY
      end if
      if (event%config%unweighted) then
        event%config%safety_factor = var_list%get_rval (&
          var_str ("safety_factor"))
      end if
    else
      event%config%norm_mode = NORM_SIGMA
    end if
    allocate (evt_trivial_t :: event%transform_first)
    event%transform_last => event%transform_first
  end subroutine event_init

```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

```

<Events: event: TBP>+≡
  procedure :: set_sigma => event_set_sigma
  procedure :: set_n => event_set_n

<Events: procedures>+≡
  elemental subroutine event_set_sigma (event, sigma)

```

```

class(event_t), intent(inout) :: event
real(default), intent(in) :: sigma
event%config%sigma = sigma
end subroutine event_set_sigma

elemental subroutine event_set_n (event, n)
class(event_t), intent(inout) :: event
integer, intent(in) :: n
event%config%n = n
end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
  procedure :: import_transform => event_import_transform

<Events: procedures>+≡
  subroutine event_import_transform (event, evt)
    class(event_t), intent(inout) :: event
    class(evt_t), intent(inout), pointer :: evt
    event%transform_last%next => evt
    evt%previous => event%transform_last
    event%transform_last => evt
    evt => null ()
  end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to **event** subobjects, therefore the **target** attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

<Events: procedures>+≡
  subroutine event_connect (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(string_t) :: id
    integer :: num_id
    class(evt_t), pointer :: evt

```

```

event%process => process_instance%process
event%instance => process_instance
id = event%process%get_id ()
if (id /= "") call event%expr%set_process_id (id)
num_id = event%process%get_num_id ()
if (num_id /= 0) call event%expr%set_process_num_id (num_id)
call event%expr%setup_vars (event%process%get_sqrts ())
call event%expr%link_var_list (event%process%get_var_list_ptr ())
call event%process%make_rng (event%rng)
evt => event%transform_first
do while (associated (evt))
    call evt%connect (process_instance, model, process_stack)
    evt => evt%next
end do
end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
    procedure :: set_selection => event_set_selection
    procedure :: set_reweight => event_set_reweight
    procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡
    subroutine event_set_selection (event, ef_selection)
        class(event_t), intent(inout) :: event
        class(expr_factory_t), intent(in) :: ef_selection
        allocate (event%config%ef_selection, source = ef_selection)
    end subroutine event_set_selection

    subroutine event_set_reweight (event, ef_reweight)
        class(event_t), intent(inout) :: event
        class(expr_factory_t), intent(in) :: ef_reweight
        allocate (event%config%ef_reweight, source = ef_reweight)
    end subroutine event_set_reweight

    subroutine event_set_analysis (event, ef_analysis)
        class(event_t), intent(inout) :: event
        class(expr_factory_t), intent(in) :: ef_analysis
        allocate (event%config%ef_analysis, source = ef_analysis)
    end subroutine event_set_analysis

```

Create evaluation trees from the parse trees. The `target` attribute is required because the expressions contain pointers to event subobjects.

```

<Events: event: TBP>+≡
    procedure :: setup_expressions => event_setup_expressions

<Events: procedures>+≡
    subroutine event_setup_expressions (event)
        class(event_t), intent(inout), target :: event
        call event%expr%setup_selection (event%config%ef_selection)
        call event%expr%setup_analysis (event%config%ef_analysis)
        call event%expr%setup_reweight (event%config%ef_reweight)
    end subroutine event_setup_expressions

```

### 31.7.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

<Events: event: TBP>+≡
  procedure :: evaluate_transforms => event_evaluate_transforms

<Events: procedures>+≡
  subroutine event_evaluate_transforms (event, r)
    class(event_t), intent(inout) :: event
    real(default), dimension(:), intent(in), optional :: r
    class(evt_t), pointer :: evt
    real(default) :: sigma_over_sqme
    integer :: i_term
    call msg_debug (D_TRANSFORMS, "event_evaluate_transforms")
    call event%discard_particle_set ()
    call event%check ()
    if (event%instance%is_complete_event ()) then
      call event%instance%select_i_term (i_term)
      event%selected_i_term = i_term
      evt => event%transform_first
      do while (associated (evt))
        call evt%prepare_new_event &
          (event%selected_i_mci, event%selected_i_term)
        evt => evt%next
      end do
      evt => event%transform_first
      call msg_debug (D_TRANSFORMS, "Before event transformations")

      call msg_debug (D_TRANSFORMS, "event%sqme_prc", event%sqme_prc)
      do while (associated (evt))
        if (evt%only_weighted_events) then
          sigma_over_sqme = event%weight_prc / event%sqme_prc
          call evt%generate_weighted (event%sqme_prc)
          event%weight_prc = sigma_over_sqme * event%sqme_prc
        else
          call evt%generate_unweighted ()
        end if
        if (signal_is_pending ()) return
        call evt%make_particle_set (event%config%factorization_mode, &
          event%config%keep_correlations)
      end do
    end if
  end subroutine

```

```

        if (signal_is_pending ()) return
        if (.not. evt%particle_set_exists) exit
        evt => evt%next
    end do
    evt => event%transform_last
    if (associated (evt) .and. evt%particle_set_exists) then
        if (event%is_nlo_event()) then
            select type (evt)
            type is (evt_nlo_t)
                call evt%build_radiated_particle_set (event%i_event+1)
                call event%link_particle_set &
                    (evt%particle_set_radiated(event%i_event+1))
            end select
        else
            call event%link_particle_set (evt%particle_set)
        end if
    end if
    call msg_debug (D_TRANSFORMS, "After event transformations")
    call msg_debug (D_TRANSFORMS, "event%weight_prc", event%weight_prc)
    call msg_debug (D_TRANSFORMS, "event%sqme_prc", event%sqme_prc)
end if
end subroutine event_evaluate_transforms

```

Evaluate the event-related expressions, given a valid `particle_set`. If `update_sqme` is set, we use the process instance for the `sqme_prc` value. The `sqme_ref` value is always taken from the event record.

Note: without the explicit `particle_set` pointer, some gfortran 4.8 version corrupts its memory.

```

<Events: event: TBP>+≡
    procedure :: evaluate_expressions => event_evaluate_expressions

<Events: procedures>+≡
    subroutine event_evaluate_expressions (event)
        class(event_t), intent(inout) :: event
        type(particle_set_t), pointer :: particle_set
        if (event%has_valid_particle_set ()) then
            particle_set => event%get_particle_set_ptr ()
            call event%expr%fill_subevt (particle_set)
        end if
        if (event%weight_ref_is_known ()) then
            call event%expr%set (weight_ref = event%get_weight_ref ())
        end if
        if (event%weight_prc_is_known ()) then
            call event%expr%set (weight_prc = event%get_weight_prc ())
        end if
        if (event%excess_prc_is_known ()) then
            call event%expr%set (excess_prc = event%get_excess_prc ())
        end if
        if (event%sqme_ref_is_known ()) then
            call event%expr%set (sqme_ref = event%get_sqme_ref ())
        end if
        if (event%sqme_prc_is_known ()) then
            call event%expr%set (sqme_prc = event%get_sqme_prc ())
        end if
    end if

```

```

    if (event%has_valid_particle_set ()) then
        call event%expr%evaluate &
            (event%passed, event%reweight, event%analysis_flag)
        event%selection_evaluated = .true.
    end if
end subroutine event_evaluate_expressions

```

Report the result of the selection evaluation.

```

<Events: event: TBP>+≡
    procedure :: passed_selection => event_passed_selection

<Events: procedures>+≡
    function event_passed_selection (event) result (flag)
        class(event_t), intent(in) :: event
        logical :: flag
        flag = event%passed
    end function event_passed_selection

```

Set alternate sqme and weight arrays. This should be merged with the previous routine, if the expressions are allowed to refer to these values.

```

<Events: event: TBP>+≡
    procedure :: store_alt_values => event_store_alt_values

<Events: procedures>+≡
    subroutine event_store_alt_values (event)
        class(event_t), intent(inout) :: event
        if (event%weight_alt_is_known ()) then
            call event%expr%set (weight_alt = event%get_weight_alt ())
        end if
        if (event%sqme_alt_is_known ()) then
            call event%expr%set (sqme_alt = event%get_sqme_alt ())
        end if
    end subroutine event_store_alt_values

```

### 31.7.5 Reset to empty state

Applying this, current event contents are marked as incomplete but are not deleted. In particular, the initialization is kept.

```

<Events: event: TBP>+≡
    procedure :: reset => event_reset

<Events: procedures>+≡
    subroutine event_reset (event)
        class(event_t), intent(inout) :: event
        class(evt_t), pointer :: evt
        call event%base_reset ()
        event%selected_i_mci = 0
        event%selected_i_term = 0
        event%selected_channel = 0
        event%is_complete = .false.
        call event%expr%reset ()
        event%selection_evaluated = .false.
    end subroutine event_reset

```

```

event%passed = .false.
event%analysis_flag = .false.
if (associated (event%instance)) then
    call event%instance%reset (reset_mci = .true.)
end if
if (allocated (event%alpha_qcd_forced)) deallocate (event%alpha_qcd_forced)
if (allocated (event%scale_forced)) deallocate (event%scale_forced)
evt => event%transform_first
do while (associated (evt))
    call evt%reset ()
    evt => evt%next
end do
end subroutine event_reset

```

### 31.7.6 Squared Matrix Element and Weight

Transfer the result of the process instance calculation to the event record header.

```

<Events: event: TBP>+≡
    procedure :: import_instance_results => event_import_instance_results

<Events: procedures>+≡
    subroutine event_import_instance_results (event)
        class(event_t), intent(inout) :: event
        if (associated (event%instance)) then
            if (event%instance%has_evaluated_trace ()) then
                call event%set ( &
                    sqme_prc = event%instance%get_sqme (), &
                    weight_prc = event%instance%get_weight (), &
                    excess_prc = event%instance%get_excess () &
                )
            end if
        end if
    end subroutine event_import_instance_results

```

Duplicate the instance result / the reference result in the event record.

```

<Events: event: TBP>+≡
    procedure :: accept_sqme_ref => event_accept_sqme_ref
    procedure :: accept_sqme_prc => event_accept_sqme_prc
    procedure :: accept_weight_ref => event_accept_weight_ref
    procedure :: accept_weight_prc => event_accept_weight_prc

<Events: procedures>+≡
    subroutine event_accept_sqme_ref (event)
        class(event_t), intent(inout) :: event
        if (event%sqme_ref_is_known ()) then
            call event%set (sqme_prc = event%get_sqme_ref ())
        end if
    end subroutine event_accept_sqme_ref

    subroutine event_accept_sqme_prc (event)
        class(event_t), intent(inout) :: event
        if (event%sqme_prc_is_known ()) then
            call event%set (sqme_ref = event%get_sqme_prc ())
        end if
    end subroutine event_accept_sqme_prc

```

```

end if
end subroutine event_accept_sqme_prc

subroutine event_accept_weight_ref (event)
class(event_t), intent(inout) :: event
if (event%weight_ref_is_known ()) then
call event%set (weight_prc = event%get_weight_ref ())
end if
end subroutine event_accept_weight_ref

subroutine event_accept_weight_prc (event)
class(event_t), intent(inout) :: event
if (event%weight_prc_is_known ()) then
call event%set (weight_ref = event%get_weight_prc ())
end if
end subroutine event_accept_weight_prc

```

Update the weight normalization, just after generation. Unweighted and weighted events are generated with a different default normalization. The intended normalization is stored in the configuration record.

```

<Events: event: TBP>+≡
  procedure :: update_normalization => event_update_normalization

<Events: procedures>+≡
  subroutine event_update_normalization (event, mode_ref)
class(event_t), intent(inout) :: event
integer, intent(in), optional :: mode_ref
integer :: mode_old
real(default) :: weight, excess
if (present (mode_ref)) then
mode_old = mode_ref
else if (event%config%unweighted) then
mode_old = NORM_UNIT
else
mode_old = NORM_SIGMA
end if
weight = event%get_weight_prc ()
call event_normalization_update (weight, &
event%config%sigma, event%config%n, &
mode_new = event%config%norm_mode, &
mode_old = mode_old)
call event%set_weight_prc (weight)
excess = event%get_excess_prc ()
call event_normalization_update (excess, &
event%config%sigma, event%config%n, &
mode_new = event%config%norm_mode, &
mode_old = mode_old)
call event%set_excess_prc (excess)
end subroutine event_update_normalization

```

The event is complete if it has a particle set plus valid entries for the sqme and weight values.

```

<Events: event: TBP>+≡

```

```

procedure :: check => event_check
<Events: procedures>+≡
subroutine event_check (event)
class(event_t), intent(inout) :: event
event%is_complete = event%has_valid_particle_set () &
.and. event%sqme_ref_is_known () &
.and. event%sqme_prc_is_known () &
.and. event%weight_ref_is_known () &
.and. event%weight_prc_is_known ()
if (event%get_n_alt () /= 0) then
event%is_complete = event%is_complete &
.and. event%sqme_alt_is_known () &
.and. event%weight_alt_is_known ()
end if
end subroutine event_check

```

### 31.7.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we accept the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
procedure :: generate => event_generate
<Events: procedures>+≡
subroutine event_generate (event, i_mci, r, i_nlo)
class(event_t), intent(inout) :: event
integer, intent(in) :: i_mci
real(default), dimension(:), intent(in), optional :: r
integer, intent(in), optional :: i_nlo
logical :: generate_new = .true.
if (present (i_nlo)) generate_new = (i_nlo == 1)
if (generate_new) call event%reset ()
event%selected_i_mci = i_mci
if (event%config%unweighted) then
call event%process%generate_unweighted_event (event%instance, i_mci)
if (signal_is_pending ()) return
call event%instance%evaluate_event_data ()
call event%instance%normalize_weight ()
else
if (event%is_nlo_event()) &
call event%process%deactivate_real_component ()
if (generate_new) call event%process%generate_weighted_event (event%instance, i_mci)
if (signal_is_pending ()) return
call event%instance%evaluate_event_data ()
end if

```

```

event%selected_channel = event%instance%get_channel ()
call event%import_instance_results ()
call event%accept_sqme_prc ()
call event%update_normalization ()
call event%accept_weight_prc ()
call event%evaluate_transforms (r)
if (signal_is_pending ()) return
call event%check ()
end subroutine event_generate

```

Get a copy of the particle set belonging to the hard process.

```

<Events: event: TBP>+≡
  procedure :: get_hard_particle_set => event_get_hard_particle_set

<Events: procedures>+≡
  subroutine event_get_hard_particle_set (event, pset)
    class(event_t), intent(in) :: event
    type(particle_set_t), intent(out) :: pset
    class(evt_t), pointer :: evt
    evt => event%transform_first
    pset = evt%particle_set
  end subroutine event_get_hard_particle_set

```

### 31.7.8 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
  procedure :: select => event_select

<Events: procedures>+≡
  subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
    if (associated (event%instance)) then
      event%selected_i_mci = i_mci
      event%selected_i_term = i_term
      event%selected_channel = channel
    else
      event%selected_i_mci = 0
      event%selected_i_term = 0
      event%selected_channel = 0
    end if
  end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. The event reader may either read in the transformed event separately, or apply all event transforms to the hard particle set to (re)generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call **reset** on them.

```

<Events: event: TBP>+≡

```

```

    procedure :: set_hard_particle_set => event_set_hard_particle_set
  <Events: procedures>+≡

      else
        allocate (event%scale_forced, source = scale)
      end if
    end subroutine event_set_scale_forced

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

## 31.8 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the **events** module which provides the concrete implementation of **event\_base**. The other I/O formats access only the methods that are defined in **event\_base**.

```

<eio_raw.f90>≡
  <File header>

  module eio_raw

    <Use kinds>
    <Use strings>
    use io_units
    use diagnostics
    use model_data
    use particles
    use event_base
    use eio_data
    use eio_base
    use events

    <Standard module head>

    <EIO raw: public>

    <EIO raw: parameters>

    <EIO raw: types>

    contains

    <EIO raw: procedures>

  end module eio_raw

```

### 31.8.1 File Format Version

This is the current default file version.

```

<EIO raw: parameters>≡

```

```
integer, parameter :: CURRENT_FILE_VERSION = 2
```

The user may change this number; this should force some compatibility mode for reading and writing. In any case, the file version stored in a event file that we read has to match the expected file version.

History of version numbers:

1. Format for WHIZARD 2.2.0 to 2.2.3. No version number stored in the raw file.
2. Format from 2.2.4 on. File contains version number. The file contains the transformed particle set (if applicable) after the hard-process particle set.

### 31.8.2 Type

Note the file version number. The default may be reset during initialization, which should enforce some compatibility mode.

```
<EIO raw: public>≡
  public :: eio_raw_t

<EIO raw: types>≡
  type, extends (eio_t) :: eio_raw_t
    logical :: reading = .false.
    logical :: writing = .false.
    integer :: unit = 0
    integer :: norm_mode = NORM_UNDEFINED
    real(default) :: sigma = 1
    integer :: n = 1
    integer :: n_alt = 0
    logical :: check = .false.
    integer :: file_version = CURRENT_FILE_VERSION
  contains
    <EIO raw: eio raw: TBP>
  end type eio_raw_t
```

Output. This is not the actual event format, but a readable account of the current object status.

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The

caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

The `passed` flag is not written. This allow us to apply different selection criteria upon rereading.

## 31.9 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```

<user_files.f90>≡
  <File header>

  module user_files

    <Use strings>
    use io_units
    use diagnostics
    use ifiles
    use analysis

    <Standard module head>

    <User files: public>

    <User files: types>

    <User files: interfaces>

    contains

    <User files: procedures>

```

```
end module user_files
```

### 31.9.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡
  type :: file_t
    private
    type(string_t) :: name
    integer :: unit = -1
    logical :: reading = .false.
    logical :: writing = .false.
    type(file_t), pointer :: prev => null ()
    type(file_t), pointer :: next => null ()
  end type file_t
```

The initializer opens the file.

```
<User files: procedures>≡
  subroutine file_init (file, name, action, status, position)
    type(file_t), intent(out) :: file
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    file%unit = free_unit ()
    file%name = name
    open (unit = file%unit, file = char (file%name), &
          action = action, status = status, position = position)
    select case (action)
    case ("read")
      file%reading = .true.
    case ("write")
      file%writing = .true.
    case ("readwrite")
      file%reading = .true.
      file%writing = .true.
    end select
  end subroutine file_init
```

The finalizer closes it.

```
<User files: procedures>+≡
  subroutine file_final (file)
    type(file_t), intent(inout) :: file
    close (unit = file%unit)
    file%unit = -1
  end subroutine file_final
```

Check if a file is open with correct status.

```
<User files: procedures>+≡
  function file_is_open (file, action) result (flag)
    logical :: flag
    type(file_t), intent(in) :: file
```

```

character(*), intent(in) :: action
select case (action)
case ("read")
    flag = file%reading
case ("write")
    flag = file%writing
case ("readwrite")
    flag = file%reading .and. file%writing
case default
    call msg_bug ("Checking file '" // char (file%name) &
        // "' : illegal action specifier")
end select
end function file_is_open

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the advancing option.

*<User files: procedures>+≡*

```

subroutine file_write_string (file, string, advancing)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: string
    logical, intent(in), optional :: advancing
    if (file%writing) then
        if (present (string)) then
            if (present (advancing)) then
                if (advancing) then
                    write (file%unit, "(A)" char (string))
                else
                    write (file%unit, "(A)", advance="no") char (string)
                end if
            else
                write (file%unit, "(A)" char (string))
            end if
        else
            write (file%unit, *)
        end if
    else
        call msg_error ("Writing to file: File '" // char (file%name) &
            // "' is not open for writing.")
    end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

*<User files: procedures>+≡*

```

subroutine file_write_ifile (file, ifile)
    type(file_t), intent(in) :: file
    type(ifile_t), intent(in) :: ifile
    type(line_p) :: line
    call line_init (line, ifile)
    do while (line_is_associated (line))
        call file_write_string (file, line_get_string_advance (line))
    end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
subroutine file_write_analysis (file, tag)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: tag
  if (file%writing) then
    if (present (tag)) then
      call analysis_write (tag, unit = file%unit)
    else
      call analysis_write (unit = file%unit)
    end if
  else
    call msg_error ("Writing analysis to file: File ' " // char (file%name) &
      // "' is not open for writing.")
  end if
end subroutine file_write_analysis

```

### 31.9.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
public :: file_list_t

<User files: types>+≡
type :: file_list_t
  type(file_t), pointer :: first => null ()
  type(file_t), pointer :: last => null ()
end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
public :: file_list_final

<User files: procedures>+≡
subroutine file_list_final (file_list)
  type(file_list_t), intent(inout) :: file_list
  type(file_t), pointer :: current
  do while (associated (file_list%first))
    current => file_list%first
    file_list%first => current%next
    call file_final (current)
    deallocate (current)
  end do
  file_list%last => null ()
end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```

<User files: procedures>+≡
function file_list_get_file_ptr (file_list, name) result (current)
  type(file_t), pointer :: current
  type(file_list_t), intent(in) :: file_list

```

```

    type(string_t), intent(in) :: name
    current => file_list%first
    do while (associated (current))
        if (current%name == name) return
        current => current%next
    end do
end function file_list_get_file_ptr

```

Check if a file is open, public version:

```

<User files: public>+≡
    public :: file_list_is_open

<User files: procedures>+≡
    function file_list_is_open (file_list, name, action) result (flag)
        logical :: flag
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            flag = file_is_open (current, action)
        else
            flag = .false.
        end if
    end function file_list_is_open

```

Append a new file entry, i.e., open this file. Error if it is already open.

