The heart of phase space generation: Now we have the invariant masses, let us generate angles. At each branch, we take a Lorentz transformation and augment it by a boost to the current particle rest frame, and by rotations ϕ and θ around the z and y axis, respectively. This transformation is passed down to the daughter particles, if present.

```

This subroutine is the most time-critical part of the whole program. Therefore, we do not exactly parallel the angle generation routine above but make sure that things get evaluated only if they are really needed, at the expense of

readability. Particularly important is to have as few multiplications of Lorentz transformations as possible.

19.8 The phase-space forest

Simply stated, a phase-space forest is a collection of phase-space trees. More precisely, a `phs_forest` object contains all parameterizations of phase space that WHIZARD will use for a single hard process, prepared in the form of `phs_tree` objects. This is suitable for evaluation by the VAMP integration package: each parameterization (tree) is a valid channel in the multi-channel adaptive integration, and each variable in a tree corresponds to an integration dimension, defined by an appropriate mapping of the $(0, 1)$ interval to the allowed range of the integration variable.

The trees are grouped in groves. The trees (integration channels) within a grove share a common weight, assuming that they are related by some approximate symmetry.

Trees/channels that are related by an exact symmetry are connected by an array of equivalences; each equivalence object holds the data that relate one channel to another.

The phase-space setup, i.e., the detailed structure of trees and forest, are read from a file. Therefore, this module also contains the syntax definition and the parser needed for interpreting this file.

19.8.1 Phase-space setup parameters

This transparent container holds the parameters that the algorithm needs for phase-space setup, with reasonable defaults.

The threshold mass (for considering a particle as effectively massless) is specified separately for s- and t-channel. The default is to treat W and Z bosons as massive in the s-channel, but as massless in the t-channel. The b -quark is treated always massless, the t -quark always massive.

```

```

19.8.2 Equivalences

This type holds information about equivalences between phase-space trees. We make a linked list, where each node contains the two trees which are equivalent and the corresponding permutation of external particles. Two more arrays are to be filled: The permutation of mass variables and the permutation of angular variables, where the signature indicates a necessary exchange of daughter branches.

```
(PHS forests: types)+≡
  type :: equivalence_t
  private
  integer :: left, right
  type(permutation_t) :: perm
  type(permutation_t) :: msq_perm, angle_perm
  logical, dimension(:), allocatable :: angle_sig
  type(equivalence_t), pointer :: next => null ()
end type equivalence_t
```

```
(PHS forests: types)+≡
  type :: equivalence_list_t
  private
  integer :: length = 0
  type(equivalence_t), pointer :: first => null ()
  type(equivalence_t), pointer :: last => null ()
end type equivalence_list_t
```

Append an equivalence to the list

```
(PHS forests: procedures)+≡
  subroutine equivalence_list_add (eql, left, right, perm)
  type(equivalence_list_t), intent(inout) :: eql
  integer, intent(in) :: left, right
  type(permutation_t), intent(in) :: perm
  type(equivalence_t), pointer :: eq
  allocate (eq)
  eq%left = left
  eq%right = right
  eq%perm = perm
  if (associated (eql%last)) then
    eql%last%next => eq
  else
    eql%first => eq
  end if
  eql%last => eq
  eql%length = eql%length + 1
end subroutine equivalence_list_add
```

Delete the list contents. Has to be pure because it is called from an elemental subroutine.

```
(PHS forests: procedures)+≡
  pure subroutine equivalence_list_final (eql)
  type(equivalence_list_t), intent(inout) :: eql
  type(equivalence_t), pointer :: eq
```

```

do while (associated (eql%first))
  eq => eql%first
  eql%first => eql%first%next
  deallocate (eq)
end do
eql%last => null ()
eql%length = 0
end subroutine equivalence_list_final

```

Make a deep copy of the equivalence list. This allows for deep copies of groves and forests.

```

(PHS forests: interfaces)+≡
interface assignment(=)
  module procedure equivalence_list_assign
end interface

(PHS forests: procedures)+≡
subroutine equivalence_list_assign (eql_out, eql_in)
  type(equivalence_list_t), intent(out) :: eql_out

  do while (associated (eq))
    allocate (eq_copy)
    eq_copy = eq
    eq_copy%next => null ()
    if (associated (eql_out%first)) then
      eql_out%last%next => eq_copy
    else
      eql_out%first => eq_copy
    end if
    eql_out%last => eq_copy
    eq => eq%next
  end do
end subroutine equivalence_list_assign

```

The number of list entries

```

(PHS forests: procedures)+≡
elemental function equivalence_list_length (eql) result (length)
  integer :: length
  type(equivalence_list_t), intent(in) :: eql
  length = eql%length
end function equivalence_list_length

```

Recursively write the equivalences list

```

(PHS forests: procedures)+≡
subroutine equivalence_list_write (eql, unit)
  type(equivalence_list_t), intent(in) :: eql
  integer, intent(in), optional :: unit
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  if (associated (eql%first)) then

```

```

        call equivalence_write_rec (eql%first, u)
    else
        write (u, *) " [empty]"
    end if
contains
recursive subroutine equivalence_write_rec (eq, u)
    type(equivalence_t), intent(in) :: eq
    integer, intent(in) :: u
    integer :: i
    write (u, "(3x,A,1x,I0,1x,I0,2x,A)", advance="no") &
        "Equivalence:", eq%left, eq%right, "Final state permutation:"
    call permutation_write (eq%perm, u)
    write (u, "(1x,12x,1x,A,1x)", advance="no") &
        "      msq permutation:  "
    call permutation_write (eq%msq_perm, u)
    write (u, "(1x,12x,1x,A,1x)", advance="no") &
        "      angle permutation:"
    call permutation_write (eq%angle_perm, u)
    write (u, "(1x,12x,1x,26x)", advance="no")
    do i = 1, size (eq%angle_sig)
        if (eq%angle_sig(i)) then
            write (u, "(1x,A)", advance="no") "+"
        else

        end if
    end do
    write (u, *)
    if (associated (eq%next)) call equivalence_write_rec (eq%next, u)
end subroutine equivalence_write_rec
end subroutine equivalence_list_write

```

19.8.3 Groves

A grove is a group of trees (phase-space channels) that share a common weight in the integration. Within a grove, channels can be declared equivalent, so they also share their integration grids (up to symmetries). The grove contains a list of equivalences. The `tree_count_offset` is the total number of trees of the preceding groves; when the trees are counted per forest (integration channels), the offset has to be added to all tree indices.

```

<PHS forests: types>+≡
    type :: phs_grove_t
    private
    integer :: tree_count_offset
    type(phs_tree_t), dimension(:), allocatable :: tree
    type(equivalence_list_t) :: equivalence_list
end type phs_grove_t

```

Call `phs_tree_init` which is also elemental:

```

<PHS forests: procedures>+≡
    elemental subroutine phs_grove_init &
        (grove, n_trees, n_in, n_out, n_masses, n_angles)

```

```

    type(phs_grove_t), intent(inout) :: grove
    integer, intent(in) :: n_trees, n_in, n_out, n_masses, n_angles
    grove%tree_count_offset = 0
    allocate (grove%tree (n_trees))
    call phs_tree_init (grove%tree, n_in, n_out, n_masses, n_angles)
end subroutine phs_grove_init

```

The trees do not have pointer components, thus no call to `phs_tree_final`:

```

<PHS forests: procedures>+≡
    elemental subroutine phs_grove_final (grove)
        type(phs_grove_t), intent(inout) :: grove
        deallocate (grove%tree)
        call equivalence_list_final (grove%equivalence_list)
    end subroutine phs_grove_final

```

Deep copy.

```

<PHS forests: interfaces>+≡
    interface assignment(=)
        module procedure phs_grove_assign0
        module procedure phs_grove_assign1
    end interface

<PHS forests: procedures>+≡
    subroutine phs_grove_assign0 (grove_out, grove_in)
        type(phs_grove_t), intent(out) :: grove_out
        type(phs_grove_t), intent(in) :: grove_in
        grove_out%tree_count_offset = grove_in%tree_count_offset
        if (allocated (grove_in%tree)) then
            allocate (grove_out%tree (size (grove_in%tree)))
            grove_out%tree = grove_in%tree
        end if
        grove_out%equivalence_list = grove_in%equivalence_list
    end subroutine phs_grove_assign0

    subroutine phs_grove_assign1 (grove_out, grove_in)
        type(phs_grove_t), dimension(:), intent(out) :: grove_out
        type(phs_grove_t), dimension(:), intent(in) :: grove_in
        integer :: i
        do i = 1, size (grove_in)
            call phs_grove_assign0 (grove_out(i), grove_in(i))
        end do
    end subroutine phs_grove_assign1

```

Get the global (s-channel) mappings. Implemented as a subroutine which returns an array (slice).

```

<PHS forests: procedures>+≡
    subroutine phs_grove_assign_s_mappings (grove, mapping)
        type(phs_grove_t), intent(in) :: grove
        type(mapping_t), dimension(:), intent(out) :: mapping
        integer :: i
        if (size (mapping) == size (grove%tree)) then
            do i = 1, size (mapping)

```

```

        call phs_tree_assign_s_mapping (grove%tree(i), mapping(i))
    end do
else
    call msg_bug ("phs_grove_assign_s_mappings: array size mismatch")
end if
end subroutine phs_grove_assign_s_mappings

```

19.8.4 The forest type

This is a collection of trees and associated particles. In a given tree, each branch code corresponds to a particle in the `prt` array. Furthermore, we have an array of mass sums which is independent of the decay tree and of the particular event. The mappings directly correspond to the decay trees, and the decay groves collect the trees in classes. The permutation list consists of all permutations of outgoing particles that map the decay forest onto itself.

The particle codes `flv` (one for each external particle) are needed for determining masses and such. The trees and associated information are collected in the `grove` array, together with a lookup table that associates tree indices to groves. Finally, the `prt` array serves as workspace for phase-space evaluation.

The `prt_combination` is a list of index pairs, namely the particle momenta pairs that need to be combined in order to provide all momentum combinations that the phase-space trees need to know.

```

<PHS forests: public>+≡
    public :: phs_forest_t

<PHS forests: types>+≡
    type :: phs_forest_t
    private
        integer :: n_in, n_out, n_tot
        integer :: n_masses, n_angles, n_dimensions
        integer :: n_trees, n_equivalences
        type(flavor_t), dimension(:), allocatable :: flv
        type(phs_grove_t), dimension(:), allocatable :: grove
        integer, dimension(:), allocatable :: grove_lookup
        type(phs_prt_t), dimension(:), allocatable :: prt_in
        type(phs_prt_t), dimension(:), allocatable :: prt_out
        type(phs_prt_t), dimension(:), allocatable :: prt
        integer(TC), dimension(:,:), allocatable :: prt_combination
        type(mapping_t), dimension(:), allocatable :: s_mapping
    contains
        <PHS forests: phs forest: TBP>
    end type phs_forest_t

```

The initialization merely allocates memory. We have to know how many trees there are in each grove, so we can initialize everything. The number of groves is the size of the `n_tree` array.

In the `grove_lookup` table we store the grove index that belongs to each absolute tree index. The difference between the absolute index and the relative (to the grove) index is stored, for each grove, as `tree_count_offset`.

The particle array is allocated according to the total number of branches each tree has, but not filled.

```

(PHS forests: public)+≡
    public :: phs_forest_init

(PHS forests: procedures)+≡
    subroutine phs_forest_init (forest, n_tree, n_in, n_out)
        type(phs_forest_t), intent(inout) :: forest

19.8.7 Read the phase space setup from file

The phase space setup is stored in a file. The file may be generated by the `cascades` module below, or by other means. This file has to be read and parsed to create the PHS forest as the internal phase-space representation.

Create lexer and syntax:

(*PHS forests: procedures*) +=

```

subroutine define_phs_forest_syntax (ifile)
    type(ifile_t) :: ifile
    call ifile_append (ifile, "SEQ phase_space_list = process_phase_space*")
    call ifile_append (ifile, "SEQ process_phase_space = " &
        // "process_def process_header phase_space")
    call ifile_append (ifile, "SEQ process_def = process process_list")
    call ifile_append (ifile, "KEY process")
    call ifile_append (ifile, "LIS process_list = process_tag*")
    call ifile_append (ifile, "IDE process_tag")
    call ifile_append (ifile, "SEQ process_header = " &
        // "md5sum_process = md5sum " &
        // "md5sum_model_par = md5sum " &
        // "md5sum_phs_config = md5sum " &
        // "sqrts = real " &
        // "m_threshold_s = real " &
        // "m_threshold_t = real " &
        // "off_shell = integer " &
        // "t_channel = integer " &
        // "keep_nonresonant = logical")
    call ifile_append (ifile, "KEY '='")
    call ifile_append (ifile, "KEY '-'")
    call ifile_append (ifile, "KEY md5sum_process")
    call ifile_append (ifile, "KEY md5sum_model_par")
    call ifile_append (ifile, "KEY md5sum_phs_config")
    call ifile_append (ifile, "KEY sqrts")
    call ifile_append (ifile, "KEY m_threshold_s")
    call ifile_append (ifile, "KEY m_threshold_t")
    call ifile_append (ifile, "KEY off_shell")
    call ifile_append (ifile, "KEY t_channel")
    call ifile_append (ifile, "KEY keep_nonresonant")
    call ifile_append (ifile, "QUO md5sum = '""' ... '""'")
    call ifile_append (ifile, "REA real")
    call ifile_append (ifile, "INT integer")
    call ifile_append (ifile, "IDE logical")
    call ifile_append (ifile, "SEQ phase_space = grove_def+")
    call ifile_append (ifile, "SEQ grove_def = grove tree_def+")
    call ifile_append (ifile, "KEY grove")
end subroutine

```

```

call ifile_append (ifile, "SEQ tree_def = tree bincodes mapping*")
call ifile_append (ifile, "KEY tree")
call ifile_append (ifile, "SEQ bincodes = bincodes*")
call ifile_append (ifile, "INT bincodes")
call ifile_append (ifile, "SEQ mapping = map bincodes channel signed_pdg")
call ifile_append (ifile, "KEY map")
call ifile_append (ifile, "ALT channel = &
    &s_channel | t_channel | u_channel | &
    &collinear | infrared | radiation | on_shell")
call ifile_append (ifile, "KEY s_channel")
! call ifile_append (ifile, "KEY t_channel")    !!! Key already exists
call ifile_append (ifile, "KEY u_channel")
call ifile_append (ifile, "KEY collinear")
call ifile_append (ifile, "KEY infrared")
call ifile_append (ifile, "KEY radiation")
call ifile_append (ifile, "KEY on_shell")
call ifile_append (ifile, "ALT signed_pdg = &
    &pdg | negative_pdg")
call ifile_append (ifile, "SEQ negative_pdg = '-' pdg")
call ifile_append (ifile, "INT pdg")
end subroutine define_phs_forest_syntax

```

The model-file syntax and lexer are fixed, therefore stored as module variables:

```

<PHS forests: variables>≡
    type(syntax_t), target, save :: syntax_phs_forest

```

```

<PHS forests: public>+≡
    public :: syntax_phs_forest_init

```

```

<PHS forests: procedures>+≡
    subroutine syntax_phs_forest_init ()
        type(ifile_t) :: ifile
        call define_phs_forest_syntax (ifile)
        call syntax_init (syntax_phs_forest, ifile)
        call ifile_final (ifile)
    end subroutine syntax_phs_forest_init

```

```

<PHS forests: procedures>+≡
    subroutine lexer_init_phs_forest (lexer)
        type(lexer_t), intent(out) :: lexer
        call lexer_init (lexer, &
            comment_chars = "#!", &
            quote_chars = '"', &
            quote_match = "'", &
            single_chars = "-", &
            special_class = ["="] , &
            keyword_list = syntax_get_keyword_list_ptr (syntax_phs_forest))
    end subroutine lexer_init_phs_forest

```

```

<PHS forests: public>+≡
    public :: syntax_phs_forest_final

```

```

<PHS forests: procedures>+≡

```

```

subroutine syntax_phs_forest_final ()
  call syntax_final (syntax_phs_forest)
end subroutine syntax_phs_forest_final

```

<PHS forests: public>+≡

```

public :: syntax_phs_forest_write

```

<PHS forests: procedures>+≡

```

subroutine syntax_phs_forest_write (unit)
  integer, intent(in), optional :: unit
  call syntax_write (syntax_phs_forest, unit)
end subroutine syntax_phs_forest_write

```

The concrete parser and interpreter. Generate an input stream for the external `unit`, read the parse tree (with given `syntax` and `lexer`) from this stream, and transfer the contents of the parse tree to the PHS forest.

We look for the matching `process` tag, count groves and trees for initializing the forest, and fill the trees.

If the optional parameters are set, compare the parameters stored in the file to those. Set `match` true if everything agrees.

<PHS forests: public>+≡

```

public :: phs_forest_read

```

19.8.8 Preparation

The trees that we read from file do not carry flavor information. This is set separately:

The flavor list must be unique for a unique set of masses; if a given particle can have different flavor, the mass must be degenerate, so we can choose one of the possible flavor combinations.

(PHS forests: public)+≡

```
public :: phs_forest_set_flavors
```

      end associate
    end do
  end do
end subroutine phs_forest_set_momentum_links

```

Once the parameter set is fixed, the masses and the widths of the particles are known and the `mass_sum` arrays as well as the mapping parameters can be computed. Note that order is important: we first compute the mass sums, then the ordinary mappings. The resonances obtained here determine the effective masses, which in turn are used to implement step mappings for resonance decay products that are not mapped otherwise.

(PHS forests: public)+≡

```
public :: phs_forest_set_parameters
```

(PHS forests: procedures)+≡

```

Generate the particle combination table. Scan all trees and merge their individual combination tables. At the end, valid entries are non-zero, and they indicate the indices of a pair of particles to be combined to a new particle. If a particle is accessible by more than one tree (this is usual), only keep the first possibility.

19.8.10 Find equivalences among phase-space trees

Scan phase space for equivalences. We generate the complete set of unique permutations for the given list of outgoing particles, and use this for scanning equivalences within each grove. We scan all pairs of trees, using all permutations. This implies that trivial equivalences are included, and equivalences between different trees are recorded twice. This is intentional.

```

19.8.12 Phase-space evaluation

Given one row of the **x** parameter array and the corresponding channel index, compute first all relevant momenta and then recover the remainder of the **x** array, the Jacobians **phs_factor**, and the phase-space volume.

The output argument **ok** indicates whether this was successful.

(PHS forests: public)+≡

```
public :: phs_forest_evaluate_selected_channel
```

(PHS forests: procedures)+≡

19.9 Finding phase space parameterizations

If the phase space configuration is not found in the appropriate file, we should generate one.

The idea is to construct all Feynman diagrams subject to certain constraints which eliminate everything that is probably irrelevant for the integration. These Feynman diagrams (cascades) are grouped in groves by finding equivalence classes related by symmetry and ordered with respect to their importance (resonances). Finally, the result (or part of it) is written to file and used for the integration.

This module may eventually disappear and be replaced by CAML code. In particular, we need here a set of Feynman rules (vertices with particle codes,

but not the factors). Thus, the module works for the Standard Model only.

Note that this module is stand-alone, it communicates to the main program only via the generated ASCII phase-space configuration file.

```

19.9.1 The mapping modes

The valid mapping modes, to be used below. We will make use of the convention that mappings of internal particles have a positive value. Only for positive values, the flavor code is propagated when combining cascades.

```

<Mapping modes>≡
  integer, parameter :: &
    & EXTERNAL_PRT = -1, &

```

```

& NO_MAPPING = 0, S_CHANNEL = 1, T_CHANNEL = 2, U_CHANNEL = 3, &
& RADIATION = 4, COLLINEAR = 5, INFRARED = 6, &
& STEP_MAPPING_E = 11, STEP_MAPPING_H = 12, &
& ON_SHELL = 99

```

$\langle \text{Cascades: parameters} \rangle \equiv$
 $\langle \text{Mapping modes} \rangle$

19.9.2 The cascade type

A cascade is essentially the same as a decay tree (both definitions may be merged in a later version). It contains a linked tree of nodes, each of which representing an internal particle. In contrast to decay trees, each node has a definite particle code. These nodes need not be modified, therefore we can use pointers and do not have to copy them. Thus, physically each cascade has only a single node, the mother particle. However, to be able to compare trees quickly, we store in addition an array of binary codes which is always sorted in ascending order. This is accompanied by a corresponding list of particle codes. The index is the location of the corresponding cascade in the cascade set, this may be used to access the daughters directly.

The real mass is the particle mass belonging to the particle code. The minimal mass is the sum of the real masses of all its daughters; this is the kinematical cutoff. The effective mass may be zero if the particle mass is below a certain threshold; it may be the real mass if the particle is resonant; or it may be some other value.

The logical `t_channel` is set if this a t -channel line, while `initial` is true only for an initial particle. Note that both initial particles are also `t_channel` by definition, and that they are distinguished by the direction of the tree: One of them decays and is the root of the tree, while the other one is one of the leaves.

The cascade is a list of nodes (particles) which are linked via the `daughter` entries. The node is the mother particle of the decay cascade. Much of the information in the nodes is repeated in arrays, to be accessible more easily. The arrays will be kept sorted by binary codes.

The counter `n_off_shell` is increased for each internal line that is neither resonant nor log-enhanced. It is set to zero if the current line is resonant, since this implies on-shell particle production and subsequent decay.

The counter `n_t_channel` is non-negative once an initial particle is included in the tree: then, it counts the number of t -channel lines.

The `multiplicity` is the number of branchings to follow until all daughters are on-shell. A resonant or non-decaying particle has multiplicity one. Merging nodes, the multiplicities add unless the mother is a resonance. An initial or final node has multiplicity zero.

The arrays correspond to the subnode tree `tree` of the current cascade. PDG codes are stored only for those positions which are resonant, with the exception of the last entry, i.e., the current node. Other positions, in particular external legs, are assigned undefined PDG code.

A cascade is uniquely identified by its tree, the tree of PDG codes, and the tree of mappings. The tree of resonances is kept only to mask the PDG tree as described above.

```

19.9.3 Creating new cascades

This initializes a single-particle cascade (external, final state). The PDG entry in the tree is set undefined because the cascade is not resonant. However, the flavor entry is set, so the cascade flavor is identified nevertheless.

```

<Cascades: procedures>+=
subroutine cascade_init_outgoing (cascade, flv, pos, m_thr)
type(cascade_t), intent(out) :: cascade
type(flavor_t), intent(in) :: flv
integer, intent(in) :: pos
real(default), intent(in) :: m_thr
call cascade_init (cascade, 1)
cascade%bincode = ibset (0_TC, pos-1)
cascade%flv = flv
cascade%pdg = cascade%flv%get_pdg ()
cascade%is_vector = flv%get_spin_type () == VECTOR
cascade%m_min = flv%get_mass ()
cascade%m_rea = cascade%m_min
if (cascade%m_rea >= m_thr) then
cascade%m_eff = cascade%m_rea
end if
cascade%on_shell = .true.
cascade%multiplicity = 1
cascade%tree(1) = cascade%bincode
cascade%tree_pdg(1) = cascade%pdg
cascade%tree_mapping(1) = EXTERNAL_PRT
cascade%tree_resonant(1) = .false.
end subroutine cascade_init_outgoing

```

The same for an incoming line:

```

<Cascades: procedures>+=
subroutine cascade_init_incoming (cascade, flv, pos, m_thr)
type(cascade_t), intent(out) :: cascade
type(flavor_t), intent(in) :: flv
integer, intent(in) :: pos

```

```

real(default), intent(in) :: m_thr
call cascade_init (cascade, 1)
cascade%incoming = .true.
cascade%bincode = ibset (0_TC, pos-1)
cascade%flv = flv%anti ()
cascade%pdg = cascade%flv%get_pdg ()
cascade%is_vector = flv%get_spin_type () == VECTOR
cascade%m_min = flv%get_mass ()
cascade%m_rea = cascade%m_min
if (cascade%m_rea >= m_thr) then
    cascade%m_eff = cascade%m_rea
end if
cascade%on_shell = .true.
cascade%n_t_channel = 0
cascade%n_off_shell = 0
cascade%tree(1) = cascade%bincode
cascade%tree_pdg(1) = cascade%pdg
cascade%tree_mapping(1) = EXTERNAL_PRT
cascade%tree_resonant(1) = .false.
end subroutine cascade_init_incoming

```

19.9.4 Tools

This function returns true if the two cascades share no common external particle. This is a requirement for joining them.

<Cascades: interfaces>≡

```

interface operator(.disjunct.)
    module procedure cascade_disjunct
end interface

```

<Cascades: procedures>+≡

```

function cascade_disjunct (cascade1, cascade2) result (flag)
    logical :: flag
    type(cascade_t), intent(in) :: cascade1, cascade2
    flag = iand (cascade1%bincode, cascade2%bincode) == 0
end function cascade_disjunct

```

Compute a hash code for the resonance pattern of a cascade. We count the number of times each particle appears as a resonance.

We pack the PDG codes of the resonances in two arrays (s-channel and t-channel), sort them both, concatenate the results, transfer to i8 integers, and compute the hash code from this byte stream.

For t/u-channel, we remove the sign for antiparticles since this is not well-defined.

<Cascades: procedures>+≡

```

subroutine cascade_assign_resonance_hash (cascade)
    type(cascade_t), intent(inout) :: cascade
    integer(i8), dimension(1) :: mold
    cascade%res_hash = hash (transfer &
        ([sort (pack (cascade%tree_pdg, &
            cascade%tree_resonant)), &

```

```

        sort (pack (abs (cascade%tree_pdg), &
                    cascade%tree_mapping == T_CHANNEL .or. &
                    cascade%tree_mapping == U_CHANNEL))], &
        mold))
end subroutine cascade_assign_resonance_hash

```

19.9.5 Hash entries for cascades

We will set up a hash array which contains keys of and pointers to cascades. We hold a list of cascade (pointers) within each bucket. This is not for collision resolution, but for keeping similar, but unequal cascades together.