```

<User files: public>+≡
    public :: file_list_open

<User files: procedures>+≡
    subroutine file_list_open (file_list, name, action, status, position)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action, status, position
        type(file_t), pointer :: current
        if (.not. associated (file_list_get_file_ptr (file_list, name))) then
            allocate (current)
            call msg_message ("Opening file '" // char (name) // "' for output")
            call file_init (current, name, action, status, position)
            if (associated (file_list%last)) then
                file_list%last%next => current
                current%prev => file_list%last
            else
                file_list%first => current
            end if
            file_list%last => current
        else
            call msg_error ("Opening file: File '" // char (name) &
                // "' is already open.")
        end if
    end subroutine file_list_open

```

Delete a file entry, i.e., close this file. Error if it is not open.

```
<User files: public>+≡
    public :: file_list_close

<User files: procedures>+≡
    subroutine file_list_close (file_list, name)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            if (associated (current%prev)) then
                current%prev%next => current%next
            else
                file_list%first => current%next
            end if
            if (associated (current%next)) then
                current%next%prev => current%prev
            else
                file_list%last => current%prev
            end if
            call msg_message ("Closing file '" // char (name) // "' for output")
            call file_final (current)
            deallocate (current)
        else
            call msg_error ("Closing file: File '" // char (name) &
                // "' is not open.")
        end if
    end subroutine file_list_close
```

Write a string to file. Error if it is not open.

```
<User files: public>+≡
    public :: file_list_write

<User files: interfaces>≡
    interface file_list_write
        module procedure file_list_write_string
        module procedure file_list_write_ifile
    end interface

<User files: procedures>+≡
    subroutine file_list_write_string (file_list, name, string, advancing)
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        type(string_t), intent(in), optional :: string

### 31.10.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn,

is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

### 31.10.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()
    type(parse_node_t), pointer :: fac_scale_expr => null ()
    type(parse_node_t), pointer :: ren_scale_expr => null ()
    type(parse_node_t), pointer :: weight_expr => null ()
    type(parse_node_t), pointer :: selection_lexpr => null ()
    type(parse_node_t), pointer :: reweight_expr => null ()
    type(parse_node_t), pointer :: analysis_lexpr => null ()
    type(parse_node_p), dimension(:), allocatable :: alt_setup
  contains
    <RT data: rt parse nodes: TBP>
  end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

```

```

<RT data: procedures>≡
subroutine rt_parse_nodes_clear (rt_pn, name)
  class(rt_parse_nodes_t), intent(inout) :: rt_pn
  type(string_t), intent(in) :: name
  select case (char (name))
  case ("cuts")
    rt_pn%cuts_lexpr => null ()
  case ("scale")

### 31.10.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init

<RT data: procedures>+≡
  subroutine rt_data_local_init (local, global, env)
    class(rt_data_t), intent(inout), target :: local
    type(rt_data_t), intent(in), target :: global
    integer, intent(in), optional :: env
    local%context => global
    call local%process_stack%link (global%process_stack)
    call local%process_stack%init_var_list (local%var_list)
    call local%process_stack%link_var_list (global%var_list)
    call var_list_append_string &
      (local%var_list, var_str ("model_name"), var_str (""), &
      intrinsic=.true.)
    call local%init_pointer_variables ()
    local%fallback_model => global%fallback_model
    local%radiation_model => global%radiation_model
    local%os_data = global%os_data
    local%logfile = global%logfile
    call local%model_list%link (global%model_list)
    local%model => global%model
    if (associated (local%model)) then
      call local%model%link_var_list (local%var_list)
    end if
    if (allocated (global%event_callback)) then
      allocate (local%event_callback, source = global%event_callback)
    end if
  end subroutine rt_data_local_init

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
  procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: procedures>+≡
  subroutine rt_data_init_pointer_variables (local)
    class(rt_data_t), intent(inout), target :: local
    logical, target, save :: known = .true.
    call var_list_append_string_ptr &
      (local%var_list, var_str ("fc"), local%os_data%fc, known, &
        intrinsic=.true.)
    call var_list_append_string_ptr &
      (local%var_list, var_str ("fcflags"), local%os_data%fcflags, known, &
        intrinsic=.true.)
  end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: activate => rt_data_activate

<RT data: procedures>+≡
  subroutine rt_data_activate (local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), pointer :: global
    global => local%context
    if (associated (global)) then

    call local%var_list%set_string (var_str ("$model_name"), &
        var_str (""), is_known = .false.)
end if
end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
    procedure :: deactivate => rt_data_deactivate

<RT data: procedures>+≡
    subroutine rt_data_deactivate (local, global, keep_local)
        class(rt_data_t), intent(inout), target :: local
        class(rt_data_t), intent(inout), optional, target :: global
        logical, intent(in), optional :: keep_local
        type(string_t) :: global_model, local_model
        logical :: same_model, delete
        delete = .true.; if (present (keep_local)) delete = .not. keep_local
        if (present (global)) then
            if (associated (global%model) .and. associated (local%model)) then
                global_model = global%model%get_name ()
                local_model = local%model%get_name ()
                same_model = global_model == local_model
            else
                same_model = .false.
            end if
            if (delete) then
                call local%process_stack%clear ()
                call local%unselect_model ()
                call local%unset_values ()
            else if (associated (local%model)) then
                call local%ensure_model_copy ()
            end if
        end if
    end subroutine

```

```

        end if
        if (.not. same_model .and. global_model /= "") then
            call msg_message ("Restoring model '" // char (global_model) // "'")
        end if
        if (associated (global%model)) then
            call global%model%link_var_list (global%var_list)
        end if
        call global%restore_globals (local)
    else
        call local%unselect_model ()
    end if
end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
    procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
    subroutine rt_data_copy_globals (global, local)
        class(rt_data_t), intent(in) :: global
        class(rt_data_t), intent(inout) :: local
        local%prclib_stack = global%prclib_stack
    end subroutine rt_data_copy_globals

```

This restores global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡
    procedure :: restore_globals => rt_data_restore_globals

<RT data: procedures>+≡
    subroutine rt_data_restore_globals (global, local)
        class(rt_data_t), intent(inout) :: global
        class(rt_data_t), intent(in) :: local
        global%prclib_stack = local%prclib_stack
    end subroutine rt_data_restore_globals

```

### 31.10.8 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
    procedure :: final => rt_data_global_final

<RT data: procedures>+≡
    subroutine rt_data_global_final (global)
        class(rt_data_t), intent(inout) :: global
        call global%process_stack%final ()
        call global%prclib_stack%final ()
        call global%model_list%final ()
        call global%var_list%final (follow_link=.false.)
        if (associated (global%out_files)) then

```

```

        call file_list_final (global%out_files)
        deallocate (global%out_files)
    end if
end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡
    procedure :: local_final => rt_data_local_final

<RT data: procedures>+≡
    subroutine rt_data_local_final (local)
        class(rt_data_t), intent(inout) :: local
        call local%process_stack%clear ()
        call local%model_list%final ()
        call local%var_list%final (follow_link=.false.)
    end subroutine rt_data_local_final

```

### 31.10.9 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
    procedure :: read_model => rt_data_read_model

<RT data: procedures>+≡
    subroutine rt_data_read_model (global, name, model)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name
        type(model_t), pointer, intent(out) :: model
        type(string_t) :: filename
        filename = name // ".mdl"
        call global%model_list%read_model &
            (name, filename, global%os_data, model)
    end subroutine rt_data_read_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
    procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: procedures>+≡
    subroutine rt_data_init_fallback_model (global, name, filename)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name, filename
        call global%model_list%read_model &
            (name, filename, global%os_data, global%fallback_model)

```

```
end subroutine rt_data_init_fallback_model
```

Initialize the radiation model. This model is used by a radiation-generator algorithm which is part of the NLO machinery. It is not supposed to be modified, and the pointer should remain linked to this model.

```
<RT data: rt data: TBP>+≡
  procedure :: init_radiation_model => rt_data_init_radiation_model

<RT data: procedures>+≡
  subroutine rt_data_init_radiation_model (global, name, filename)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name, filename
    call global%model_list%read_model &
      (name, filename, global%os_data, global%radiation_model)
  end subroutine rt_data_init_radiation_model
```

Activate a model: assign the current-model pointer and set the model name in the variable list. If necessary, read the model from file. Link the global variable list to the model variable list.

```
<RT data: rt data: TBP>+≡
  procedure :: select_model => rt_data_select_model

<RT data: procedures>+≡
  subroutine rt_data_select_model (global, name)
    class(rt_data_t), intent(inout), target :: global
    type(string_t), intent(in) :: name
    logical :: same_model
    if (associated (global%model)) then
      same_model = global%model%get_name () == name
    else
      same_model = .false.
    end if
    if (.not. same_model) then
      global%model => global%model_list%get_model_ptr (name)
      if (.not. associated (global%model)) then
        call global%read_model (name, global%model)
        global%model_is_copy = .false.
      else if (associated (global%context)) then
        global%model_is_copy = &
          global%model_list%model_exists (name, follow_link=.false.)
      else
        global%model_is_copy = .false.
      end if
    end if
    if (associated (global%model)) then
      call global%model%link_var_list (global%var_list)
      call global%var_list%set_string (var_str ("$model_name"), &
        name, is_known = .true.)
      call msg_message ("Switching to model '" // char (name) // "'")
    else
      call global%var_list%set_string (var_str ("model_name"), &
        var_str (""), is_known = .false.)
    end if
```

```
end subroutine rt_data_select_model
```

Remove the model link and unset the model name variable.

```
<RT data: rt data: TBP>+≡
  procedure :: unselect_model => rt_data_unselect_model

<RT data: procedures>+≡
  subroutine rt_data_unselect_model (global)
    class(rt_data_t), intent(inout), target :: global
    if (associated (global%model)) then
      global%model => null ()
      global%model_is_copy = .false.
      call global%var_list%set_string (var_str ("model_name"), &
        var_str (""), is_known = .false.)
    end if
  end subroutine rt_data_unselect_model
```

Create a copy of the currently selected model and append it to the local model list. The model pointer is redirected to the copy. (Not applicable for the global model list, those models will be modified in-place.)

```
<RT data: rt data: TBP>+≡
  procedure :: ensure_model_copy => rt_data_ensure_model_copy

<RT data: procedures>+≡
  subroutine rt_data_ensure_model_copy (global)
    class(rt_data_t), intent(inout), target :: global
    if (associated (global%context)) then
      if (.not. global%model_is_copy) then
        call global%model_list%append_copy (global%model, global%model)
        global%model_is_copy = .true.
        call global%model%link_var_list (global%var_list)
      end if
    end if
  end subroutine rt_data_ensure_model_copy
```

Modify a model variable. The update mechanism will ensure that the model parameter set remains consistent. This has to take place in a local copy of the current model. If there is none yet, create one.

```
<RT data: rt data: TBP>+≡
  procedure :: model_set_real => rt_data_model_set_real

<RT data: procedures>+≡
  subroutine rt_data_model_set_real (global, name, rval, verbose, pacified)
    class(rt_data_t), intent(inout), target :: global
    type(string_t), intent(in) :: name
    real(default), intent(in) :: rval
    logical, intent(in), optional :: verbose, pacified
    call global%ensure_model_copy ()
    call global%model%set_real (name, rval, verbose, pacified)
  end subroutine rt_data_model_set_real
```

Modify particle properties. This has to take place in a local copy of the current model. If there is none yet, create one.

```

<RT data: rt data: TBP>+≡
  procedure :: modify_particle => rt_data_modify_particle

<RT data: procedures>+≡
  subroutine rt_data_modify_particle &

      end if
    end if
  end subroutine rt_data_modify_particle

```

### 31.10.10 Managing Variables

Return a pointer to the currently active variable list. If there is no model, this is the global variable list. If there is one, it is the model variable list, which should be linked to the former.

```

<RT data: rt data: TBP>+≡
  procedure :: get_var_list_ptr => rt_data_get_var_list_ptr

<RT data: procedures>+≡
  function rt_data_get_var_list_ptr (global) result (var_list)
    class(rt_data_t), intent(in), target :: global
    type(var_list_t), pointer :: var_list
    if (associated (global%model)) then
      var_list => global%model%get_var_list_ptr ()
    else
      var_list => global%var_list
    end if
  end function rt_data_get_var_list_ptr

```

Initialize a local variable: append it to the current variable list. No initial value, yet.

```

<RT data: rt data: TBP>+≡
  procedure :: append_log => rt_data_append_log
  procedure :: append_int => rt_data_append_int
  procedure :: append_real => rt_data_append_real
  procedure :: append_cmplx => rt_data_append_cmplx
  procedure :: append_subevt => rt_data_append_subevt
  procedure :: append_pdg_array => rt_data_append_pdg_array
  procedure :: append_string => rt_data_append_string

## Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```

<RT data: test auxiliary>≡

## 31.11 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

This module provides no new types, just procedures.

```

### 31.11.1 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable.

Note: `core_def` has `intent(inout)` because gfortran 4.7.1 crashes for `intent(out)`.

*<Dispatch: public>*≡

```
public :: dispatch_core_def
```

*<Dispatch: procedures>*≡

```
subroutine dispatch_core_def (core_def, prt_in, prt_out, &  
                             global, id, nlo_type)
```

```
class(prc_core_def_t), allocatable, intent(inout) :: core_def  
type(string_t), dimension(:), intent(in) :: prt_in  
type(string_t), dimension(:), intent(in) :: prt_out  
type(rt_data_t), intent(in) :: global  
type(string_t), intent(in), optional :: id  
integer, intent(in), optional :: nlo_type  
type(string_t) :: method  
type(string_t) :: model_name  
type(string_t) :: restrictions  
logical :: openmp_support  
logical :: report_progress  
logical :: diags, diags_color  
type(string_t) :: extra_options  
type(model_t), pointer :: model
```

```
model => global%model  
associate (var_list => global%get_var_list_ptr ())  
  method = var_list%get_sval (var_str (" $method"))  
  if (associated (model)) then

```

### 31.11.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```

<Dispatch: public>+≡
    public :: dispatch_core

<Dispatch: procedures>+≡
    subroutine dispatch_core (core, core_def, model, &
        helicity_selection, qcd, use_color_factors)

    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_def_t), intent(in) :: core_def

```

```

class(model_data_t), intent(in), target, optional :: model
type(helicity_selection_t), intent(in), optional :: helicity_selection
type(qcd_t), intent(in), optional :: qcd
logical, intent(in), optional :: use_color_factors

select type (core_def)
type is (prc_test_def_t)
    allocate (test_t :: core)
type is (template_me_def_t)
    allocate (prc_template_me_t :: core)
    select type (core)
    type is (prc_template_me_t)
        call core%set_parameters (model)
    end select
class is (omega_def_t)
    if (.not. allocated (core)) allocate (prc_omega_t :: core)
    select type (core)
    type is (prc_omega_t)
        call core%set_parameters (model, &
            helicity_selection, qcd, use_color_factors)
    end select
type is (gosam_def_t)
    if (.not. allocated (core)) allocate (prc_gosam_t :: core)
    select type (core)
    type is (prc_gosam_t)
        call core%set_parameters (qcd, use_color_factors)
    end select
type is (openloops_def_t)
    if (.not. allocated (core)) allocate (prc_openloops_t :: core)
    select type (core)
    type is (prc_openloops_t)
        call core%set_parameters (qcd, use_color_factors)
    end select
type is (user_defined_test_def_t)
    if (.not. allocated (core)) allocate (prc_user_defined_test_t :: core)
    select type (core)
    type is (prc_user_defined_test_t)
        call core%set_parameters (qcd, use_color_factors)
    end select
type is (threshold_def_t)
    if (.not. allocated (core)) allocate (prc_threshold_t :: core)
    select type (core)
    type is (prc_threshold_t)
        call core%set_parameters (qcd, use_color_factors, model)
    end select
class default
    call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

### 31.11.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

*<Dispatch: public>+≡*

```
public :: dispatch_core_update
public :: dispatch_core_restore
```

*<Dispatch: procedures>+≡*

```
subroutine dispatch_core_update (core, model, helicity_selection, qcd, &
    saved_core)
```

```
class(prc_core_t), allocatable, intent(inout) :: core
class(model_data_t), intent(in), optional, target :: model
type(helicity_selection_t), intent(in), optional :: helicity_selection
type(qcd_t), intent(in), optional :: qcd
class(prc_core_t), allocatable, intent(inout), optional :: saved_core
```

```
if (present (saved_core)) then
    allocate (saved_core, source = core)
end if
select type (core)
type is (test_t)
type is (prc_omega_t)
    call core%set_parameters (model, helicity_selection, qcd)
    call core%activate_parameters ()
type is (prc_gosam_t)
    call msg_message ("dispatch core restore: Gosam implementation not present yet!")
class default
    call msg_bug ("Process core update: unexpected process definition type")
end select
end subroutine dispatch_core_update
```

```
subroutine dispatch_core_restore (core, saved_core)
```

```
class(prc_core_t), allocatable, intent(inout) :: core
class(prc_core_t), allocatable, intent(inout) :: saved_core

call move_alloc (from = saved_core, to = core)
select type (core)
type is (test_t)
type is (prc_omega_t)
    call core%activate_parameters ()
class default
    call msg_bug ("Process core restore: unexpected process definition type")
end select
end subroutine dispatch_core_restore
```

### 31.11.4 Integrator allocation

Allocate an integrator according to the variable `$integration_method`.

```
(Dispatch: public)+≡
    public :: dispatch_mci

(Dispatch: procedures)+≡
    subroutine dispatch_mci (mci, global, process_id, is_nlo)

        class(mci_t), allocatable, intent(inout) :: mci
        logical, intent(in), optional :: is_nlo
        type(rt_data_t), intent(in) :: global
        type(string_t), intent(in) :: process_id
        type(string_t) :: run_id
        type(string_t) :: integration_method
        type(grid_parameters_t) :: grid_par
        type(history_parameters_t) :: history_par
        logical :: rebuild_grids, check_grid_file, negative_weights, verbose
        logical :: neg_w

        neg_w = .false.; if (present (is_nlo)) neg_w = is_nlo
        integration_method = &
            global%var_list%get_sval (var_str ("integration_method"))
        select case (char (integration_method))
        case ("midpoint")
            allocate (mci_midpoint_t :: mci)
        case ("vamp", "default")
            associate (var_list => global%get_var_list_ptr ())

```

### 31.11.7 Random-number generator

Allocate a random-number generator factory according to the variable `$rng_method`, using the current seed in the global record. We take only the lower 15 bits of the seed, so the actual value fits into a positive 16-bit signed integer.

Since we want to guarantee that all random-number generators in a run are independent, we increment the global seed by one after creating the rng factory. If the user wants to have identical sequences, he can always set the seed manually, before it is used.

```

<Dispatch: public>+≡

```

```

public :: dispatch_rng_factory
<Dispatch: procedures>+=
subroutine dispatch_rng_factory (rng_factory, global, local_input)
  class(rng_factory_t), allocatable, intent(inout) :: rng_factory
  type(rt_data_t), intent(inout), target :: global
  type(rt_data_t), intent(in), target, optional :: local_input
  type(rt_data_t), pointer :: local
  type(string_t) :: rng_method
  integer :: seed
  character(30) :: buffer
  integer(i16) :: s
  if (present (local_input)) then
    local => local_input
  else
    local => global
  end if
  rng_method = &
    local%var_list%get_sval (var_str ("rng_method"))
  seed = &
    local%var_list%get_ival (var_str ("seed"))
  s = int (mod (seed, 32768), i16)
  select case (char (rng_method))
  case ("tao")
    allocate (rng_tao_factory_t :: rng_factory)
    call msg_message ("RNG: Initializing TAO random-number generator")
  case default
    if (associated (dispatch_rng_factory_extra)) then
      call dispatch_rng_factory_extra (rng_factory, global, local_input)
    end if
    if (.not. allocated (rng_factory)) then
      call msg_fatal ("Random-number generator '" &
        // char (rng_method) // "' not implemented")
    end if
  end select
  write (buffer, "(I0)") s
  call msg_message ("RNG: Setting seed for random-number generator to " &
    // trim (buffer))
  call rng_factory%init (s)
  call global%set_int (var_str ("seed"), seed + 1, &
    is_known = .true.)
end subroutine dispatch_rng_factory

```

This is a hook that allows us to inject further handlers for RNG factory objects, in particular a test RNG.

```

<Dispatch: public>+=
public :: dispatch_rng_factory_extra
<Dispatch: variables>=
procedure (dispatch_rng_factory), pointer :: &
  dispatch_rng_factory_extra => null ()

```

### 31.11.8 Structure function configuration data

This data type is a container for transferring structure-function specific data from the `dispatch_sf_data` to the `dispatch_sf_channels` subroutine.

*(Dispatch: public)+≡*

```
public :: sf_prop_t
```

*(Dispatch: types)≡*

```
type :: sf_prop_t
```

```
real(default), dimension(2) :: isr_eps = 1
```

```
end type sf_prop_t
```

Allocate a structure-function configuration object according to the `sf_method` string.

The `sf_prop` object can be used to transfer structure-function specific data up and to the `dispatch_sf_channels` subroutine below, so they can be used for particular mappings.

The `global` object is intent(inout) because the RNG generator seed may change during initialization.

The `pdg_in` array is the array of incoming flavors, corresponding to the upstream structure function or the beam array. This will be checked for the structure function in question and replaced by the outgoing flavors. The `pdg_prc` array is the array of incoming flavors (beam index, component index) for the hard process.

*(Dispatch: public)+≡*

```
public :: dispatch_sf_data
```

        end select
    end function strfun_mode

```

Dispatch a whole structure-function chain, given beam data and beam structure data.

This could be done generically, but we should look at the specific combination of structure functions in order to select appropriate mappings.

The `beam_structure` argument gets copied because we want to expand it to canonical form (one valid structure-function entry per record) before proceeding further.

The `pdg_prc` argument is the array of incoming flavors. The first index is the beam index, the second one the process component index. Each element is itself a PDG array, notrivial if there is a flavor sum for the incoming state of this component.

The dispatcher is divided in two parts. The first part configures the structure function data themselves. After this, we can configure the phase space for the elementary process.

```

```

The second part configures channel mappings, using some conditions from the phase space configuration. If there are no structure functions, we enable a default setup with a single (dummy) structure-function channel. Otherwise, we look at the channel collection that we got from the phase-space configuration step. Each entry should be translated into an independent structure-function channel, where typically there is one default entry, which could be mapped using a standard s-channel mapping if the structure function setup recommends this, and other entries with s-channel resonances. The latter need to be translated into global mappings from the structure-function chain.

### 31.11.10 QCD coupling

Allocate the `alpha` (running coupling) component of the `qcd` block with a concrete implementation, depending on the variable settings in the `global` record.

If a fixed  $\alpha_s$  is requested, we do not allocate the `qcd%alpha` object. In this case, the matrix element code will just take the model parameter as-is, which implies fixed  $\alpha_s$ . If the object is allocated, the  $\alpha_s$  value is computed and updated for each matrix-element call.

```

write (u, "(A)")  
write (u, "(A)")  "* Test output end: dispatch_14"  
  
end subroutine dispatch_14
```

## 31.12 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

```
<process_configurations.f90>≡  
  <File header>  
  
  module process_configurations  
  
    <Use strings>  
    use diagnostics  
    use models  
    use prc_core_def  
    use particle_specifiers  
    use process_libraries  
    use rt_data  
  
    use dispatch, only: dispatch_core_def  
  
    <Standard module head>  
  
    <Process configurations: public>  
  
    <Process configurations: types>  
  
    contains  
  
    <Process configurations: procedures>  
  
  end module process_configurations
```

### 31.12.1 Data Type

```
<Process configurations: public>≡  
  public :: process_configuration_t  
  
<Process configurations: types>≡  
  type :: process_configuration_t  
    type(process_def_entry_t), pointer :: entry => null ()  
    type(string_t) :: id  
    integer :: num_id = 0  
    contains  
    <Process configurations: process configuration: TBP>  
  end type process_configuration_t
```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

```
<Process configurations: process configuration: TBP>≡  
  procedure :: init => process_configuration_init
```

```

(Process configurations: procedures)≡
  subroutine process_configuration_init &
    (config, prc_name, n_in, n_components, global)
    class(process_configuration_t), intent(out) :: config
    type(string_t), intent(in) :: prc_name
    integer, intent(in) :: n_in
    integer, intent(in) :: n_components
    type(rt_data_t), intent(in) :: global
    type(model_t), pointer :: model
    logical :: nlo_process
    model => global%model
    config%id = prc_name
    nlo_process = global%nlo_fixed_order .or. global%nlo_threshold_matching
    allocate (config%entry)
    if (global%var_list%is_known (var_str ("process_num_id"))) then
      config%num_id = &
        global%var_list%get_ival (var_str ("process_num_id"))
      call config%entry%init (prc_name, &
        model = model, n_in = n_in, n_components = n_components, &
        num_id = config%num_id, nlo_process = nlo_process)
    else
      call config%entry%init (prc_name, &
        model = model, n_in = n_in, n_components = n_components, &
        nlo_process = nlo_process)
    end if
  end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

```

(Process configurations: process configuration: TBP)+≡
  procedure :: setup_component => process_configuration_setup_component

(Process configurations: procedures)+≡
  subroutine process_configuration_setup_component &

        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Process configurations: execute tests>
    end subroutine process_configurations_test

```

## Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

This is re-exported by the UT module.

```

<Process configurations: public test auxiliary>≡
    public :: prepare_test_library

<Process configurations: test auxiliary>≡
    subroutine prepare_test_library (global, libname, mode, procname)

## 31.13 Compilation

This module manages compilation and loading of process libraries. It is needed as a separate module because integration depends on it.

```
<compilations.f90>≡  
  <File header>  
  
  module compilations  
  
    <Use strings>  
    use io_units  
    use system_defs, only: TAB  
    use diagnostics  
    use os_interface  
    use variables  
    use model_data  
    use process_libraries  
    use prclib_stacks  
    use rt_data  
  
    <Standard module head>  
  
    <Compilations: public>  
  
    <Compilations: types>  
  
    contains  
  
    <Compilations: procedures>  
  
  end module compilations
```

### 31.13.1 The data type

The compilation item handles the compilation and loading of a single process library.

```
<Compilations: public>≡  
  public :: compilation_item_t  
  
<Compilations: types>≡  
  type :: compilation_item_t  
    private  
    type(string_t) :: libname  
    type(string_t) :: static_external_tag  
    type(process_library_t), pointer :: lib => null ()  
    logical :: recompile_library = .false.  
    contains  
    <Compilations: compilation item: TBP>  
  end type compilation_item_t
```

Initialize:

```
<Compilations: compilation item: TBP>≡  
  procedure :: init => compilation_item_init
```

```

<Compilations: procedures>≡
subroutine compilation_item_init (comp, libname, stack, var_list)
  class(compilation_item_t), intent(out) :: comp
  type(string_t), intent(in) :: libname
  type(prclib_stack_t), intent(inout) :: stack
  type(var_list_t), intent(in) :: var_list
  comp%libname = libname
  comp%lib => stack%get_library_ptr (comp%libname)
  if (.not. associated (comp%lib)) then
    call msg_fatal ("Process library '" // char (comp%libname) &
      // "' has not been declared.")
  end if
  comp%recompile_library = &
    var_list%get_lval (var_str ("?recompile_library"))
end subroutine compilation_item_init

```

Compile the current library. The force flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

```

<Compilations: compilation item: TBP>+≡
  procedure :: compile => compilation_item_compile

<Compilations: procedures>+≡
subroutine compilation_item_compile (comp, model, os_data, force, recompile)
  class(compilation_item_t), intent(inout) :: comp
  class(model_data_t), intent(in), target :: model
  type(os_data_t), intent(in) :: os_data
  logical, intent(in) :: force, recompile
  if (associated (comp%lib)) then
    call msg_message ("Process library '" &
      // char (comp%libname) // "': compiling ...")
    call comp%lib%configure (os_data)
    if (signal_is_pending ()) return
    call comp%lib%compute_md5sum (model)
    call comp%lib%write_makefile (os_data, force)
    if (signal_is_pending ()) return
    if (force) then
      call comp%lib%clean (os_data, distclean = .false.)
      if (signal_is_pending ()) return
    end if
    call comp%lib%write_driver (force)
    if (signal_is_pending ()) return
    if (recompile) then
      call comp%lib%load (os_data, keep_old_source = .true.)
      if (signal_is_pending ()) return
    end if
    call comp%lib%update_status (os_data)
  end if
end subroutine compilation_item_compile

```

Load the current library, just after compiling it.

```

<Compilations: compilation item: TBP>+≡
  procedure :: load => compilation_item_load

```

```

<Compilations: procedures>+≡
  subroutine compilation_item_load (comp, os_data)
    class(compilation_item_t), intent(inout) :: comp
    type(os_data_t), intent(in) :: os_data
    if (associated (comp%lib)) then
      call comp%lib%load (os_data)
    end if
  end subroutine compilation_item_load

```

Message as a separate call:

```

<Compilations: compilation item: TBP>+≡
  procedure :: success => compilation_item_success

<Compilations: procedures>+≡
  subroutine compilation_item_success (comp)
    class(compilation_item_t), intent(in) :: comp
    if (associated (comp%lib)) then
      call msg_message ("Process library '" // char (comp%libname) &
        // "' : ... success.")
    else
      call msg_fatal ("Process library '" // char (comp%libname) &
        // "' : ... failure.")
    end if
  end subroutine compilation_item_success

```

### 31.13.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
  public :: compile_library

<Compilations: procedures>+≡
  subroutine compile_library (libname, global)
    type(string_t), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
    type(compilation_item_t) :: comp
    logical :: force, recompile
    force = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    recompile = &
      global%var_list%get_lval (var_str ("?recompile_library"))
    if (associated (global%model)) then
      call comp%init (libname, global%prclib_stack, global%var_list)
      call comp%compile (global%model, global%os_data, force, recompile)
      if (signal_is_pending ()) return
      call comp%load (global%os_data)
      if (signal_is_pending ()) return
    else

```

```

        call msg_fatal ("Process library compilation: " &
            // " model is undefined.")
    end if
    call comp%success ()
end subroutine compile_library

```

### 31.13.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```

<Compilations: public>+≡
    public :: compilation_t

<Compilations: types>+≡
    type :: compilation_t
        private
        type(string_t) :: exe_name
        type(string_t), dimension(:), allocatable :: lib_name
    contains
        <Compilations: compilation: TBP>
    end type compilation_t

```

Output.

```

<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write

<Compilations: procedures>+≡
    subroutine compilation_write (object, unit)
        class(compilation_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i

            // " -f " // compilation%exe_name // ".makefile")
    end subroutine compilation_make_clean_exe
```

### 31.13.4 API for executable compilation

This is a shorthand for compiling and loading an executable, including the enclosed libraries. The `compilation` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```
<Compilations: public>+≡
    public :: compile_executable
```

```

<Compilations: procedures>+≡
subroutine compile_executable (exename, libname, global)
  type(string_t), intent(in) :: exename
  type(string_t), dimension(:), intent(in) :: libname
  type(rt_data_t), intent(inout), target :: global
  type(compilation_t) :: compilation
  type(compilation_item_t) :: item
  type(string_t) :: ext_libtag
  logical :: force, recompile
  integer :: i
  ext_libtag = ""
  force = &
    global%var_list%get_lval (var_str ("?rebuild_library"))
  recompile = &
    global%var_list%get_lval (var_str ("?recompile_library"))
  call compilation%init (exename, [libname])
  if (signal_is_pending ()) return
  call compilation%write_dispatcher ()
  if (signal_is_pending ()) return
  do i = 1, size (libname)
    call item%init (libname(i), global%prclib_stack, global%var_list)
    call item%compile (global%model, global%os_data, &
      force=force, recompile=recompile)
    ext_libtag = "" // item%lib%get_static_modelname (global%os_data)
    if (signal_is_pending ()) return
    call item%success ()
  end do
  call compilation%write_makefile (global%os_data, ext_libtag)
  if (signal_is_pending ()) return
  call compilation%make_compile (global%os_data)
  if (signal_is_pending ()) return
  call compilation%make_link (global%os_data)
end subroutine compile_executable

```

### 31.13.5 Unit Tests

Test module, followed by the stand-alone unit-test procedures.

```

<compilations_ut.f90>≡
<File header>

module compilations_ut
  use unit_tests
  use compilations_util

<Standard module head>

<Compilations: public test>

contains

<Compilations: test driver>

```

```

    end module compilations_ut
<compilations_util.f90>≡

## 31.14 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

`<integrations.f90>`≡

### 31.14.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

*⟨Integrations: public⟩*≡

public :: integration\_t

*⟨Integrations: types⟩*≡

```
type :: integration_t
  private
  type(string_t) :: process_id
  type(string_t) :: run_id
  type(process_t), pointer :: process => null ()
  type(var_list_t), pointer :: model_vars => null ()
  type(qcd_t) :: qcd
  logical :: rebuild_phs = .false.
  logical :: ignore_phs_mismatch = .false.
  logical :: phs_only = .false.
  logical :: process_has_me = .true.
  integer :: n_calls_test = 0
  logical :: vis_history = .true.
  type(string_t) :: history_filename
  type(string_t) :: log_filename
  logical :: combined_integration = .false.
  type(iteration_multipliers_t) :: iteration_multipliers
contains
  ⟨Integrations: integration: TBP⟩
end type integration_t
```

### 31.14.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied.

*⟨Integrations: integration: TBP⟩*≡

procedure :: create\_process => integration\_create\_process

*⟨Integrations: procedures⟩*≡

```
subroutine integration_create_process (intg, process_id, global)
  class(integration_t), intent(out) :: intg
  type(rt_data_t), intent(inout), optional, target :: global
  type(string_t), intent(in) :: process_id
  type(process_entry_t), pointer :: process_entry
```

```

    intg%process_id = process_id
    if (present (global)) then
        allocate (process_entry)
        intg%process => process_entry%process_t
        call global%process_stack%push (process_entry)
    else
        allocate (process_t :: intg%process)
    end if
    intg%model_vars => null ()
end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the `local` stack directly. The `intent(inout)` attribute for the `local` data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

*(Integrations: integration: TBP)+≡*

```

    procedure :: init_process => integration_init_process

```

*(Integrations: procedures)+≡*

```

subroutine integration_init_process (intg, local)
    class(integration_t), intent(inout) :: intg
    type(rt_data_t), intent(inout), target :: local
    type(string_t) :: model_name
    type(model_t), pointer :: model
    class(model_data_t), pointer :: model_instance
    class(rng_factory_t), allocatable :: rng_factory
    if (.not. local%prclib%contains (intg%process_id)) then
        call msg_fatal ("Process '" // char (intg%process_id) // "' not found" &
            // " in library '" // char (local%prclib%get_name ()) // "'")
        return
    end if
    intg%run_id = &

### 31.14.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

<Integrations: integration: TBP>+≡

  end subroutine integration_make_iterations_list

```

In NLO calculations, the individual components might scale very differently with the number of calls. This especially applies to the real-subtracted component, which usually fluctuates more than the Born and virtual component, making it a bottleneck of the calculation. Thus, the calculation is throttled twice, first by the number of calls for the real component, second by the number of surplus calls of computation-intensive virtual matrix elements. Therefore, we want to set a different number of calls for each component, which is done by the subroutine `integration_apply_multipliers`.

```

Return the process pointer (needed by simulate):

```

<Integrations: integration: TBP>+≡
    procedure :: get_process_ptr => integration_get_process_ptr

<Integrations: procedures>+≡
    function integration_get_process_ptr (intg) result (ptr)
        class(integration_t), intent(in) :: intg
        type(process_t), pointer :: ptr
        ptr => intg%process
    end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the `global` environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the `process` object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

```

<Integrations: public>+≡
    public :: integrate_process

<Integrations: procedures>+≡
    subroutine integrate_process (process_id, local, global, local_stack, init_only, eff_reset)

### Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the

integrator is `mci_midpoint`.

The cross section for the  $2 \rightarrow 2$  process  $ss \rightarrow ss$  with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (31.1)$$

$c$  is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (31.2)$$

$f$  is the flux of the incoming particles with mass  $m = 125 \text{ GeV}$  and energy  $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (31.3)$$

$\Phi_2$  is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (31.4)$$

The squared matrix element  $|M|^2$  is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (31.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

## Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function  $f(x) = x$  for both beams. Together with the  $1/x_1x_2$  factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the  $m_s$  mass which we set to zero here.

```

### Integration with sign change

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`. The weight that is applied changes the sign in half of phase space. The weight is  $-3$  and  $1$ , respectively, so the total result is equal to the original, but negative sign.

The efficiency should (approximately) become the average of  $1$  and  $1/3$ , that is  $2/3$ .

```

## 31.15 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
(event_streams.f90)≡  
  <File header>  
  
  module event_streams  
  
    <Use strings>  
    use io_units  
    use diagnostics  
    use events  
    use eio_data  
    use eio_base  
    use rt_data  
  
    use dispatch, only: dispatch_eio  
  
    <Standard module head>  
  
    <Event streams: public>  
  
    <Event streams: types>  
  
    contains  
  
    <Event streams: procedures>  
  
  end module event_streams
```

### 31.15.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡  
  type :: event_stream_entry_t  
    class(eio_t), allocatable :: eio  
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```
<Event streams: public>≡  
  public :: event_stream_array_t  
  
<Event streams: types>+≡  
  type :: event_stream_array_t  
    type(event_stream_entry_t), dimension(:), allocatable :: entry  
    integer :: i_in = 0  
    contains  
    <Event streams: event stream array: TBP>  
  end type event_stream_array_t
```

Output.