```

<Cascades: types>+≡
  type :: cascade_p
    type(cascade_t), pointer :: cascade => null ()
    type(cascade_p), pointer :: next => null ()
  end type cascade_p

```

Here is the bucket or hash entry type:

```

<Cascades: types>+≡
  type :: hash_entry_t
    integer(i32) :: hashval = 0
    integer(i8), dimension(:), allocatable :: key
    type(cascade_p), pointer :: first => null ()
    type(cascade_p), pointer :: last => null ()
  end type hash_entry_t

```

```

<Cascades: public>≡
  public :: hash_entry_init

```

```

<Cascades: procedures>+≡
  subroutine hash_entry_init (entry, entry_in)
    type(hash_entry_t), intent(out) :: entry
    type(hash_entry_t), intent(in) :: entry_in
    type(cascade_p), pointer :: casc_iter, casc_copy
    entry%hashval = entry_in%hashval
    entry%key = entry_in%key
    casc_iter => entry_in%first
    do while (associated (casc_iter))
      allocate (casc_copy)
      casc_copy = casc_iter
      casc_copy%next => null ()
      if (associated (entry%first)) then
        entry%last%next => casc_copy
      else
        entry%first => casc_copy
      end if
      entry%last => casc_copy
      casc_iter => casc_iter%next
    end do
  end subroutine hash_entry_init

```

Finalize: just deallocate the list; the contents are just pointers.

```

(Cascades: procedures)+=≡
  subroutine hash_entry_final (hash_entry)
    type(hash_entry_t), intent(inout) :: hash_entry
    type(cascade_p), pointer :: current
    do while (associated (hash_entry%first))
      current => hash_entry%first
      hash_entry%first => current%next
      deallocate (current)
    end do
  end subroutine hash_entry_final

```

Output: concise format for debugging, just list cascade indices.

```

(Cascades: procedures)+=≡
  subroutine hash_entry_write (hash_entry, unit)
    type(hash_entry_t), intent(in) :: hash_entry

  end subroutine hash_entry_add_cascade_ptr

```

```

else
    hash_entry%first => current
end if
hash_entry%last => current
end subroutine hash_entry_add_cascade_ptr

```

This function checks whether a cascade is already in the bucket. For incomplete cascades, we look for an exact match. It should suffice to verify the tree, the PDG codes, and the mapping modes. This is the information that is written to the phase space file.

For complete cascades, we ignore the PDG code at positions with mappings infrared, collinear, or t/u-channel. Thus a cascade which is distinguished only by PDG code at such places, is flagged existent. If the convention is followed that light particles come before heavier ones (in the model definition), this ensures that the lightest particle is kept in the appropriate place, corresponding to the strongest peak.

For external cascades (incoming/outgoing) we take the PDG code into account even though it is zeroed in the PDG-code tree.

```

19.9.6 The cascade set

The cascade set will later be transformed into the decay forest. It is set up as a linked list. In addition to the usual **first** and **last** pointers, there is a **first_t** pointer which points to the first t-channel cascade (after all s-channel cascades), and a **first_k** pointer which points to the first final cascade (with a keystone).

As an auxiliary device, the object contains a hash array with associated parameters where an additional pointer is stored for each cascade. The keys are made from the relevant cascade data. This hash is used for fast detection (and thus avoidance) of double entries in the cascade list.

```

The initializer sets up the hash table with some initial size guessed by looking at the number of external particles. We choose 256 for 3 external particles and a factor of 4 for each additional particle, limited at $2^{30}=1\text{G}$.

Note: the explicit initialization loop might be avoided (ELEMENTAL), but a bug in nagfor 5.3.2 prevents this.

end subroutine cascade_set_write

```

19.9.7 Adding cascades

Add a deep copy of a cascade to the set. The copy has all content of the original, but the pointers are nullified. We do not care whether insertion was successful or not. The pointer argument, if present, is assigned to the input cascade, or to the hash entry if it is already present.

The procedure is recursive: any daughter or mother entries are also deep-copied and added to the cascade set before the current copy is added.

<Cascades: procedures>+≡

```

recursive subroutine cascade_set_add_copy &
  (cascade_set, cascade_in, cascade_ptr)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in) :: cascade_in
  type(cascade_t), optional, pointer :: cascade_ptr
  type(cascade_t), pointer :: cascade
  logical :: ok
  allocate (cascade)
  cascade = cascade_in
  if (associated (cascade_in%daughter1)) call cascade_set_add_copy &
    (cascade_set, cascade_in%daughter1, cascade%daughter1)
  if (associated (cascade_in%daughter2)) call cascade_set_add_copy &
    (cascade_set, cascade_in%daughter2, cascade%daughter2)
  if (associated (cascade_in%mother)) call cascade_set_add_copy &
    (cascade_set, cascade_in%mother, cascade%mother)
  cascade%next => null ()
  call cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
  if (.not. ok) deallocate (cascade)
end subroutine cascade_set_add_copy

```

Add a cascade to the set. This does not deep-copy. We first try to insert it in the hash array. If successful, add it to the list. Failure indicates that it is already present, and we drop it.

The hash key is built solely from the tree array, so neither particle codes nor resonances count, just topology.

Technically, hash and list receive only pointers, so the cascade can be considered as being in either of both. We treat it as part of the list.

<Cascades: procedures>+≡

```

subroutine cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in), target :: cascade

```

```

logical, intent(out) :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i8), dimension(1) :: mold
call cascade_set_hash_insert &
    (cascade_set, transfer (cascade%tree, mold), cascade, ok, cascade_ptr)
if (ok) call cascade_set_list_add (cascade_set, cascade)
end subroutine cascade_set_add

```

Add a new cascade to the list:

```

<Cascades: procedures>+=
subroutine cascade_set_list_add (cascade_set, cascade)
    type(cascade_set_t), intent(inout) :: cascade_set
    type(cascade_t), intent(in), target :: cascade
    if (associated (cascade_set%last)) then
        cascade_set%last%next => cascade
    else
        cascade_set%first => cascade
    end if
    cascade_set%last => cascade
end subroutine cascade_set_list_add

```

Add a cascade entry to the hash array:

```

<Cascades: procedures>+=
subroutine cascade_set_hash_insert &
    (cascade_set, key, cascade, ok, cascade_ptr)
    type(cascade_set_t), intent(inout), target :: cascade_set
    integer(i8), dimension(:), intent(in) :: key
    type(cascade_t), intent(in), target :: cascade
    logical, intent(out) :: ok
    type(cascade_t), optional, pointer :: cascade_ptr
    integer(i32) :: h
    if (cascade_set%n_entries >= cascade_set%n_entries_max) &
        call cascade_set_hash_expand (cascade_set)
    h = hash (key)
    call cascade_set_hash_insert_rec &
        (cascade_set, h, h, key, cascade, ok, cascade_ptr)
end subroutine cascade_set_hash_insert

```

Double the hashtable size when necessary:

```

<Cascades: procedures>+=
subroutine cascade_set_hash_expand (cascade_set)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(hash_entry_t), dimension(:), allocatable, target :: table_tmp
    type(cascade_p), pointer :: current
    integer :: i, s
    allocate (table_tmp (0:cascade_set%mask))
    table_tmp = cascade_set%entry
    deallocate (cascade_set%entry)
    s = 2 * size (table_tmp)
    cascade_set%n_entries = 0
    cascade_set%n_entries_max = s * cascade_set%fill_ratio
    cascade_set%mask = s - 1

```

```

allocate (cascade_set%entry (0:cascade_set%mask))
do i = 0, ubound (table_tmp, 1)
  current => table_tmp(i)%first
  do while (associated (current))
    call cascade_set_hash_insert_rec &
      (cascade_set, table_tmp(i)%hashval, table_tmp(i)%hashval, &
        table_tmp(i)%key, current%cascade)
    current => current%next
  end do
end do
end subroutine cascade_set_hash_expand

```

Insert the cascade at the bucket determined by the hash value. If the bucket is filled, check first for a collision (unequal keys). In that case, choose the following bucket and repeat. Otherwise, add the cascade to the bucket.

If the bucket is empty, record the hash value, allocate and store the key, and then add the cascade to the bucket.

If ok is present, before insertion we check whether the cascade is already stored, and return failure if yes.

(Cascades: procedures)+≡

```

recursive subroutine cascade_set_hash_insert_rec &
  (cascade_set, h, hashval, key, cascade, ok, cascade_ptr)
type(cascade_set_t), intent(inout) :: cascade_set
integer(i32), intent(in) :: h, hashval
integer(i8), dimension(:), intent(in) :: key
type(cascade_t), intent(in), target :: cascade
logical, intent(out), optional :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i32) :: i
i = iand (h, cascade_set%mask)
if (allocated (cascade_set%entry(i)%key)) then
  if (size (cascade_set%entry(i)%key) /= size (key)) then
    call cascade_set_hash_insert_rec &
      (cascade_set, h + 1, hashval, key, cascade, ok, cascade_ptr)
  else if (any (cascade_set%entry(i)%key /= key)) then
    call cascade_set_hash_insert_rec &
      (cascade_set, h + 1, hashval, key, cascade, ok, cascade_ptr)
  else
    call hash_entry_add_cascade_ptr &
      (cascade_set%entry(i), cascade, ok, cascade_ptr)
  end if
else
  cascade_set%entry(i)%hashval = hashval
  allocate (cascade_set%entry(i)%key (size (key)))
  cascade_set%entry(i)%key = key
  call hash_entry_add_cascade_ptr &
    (cascade_set%entry(i), cascade, ok, cascade_ptr)
  cascade_set%n_entries = cascade_set%n_entries + 1
end if
end subroutine cascade_set_hash_insert_rec

```

19.9.8 External particles

We want to initialize the cascade set with the outgoing particles. In case of multiple processes, initial cascades are prepared for all of them. The hash array check ensures that no particle appears more than once at the same place.

```
(Cascades: interfaces) +=  
    interface cascade_set_add_outgoing  
        module procedure cascade_set_add_outgoing1  
        module procedure cascade_set_add_outgoing2  
    end interface  
  
(Cascades: procedures) +=  
    subroutine cascade_set_add_outgoing2 (cascade_set, flv)  
        type(cascade_set_t), intent(inout), target :: cascade_set  
        type(flavor_t), dimension(:,:), intent(in) :: flv  
        integer :: pos, prc, n_out, n_prc  
        type(cascade_t), pointer :: cascade  
        logical :: ok  
        n_out = size (flv, dim=1)  
        n_prc = size (flv, dim=2)  
        do prc = 1, n_prc  
            do pos = 1, n_out  
                allocate (cascade)  
                call cascade_init_outgoing &  
                    (cascade, flv(pos,prc), pos, cascade_set%m_threshold_s)  
                call cascade_set_add (cascade_set, cascade, ok)  
                if (.not. ok) then  
                    deallocate (cascade)  
                end if  
            end do  
        end do  
    end subroutine cascade_set_add_outgoing2  
  
    subroutine cascade_set_add_outgoing1 (cascade_set, flv)  
        type(cascade_set_t), intent(inout), target :: cascade_set  
        type(flavor_t), dimension(:), intent(in) :: flv  
        integer :: pos, n_out  
        type(cascade_t), pointer :: cascade  
        logical :: ok  
        n_out = size (flv, dim=1)  
        do pos = 1, n_out  
            allocate (cascade)  
            call cascade_init_outgoing &  
                (cascade, flv(pos), pos, cascade_set%m_threshold_s)  
            call cascade_set_add (cascade_set, cascade, ok)  
            if (.not. ok) then  
                deallocate (cascade)  
            end if  
        end do  
    end subroutine cascade_set_add_outgoing1
```

The incoming particles are added one at a time. Nevertheless, we may have several processes which are looped over. At the first opportunity, we set the

pointer `first_t` in the cascade set which should point to the first t-channel cascade.

Return the indices of the first and last cascade generated.

(Cascades: interfaces)+≡

if (.not. associated (cascade_set%first_t)) then
  cascade_set%first_t => cascade
end if
else
  deallocate (cascade)
end if
end subroutine cascade_set_add_incoming0

```

19.9.9 Cascade combination I: flavor assignment

We have two disjunct cascades, now use the vertex table to determine the possible flavors of the combination cascade. For each possibility, try to generate a new cascade. The total cascade depth has to be one less than the limit, because this is reached by setting the keystone.

```

<Cascades: procedures>+=
subroutine cascade_match_pair (cascade_set, cascade1, cascade2, s_channel)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in), target :: cascade1, cascade2
  logical, intent(in) :: s_channel
  integer, dimension(:), allocatable :: pdg3
  integer :: i, depth_max
  type(flavor_t) :: flv
  if (s_channel) then
    depth_max = cascade_set%depth_out
  else
    depth_max = cascade_set%depth_tot
  end if
  if (cascade1%depth + cascade2%depth < depth_max) then
    call cascade_set%model%match_vertex ( &
      cascade1%flv%get_pdg (), &
      cascade2%flv%get_pdg (), &
      pdg3)
    do i = 1, size (pdg3)
      call flv%init (pdg3(i), cascade_set%model)
      if (s_channel) then
        call cascade_combine_s (cascade_set, cascade1, cascade2, flv)
      else
        call cascade_combine_t (cascade_set, cascade1, cascade2, flv)
      end if
    end do
    deallocate (pdg3)
  end if
end subroutine cascade_match_pair

```

The triplet version takes a third cascade, and we check whether this triplet has a matching vertex in the database. If yes, we make a keystone cascade.

```

<Cascades: procedures>+=
subroutine cascade_match_triplet &
  (cascade_set, cascade1, cascade2, cascade3, s_channel)
  type(cascade_set_t), intent(inout), target :: cascade_set

```

```

type(cascade_t), intent(in), target :: cascade1, cascade2, cascade3
logical, intent(in) :: s_channel
integer :: depth_max
depth_max = cascade_set%depth_tot
if (cascade1%depth + cascade2%depth + cascade3%depth == depth_max) then
  if (cascade_set%model%check_vertex ( &
    cascade1%flv%get_pdg (), &
    cascade2%flv%get_pdg (), &
    cascade3%flv%get_pdg ())) then
    call cascade_combine_keystone &
      (cascade_set, cascade1, cascade2, cascade3, s_channel)
  end if
end if
end subroutine cascade_match_triplet

```

19.9.10 Cascade combination II: kinematics setup and check

Having three matching flavors, we start constructing the combination cascade. We look at the mass hierarchies and determine whether the cascade is to be kept. In passing we set mapping modes, resonance properties and such.

If successful, the cascade is finalized. For a resonant cascade, we prepare in addition a copy without the resonance.

```

(Cascades: procedures)+≡
subroutine cascade_combine_s (cascade_set, cascade1, cascade2, flv)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in), target :: cascade1, cascade2

Here we complete a decay cascade. The third input is the single-particle cascade for the initial particle. There is no resonance or mapping assignment. The only condition for keeping the cascade is the mass sum of the final state, which must be less than the available energy.

Two modifications are necessary for scattering cascades: a pure s-channel diagram (cascade1 is the incoming particle) do not have a logarithmic mapping at top-level. And in a t-channel diagram, the last line exchanged is mapped t-channel, not u-channel. Finally, we can encounter the case of a $2 \rightarrow 1$ process, where cascade1 is incoming, and cascade2 is the outgoing particle. In all three cases we register a new cascade with the modified mapping.

19.9.11 Cascade combination III: node connections and tree fusion

Here we assign global tree properties. If the allowed number of off-shell lines is exceeded, discard the new cascade. Otherwise, assign the trees, sort them, and assign connections. Finally, append the cascade to the list. This may fail (because in the hash array there is already an equivalent cascade). On failure, discard the cascade.

```

19.9.13 Groves

Before assigning groves, assign hashcodes to the resonance patterns, so they can easily be compared.

(Cascades: procedures) +=

```

subroutine cascade_set_assign_resonance_hash (cascade_set)
  type(cascade_set_t), intent(inout) :: cascade_set
  type(cascade_t), pointer :: cascade
  cascade => cascade_set%first_k
  do while (associated (cascade))
    call cascade_assign_resonance_hash (cascade)
    cascade => cascade%next
  end do
end subroutine cascade_set_assign_resonance_hash

```

After all cascades are recorded, we group the complete cascades in groves. A grove consists of cascades with identical multiplicity, number of resonances, log-enhanced, t-channel lines, and resonance flavors.

(Cascades: procedures) +=

```

subroutine cascade_set_assign_groves (cascade_set)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), pointer :: cascade1, cascade2
  integer :: multiplicity
  integer :: n_resonances, n_log_enhanced, n_t_channel, n_off_shell
  integer :: res_hash
  integer :: grove
  grove = 0
  cascade1 => cascade_set%first_k
  do while (associated (cascade1))
    if (cascade1%active .and. cascade1%complete &
      .and. cascade1%grove == 0) then
      grove = grove + 1
      cascade1%grove = grove
    end if
    cascade1 => cascade1%next
  end do
end subroutine cascade_set_assign_groves

```

```

multiplicity = cascade1%multiplicity
n_resonances = cascade1%n_resonances
n_log_enhanced = cascade1%n_log_enhanced
n_off_shell = cascade1%n_off_shell
n_t_channel = cascade1%n_t_channel
res_hash = cascade1%res_hash
cascade2 => cascade1%next
do while (associated (cascade2))
  if (cascade2%grove == 0) then
    if (cascade2%multiplicity == multiplicity &
        .and. cascade2%n_resonances == n_resonances &
        .and. cascade2%n_log_enhanced == n_log_enhanced &
        .and. cascade2%n_off_shell == n_off_shell &
        .and. cascade2%n_t_channel == n_t_channel &
        .and. cascade2%res_hash == res_hash) then
      cascade2%grove = grove
    end if
  end if
  call terminate_now_if_signal ()
  cascade2 => cascade2%next
end do
end if
call terminate_now_if_signal ()
cascade1 => cascade1%next
end do
cascade_set%n_groves = grove
end subroutine cascade_set_assign_groves

```

19.9.14 Generate the phase space file

Generate a complete phase space configuration.

For each flavor assignment: First, all s-channel graphs that can be built up from the outgoing particles. Then we distinguish (1) decay, where we complete the s-channel graphs by connecting to the input line, and (2) scattering, where we now generate t-channel graphs by introducing an incoming particle, and complete this by connecting to the other incoming particle.

After all cascade sets have been generated, merge them into a common set. This eliminates redundancies between flavor assignments.

```

<Cascades: public>+≡
  public :: cascade_set_generate

<Cascades: procedures>+≡
  subroutine cascade_set_generate &
    (cascade_set, model, n_in, n_out, flv, phs_par, fatal_beam_decay)
    type(cascade_set_t), intent(out) :: cascade_set
    class(model_data_t), intent(in), target :: model
    integer, intent(in) :: n_in, n_out
    type(flavor_t), dimension(:,:), intent(in) :: flv
    type(phs_parameters_t), intent(in) :: phs_par
    logical, intent(in) :: fatal_beam_decay
    type(cascade_set_t), dimension(:), allocatable :: cset

19.10 WOOD phase space

This is the module that interfaces the `phs_forests` phase-space treatment and the `cascades` module for generating phase-space channels. As an extension of the `phs_base` abstract type, the phase-space configuration and instance implement the standard API.

(Currently, this is the only generic phase-space implementation of WHIZARD. For trivial two-particle phase space, there is `phs_wood` as an alternative.)

```

<phs_wood.f90>≡

19.10.3 Phase-space configuration

We read the phase-space configuration from the stored I/O unit. If this is not set, we assume that we have to generate a phase space configuration. When done, we open a scratch file and write the configuration.

If `rebuild` is set, we should trash any existing phase space file and build a new one. Otherwise, we try to use an old one, which we check for existence and integrity. If `ignore_mismatch` is set, we reuse an existing file even if it does not match the current setup.

```

The MD5 sum of the forest is computed in addition to the MD5 sum of the configuration. The reason is that the forest may depend on a user-provided external file. On the other hand, this MD5 sum encodes all information that is relevant for further processing. Therefore, the `get_md5sum` method returns this result, once it is available.

```

Create filenames according to standard conventions. The `id` is the process name including the suffix `_iX` where `X` stands for the component identifier (an integer). The `run_id` may be set or unset.

The convention for file names that include the run ID is to separate prefix, run ID, and any extensions by dots. We construct the file name by concatenating the individual elements accordingly. If there is no run ID, we nevertheless replace `_iX` by `.iX`.

19.10.5 Evaluation

We compute the outgoing momenta from the incoming momenta and the input parameter set `r_in` in channel `r_in`. We also compute the `r` parameters and Jacobians `f` for all other channels.

We do *not* need to apply a transformation from/to the c.m. frame, because in `phs_base` the momenta are already boosted to the c.m. frame before assigning them in the `phs` object, and inversely boosted when extracting them.

The boost to the center-of-mass system only has a reasonable meaning above the threshold. Below the threshold, we do not apply boost at all, so that the top quarks stay in the rest frame. However, with top quarks exactly at rest, problems arise in the matrix elements (e.g. in the computation of angles). Therefore, we apply a boost which is not exactly 1, but has a tiny value differing from that.

The fks phase space type contains the wood phase space and separately the in- and outgoing momenta for the real process and the corresponding Born momenta. Additionally, there are the variables ξ, ξ_{max}, y and ϕ which are used to create the real phase space, as well as the jacobian and its corresponding soft

and collinear limit. Lastly, the array `ch_to_em` connects each channel with an emitter.

19.11.1 Creation of the real phase space - FSR

At this point, the Born phase space has been generated, as well as the three random variables ξ , y and ϕ . The question is how the real phase space is generated for a final-state emission configuration. We work with two different sets of momenta, the Born configuration $\{\bar{k}_\oplus, \bar{k}_\ominus, \bar{k}_1, \dots, \bar{k}_n\}$ and the real configuration $\{k_\oplus, k_\ominus, k_1, \dots, k_n, k_{n+1}\}$. We define the momentum of the emitter to be on the n -th position and the momentum of the radiated particle to be at position $n+1$. The magnitude of the spatial component of k is denoted by \underline{k} .

For final-state emissions, it is $\bar{k}_\oplus = k_\oplus$ and $\bar{k}_\ominus = k_\ominus$. Thus, the center-of-mass systems coincide and it is

$$q = \sum_{i=1}^n \bar{k}_i = \sum_{i=1}^{n+1} k_i, \quad (19.65)$$

with $\vec{q} = 0$ and $q^2 = (q^0)^2$.

We want to construct the real phase space from the Born phase space using three random numbers. They are defined as follows:

- $\xi = \frac{2k_{n+1}^0}{\sqrt{s}} \in [0, \xi_{max}]$, where k_{n+1} denotes the four-momentum of the radiated particle.
- $y = \cos \theta = \frac{\vec{k}_n \cdot \vec{k}_{n+1}}{\underline{k}_n \underline{k}_{n+1}}$ is the splitting angle.
- The angle between the two splitting particles in the transversal plane, $\phi \in [0, 2\pi]$.

Further, $k_{rec} = \sum_{i=1}^{n-1} k_i$ denotes the sum of all recoiling momenta.

Construction of the recoiling momenta. The reshuffling of momenta must not change the invariant mass of the recoiling system, which means $k_{\text{rec}}^2 = k_{\text{rec}}^{-2}$. Therefore, the momenta are related by a boost, $\bar{k}_i = \Lambda k_i$. The boost parameter is

$$\beta = \frac{q^2 - (k_{\text{rec}}^0 + \underline{k}_{\text{rec}})^2}{q^2 + (k_{\text{rec}}^0 + \underline{k}_{\text{rec}})^2}$$

The momentum of the radiated particle is computed according to

$$\underline{k}_n = \frac{q^2 - M_{\text{rec}}^2 - 2q^0 \underline{k}_{n+1}}{2(q^0 - \underline{k}_{n+1}(1 - y))}, \quad (19.66)$$

with $k = k_n + k_{n+1}$ and $M_{\text{rec}}^2 = k_{\text{rec}}^2 = (q - k)^2$. Because of $\bar{\mathbf{k}}_n \parallel \mathbf{k}_n + \mathbf{k}_{n+1}$ we find $M_{\text{rec}}^2 = (q - \bar{k}_n)^2$. Equation ?? follows from the fact that $(\mathbf{k} - \mathbf{k}_n)^2 = \mathbf{k}_{n+1}^2$, which is equivalent to $\mathbf{k}_n \cdot \mathbf{k} = \frac{1}{2} (k_n^2 + k^2 - k_{n+1}^2)$. \mathbf{k}_n and \mathbf{k}_{n+1} are obtained by first setting up vectors parallel to $\bar{\mathbf{k}}_n$,

$$\mathbf{k}'_n = \underline{k}_n \frac{\bar{\mathbf{k}}_n}{\bar{k}_n}, \quad \mathbf{k}'_{n+1} = \underline{k}_{n+1} \frac{\bar{\mathbf{k}}_n}{\bar{k}_n},$$

and then rotating these vectors by an amount of $\cos \psi_n = \frac{\mathbf{k}_n \cdot \mathbf{k}}{\underline{k}_n \bar{k}}$. The emitted particle cannot have more momentum than the emitter has in the Born phase space. Thus, there is an upper bound for ξ , determined by the condition $k_{n+1}^0 = \bar{k}_n$, which is equal to

$$\xi_{\text{max}} = \frac{2}{\bar{k}_n} q^0.$$

end function get_xi_max_fsr_massless

```

The computation of ξ_{\max} for massive emitters is described in arXiv:1202.0465. Let's recapitulate it here.