```

(Event streams: event stream array: TBP)≡
    procedure :: write => event_stream_array_write

(Event streams: procedures)≡
    subroutine event_stream_array_write (object, unit)
        class(event_stream_array_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Event stream array:"
        if (allocated (object%entry)) then
            select case (size (object%entry))
            case (0)
                write (u, "(3x,A)") "[empty]"
            case default
                do i = 1, size (object%entry)
                    if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
                    call object%entry(i)%eio%write (u)
                end do
            end select
        else
            write (u, "(3x,A)") "[undefined]"
        end if
    end subroutine event_stream_array_write

```

Finalize all streams.

```

(Event streams: event stream array: TBP)+≡
    procedure :: final => event_stream_array_final

(Event streams: procedures)+≡
    subroutine event_stream_array_final (es_array)
        class(event_stream_array_t), intent(inout) :: es_array
        integer :: i
        do i = 1, size (es_array%entry)
            call es_array%entry(i)%eio%final ()
        end do
    end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

```

(Event streams: event stream array: TBP)+≡

```

## Empty event stream

This should set up an empty event output stream array, including initialization, output, and finalization (which are all no-ops).

```

<Event streams: execute tests>≡
    call test (event_streams_1, "event_streams_1", &
        "empty event stream array", &
        u, results)

<Event streams: test declarations>≡
    public :: event_streams_1

<Event streams: tests>≡
    subroutine event_streams_1 (u)
        integer, intent(in) :: u
        type(event_stream_array_t) :: es_array
        type(rt_data_t) :: global
        type(event_t) :: event
        type(string_t) :: sample
        type(string_t), dimension(0) :: empty_string_array

        write (u, "(A)")  "* Test output: event_streams_1"
        write (u, "(A)")  "* Purpose: handle empty event stream array"
        write (u, "(A)")

        sample = "event_streams_1"

        call es_array%init (sample, empty_string_array, global)
        call es_array%output (event, 42, 1)
        call es_array%write (u)
        call es_array%final ()

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: event_streams_1"

    end subroutine event_streams_1

```

## Nontrivial event stream

Here we generate a trivial event and choose `raw` output as an entry in the stream array.

```

<Event streams: execute tests>+≡
    call test (event_streams_2, "event_streams_2", &
        "nontrivial event stream array", &
        u, results)

<Event streams: test declarations>+≡
    public :: event_streams_2

```

*<Event streams: tests>+≡*

```

subroutine event_streams_2 (u)

            object%has_integral = .true.
        end if
    end subroutine mci_set_init

```

### 31.16.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

```

<Simulations: types>+≡
    type :: core_safe_t
        class(prc_core_t), allocatable :: core
    end type core_safe_t

```

### 31.16.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

```

<Simulations: procedures>+≡
    subroutine prepare_process &
        (process, process_id, use_process, integrate, local, global)
        type(process_t), pointer, intent(out) :: process
        type(string_t), intent(in) :: process_id

```

```

logical, intent(in) :: use_process, integrate
type(rt_data_t), intent(inout), target :: local
type(rt_data_t), intent(inout), optional, target :: global
if (present (global)) then
    process => global%process_stack%get_process_ptr (process_id)
else
    process => local%process_stack%get_process_ptr (process_id)
end if
if (use_process .and. .not. associated (process)) then
    if (integrate) then
        call msg_message ("Simulate: process '" &
            // char (process_id) // "' needs integration")
    else
        call msg_message ("Simulate: process '" &
            // char (process_id) // "' needs initialization")
    end if
    if (present (global)) then
        call integrate_process (process_id, local, global, &
            init_only = .not. integrate)
    else
        call integrate_process (process_id, local, local_stack=.true., &
            init_only = .not. integrate)
    end if
    if (signal_is_pending ()) return
    process => global%process_stack%get_process_ptr (process_id)
    if (associated (process)) then
        if (integrate) then
            call msg_message ("Simulate: integration done")
            call global%process_stack%fill_result_vars (process_id)

### 31.16.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting

particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

For the purpose of NLO events, `entry_t` contains a pointer list to other simulation-entries. This is due to the fact that we have to associate an event for each component of the fixed order simulation, i.e. one  $N$ -particle event and  $N_\alpha$   $N+1$ -particle events. However, all entries share the same event transforms.

```

<Simulations: types>+≡
  type, extends (event_t) :: entry_t
  private
    type(string_t) :: process_id
    type(string_t) :: library
    type(string_t) :: run_id

end subroutine entry_copy_entry

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the `process_instance` pointer. Assign data by looking at the process object and at the environment.

If `n_alt` is set, we prepare for additional alternate sqme and weight entries.

The `compile` flag is only false if we don't need the Whizard process at all, just its definition. In that case, we skip process initialization.

Otherwise, and if the process object is not found initially: if `integrate` is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If `generate` is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the `instance` and `process` pointers of the base type by the `connect` method, so we can reference them later.

### 31.16.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
    type, extends (entry_t) :: alt_entry_t
    contains
        <Simulations: alt entry: TBP>
    end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

### 31.16.7 The simulation type

Each simulation object corresponds to an event sample, identified by the `sample_id`.

The simulation may cover several processes simultaneously. All process-specific data, including the event records, are stored in the `entry` subobjects. The `current` index indicates which record was selected last. `version` is foreseen to contain a tag on the WHIZARD event file version. It can be

```

  <Simulations: public>≡
    public :: simulation_t

  <Simulations: types>+≡
    type :: simulation_t
      private
      type(rt_data_t), pointer :: local => null ()

```

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

```

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the luminosity setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the luminosity, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

NB: When reading from file, event transforms can't be applied because the process instance will not be complete. This should be fixed.

```

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set,

then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

```

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

### 31.16.8 Event Stream I/O

Write an event to a generic `eio` event stream. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+≡
    generic :: write_event => write_event_eio
    procedure :: write_event_eio => simulation_write_event_eio

<Simulations: procedures>+≡
    subroutine simulation_write_event_eio (object, eio, i_prc)
        class(simulation_t), intent(in) :: object
        class(eio_t), intent(inout) :: eio
        integer, intent(in), optional :: i_prc
        logical :: increased
        integer :: current
        if (present (i_prc)) then
            current = i_prc
        else
            current = object%i_prc
        end if
        if (current > 0) then
            if (object%split_n_evt > 0 &
                .and. object%counter%total > 1 &
                .and. mod (object%counter%total, object%split_n_evt) == 1) then
                call eio%split_out ()
            else if (object%split_n_kbytes > 0) then
                call eio%update_split_count (increased)
                if (increased) call eio%split_out ()
            end if
            call eio%output (object%entry(current)%event_t, current, pacify = object%pacify)
        else
            call msg_fatal ("Simulation: write event: no process selected")
        end if
    end subroutine simulation_write_event_eio

```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```

<Simulations: simulation: TBP>+≡
    generic :: read_event => read_event_eio
    procedure :: read_event_eio => simulation_read_event_eio

<Simulations: procedures>+≡
    subroutine simulation_read_event_eio (object, eio)
        class(simulation_t), intent(inout) :: object

```

```

class(eio_t), intent(inout) :: eio

call eio%input_i_prc (current, iostat)
select case (iostat)
case (0)
    object%i_prc = current
    call eio%input_event (object%entry(current)%event_t, iostat)
end select
select case (iostat)
case (:-1)
    object%i_prc = 0
    object%i_mci = 0
case (1:)
    call msg_error ("Reading events: I/O error, aborting read")
    object%i_prc = 0
    object%i_mci = 0
case default
    object%i_mci = object%entry(current)%get_i_mci ()
end select
end subroutine simulation_read_event_eio

```

### 31.16.9 Event Stream Array

Write an event using an array of event I/O streams. The process index must be selected, or the current index must be available.

*<Simulations: simulation: TBP>+≡*

```

generic :: write_event => write_event_es_array
procedure :: write_event_es_array => simulation_write_event_es_array

```

*<Simulations: procedures>+≡*

```

subroutine simulation_write_event_es_array (object, es_array, passed)
class(simulation_t), intent(in), target :: object
class(event_stream_array_t), intent(inout) :: es_array
logical, intent(in), optional :: passed
integer :: i_prc, event_index
integer :: i
type(entry_t), pointer :: current_entry
i_prc = object%i_prc
if (i_prc > 0) then
    event_index = object%counter%total
    current_entry => object%entry(i_prc)%get_first ()
    do i = 1, current_entry%count_nlo_entries ()
        if (i > 1) current_entry => current_entry%get_next ()
        call es_array%output (current_entry%event_t, i_prc, &
            event_index, passed = passed, pacify = object%pacify)
    end do
else
    call msg_fatal ("Simulation: write event: no process selected")
end if
end subroutine simulation_write_event_es_array

```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

*<Simulations: simulation: TBP>+≡*

```
generic :: read_event => read_event_es_array
procedure :: read_event_es_array => simulation_read_event_es_array
```

*<Simulations: procedures>+≡*

```

    fail = .true.
end if
end subroutine simulation_read_event_es_array

```

### 31.16.10 Recover event

Recalculate the process instance contents, given an event with known particle set. The indices for MC, term, and channel must be already set. The `recalculate` method of the selected entry will import the result into `sqme_prc` and `weight_prc`.

```

<Simulations: simulation: TBP>+≡
    procedure :: recalculate => simulation_recalculate

<Simulations: procedures>+≡
    subroutine simulation_recalculate (simulation)
        class(simulation_t), intent(inout) :: simulation
        integer :: i_prc
        i_prc = simulation%i_prc
        associate (entry => simulation%entry(i_prc))
            if (simulation%update_weight) then
                call simulation%entry(i_prc)%recalculate &
                    (update_sqme = simulation%update_sqme, &
                     recover_beams = simulation%recover_beams, &
                     weight_factor = entry%get_kinematical_weight ())
            else
                call simulation%entry(i_prc)%recalculate &
                    (update_sqme = simulation%update_sqme, &
                     recover_beams = simulation%recover_beams)
            end if
        end associate
    end subroutine simulation_recalculate

```

### 31.16.11 Extract contents

Return the MD5 sum that summarizes configuration and integration (but not the event file). Used for initializing the event streams.

```

<Simulations: simulation: TBP>+≡
    procedure :: get_md5sum_prc => simulation_get_md5sum_prc
    procedure :: get_md5sum_cfg => simulation_get_md5sum_cfg
    procedure :: get_md5sum_alt => simulation_get_md5sum_alt

<Simulations: procedures>+≡
    function simulation_get_md5sum_prc (simulation) result (md5sum)
        class(simulation_t), intent(in) :: simulation

```

```

character(32) :: md5sum
md5sum = simulation%md5sum_prc
end function simulation_get_md5sum_prc

function simulation_get_md5sum_cfg (simulation) result (md5sum)
class(simulation_t), intent(in) :: simulation
character(32) :: md5sum
md5sum = simulation%md5sum_cfg
end function simulation_get_md5sum_cfg

function simulation_get_md5sum_alt (simulation, i) result (md5sum)
class(simulation_t), intent(in) :: simulation
integer, intent(in) :: i
character(32) :: md5sum
md5sum = simulation%md5sum_alt(i)
end function simulation_get_md5sum_alt

```

Return data that may be useful for writing event files.

Usually we can refer to a previously integrated process, for which we can fetch a process pointer. Occasionally, we don't have this because we're just rescanning an externally generated file without calculation. For that situation, we generate our local beam data object using the current environment, or, in simple cases, just fetch the necessary data from the process definition and environment.

```

## Chapter 32

# More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in init/final hooks that we can set at runtime.)

### 32.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
(expr_tests_ut.f90)≡
  <File header>
  module expr_tests_ut

    use unit_tests
    use expr_tests_uti

    <Standard module head>

    <Expr tests: public test>

    contains

    <Expr tests: test driver>

  end module expr_tests_ut
(expr_tests_uti.f90)≡
  <File header>

  module expr_tests_uti

    <Use kinds>
    <Use strings>
    use format_defs, only: FMT_12
    use format_utils, only: write_separator
```

```

    use os_interface
    use sm_qcd
    use lorentz
    use ifiles
    use lexers
    use parser
    use model_data
    use interactions, only: reset_interaction_counter
    use process_libraries
    use subevents
    use subvt_expr
    use rng_base
    use mci_base
    use phs_base
    use variables
    use eval_trees

## Chapter 33

# Top Level

The top level consists of

**commands** Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

**whizard** This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

**main** The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

**whizard\_c\_interface** Alternative top-level procedures, for use in the context of a C-compatible caller program.

## 33.1 Commands

This module defines the command language of the main input file.

```
<commands.f90>≡  
  <File header>  
  
  module commands  
  
    <Use kinds>

```

### 33.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```

<Commands: types>≡
    type, abstract :: command_t
        type(parse_node_t), pointer :: pn => null ()
        class(command_t), pointer :: next => null ()
        type(parse_node_t), pointer :: pn_opt => null ()
        type(command_list_t), pointer :: options => null ()
        type(rt_data_t), pointer :: local => null ()
    contains
        <Commands: command: TBP>
    end type command_t

```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```

<Commands: command: TBP>≡
    procedure :: final => command_final

<Commands: procedures>≡
    recursive subroutine command_final (cmd)
        class(command_t), intent(inout) :: cmd
        if (associated (cmd%options)) then
            call cmd%options%final ()
            deallocate (cmd%options)
            call cmd%local%local_final ()
            deallocate (cmd%local)
        else
            cmd%local => null ()
        end if
    end if

```

```
end subroutine command_final
```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

*(Commands: procedures)*+≡

```
subroutine dispatch_command (command, pn)

```

```

case ("cmd_quit")
  allocate (cmd_quit_t :: command)
case default
  print *, char (parse_node_get_rule_key (pn))
  call msg_bug ("Command not implemented")
end select
command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_write), deferred :: write

⟨Commands: interfaces⟩≡
  abstract interface
    subroutine command_write (cmd, unit, indent)
      import
      class(command_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
    end subroutine command_write
  end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_compile), deferred :: compile

⟨Commands: interfaces⟩+≡
  abstract interface
    subroutine command_compile (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_compile
  end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_execute), deferred :: execute

⟨Commands: interfaces⟩+≡
  abstract interface
    subroutine command_execute (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_execute
  end interface

```

### 33.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```
<Commands: command: TBP>+≡
  procedure :: write_options => command_write_options

<Commands: procedures>+≡
  recursive subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options
```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```
<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
  recursive subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call cmd%options%compile (cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
      call cmd%local%deactivate ()
    else
      cmd%local => global
    end if
  end subroutine command_compile_options
```

Execute options. First prepare the local environment, then execute the command list.

```
<Commands: command: TBP>+≡
  procedure :: execute_options => cmd_execute_options

<Commands: procedures>+≡
  recursive subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call cmd%local%activate ()
      call cmd%options%execute (cmd%local)
```

```

        end if
    end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

⟨Commands: command: TBP⟩+≡
    procedure :: reset_options => cmd_reset_options

⟨Commands: procedures⟩+≡
    subroutine cmd_reset_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call cmd%local%deactivate (global)
        end if
    end subroutine cmd_reset_options

```

### 33.1.3 Specific command types

#### Model configuration

The command declares a model, looks for the specified file and loads it.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_model_t
    private
        type(string_t) :: name
    contains
        ⟨Commands: cmd model: TBP⟩
    end type cmd_model_t

```

#### Output

```

⟨Commands: cmd model: TBP⟩≡
    procedure :: write => cmd_model_write

⟨Commands: procedures⟩+≡
    subroutine cmd_model_write (cmd, unit, indent)
        class(cmd_model_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,1x,'"',A,'\"') "model =", char (cmd%name)
    end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

```

⟨Commands: cmd model: TBP⟩+≡
    procedure :: compile => cmd_model_compile

```

```

<Commands: procedures>+≡
subroutine cmd_model_compile (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_name
  type(model_t), pointer :: model
  pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
  cmd%name = parse_node_get_string (pn_name)
  model => null ()
  if (associated (global%model)) then
    if (global%model%get_name () == cmd%name) model => global%model
  end if
  if (.not. associated (model)) then
    if (global%model_list%model_exists (cmd%name)) then
      model => global%model_list%get_model_ptr (cmd%name)
    else
      call global%read_model (cmd%name, model)
    end if
  end if
  global%model => model
  if (associated (global%model)) then
    call global%model%link_var_list (global%var_list)
  end if
end subroutine cmd_model_compile

```

Execute: Insert a pointer into the global data record and reassign the variable list.

```

<Commands: cmd model: TBP>+≡
procedure :: execute => cmd_model_execute

<Commands: procedures>+≡
subroutine cmd_model_execute (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  call global%select_model (cmd%name)
  if (.not. associated (global%model)) &
    call msg_fatal ("Switching to model '" &
      // char (cmd%name) // "' : model not found")
end subroutine cmd_model_execute

```

## Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_library_t
  private
  type(string_t) :: name
contains
  <Commands: cmd library: TBP>
end type cmd_library_t

```

Output.

```
<Commands: cmd library: TBP>≡
  procedure :: write => cmd_library_write

<Commands: procedures>+≡
  subroutine cmd_library_write (cmd, unit, indent)
    class(cmd_library_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit)
    call write_indent (u, indent)
    write (u, "(1x,A,1x,'"',A,'\"')") "library =", char (cmd%name)
  end subroutine cmd_library_write
```

Compile. Get the library name.

```
<Commands: cmd library: TBP>+≡
  procedure :: compile => cmd_library_compile

<Commands: procedures>+≡
  subroutine cmd_library_compile (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_name
    pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
    cmd%name = parse_node_get_string (pn_name)
  end subroutine cmd_library_compile
```

Execute: Initialize a new library and push it on the library stack (if it does not yet exist). Insert a pointer to the library into the global data record. Then, try to load the library unless the rebuild flag is set.

```
<Commands: cmd library: TBP>+≡
  procedure :: execute => cmd_library_execute

<Commands: procedures>+≡
  subroutine cmd_library_execute (cmd, global)
    class(cmd_library_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(prclib_entry_t), pointer :: lib_entry
    type(process_library_t), pointer :: lib
    logical :: rebuild_library
    lib => global%prclib_stack%get_library_ptr (cmd%name)
    rebuild_library = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    if (.not. (associated (lib))) then
      allocate (lib_entry)
      call lib_entry%init (cmd%name)
      lib => lib_entry%process_library_t
      call global%add_prclib (lib_entry)
    else
      call global%update_prclib (lib)
    end if
    if (associated (lib) .and. .not. rebuild_library) then
      call lib%update_status (global%os_data)
```

```

    end if
end subroutine cmd_library_execute

```

## Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_process_t
    private
    type(string_t) :: id
    integer :: n_in = 0
    type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
    type(parse_node_t), pointer :: pn_out => null ()
    contains
    ⟨Commands: cmd process: TBP⟩
  end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

⟨Commands: cmd process: TBP⟩≡
  procedure :: write => cmd_process_write

⟨Commands: procedures⟩+≡
  subroutine cmd_process_write (cmd, unit, indent)
    class(cmd_process_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)") "process: ", char (cmd%id), " (", &
      size (cmd%pn_pdg_in), " -> X)"
    call cmd%write_options (u, indent)
  end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

⟨Commands: cmd process: TBP⟩+≡
  procedure :: compile => cmd_process_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_process_compile (cmd, global)
  class(cmd_process_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_id, pn_in, pn_codes
  integer :: i
  pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
  pn_in => parse_node_get_next_ptr (pn_id, 2)
  cmd%pn_out => parse_node_get_next_ptr (pn_in, 2)
  cmd%pn_opt => parse_node_get_next_ptr (cmd%pn_out)
  call cmd%compile_options (global)
  cmd%id = parse_node_get_string (pn_id)
  cmd%n_in = parse_node_get_n_sub (pn_in)
  pn_codes => parse_node_get_sub_ptr (pn_in)
  allocate (cmd%pn_pdg_in (cmd%n_in))
  do i = 1, cmd%n_in
    cmd%pn_pdg_in(i)%ptr => pn_codes
    pn_codes => parse_node_get_next_ptr (pn_codes)
  end do
end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

```

    end do
  end if
  if (associated (pn_exec_name)) then
    cmd%make_executable = .true.
    cmd%exec_name = parse_node_get_string (pn_exec_name)
  end if
end subroutine cmd_compile_compile

```

Command execution. Generate code, write driver, compile and link. Do this for all libraries in the list.

If no library names have been given and stored while compiling this command, we collect all libraries from the current stack and compile those.

We can compile static libraries (which actually just loads them). However, we can't incorporate in a generated executable.