We consider the Dalitz-domain created by k_{n+1}^0 , k_n^0 and k_{rec}^0 and introduce the parameterization

$$k_n^0 = \bar{k}_n^0 - z k_{n+1}^0$$

Then, for each value of z , there exists a maximum value of \underline{k}_{n+1} from which ξ_{\max} can be extracted via $\xi_{\max} = 2k_{n+1}^0/q$. It is determined by the condition

$$\underline{k}_{n+1} \pm \underline{k}_n \pm \underline{k}_{\text{rec}} = 0.$$

This can be manipulated to yield

$$(\underline{k}_{n+1}^2 + \underline{k}_n^2 - \underline{k}_{\text{rec}}^2)^2 = 4k_{n+1}^2 \underline{k}_n^2.$$

Here we can use $\underline{k}_n^2 = (k_n^0)^2 - m^2$ and $\underline{k}_{\text{rec}}^2 = (q - k_n^0 - k_{n+1}^0)^2 - M_{\text{rec}}^2$, as well as the above parameterization of k_n^0 , to obtain

$$4k_{n+1}^2 (2k_{n+1} q z (1 - z) + q^2 z^2 - 2q \bar{k}_{\text{rec}}^0 z + M_{\text{rec}}^2) = 0.$$

Solving for k_{n+1}^0 gives

$$k_{n+1}^0 = \frac{2q \bar{k}_{\text{rec}}^0 z - q^2 z^2 - M_{\text{rec}}^2}{2q z (1 - z)}. \quad (19.67)$$

It is still open how to compute z . For this, consider that the right-hand-side of equation (19.67) vanishes for

$$z_{1,2} = \left(\bar{k}_{\text{rec}}^0 \pm \sqrt{(\bar{k}_{\text{rec}}^0)^2 - M_{\text{rec}}^2} \right) / q,$$

which corresponds to the borders of the Dalitz-region where the gluon momentum vanishes. Thus we define

$$z = z_2 - \frac{1}{2}(z_2 - z_1)(1 + y).$$

The real phase space for an initial-state emission involved in a decay process is generated by first setting the gluon momentum like in the scattering case by using its angular coordinates y and ϕ and then adjusting the gluon energy with ξ . The emitter momentum is kept identical to the Born case, i.e. $p_{\text{in}} = \bar{p}_{\text{in}}$, so that after the emission it has momentum $p_{\text{virt}} = p_{\text{in}} - p_g$ and invariant mass $m^2 = p_{\text{virt}}^2$. Note that the final state momenta have to remain on-shell, so that $p_1^2 = \bar{p}_1^2 = m_1^2$ and $p_2^2 = \bar{p}_2^2 = m_2^2$. Let Λ be the boost from into the rest frame of the emitter after emission, i.e. $\Lambda p_{\text{virt}} = (m, 0, 0, 0)$. In this reference frame, the spatial components of the final-state momenta sum up to zero, and their magnitude is

$$p = \frac{\sqrt{\lambda(m^2, m_1^2, m_2^2)}}{2m},$$

a fact already used in the evaluation of the phase space trees of `phs_forest`. Obviously, from this, the final-state energies can be deferred via $E_i^2 = m_i^2 - p^2$. In the next step, the $p_{1,2}$ are set up as vectors $(E, 0, 0, \pm p)$ along the z-axis and then rotated about the same azimuthal and polar angles as in the Born system. Finally, the momenta are boosted out of the rest frame by multiplying with Λ .

Configure channel mappings, using some conditions from the phase space configuration. If there are no structure functions, we enable a default setup with a single (dummy) structure-function channel. Otherwise, we look at the channel collection that we got from the phase-space configuration step. Each entry should be translated into an independent structure-function channel, where typically there is one default entry, which could be mapped using a standard s-channel mapping if the structure function setup recommends this, and other entries with s-channel resonances. The latter need to be translated into global mappings from the structure-function chain.

@

19.13 A lexer for O’Mega’s phase-space output

This module provides three data types. One of them is the type `dag_string_t` which should contain the information of all Feynman diagrams in the factorized form which is provided by O’Mega in its phase-space output. This output is translated into a string of tokens (in the form of an array of the type `dag_token_t`) which have a certain meaning. The purpose of this module is only to identify these tokens correctly and to provide some procedures and interfaces which allow us to use these strings in a similar way as variables of the basic character type or the type `iso_varying_string`. Both `character` and `iso_varying_string` have some disadvantages at least if one wants to keep support for some older compiler versions. These can be circumvented by the `dag_string_t` type. Finally the `dag_chain_t` type is used to create a larger string in several steps without always recreating the string, which is done in the form of a simple linked list. In the end one can create a single `dag_string` out of this list, which is more useful.

```

<cascades2_lexer.f90>≡
  <File header>

  module cascades2_lexer

    <Use kinds>
    use kinds, only: TC, i8

    <Standard module head>

    <Cascades2 lexer: public>

    <Cascades2 lexer: parameters>

    <Cascades2 lexer: types>

```

```

<Cascades2 lexer: interfaces>

contains

<Cascades2 lexer: procedures>

end module cascades2_lexer

```

This is the token type. By default the variable `type` is `EMPTY_TK` but can obtain other values corresponding to the parameters defined below. The type of the token corresponds to a particular sequence of characters. When the token corresponds to a node of a tree, i.e. some particle in the Feynman diagram, the type is `NODE_TK` and the `particle_name` variable is holding the name of the particle. O'Megas output contains in addition to the particle name some numbers which indicate the external momenta that are flowing through this line. These numbers are translated into a binary code and saved in the variable `bincode`. In this case the number 1 corresponds to a bit set at position 0, 2 corresponds to a bit set at position 1, etc. Instead of numbers which are composed out of several digits, letters are used, i.e. A instead of 10 (bit at position 9), B instead of 11 (bit at position 10), etc.

When the DAG is reconstructed from a `dag_string` which was built from O'Mega's output, this string is modified such that a substring (a set of tokens) is replaced by a single token where the type variable is one of the three parameters `DAG_NODE_TK`, `DAG_OPTIONS_TK` and `DAG_COMBINATION_TK`. These parameters correspond to the three types `dag_node_t`, `dag_options_t` and `dag_combination_t` (see `cascades2` for more information. In this case, since these objects are organized in arrays, the `index` variable holds the corresponding position in the array.

In any case, we want to be able to reproduce the character string from which a token (or a string) has been created. The variable `char_len` is the length of this string. For tokens with the type `DAG_NODE_TK`, `DAG_OPTIONS_TK` and `DAG_COMBINATION_TK` we use output of the form `<N23>`, `<O23>` or `<C23>` which is useful for debugging the parser. Here 23 is the `index` and N, O or C obviously corresponds to the `type`.

```

<Cascades2 lexer: parameters>≡
    integer, parameter :: PRT_NAME_LEN = 20

<Cascades2 lexer: public>≡
    public :: dag_token_t

<Cascades2 lexer: types>≡
    type :: dag_token_t
        integer :: type = EMPTY_TK
        integer :: char_len = 0
        integer(TC) :: bincode = 0
        character (PRT_NAME_LEN) :: particle_name=""
        integer :: index = 0
    contains
        <Cascades2 lexer: dag token: TBP>
    end type dag_token_t

```

This is the string type. It also holds the number of characters in the corre-

sponding character string. It contains an array of tokens. If the `dag_string` is constructed using the type `dag_chain_t`, which creates a linked list, we also need the pointer `next`.

```

<Cascades2 lexer: public>+≡
    public :: dag_string_t

<Cascades2 lexer: types>+≡
    type :: dag_string_t
        integer :: char_len = 0
        type (dag_token_t), dimension(:), allocatable :: t
        type (dag_string_t), pointer :: next => null ()
    contains
        <Cascades2 lexer: dag string: TBP>
    end type dag_string_t

```

This is the chain of `dag_strings`. It allows us to construct a large string by appending new strings to the linked list, which can later be merged to a single string. This is very useful because the file written by O'Mega contains large strings where each string contains all Feynman diagrams in a factorized form, but these large strings are cut into several pieces and distributed over many lines. As the file can become large, rewriting a new `dag_string` (or `iso_varying_string`) would consume more and more time with each additional line. For recreating a single `dag_string` out of this chain, we need the total character length and the sum of all sizes of the `dag_token` arrays `t`.

```

<Cascades2 lexer: public>+≡
    public :: dag_chain_t

<Cascades2 lexer: types>+≡
    type :: dag_chain_t
        integer :: char_len = 0
        integer :: t_size = 0
        type (dag_string_t), pointer :: first => null ()
        type (dag_string_t), pointer :: last => null ()
    contains
        <Cascades2 lexer: dag chain: TBP>
    end type dag_chain_t

```

We define two parameters holding the characters corresponding to a backslash and a blanc space.

```

<Cascades2 lexer: parameters>+≡
    character(len=1), parameter, public :: BACKSLASH_CHAR = "\\"
    character(len=1), parameter :: BLANC_CHAR = " "

```

These are the parameters which correspond to meaningful types of token.

```

<Cascades2 lexer: parameters>+≡
    integer, parameter, public :: NEW_LINE_TK = -2
    integer, parameter :: BLANC_SPACE_TK = -1
    integer, parameter :: EMPTY_TK = 0
    integer, parameter, public :: NODE_TK = 1
    integer, parameter, public :: DAG_NODE_TK = 2
    integer, parameter, public :: DAG_OPTIONS_TK = 3
    integer, parameter, public :: DAG_COMBINATION_TK = 4
    integer, parameter, public :: COLON_TK = 11

```

```

integer, parameter, public :: COMMA_TK = 12
integer, parameter, public :: VERTICAL_BAR_TK = 13
integer, parameter, public :: OPEN_PAR_TK = 21
integer, parameter, public :: CLOSED_PAR_TK = 22
integer, parameter, public :: OPEN_CURLY_TK = 31
integer, parameter, public :: CLOSED_CURLY_TK = 32

```

Different sorts of assignment. This contains the conversion of a character variable into a `dag_token` or `dag_string`.

```

<Cascades2 lexer: public>+≡
    public :: assignment (=)

<Cascades2 lexer: interfaces>≡

Compare strings/tokens/characters. Each character is relevant, including all blanc spaces. An exception is the `newline` character which is not treated by the types used in this module (not to confused with the type parameter `NEW_LINE_TK` which corresponds to the backslash character and simply tells us that the string continues on the next line in the file).

19.14 An alternative cascades module

This module might replace the module `cascades`, which generates suitable phase space parametrizations and generates the phase space file. The mappings, as well as the criteria to determine these, do not change.

The advantage of this module is that it makes use of the O'Mega matrix element generator which provides the relevant Feynman diagrams (the ones which can be constructed only from 3-vertices). In principle, the construction of these diagrams is also one of the tasks of the existing `cascades` module, in which the diagrams would correspond to a set of cascades. It starts by creating cascades which correspond to the outgoing particles. These are combined to a new cascade using the vertices of the model. In this way, since each cascade knows the daughter cascades from which it is built, complete Feynman diagrams

are represented by sets of cascades, as soon as the existing cascades can be recombined with the incoming particle(s).

In this module, the Feynman diagrams are represented by the type `feyngraph_t`, which represents the Feynman diagrams as a tree of nodes. The object which contains the necessary kinematical information to determine mappings, and hence sensible phase space parametrizations is of another type, called `kingraph_t`, which is built from a corresponding `feyngraph` object.

There are two types of output which can be produced by `O'Mega` and are potentially relevant here. The first type contains all tree diagrams for the process under consideration, where each line of the output corresponds to one Feynman diagram. This output is easy to read, but can be very large, depending on the number of particles involved in the process. Moreover, it repeats substructures of the diagrams which are part of more than one diagram. One could in principle work with this output and construct a `feyngraph` from each line, if allowed, i.e. if there are only 3-vertices.

The other output contains also all of these Feynman diagrams, but in a factorized form. This means that the substructures which appear in several Feynman diagrams, are written only once, if possible. This leads to a much shorter input file, which speeds up the parsing process. Furthermore it makes it possible to reconstruct the `feyngraphs` in such a way that the calculations concerning subdiagrams which reappear in other `feyngraphs` have to be performed only once. This is already the case in the existing `cascades` module but can be exploited more efficiently here because the possible graphs are well known from the input file, whereas the `cascades` module would create a large number of `cascades` which do not lead to a complete Feynman diagram of the given process.

19.14.1 Particle properties

We define a type holding the properties of the particles which are needed for parsing and finding the phase space parametrizations and mappings. The properties of all particles which appear in the parsed Feynman diagrams for the given process will be stored in a central place, and only pointers to these objects are used.

```
<Cascades2: types>≡
  type :: part_prop_t
    character (len=LABEL_LEN) :: particle_label
    integer :: pdg = 0
    real(default) :: mass = 0.
    real :: width = 0.
    integer :: spin_type = 0
    logical :: is_vector = .false.
    logical :: empty = .true.
    type (part_prop_t), pointer :: anti => null ()
    type (string_t) :: tex_name
  contains
    <Cascades2: part prop: TBP>
  end type part_prop_t
```

The `particle_label` in `part_prop_t` is simply the particle name (e.g. 'W+'). The corresponding variable in the type `f_node_t` contains some additional information related to the external momenta, see below. The length of the `character` variable is fixed as:

```
<Cascades2: parameters>≡
  integer, parameter :: LABEL_LEN=30

<Cascades2: part prop: TBP>≡
  procedure :: final => part_prop_final

<Cascades2: procedures>≡
  subroutine part_prop_final (part)
    class(part_prop_t), intent(inout) :: part
    part%anti => null ()
  end subroutine part_prop_final
```

19.14.2 The mapping modes

The possible mappings are essentially the same as in `cascades`, but we introduce in addition the mapping constant `NON_RESONANT`, which does not refer to a new mapping; it corresponds to the nonresonant version of a potentially resonant particle (or `k_node`). This becomes relevant when we compare `k_nodes` to eliminate equivalences.

```
(Cascades2: parameters)+≡  
  integer, parameter :: &  
    & NONRESONANT = -2, EXTERNAL_PRT = -1, &  
    & NO_MAPPING = 0, S_CHANNEL = 1, T_CHANNEL = 2, U_CHANNEL = 3, &  
    & RADIATION = 4, COLLINEAR = 5, INFRARED = 6, &  
    & STEP_MAPPING_E = 11, STEP_MAPPING_H = 12, &  
    & ON_SHELL = 99
```

19.14.3 Grove properties

The channels or `kingraphs` will be grouped in groves, i.e. sets of channels, which share some characteristic numbers. These numbers are stored in the following type:

```
(Cascades2: types)+≡  
  type :: grove_prop_t  
    integer :: multiplicity = 0  
    integer :: n_resonances = 0  
    integer :: n_log_enhanced = 0  
    integer :: n_off_shell = 0  
    integer :: n_t_channel = 0  
    integer :: res_hash = 0  
  end type grove_prop_t
```

19.14.4 The tree type

This type contains all the information which is needed to reconstruct a `feyngraph` or `kingraph`. We store bincodes, pdg codes and mappings for all nodes of a valid `kingraph`. If we label the external particles as given in the process definition with integer numbers representing their position in the process definition, the bincode would be the number that one obtains by setting the bit at the position that is given by this number. If we combine two particles/nodes to a third one (using a three-vertex of the given model), the bincode is the number which one obtains by setting all the bits which are set for the two particles. The `pdg` and `mapping` are simply the pdg-code and mapping at the position (i.e. propagator or external particle) which is specified by the corresponding bincode. We use `tree_t` not only for completed `kingraphs`, but also for all `k_nodes`, which are a subtree of a `kingraph`.

```
(Cascades2: types)+≡  
  type :: tree_t  
    integer(TC), dimension(:), allocatable :: bc  
    integer, dimension(:), allocatable :: pdg  
    integer, dimension(:), allocatable :: mapping  
    integer :: n_entries = 0
```

```

        logical :: keep = .true.
        logical :: empty = .true.
    contains
        <Cascades2: tree: TBP>
    end type tree_t

<Cascades2: tree: TBP>≡
    procedure :: final => tree_final

<Cascades2: procedures>+≡
    subroutine tree_final (tree)
        class (tree_t), intent (inout) :: tree
        if (allocated (tree%bc)) deallocate (tree%bc)
        if (allocated (tree%pdg)) deallocate (tree%pdg)
        if (allocated (tree%mapping)) deallocate (tree%mapping)
    end subroutine tree_final

<Cascades2: interfaces>≡
    interface assignment (=)
        module procedure tree_assign
    end interface assignment (=)

<Cascades2: procedures>+≡
    subroutine tree_assign (tree1, tree2)
        type (tree_t), intent (inout) :: tree1
        type (tree_t), intent (in) :: tree2
        if (allocated (tree2%bc)) then
            allocate (tree1%bc(size(tree2%bc)))
            tree1%bc = tree2%bc
        end if
        if (allocated (tree2%pdg)) then
            allocate (tree1%pdg(size(tree2%pdg)))
            tree1%pdg = tree2%pdg
        end if
        if (allocated (tree2%mapping)) then
            allocate (tree1%mapping(size(tree2%mapping)))
            tree1%mapping = tree2%mapping
        end if
        tree1%n_entries = tree2%n_entries
        tree1%keep = tree2%keep
        tree1%empty = tree2%empty
    end subroutine tree_assign

```

19.14.5 Add entries to the tree

The following procedures fill the arrays in `tree_t` with entries resulting from the bincode and mapping assignment.

```

<Cascades2: tree: TBP>+≡
    procedure :: add_entry_from_numbers => tree_add_entry_from_numbers
    procedure :: add_entry_from_node => tree_add_entry_from_node
    generic :: add_entry => add_entry_from_numbers, add_entry_from_node

```

Here we add a single entry to each of the arrays. This will exclusively be used for external particles.

```

(Cascades2: procedures)+≡
subroutine tree_add_entry_from_numbers (tree, bincode, pdg, mapping)
  class (tree_t), intent (inout) :: tree
  integer(TC), intent (in) :: bincode
  integer, intent (in) :: pdg
  integer, intent (in) :: mapping
  integer :: pos
  if (tree%empty) then
    allocate (tree%bc(1))
    allocate (tree%pdg(1))
    allocate (tree%mapping(1))
    pos = tree%n_entries + 1
    tree%bc(pos) = bincode
    tree%pdg(pos) = pdg
    tree%mapping(pos) = mapping
    tree%n_entries = pos
    tree%empty = .false.
  end if
end subroutine tree_add_entry_from_numbers

```

Here we merge two existing subtrees and a single entry (bc, pdg and mapping).

```

(Cascades2: procedures)+≡
subroutine tree_merge (tree, tree1, tree2, bc, pdg, mapping)
  class (tree_t), intent (inout) :: tree
  type (tree_t), intent (in) :: tree1, tree2
  integer(TC), intent (in) :: bc
  integer, intent (in) :: pdg, mapping
  integer :: tree_size
  integer :: i1, i2
  if (tree%empty) then
    i1 = tree1%n_entries
    i2 = tree1%n_entries + tree2%n_entries
    tree_size = tree1%n_entries + tree2%n_entries + 1
    allocate (tree%bc (tree_size))
    allocate (tree%pdg (tree_size))
    allocate (tree%mapping (tree_size))
    tree%bc(i1) = tree1%bc
    tree%pdg(i1) = tree1%pdg
    tree%mapping(i1) = tree1%mapping
    tree%bc(i1+1:i2) = tree2%bc
    tree%pdg(i1+1:i2) = tree2%pdg
    tree%mapping(i1+1:i2) = tree2%mapping
    tree%bc(tree_size) = bc
    tree%pdg(tree_size) = pdg
    tree%mapping(tree_size) = mapping
    tree%n_entries = tree_size
    tree%empty = .false.
  end if
end subroutine tree_merge

```

Here we add entries to a tree for a given `k_node`, which means that we first have

to determine whether the node is external or internal. The arrays are sorted after the entries have been added (see below for details).

```

(Cascades2: procedures)+≡
subroutine tree_add_entry_from_node (tree, node)
  class (tree_t), intent (inout) :: tree
  type (k_node_t), intent (in) :: node
  integer :: pdg
  if (node%t_line) then
    pdg = abs (node%particle%pdg)
  else
    pdg = node%particle%pdg
  end if
  if (associated (node%daughter1) .and. &
      associated (node%daughter2)) then
    call tree_merge (tree, node%daughter1%subtree, &
                    node%daughter2%subtree, node%bincode, &
                    node%particle%pdg, node%mapping)
  else
    call tree_add_entry_from_numbers (tree, node%bincode, &
                                     node%particle%pdg, node%mapping)
  end if
  call tree%sort ()
end subroutine tree_add_entry_from_node

```

For a well-defined order of the elements of the arrays in `tree_t`, the elements can be sorted. The bincodes (entries of `bc`) are simply ordered by size, the `pdg` and `mapping` entries go to the positions of the corresponding `bc` values.

```

(Cascades2: tree: TBP)+≡
procedure :: sort => tree_sort

(Cascades2: procedures)+≡
subroutine tree_sort (tree)
  class (tree_t), intent (inout) :: tree
  integer(TC), dimension(size(tree%bc)) :: bc_tmp
  integer, dimension(size(tree%pdg)) :: pdg_tmp, mapping_tmp
  integer, dimension(1) :: pos
  integer :: i
  bc_tmp = tree%bc
  pdg_tmp = tree%pdg
  mapping_tmp = tree%mapping
  do i = size(tree%bc), 1, -1
    pos = maxloc (bc_tmp)
    tree%bc(i) = bc_tmp (pos(1))
    tree%pdg(i) = pdg_tmp (pos(1))
    tree%mapping(i) = mapping_tmp (pos(1))
    bc_tmp(pos(1)) = 0
  end do
end subroutine tree_sort

```

19.14.6 Graph types

We define an abstract type which will give rise to two different types: The type `feyngraph_t` contains the pure information of the corresponding Feynman diagram, but also a list of objects of the `kingraph` type which contain the kinematically relevant data for the mapping calculation as well as the mappings themselves. Every graph should have an index which is unique. Graphs which are not needed any more can be disabled by setting the `keep` variable to `false`.

```

<Cascades2: types>+≡
  type, abstract :: graph_t
    integer :: index = 0
    integer :: n_nodes = 0
    logical :: keep = .true.
  end type graph_t

```

This is the type representing the Feynman diagrams which are read from an input file created by O'Mega. It is a tree of nodes, which we call `f_nodes`, so that `feyngraph_t` contains a pointer to the root of this tree, and each node can have two daughter nodes. The case of only one associated daughter should never appear, because in the method of phase space parametrization which is used here, we combine always two particle momenta to a third one. The `feyngraphs` will be arranged in a linked list. This is why we have a pointer to the next graph. The `kingraphs` on the other hand are arranged in linked lists which are attached to the corresponding `feyngraph`. In general, a `feyngraph` can give rise to more than one `kingraph` because we make a copy every time a particle can be resonant, so that in the copy we keep the particle nonresonant.

```

<Cascades2: types>+≡
  type, extends (graph_t) :: feyngraph_t
    type (string_t) :: omega_feyngraph_output
    type (f_node_t), pointer :: root => null ()
    type (feyngraph_t), pointer :: next => null ()
    type (kingraph_t), pointer :: kin_first => null ()
    type (kingraph_t), pointer :: kin_last => null ()
  contains
    <Cascades2: feyngraph: TBP>
  end type feyngraph_t

```

A container for a pointer of type `feyngraph_t`. This is used to realize arrays of these pointers.

```

<Cascades2: types>+≡
  type :: feyngraph_ptr_t
    type (feyngraph_t), pointer :: graph => null ()
  end type feyngraph_ptr_t

```

The length of a string describing a Feynman diagram which is produced by O'Mega is fixed by the parameter

```

<Cascades2: parameters>+≡
  integer, parameter :: FEYNGRAPH_LEN=300

<Cascades2: feyngraph: TBP>≡
  procedure :: final => feyngraph_final

```

```

<Cascades2: procedures>+≡
  subroutine feyngraph_final (graph)
    class(feyngraph_t), intent(inout) :: graph
    type (kingraph_t), pointer :: current
    graph%root => null ()
    graph%kin_last => null ()
    do while (associated (graph%kin_first))
      current => graph%kin_first
      graph%kin_first => graph%kin_first%next
      call current%final ()
      deallocate (current)
    enddo
  end subroutine feyngraph_final

```

This is the type of graph which is used to find the phase space channels, or in other words, each kingraph could correspond to a channel, if it is not eliminated for kinematical reasons or due to an equivalence. For the linked list which is attached to the corresponding feyngraph, we need the `next` pointer, whereas `grove_next` points to the next kingraph within a grove. The information which is relevant for the specification of a channel is stored in `tree`. We use `grove_prop` to sort the kingraph in a grove in which all kingraphs are characterized by the numbers contained in `grove_prop`. Later these groves are further subdivided using the resonance hash. A kingraph which is constructed directly from the output of O'Mega, is not `inverse`. In this case the first incoming particle is the root of the tree. In a scattering process, we can also construct a kingraph where the root of the tree is the second incoming particle. In this case the value of `inverse` is `.true.`

```

<Cascades2: types>+≡
  type, extends (graph_t) :: kingraph_t
    type (k_node_t), pointer :: root => null ()
    type (kingraph_t), pointer :: next => null()
    type (kingraph_t), pointer :: grove_next => null ()
    type (tree_t) :: tree
    type (grove_prop_t) :: grove_prop
    logical :: inverse = .false.
    integer :: prc_component = 0
    contains
    <Cascades2: kingraph: TBP>
  end type kingraph_t

```

Another container for a pointer to emulate arrays of pointers:

```

<Cascades2: types>+≡
  type :: kingraph_ptr_t
    type (kingraph_t), pointer :: graph => null ()
  end type kingraph_ptr_t

```

```

<Cascades2: kingraph: TBP>≡
  procedure :: final => kingraph_final

```

```

<Cascades2: procedures>+≡
  subroutine kingraph_final (graph)
    class(kingraph_t), intent(inout) :: graph

```

```

graph%root => null ()
graph%next => null ()
graph%grove_next => null ()
call graph%tree%final ()
end subroutine kingraph_final

```

19.14.7 The node types

We define an abstract type containing variables which are needed for `f_node_t` as well as `k_node_t`. We say that a node is on the t-line if it lies between the two nodes which correspond to the two incoming particles. `incoming` and `tline` are used only for scattering processes and remain `.false.` in decay processes. The variable `n_subtree_nodes` holds the number of nodes (including the node itself) of the subtree of which the node is the root.