```

<Commands: cmd compile: TBP>+≡
  procedure :: execute => cmd_compile_execute

<Commands: procedures>+≡
subroutine cmd_compile_execute (cmd, global)
  class(cmd_compile_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(string_t), dimension(:), allocatable :: libname, libname_static
  integer :: i
  if (allocated (cmd%libname)) then
    allocate (libname (size (cmd%libname)))

```

```

        libname = cmd%libname
    else
        call cmd%local%prclib_stack%get_names (libname)
    end if
    if (cmd%make_executable) then
        call get_prclib_static (libname_static)
        do i = 1, size (libname)
            if (any (libname_static == libname(i))) then
                call msg_fatal ("Compile: can't include static library '" &
                               // char (libname(i)) // "'")
            end if
        end do
        call compile_executable (cmd%exec_name, libname, cmd%local)
    else
        do i = 1, size (libname)
            call compile_library (libname(i), cmd%local)
        end do
    end if
end subroutine cmd_compile_execute

```

This is the interface to the external procedure which returns the names of all static libraries which are part of the executable. (The default is none.) The routine must allocate the array.

```

<Commands: public>≡
    public :: get_prclib_static

<Commands: interfaces>+≡
    interface
        subroutine get_prclib_static (libname)
            import
            type(string_t), dimension(:), intent(inout), allocatable :: libname
        end subroutine get_prclib_static
    end interface

```

## Execute a shell command

The argument is a string expression.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_exec_t
    private
    type(parse_node_t), pointer :: pn_command => null ()
    contains
    <Commands: cmd exec: TBP>
    end type cmd_exec_t

```

Simply tell the status.

```

<Commands: cmd exec: TBP>≡
    procedure :: write => cmd_exec_write

<Commands: procedures>+≡
    subroutine cmd_exec_write (cmd, unit, indent)
        class(cmd_exec_t), intent(in) :: cmd

```

```

integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
if (associated (cmd%pn_command)) then
    write (u, "(1x,A)") "exec: [command associated]"
else
    write (u, "(1x,A)") "exec: [undefined]"
end if
end subroutine cmd_exec_write

```

Compile the exec command.

```

⟨Commands: cmd exec: TBP⟩+≡
    procedure :: compile => cmd_exec_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_exec_compile (cmd, global)

        pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
        pn_command => parse_node_get_sub_ptr (pn_arg)
        cmd%pn_command => pn_command
    end subroutine cmd_exec_compile

```

Execute the specified shell command.

```

⟨Commands: cmd exec: TBP⟩+≡
    procedure :: execute => cmd_exec_execute

⟨Commands: procedures⟩+≡
    subroutine cmd_exec_execute (cmd, global)
        class(cmd_exec_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(string_t) :: command
        logical :: is_known
        integer :: status
        command = eval_string (cmd%pn_command, global%var_list, is_known=is_known)
        if (is_known) then
            if (command /= "") then
                call os_system_call (command, status, verbose=.true.)
                if (status /= 0) then
                    write (msg_buffer, "(A,I0)") "Return code = ", status
                    call msg_message ()
                    call msg_error ("System command returned with nonzero status code")
                end if
            end if
        end if
    end subroutine cmd_exec_execute

```

## Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_var_t
    private
      type(string_t) :: name
      integer :: type = V_NONE
      type(parse_node_t), pointer :: pn_value => null ()
      logical :: is_intrinsic = .false.
      logical :: is_model_var = .false.
    contains
      ⟨Commands: cmd var: TBP⟩
    end type cmd_var_t

```

Output. We know name, type, and properties, but not the value.

```

⟨Commands: cmd var: TBP⟩≡
  procedure :: write => cmd_var_write

⟨Commands: procedures⟩+≡
  subroutine cmd_var_write (cmd, unit, indent)
    class(cmd_var_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A)", advance="no") "var: ", char (cmd%name), " ("
    select case (cmd%type)
    case (V_NONE)
      write (u, "(A)", advance="no") "[unknown]"
    case (V_LOG)
      write (u, "(A)", advance="no") "logical"
    case (V_INT)

```

```

        write (u, "(A)", advance="no") "int"
    case (V_REAL)
        write (u, "(A)", advance="no") "real"
    case (V_CMPLX)
        write (u, "(A)", advance="no") "complex"
    case (V_STR)
        write (u, "(A)", advance="no") "string"
    case (V_PDG)
        write (u, "(A)", advance="no") "alias"
    end select
    if (cmd%is_intrinsic) then
        write (u, "(A)", advance="no") ", intrinsic"
    end if
    if (cmd%is_model_var) then
        write (u, "(A)", advance="no") ", model"
    end if
    write (u, "(A)" ) ")"
end subroutine cmd_var_write

```

Compile the lhs and determine the variable name and type. Check whether this variable can be created or modified as requested, and append the value to the variable list, if appropriate. The value is initially undefined. The rhs is assigned to a pointer, to be compiled and evaluated when the command is executed.

## SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_slha_t
  private
  type(string_t) :: file
  logical :: write_mode = .false.
  contains
  <Commands: cmd slha: TBP>
end type cmd_slha_t

```

Output.

```

<Commands: cmd slha: TBP>≡
  procedure :: write => cmd_slha_write

<Commands: procedures>+≡
  subroutine cmd_slha_write (cmd, unit, indent)
    class(cmd_slha_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "slha: file name = ", char (cmd%file)
    write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
  end subroutine cmd_slha_write

```

Compile. Read the filename and store it.

```

(Commands: cmd slha: TBP)+≡
  procedure :: compile => cmd_slha_compile

(Commands: procedures)+≡
  subroutine cmd_slha_compile (cmd, global)
    class(cmd_slha_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_key, pn_arg, pn_file
    pn_key => parse_node_get_sub_ptr (cmd%pn)

## Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

$\langle \text{Commands: types} \rangle + \equiv$

```

type, extends (command_t) :: cmd_expect_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
contains
   $\langle \text{Commands: cmd expect: TBP} \rangle$ 

```

```
end type cmd_expect_t
```

Simply tell the status.

```
<Commands: cmd expect: TBP>≡
  procedure :: write => cmd_expect_write

<Commands: procedures>+≡
  subroutine cmd_expect_write (cmd, unit, indent)
    class(cmd_expect_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    if (associated (cmd%pn_lexpr)) then
      write (u, "(1x,A)") "expect: [expression associated]"
    else
      write (u, "(1x,A)") "expect: [undefined]"
    end if
  end subroutine cmd_expect_write
```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

```
<Commands: cmd expect: TBP>+≡
  procedure :: compile => cmd_expect_compile

<Commands: procedures>+≡
  subroutine cmd_expect_compile (cmd, global)
    class(cmd_expect_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_arg
    pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)

## Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by

evaluate, i.e., compiled just-in-time and evaluated immediately.

```

<Commands: types>+≡
  type :: sentry_expr_t
    type(parse_node_p), dimension(:), allocatable :: expr
    contains
    <Commands: sentry expr: TBP>
  end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

<Commands: sentry expr: TBP>≡
  procedure :: compile => sentry_expr_compile

<Commands: procedures>+≡
  subroutine sentry_expr_compile (sentry, pn)
    class(sentry_expr_t), intent(out) :: sentry
    type(parse_node_t), intent(in), target :: pn
    type(parse_node_t), pointer :: pn_expr, pn_extra
    integer :: n_expr, i
    n_expr = parse_node_get_n_sub (pn)
    allocate (sentry%expr (n_expr))
    if (n_expr > 0) then
      i = 0
      pn_expr => parse_node_get_sub_ptr (pn)
      pn_extra => parse_node_get_next_ptr (pn_expr)
      do i = 1, n_expr
        sentry%expr(i)%ptr => pn_expr
        if (associated (pn_extra)) then
          pn_expr => parse_node_get_sub_ptr (pn_extra, 2)
          pn_extra => parse_node_get_next_ptr (pn_extra)
        end if
      end do
    end if
  end subroutine sentry_expr_compile

```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

```

<Commands: sentry expr: TBP>+≡
  procedure :: evaluate => sentry_expr_evaluate

      end if
      call expr%final ()
    end do
    call global%beam_structure%set_phi (phi)
  end subroutine cmd_beams_phi_execute

```

## Cuts

Define a cut expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the cut expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_cuts_t
  private
    type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
    ⟨Commands: cmd cuts: TBP⟩
  end type cmd_cuts_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```

⟨Commands: cmd cuts: TBP⟩≡
  procedure :: write => cmd_cuts_write

⟨Commands: procedures⟩+≡
  subroutine cmd_cuts_write (cmd, unit, indent)
    class(cmd_cuts_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "cuts: [defined]"
  end subroutine cmd_cuts_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd cuts: TBP⟩+≡
  procedure :: compile => cmd_cuts_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_cuts_compile (cmd, global)
    class(cmd_cuts_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_cuts_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd cuts: TBP⟩+≡
  procedure :: execute => cmd_cuts_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_cuts_execute (cmd, global)
    class(cmd_cuts_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%cuts_lexpr => cmd%pn_lexpr
  end subroutine cmd_cuts_execute

```

## General, Factorization and Renormalization Scales

Define a scale expression for either the renormalization or the factorization scale. We store the parse tree for the right-hand side instead of compiling

it. Compilation is deferred to the process environment where the expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_scale_t
    private
      type(parse_node_t), pointer :: pn_expr => null ()
    contains
      ⟨Commands: cmd scale: TBP⟩
  end type cmd_scale_t

```

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_fac_scale_t
    private
      type(parse_node_t), pointer :: pn_expr => null ()
    contains
      ⟨Commands: cmd fac scale: TBP⟩
  end type cmd_fac_scale_t

```

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_ren_scale_t
    private
      type(parse_node_t), pointer :: pn_expr => null ()
    contains
      ⟨Commands: cmd ren scale: TBP⟩
  end type cmd_ren_scale_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

⟨Commands: cmd scale: TBP⟩≡
  procedure :: write => cmd_scale_write

⟨Commands: procedures⟩+≡
  subroutine cmd_scale_write (cmd, unit, indent)
    class(cmd_scale_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "scale: [defined]"
  end subroutine cmd_scale_write

⟨Commands: cmd fac scale: TBP⟩≡
  procedure :: write => cmd_fac_scale_write

⟨Commands: procedures⟩+≡
  subroutine cmd_fac_scale_write (cmd, unit, indent)
    class(cmd_fac_scale_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "factorization scale: [defined]"
  end subroutine cmd_fac_scale_write

```

```

⟨Commands: cmd ren scale: TBP⟩≡
  procedure :: write => cmd_ren_scale_write
⟨Commands: procedures⟩+≡
  subroutine cmd_ren_scale_write (cmd, unit, indent)
    class(cmd_ren_scale_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "renormalization scale: [defined]"
  end subroutine cmd_ren_scale_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd scale: TBP⟩+≡
  procedure :: compile => cmd_scale_compile
⟨Commands: procedures⟩+≡
  subroutine cmd_scale_compile (cmd, global)
    class(cmd_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_scale_compile

```

```

⟨Commands: cmd fac scale: TBP⟩+≡
  procedure :: compile => cmd_fac_scale_compile
⟨Commands: procedures⟩+≡
  subroutine cmd_fac_scale_compile (cmd, global)
    class(cmd_fac_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_fac_scale_compile

```

```

⟨Commands: cmd ren scale: TBP⟩+≡
  procedure :: compile => cmd_ren_scale_compile
⟨Commands: procedures⟩+≡
  subroutine cmd_ren_scale_compile (cmd, global)
    class(cmd_ren_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_ren_scale_compile

```

Instead of evaluating the scale expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd scale: TBP⟩+≡
  procedure :: execute => cmd_scale_execute
⟨Commands: procedures⟩+≡
  subroutine cmd_scale_execute (cmd, global)
    class(cmd_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%scale_expr => cmd%pn_expr
  end subroutine cmd_scale_execute

```

```

<Commands: cmd fac scale: TBP>+≡
  procedure :: execute => cmd_fac_scale_execute

<Commands: procedures>+≡
  subroutine cmd_fac_scale_execute (cmd, global)
    class(cmd_fac_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%fac_scale_expr => cmd%pn_expr
  end subroutine cmd_fac_scale_execute

<Commands: cmd ren scale: TBP>+≡
  procedure :: execute => cmd_ren_scale_execute

<Commands: procedures>+≡
  subroutine cmd_ren_scale_execute (cmd, global)
    class(cmd_ren_scale_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%ren_scale_expr => cmd%pn_expr
  end subroutine cmd_ren_scale_execute

```

## Weight

Define a weight expression. The weight is applied to a process to be integrated, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_weight_t
    private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd weight: TBP>
  end type cmd_weight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd weight: TBP>≡
  procedure :: write => cmd_weight_write

<Commands: procedures>+≡
  subroutine cmd_weight_write (cmd, unit, indent)
    class(cmd_weight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "weight expression: [defined]"
  end subroutine cmd_weight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd weight: TBP>+≡
  procedure :: compile => cmd_weight_compile

```

```

<Commands: procedures>+≡
  subroutine cmd_weight_compile (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_weight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd weight: TBP>+≡
  procedure :: execute => cmd_weight_execute

<Commands: procedures>+≡
  subroutine cmd_weight_execute (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%weight_expr => cmd%pn_expr
  end subroutine cmd_weight_execute

```

## Selection

Define a selection expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_selection_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd selection: TBP>
  end type cmd_selection_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd selection: TBP>≡
  procedure :: write => cmd_selection_write

<Commands: procedures>+≡
  subroutine cmd_selection_write (cmd, unit, indent)
    class(cmd_selection_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "selection expression: [defined]"
  end subroutine cmd_selection_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd selection: TBP>+≡
  procedure :: compile => cmd_selection_compile

```

```

<Commands: procedures>+≡
  subroutine cmd_selection_compile (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_selection_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd selection: TBP>+≡
  procedure :: execute => cmd_selection_execute

<Commands: procedures>+≡
  subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

## Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_reweight_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd reweight: TBP>
  end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd reweight: TBP>≡
  procedure :: write => cmd_reweight_write

<Commands: procedures>+≡
  subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: compile => cmd_reweight_compile

```

```

<Commands: procedures>+≡
  subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: execute => cmd_reweight_execute

<Commands: procedures>+≡
  subroutine cmd_reweight_execute (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%reweight_expr => cmd%pn_expr
  end subroutine cmd_reweight_execute

```

## Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_alt_setup_t
  private
    type(parse_node_p), dimension(:), allocatable :: setup
  contains
    <Commands: cmd alt setup: TBP>
  end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

<Commands: cmd alt setup: TBP>≡
  procedure :: write => cmd_alt_setup_write

<Commands: procedures>+≡
  subroutine cmd_alt_setup_write (cmd, unit, indent)
    class(cmd_alt_setup_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
  end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

<Commands: cmd alt setup: TBP>+≡
  procedure :: compile => cmd_alt_setup_compile

```

```

⟨Commands: procedures⟩+=
  subroutine cmd_alt_setup_compile (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_list, pn_setup
    integer :: i
    pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
    if (associated (pn_list)) then
      allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
      i = 1
      pn_setup => parse_node_get_sub_ptr (pn_list)
      do while (associated (pn_setup))
        cmd%setup(i)%ptr => pn_setup
        i = i + 1
        pn_setup => parse_node_get_next_ptr (pn_setup)
      end do
    else
      allocate (cmd%setup (0))
    end if
  end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

⟨Commands: cmd alt setup: TBP⟩+=
  procedure :: execute => cmd_alt_setup_execute

⟨Commands: procedures⟩+=
  subroutine cmd_alt_setup_execute (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (allocated (global%pn%alt_setup)) deallocate (global%pn%alt_setup)
    allocate (global%pn%alt_setup (size (cmd%setup)), source = cmd%setup)
  end subroutine cmd_alt_setup_execute

```

## Integration

Integrate several processes, consecutively with identical parameters.

```

⟨Commands: types⟩+=
  type, extends (command_t) :: cmd_integrate_t
  private
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id
  contains
  ⟨Commands: cmd integrate: TBP⟩
  end type cmd_integrate_t

```

Output: we know the process IDs.

```

⟨Commands: cmd integrate: TBP⟩=
  procedure :: write => cmd_integrate_write

⟨Commands: procedures⟩+=
  subroutine cmd_integrate_write (cmd, unit, indent)
    class(cmd_integrate_t), intent(in) :: cmd

```

```

integer, intent(in), optional :: unit, indent
integer :: u, i
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)", advance="no") "integrate ("
do i = 1, cmd%n_proc
    if (i > 1) write (u, "(A,1x)", advance="no") ", "
    write (u, "(A)", advance="no") char (cmd%process_id(i))
end do
write (u, "(A)") ")"
end subroutine cmd_integrate_write

```

Compile.

*<Commands: cmd integrate: TBP>+≡*

```
procedure :: compile => cmd_integrate_compile
```

*<Commands: procedures>+≡*

```

subroutine cmd_integrate_compile (cmd, global)
    class(cmd_integrate_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_proclist, pn_proc
    integer :: i
    pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
    call cmd%compile_options (global)
    cmd%n_proc = parse_node_get_n_sub (pn_proclist)
    allocate (cmd%process_id (cmd%n_proc))
    pn_proc => parse_node_get_sub_ptr (pn_proclist)
    do i = 1, cmd%n_proc
        cmd%process_id(i) = parse_node_get_string (pn_proc)
        call global%process_stack%init_result_vars (cmd%process_id(i))
        pn_proc => parse_node_get_next_ptr (pn_proc)
    end do
end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

*<Commands: cmd integrate: TBP>+≡*

```
procedure :: execute => cmd_integrate_execute
```

*<Commands: procedures>+≡*

```

subroutine cmd_integrate_execute (cmd, global)
    class(cmd_integrate_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    integer :: i

```

```

do i = 1, cmd%n_proc
  call integrate_process (cmd%process_id(i), cmd%local, global)
  call global%process_stack%fill_result_vars (cmd%process_id(i))
  if (signal_is_pending ()) return
end do
end subroutine cmd_integrate_execute

```

## Observables

Declare an observable. After the declaration, it can be used to record data, and at the end one can retrieve average and error.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_observable_t
  private
  type(string_t) :: id
  contains
  ⟨Commands: cmd_observable: TBP⟩
end type cmd_observable_t

```

Output. We know the ID.

```

⟨Commands: cmd_observable: TBP⟩≡
  procedure :: write => cmd_observable_write

⟨Commands: procedures⟩+≡
  subroutine cmd_observable_write (cmd, unit, indent)
    class(cmd_observable_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "observable: ", char (cmd%id)
  end subroutine cmd_observable_write

```

Compile. Just record the observable ID.

```

⟨Commands: cmd_observable: TBP⟩+≡
  procedure :: compile => cmd_observable_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_observable_compile (cmd, global)
    class(cmd_observable_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_tag
    pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
    if (associated (pn_tag)) then
      cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    end if
    call cmd%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      cmd%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("observable: name expression not implemented (yet)")
    end select
  end subroutine cmd_observable_compile

```

```

end select
end subroutine cmd_observable_compile

```

Command execution. This declares the observable and allocates it in the analysis store.

```

⟨Commands: cmd observable: TBP⟩+≡
  procedure :: execute => cmd_observable_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_observable_execute (cmd, global)
    class(cmd_observable_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(string_t) :: label, unit
    var_list => cmd%local%get_var_list_ptr ()
    label = var_list%get_sval (var_str ("$_obs_label"))
    unit = var_list%get_sval (var_str ("$_obs_unit"))
    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call analysis_init_observable (cmd%id, label, unit, graph_options)
  end subroutine cmd_observable_execute

```

## Histograms

Declare a histogram. At minimum, we have to set lower and upper bound and bin width.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_histogram_t
  private
  type(string_t) :: id
  type(parse_node_t), pointer :: pn_lower_bound => null ()
  type(parse_node_t), pointer :: pn_upper_bound => null ()
  type(parse_node_t), pointer :: pn_bin_width => null ()
  contains
  ⟨Commands: cmd histogram: TBP⟩
end type cmd_histogram_t

```

Output. Just print the ID.

```

⟨Commands: cmd histogram: TBP⟩≡
  procedure :: write => cmd_histogram_write

```

## Plots

Declare a plot. No mandatory arguments, just options.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_plot_t
  private
  type(string_t) :: id
  contains
  <Commands: cmd plot: TBP>
end type cmd_plot_t
```

Output. Just print the ID.

```
<Commands: cmd plot: TBP>≡
  procedure :: write => cmd_plot_write

<Commands: procedures>+≡
  subroutine cmd_plot_write (cmd, unit, indent)
    class(cmd_plot_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "plot: ", char (cmd%id)
  end subroutine cmd_plot_write
```

Compile. Record the plot ID and initialize lower, upper bound and bin width.

```
<Commands: cmd plot: TBP>+≡
  procedure :: compile => cmd_plot_compile

<Commands: procedures>+≡
  subroutine cmd_plot_compile (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_tag
    pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%init (pn_tag, global)
  end subroutine cmd_plot_compile
```

This init routine is separated because it is reused below for graph initialization.

```
<Commands: cmd plot: TBP>+≡
  procedure :: init => cmd_plot_init

<Commands: procedures>+≡
  subroutine cmd_plot_init (plot, pn_tag, global)
    class(cmd_plot_t), intent(inout) :: plot
    type(parse_node_t), intent(in), pointer :: pn_tag
    type(rt_data_t), intent(inout), target :: global
    call plot%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      plot%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("plot: name expression not implemented (yet)")
```

```

    end select
end subroutine cmd_plot_init

```

Command execution. This declares the plot and allocates it in the analysis store.

```

⟨Commands: cmd plot: TBP⟩+≡
  procedure :: execute => cmd_plot_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_plot_execute (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call drawing_options_init_plot (drawing_options)
    call set_drawing_options (drawing_options, var_list)

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

## Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_graph_t
    private
    type(string_t) :: id
    integer :: n_elements = 0
    type(cmd_plot_t), dimension(:), allocatable :: el
    type(string_t), dimension(:), allocatable :: element_id
  contains
    ⟨Commands: cmd graph: TBP⟩
  end type cmd_graph_t

```

Output. Just print the ID.

```

⟨Commands: cmd graph: TBP⟩≡
  procedure :: write => cmd_graph_write

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return

```

```

    call write_indent (u, indent)
    write (u, "(1x,A,A,A,IO,A)" "graph: ", char (cmd%id), &
           " (" , cmd%n_elements, " entries)"
end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

⟨Commands: cmd graph: TBP⟩+≡
    procedure :: compile => cmd_graph_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_graph_compile (cmd, global)
        class(cmd_graph_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
        integer :: i

        pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
        pn_tag => parse_node_get_sub_ptr (pn_term)
        cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
        call cmd%compile_options (global)
        select case (char (parse_node_get_rule_key (pn_tag)))
        case ("analysis_id")
            cmd%id = parse_node_get_string (pn_tag)
        case default
            call msg_bug ("graph: name expression not implemented (yet)")
        end select
        pn_def => parse_node_get_next_ptr (pn_term, 2)
        cmd%n_elements = parse_node_get_n_sub (pn_def)
        allocate (cmd%element_id (cmd%n_elements))
        allocate (cmd%el (cmd%n_elements))
        pn_term => parse_node_get_sub_ptr (pn_def)
        pn_tag => parse_node_get_sub_ptr (pn_term)
        cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
        call cmd%el(1)%init (pn_tag, global)
        cmd%element_id(1) = parse_node_get_string (pn_tag)
        pn_app => parse_node_get_next_ptr (pn_term)
        do i = 2, cmd%n_elements
            pn_term => parse_node_get_sub_ptr (pn_app, 2)
            pn_tag => parse_node_get_sub_ptr (pn_term)
            cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
            call cmd%el(i)%init (pn_tag, global)
            cmd%element_id(i) = parse_node_get_string (pn_tag)
            pn_app => parse_node_get_next_ptr (pn_app)
        end do

    end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: execute => cmd_graph_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_execute (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options
    integer :: i, type

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

    do i = 1, cmd%n_elements
      if (associated (cmd%el(i)%options)) then
        call cmd%el(i)%options%execute (cmd%el(i)%local)
      end if
      type = analysis_store_get_object_type (cmd%element_id(i))
      select case (type)
        case (AN_HISTOGRAM)
          call drawing_options_init_histogram (drawing_options)
        case (AN_PLOT)
          call drawing_options_init_plot (drawing_options)
        end select
      call set_drawing_options (drawing_options, var_list)
      if (associated (cmd%el(i)%options)) then
        call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
      end if
      call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
    end do
  end subroutine cmd_graph_execute

```

## Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
  type :: analysis_id_t
    type(string_t) :: tag
    type(parse_node_t), pointer :: pn_sexpr => null ()
  end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡

```

```

type, extends (command_t) :: cmd_analysis_t
  private
    type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
    <Commands: cmd analysis: TBP>
end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

<Commands: cmd analysis: TBP>≡
  procedure :: write => cmd_analysis_write

<Commands: procedures>+≡
  subroutine cmd_analysis_write (cmd, unit, indent)
    class(cmd_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "analysis: [defined]"
  end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd analysis: TBP>+≡
  procedure :: compile => cmd_analysis_compile

<Commands: procedures>+≡
  subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd analysis: TBP>+≡
  procedure :: execute => cmd_analysis_execute

<Commands: procedures>+≡
  subroutine cmd_analysis_execute (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%analysis_lexpr => cmd%pn_lexpr
  end subroutine cmd_analysis_execute

```

## Write histograms and plots

The data type encapsulating the command:

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_write_analysis_t
    private
      type(analysis_id_t), dimension(:), allocatable :: id
      type(string_t), dimension(:), allocatable :: tag

```

```

contains
  <Commands: cmd write analysis: TBP>
end type cmd_write_analysis_t

```

Output. Just the keyword.

```

<Commands: cmd write analysis: TBP>≡
  procedure :: write => cmd_write_analysis_write

<Commands: procedures>+≡
  subroutine cmd_write_analysis_write (cmd, unit, indent)
    class(cmd_write_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "write_analysis"
  end subroutine cmd_write_analysis_write

```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: compile => cmd_write_analysis_compile

<Commands: procedures>+≡
  subroutine cmd_write_analysis_compile (cmd, global)
    class(cmd_write_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
    integer :: n, i
    pn_clause => parse_node_get_sub_ptr (cmd%pn)
    pn_args => parse_node_get_sub_ptr (pn_clause, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
    call cmd%compile_options (global)
    if (associated (pn_args)) then
      n = parse_node_get_n_sub (pn_args)
      allocate (cmd%id (n))
      do i = 1, n
        pn_id => parse_node_get_sub_ptr (pn_args, i)
        if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
          cmd%id(i)%tag = parse_node_get_string (pn_id)
        else
          cmd%id(i)%pn_sexpr => pn_id
        end if
      end do
    else
      allocate (cmd%id (0))
    end if
  end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

<Commands: parameters>+≡
  character(*), parameter, public :: &
    DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
  character(len=1), dimension(2), parameter, public :: &

```

```

FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(5), parameter, public :: &
FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "lo", "la" ]
character(len=3), dimension(16), parameter, public :: &
FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
    "f95", "log", "ltp", "mpx", "olc", "olp", "pdf", "phs", "sin", "tex" ]

```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```

<Commands: cmd write analysis: TBP>+≡
    procedure :: execute => cmd_write_analysis_execute

<Commands: procedures>+≡
    subroutine cmd_write_analysis_execute (cmd, global)
        class(cmd_write_analysis_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(var_list_t), pointer :: var_list
        var_list => cmd%local%get_var_list_ptr ()
        call write_analysis_wrap (var_list, global%out_files, &
            cmd%id, tag = cmd%tag)
    end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

```

<Commands: procedures>+≡
    subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
        type(var_list_t), intent(inout), target :: var_list
        type(file_list_t), intent(inout), target :: out_files

### 33.1.4 User-controlled output to data files

#### Open file (output)

Open a file for output.

*(Commands: types)+≡*

```

type, extends (command_t) :: cmd_open_out_t
    private
    type(parse_node_t), pointer :: file_expr => null ()
contains
    (Commands: cmd open out: TBP)
end type cmd_open_out_t

```

Finalizer for the embedded eval tree.

```
<Commands: procedures>+≡  
  subroutine cmd_open_out_final (object)  
    class(cmd_open_out_t), intent(inout) :: object  
  end subroutine cmd_open_out_final
```

Output (trivial here).

```
<Commands: cmd open out: TBP>≡  
  procedure :: write => cmd_open_out_write  
  
<Commands: procedures>+≡  
  subroutine cmd_open_out_write (cmd, unit, indent)  
    class(cmd_open_out_t), intent(in) :: cmd  
    integer, intent(in), optional :: unit, indent  
    integer :: u  
    u = given_output_unit (unit); if (u < 0) return  
    call write_indent (u, indent)  
    write (u, "(1x,A)", advance="no") "open_out: <filename>"  
  end subroutine cmd_open_out_write
```

Compile: create an eval tree for the filename expression.

```
<Commands: cmd open out: TBP>+≡  
  procedure :: compile => cmd_open_out_compile  
  
<Commands: procedures>+≡  
  subroutine cmd_open_out_compile (cmd, global)  
    class(cmd_open_out_t), intent(inout) :: cmd  
    type(rt_data_t), intent(inout), target :: global  
    cmd%file_expr => parse_node_get_sub_ptr (cmd%pn, 2)  
    if (associated (cmd%file_expr)) then  
      cmd%pn_opt => parse_node_get_next_ptr (cmd%file_expr)  
    end if  
    call cmd%compile_options (global)  
  end subroutine cmd_open_out_compile
```

Execute: append the file to the global list of open files.

```
<Commands: cmd open out: TBP>+≡  
  procedure :: execute => cmd_open_out_execute  
  
<Commands: procedures>+≡  
  subroutine cmd_open_out_execute (cmd, global)  
    class(cmd_open_out_t), intent(inout) :: cmd  
    type(rt_data_t), intent(inout), target :: global  
    type(var_list_t), pointer :: var_list  
    type(eval_tree_t) :: file_expr  
    type(string_t) :: file  
    var_list => cmd%local%get_var_list_ptr ()  
    call file_expr%init_sexpr (cmd%file_expr, var_list)  
    call file_expr%evaluate ()  
    if (file_expr%is_known ()) then  
      file = file_expr%get_string ()  
      call file_list_open (global%out_files, file, &  
        action = "write", status = "replace", position = "asis")
```

```

else
  call msg_fatal ("open_out: file name argument evaluates to unknown")
end if
call file_expr%final ()
end subroutine cmd_open_out_execute

```

### Open file (output)

Close an output file. Except for the `execute` method, everything is analogous to the `open` command, so we can just inherit.

```

⟨Commands: types⟩+=
  type, extends (cmd_open_out_t) :: cmd_close_out_t
  private
  contains
  ⟨Commands: cmd close out: TBP⟩
end type cmd_close_out_t

```

Execute: remove the file from the global list of output files.

```

⟨Commands: cmd close out: TBP⟩=
  procedure :: execute => cmd_close_out_execute

⟨Commands: procedures⟩+=
  subroutine cmd_close_out_execute (cmd, global)
    class(cmd_close_out_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(eval_tree_t) :: file_expr
    type(string_t) :: file
    var_list => cmd%local%var_list
    call file_expr%init_sexpr (cmd%file_expr, var_list)
    call file_expr%evaluate ()
    if (file_expr%is_known ()) then
      file = file_expr%get_string ()
      call file_list_close (global%out_files, file)
    else
      call msg_fatal ("close_out: file name argument evaluates to unknown")
    end if
    call file_expr%final ()
  end subroutine cmd_close_out_execute

```

### 33.1.5 Print custom-formatted values

```

⟨Commands: types⟩+=
  type, extends (command_t) :: cmd_printf_t
  private
  type(parse_node_t), pointer :: sexpr => null ()
  type(parse_node_t), pointer :: sprintf_fun => null ()
  type(parse_node_t), pointer :: sprintf_clause => null ()
  type(parse_node_t), pointer :: sprintf => null ()
  contains
  ⟨Commands: cmd printf: TBP⟩

```

```
end type cmd_printf_t
```

Finalize.

```
<Commands: cmd printf: TBP>≡
  procedure :: final => cmd_printf_final

<Commands: procedures>+≡
  subroutine cmd_printf_final (cmd)
    class(cmd_printf_t), intent(inout) :: cmd
    call parse_node_final (cmd%sexpr, recursive = .false.)
    deallocate (cmd%sexpr)
    call parse_node_final (cmd%sprintf_fun, recursive = .false.)
    deallocate (cmd%sprintf_fun)
    call parse_node_final (cmd%sprintf_clause, recursive = .false.)
    deallocate (cmd%sprintf_clause)
    call parse_node_final (cmd%sprintf, recursive = .false.)
    deallocate (cmd%sprintf)
  end subroutine cmd_printf_final
```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```
<Commands: cmd printf: TBP>+≡
  procedure :: write => cmd_printf_write

<Commands: procedures>+≡
  subroutine cmd_printf_write (cmd, unit, indent)
    class(cmd_printf_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "printf:"
  end subroutine cmd_printf_write
```

Compile. We create a fake parse node (subtree) with a `sprintf` command with identical arguments which can then be handled by the corresponding evaluation procedure.

```
<Commands: cmd printf: TBP>+≡
  procedure :: compile => cmd_printf_compile

<Commands: procedures>+≡
  subroutine cmd_printf_compile (cmd, global)
    class(cmd_printf_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_cmd, pn_clause, pn_args, pn_format
    pn_cmd => parse_node_get_sub_ptr (cmd%pn)
    pn_clause => parse_node_get_sub_ptr (pn_cmd)
    pn_format => parse_node_get_sub_ptr (pn_clause, 2)
    pn_args => parse_node_get_next_ptr (pn_clause)
    cmd%pn_opt => parse_node_get_next_ptr (pn_cmd)
    call cmd%compile_options (global)
    allocate (cmd%sexpr)
    call parse_node_create_branch (cmd%sexpr, &
```

```

        syntax_get_rule_ptr (syntax_cmd_list, var_str ("sexpr"))
allocate (cmd%sprintf_fun)
call parse_node_create_branch (cmd%sprintf_fun, &
    syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf_fun")))
allocate (cmd%sprintf_clause)
call parse_node_create_branch (cmd%sprintf_clause, &
    syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf_clause")))
allocate (cmd%sprintf)
call parse_node_create_key (cmd%sprintf, &
    syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf")))
call parse_node_append_sub (cmd%sprintf_clause, cmd%sprintf)
call parse_node_append_sub (cmd%sprintf_clause, pn_format)
call parse_node_freeze_branch (cmd%sprintf_clause)
call parse_node_append_sub (cmd%sprintf_fun, cmd%sprintf_clause)
if (associated (pn_args)) then
    call parse_node_append_sub (cmd%sprintf_fun, pn_args)
end if
call parse_node_freeze_branch (cmd%sprintf_fun)
call parse_node_append_sub (cmd%sexpr, cmd%sprintf_fun)
call parse_node_freeze_branch (cmd%sexpr)
end subroutine cmd_printf_compile

```

Execute. Evaluate the string (pretending this is a `sprintf` expression) and print it.

*(Commands: cmd printf: TBP)+≡*

```

procedure :: execute => cmd_printf_execute

```

*(Commands: procedures)+≡*

```

subroutine cmd_printf_execute (cmd, global)
class(cmd_printf_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(var_list_t), pointer :: var_list
type(string_t) :: string, file
type(eval_tree_t) :: sprintf_expr
logical :: advance
var_list => cmd%local%get_var_list_ptr ()
advance = var_list%get_lval (&
    var_str ("?out_advance"))
file = var_list%get_sval (&
    var_str ("out_file"))
call sprintf_expr%init_sexpr (cmd%sexpr, var_list)
call sprintf_expr%evaluate ()
if (sprintf_expr%is_known ()) then
    string = sprintf_expr%get_string ()
    if (len (file) == 0) then
        call msg_result (char (string))
    else
        call file_list_write (global%out_files, file, string, advance)
    end if
end if
end if
end subroutine cmd_printf_execute

```

## Record data

The expression syntax already contains a `record` keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```
(Commands: types)+≡
  type, extends (command_t) :: cmd_record_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  (Commands: cmd record: TBP)
end type cmd_record_t
```

Output. With the compile hack below, there is nothing of interest to print here.

```
(Commands: cmd record: TBP)≡
  procedure :: write => cmd_record_write

(Commands: procedures)+≡
  subroutine cmd_record_write (cmd, unit, indent)
    class(cmd_record_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "record"
  end subroutine cmd_record_write
```

Compile. This is a hack which transforms the `record` command into a `record` expression, which we handle in the expressions module.

```
(Commands: cmd record: TBP)+≡
  procedure :: compile => cmd_record_compile

(Commands: procedures)+≡
  subroutine cmd_record_compile (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
    call parse_node_create_branch (pn_lexpr, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))
    call parse_node_create_branch (pn_lsinglet, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lsinglet")))
    call parse_node_append_sub (pn_lexpr, pn_lsinglet)
    call parse_node_create_branch (pn_lterm, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lterm")))
    call parse_node_append_sub (pn_lsinglet, pn_lterm)
    pn_record => parse_node_get_sub_ptr (cmd%pn)
    call parse_node_append_sub (pn_lterm, pn_record)
    cmd%pn_lexpr => pn_lexpr
  end subroutine cmd_record_compile
```

Command execution. Again, transfer this to the embedded expression and just forget the logical result.

```
(Commands: cmd record: TBP)+≡
  procedure :: execute => cmd_record_execute
```

```

<Commands: procedures>+≡
subroutine cmd_record_execute (cmd, global)
  class(cmd_record_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  logical :: lval
  var_list => global%get_var_list_ptr ()
  lval = eval_log (cmd%pn_lexpr, var_list)
end subroutine cmd_record_execute

```

## Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_unstable_t
  private
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

## Polarized particles

These commands mark particles as (un)polarized, to be applied in subsequent simulation passes. Since this is technically the same as the `stable` command, we take a shortcut and make this an extension, just overriding methods.

```

<Commands: types>+≡
  type, extends (cmd_stable_t) :: cmd_polarized_t
    contains
    <Commands: cmd polarized: TBP>
  end type cmd_polarized_t

  type, extends (cmd_stable_t) :: cmd_unpolarized_t
    contains
    <Commands: cmd unpolarized: TBP>
  end type cmd_unpolarized_t

```

Output: we know only the number of particles.

```

<Commands: cmd polarized: TBP>≡
  procedure :: write => cmd_polarized_write

<Commands: cmd unpolarized: TBP>≡
  procedure :: write => cmd_unpolarized_write

```

```

<Commands: procedures>+≡
subroutine cmd_polarized_write (cmd, unit, indent)
  class(cmd_polarized_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,1x,I0)") "polarized:", size (cmd%pn_pdg)
end subroutine cmd_polarized_write

subroutine cmd_unpolarized_write (cmd, unit, indent)
  class(cmd_unpolarized_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,1x,I0)") "unpolarized:", size (cmd%pn_pdg)
end subroutine cmd_unpolarized_write

```

Compile: accounted for by the base command.