```

⟨Cascades2: types⟩+≡
  type, abstract :: node_t
    type (part_prop_t), pointer :: particle => null ()
    logical :: incoming = .false.
    logical :: t_line = .false.
    integer :: index = 0
    logical :: keep = .true.
    integer :: n_subtree_nodes = 1
  end type node_t

```

We use two different list types for the different kinds of nodes. We therefore start with an abstract type:

```

⟨Cascades2: types⟩+≡
  type, abstract :: list_t
    integer :: n_entries = 0
  end type list_t

```

Since the contents of the lists are different, we introduce two different entry types. Since the trees of nodes use pointers, the nodes should only be allocated by a type-bound procedure of the corresponding list type, such that we can keep track of all nodes, eventually reuse and in the end deallocate nodes correctly, without forgetting any nodes. Here is the type for the `k_nodes`. The list is a linked list. We want to reuse (recycle) the `k_nodes` which are neither `incoming` nor `t_line`.

```

⟨Cascades2: types⟩+≡
  type :: k_node_entry_t
    type (k_node_t), pointer :: node => null ()
    type (k_node_entry_t), pointer :: next => null ()
    logical :: recycle = .false.
  contains
    ⟨Cascades2: k node entry: TBP⟩
  end type k_node_entry_t

```

```

⟨Cascades2: k node entry: TBP⟩≡
  procedure :: final => k_node_entry_final

```

```

<Cascades2: procedures>+≡
  subroutine k_node_entry_final (entry)
    class(k_node_entry_t), intent(inout) :: entry
    if (associated (entry%node)) then
      call entry%node%final
      deallocate (entry%node)
    end if
    entry%next => null ()
  end subroutine k_node_entry_final

<Cascades2: k node entry: TBP>+≡
  procedure :: write => k_node_entry_write

<Cascades2: procedures>+≡
  subroutine k_node_entry_write (k_node_entry, u)
    class (k_node_entry_t), intent (in) :: k_node_entry
    integer, intent (in) :: u
  end subroutine k_node_entry_write

```

Here is the list type for `k_nodes`. A `k_node_list` can be declared to be an observer. In this case it does not create any nodes by itself, but the entries set their pointers to existing nodes. In this way we can use the list structure and the type bound procedures for existing nodes.

```

<Cascades2: types>+≡
  type, extends (list_t) :: k_node_list_t
    type (k_node_entry_t), pointer :: first => null ()
    type (k_node_entry_t), pointer :: last => null ()
    integer :: n_recycle
    logical :: observer = .false.
  contains
    <Cascades2: k node list: TBP>
  end type k_node_list_t

```

The `f_node_t` type contains the `particle_label` variable which is extracted from the input file. It consists not only of the particle name, but also of some numbers in brackets. These numbers indicate which external particles are part of the subtree of this node. The `f_node` contains also a list of `k_nodes`. Therefore,

if the nodes are not incoming or t_line, the mapping calculations for these k_nodes which can appear in several kingraphs have to be performed only once.

```

<Cascades2: types>+≡
  type, extends (node_t) :: f_node_t
    type (f_node_t), pointer :: daughter1 => null ()

      f_node%index = counter
    end if
  end subroutine f_node_set_index

```

Type for the nodes of the tree (lines of the Feynman diagrams). We also need a type containing a pointer to a node, which is needed for creating arrays of pointers. This will be used for scattering processes where we can take either the first or the second particle to be the root of the tree. Since we need both cases for the calculations and O'Mega only gives us one of these, we have to perform a transformation of the graph in which some nodes (on the line which we hereafter call t-line) need to know their mother and sister nodes, which become their daughters within this transformation.

```

  end if
  list%n_entries = list%n_entries + 1
  list%first%subtree_string = trim(subtree_string)
  list%first%string_len = subtree_len
  if (present (subtree_size)) list%first%subtree_size = subtree_size
  allocate (list%first%node)
  call list%first%node%set_index ()
  ptr_to_node => list%first%node
end if
end subroutine f_node_list_add_entry

```

A write method for debugging.

<Cascades2: f node list: TBP>+≡

```

  procedure :: write => f_node_list_write

```

<Cascades2: procedures>+≡

```

  subroutine f_node_list_write (f_node_list, u)
    class (f_node_list_t), intent (in) :: f_node_list
    integer, intent (in) :: u
    type (f_node_entry_t), pointer :: current
    integer :: pos = 0
    current => f_node_list%first
    do while (associated (current))
      pos = pos + 1
      write (unit=u, fmt='(A,I10)') 'entry #: ', pos
      call current%write (u)
      write (unit=u, fmt=*)
      current => current%next
    enddo
  end subroutine

```

```

        enddo
    end subroutine f_node_list_write

    <Cascades2: interfaces>+≡
    interface assignment (=)
        module procedure k_node_entry_assign
    end interface assignment (=)

    <Cascades2: procedures>+≡
    subroutine k_node_entry_assign (entry1, entry2)
        type (k_node_entry_t), intent (out) :: entry1
        type (k_node_entry_t), intent (in) :: entry2
        entry1%node => entry2%node
        entry1%recycle = entry2%recycle
    end subroutine k_node_entry_assign

```

Add an entry to the `k_node_list`. We have to specify if the node can be reused. The check for existing reusable nodes happens with `k_node_list_get_nodes` (see below).

```

    <Cascades2: k node list: TBP>+≡
    procedure :: add_entry => k_node_list_add_entry

    <Cascades2: procedures>+≡
    recursive subroutine k_node_list_add_entry (list, ptr_to_node, recycle)
        class (k_node_list_t), intent (inout) :: list
        type (k_node_t), pointer, intent (out) :: ptr_to_node
        logical, intent (in) :: recycle
        if (list%n_entries == 0) then
            allocate (list%first)
            list%last => list%first
        else
            allocate (list%last%next)
            list%last => list%last%next
        end if
        list%n_entries = list%n_entries + 1
        list%last%recycle = recycle
        allocate (list%last%node)
        call list%last%node%set_index ()
        ptr_to_node => list%last%node
    end subroutine k_node_list_add_entry

```

We need a similar subroutine for adding only a pointer to a list. This is needed for a `k_node_list` which is only an observer, i.e. it does not create any nodes by itself.

```

    <Cascades2: k node list: TBP>+≡
    procedure :: add_pointer => k_node_list_add_pointer

    <Cascades2: procedures>+≡
    subroutine k_node_list_add_pointer (list, ptr_to_node, recycle)
        class (k_node_list_t), intent (inout) :: list
        type (k_node_t), pointer, intent (in) :: ptr_to_node
        logical, optional, intent (in) :: recycle
        logical :: rec
        if (present (recycle)) then

```

```

        rec = recycle
    else
        rec = .false.
    end if
    if (list%n_entries == 0) then
        allocate (list%first)
        list%last => list%first
    else
        allocate (list%last%next)
        list%last => list%last%next
    end if
    list%n_entries = list%n_entries + 1
    list%last%recycle = rec
    list%last%node => ptr_to_node
end subroutine k_node_list_add_pointer

```

The `k_node_list` can also be used to collect `k_nodes` which belong to different `f_nodes` in order to compare these. This is done only for nodes which have the same number of subtree nodes. We compare all nodes of the list with each other (as long as the node is not deactivated, i.e. if the `keep` variable is set to `.true.`) using the subroutine `subtree_select`. If it turns out that two nodes are equivalent, we keep only one of them. The term equivalent in this module refers to trees or subtrees which differ in the pdg codes at positions where the trivial mapping is used (`NO_MAPPING` or `NON_RESONANT`) so that the mass of the particle does not matter. Depending on the available couplings, two equivalent subtrees could eventually lead to the same phase space channels, which is why only one of them is kept.

(Cascades2: k node list: TBP)+≡

```

    procedure :: check_subtree_equivalences => k_node_list_check_subtree_equivalences

```

(Cascades2: procedures)+≡

```

subroutine k_node_list_check_subtree_equivalences (list, model)
    class (k_node_list_t), intent (inout) :: list
    type (model_data_t), intent (in) :: model
    type (k_node_ptr_t), dimension (:), allocatable :: set
    type (k_node_entry_t), pointer :: current
    integer :: pos
    integer :: i,j
    if (list%n_entries == 0) return
    allocate (set (list%n_entries))
    current => list%first
    pos = 0
    do while (associated (current))
        pos = pos + 1
        set(pos)%node => current%node
        current => current%next
    enddo
    do i=1, list%n_entries
        if (set(i)%node%keep) then
            do j=i+1, list%n_entries
                if (set(j)%node%keep) then
                    if (set(i)%node%bincode == set(j)%node%bincode) then
                        call subtree_select (set(i)%node%subtree,set(j)%node%subtree, model)
                    end if
                end if
            enddo
        end if
    enddo

```

```

        if (.not. set(i)%node%subtree%keep) then
            set(i)%node%keep = .false.
            exit
        else if (.not. set(j)%node%subtree%keep) then

19.14.8 The grove list

First a type is introduced in order to speed up the comparison of kingraphs with the purpose to quickly find the graphs that might be equivalent. This is done solely on the basis of a number (which is given by the value of **depth** in **compare_tree_t**) of bincodes, which are the highest ones that do not belong to external particles. The highest such value determines the index of the element in the **entry** array of the **compare_tree**. The next lower such value determines the index of the element in the **entry** array of this **entry**, and so on and so forth. This results in a tree structure where the number of levels is given by **depth** and should not be too large for reasons of memory. This is the entry type.

 type (kingraph_ptr_t), dimension(:), allocatable :: graph_entry
 contains
<Cascades2: compare tree entry: TBP>
 end type compare_tree_entry_t

This is the tree type.

<Cascades2: types>+≡
 type :: compare_tree_t
 integer :: depth = 3
 type (compare_tree_entry_t), dimension(:), pointer :: entry => null ()

```

contains
  <Cascades2: compare tree: TBP>
end type compare_tree_t

```

Finalizers for both types. The one for the entry type has to be recursive.

```

<Cascades2: compare tree: TBP>≡
  procedure :: final => compare_tree_final

<Cascades2: procedures>+≡
  subroutine compare_tree_final (ctree)
    class (compare_tree_t), intent (inout) :: ctree
    integer :: i
    if (associated (ctree%entry)) then
      do i=1, size (ctree%entry)
        call ctree%entry(i)%final ()
        deallocate (ctree%entry)
      end do
    end if
  end subroutine compare_tree_final

<Cascades2: compare tree entry: TBP>≡
  procedure :: final => compare_tree_entry_final

<Cascades2: procedures>+≡
  recursive subroutine compare_tree_entry_final (ct_entry)
    class (compare_tree_entry_t), intent (inout) :: ct_entry
    integer :: i
    if (associated (ct_entry%entry)) then
      do i=1, size (ct_entry%entry)
        call ct_entry%entry(i)%final ()
      enddo
      deallocate (ct_entry%entry)
    else
      deallocate (ct_entry%graph_entry)
    end if
  end subroutine compare_tree_entry_final

```

Check the presence of a graph which is considered as equivalent and select between the two. If there is no such graph, the current one is added to the list. First the entry has to be found:

```

<Cascades2: compare tree: TBP>+≡
  procedure :: check_kingraph => compare_tree_check_kingraph

<Cascades2: procedures>+≡
  subroutine compare_tree_check_kingraph (ctree, kingraph, model, preliminary)
    class (compare_tree_t), intent (inout) :: ctree
    type (kingraph_t), intent (inout), pointer :: kingraph
    type (model_data_t), intent (in) :: model
    logical, intent (in) :: preliminary
    integer :: i
    integer :: pos
    integer(TC) :: sz
    integer(TC), dimension(:), allocatable :: identifier
    if (.not. associated (ctree%entry)) then

```

```

sz = 0_TC
do i = size(kingraph%tree%bc), 1, -1
  sz = ior (sz, kingraph%tree%bc(i))
enddo
if (sz > 0) then
  allocate (ctree%entry (sz))
else
  call msg_bug ("Compare tree could not be created")
end if
end if
allocate (identifier (ctree%depth))
pos = 0
do i = size(kingraph%tree%bc), 1, -1
  if (popcnt (kingraph%tree%bc(i)) /= 1) then
    pos = pos + 1
    identifier(pos) = kingraph%tree%bc(i)
    if (pos == ctree%depth) exit
  end if
enddo
if (size (identifier) > 1) then
  call ctree%entry(identifier(1))%check_kingraph (kingraph, model, &
    preliminary, identifier(1), identifier(2:))
else if (size (identifier) == 1) then
  call ctree%entry(identifier(1))%check_kingraph (kingraph, model, preliminary)
end if
deallocate (identifier)
end subroutine compare_tree_check_kingraph

```

Then the graphs of the entry are checked.

```

The grove to which a completed kingraph will be added is determined by the entries of `grove_prop`. We use another list type (linked list) to arrange the groves. Each grove contains again a linked list of kingraphs.

```

<Cascades2: types>+≡
  type :: grove_t
    type (grove_prop_t) :: grove_prop
    type (grove_t), pointer :: next => null ()
    type (kingraph_t), pointer :: first => null ()
    type (kingraph_t), pointer :: last => null ()
    type (compare_tree_t) :: compare_tree
  contains
    <Cascades2: grove: TBP>
  end type grove_t

```

Container for a pointer of type grove_t:

```

<Cascades2: types>+≡
  type :: grove_ptr_t
    type (grove_t), pointer :: grove => null ()
  end type grove_ptr_t

```

```

<Cascades2: grove: TBP>≡
  procedure :: final => grove_final

```

```

<Cascades2: procedures>+≡
  subroutine grove_final (grove)
    class(grove_t), intent(inout) :: grove
    grove%first => null ()
    grove%last  => null ()
    grove%next => null ()
  end subroutine grove_final

```

This is the list type:

```

<Cascades2: types>+≡
  type :: grove_list_t
    type (grove_t), pointer :: first => null ()
  contains
    <Cascades2: grove list: TBP>
  end type grove_list_t

```

```

<Cascades2: grove list: TBP>≡
  procedure :: final => grove_list_final

```

```

<Cascades2: procedures>+≡

    class(grove_list_t), intent(inout) :: list
    class(grove_t), pointer :: current
    do while (associated (list%first))
      current => list%first
      list%first => list%first%next
      call current%final ()
      deallocate (current)
    end do
  end subroutine grove_list_final

```

19.14.9 The feyngraph set

The fundament of the module is the public type `feyngraph_set_t`. It is not only a linked list of all `feyngraphs` but contains an array of all particle properties (`particle`), an `f_node_list` and a pointer of the type `grove_list_t`, since several `feyngraph_sets` can share a common `grove_list`. In addition it keeps the data which unambiguously specifies the process, as well as the model which provides information which allows us to choose between equivalent subtrees or complete `kingraphs`.

```

<Cascades2: public>+≡
    public :: feyngraph_set_t

<Cascades2: types>+≡
    type :: feyngraph_set_t
        type (model_data_t), pointer :: model => null ()

  end if
end if
end subroutine feyngraph_set_final

```

19.14.10 Construct the feyngraph set

We construct the `feyngraph_set` from an input file. Therefore we pass a unit to `feyngraph_set_build`. The parsing subroutines are chosen depending on the value of `use_dag`. In the DAG output, which is the one that is produced by default, we have to work on a string of one line, where the length of this string becomes larger the more particles are involved in the process. The other output (which is now only used in a unit test) contains one Feynman diagram per line and each line starts with an open parenthesis so that we read the file line per line and create a `feyngraph` for every line. Only after this, nodes are created. In both decay and scattering processes the diagrams are represented like in a decay process, i.e. in a scattering process one of the incoming particles appears as an outgoing particle.

```

<Cascades2: feyngraph set: TBP>+≡
  procedure :: build => feyngraph_set_build

<Cascades2: procedures>+≡

```

```
end subroutine feyngraph_set_build
```

Read the string from the file. The output which is produced by O'Mega contains the DAG in a factorised form as a long string, distributed over several lines (in addition, in the case of a scattering process, it contains a similar string for the same process, but with the other incoming particle as the root of the tree structure). In general, such a file can contain many of these strings, belonging to different process components. Therefore we first have to find the correct position of the string for the process in question. Therefore we look for a line containing a pair of colons, in which case the line contains a process string. Then we check if the process string describes the correct process, which is done by checking for all the incoming and outgoing particle names. If the process is correct, the dag output should start in the following line. As long as we do not find the correct process string, we continue searching. If we reach the end of the file, we rewind the unit once, and repeat searching. If the process is still not found, there must be some sort of error.

```
<Cascades2: dag: TBP>≡
  procedure :: read_string => dag_read_string

<Cascades2: procedures>+≡
  subroutine dag_read_string (dag, u_in, flv)
    class (dag_t), intent (inout) :: dag
    integer, intent (in) :: u_in
    type(flavor_t), dimension(:), intent(in) :: flv
    character (len=BUFFER_LEN) :: process_string
    logical :: process_found
    logical :: rewind
    !!! find process string in file
    process_found = .false.
    rewind = .false.
    do while (.not. process_found)
      process_string = ""
      read (unit=u_in, fmt='(A)') process_string
      if (len_trim(process_string) /= 0) then
        if (index (process_string, "::") > 0) then
          process_found = process_string_match (trim (process_string), flv)
        end if
      else if (.not. rewind) then
        rewind (u_in)
        rewind = .true.
      else
        call msg_bug ("Process string not found in O'Mega input file.")
      end if
    enddo
    call fds_file_get_line (u_in, dag%string)
    call dag%string%clean ()
    if (.not. allocated (dag%string%t) .or. dag%string%char_len == 0) &
      call msg_bug ("Process string not found in O'Mega input file.")
  end subroutine dag_read_string
```

The output of factorized Feynman diagrams which is created by O'Mega for a given process could in principle be written to a single line in the file. This can

however lead to different problems with different compilers as soon as such lines become too long. This is the reason why the line is cut into smaller pieces. This means that a new line starts after each vertical bar. For this long string the type `dag_string_t` has been introduced. In order to read the file quickly into such a `dag_string` we use another type, `dag_chain_t` which is a linked list of such `dag_strings`. This has the advantage that we do not have to recreate a new `dag_string` for every line which has been read from file. Only in the end of this operation we compress the list of strings to a single string, removing useless `dag_tokens`, such as blank space tokens. This subroutine reads all lines starting from the position in the file the unit is connected to, until no backslash character is found at the end of a line (the backslash means that the next line also belongs to the current string).

```

<Cascades2: parameters>+=
    integer, parameter :: BUFFER_LEN = 1000
    integer, parameter :: STACK_SIZE = 100

<Cascades2: procedures>+=
    subroutine fds_file_get_line (u, string)
        integer, intent (in) :: u
        type (dag_string_t), intent (out) :: string
        type (dag_chain_t) :: chain
        integer :: string_size, current_len
        character (len=BUFFER_LEN) :: buffer
        integer :: fragment_len
        integer :: stat
        current_len = 0
        stat = 0
        string_size = 0
        do while (stat == 0)
            read (unit=u, fmt='(A)', iostat=stat) buffer
            if (stat /= 0) exit
            fragment_len = len_trim (buffer)
            if (fragment_len == 0) then
                exit
            else if (buffer (fragment_len:fragment_len) == BACKSLASH_CHAR) then
                fragment_len = fragment_len - 1
            end if
            call chain%append (buffer(:fragment_len))
            if (buffer(fragment_len+1:fragment_len+1) /= BACKSLASH_CHAR) exit
        enddo
        if (associated (chain%first)) then
            call chain%compress ()

Initialize a `part_prop` object by passing a `particle.label`, which is simply the

particle name. `part_prop` should be part of the `particle` array of `feyngraph_set`. We use the model of `feyngraph_set` to obtain the relevant data of the particle which is needed to find `phase_space` parametrizations. When a `part_prop` is initialized, we add and initialize also the corresponding anti- particle `part_prop` if it is not yet in the array.

```

This subroutine assigns to a node the particle properties. Since these properties do not change and are simply read from the model file, we use pointers to the elements of the `particle` array of the `feyngraph_set`. If there is no corresponding array element, we have to initialize the first empty element of the array.

```

    node%particle => node%particle%anti
  end subroutine f_node_assign_particle_properties

```

From the output of a Feynman diagram (in the non-factorized output) we need to find out how many daughter nodes would be required to reconstruct it correctly, to make sure that we keep only those **feyngraphs** which are constructed solely on the basis of the 3-vertices which are provided by the model. The number of daughter particles can easily be determined from the syntax of O'Mega's output: The particle which appears before the colon ':' is the mother particle. The particles or subtrees (i.e. whole parentheses) follow after the colon and are separated by commas.

```

<Cascades2: procedures>+=
  function get_n_daughters (subtree_string, pos_first_colon) &
    result (n_daughters)
    character (len=*), intent (in) :: subtree_string

          if (subtree_string(i:i) == ',') then
            if (n_open_par == 1) n_daughters = n_daughters + 1
          else if (subtree_string(i:i) == '(') then

```

```

        n_open_par = n_open_par + 1
    else if (subtree_string(i:i) == ' ') then
        n_open_par = n_open_par - 1
    end if
end do
if (n_open_par == 0) then
    n_daughters = n_daughters + 1
end if
end if
end if
end function get_n_daughters

```

19.14.12 Reconstruction of trees

The reconstruction of a tree or subtree with the non-factorized input can be done recursively, i.e. we first find the root of the tree in the string and create an `f_node`. Then we look for daughters, which in the string appear either as single particles or subtrees (which are of the same form as the tree which we want to reconstruct. Therefore the subroutine can simply be called again and again until there are no more daughter nodes to create. When we meet a vertex which requires more than two daughter particles, we stop the recursion and disable the node using its `keep` variable. Whenever a daughter node is not kept, we do not keep the mother node as well.

(*Cascades2: procedures*) +=

```

When the non-factorized version of the O'Mega output is used, the `feyngraph` is reconstructed from the contents of its `string_t` variable `omega_feyngraph_output`. This can be used for the recursive reconstruction of the tree of `k_nodes` with `node_construct_subtree_rec`.

(*Cascades2: procedures*) +≡

```

subroutine feyngraph_construct (feyngraph_set, feyngraph)
  type (feyngraph_set_t), intent (inout) :: feyngraph_set
  type (feyngraph_t), pointer, intent (inout) :: feyngraph
  call node_construct_subtree_rec (feyngraph_set, feyngraph, &
    char(feyngraph%omega_feyngraph_output), feyngraph%root)
  feyngraph%n_nodes = feyngraph%root%n_subtree_nodes
end subroutine feyngraph_construct

```

We introduce another node type, which is called `dag_node_t` and is used to reproduce the dag structure which is represented by the input. The `dag_nodes` can have several combinations of daughters 1 and 2. The `dag` type contains an array of `dag_nodes` and is only used for the reconstruction of `feyngraphs` which are factorized as well, but in the other direction as the original output. This means in particular that the outgoing particles in the output file (which there can appear many times) exist only once as `f_nodes`. To represent combinations of daughters and alternatives (options), we further use the types `dag_options_t` and `dag_combination_t`. The `dag_nodes`, `dag_options` and `dag_combinations` correspond to a substring of the string which has been read from file (and transformed into an object of type `dag_string_t`, which is simply another compact representation of this string), or a modified version of this substring. The aim is to create only one object for a given substring, even if it appears several times in the original string and then create trees of `f_nodes`, which build up the `feyngraph`, such that as many `f_nodes` as possible can be reused. An outgoing particle (always interpreting the input as a decay) is called a `leaf` in the context of a `dag`.