Execute: apply the modifications to the current model.

  integer :: u, i
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A)", advance="no") "simulate ("
  do i = 1, cmd%n_proc
    if (i > 1) write (u, "(A,1x)", advance="no") ", "
    write (u, "(A)", advance="no") char (cmd%process_id(i))
  end do
  write (u, "(A)") ")"
end subroutine cmd_simulate_write
```

Compile. In contrast to WHIZARD 1 the confusing option to give the number of unweighted events for weighted events as if unweighting were to take place has been abandoned. (We both use `n_events` for weighted and unweighted events, the variable `n_calls` from WHIZARD 1 has been discarded.

*<Commands: cmd simulate: TBP>+≡*

```

  end do
end subroutine cmd_simulate_compile
```

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels

are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

    end subroutine cmd_iterations_execute

```

## Range expressions

We need a special type for storing and evaluating range expressions.

```

<Commands: parameters>+≡
    integer, parameter :: STEP_NONE = 0
    integer, parameter :: STEP_ADD = 1
    integer, parameter :: STEP_SUB = 2
    integer, parameter :: STEP_MUL = 3
    integer, parameter :: STEP_DIV = 4
    integer, parameter :: STEP_COMP_ADD = 11
    integer, parameter :: STEP_COMP_MUL = 13

```

There is an abstract base type and two implementations: scan over integers and scan over reals.

```

<Commands: types>+≡
    type, abstract :: range_t
        type(parse_node_t), pointer :: pn_expr => null ()
        type(parse_node_t), pointer :: pn_term => null ()

```

```

type(parse_node_t), pointer :: pn_factor => null ()
type(parse_node_t), pointer :: pn_value => null ()
type(parse_node_t), pointer :: pn_literal => null ()
type(parse_node_t), pointer :: pn_beg => null ()
type(parse_node_t), pointer :: pn_end => null ()
type(parse_node_t), pointer :: pn_step => null ()
type(eval_tree_t) :: expr_beg
type(eval_tree_t) :: expr_end
type(eval_tree_t) :: expr_step
integer :: step_mode = 0
integer :: n_step = 0
contains
  <Commands: range: TBP>
end type range_t

```

These are the implementations:

```

<Commands: types>+≡
type, extends (range_t) :: range_int_t
  integer :: i_beg = 0
  integer :: i_end = 0
  integer :: i_step = 0
contains
  <Commands: range int: TBP>
end type range_int_t

type, extends (range_t) :: range_real_t
  real(default) :: r_beg = 0
  real(default) :: r_end = 0
  real(default) :: r_step = 0
  real(default) :: lr_beg = 0
  real(default) :: lr_end = 0
  real(default) :: lr_step = 0
contains
  <Commands: range real: TBP>
end type range_real_t

```

Finalize the allocated dummy node. The other nodes are just pointers.

```

<Commands: range: TBP>≡
  procedure :: final => range_final

<Commands: procedures>+≡
  subroutine range_final (object)
    class(range_t), intent(inout) :: object
    if (associated (object%pn_expr)) then
      call parse_node_final (object%pn_expr, recursive = .false.)
      call parse_node_final (object%pn_term, recursive = .false.)
      call parse_node_final (object%pn_factor, recursive = .false.)
      call parse_node_final (object%pn_value, recursive = .false.)
      call parse_node_final (object%pn_literal, recursive = .false.)
      deallocate (object%pn_expr)
      deallocate (object%pn_term)
      deallocate (object%pn_factor)
      deallocate (object%pn_value)
      deallocate (object%pn_literal)
    end if
  end subroutine range_final

```

```

        end if
    end subroutine range_final

```

Output.

```

end subroutine range_init

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

*<Commands: range: TBP>+≡*

Return the number of iterations:

```

<Commands: range: TBP>+≡
  procedure :: get_n_iterations => range_get_n_iterations

<Commands: procedures>+≡
  function range_get_n_iterations (range) result (n)
    class(range_t), intent(in) :: range
    integer :: n
    n = range%n_step
  end function range_get_n_iterations

```

Compute the value for iteration i and store it in the embedded token.

```

<Commands: range: TBP>+≡
  procedure (range_set_value), deferred :: set_value

<Commands: interfaces>+≡
  abstract interface
    subroutine range_set_value (range, i)
      import
      class(range_t), intent(inout) :: range
      integer, intent(in) :: i
    end subroutine range_set_value
  end interface

```

In the integer case, we compute the value directly for additive step. For multiplicative step, we perform a loop in the same way as above, where the number of iteration was determined.

```

<Commands: range int: TBP>+≡
  procedure :: set_value => range_int_set_value

<Commands: procedures>+≡
  subroutine range_int_set_value (range, i)
    class(range_int_t), intent(inout) :: range

```

```

## Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

Note: for the integer/real range array, the obvious implementation as a polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are apparently broken.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_scan_t
    private
    type(string_t) :: name
    integer :: n_values = 0
    type(parse_node_p), dimension(:), allocatable :: scan_cmd
    !!! !!! gfortran 4.7.x memory corruption
    !!! class(range_t), dimension(:), allocatable :: range
    type(range_int_t), dimension(:), allocatable :: range_int
    type(range_real_t), dimension(:), allocatable :: range_real
contains
    <Commands: cmd scan: TBP>
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

<Commands: cmd scan: TBP>≡
    procedure :: final => cmd_scan_final

<Commands: procedures>+≡
    recursive subroutine cmd_scan_final (cmd)
    class(cmd_scan_t), intent(inout) :: cmd
    type(parse_node_t), pointer :: pn_var_single, pn_decl_single
    type(string_t) :: key
    integer :: i
    if (allocated (cmd%scan_cmd)) then
        do i = 1, size (cmd%scan_cmd)
            pn_var_single => parse_node_get_sub_ptr (cmd%scan_cmd(i)%ptr)
            key = parse_node_get_rule_key (pn_var_single)
            select case (char (key))
            case ("scan_string_decl", "scan_log_decl")
                pn_decl_single => parse_node_get_sub_ptr (pn_var_single, 2)
                call parse_node_final (pn_decl_single, recursive=.false.)
                deallocate (pn_decl_single)
            end select
        end do
    end if
end subroutine cmd_scan_final

```

```

        call parse_node_final (pn_var_single, recursive=.false.)
        deallocate (pn_var_single)
    end do
    deallocate (cmd%scan_cmd)
end if
!!! !!! gfortran 4.7.x memory corruption
!!! if (allocated (cmd%range)) then
!!!     do i = 1, size (cmd%range)
!!!         call cmd%range(i)%final ()
!!!     end do
!!! end if
if (allocated (cmd%range_int)) then
    do i = 1, size (cmd%range_int)
        call cmd%range_int(i)%final ()
    end do
end if
if (allocated (cmd%range_real)) then
    do i = 1, size (cmd%range_real)
        call cmd%range_real(i)%final ()
    end do
end if
end subroutine cmd_scan_final

```

Output.

```

<Commands: cmd scan: TBP>+≡
    procedure :: write => cmd_scan_write

<Commands: procedures>+≡
    subroutine cmd_scan_write (cmd, unit, indent)
        class(cmd_scan_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,1x,A,1x,'(',I0,')')") "scan:", char (cmd%name), &
            cmd%n_values
    end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

```

## Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of **else if** constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```
(Commands: types)+≡
  type, extends (command_t) :: cmd_if_t
  private
    type(parse_node_t), pointer :: pn_if_lexpr => null ()
    type(command_list_t), pointer :: if_body => null ()
    type(cmd_if_t), dimension(:), pointer :: elsif_cmd => null ()
    type(command_list_t), pointer :: else_body => null ()
  contains
    (Commands: cmd if: TBP)
  end type cmd_if_t
```

Finalizer. There are no local options, therefore we can simply override the default finalizer.

```
(Commands: cmd if: TBP)≡
  procedure :: final => cmd_if_final

(Commands: procedures)+≡
  recursive subroutine cmd_if_final (cmd)
    class(cmd_if_t), intent(inout) :: cmd
    integer :: i
    if (associated (cmd%if_body)) then

### Include another command-list file

The include command allocates a local parse tree. This must not be deleted before the command object itself is deleted, since pointers may point to subobjects of it.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_include_t
    private
        type(string_t) :: file
        type(command_list_t), pointer :: command_list => null ()
        type(parse_tree_t) :: parse_tree
    contains
        <Commands: cmd include: TBP>
    end type cmd_include_t

```

Finalizer: delete the command list. No options, so we can simply override the default finalizer.

```

<Commands: cmd include: TBP>≡
    procedure :: final => cmd_include_final

<Commands: procedures>+≡
    subroutine cmd_include_final (cmd)
        class(cmd_include_t), intent(inout) :: cmd
        call parse_tree_final (cmd%parse_tree)
        if (associated (cmd%command_list)) then
            call cmd%command_list%final ()
            deallocate (cmd%command_list)
        end if
    end subroutine cmd_include_final

```

Write: display the command list as-is, if allocated.

```

<Commands: cmd include: TBP>+≡
    procedure :: write => cmd_include_write

```

```

{Commands: procedures}+≡
subroutine cmd_include_write (cmd, unit, indent)
  class(cmd_include_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u, ind
  u = given_output_unit (unit)
  ind = 0; if (present (indent)) ind = indent
  call write_indent (u, indent)
  write (u, "(A,A,A,A)") "include ", "'", char (cmd%file), "'"
  if (associated (cmd%command_list)) then
    call cmd%command_list%write (u, ind + 1)
  end if
end subroutine cmd_include_write

```

Compile file contents: First parse the file, then immediately compile its contents.  
Use the global data set.

```

{Commands: cmd include: TBP}+≡
procedure :: compile => cmd_include_compile

{Commands: procedures}+≡
subroutine cmd_include_compile (cmd, global)
  class(cmd_include_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_arg, pn_file
  type(string_t) :: file
  logical :: exist
  integer :: u
  type(stream_t), target :: stream
  type(lexer_t) :: lexer
  pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
  pn_file => parse_node_get_sub_ptr (pn_arg)
  file = parse_node_get_string (pn_file)
  inquire (file=char(file), exist=exist)
  if (exist) then
    cmd%file = file
  else
    cmd%file = global%os_data%whizard_cutspath // "/" // file
    inquire (file=char(cmd%file), exist=exist)
    if (.not. exist) then
      call msg_error ("Include file '" // char (file) // "' not found")
      return
    end if
  end if
  u = free_unit ()
  call lexer_init_cmd_list (lexer, global%lexer)
  call stream_init (stream, char (cmd%file))
  call lexer_assign_stream (lexer, stream)
  call parse_tree_init (cmd%parse_tree, syntax_cmd_list, lexer)
  call stream_final (stream)
  call lexer_final (lexer)
  close (u)
  allocate (cmd%command_list)
  call cmd%command_list%compile (cmd%parse_tree%get_root_ptr (), &
    global)

```

```
end subroutine cmd_include_compile
```

Execute file contents in the global context.

```
<Commands: cmd include: TBP>+≡
  procedure :: execute => cmd_include_execute

<Commands: procedures>+≡
  subroutine cmd_include_execute (cmd, global)
    class(cmd_include_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%command_list)) then
      call msg_message &
        ("Including Sindarin from '" // char (cmd%file) // "'")
      call cmd%command_list%execute (global)
      call msg_message &
        ("End of included '" // char (cmd%file) // "'")
    end if
  end subroutine cmd_include_execute
```

## Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_quit_t
  private
  logical :: has_code = .false.
  type(parse_node_t), pointer :: pn_code_expr => null ()
  contains
  <Commands: cmd quit: TBP>
  end type cmd_quit_t
```

Output.

```
<Commands: cmd quit: TBP>≡
  procedure :: write => cmd_quit_write

<Commands: procedures>+≡
  subroutine cmd_quit_write (cmd, unit, indent)
    class(cmd_quit_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,L1)" "quit: has_code = ", cmd%has_code
  end subroutine cmd_quit_write
```

Compile: allocate a quit object which serves as a placeholder.

```
<Commands: cmd quit: TBP>+≡
  procedure :: compile => cmd_quit_compile
```

```

⟨Commands: procedures⟩+≡
subroutine cmd_quit_compile (cmd, global)
  class(cmd_quit_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_arg
  pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
  if (associated (pn_arg)) then
    cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
    cmd%has_code = .true.
  end if
end subroutine cmd_quit_compile

```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```

⟨Commands: cmd quit: TBP⟩+≡
  procedure :: execute => cmd_quit_execute

⟨Commands: procedures⟩+≡
subroutine cmd_quit_execute (cmd, global)
  class(cmd_quit_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  logical :: is_known
  var_list => global%get_var_list_ptr ()
  if (cmd%has_code) then
    global%quit_code = eval_int (cmd%pn_code_expr, var_list, &
      is_known=is_known)
    if (.not. is_known) then
      call msg_error ("Undefined return code of quit/exit command")
    end if
  end if
  global%quit = .true.
end subroutine cmd_quit_execute

```

### 33.1.6 The command list

The command list holds a list of commands and relevant global data.

```

⟨Commands: public⟩+≡
  public :: command_list_t

⟨Commands: types⟩+≡
  type :: command_list_t
    ! not private anymore as required by the whizard-c-interface
    class(command_t), pointer :: first => null ()
    class(command_t), pointer :: last => null ()
  contains
    ⟨Commands: command list: TBP⟩
  end type command_list_t

```

Output.

```
<Commands: command list: TBP>≡
  procedure :: write => command_list_write

<Commands: procedures>+≡
  recursive subroutine command_list_write (cmd_list, unit, indent)
    class(command_list_t), intent(in) :: cmd_list
    integer, intent(in), optional :: unit, indent
    class(command_t), pointer :: cmd
    cmd => cmd_list%first
    do while (associated (cmd))
      call cmd%write (unit, indent)
      cmd => cmd%next
    end do
  end subroutine command_list_write
```

Append a new command to the list and free the original pointer.

```
<Commands: command list: TBP>+≡
  procedure :: append => command_list_append

<Commands: procedures>+≡
  subroutine command_list_append (cmd_list, command)
    class(command_list_t), intent(inout) :: cmd_list
    class(command_t), intent(inout), pointer :: command
    if (associated (cmd_list%last)) then
      cmd_list%last%next => command
    else
      cmd_list%first => command
    end if
    cmd_list%last => command
    command => null ()
  end subroutine command_list_append
```

Finalize.

```
<Commands: command list: TBP>+≡
  procedure :: final => command_list_final

<Commands: procedures>+≡
  recursive subroutine command_list_final (cmd_list)
    class(command_list_t), intent(inout) :: cmd_list
    class(command_t), pointer :: command
    do while (associated (cmd_list%first))
      command => cmd_list%first
      cmd_list%first => cmd_list%first%next
      call command%final ()
      deallocate (command)
    end do
    cmd_list%last => null ()
  end subroutine command_list_final
```

### 33.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```
(Commands: command list: TBP)+≡
  procedure :: compile => command_list_compile

(Commands: procedures)+≡
  recursive subroutine command_list_compile (cmd_list, pn, global)
    class(command_list_t), intent(inout), target :: cmd_list
    type(parse_node_t), intent(in), target :: pn
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_cmd
    class(command_t), pointer :: command
    integer :: i
    pn_cmd => parse_node_get_sub_ptr (pn)
    do i = 1, parse_node_get_n_sub (pn)
      call dispatch_command (command, pn_cmd)
      call command%compile (global)
      call cmd_list%append (command)
      call terminate_now_if_signal ()
      pn_cmd => parse_node_get_next_ptr (pn_cmd)
    end do
  end subroutine command_list_compile
```

### 33.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```
(Commands: command list: TBP)+≡
  procedure :: execute => command_list_execute

(Commands: procedures)+≡
  recursive subroutine command_list_execute (cmd_list, global)
    class(command_list_t), intent(in) :: cmd_list
    type(rt_data_t), intent(inout), target :: global
    class(command_t), pointer :: command
    command => cmd_list%first
    COMMAND_COND: do while (associated (command))
      call command%execute_options (global)
      call command%execute (global)
      call command%reset_options (global)
      call terminate_now_if_signal ()
      if (global%quit) exit COMMAND_COND
      command => command%next
    end do COMMAND_COND
  end subroutine command_list_execute
```

### 33.1.9 Command list syntax

```
<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡
    public :: syntax_cmd_list_init

<Commands: procedures>+≡
    subroutine syntax_cmd_list_init ()

## Rescan events

Read a model, then declare a process, compile the library, and generate weighted events. We take the default (`unit_test`) method and use the simplest methods of phase-space parameterization and integration. Then, rescan the generated event sample.

```
(Commands: execute tests)+≡

  call analysis_write (event_callback%u)
end subroutine event_callback_34
```

## 33.2 Toplevel module WHIZARD

```
<whizard.f90>≡  
  <File header>  
  
  module whizard  
  
    use io_units  
    <Use strings>  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF, BACKSLASH  
    use diagnostics  
    use os_interface  
    use ifiles  
    use lexers  
    use parser  
    use variables  
    use eval_trees  
    use models  
    use phs_forests  
    use prclib_stacks  
    use slha_interface  
    use blha_config  
    use rt_data  
    use commands  
  
    <Standard module head>  
  
    <WHIZARD: public>  
  
    <WHIZARD: types>  
  
    save  
  
    contains  
  
    <WHIZARD: procedures>  
  
  end module whizard
```

### 33.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```
<WHIZARD: public>≡  
  public :: whizard_options_t  
  
<WHIZARD: types>≡  
  type :: whizard_options_t  
    type(string_t) :: preload_model  
    type(string_t) :: default_lib  
    type(string_t) :: preload_libraries  
    logical :: rebuild_library = .false.
```

```

        logical :: recompile_library = .false.
        logical :: rebuild_user
        logical :: rebuild_phs = .false.
        logical :: rebuild_grids = .false.
        logical :: rebuild_events = .false.
    end type whizard_options_t

```

### 33.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

<WHIZARD: types> +=
    type, extends (parse_tree_t) :: pt_entry_t
        type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the `last` pointer.

```

<WHIZARD: types> +=
    type :: pt_stack_t
        type(pt_entry_t), pointer :: last => null ()
        contains
            <WHIZARD: pt_stack: TBP>
    end type pt_stack_t

```

The finalizer is called at the very end.

```

<WHIZARD: pt_stack: TBP> =
    procedure :: final => pt_stack_final

<WHIZARD: procedures> =
    subroutine pt_stack_final (pt_stack)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(pt_entry_t), pointer :: current
        do while (associated (pt_stack%last))
            current => pt_stack%last
            pt_stack%last => current%previous
            call parse_tree_final (current%parse_tree_t)
            deallocate (current)
        end do
    end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt_stack: TBP> +=
    procedure :: push => pt_stack_push

<WHIZARD: procedures> +=
    subroutine pt_stack_push (pt_stack, parse_tree)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(parse_tree_t), intent(out), pointer :: parse_tree
        type(pt_entry_t), pointer :: current

```

```

allocate (current)
parse_tree => current%parse_tree_t
current%previous => pt_stack%last
pt_stack%last => current
end subroutine pt_stack_push

```

### 33.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a `WHIZARD` instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+≡
public :: whizard_t

<WHIZARD: types>+≡
type :: whizard_t
type(whizard_options_t) :: options
type(rt_data_t) :: global
type(pt_stack_t) :: pt_stack
contains
<WHIZARD: whizard: TBP>
end type whizard_t

```

### 33.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>≡
procedure :: init => whizard_init

<WHIZARD: procedures>+≡
subroutine whizard_init (whizard, options, paths, logfile)
class(whizard_t), intent(out), target :: whizard
type(whizard_options_t), intent(in) :: options
type(paths_t), intent(in), optional :: paths
type(string_t), intent(in), optional :: logfile
call init_syntax_tables ()
whizard%options = options
call whizard%global%global_init (paths, logfile)
call whizard%init_rebuild_flags ()
call whizard%preload_model ()
call whizard%preload_library ()
call whizard%global%init_fallback_model &
(var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))

```

```

        call whizard%global%init_radiation_model &
            (var_str ("SM_rad"), var_str ("SM_rad.mdl"))
    end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+=
    procedure :: final => whizard_final

<WHIZARD: procedures>+=
    subroutine whizard_final (whizard)
        class(whizard_t), intent(inout), target :: whizard
        call whizard%global%final ()
        call whizard%pt_stack%final ()
        !!! JRR: WK please check (#529)
        !    call user_code_final ()
        call final_syntax_tables ()
    end subroutine whizard_final

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+=
    procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: procedures>+=
    subroutine whizard_init_rebuild_flags (whizard)
        class(whizard_t), intent(inout), target :: whizard
        associate (var_list => whizard%global%var_list, options => whizard%options)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_library"), options%rebuild_library, &
                intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?recompile_library"), &
                options%recompile_library, &
                intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_phase_space"), options%rebuild_phs, &
                intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_grids"), options%rebuild_grids, &
                intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?powheg_rebuild_grids"), options%rebuild_grids, &
                intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_events"), options%rebuild_events, &
                intrinsic=.true.)
        end associate
    end subroutine whizard_init_rebuild_flags

```

This procedure preloads a model, if a model name is given.

```

<WHIZARD: whizard: TBP>+=
    procedure :: preload_model => whizard_preload_model

```

```

{WHIZARD: procedures}+=
subroutine whizard_preload_model (whizard)
  class(whizard_t), intent(inout), target :: whizard
  type(string_t) :: model_name
  model_name = whizard%options%preload_model

  end do
  libs = adjustl (whizard%options%preload_libraries)
  if (libs == "" .and. whizard%options%default_lib /= "") then
    allocate (lib_entry)
    call lib_entry%init (whizard%options%default_lib)
    call whizard%global%add_prclib (lib_entry)
    call msg_message ("Preloaded library: " // &
      char (whizard%options%default_lib))
  end if
SCAN_LIBS: do while (libs /= "")
  call split (libs, library_name, " ")
  if (library_name /= "") then
    allocate (lib_entry)
    call lib_entry%init (library_name)
    call whizard%global%add_prclib (lib_entry)
  end if
end do

```

```

        call msg_message ("Preloaded library: " // char (library_name))
    end if
end do SCAN_LIBS
end subroutine whizard_preload_library

```

### 33.2.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

```

<WHIZARD: public>+≡
    public :: init_syntax_tables
    public :: final_syntax_tables

<WHIZARD: procedures>+≡
    subroutine init_syntax_tables ()
        call syntax_model_file_init ()
        call syntax_phs_forest_init ()
        call syntax_pexpr_init ()
        call syntax_slha_init ()
        call syntax_cmd_list_init ()
    end subroutine init_syntax_tables

    subroutine final_syntax_tables ()
        call syntax_model_file_final ()
        call syntax_phs_forest_final ()
        call syntax_pexpr_final ()
        call syntax_slha_final ()
        call syntax_cmd_list_final ()
    end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
    public :: write_syntax_tables

<WHIZARD: procedures>+≡
    subroutine write_syntax_tables ()
        integer :: unit
        character(*), parameter :: file_model = "whizard.model_file.syntax"
        character(*), parameter :: file_phs = "whizard.phase_space_file.syntax"
        character(*), parameter :: file_pexpr = "whizard.prt_expressions.syntax"
        character(*), parameter :: file_slha = "whizard.slha.syntax"
        character(*), parameter :: file_sindarin = "whizard.sindarin.syntax"
        unit = free_unit ()
        print *, "Writing file '" // file_model // "'"
        open (unit=unit, file=file_model, status="replace", action="write")

```

```

write (unit, "(A)")  VERSION_STRING
write (unit, "(A)")  "Syntax definition file: " // file_model
call syntax_model_file_write (unit)
close (unit)
print *, "Writing file '" // file_phs // "'"

write (unit, "(A)")  VERSION_STRING
write (unit, "(A)")  "Syntax definition file: " // file_slha
call syntax_slha_write (unit)
close (unit)
print *, "Writing file '" // file_sindarin // "'"
open (unit=unit, file=file_sindarin, status="replace", action="write")
write (unit, "(A)")  VERSION_STRING
write (unit, "(A)")  "Syntax definition file: " // file_sindarin
call syntax_cmd_list_write (unit)
close (unit)
end subroutine write_syntax_tables

```

### 33.2.6 Execute command lists

Process commands given on the command line, stored as an `ifile`. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: process_ifile => whizard_process_ifile

<WHIZARD: procedures>+≡
  subroutine whizard_process_ifile (whizard, ifile, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    type(ifile_t), intent(in) :: ifile
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    call msg_message ("Reading commands given on the command line")
    call lexer_init_cmd_list (lexer)
    call stream_init (stream, ifile)
    call whizard%process_stream (stream, lexer, quit, quit_code)
    call stream_final (stream)
    call lexer_final (lexer)
  end subroutine whizard_process_ifile

```

Process standard input as a command list. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: process_stdin => whizard_process_stdin
<WHIZARD: procedures>+≡
    subroutine whizard_process_stdin (whizard, quit, quit_code)
        class(whizard_t), intent(inout), target :: whizard
        logical, intent(out) :: quit
        integer, intent(out) :: quit_code
        type(lexer_t), target :: lexer
        type(stream_t), target :: stream
        call msg_message ("Reading commands from standard input")
        call lexer_init_cmd_list (lexer)
        call stream_init (stream, 5)
        call whizard%process_stream (stream, lexer, quit, quit_code)
        call stream_final (stream)
        call lexer_final (lexer)
    end subroutine whizard_process_stdin

```

Process a file as a command list.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: process_file => whizard_process_file
<WHIZARD: procedures>+≡
    subroutine whizard_process_file (whizard, file, quit, quit_code)
        class(whizard_t), intent(inout), target :: whizard
        type(string_t), intent(in) :: file
        logical, intent(out) :: quit
        integer, intent(out) :: quit_code
        type(lexer_t), target :: lexer
        type(stream_t), target :: stream
        logical :: exist
        call msg_message ("Reading commands from file '" // char (file) // "'")
        inquire (file=char(file), exist=exist)
        if (exist) then
            call lexer_init_cmd_list (lexer)
            call stream_init (stream, char (file))
            call whizard%process_stream (stream, lexer, quit, quit_code)
            call stream_final (stream)
            call lexer_final (lexer)
        else
            call msg_error ("File '" // char (file) // "' not found")
        end if
    end subroutine whizard_process_file

```

```

<WHIZARD: whizard: TBP>+≡
    procedure :: process_stream => whizard_process_stream
<WHIZARD: procedures>+≡
    subroutine whizard_process_stream (whizard, stream, lexer, quit, quit_code)
        class(whizard_t), intent(inout), target :: whizard
        type(stream_t), intent(inout), target :: stream
        type(lexer_t), intent(inout), target :: lexer

```

```

        type(stream_t), target :: stream
        type(string_t) :: prompt1
        type(string_t) :: prompt2
        type(string_t) :: input
        type(string_t) :: extra
        integer :: last
        integer :: iostat
        logical :: mask_tmp
        logical :: quit
        call msg_message ("Launching interactive shell")
        call lexer_init_cmd_list (lexer)
        prompt1 = "whish? "
        prompt2 = "      > "
        COMMAND_LOOP: do
            call put (6, prompt1)
            call get (5, input, iostat=iostat)
            if (iostat > 0 .or. iostat == EOF) exit COMMAND_LOOP
            CONTINUE_INPUT: do
                last = len_trim (input)
                if (extract (input, last, last) /= BACKSLASH) exit CONTINUE_INPUT
                call put (6, prompt2)
                call get (5, extra, iostat=iostat)
                if (iostat > 0) exit COMMAND_LOOP
            end do
        end do
    end subroutine whizard_shell

```

```

        input = replace (input, last, extra)
    end do CONTINUE_INPUT
    call stream_init (stream, input)
    mask_tmp = mask_fatal_errors
    mask_fatal_errors = .true.
    call whizard%process_stream (stream, lexer, quit, quit_code)
    msg_count = 0
    mask_fatal_errors = mask_tmp
    call stream_final (stream)
    if (quit) exit COMMAND_LOOP
end do COMMAND_LOOP
print *
call lexer_final (lexer)
end subroutine whizard_shell

```

### 33.3 Tools for the command line

We don't intent to be very smart here, but this module provides a few small tools that simplify dealing with the command line.

```
<cmdline_options.f90>≡
  <File header>

  module cmdline_options

    <Use strings>
    use diagnostics

    <Standard module head>

    public :: init_options
    public :: no_option_value
    public :: get_option_value

    <Main: cmdline arg len declaration>

    abstract interface
      subroutine msg
      end subroutine msg
    end interface

    procedure (msg), pointer :: print_usage => null ()

  contains

    subroutine init_options (usage_msg)
      procedure (msg) :: usage_msg
      print_usage => usage_msg
    end subroutine init_options

    subroutine no_option_value (option, value)
      type(string_t), intent(in) :: option, value
      if (value /= "") then
        call msg_error (" Option ' " // char (option) // "' should have no value")
      end if
    end subroutine no_option_value

    function get_option_value (i, option, value) result (string)
      type(string_t) :: string
      integer, intent(inout) :: i
      type(string_t), intent(in) :: option
      type(string_t), intent(in), optional :: value
      character(CMDLINE_ARG_LEN) :: arg_value
      integer :: arg_len, arg_status
      logical :: has_value
      if (present (value)) then
        has_value = value /= ""
      else
        has_value = .false.
      end if
```

```

if (has_value) then
    string = value
else
    i = i + 1
    call get_command_argument (i, arg_value, arg_len, arg_status)
    select case (arg_status)
    case (0)
    case (-1)
        call msg_error (" Option value truncated: '" // arg_value // "'")
    case default
        call print_usage ()
        call msg_fatal (" Option '" // char (option) // "' needs a value")
    end select
    select case (arg_value(1:1))
    case ("-")
        call print_usage ()
        call msg_fatal (" Option '" // char (option) // "' needs a value")
    end select
    string = trim (arg_value)
end if
end function get_option_value

end module cmdline_options

```

## 33.4 Query Feature Support

This module accesses the various optional features (modules) that WHIZARD can support and reports on their availability.

```
<features.f90>≡
  module features

### 33.4.1 Output

```
<Features: public>≡
  public :: print_features

<Features: procedures>≡
  subroutine print_features ()
    print "(A)", "WHIZARD " // WHIZARD_VERSION
    print "(A)", "Build configuration:"
    <Features: config>
    print "(A)", "Optional features available in this build:"
    <Features: print>
  end subroutine print_features
```

### 33.4.2 Query function

```
<Features: procedures>+≡
  subroutine check (feature, recognized, result, help)
    character(*), intent(in) :: feature
    logical, intent(out) :: recognized
    character(*), intent(out) :: result, help
    recognized = .true.
    result = "no"
    select case (lower_case (trim (feature)))
    <Features: cases>
    case default
      recognized = .false.
    end select
  end subroutine check
```

Print this result:

```
<Features: procedures>+≡
  subroutine print_check (feature)
    character(*), intent(in) :: feature
    character(16) :: f
    logical :: recognized
    character(10) :: result

## 33.5 Driver program

The main program handles command options, initializes the environment, and runs WHIZARD in a particular mode (interactive, file, standard input).

This is also used in the C interface:

```
<Main: cmdline arg len declaration>≡  
integer, parameter :: CMDLINE_ARG_LEN = 1000
```

The actual main program:

```
<main.f90>≡  
<File header>  
  
program main  
  
<Use strings>  
use unit_tests  
use system_dependencies  
use diagnostics  
use ifiles  
use os_interface  
use whizard  
  
use cmdline_options  
use features  
  
implicit none  
  
<Main: cmdline arg len declaration>  
  
! Main program variable declarations

### 33.6.1 Self-tests

For those self-tests, we need some auxiliary routines that provide an environment. The environment depends on things that are not available at the level of the module that we want to test.

#### Testbed for event I/O

This subroutine prepares a test process with a single event. All objects are allocated via anonymous pointers, because we want to recover the pointers and delete the objects in a separate procedure.

```
<Main: tests>≡
subroutine prepare_eio_test (event, unweighted, n_alt)
  use variables
  use model_data
  use processes
  use processes_ut, only: prepare_test_process
  use event_base
  use events

  class(generic_event_t), intent(inout), pointer :: event
  logical, intent(in), optional :: unweighted
  integer, intent(in), optional :: n_alt
  type(model_data_t), pointer :: model
  type(var_list_t) :: var_list
  type(process_t), pointer :: process
  type(process_instance_t), pointer :: process_instance

  allocate (model)
  call model%init_test ()

  allocate (process)
  allocate (process_instance)

  call prepare_test_process (process, process_instance, model)
  call process_instance%setup_event_data ()

  call model%final ()
  deallocate (model)

  allocate (event_t :: event)
  select type (event)
  type is (event_t)
    if (present (unweighted)) then
      call var_list_append_log (var_list, &
        var_str ("?unweighted"), unweighted, &
        intrinsic = .true.)
    else
      call var_list_append_log (var_list, &
        var_str ("?unweighted"), .true., &
        intrinsic = .true.)
    end if
  call var_list_append_string (var_list, &
    var_str ("sample_normalization"), &
```

```

        var_str ("auto"), intrinsic = .true.)
    call event%basic_init (var_list, n_alt)
    call event%connect (process_instance, process%get_model_ptr ())
    call var_list%final ()
end select

end subroutine prepare_eio_test

```

Recover those pointers, finalize the objects and deallocate.

*(Main: tests)*+≡

```

subroutine cleanup_eio_test (event)
    use model_data
    use processes
    use event_base
    use events

    class(generic_event_t), intent(inout), pointer :: event
    type(process_t), pointer :: process
    type(process_instance_t), pointer :: process_instance

    select type (event)
    type is (event_t)
        process => event%get_process_ptr ()
        process_instance => event%get_process_instance_ptr ()
        call cleanup_test_process (process, process_instance)
        deallocate (process_instance)
        deallocate (process)
        call event%final ()
    end select
    deallocate (event)

end subroutine cleanup_eio_test

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

*(Main: use tests)*≡

```

    use eio_base_ut, only: eio_prepare_test
    use eio_base_ut, only: eio_cleanup_test

```

*(Main: prepare testbed)*≡

```

    eio_prepare_test => prepare_eio_test
    eio_cleanup_test => cleanup_eio_test

```

## Any Model

This procedure reads any model from file and, optionally, assigns a var-list pointer.

*(Main: tests)*+≡

```

subroutine prepare_whizard_model (model, name, vars)
    (Use strings)
    use os_interface
    use model_data
    use var_base

```

```

use models
class(model_data_t), intent(inout), pointer :: model
type(string_t), intent(in) :: name
class(vars_t), pointer, intent(out), optional :: vars
type(os_data_t) :: os_data
call syntax_model_file_init ()
call os_data_init (os_data)
allocate (model_t :: model)
select type (model)
type is (model_t)
    call model%read (name // ".mdl", os_data)
    if (present (vars)) then
        vars => model%get_var_list_ptr ()
    end if
end select
end subroutine prepare_whizard_model

```

Cleanup after use. Includes deletion of the model-file syntax.

```

(Main: tests)+≡
subroutine cleanup_whizard_model (model)
    use model_data
    use models
    class(model_data_t), intent(inout), pointer :: model
    call model%final ()
    deallocate (model)
    call syntax_model_file_final ()
end subroutine cleanup_whizard_model

```

Assign those procedures to appropriate pointers (module variables) in the `model_testbed` module, so they can be called as if they were module procedures.

```

(Main: prepare testbed)+≡
prepare_model => prepare_whizard_model
cleanup_model => cleanup_whizard_model

```

### Fallback model: hadrons

Some event format tests require the hadronic SM implementation, which has to be read from file. We provide the functionality here, so the tests do not depend on model I/O.

```

(Main: tests)+≡
subroutine prepare_fallback_model (model)
    use model_data
    class(model_data_t), intent(inout), pointer :: model
    call prepare_whizard_model (model, var_str ("SM_hadrons"))
end subroutine prepare_fallback_model

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

(Main: use tests)+≡
use eio_base_ut, only: eio_prepare_fallback_model
use eio_base_ut, only: eio_cleanup_fallback_model

```

```

⟨Main: prepare testbed⟩+≡
    eio_prepare_fallback_model => prepare_fallback_model
    eio_cleanup_fallback_model => cleanup_model

```

### Access to the test random-number generator

This generator is not normally available for the dispatcher. We assign an additional dispatch routine to the hook in the `dispatch` module which will be checked before the default rule.

```

⟨Main: use tests⟩+≡
    use dispatch, only: dispatch_rng_factory_extra
    use dispatch_ut, only: dispatch_rng_factory_test

⟨Main: prepare testbed⟩+≡
    dispatch_rng_factory_extra => dispatch_rng_factory_test

```

### Access to the test structure functions

These are not normally available for the dispatcher. We assign an additional dispatch routine to the hook in the `dispatch` module which will be checked before the default rule.

```

⟨Main: use tests⟩+≡
    use dispatch, only: dispatch_sf_data_extra
    use dispatch_ut, only: dispatch_sf_data_test

⟨Main: prepare testbed⟩+≡
    dispatch_sf_data_extra => dispatch_sf_data_test

```

### Procedure for Checking

This is for developers only, but needs a well-defined interface.

```

⟨Main: tests⟩+≡
    subroutine whizard_check (check, results)
        use io_units
        use model_testbed

    ⟨Main: use tests⟩

        type(string_t), intent(in) :: check
        type(test_results_t), intent(inout) :: results
        type(os_data_t) :: os_data
        integer :: u

        call os_data_init (os_data)
        u = free_unit ()
        open (u, file="whizard_check." // char (check) // ".log", &
            action="write", status="replace")
        call msg_message (repeat ('=', 76), 0)
        call msg_message ("Running self-test: " // char (check), 0)
        call msg_message (repeat ('-', 76), 0)
    ⟨Main: prepare testbed⟩
        select case (char (check))
    ⟨Main: test cases⟩

```

```

    case ("all")
        <Main: all tests>
    case default
        call msg_fatal ("Self-test ' " // char (check) // "' not implemented.")
    end select
    close (u)
end subroutine whizard_check

```

### 33.6.2 Unit test references

#### Formats

```

<Main: use tests>+≡
    use formats_ut, only: format_test

<Main: test cases>+≡
    case ("formats")
        call format_test (u, results)