<Cascades2: types>+≡

      enddo
      deallocate (dag%combination)
    end if
  end subroutine dag_final

```

We construct the DAG from the given `dag_string` which is modified several times so that in the end the remaining string corresponds to a simple `dag_node`, the root of the factorized tree. This means that we first identify the leaves, i.e. outgoing particles. Then we identify `dag_nodes`, `dag_combinations` and `options` until the number of these objects does not change any more. Identifying means that we add a corresponding object to the array (if not yet present), which can be identified with the corresponding substring, and replace the substring in the original `dag_string` by a `dag_token` of the corresponding type (in the char output of this token, this corresponds to a place holder like e.g. `'iO23i'` which in this particular case corresponds to an option and can be found at the position 23 in the array). The character output of the substrings turns out to be very useful for debugging.

Identify `dag_nodes` and `dag_combinations`. Leaves are simply nodes (i.e. of type `NODE_TK`) where only one bit in the bincode is set. The `dag_nodes` and `dag_combinations` have in common that they are surrounded by parentheses. There is however a way to distinguish between them because the corresponding substring contains a colon (or `dag_token` with type `COLON_TK`) if it is a `dag_node`. Otherwise it is a `dag_combination`. The string of the `dag_node` or `dag_combination` should not contain curly braces, because these correspond to `dag_options` and should be identified before.

For a given `dag_node` we want to create all `f_nodes`. If the node is not a leaf, it contains in its string placeholders for options or combinations. For these objects there are similar subroutines which are needed here to obtain the sets of daughter nodes. If the `dag_node` is a leaf, it corresponds to an external particle and the token contains the particle name.

<Cascades2: dag node: TBP>+≡

```

In `dag_options.make_f_nodes.single` we obtain all `f_nodes` for `dag_nodes` which correspond to a set of rival subtrees or nodes, which is the first possibility for which `dag_options` can appear. In `dag_options.make_f_nodes.pair` the options are rival pairs (`daughter1`, `daughter2`). Therefore we have to pass two allocatable arrays of type `f_node_ptr_t` to the subroutine.

We create all combinations of daughter `f_nodes` for a combination. In the combination each daughter can be either a single `dag_node` or `dag_options` which are a set of single `dag_nodes`. Therefore, we first create all possible `f_nodes` for daughter1, then all possible `f_nodes` for daughter2. In the end we combine all daughter1 nodes with all daughter2 nodes.

```

Here we create the `feyngraphs`. After the construction of the `dag` the remaining `dag_string` should contain a token for a single `dag_node` which corresponds to the roots of the `feyngraphs`. Therefore we make all `f_nodes` for this `dag_node` and create a `feyngraph` for each `f_node`. Note that only 3-vertices are accepted. All other vertices are rejected. The starting point is the last dag node which has been added to the list, since this corresponds to the root of the tree. It is important to understand that the structure of `feyngraphs` is not the same as the structure of the `dag` which is read from file, because for the calculations which are performed in this module we want to reuse the nodes for the outgoing particles, which means that they appear only once. In O'Mega's output, it is the first incoming particle which appears only once and the outgoing particles appear many times. This transition is incorporated in the subroutines which create `f_nodes` from the different `dag` objects.

    copy%is_nonresonant_copy = .true.
end subroutine k_node_make_nonresonant_copy

```

For a given `feyngraph` we create all possible `kingraphs`. Here we use existing `k_nodes` which have already been created when the mapping calculations of the pure s-channel subgraphs are performed. The nodes for the incoming particles or the nodes on the t-line will have to be created in all cases because they are not used in several graphs. To obtain the existing `k_nodes`, we use the subroutine `k_node_init_from_f_node` which itself uses `f_node_list.get_nodes` to obtain all active `k_nodes` in the `k_node_list` of the `f_node`. The created `kingraphs` are attached to the linked list of the `feyngraph`. For scattering processes we have to split up the t-line, because since all graphs are represented as a decay, different nodes can share daughter nodes. This happens also for the t-line or the incoming particle which appears as an outgoing particle. For the `t_line` or `incoming` nodes we do not want to recycle nodes but rather create a copy of this line for each `kingraph`.

```

```

The graphs resulting from `k_node_init_from_f_node` are fine if they are used only in one direction. This is however not the case when one wants to invert the graphs, i.e. take the other incoming particle of a scattering process as the decaying particle, because the outgoing `f_nodes` (and hence also the `k_nodes`) exist only once. This problem is solved here by creating a distinct t-line for each of the graphs. The following subroutine disentangles the data structure by

creating new nodes such that the different t-lines are not connected any more.

(*Cascades2: procedures*) +=

```

recursive subroutine split_up_t_lines (t_node)
  type (k_node_ptr_t), dimension(:), intent (inout) :: t_node

    end if
  enddo
  call split_up_t_lines (t_daughter)
  deallocate (t_daughter)
end subroutine split_up_t_lines

```

This subroutine sets the `inverse_daughters` of a `k_node`. If we invert a `kingraph` such that not the first but the second incoming particle appears as the root of the tree, the `incoming` and `t_line` particles obtain other daughters. These are the former mother node and the sister node `s_daughter`. Here we set only the pointers for the `inverse_daughters`. The inversion happens in `kingraph_make_inverse_copy`

and node_inverse_deep_copy.

```

<Cascades2: procedures>+≡
subroutine kingraph_set_inverse_daughters (kingraph)
  type (kingraph_t), intent (inout) :: kingraph
  type (k_node_t), pointer :: mother
  type (k_node_t), pointer :: t_daughter
  type (k_node_t), pointer :: s_daughter
  mother => kingraph%root
  do while (associated (mother))
    if (associated (mother%daughter1) .and. &
        associated (mother%daughter2)) then
      if (mother%daughter1%t_line .or. mother%daughter1%incoming) then
        t_daughter => mother%daughter1; s_daughter => mother%daughter2
      else if (mother%daughter2%t_line .or. mother%daughter2%incoming) then
        t_daughter => mother%daughter2; s_daughter => mother%daughter1
      else
        exit
      end if
      t_daughter%inverse_daughter1 => mother
      t_daughter%inverse_daughter2 => s_daughter
      mother => t_daughter
    else
      exit
    end if
  enddo
end subroutine kingraph_set_inverse_daughters

```

Set the bincode of an `f_node` which corresponds to an external particle. This is done on the basis of the `particle_label` which is a substring of the input file. Here it is not the particle name which is important, but the number(s) in brackets which in general indicate the external particles which are connected to the current node. This function is however only used for external particles, so there can either be one or `n_out + 1` particles in the brackets (in the DAG input file always one, because also for the root there is only a single number). In all cases we check the number of particles (in the DAG input the numbers are separated by a slash).

```

<Cascades2: procedures>+≡
function f_node_get_external_bincode (feyngraph_set, f_node) result (bincode)
  type (feyngraph_set_t), intent (in) :: feyngraph_set
  type (f_node_t), intent (in) :: f_node
  integer (TC) :: bincode
  character (len=LABEL_LEN) :: particle_label
  integer :: start_pos, end_pos, n_out_decay
  integer :: n_prt ! for DAG
  integer :: i
  bincode = 0
  if (feyngraph_set%process_type == DECAY) then
    n_out_decay = feyngraph_set%n_out
  else
    n_out_decay = feyngraph_set%n_out + 1
  end if
  particle_label = f_node%particle_label
  start_pos = index (particle_label, '/') + 1

```

```

end_pos = index (particle_label, ']') - 1
particle_label = particle_label(start_pos:end_pos)
!!! n_out_decay is the number of outgoing particles in the
!!! 0'Mega output, which is always represented as a decay
if (feyngraph_set%use_dag) then
  n_prt = 1
  do i=1, len(particle_label)
    if (particle_label(i:i) == '/') n_prt = n_prt + 1
  enddo
else
  n_prt = end_pos - start_pos + 1
end if

19.14.13 Mapping calculations

Once a `k_node` and its subtree nodes have been created, we can perform the kinematical calculations and assign mappings, depending on the particle properties and the results for the subtree nodes. This could in principle be done recursively, calling the procedure first for the daughter nodes and then perform the calculations for the actual node. But for parallization and comparing the nodes, this will be done simultaneously for all nodes with the same number of subtree nodes, and the number of subtree nodes increases, starting from one, in steps of two. The actual mapping calculations are done in complete analogy to cascades.

```

After all pure s-channel subdiagrams have already been created from the corresponding **f_nodes** and mappings have been determined for their nodes, we complete the calculations here. In a first step, the **kingraphs** have to be created on the basis of the existing **k_nodes**, which means in particular that a **feyngraph** can give rise to several **kingraphs** which will all be attached to the linked list of the **feyngraph**. The calculations which remain are of different kinds for decay and scattering processes. In a decay process the kinematical calculations have to be done for the **root** node. In a scattering process, after the creation of **kingraphs** in the first step, there will be only **kingraphs** with the first incoming particle as the **root** of the tree. For these graphs the **inverse** variable has the value **.false..** Before performing any calculations on these graphs we make a so-called inverse copy of the graph (see below), which will also be attached to the linked list. Since the s-channel subgraph calculations have already been completed, only the t-line computations remain.

```

```

Here we control the mapping calculations for the nodes of s-channel subgraphs. We start with the nodes with the smallest number of subtree nodes and always increase this number by two because nodes have exactly zero or two daughter nodes. We create the `k_nodes` using the `k_node_list` of each `f_node`. The number of nodes which have to be created depends of the number of existing daughter nodes, which means that we have to create a node for each combination of existing and valid (the ones which we keep) daughter nodes. If the node corresponds to an external particle, we create only one node, since there are no daughter nodes. If the particle is not external and the daughter `f_nodes` do not contain any valid `k_nodes`, we do not create a new `k_nodes` either. When the calculations for all nodes with the same number of subtree nodes have been completed, we compare the valid nodes to eliminate equivalences (see below).

19.14.14 Fill the grove list

Find the **grove** within the **grove_list** for a **kingraph** for which the kinematical calculations and mapping assignments have been completed. The **groves** are defined by the **grove_prop** entries and the value of the resonance hash (**res_hash**). Whenever a matching grove does not exist, we create one. In a first step we consider only part of the grove properties (see **grove_prop_match**) and the resonance hash is ignored, which leads to a preliminary grove list. In the end all numbers in **grove_prop** as well as the resonance hash are compared, i.e. we create a new **grove_list**.

<Cascades2: grove list: TBP>+≡

```

    procedure :: get_grove => grove_list_get_grove

```

<Cascades2: procedures>+≡

```

    subroutine grove_list_get_grove (grove_list, kingraph, return_grove, preliminary)

  do while (associated (feyngraph%kin_first))
    if (feyngraph%kin_first%keep) then
      add_kingraph => feyngraph%kin_first
      feyngraph%kin_first => feyngraph%kin_first%next
      add_kingraph%next => null ()
      call grove_list%add_kingraph (kingraph=add_kingraph, &
        preliminary=.true., check=.true., model=model)
    else
      exit
    end if
  enddo
  if (associated (feyngraph%kin_first)) then
    current_kingraph => feyngraph%kin_first
    do while (associated (current_kingraph%next))
      if (current_kingraph%next%keep) then
        add_kingraph => current_kingraph%next
        current_kingraph%next => current_kingraph%next%next
        add_kingraph%next => null ()
        call grove_list%add_kingraph (kingraph=add_kingraph, &
          preliminary=.true., check=.true., model=model)
      else
        current_kingraph => current_kingraph%next
      end if
    enddo
  end if
end subroutine grove_list_add_feyngraph
```

Compare two `grove_prop` objects. The `.match.` operator is used for preliminary groves in which the kingraphs share only the 3 numbers `n_resonances`, `n_log_enhanced` and `n_t_channel`. These groves are only used for comparing the kingraphs, because only graphs within these preliminary groves can be equivalent (the numbers which are compared here are unambiguously fixed by the combination of mappings in these channels).

<Cascades2: interfaces>+≡

```
interface operator (.match.)
  module procedure grove_prop_match
end interface operator (.match.)
```

<Cascades2: procedures>+≡

```
function grove_prop_match (grove_prop1, grove_prop2) result (gp_match)
  type (grove_prop_t), intent (in) :: grove_prop1
```

```

type (grove_prop_t), intent (in) :: grove_prop2
logical :: gp_match
gp_match = (grove_prop1%n_resonances == grove_prop2%n_resonances) &
    .and. (grove_prop1%n_log_enhanced == grove_prop2%n_log_enhanced) &
    .and. (grove_prop1%n_t_channel == grove_prop2%n_t_channel)
end function grove_prop_match

```

The equal operator on the other hand will be used when all valid **kingraphs** have been created and mappings have been determined, to split up the existing (preliminary) grove list, i.e. to create new groves which are determined by all entries in **grove_prop_t**.

```

<Cascades2: interfaces>+≡
interface operator (==)
    module procedure grove_prop_equal
end interface operator (==)

<Cascades2: procedures>+≡
function grove_prop_equal (grove_prop1, grove_prop2) result (gp_equal)
    type (grove_prop_t), intent (in) :: grove_prop1
    type (grove_prop_t), intent (in) :: grove_prop2
    logical :: gp_equal
    gp_equal = (grove_prop1%res_hash == grove_prop2%res_hash) &
        .and. (grove_prop1%n_resonances == grove_prop2%n_resonances) &
        .and. (grove_prop1%n_log_enhanced == grove_prop2%n_log_enhanced) &
        .and. (grove_prop1%n_off_shell == grove_prop2%n_off_shell) &
        .and. (grove_prop1%multiplicity == grove_prop2%multiplicity) &
        .and. (grove_prop1%n_t_channel == grove_prop2%n_t_channel)
end function grove_prop_equal

```

19.14.15 Remove equivalent channels

Here we define the equivalence condition for completed **kingraphs**. The aim is to keep those **kingraphs** which describe the strongest peaks of the amplitude. The **bincodes** and **mappings** have to be the same for an equivalence, but the **pdgs** can be different. At the same time we check if the trees are exactly the same (up to the sign of pdg codes) in which case we do not keep both of them. This can be the case when the incoming particles are the same or their mutual anti-particles and there are no t-channel lines in the Feynman diagram to which the kingraph belongs.

```

<Cascades2: parameters>+≡

  eqv = .true.
end if
end function kingraph_eqv

```

Select between two **kingraphs** which fulfill the equivalence condition above. This is done by comparing the **pdg** values of the **tree** for increasing bincode. If the particles are different at some place, we usually choose the one which would be returned first by the subroutine **match_vertex** of the model for the daughter **pdg** codes. Since we work here only on the basis of the the **trees** of the completed **kingraphs**, we have to use the **bc** array to determine the positions of the daughter nodes' entries in the array. The graph which has to be kept should correspond to the stronger peak at the place which is compared.

```

At the beginning we do not care about the resonance hash, but only about part of the grove properties, which is defined in `grove_prop_match`. In these resulting preliminary groves the kingraphs can be equivalent, i.e. we do not have to compare all graphs with each other but only all graphs within each of these preliminary groves. In the end we create a new grove list where the grove properties of the kingraphs within a grove have to be exactly the same and

in addition the groves are distinguished by the resonance hash values. Here the kingraphs are not compared any more, which means that the number of channels is not reduced any more.

19.14.17 Invert a graph

All Feynman diagrams given by O'Mega look like a decay. The `feyngraph` which is constructed from this output also looks like a decay, where one of the incoming particles is the decaying particle (or the root of the tree). The calculations can in principle be done on this data structure. However, it is also performed with the other incoming particle as the root. The first part of the calculation is the same for both cases. For the second part we need to transform/turn the graphs such that the other incoming particle becomes the root. This is done by identifying the incoming particles from the O'Mega output (the first one is simply the root of the existing tree, the second contains [2] in the `particle_label`) and the nodes/particles which connect both incoming particles (here we set `t_line = .true.`). At the same time we set the pointers `inverse_daughter1` and `inverse_daughter2` for the corresponding node, which point to the mother node and the other daughter of the mother node; these will be the daughters of the node in the inverted `feyngraph`.

```

end subroutine feyngraph_set_generate_single

```

Find the phase space parametrizations. We start with the computation of pure s-channel subtrees, i.e. we determine mappings and compare subtrees in order to reduce the number of channels. This can be parallelized easily. When all s-channel `k_nodes` exist, the possible `kingraphs` are created using these nodes and we determine mappings for t-channel nodes.

Chapter 20

VEGAS Integration

The backbone integrator of WHIZARD is a object-oriented implemetation of the VEGAS algorithm.

```
<vegas.f90>≡  
  <File header>  
  
  module vegas  
    <Use kinds>  
  
    <vegas: modules>  
  
    <Standard module head>  
  
    <vegas: public>  
  
    <vegas: parameters>  
  
    <vegas: types>  
  
    <vegas: interfaces>  
  
    contains  
  
    <vegas: procedures>  
  
  end module vegas  
<vegas: modules>≡  
  use diagnostics  
  use io_units  
  use format_utils, only: write_indent  
  use format_defs, only: FMT_17  
  use rng_base, only: rng_t  
  use rng_stream, only: rng_stream_t  
MPI Module.  
<MPI: vegas: modules>≡  
  use mpi_f08 !NODEP!
```

20.1 Integration modes

VEGAS operates in three different modes: `vegas_mode_importance_only`, `vegas_mode_importance` or `vegas_mode_stratified`. The default mode is `vegas_mode_importance`, where the algorithm decides whether if it is possible to use importance sampling or stratified sampling. In low dimensions VEGAS uses strict stratified sampling.

```
<vegas: parameters>≡  
  integer, parameter, public :: VEGAS_MODE_IMPORTANCE = 0, &  
    & VEGAS_MODE_STRATIFIED = 1, VEGAS_MODE_IMPORTANCE_ONLY = 2
```

20.2 Type: vegas_func_t

We define a abstract `func` type which only gives an interface to an `evaluate` procedure. The inside of implementation and also the optimization of are not a concern of the `vegas` implementation.

```
<vegas: public>≡  
  public :: vegas_func_t  
<vegas: types>≡  
  type, abstract :: vegas_func_t  
    !  
    contains  
    procedure(vegas_func_evaluate), deferred, pass, public :: evaluate  
  end type vegas_func_t
```

The only procedure called in `vegas` is `vegas_func_evaluate`. It takes a real value `x` and returns a real value `f`.

```
<vegas: interfaces>≡  
  abstract interface  
    real(default) function vegas_func_evaluate (self, x) result (f)  
      import :: default, vegas_func_t  
      class(vegas_func_t), intent(inout) :: self  
      real(default), dimension(:), intent(in) :: x  
    end function vegas_func_evaluate  
  end interface
```

20.3 Type: vegas_config_t

We store the complete configuration in a transparent container. The `vegas_config_t` object inside VEGAS must not be directly accesible. We provide a `get` method which returns a copy of the `vegas_config_t` object.

Apart from the options which can be set by the constructor of `vegas_t` object, we store the run-time configuration `n_calls`, `calls_per_box`, `n_bins` and `n_boxes`. Those are calculated and set accordingly by VEGAS.

```
<vegas: public>+≡  
  public :: vegas_config_t
```

```

<vegas: types>+≡
  type :: vegas_config_t
    integer :: n_dim = 0
    real(default) :: alpha = 1.5
    integer :: n_bins_max = 50
    integer :: iterations = 5
    integer :: mode = VEGAS_MODE_STRATIFIED
    integer :: calls_per_box = 0
    integer :: n_calls = 0
    integer :: n_calls_min = 20
    integer :: n_boxes = 1
    integer :: n_bins = 1
  contains
    <vegas: vegas config: TBP>
  end type vegas_config_t

```

Write out the configuration of the grid.

```

<vegas: vegas config: TBP>≡
  procedure, public :: write => vegas_config_write

<vegas: procedures>≡
  subroutine vegas_config_write (self, unit, indent)
    class(vegas_config_t), intent(in) :: self
    integer, intent(in), optional :: unit
    integer, intent(in), optional :: indent
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(2x,A,I0)") &
      & "Number of dimensions" = ", self%n_dim
    call write_indent (u, ind)
    write (u, "(2x,A," // FMT_17 // ")") &
      & "Adaption power (alpha)" = ", self%alpha
    call write_indent (u, ind)
    write (u, "(2x,A,I0)") &
      & "Max. number of bins (per dim.)" = ", self%n_bins_max
    call write_indent (u, ind)
    write (u, "(2x,A,I0)") &
      & "Number of iterations" = ", self%iterations
    call write_indent (u, ind)
    write (u, "(2x,A,I0)") &
      & "Mode (stratified or importance)" = ", self%mode
    call write_indent (u, ind)

      & "Calls per box" = ", self%calls_per_box
    call write_indent (u, ind)
    write (u, "(2x,A,I0)") &
      & "Number of calls" = ", self%n_calls
    call write_indent (u, ind)
    write (u, "(2x,A,I0)") &
      & "Min. number of calls" = ", self%n_calls_min
    call write_indent (u, ind)
    write (u, "(2x,A,I0)") &

```

```

        & "Number of bins" = ", self%n_bins
    call write_indent (u, ind)
    write (u, "(2x,A,I0)" &
        & "Number of boxes" = ", self%n_boxes
end subroutine vegas_config_write

```

20.4 Type: vegas_grid_t

We provide a simple and transparent grid container. The container can then later be used, to export the actual grid.

```

<vegas: public>+≡
    public :: vegas_grid_t

<vegas: types>+≡
    type :: vegas_grid_t
        integer :: n_dim = 1
        integer :: n_bins = 1
        real(default), dimension(:), allocatable :: x_lower
        real(default), dimension(:), allocatable :: x_upper
        real(default), dimension(:), allocatable :: delta_x

Resize each bin accordingly to its corresponding weight *w*. Can be used to resize the grid to a new size of bins or refinement.

The procedure expects two arguments, firstly, `n_bins` and, secondly, the refinement weights `w`. If `n_bins` differs from the internally stored one, we resize the grid under consideration of `w`. If each element of `w` equals one, then the bins are resized preserving their original bin density.

Anytime else, we refine the grid accordingly to `w`.

Find the probability for a given `x` in the unit hypercube.

For the case `n_bins < N_BINARY_SEARCH`, we utilize linear search which is faster for short arrays. Else we make use of a binary search. Furthermore, we

calculate the inverse of the probability and invert the result only at the end (saving some time on division).

Broadcast the grid information. As safety measure, we get the actual grid object from VEGAS (correctly allocated, but for non-root unfilled) and broadcast the root object. On success, we set grid into VEGAS.

We use the non-blocking broadcast routine, because we have to send quite a bunch of integers and reals.

We have to be very careful with `n_bins`, the number of bins can actually change during different iterations. If we reuse a grid, we have to take that, every grid uses the same `n_bins`. We expect, that the number of dimension does not change, which is in principle possible, but will be checked onto in `vegas_set_grid`.

```

20.5 Type: vegas_result_t

We store the result of the latest iteration(s) in a transparent container. The `vegas_result_t` object inside VEGAS must not be directly accessible. We export the a copy of the result via a get-method of the `vegas_t` object.

We store latest event weight in `evt_weight` and a (possible) event weight excess in `evt_weight_excess`, if the event weight is larger than `max_abs_f`.

20.7 Get-/Set-methods

The VEGAS object prohibits direct access from outside. Communication is handle via get- or set-methods. Set the limits of integration. The defaults limits correspong the n -dimensionl unit hypercube.

Remark: After setting the limits, the grid is initialised, again. Previous results are lost due to recalculation of the overall jacobian.

```

<vegas: vegas: TBP>+≡
  procedure, public :: set_limits => vegas_set_limits

```

```

<vegas: procedures>+≡
subroutine vegas_set_limits (self, x_lower, x_upper)
class(vegas_t), intent(inout) :: self
real(default), dimension(:), intent(in) :: x_lower
real(default), dimension(:), intent(in) :: x_upper
if (size (x_lower) /= self%config%n_dim &
    & .or. size (x_upper) /= self%config%n_dim) then

20.8 Grid resize- and refinement

Before integration the grid itself must be initialised. Given the number of `n.calls` and `n.dim` we prepare the grid for the integration.

The grid is binned according to the VEGAS mode and `n.calls`. If the mode is not set to `vegas.importance_only`, the grid is divided in to equal boxes. We try for 2 calls per box

$$boxes = \sqrt[n_{dim}]{\frac{calls}{2}}. \quad (20.1)$$

If the numbers of boxes exceeds the number of bins, which is the case for low dimensions, the algorithm switches to stratified sampling. Otherwise, we are still using importance sampling, but keep the boxes for book keeping. If the number of bins changes from the previous invocation, bins are expanded or contracted accordingly, while preserving bin density.

```

<vegas: vegas: TBP>+≡
  procedure, private :: init_grid => vegas_init_grid
<vegas: procedures>+≡
subroutine vegas_init_grid (self)
  class(vegas_t), intent(inout) :: self
  integer :: n_bins, n_boxes, box_per_bin, n_total_boxes
  real(default), dimension(:, :), allocatable :: w
  n_bins = self%config%n_bins_max
  n_boxes = 1
  if (self%config%mode /= VEGAS_MODE_IMPORTANCE_ONLY) then
    ! We try for 2 calls per box
    n_boxes = max (floor ((self%config%n_calls / 2.)*(1. / self%config%n_dim)), 1)
    self%config%mode = VEGAS_MODE_IMPORTANCE
    if (2 * n_boxes >= self%config%n_bins_max) then
      ! if n_bins/box < 2
      box_per_bin = max (n_boxes / self%config%n_bins_max, 1)
      n_bins = min (n_boxes / box_per_bin, self%config%n_bins_max)
    end if
  end if
end subroutine vegas_init_grid

```

```

        n_boxes = box_per_bin * n_bins
        self%config%mode = VEGAS_MODE_STRATIFIED
    end if
end if
n_total_boxes = n_boxes**self%config%n_dim
self%config%calls_per_box = max (floor (real (self%config%n_calls) / n_total_boxes), 2)
self%config%n_calls = self%config%calls_per_box * n_total_boxes
! Total volume of x-space/(average n_calls per bin)

        self%grid%xi(2, :) = 1._default
    end subroutine vegas_reset_grid

```

```

    call self%reset_result ()
end subroutine vegas_reset_grid

```

Refine the grid to match the distribution *d*.

Average the distribution over neighbouring bins, then contract or expand the bins. The averaging dampens high fluctuations among the integrand or the variance.

We make the type-bound procedure public accessible because the multi-channel integration refines each grid after integration over all grids.

```

<vegas: vegas: TBP>+≡
  procedure, public :: refine => vegas_refine_grid

<vegas: procedures>+≡
  subroutine vegas_refine_grid (self)
    class(vegas_t), intent(inout) :: self
    integer :: j
    real(default), dimension(self%config%n_bins, self%config%n_dim) :: w
    ndim: do j = 1, self%config%n_dim
      call average_distribution (self%config%n_bins, self%d(:,self%config%
        &n_bins, j), self%config%alpha, w(:, j))
    end do ndim
    call self%grid%resize (self%config%n_bins, w)
contains
  <vegas: vegas refine grid: procedures>
end subroutine vegas_refine_grid

```

We average the collected values *d* of the (sq.) weighted *f* over neighbouring bins. The averaged *d* are then again damped by a logarithm to enhance numerical stability. The results are then the refinement weights *w*.

We have to take care of the special case where we have a very low sampling rate. In those cases we can not be sure that the distribution is satisfying filled, although we have already averaged over neighbouring bins. This will lead to a squashing of the unfilled bins and such the boundaries of those will be pushed together. We circumvent this problem by setting those unfilled bins to the smallest representable value of a default real.

The problem becomes very annoying in the multi-channel formulae where have to look up via binary search the corresponding probability of *x* and if the width is zero, the point will be neglected.

```

<vegas: vegas refine grid: procedures>≡
  subroutine average_distribution (n_bins, d, alpha, w)
    integer, intent(in) :: n_bins
    real(default), dimension(:), intent(inout) :: d
    real(default), intent(in) :: alpha
    real(default), dimension(n_bins), intent(out) :: w
    if (n_bins > 2) then
      d(1) = (d(1) + d(2)) / 2.0_default
      d(2:n_bins - 1) = (d(1:n_bins - 2) + d(2:n_bins - 1) + d(3:n_bins)) / &
        & 3.0_default
      d(n_bins) = d(n_bins - 1) + d(n_bins) / 2.0_default
    end if

where (d < tiny (1.0_default))
  d = tiny (1.0_default)
end where
where (d /= 1.0_default)
  w = ((d - 1.) / log(d))**alpha
elsewhere
  ! Analytic limes for d -> 1
  w = 1.0_default
end where
end if
end subroutine average_distribution

```

20.9 Integration

Integrate `func`, in the previous set bounds `x.lower` to `x.upper`, with `n.calls`. Use results from previous invocations of `integrate` with `opt.reset.result = .false.` and better with subsequent calls.

Before we walk through the hybercube, we initialise the grid (at a central position).

We step through the (equidistant) boxes which ensure we do not miss any place in the n -dim. hypercube. In each box we sample `calls_per_box` random points and transform them to bin coordinates. The total integral and the total (sample) variance over each box i is then calculated by

$$E(I)_i = \sum_j^{\text{calls per box}} I_{i,j},$$

$$V(I)_i = \text{calls per box} \frac{\sum_j^{\text{calls per box}} I_{i,j}^2}{I} - \left(\sum_j^{\text{calls per box}} I_{i,j} \right) * 2 \frac{\text{calls per box}}{\text{calls per box} - 1}.$$

The stratification of the n -dimensional hypercube allows a simple parallelisation of the algorithm (R. Kreckel, "Parallelization of adaptive MC integrators", Computer Physics Communications, vol. 106, no. 3, pp. 258266, Nov. 1997.). We have to ensure that all boxes are sampled, but the number of boxes to distribute is too large. We allow each thread to sample a fraction r of all boxes k such that $r \ll k$. Furthermore, we constrain that the number of process p is much smaller than r .

The overall constraint is

$$p \ll r \ll k. \quad (20.2)$$

We divide the integration into a parallel and a perpendicular subspace. The number of parallel dimensions is $D_{\parallel} = \lfloor \frac{D}{2} \rfloor$.

    box(j) = 1
end do
success = .false.
end subroutine increment_box_coord

```

We parallelize VEGAS in simple forward manner. The hyper-cube is dissambled in to equidistant boxes in which we sample the integrand `calls_per_box` times. The workload of calculating those boxes is distributed along the worker.

The number of dimensions which will be parallelised are $\lfloor \frac{D}{2} \rfloor$, such MPI Variables for `vegas_integrate`. We have to duplicate all buffers for `MPI_Ireduce`, because we cannot use the same send or receive buffer.

We temporarily store a (empty) grid, before communicating.

```

(MPI: vegas: vegas integrate: variables)≡
integer :: rank
type(vegas_grid_t) :: grid

```

MPI procedure-specific initialization.

```

(MPI: vegas: vegas integrate: initialization)≡
call MPI_Comm_size (MPI_COMM_WORLD, n_size)
call MPI_Comm_rank (MPI_COMM_WORLD, rank)

```

Pre-sampling communication.

We make a copy of the (actual) grid, which is unfilled when non-root. The actual grid is then broadcasted among the workers and inserted into the `VEGAS` object.

```

(MPI: vegas: vegas integrate: pre sampling)≡
if (self%is_parallelizable ()) then
    grid = self%get_grid ()
    call grid%broadcast ()
    call self%set_grid (grid)
end if

```

Start index of the boxes for different ranks. If the random number generator is `RngStream`, we can advance the current stream in such a way, that we will getting matching numbers. Iff `n_boxes` is larger than 2, otherwise parallelization is useless.

```

```

Generate random event. We accept on the rate

$$\frac{|f(x)|}{\max_x |f(x)|}. \quad (20.5)$$

We keep separate maximum weights for positive and negative weights, and use them, accordingly. In the case of unweighted event generation, if the current weight exceeds the the maximum weight, we update the maximum, accordingly.

API: driver for the unit tests below.
<vegas: public test>≡
  public :: vegas_test

<vegas: test driver>≡
  subroutine vegas_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <vegas: execute tests>
  end subroutine vegas_test

```

Test function

We use the example from the Monte Carlo Examples of the GSL library

$$I = \int_{-pi}^{+pi} dk_x / (2pi) \int_{-pi}^{+pi} dk_y / (2pi) \int_{-pi}^{+pi} dk_z / (2pi) 1 / (1 - \cos(k_x) \cos(k_y) \cos(k_z)). \quad (20.6)$$

The integral is reduced to region $(0,0,0) \rightarrow (\pi, \pi, \pi)$ and multiplied by 8.

```

<vegas: test types>≡
  type, extends (vegas_func_t) :: vegas_test_func_t
  !
  contains
  <vegas: vegas test func: TBP>
end type vegas_test_func_t

```

Evaluate the integrand.

```

<vegas: vegas test func: TBP>≡
  procedure, public :: evaluate => vegas_test_func_evaluate

```

```

<vegas: tests>≡
  real(default) function vegas_test_func_evaluate (self, x) result (f)
    class(vegas_test_func_t), intent(inout) :: self
    real(default), dimension(:), intent(in) :: x
    f = 1.0 / (pi**3)
    f = f / ( 1.0 - cos (x(1)) * cos (x(2)) * cos (x(3)))
  end function vegas_test_func_evaluate

```

The second test function is the normalised n-dim. gaussian distribution.

```

<vegas: test types>+≡
  type, extends (vegas_func_t) :: vegas_gaussian_test_func_t
  !
  contains
  <vegas: vegas gaussian test func: TBP>
  end type vegas_gaussian_test_func_t

```

Evaluate the integrand.

```

<vegas: vegas gaussian test func: TBP>≡
  procedure, public :: evaluate => vegas_gaussian_evaluate

<vegas: tests>+≡
  real(default) function vegas_gaussian_evaluate (self, x) result (f)
    class(vegas_gaussian_test_func_t), intent(inout) :: self
    real(default), dimension(:), intent(in) :: x
    real(default), parameter :: inv_sqrt_pi = 1._default / sqrt(pi)
    f = inv_sqrt_pi**size (x)
    f = f * exp (- dot_product(x, x))
  end function vegas_gaussian_evaluate

```

The third test function is a three-dimensional polynomial function which factorises. The function is defined in such a way that the integral in the unit range is normalised to zero.

$$f(x) = -\frac{8}{3}(x+1)*(y-1)*z \quad (20.7)$$

```

<vegas: test types>+≡
  type, extends (vegas_func_t) :: vegas_polynomial_func_t
  !
  contains
  <vegas: vegas polynomial func: TBP>
  end type vegas_polynomial_func_t

<vegas: vegas polynomial func: TBP>≡
  procedure, public :: evaluate => vegas_polynomial_evaluate

<vegas: tests>+≡
  real(default) function vegas_polynomial_evaluate (self, x) result (f)
    class(vegas_polynomial_func_t), intent(inout) :: self
    real(default), dimension(:), intent(in) :: x
    f = - 8. / 3. * (x(1) + 1.) * (x(2) - 1.) * x(3)
  end function vegas_polynomial_evaluate

```

20.12.1 Type: `vamp2_func_t`

We extend `vegas_func_t` with the multi-channel weights and the `vegas_grid_t`, such that, the overall multi-channel weight can be calculated by the function itself.

We add an additional logical `valid_x`, if it is set to `.false.`, we do not compute weighted function and just set the weighted integrand to zero. This behavior is in particular very useful, if a mapping is prohibited or fails. Or in the case of WHIZARD, a phase cut is applied.

20.12.2 Type: `vamp2_config_t`

This is a transparent container which incorporates and extends the definitions in `vegas_config`. The parent object can then be used to parametrise the VEGAS grids directly, where the new parameters are exclusively used in the multi-channel implementation of VAMP2. `n_calls_min` is calculated by `n_calls_min_per_channel` and `n_channel`. The channels weights (and the result `n_calls` for each channel) are calculated regarding `n_calls_threshold`.

```

Integrate. We integrate each channel separately and combine the results

$$I = \sum_i \alpha_i I_i, \quad (20.10)$$

$$\sigma^2 = \sum_i \alpha_i^2 \sigma_i^2. \quad (20.11)$$

Although, the (population) variance is given by

$$\begin{aligned}
\sigma^2 &= \frac{1}{N} \left(\sum_i \alpha_i I_i^2 - I^2 \right) \\
&= \frac{1}{N-1} \left(\sum_i (N_i \sigma_i^2 + I_i^2) - I^2 \right) \\
&= \frac{1}{N-1} \left(\sum_i \alpha_i \sigma_i^2 + \alpha_i I_i^2 - I^2 \right),
\end{aligned} \tag{20.12}$$

where we used $\sigma_i^2 = \frac{1}{N} (\langle I_i^2 \rangle - \langle I_i \rangle^2)$, we use the approximation for numeric stability. The population variance relates to sample variance

$$s^2 = \frac{n}{n-1} \sigma^2, \tag{20.13}$$

which gives an unbiased error estimate.

Beside those adaption to multichannel, the overall processing of `total_integral`, `total_sq_integral` and `total_variance` is the same as in `vegas_integrate`.

<vamp2: vamp2 generate event: procedures>
end subroutine vamp2_generate_unweighted_event

```

Prepare event generation. We have to set the channel weights and the grids for the integrand's object.

We use an ansatz proposed by T. Ohl in the original VAMP code where we do not have to accept on

$$\frac{w_i(x)}{\max_{i,x} w_i(x)},$$

after we have selected a channel by the weights α_i . But rather, we use a more efficient way where we rescale the channel weights α_i

$$\alpha_i \rightarrow \alpha_i \frac{\max_x w_i(x)}{\max_{i,x} w_i(x)}.$$

The overall magic is to insert a "1" and to move the uneasy part into the channel selection, such that we can generate events likewise in the single channel mode. We generate an unweighted event by

$$\frac{w_i(x)}{\max_x w_i x},$$

after we have selected a channel by the rescaled event channel weights. The overall normalization $\max_{i,x}$ is not needed because we normalize the event channel weights to one and therefore the overall normalization cancels.

```

API: driver for the unit tests below.

```

<vamp2: public test>≡
  public :: vamp2_test

<vamp2: test driver>≡
  subroutine vamp2_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <vamp2: execute tests>
  end subroutine vamp2_test

```

Test function

We use the example from the Monte Carlo Examples of the GSL library

$$I = \int_{-pi}^{+pi} dk_x / (2pi) \int_{-pi}^{+pi} dk_y / (2pi) \int_{-pi}^{+pi} dk_z / (2pi) 1 / (1 - \cos(k_x) \cos(k_y) \cos(k_z)). \quad (20.14)$$

The integral is reduced to region $(0,0,0) \rightarrow (\pi, \pi, \pi)$ and multiplied by 8.

```

<vamp2: test types>≡
    type, extends (vamp2_func_t) :: vamp2_test_func_t
    !
    contains
    <vamp2: vamp2 test func: TBP>
end type vamp2_test_func_t

<vamp2: vamp2 test func: TBP>≡
    procedure, public :: evaluate_maps => vamp2_test_func_evaluate_maps

<vamp2: tests>≡
    subroutine vamp2_test_func_evaluate_maps (self, x)
        class(vamp2_test_func_t), intent(inout) :: self
        real(default), dimension(:), intent(in) :: x
        self%xi(:, 1) = x
        self%det(1) = 1
        self%valid_x = .true.
    end subroutine vamp2_test_func_evaluate_maps

```

Evaluate the integrand.

```

<vamp2: vamp2 test func: TBP>+≡
    procedure, public :: evaluate_func => vamp2_test_func_evaluate

<vamp2: tests>+≡
    real(default) function vamp2_test_func_evaluate (self, x) result (f)
        class(vamp2_test_func_t), intent(in) :: self
        real(default), dimension(:), intent(in) :: x

Chapter 21

Multi-Channel Integration

The abstract representation of multi-channel Monte Carlo algorithms for integration and event generation.

Module `mci_base`: The abstract types and their methods. It provides a test integrator that is referenced in later unit tests.

iterations Container for defining integration call and pass settings.

integration_results This module handles results from integrating processes. It records passes and iterations, calculates statistical averages, and provides the user output of integration results.

These are the implementations:

Module `mci_midpoint`: A simple integrator that uses the midpoint rule to sample the integrand uniformly over the unit hypercube. There is only one integration channel, so this can be matched only to single-channel phase space.

Module `mci_vamp`: Interface for the VAMP package.

Figure 21.1: Module dependencies in `src/mci`.

21.1 Generic Integrator

This module provides a multi-channel integrator (MCI) base type, a corresponding configuration type, and methods for integration and event generation.

```
<mci_base.f90>≡  
  <File header>  
  
  module mci_base  
  
    use kinds  
    use io_units  
    use format_utils, only: pac_fmt  
    use format_defs, only: FMT_14, FMT_17  
    use diagnostics  
    use cputime  
    use phs_base  
    use rng_base  
  
    <Standard module head>  
  
    <MCI base: public>  
  
    <MCI base: types>  
  
    <MCI base: interfaces>  
  
    contains  
  
    <MCI base: procedures>  
  
  end module mci_base
```

21.1.1 MCI: integrator

The MCI object contains the methods for integration and event generation. For the actual work and data storage, it spawns an MCI instance object.

The base object contains the number of integration dimensions and the number of channels as configuration data. Further configuration data are stored in the concrete extensions.

The MCI sum contains all relevant information about the integrand. It can be used for comparing the current configuration against a previous one. If they match, we can skip an actual integration. (Implemented only for the VAMP version.)

There is a random-number generator (its state with associated methods) available as `rng`. It may or may not be used for integration. It will be used for event generation.

```
<MCI base: public>≡  
  public :: mci_t

        mci%n_dim, "dimensions"
    end if
    call msg_message (unit = unit)
  end subroutine mci_startup_message

```

Dump type-specific info to a logfile.

```

<MCI base: mci: TBP>+≡
  procedure(mci_write_log_entry), deferred :: write_log_entry

<MCI base: interfaces>≡
  abstract interface

```

```

subroutine mci_write_log_entry (mci, u)
  import
  class(mci_t), intent(in) :: mci
  integer, intent(in) :: u
end subroutine mci_write_log_entry
end interface

```

In order to avoid dependencies on definite MCI implementations, we introduce a MD5 sum calculator.

```

⟨MCI base: mci: TBP⟩+≡
  procedure(mci_compute_md5sum), deferred :: compute_md5sum
⟨MCI base: interfaces⟩+≡
  abstract interface
    subroutine mci_compute_md5sum (mci, pacify)
      import
      class(mci_t), intent(inout) :: mci
      logical, intent(in), optional :: pacify
    end subroutine mci_compute_md5sum
  end interface

```

Record the index of the MCI object within a process. For multi-component processes with more than one integrator, the integrator should know about its own index, so file names can be unique, etc. The default implementation does nothing, however.

```

⟨MCI base: mci: TBP⟩+≡
  procedure :: record_index => mci_record_index
⟨MCI base: procedures⟩+≡
  subroutine mci_record_index (mci, i_mci)
    class(mci_t), intent(inout) :: mci
    integer, intent(in) :: i_mci
  end subroutine mci_record_index

```

There is no Initializer for the abstract type, but a generic setter for the number of channels and dimensions. We make two aliases available, to be able to override it.

```

⟨MCI base: mci: TBP⟩+≡
  procedure :: set_dimensions => mci_set_dimensions
  procedure :: base_set_dimensions => mci_set_dimensions
⟨MCI base: procedures⟩+≡
  subroutine mci_set_dimensions (mci, n_dim, n_channel)
    class(mci_t), intent(inout) :: mci
    integer, intent(in) :: n_dim
    integer, intent(in) :: n_channel
    mci%n_dim = n_dim
    mci%n_channel = n_channel
  end subroutine mci_set_dimensions

```

Declare particular dimensions as flat. This information can be used to simplify integration. When generating events, the flat dimensions should be sampled with uniform and uncorrelated distribution. It depends on the integrator what to do with that information.

```

<MCI base: mci: TBP>+≡
  procedure (mci_declare_flat_dimensions), deferred :: declare_flat_dimensions

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_declare_flat_dimensions (mci, dim_flat)
      import
      class(mci_t), intent(inout) :: mci
      integer, dimension(:), intent(in) :: dim_flat
    end subroutine mci_declare_flat_dimensions
  end interface

```

Declare particular channels as equivalent, possibly allowing for permutations or reflections of dimensions. We use the information stored in the `phs_channel_t` object array that the phase-space module provides.

(We do not test this here, deferring the unit test to the `mci_vamp` implementation where we actually use this feature.)

```

<MCI base: mci: TBP>+≡
  procedure (mci_declare_equivalences), deferred :: declare_equivalences

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_declare_equivalences (mci, channel, dim_offset)
      import
      class(mci_t), intent(inout) :: mci
      type(phs_channel_t), dimension(:), intent(in) :: channel
      integer, intent(in) :: dim_offset
    end subroutine mci_declare_equivalences
  end interface

```

Declare particular channels as chained together. The implementation may use this array for keeping their weights equal to each other, etc.

The chain array is an array sized by the number of channels. For each channel, there is an integer entry that indicates the corresponding chains. The total number of chains is the maximum value of this entry.

```

<MCI base: mci: TBP>+≡
  procedure :: declare_chains => mci_declare_chains

<MCI base: procedures>+≡
  subroutine mci_declare_chains (mci, chain)
    class(mci_t), intent(inout) :: mci
    integer, dimension(:), intent(in) :: chain
    allocate (mci%chain (size (chain)))
    mci%n_chain = maxval (chain)
    allocate (mci%chain_weights (mci%n_chain), source = 0._default)
    mci%chain = chain
  end subroutine mci_declare_chains

```

Collect channel weights according to chains and store them in the `chain_weights` for output. We sum up the weights for all channels that share the same `chain` index and store the results in the `chain_weights` array.

```

(MCI base: mci: TBP)+≡
  procedure :: collect_chain_weights => mci_collect_chain_weights

(MCI base: procedures)+≡
  subroutine mci_collect_chain_weights (mci, weight)
    class(mci_t), intent(inout) :: mci
    real(default), dimension(:), intent(in) :: weight
    integer :: i, c

    real(default), dimension(:,:), allocatable :: x_out
    real(default) :: val
    integer :: i, c
    allocate (x_in (mci%n_dim))
    allocate (f (mci%n_channel))
    allocate (x_out (mci%n_dim, mci%n_channel))
    do i = 1, n_calls
      c = mod (i, mci%n_channel) + 1
      call mci%rng%generate_array (x_in)
      call sampler%evaluate (c, x_in, val, x_out, f)
    end do
  end subroutine mci_sampler_test

```

Integrate: this depends on the implementation. We foresee a pacify flag to take care of small numerical noise on different platforms.

```

<MCI base: mci: TBP>+≡
  procedure (mci_integrate), deferred :: integrate

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_integrate (mci, instance, sampler, &
      n_it, n_calls, results, pacify)
    import
    class(mci_t), intent(inout) :: mci
    class(mci_instance_t), intent(inout), target :: instance
    class(mci_sampler_t), intent(inout), target :: sampler
    integer, intent(in) :: n_it
    integer, intent(in) :: n_calls
    logical, intent(in), optional :: pacify
    class(mci_results_t), intent(inout), optional :: results
  end subroutine mci_integrate
end interface

```

Event generation. Depending on the implementation, event generation may or may not require a previous integration pass.

Instead of a black-box `simulate` method, we require an initializer, a finalizer, and procedures for generating a single event. This allows us to interface simulation event by event from the outside, and it facilitates the further processing of an event after successful generation. For integration, this is not necessary.

The initializer has `intent(inout)` for the `mci` passed object. The reason is that the initializer can read integration results and grids from file, where the results can modify the `mci` record.

```

<MCI base: mci: TBP>+≡
  procedure (mci_prepare_simulation), deferred :: prepare_simulation

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_prepare_simulation (mci)
    import
    class(mci_t), intent(inout) :: mci
  end subroutine mci_prepare_simulation
end interface

```

The generated event will reside in in the `instance` object (overall results and weight) and in the `sampler` object (detailed data). In the real application, we can subsequently call methods of the `sampler` in order to further process the generated event.

The `target` attributes are required by the VAMP implementation, which uses pointers to refer to the instance and sampler objects from within the integration function.

```

<MCI base: mci: TBP>+≡
  procedure (mci_generate), deferred :: generate_weighted_event
  procedure (mci_generate), deferred :: generate_unweighted_event

```

```

<MCI base: interfaces>+≡

        real(default) :: value
        if (mci%valid) then
            value = mci%integrand * mci%mci_weight
        else
            value = 0
        end if
    end function mci_instance_get_value

```

This is an extra routine. By default, the event weight is equal to the value returned by the previous routine. However, if we select a channel for event generation not just based on the channel weights, the event weight has to account for this bias, so the event weight that applies to event generation is different. In that case, we should override the default routine.

```

⟨MCI base: mci instance: TBP⟩+≡
    procedure :: get_event_weight => mci_instance_get_value

```

Excess weight can occur during unweighted event generation, if the assumed maximum value of the integrand is too small. This excess should be normalized in the same way as the event weight above (which for unweighted events becomes unity).

```

<MCI base: mci_instance: TBP>+≡
  procedure (mci_instance_get_event_excess), deferred :: get_event_excess

<MCI base: interfaces>+≡
  abstract interface
    function mci_instance_get_event_excess (mci) result (excess)
      import
      class(mci_instance_t), intent(in) :: mci
      real(default) :: excess
    end function mci_instance_get_event_excess
  end interface

```

Dropped events (i.e., events with zero weight that are not retained) are counted within the `mci_instance` object.

```

<MCI base: mci_instance: TBP>+≡
  procedure :: get_n_event_dropped => mci_instance_get_n_event_dropped
  procedure :: reset_n_event_dropped => mci_instance_reset_n_event_dropped
  procedure :: record_event_dropped => mci_instance_record_event_dropped

<MCI base: procedures>+≡
  function mci_instance_get_n_event_dropped (mci) result (n_dropped)
    class(mci_instance_t), intent(in) :: mci

    n_dropped = mci%n_dropped
  end function mci_instance_get_n_event_dropped

  subroutine mci_instance_reset_n_event_dropped (mci)
    class(mci_instance_t), intent(inout) :: mci
    mci%n_dropped = 0
  end subroutine mci_instance_reset_n_event_dropped

  subroutine mci_instance_record_event_dropped (mci)
    class(mci_instance_t), intent(inout) :: mci
    mci%n_dropped = mci%n_dropped + 1
  end subroutine mci_instance_record_event_dropped

```

21.1.3 MCI state

This object can hold the relevant information that allows us to reconstruct the MCI instance without re-evaluating the sampler completely.

We store the `x_in` MC input parameter set, which coincides with the section of the complete `x` array that belongs to a particular channel. We also store the MC function value. When we want to reconstruct the state, we can use the input array to recover the complete `x` and `f` arrays (i.e., the kinematics), but do not need to recompute the MC function value (the dynamics).

The `mci_state_t` may be extended, to allow storing/recalling more information. In that case, we would override the type-bound procedures. However, the

base type is also a concrete type and self-contained.

```

<MCI base: public>+≡
    public :: mci_state_t

<MCI base: types>+≡
    type :: mci_state_t
        integer :: selected_channel = 0
        real(default), dimension(:), allocatable :: x_in
        real(default) :: val
    contains
        <MCI base: mci state: TBP>
    end type mci_state_t

```

Output:

```

<MCI base: mci state: TBP>≡
    procedure :: write => mci_state_write

<MCI base: procedures>+≡
    subroutine mci_state_write (object, unit)
        class(mci_state_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)
        write (u, "(1x,A)") "MCI state:"
        write (u, "(3x,A,I0)") "Channel   = ", object%selected_channel
        write (u, "(3x,A,999(1x,F12.10))") "x (in)   =", object%x_in
        write (u, "(3x,A,ES19.12)") "Integrand = ", object%val
    end subroutine mci_state_write

```

To store the object, we take the relevant section of the **x** array. The channel used for storing data is taken from the **instance** object, but it could be arbitrary in principle.

```

<MCI base: mci instance: TBP>+≡
    procedure :: store => mci_instance_store

<MCI base: procedures>+≡
    subroutine mci_instance_store (mci, state)
        class(mci_instance_t), intent(in) :: mci
        class(mci_state_t), intent(out) :: state
        state%selected_channel = mci%selected_channel
        allocate (state%x_in (size (mci%x, 1)))
        state%x_in = mci%x(:,mci%selected_channel)
        state%val = mci%integrand
    end subroutine mci_instance_store

```

Recalling the state, we must consult the sampler in order to fully reconstruct the **x** and **f** arrays. The integrand value is known, and we also give it to the sampler, bypassing evaluation.

The final steps are equivalent to the **evaluate** method above.

```

<MCI base: mci instance: TBP>+≡
    procedure :: recall => mci_instance_recall

```

```

<MCI base: procedures>+≡
subroutine mci_instance_recall (mci, sampler, state)
  class(mci_instance_t), intent(inout) :: mci
  class(mci_sampler_t), intent(inout) :: sampler
  class(mci_state_t), intent(in) :: state
  if (size (state%x_in) == size (mci%x, 1) &
      .and. state%selected_channel <= size (mci%x, 2)) then
    call sampler%rebuild (state%selected_channel, &
        state%x_in, state%val, mci%x, mci%f)
    call mci%compute_weight (state%selected_channel)
    call mci%record_integrand (state%val)
  else
    call msg_fatal ("Recalling event: mismatch in channel or dimension")
  end if
end subroutine mci_instance_recall

```

21.1.4 MCI sampler

A sampler is an object that implements a multi-channel parameterization of the unit hypercube. Specifically, it is able to compute, given a channel and a set of x MC parameter values, a the complete set of x values and associated Jacobian factors f for all channels.

Furthermore, the sampler should return a single real value, the integrand, for the given point in the hypercube.

It must implement a method `evaluate` for performing the above computations.

```

<MCI base: public>+≡
public :: mci_sampler_t

<MCI base: types>+≡
type, abstract :: mci_sampler_t
contains
  <MCI base: mci sampler: TBP>
end type mci_sampler_t

```

Output, deferred to the implementation.

```

<MCI base: mci sampler: TBP>≡
procedure (mci_sampler_write), deferred :: write

<MCI base: interfaces>+≡
abstract interface
  subroutine mci_sampler_write (object, unit, testflag)
    import
    class(mci_sampler_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
  end subroutine mci_sampler_write
end interface

```

The evaluation routine. Input is the channel index `c` and the one-dimensional parameter array `x_in`. Output are the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

```

(MCI base: mci_sampler: TBP)+≡
  procedure (mci_sampler_evaluate), deferred :: evaluate

(MCI base: interfaces)+≡

      real(default), dimension(:), intent(in) :: x_in
      real(default), intent(out) :: val
      real(default), dimension(:, :), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_evaluate
  end interface

```

Query the validity of the sampling point. Can be called after `evaluate`.

```

(MCI base: mci_sampler: TBP)+≡
  procedure (mci_sampler_is_valid), deferred :: is_valid

(MCI base: interfaces)+≡
  abstract interface
    function mci_sampler_is_valid (sampler) result (valid)
      import
      class(mci_sampler_t), intent(in) :: sampler
      logical :: valid
    end function mci_sampler_is_valid
  end interface

```

The shortcut. Again, the channel index `c` and the parameter array `x_in` are input. However, we also provide the integrand value `val`, and we just require that the complete parameter array `x` and Jacobian array `f` are recovered.

```

(MCI base: mci_sampler: TBP)+≡
  procedure (mci_sampler_rebuild), deferred :: rebuild

(MCI base: interfaces)+≡
  abstract interface
    subroutine mci_sampler_rebuild (sampler, c, x_in, val, x, f)
      import
      class(mci_sampler_t), intent(inout) :: sampler
      integer, intent(in) :: c
      real(default), dimension(:), intent(in) :: x_in
      real(default), intent(in) :: val
      real(default), dimension(:, :), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_rebuild
  end interface

```

This routine should extract the important data from a sampler that has been filled by other means. We fetch the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

```

<MCI base: mci_sampler: TBP>+≡
  procedure (mci_sampler_fetch), deferred :: fetch

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_sampler_fetch (sampler, val, x, f)
      import
      class(mci_sampler_t), intent(in) :: sampler
      real(default), intent(out) :: val
      real(default), dimension(:,:), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_fetch
  end interface

```

21.1.5 Results record

This is an abstract type which allows us to implement callback: each integration results can optionally be recorded to an instance of this object. The actual object may store a new result, average results, etc. It may also display a result on-line or otherwise, whenever the `record` method is called.

```

<MCI base: public>+≡
  public :: mci_results_t

<MCI base: types>+≡
  type, abstract :: mci_results_t
  contains
    <MCI base: mci_results: TBP>
  end type mci_results_t

```

The output routine is deferred. We provide an extra `verbose` flag, which could serve any purpose.

```

<MCI base: mci_results: TBP>≡
  procedure (mci_results_write), deferred :: write
  procedure (mci_results_write_verbose), deferred :: write_verbose

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_results_write (object, unit, suppress)
      import
      class(mci_results_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: suppress
    end subroutine mci_results_write

    subroutine mci_results_write_verbose (object, unit)
      import
      class(mci_results_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine mci_results_write_verbose

```

```
end interface
```

This is the generic `record` method, which can be called directly from the integrator. The `record_extended` procedure store additionally the valid calls, positive and negative efficiency.

```
<MCI base: mci results: TBP>+=
  generic :: record => record_simple, record_extended

Test implementation of the configuration type

The concrete type contains the number of requested calls and the integral result, to be determined.

The `max_factor` entry is set for the actual test integration, where the integrand is not unity but some other constant value. This value should be set here, such that the actual maximum of the integrand is known when vetoing unweighted events.

    class(mci_state_t), intent(in) :: state
    select type (instance)
    type is (mci_test_instance_t)
        call instance%recall (sampler, state)
    end select
end subroutine mci_test_rebuild_event

```

Instance of the test MCI type

This instance type simulates the VAMP approach. We implement the VAMP multi-channel formula, but keep the channel-specific probability functions g_i

smooth and fixed. We also keep the weights fixed.

The setup is as follows: we have n mappings of the unit hypercube

$$x = x(x^{(k)}) \quad \text{where } x = (x_1, \dots). \quad (21.1)$$

The Jacobian factors are the determinants

$$f^{(k)}(x^{(k)}) = \left| \frac{\partial x}{\partial x^{(k)}} \right| \quad (21.2)$$

We introduce arbitrary probability functions

$$g^{(k)}(x^{(k)}) \quad \text{with} \quad \int dx^{(k)} g^{(k)}(x^{(k)}) = 1 \quad (21.3)$$

and weights

$$w_k \quad \text{with} \quad \sum_k w_k = 1 \quad (21.4)$$

and construct the joint probability function

$$g(x) = \sum_k w_k \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \quad (21.5)$$

which also satisfies

$$\int g(x) dx = 1. \quad (21.6)$$

The algorithm implements a resolution of unity as follows

$$\begin{aligned} 1 &= \int dx = \int \frac{g(x)}{g(x)} dx \\ &= \sum_k w_k \int \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \frac{dx}{g(x)} \\ &= \sum_k w_k \int g^{(k)}(x^{(k)}) \frac{dx^{(k)}}{g(x^{(k)})} \end{aligned} \quad (21.7)$$

where each of the integrals in the sum is evaluated using the channel-specific variables $x^{(k)}$.

We provide two examples: (1) trivial with one channel, one dimension, and all functions unity and (2) two channels and two dimensions with

$$\begin{aligned} x(x^{(1)}) &= (x_1^{(1)}, x_2^{(1)}) \\ x(x^{(2)}) &= (x_1^{(2)2}, x_2^{(2)}) \end{aligned} \quad (21.8)$$

hence

$$f^{(1)} \equiv 1, \quad f^{(2)}(x^{(2)}) = 2x_1^{(2)} \quad (21.9)$$

The probability functions are

$$g^{(1)} \equiv 1, \quad g^{(2)}(x^{(2)}) = 2x_2^{(2)} \quad (21.10)$$

In the concrete implementation of the integrator instance we store values for the channel probabilities g_i and the accumulated probability g .

We also store the result (product of integrand and MCI weight), the expected maximum for the result in each channel.

```

Return always zero.

```

<MCI base: tests>+≡
  function mci_test_instance_get_event_excess (mci) result (excess)
    class(mci_test_instance_t), intent(in) :: mci
    real(default) :: excess
    excess = 0
  end function mci_test_instance_get_event_excess

```

Test sampler

The test sampler implements a fixed configuration, either trivial (one-channel, one-dimension), or slightly nontrivial (two-channel, two-dimension). In the second channel, the first parameter is mapped according to $x_1 = x_1^{(2)2}$, so we have $f^{(2)}(x^{(2)}) = 2x_1^{(2)}$.

For display purposes, we store the return values inside the object. This is not strictly necessary.

```

```

21.2 Iterations

This module defines a container for the list of iterations and calls, to be submitted to integration.

`<iterations.f90>`≡
<File header>

`module iterations`

<Use kinds>

<Use strings>

`use io_units`

`use diagnostics`

<Standard module head>

<Iterations: public>

<Iterations: types>

```
contains

<Iterations: procedures>

end module iterations
```

21.2.1 The iterations list

Each integration pass has a number of iterations and a number of calls per iteration. The last pass produces the end result; the previous passes are used for adaptation.

The flags `adapt_grid` and `adapt_weight` are used only if `custom_adaptation` is set. Otherwise, default settings are used that depend on the integration pass.

```
<Iterations: types>≡
  type :: iterations_spec_t
  private
    integer :: n_it = 0
    integer :: n_calls = 0
    logical :: custom_adaptation = .false.
    logical :: adapt_grids = .false.
    logical :: adapt_weights = .false.
  end type iterations_spec_t
```

We build up a list of iterations.

```
<Iterations: public>≡
  public :: iterations_list_t

<Iterations: types>+≡
  type :: iterations_list_t
  private
    integer :: n_pass = 0
    type(iterations_spec_t), dimension(:), allocatable :: pass
  contains
    <Iterations: iterations list: TBP>
  end type iterations_list_t
```

Initialize an iterations list. For each pass, we have to specify the number of iterations and calls. We may provide the adaption conventions explicitly, either as character codes or as logicals.

For passes where the adaptation conventions are not specified, we use the following default setting: adapt weights and grids for all passes except the last one.

```
<Iterations: iterations list: TBP>≡
  procedure :: init => iterations_list_init

<Iterations: procedures>≡
  subroutine iterations_list_init &
    (it_list, n_it, n_calls, adapt, adapt_code, adapt_grids, adapt_weights)
    class(iterations_list_t), intent(inout) :: it_list
    integer, dimension(:), intent(in) :: n_it, n_calls
    logical, dimension(:), intent(in), optional :: adapt
```

```

type(string_t), dimension(:), intent(in), optional :: adapt_code
logical, dimension(:), intent(in), optional :: adapt_grids, adapt_weights
integer :: i
it_list%n_pass = size (n_it)
if (allocated (it_list%pass)) deallocate (it_list%pass)
allocate (it_list%pass (it_list%n_pass))
it_list%pass%n_it = n_it
it_list%pass%n_calls = n_calls
if (present (adapt)) then
  it_list%pass%custom_adaptation = adapt
  do i = 1, it_list%n_pass
    if (adapt(i)) then
      if (verify (adapt_code(i), "wg") /= 0) then
        call msg_error ("iteration specification: " &
          // "adaptation code letters must be 'w' or 'g'")
      end if
      it_list%pass(i)%adapt_grids = scan (adapt_code(i), "g") /= 0
      it_list%pass(i)%adapt_weights = scan (adapt_code(i), "w") /= 0
    end if
  end do
else if (present (adapt_grids) .and. present (adapt_weights)) then
  it_list%pass%custom_adaptation = .true.
  it_list%pass%adapt_grids = adapt_grids
  it_list%pass%adapt_weights = adapt_weights
end if
do i = 1, it_list%n_pass - 1
  if (.not. it_list%pass(i)%custom_adaptation) then
    it_list%pass(i)%adapt_grids = .true.
    it_list%pass(i)%adapt_weights = .true.
  end if
end do
end subroutine iterations_list_init

```

<Iterations: iterations list: TBP>+≡

```

procedure :: clear => iterations_list_clear

```

<Iterations: procedures>+≡

```

subroutine iterations_list_clear (it_list)
  class(iterations_list_t), intent(inout) :: it_list
  it_list%n_pass = 0
  deallocate (it_list%pass)
end subroutine iterations_list_clear

```

Write the list of iterations.

<Iterations: iterations list: TBP>+≡

```

procedure :: write => iterations_list_write

```

<Iterations: procedures>+≡

```

subroutine iterations_list_write (it_list, unit)

    end subroutine iterations_2

```

21.3 Integration results

We record integration results and errors in a dedicated type. This allows us to do further statistics such as weighted average, chi-squared, grouping by integration

passes, etc.

Note WHIZARD 2.2.0: This code is taken from the previous `processes` module essentially unchanged and converted into a separate module. It lacks an overhaul and, in particular, self-tests.

```

<integration_results.f90>≡
  module integration_results

    <Use kinds>
    <Use strings>
    use io_units
    use format_utils, only: mp_format, pac_fmt
    use format_defs, only: FMT_10, FMT_14
    use diagnostics
    use md5
    use os_interface
    use mci_base

    <Standard module head>

    <Integration results: public>

    <Integration results: parameters>

    <Integration results: types>

    <Integration results: interfaces>

    contains

    <Integration results: procedures>

  end module integration_results

```

21.3.1 Integration results entry

This object collects the results of an integration pass and makes them available to the outside.

The results object has to distinguish the process type:

We store the process type, the index of the integration pass and the absolute iteration index, the number of iterations contained in this result (for averages), and the integral (cross section or partial width), error estimate, efficiency.

For intermediate results, we set a flag if this result is an improvement w.r.t. previous ones.

The process type indicates decay or scattering. Dummy entries (skipped iterations) have a process type of `PRC_UNKNOWN`.

The additional information `n_calls_valid`, `efficiency_pos` and `efficiency_neg` are stored, but only used in verbose mode.

```

<Integration results: public>≡
  public :: integration_entry_t

<Integration results: types>≡
  type :: integration_entry_t

```

```

private
integer :: process_type = PRC_UNKNOWN
integer :: pass = 0
integer :: it = 0
integer :: n_it = 0
integer :: n_calls = 0
integer :: n_calls_valid = 0
logical :: improved = .false.
real(default) :: integral = 0
real(default) :: error = 0
real(default) :: efficiency = 0
real(default) :: efficiency_pos = 0
real(default) :: efficiency_neg = 0
real(default) :: chi2 = 0
real(default), dimension(:), allocatable :: chain_weights
contains
<Integration results: integration entry: TBP>
end type integration_entry_t

```

The possible values of the type indicator:

```

<Integration results: parameters>≡
integer, parameter, public :: PRC_UNKNOWN = 0
integer, parameter, public :: PRC_DECAY = 1
integer, parameter, public :: PRC_SCATTERING = 2

```

Initialize with all relevant data.

```

<Integration results: interfaces>≡
interface integration_entry_t
module procedure integration_entry_init
end interface integration_entry_t

```

```

<Integration results: procedures>≡
type(integration_entry_t) function integration_entry_init (process_type, pass,&
& it, n_it, n_calls, n_calls_valid, improved, integral, error,&
& efficiency, efficiency_pos, efficiency_neg, chi2, chain_weights)&
& result (entry)
integer, intent(in) :: process_type, pass, it, n_it, n_calls, n_calls_valid
logical, intent(in) :: improved
real(default), intent(in) :: integral, error, efficiency, efficiency_pos, efficiency_neg

21.3.2 Combined integration results

We collect a list of results which grows during the execution of the program. This is implemented as an array which grows if necessary; so we can easily compute averages.

We implement this as an extension of the `mci_results_t` which is defined in `mci_base` as an abstract type. We thus decouple the implementation of the integrator from the implementation of the results display, but nevertheless can record intermediate results during integration. This implies that the present extension implements a `record` method.

```

<Integration results: public>+=
    public :: integration_results_t

```

```

<Integration results: types>+≡
  type, extends (mci_results_t) :: integration_results_t
    private
      integer :: process_type = PRC_UNKNOWN
      integer :: current_pass = 0
      integer :: n_pass = 0
      integer :: n_it = 0
      logical :: screen = .false.
      integer :: unit = 0
      integer :: verbosity = 0
      real(default) :: error_threshold = 0
      type(integration_entry_t), dimension(:), allocatable :: entry
      type(integration_entry_t), dimension(:), allocatable :: average
    contains
      <Integration results: integration results: TBP>
end type integration_results_t

```

The array is extended in chunks of 10 entries.

```

<Integration results: parameters>+≡
  integer, parameter :: RESULTS_CHUNK_SIZE = 10

```

The standard does not require to explicitly initialize the integers; however, some gfortran version has a bug here and misses the default initialization in the type definition.

```

<Integration results: integration results: TBP>≡
  procedure :: init => integration_results_init

<Integration results: procedures>+≡
  subroutine integration_results_init (results, process_type)
    class(integration_results_t), intent(out) :: results
    integer, intent(in) :: process_type
    results%process_type = process_type
    results%n_pass = 0
    results%n_it = 0
    allocate (results%entry (RESULTS_CHUNK_SIZE))
    allocate (results%average (RESULTS_CHUNK_SIZE))
  end subroutine integration_results_init

```

Set verbose output of the integration results. In verbose mode, valid calls, negative as positive efficiency will be printed.

```

<Integration results: integration results: TBP>+≡
  procedure :: set_verbosity => integration_results_set_verbosity

<Integration results: procedures>+≡
  subroutine integration_results_set_verbosity (results, verbosity)
    class(integration_results_t), intent(inout) :: results
    integer, intent(in) :: verbosity
    results%verbosity = verbosity
  end subroutine integration_results_set_verbosity

```

Set additional parameters: the `error_threshold` declares that any error value (in absolute numbers) smaller than this is to be considered zero.

```

<Integration results: integration results: TBP>+≡

```

```

    procedure :: set_error_threshold => integration_results_set_error_threshold
<Integration results: procedures>+≡
    subroutine integration_results_set_error_threshold (results, error_threshold)

```

During integration, we do not want to print all results at once, but each intermediate result as soon as we get it. Thus, the previous procedure is chopped in pieces. First piece: store the output unit and a flag whether we want to print to standard output as well. Then write the header if the results are still empty, i.e., before integration has started. The second piece writes a single result to the saved output channels. We call this from the `record` method, which can be called from the integrator directly. The third piece writes the average result, once a pass has been completed. The fourth piece writes a footer (if any), assuming that this is the final result.

```

Compute the average for all entries in the specified integration pass. The integrals are weighted w.r.t. their individual errors.

The quoted error of the result is the expected error, computed from the weighted average of the given individual errors.

This should be compared to the actual distribution of the results, from which we also can compute an error estimate if there is more than one iteration. The ratio of the distribution error and the averaged error, is the χ^2 value.

All error distributions are assumed Gaussian, of course. The χ^2 value is a partial check for this assumption. If it is significantly greater than unity, there is something wrong with the individual errors.

The efficiency returned is the one of the last entry in the integration pass.

If any error vanishes, averaging by this algorithm would fail. In this case, we simply average the entries and use the deviations from this average (if any) to estimate the error.

(Integration results: procedures)+≡

21.3.3 Access results

Return true if the results object has entries.

<Integration results: integration results: TBP>+≡

```
procedure :: exist => integration_results_exist
```

<Integration results: procedures>+≡

```

function integration_results_exist (results) result (flag)
  logical :: flag
  class(integration_results_t), intent(in) :: results
  flag = results%n_pass > 0
end function integration_results_exist

```

Retrieve information from the results record. If **last** is set and true, take the last iteration. If it is set instead, take this iteration. If **pass** is set, take this average. If none is set, take the final average.

If the result would be invalid, the entry is not assigned. Due to default initialization, this returns a null entry.

(Integration results: integration results: TBP)+≡

```

procedure :: get_entry => results_get_entry

  contains  
  
  <MCI none: procedures>  
  
end module mci_none
```

21.4.1 Integrator

The object contains the methods for integration and event generation. For the actual work and data storage, it spawns an instance object.

After an integration pass, we update the `max` parameter to indicate the maximum absolute value of the integrand that the integrator encountered. This is required for event generation.

```
<MCI none: public>≡  
  public :: mci_none_t

```

21.5 Simple midpoint integration

This is a most simple implementation of an integrator. The algorithm is the straightforward multi-dimensional midpoint rule, i.e., the integration hypercube is binned uniformly, the integrand is evaluated at the midpoints of each bin, and the result is the average. The binning is equivalent for all integration dimensions.

This rule is accurate to the order h^2 , where h is the bin width. Given that $h = N^{-1/d}$, where d is the integration dimension and N is the total number of sampling points, we get a relative error of order $N^{-2/d}$. This is superior to MC integration if $d < 4$, and equivalent if $d = 4$. It is not worse than higher-order formulas (such as Gauss integration) if the integrand is not smooth, e.g., if it contains cuts.

The integrator is specifically single-channel. However, we do not limit the dimension.

```
<mci_midpoint.f90>≡  
  <File header>  
  
  module mci_midpoint  
  
    <Use kinds>  
    use io_units  
    use diagnostics  
    use phs_base  
  
    use mci_base  
  
    <Standard module head>  
  
    <MCI midpoint: public>  
  
    <MCI midpoint: types>  
  
    contains  
  
    <MCI midpoint: procedures>  
  
  end module mci_midpoint
```

21.5.1 Integrator

The object contains the methods for integration and event generation. For the actual work and data storage, it spawns an instance object.

After an integration pass, we update the `max` parameter to indicate the maximum absolute value of the integrand that the integrator encountered. This is required for event generation.

```
<MCI midpoint: public>≡  
  public :: mci_midpoint_t

```

Integrate. The number of dimensions is arbitrary. We make sure that the number of calls is evenly distributed among the dimensions. The actual number of calls will typically be smaller than the requested number, but never smaller than 1.

The sampling over a variable number of dimensions implies a variable number of nested loops. We implement this by a recursive subroutine, one loop in each recursion level.

The number of iterations `n_it` is ignored. Also, the error is set to zero in the current implementation.

With this integrator, we allow the calculation to abort immediately when forced by a signal. There is no state that we can save, hence we do not catch an interrupt.

```

For unweighted events, we generate weighted events and apply a simple rejection step to the relative event weight, until an event passes.

Note that we use the `max_abs` value stored in the configuration record, not the one stored in the instance. The latter may change during event generation. After an event generation pass is over, we may update the value for a subsequent pass.

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

This is the function $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

Mimicking the behavior of a process object, we store the argument and result inside the sampler, so we can fetch results.

<MCI midpoint: test types>≡

21.6 VAMP interface

The standard method for integration is **VAMP**: the multi-channel version of the VEGAS algorithm. Each parameterization (channel) of the hypercube is binned in each dimension. The binning is equally equidistant, but an iteration of the integration procedure, the binning is updated for each dimension, according to the variance distribution of the integrand, summed over all other dimension. In the next iteration, the binning approximates (hopefully) follows the integrand more closely, and the accuracy of the result is increased. Furthermore, the relative weight of the individual channels is also updated after an iteration.

The bin distribution is denoted as the grid for a channel, which we can write to file and reuse later.

In our implementation we specify the generic **VAMP** algorithm more tightly: the number of bins is equal for all dimensions, the initial weights are all equal. The user controls whether to update bins and/or weights after each iteration. The integration is organized in passes, each one consisting of several iterations with a common number of calls to the integrand. The first passes are intended as warmup, so the results are displayed but otherwise discarded. In the final pass, the integration estimates for the individual iterations are averaged for the final result.

Integrate. Perform a new integration pass (possibly reusing previous results), which may consist of several iterations.

Note: we record the integral once per iteration. The integral stored in the `mci` record itself is the last integral of the current iteration, no averaging done. The `results` record may average results.

Note: recording the efficiency is not supported yet.

21.6.5 Sampler as Workspace

In the full setup, the sampling function requires the process instance object as workspace. We implement this by (i) implementing the process instance as a

type extension of the abstract `sampler_t` object used by the MCI implementation and (ii) providing such an object as an extra argument to the sampling function that VAMP can call. To minimize cross-package dependencies, we use an abstract type `vamp_workspace` that VAMP declares and extend this by including a pointer to the `sampler` and `instance` objects. In the body of the sampling function, we dereference this pointer and can then work with the contents.

```

(MCI vamp: types)+≡
  type, extends (vamp_data_t) :: mci_workspace_t
    class(mci_sampler_t), pointer :: sampler => null ()
    class(mci_vamp_instance_t), pointer :: instance => null ()
  end type mci_workspace_t

```

21.6.6 Integrator instance

The history entries should point to the corresponding history entry in the `pass_t` object. If there is none, we may allocate a local history, which is then just transient.

```

Prepare a new integration pass: write the pass-specific settings to the `instance` object. This should be called initially, together with the `create_grids` procedure, and whenever we start a new integration pass.

Set `reshape` if the number of calls is different than previously (unless it was zero, indicating the first pass).

We link VAMP histories to the allocated histories in the current pass object, so the recorded results are persistent. However, if there are no histories present there, we allocate them locally. In that case, the histories will disappear together with the MCI instance object.

```

Adapt weights. Use the variance array returned by VAMP for recalculating the weight array. The parameter `channel_weights_power` dampens fluctuations.

If the number of calls in a given channel falls below a user-defined threshold, the weight is not lowered further but kept at this threshold. The other channel weights are reduced accordingly.

```

```

Integration: sample the VAMP grids. The number of calls etc. are already stored inside the grids. We provide the random-number generator, the sampling function, and a link to the workspace object, which happens to contain a pointer to the sampler object. The sampler object thus becomes the workspace of the sampling function.

Note: in the current implementation, the random-number generator must be the TAO generator. This explicit dependence should be removed from the VAMP implementation.

    end subroutine mci_vamp_instance_final_simulation

```

21.6.7 Sampling function

The VAMP sampling function has a well-defined interface which we have to implement. The `data` argument allows us to pass pointers to the `sampler` and `instance` objects, so we can access configuration data and fill point-dependent contents within these objects.

The `weights` and `channel` argument must be present in the call.

Note: we would normally declare the `instance` pointer with the concrete type, or just use the `data` component directly. Unfortunately, gfortran 4.6 forgets the inherited base-type methods in that case.

Note: this is the place where we must look for external signals, i.e., interrupt from the OS. We would like to raise a VAMP exception which is then caught by `vamp_sample_grids` as the caller, so it dumps its current state and returns (with the signal still pending). WHIZARD will then terminate gracefully. Of course, VAMP should be able to resume from the dump.

In the current implementation, we handle the exception in place and terminate immediately. The incomplete current integration pass is lost.

```

<MCI vamp: procedures>+≡
    function vamp_sampling_function &
        (xi, data, weights, channel, grids) result (f)
        real(default) :: f
        real(default), dimension(:), intent(in) :: xi
        class(vamp_data_t), intent(in) :: data
        real(default), dimension(:), intent(in), optional :: weights
        integer, intent(in), optional :: channel

```

```

type(vamp_grid), dimension(:), intent(in), optional :: grids
type(exception) :: exc
logical :: verbose
character(*), parameter :: FN = "WHIZARD sampling function"
class(mci_instance_t), pointer :: instance
select type (data)
type is (mci_workspace_t)
    instance => data%instance
    select type (instance)
    class is (mci_vamp_instance_t)
        verbose = instance%mci%verbose
        call instance%evaluate (data%sampler, channel, xi)
        if (signal_is_pending ()) then
            call raise_exception (exc, EXC_FATAL, FN, "signal received")
            call handle_vamp_exception (exc, verbose)
            call terminate_now_if_signal ()
        end if
        instance%calls = instance%calls + 1
        if (data%sampler%is_valid ()) &
            & instance%calls_valid = instance%calls_valid + 1
        f = instance%get_value ()
        call terminate_now_if_single_event ()
    class default
        call msg_bug("VAMP: " // FN // ": unknown MCI instance type")
    end select
end select
end function vamp_sampling_function

```

This is supposed to be the mapping between integration channels. The VAMP event generating procedures technically require it, but it is meaningless in our setup where all transformations happen inside the sampler object. So, this implementation is trivial:

```

⟨MCI vamp: procedures⟩+≡
pure function phi_trivial (xi, channel_dummy) result (x)
    real(default), dimension(:), intent(in) :: xi
    integer, intent(in) :: channel_dummy
    real(default), dimension(size(xi)) :: x
    x = xi
end function phi_trivial

```

21.6.8 Integrator instance: evaluation

Here, we compute the multi-channel reweighting factor for the current channel, that accounts for the Jacobians of the transformations from/to all other channels.

The computation of the VAMP probabilities may consume considerable time, therefore we enable parallel evaluation. (Collecting the contributions to `mci%g` is a reduction, which we should also implement via OpenMP.)

```

⟨MCI vamp: mci vamp instance: TBP⟩+≡
procedure :: compute_weight => mci_vamp_instance_compute_weight

```

```

<MCI vamp: procedures>+=
subroutine mci_vamp_instance_compute_weight (mci, c)
  class(mci_vamp_instance_t), intent(inout) :: mci
  integer, intent(in) :: c
  integer :: i
  mci%selected_channel = c
  !$OMP PARALLEL PRIVATE(i) SHARED(mci)
  !$OMP DO
  do i = 1, mci%nc
    if (mci%w(i) /= 0) then
      mci%gi(i) = vamp_probability (mci%gids%gids(i), mci%x(:,i))
    else
      mci%gi(i) = 0
    end if
  end do
  !$OMP END DO
  !$OMP END PARALLEL
  mci%g = 0
  if (mci%gi(c) /= 0) then
    do i = 1, mci%nc
      if (mci%w(i) /= 0 .and. mci%f(i) /= 0) then
        mci%g = mci%g + mci%w(i) * mci%gi(i) / mci%f(i)
      end if
    end do
  end if
  if (mci%g /= 0) then
    mci%weight = mci%gi(c) / mci%g
  else
    mci%weight = 0
  end if
end subroutine mci_vamp_instance_compute_weight

```

Record the integrand.

```

<MCI vamp: mci vamp instance: TBP>+=
procedure :: record_integrand => mci_vamp_instance_record_integrand

<MCI vamp: procedures>+=
subroutine mci_vamp_instance_record_integrand (mci, integrand)
  class(mci_vamp_instance_t), intent(inout) :: mci
  real(default), intent(in) :: integrand
  mci%integrand = integrand
end subroutine mci_vamp_instance_record_integrand

```

Get the event weight. The default routine returns the same value that we would use for integration. This is correct if we select the integration channel according to the channel weight. `vamp_next_event` does differently, so we should rather rely on the weight that VAMP returns. This is the value stored in `vamp_weight`. We override the default TBP accordingly.

```

<MCI vamp: mci vamp instance: TBP>+=
procedure :: get_event_weight => mci_vamp_instance_get_event_weight
procedure :: get_event_excess => mci_vamp_instance_get_event_excess

```

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is $11x^{10}$, also with integral 1.

Mode 4 includes ranges of zero and negative function value, the integral is negative. The results should be identical to the results of `mci_midpoint_4`, where the same function is evaluated. The function is $f(x) = (1 - 3x^2)\theta(x - 1/2)$ with integral $\int_0^1 f(x) dx = -3/8$, minimum $f(1) = -2$ and maximum $f(1/2) = 1/4$.

```

<MCI vamp: test types>≡
type, extends (mci_sampler_t) :: test_sampler_1_t
    real(default), dimension(:), allocatable :: x
    real(default) :: val
    integer :: mode = 1
contains
    <MCI vamp: test sampler 1: TBP>
end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

<MCI vamp: test sampler 1: TBP>≡
    procedure :: write => test_sampler_1_write

<MCI vamp: tests>≡
    subroutine test_sampler_1_write (object, unit, testflag)
        class(test_sampler_1_t), intent(in) :: object

Two-channel, two dimension test sampler

This sampler implements the function

$$f(x, y) = 4 \sin^2(\pi x) \sin^2(\pi y) + 2 \sin^2(\pi v) \quad (21.11)$$

where

$$x = u^v \quad u = xy \quad (21.12)$$

$$y = u^{(1-v)} \quad v = \frac{1}{2} \left(1 + \frac{\log(x/y)}{\log xy} \right) \quad (21.13)$$

Each term contributes 1 to the integral. The first term in the function is peaked along a cross aligned to the coordinates x and y , while the second term is peaked along the diagonal $x = y$.

The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = |\log u| \quad (21.14)$$

```

Two-channel, one dimension test sampler

This sampler implements the function

$$f(x, y) = a * 5x^4 + b * 5(1 - x)^4 \quad (21.15)$$

Each term contributes 1 to the integral, multiplied by a or b , respectively. The first term is peaked at $x = 1$, the second one at $x = 0$.

We implement the two mappings

$$x = u^{1/5} \quad \text{and} \quad x = 1 - v^{1/5}, \quad (21.16)$$

with Jacobians

$$\frac{\partial(x)}{\partial(u)} = u^{-4/5}/5 \quad \text{and} \quad v^{-4/5}/5, \quad (21.17)$$

respectively. The first mapping concentrates points near $x = 1$, the second one near $x = 0$.

One-dimensional integration

Construct an integrator and use it for a one-dimensional sampler.

Note: We would like to check the precise contents of the grid allocated during integration, but the output format for reals is very long (for good reasons), so the last digits in the grid content display are numerical noise. So, we just check the integration results.

21.7 Multi-channel integration with VAMP2

The multi-channel integration uses VEGAS as backbone integrator. The base interface for the multi-channel integration is given by `mci_base` module.

We interface the VAMP2 interface given by `vamp2` module.

```

⟨mci_vamp2.f90⟩≡
  ⟨File header⟩

```

```

module mci_vamp2

```

```

  ⟨Use kinds⟩

```

```

  ⟨Use strings⟩

```

```

  use io_units

```

```

  use format_utils, only: pac_fmt

```

```

  use format_utils, only: write_separator, write_indent

```

```

  use format_defs, only: FMT_12, FMT_14, FMT_17, FMT_19

```

```

    use constants, only: tiny_13
    use diagnostics
    use md5
    use phs_base
    use rng_base

    use mci_base

    use vegas, only: VEGAS_MODE_IMPORTANCE, VEGAS_MODE_IMPORTANCE_ONLY
    use vamp2

```

21.7.4 Integrator

We store the different passes of integration, adaptation and actual sampling, in a linked list.

We store the total number of calls `n_calls` and the minimal number of calls `n_calls_min`. The latter is calculated based on `n_channel` and `min_calls_per_channel`. If `n_calls` is smaller than `n_calls_min`, then we replace `n_calls` with `n_min_calls`.

Update the MCI record (i.e., the integration passes) by reading from input stream. The stream should contain a write output from a previous run. We first check the MD5 sum of the configuration parameters. If that matches, we proceed directly to the stored integration passes. If successful, we may continue to read the file; the position will be after a blank line that must follow the MCI record.

Interface: VAMP2

We define the interfacing procedures, as such, initialising the VAMP2 integrator or resetting the results.

Initialise the VAMP2 integrator which is stored within the `mci` object, using the data of the current integration pass. Furthermore, reset the counters that track this set of integrator.

```

```

Integrate. Perform a new integration pass (possibly reusing previous results), which may consist of several iterations. We reinitialise the sampling new each time and set the workspace again. Note: we record the integral once per iteration. The integral stored in the mci record itself is the last integral of the current iteration, no averaging done. The results record may average results. Note: recording the efficiency is not supported yet.

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is $11x^{10}$, also with integral 1.

Mode 4 includes ranges of zero and negative function value, the integral is negative. The results should be identical to the results of `mci_midpoint_4`, where the same function is evaluated. The function is $f(x) = (1 - 3x^2)\theta(x - 1/2)$ with integral $\int_0^1 f(x) dx = -3/8$, minimum $f(1) = -2$ and maximum $f(1/2) = 1/4$.

```

<MCI vamp2: test types>≡
type, extends (mci_sampler_t) :: test_sampler_1_t
    real(default), dimension(:), allocatable :: x
    real(default) :: val
    integer :: mode = 1
contains
    <MCI vamp2: test sampler 1: TBP>
end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

Two-channel, two dimension test sampler

This sampler implements the function

$$f(x, y) = 4 \sin^2(\pi x) \sin^2(\pi y) + 2 \sin^2(\pi v) \quad (21.19)$$

where

$$x = u^v \quad u = xy \quad (21.20)$$

$$y = u^{(1-v)} \quad v = \frac{1}{2} \left(1 + \frac{\log(x/y)}{\log xy} \right) \quad (21.21)$$

Each term contributes 1 to the integral. The first term in the function is peaked along a cross aligned to the coordinates x and y , while the second term is peaked along the diagonal $x = y$.

The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = |\log u| \quad (21.22)$$

22.1.2 Shower settings

These the general shower settings, the settings and parameters for the matching are defined in the corresponding matching modules. The width and the cutoff of the Gaussian primordial k_t distribution, PARP(91) and PARP(93), in GeV, are called `isr_primordial_kt_width` and `isr_primordial_kt_cutoff` in WHIZARD. The parameter MSTJ(45) gives the maximum number of flavors in gluon decay to quarks, and is here called `max_n_flavors`.

The two parameters `isr_alphas_running` and `[fsr_alphas_running` decide whether to use constant or running α_s in the form of the function $D_{\alpha_s}(t)$ for the FSR and ISR (MSTJ(44), MSTP(64)), respectively. The next parameter, `fixed_alpha_s` is the parameter PARU(111), which sets the value for constant α_s , and the flag whether to use P_t -ordered ISR is `isr_pt_ordered`. From the entry `min_voirtuality` on, parameters have meanings both for the PYTHIA and WHIZARD parton shower(s), where PYTHIA values are denoted at the end of the line.

```

Mass and mass squared selection functions. All masses are in GeV. Light quarks are assumed to be ordered, $m_1 < m_2 < m_3 \dots$, and they get current masses, not elementary ones. Mesons and baryons other than proton and neutron are needed as beam-remnants. Particles with PDG number zero are taken massless, as well as proper beam remnants and any other particles.

22.2.1 The basic type defintions

The type `parton_t` defines a parton for the shower. The `x` value of the parton is only needed for spacelike showers. The pointer `initial` is only needed for partons in initial showers, it points to the hadron the parton is coming from. An auxiliary value for the P_t -ordered ISR is `aux_pt`. Then, there are two auxiliary entries for the clustering of CKKW pseudo weights and CKKW matching, `ckkwlabel` and `ckkwscale`. In order to make shower settings available to all operations on the shower partons, we endow the `parton_t` type with a pointer to `shower_settings_t`.

```

<Shower partons: public>≡
    public :: parton_t

<Shower partons: types>≡

The parameters of the shower module:

```

(Shower core: parameters)≡
real(default), save :: alphasxpdfmax = 12._default

```

In this routine, *y* and *ymin* are the jet measures, *w* and *wmax* are weights, *s* is the kinematic energy squared of the interaction. The flag *isr_is_possible_and_allowed* checks whether the initial parton is set, lepton-hadron collisions are not implemented (yet).

As a workaround: as WHIZARD can treat partons as massless, there might be partons with $E < m$: if such a parton is found, quarks will be treated massless.

```

We combine the `particle_set` from the hard interaction with the partons of the shower. For simplicity, we do not maintain the mother-daughter-relations of the shower. Hadronic `beam_remnants` of the old `particle_set` are removed as they are provided, including proper flavor information, by the ISR shower.

!C      KTCLUS: written by Mike Seymour, July 1992.
!C      Last modified November 2000.
!C      Please send comments or suggestions to Mike.Seymour@rl.ac.uk
!C
!C      This is a general-purpose kt clustering package.
!C      It can handle ee, ep and pp collisions.
!C      It is loosely based on the program of Siggi Bethke.
!C
!C      The time taken (on a 10MIP machine) is (0.2microsec)*N**3
!C      where N is the number of particles.
!C      Over 90 percent of this time is used in subroutine KTPMIN, which
!C      simply finds the minimum member of a one-dimensional array.
!C      It is well worth thinking about optimization: on the SPARCstation
!C      a factor of two increase was obtained simply by increasing the
!C      optimization level from its default value.
!C
!C      The approach is to separate the different stages of analysis.
!C      KTCLUS does all the clustering and records a merging history.
!C      It returns a simple list of the y values at which each merging
!C      occurred. Then the following routines can be called to give extra
!C      information on the most recently analysed event.
!C      KTCLUR is identical but includes an R parameter, see below.
!C      KTYCUT gives the number of jets at each given YCUT value.
!C      KTYSUB gives the number of sub-jets at each given YCUT value.
!C      KTBEAM gives same info as KTCLUS but only for merges with the beam
!C      KTJOIN gives same info as KTCLUS but for merges of sub-jets.
!C      KTRECO reconstructs the jet momenta at a given value of YCUT.
!C      It also gives information on which jets at scale YCUT belong to
!C      which macro-jets at scale YMAC, for studying sub-jet properties.
!C      K TINCL reconstructs the jet momenta according to the inclusive jet
!C      definition of Ellis and Soper.
!C      KTISUB, KTIJOI and KTIREC are like KTYSUB, KTJOIN and KTRECO,
!C      except that they only apply to one inclusive jet at a time,
!C      with the pt of that jet automatically used for ECUT.
!C      KTWICH gives a list of which particles ended up in which jets.
!C      KTWCHS gives the same thing, but only for subjets.
!C      Note that the numbering of jets used by these two routines is
!C      guaranteed to be the same as that used by KTRECO.
!C
!C      The collision type and analysis type are indicated by the first
!C      argument of KTCLUS. IMODE=<TYPE><ANGLE><MONO><RECOM> where
!C      TYPE:  1=>ee, 2=>ep with p in -z direction, 3=>pe, 4=>pp
!C      ANGLE: 1=>angular kt def., 2=>DeltaR, 3=>f(DeltaEta,DeltaPhi)
!C              where f()=2(cosh(eta)-cos(phi)) is the QCD emission metric
!C      MONO:  1=>derive relative pseudoparticle angles from jets
!C              2=>monotonic definitions of relative angles
!C      RECOM: 1=>E recombination scheme, 2=>pt scheme, 3=>pt**2 scheme
!C
!C      There are also abbreviated forms for the most common combinations:
!C      IMODE=1 => E scheme in e+e-                      (=1111)

```

```

```

Setup the user process for the LHA interface.

We fill the user process with the correct information on the beams, and set the strategy of the user process to weighted events. `process_id` and `n_processes` are not used by LHA user process for weighted (or unweighted) events, but

required by the LHA user process interface. Therefore, we choose arbitrary defaults.

Chapter 23

Multiple Interactions (MPI) Code

This is the code for the `WHIZARD` module for multiple interactions (MPI) in hadron collisions. It also provides the interleaved shower with together with the shower module.

23.1 Basic types

This file contains the module `multi_basic` which is included by all other modules of the MPI code. It's main purpose is serialization and deserialization, but it also contains some bitmodel parameters and some minor definitions common to all modules and types.

Serialization is implemented in three layers:

1. **I/O layer:** streamfile access and exact, retrievable and compiler independent representation of all intrinsic types
2. **Marking layer:** storing/restoring pointer association and better human readability
3. **Derived type layer:** abstract type as parent for all serializable derived types

The I/O Layer The I/O layer is implemented by `page_ring.t` and its type bound procedures. We chose not to use the standard formatted sequential I/O for several reasons:

- Sequential I/O is line orientated, but serialization is not.
- Formatted I/O of floating point numbers is inexact. There were problems in reading numbers like `1+epsilon(1)` or `huge(1)` including arithmetic exceptions and wrong results.
- Formatted reading is slow. This does matter, when you read files of $\mathcal{O}(100)$ MB.

Figure 23.1: Module dependencies in `src/muli`.

`page_ring_t` is a ring buffer of default kind characters holding a region of the addressed file. All read and write procedures use the ring buffer, not the file. `page_ring` automatically reads more characters from the file when needed and writes and discards parts of the ring buffer when not any longer needed.

Marking layer Marking is done by `marking_t` and its type bound procedures. Files written by `marking_t` are regular XML files, so you can use your favorite XML editor to examine or edit serialized contents. The main purpose of this layer is to recover the type of polymorphic entities and to restore association of pointers, but it also assigns names to all contents, so it is much easier to read generated files.

Type recovery is done by a reference list. You must push a representative object to this reference list for each type that might get resolved before starting deserialization. `marker_t` will care for comparing these representatives to the contents of the files.

Association restoration is done by a heap list. It is technically equal to the reference list, but holds all targets that have been processed so far. Generation of this list is handled by `marking_t`, so you don't have to care for this aspect at all. Up to the present it is not possible to restore association, when a non-pointer target is serialized after its associated pointer is serialized. There is no trivial solution and this case does not appear here, so we will not take care of this.

Derived type layer Each instance that shall become serialized must extend `ser_class_t`. Essential for type recovery is the virtual type bound procedure `get_type`. Each non-virtual type shall override `get_type` and return the actual name of its type in lower-case letters. Each type which adds new, non-redundant components shall override `write_to_marker` and `read_from_marker`. These type-bound procedures define, what contents get serialized. While the marker cares about tagging the type and association of the instance, every instance still has to define what to serialize. The rule is to mark the begin of its contents, then its parents procedure, then mark all non-redundant components, then mark the end of its contents. Finally, each serializable type shall override `print_to_unit`. This procedure is called for an arbitrary human-readable output. It is quite similar to `write_to_ring`, but without strict format and ignoring machine-readability.

`ser_class_t` has strictly speaking two layers. `write_to_marker` and `read_from_marker` are only for internal usage. Serialization and deserialization are triggered by the TBPs `serialize` and `deserialize`. These procedures take care of initialization and finalization of the marker. A serializable type should override these procedures to push a representative of itself and any other references to the reference list of its marker before (de)serialization and to pop them from the list afterwards.

`<multi_base.f90>`≡

<File header>

```
module multi_base
  use, intrinsic :: iso_fortran_env
<Use kinds with double>
  use kinds, only: i64
<Use strings>
  use constants
  use io_units
  use diagnostics
```

<Standard module head>

<Multi base: variables>

<Multi base: public>

<Multi base: types>

<Multi base: interfaces>

`contains`

<Multi base: procedures>

`end module multi_base`

These are the bitmodel parameters.

<Multi base: variables>≡

```
integer, public, parameter :: dik = i64
integer(dik), public, parameter :: i_one = int(1, kind=dik)
integer(dik), public, parameter :: i_zero = int(0, kind=dik)
```

These are the serialization parameters.

```

<Multi base: variables>+=
integer(dik), public, parameter :: serialize_page_size = 1024
integer(dik), public, parameter :: serialize_ok = 0000
integer(dik), public, parameter :: serialize_syntax_error = 1001
integer(dik), public, parameter :: serialize_wrong_tag = 1002
integer(dik), public, parameter :: serialize_wrong_id = 1003
integer(dik), public, parameter :: serialize_wrong_type = 1004
integer(dik), public, parameter :: serialize_wrong_name = 1005
integer(dik), public, parameter :: serialize_no_target = 1006
integer(dik), public, parameter :: serialize_no_pointer = 1007
integer(dik), public, parameter :: serialize_wrong_action = 1008
integer(dik), public, parameter :: serialize_unexpected_content = 1009
integer(dik), public, parameter :: serialize_null = 1010
integer(dik), public, parameter :: serialize_nothing = 1011
logical, public, parameter :: serialize_default_indent = .true.
logical, public, parameter :: serialize_default_line_break = .true.
logical, public, parameter :: serialize_default_asynchronous = .false.

```

And some private variables:

```

<Multi base: variables>+=
integer(dik) :: last_id = 0
character(len=*) , parameter :: serialize_integer_characters = &
    "-0123456789"

```

```

23.2 Transverse momenta

This file contains the module `multi_momentum`. Its purpose is to store the actual value of the evolution parameter p_t^2 in a convenient way. We use the normalized value $p_t^2/p_{t,\max}^2$ for generating the next value of the scale, also need the square root of both p_t^2 and $p_t^2/p_{t,\max}^2$ for other purposes. That's why I store all four combinations together with $p_{t,\max}$ in an array.

```

23.3 Multi parton interactions

This file contains the module `muli_interactions`. The allowed interactions and their cross sections are defined here. Additionally, some coordinate transformations which annihilate divergencies of the cross sections are defined. Since the phase space border is hyperbolic, this transformations are also hyperbolic. That's why all interactions are named `x_cart` for cartesian or `x_hyp` for hyperbolic to avoid confusion.

```

23.4 VEGAS and CUBA integration routines

This file contains the module `muli_cuba`, a wrapper for the CUBA integration library. Different algorithms and settings have been tried out for the integration, including VEGAS, and this wrapper has been mainly written for that purpose.

```

23.5 Trapezoidal integration routines

This file contains the module "multi_trapezium". The name is derived from the trapezoidal integration rule. The purpose of this module is to define a binary tree `multi_trapezium_tree_t` which holds a probability function in terms of trapezoidal segments. Its leaves of type `multi_trapezium_list_t` are connected to form a list, so you can either walk the root function back and forth or pick a certain segment in logarithmic time by walking down the tree. All nodes extend `multi_trapezium_t` which holds the actual values. Those are the values of the density function, the integral from this segment to the end of the integration area and a probability function calculated from these values. All values are taken at the upper "right" bound of the segment. Additionally the differences of these values to the values of the left neighbor is stored.

```

    end subroutine muli_trapezium_final_interface
end interface

This is the base type muli_trapezium_t. Its component values has a first index
is in  $\{0, \dots, \text{dim} - 1\}$ , while the second index distinguishes between r_value,
d_value, r_integral, d_integral, r_probability, d_probability.

23.6 Fibonacci trees

This file contains the module `muli_fibonacci_tree`. A fibonacci tree is a self-balancing binary tree. "Balanced" means that the depth of the left successor may differ from the depth of the right successor in any node by maximally one. The maximally unbalanced tree is maximally unbalanced in every node. So the number of leaves of a maximally unbalanced fibonacci tree of depth n is precisely the n th fibonacci number.

We use this tree for the adaptive quadrature. In every iteration of the algorithm, we have to pick the segment with largest integration error, cut it into pieces and calculate the new integration error for the pieces. A binary tree is obviously a good choice for sorting these segments. The problem is, that we always pick leaves from the same side of the tree. So the tree must decline at one side and grow at the other side. Sorting gets less efficient and finally most of the overall CPU time gets wasted for sorting. This tree outperforms a naive binary tree significantly in this particular job.
