    type(ps_entry_t), pointer :: current
    current => table%first
    do while (associated (current))
      call table%split (current, 0, constraints, record = .true., &
        do_not_check_regular = do_not_check_regular)
      current => current%next
    end do
  end subroutine fs_table_radiate

```

28.1.5 Splitting algorithm

Recursive splitting. First of all, we record the current `pdg_list` in the table, subject to `constraints`, if requested. We also record copies of the list marked as loop corrections.

When we record a particle list, we sort it first.

If there is room for splitting, We take a PDG array list and the index of an element, and split this element in all possible ways. The split entry is inserted into the list, which we split further.

The recursion terminates whenever the split array would have a length greater than n_{\max} .

```

<Auto components: ps table: TBP>+≡
  procedure :: split => ps_table_split

<Auto components: sub interfaces>+≡
  recursive module subroutine ps_table_split (table, pl, n_rad, constraints, &
    record, do_not_check_regular)

        exit SCAN_VERTICES
      end if
    end do SCAN_VERTICES
  end if
end do
end subroutine ps_table_split

```

The worker part: insert the list of particles found by vertex matching in place of entry *i* in the PDG list. Then split/record further.

The *n_in* parameter tells the replacement routine to insert the new particles after entry *n_in*. Otherwise, they follow index *i*.

<Auto components: ps table: TBP>+≡

      end if
    end if
  end function is_colored_isr
end subroutine ps_table_insert

```

Special case: If we are splitting an initial particle, there is slightly more to do. We loop over the particles from the vertex match and replace the initial particle by each of them in turn. The remaining particles must be appended after the second initial particle, so they will end up in the out state. This is done by providing the `n_in` argument to the base method as an optional argument.

Note that we must call the base-method procedure explicitly, so the `table` argument keeps its dynamic type as `if_table` inside this procedure.

```

```

We need to reset the `reshuffle_list` in order to deal with subsequent usages of the `radiation_generator`. Below is obviously the lazy and dirty solution. Otherwise, we would have to equip this auxiliary type with additional information about `last` and `previous` pointers. Considering that at most n_{legs} integers are saved in the lists, and that the subroutine is only called during the initialization phase (more precisely: at the moment only in the `radiation_generator` unit tests), I think this quick fix is justified.

```

<Radiation generator: reshuffle list: TBP>+≡
    procedure :: reset => reshuffle_list_reset

28.3 Sindarin Expression Implementation

This module defines expressions of all kinds, represented in a tree structure, for repeated evaluation. This provides an implementation of the `expr_base` abstract type.

We have two flavors of expressions: one with particles and one without particles. The latter version is used for defining cut/selection criteria and for online analysis.

```

28.3.1 Tree nodes

The evaluation tree consists of branch nodes (unary and binary) and of leaf nodes, originating from a common root. The node object should be polymorphic. For the time being, polymorphism is emulated here. This means that we have to maintain all possibilities that the node may hold, including associated procedures as pointers.

The following parameter values characterize the node. Unary and binary operators have sub-nodes. The other are leaf nodes. Possible leafs are literal constants or named-parameter references.

```

<Eval trees: types>≡
    integer, parameter :: EN_UNKNOWN = 0, EN_UNARY = 1, EN_BINARY = 2
    integer, parameter :: EN_CONSTANT = 3, EN_VARIABLE = 4
    integer, parameter :: EN_CONDITIONAL = 5, EN_BLOCK = 6
    integer, parameter :: EN_RECORD_CMD = 7
    integer, parameter :: EN_OBS1_INT = 11, EN_OBS2_INT = 12
    integer, parameter :: EN_OBSEV_INT = 13
    integer, parameter :: EN_OBS1_REAL = 21, EN_OBS2_REAL = 22
    integer, parameter :: EN_OBSEV_REAL = 23
    integer, parameter :: EN_PRT_FUN_UNARY = 101, EN_PRT_FUN_BINARY = 102
    integer, parameter :: EN_EVAL_FUN_UNARY = 111, EN_EVAL_FUN_BINARY = 112
    integer, parameter :: EN_LOG_FUN_UNARY = 121, EN_LOG_FUN_BINARY = 122
    integer, parameter :: EN_INT_FUN_UNARY = 131, EN_INT_FUN_BINARY = 132
    integer, parameter :: EN_REAL_FUN_UNARY = 141, EN_REAL_FUN_BINARY = 142
    integer, parameter :: EN_REAL_FUN_CUM = 151
    integer, parameter :: EN_FORMAT_STR = 161

```

This is exported only for use within unit tests.

```

case (V_STR); allocate (node%sval)
end select
allocate (node%value_is_known)
node%value_is_known = .false.
end subroutine eval_node_allocate_value

```

Initialize a block node which contains, in addition to the expression to be evaluated, a variable definition. The result type is not yet assigned, because we can compile the enclosed expression only after the var list is set up.

Note that the node always allocates a new variable list and appends it to the current one. Thus, if the variable redefines an existing one, it only shadows it but does not reset it. Any side-effects are therefore absent and need not be undone outside the block.

If the flag **new** is set, a variable is (re)declared. This must not be done for intrinsic variables. Vice versa, if the variable is not existent, the **new** flag is required.

(Eval trees: procedures)+≡

```

subroutine eval_node_init_block (node, name, type, var_def, var_list)
  type(eval_node_t), intent(out), target :: node
  type(string_t), intent(in) :: name

        end select
    end if
end subroutine eval_node_init_block

```

Complete block initialization by assigning the expression to evaluate to `arg0`.

(Eval trees: procedures)+≡

```

subroutine eval_node_set_expr (node, arg, result_type)
    type(eval_node_t), intent(inout) :: node
    type(eval_node_t), intent(in), target :: arg
    integer, intent(in), optional :: result_type
    if (present (result_type)) then
        node%result_type = result_type
    else
        node%result_type = arg%result_type
    end if
    call eval_node_allocate_value (node)
    node%arg0 => arg
end subroutine eval_node_set_expr

```

Initialize a conditional. There are three branches: the condition (evaluates to logical) and the two alternatives (evaluate both to the same arbitrary type).

(Eval trees: procedures)+≡

```

subroutine eval_node_init_conditional (node, result_type, cond, arg1, arg2)
    type(eval_node_t), intent(out) :: node
    integer, intent(in) :: result_type
    type(eval_node_t), intent(in), target :: cond, arg1, arg2
    node%type = EN_CONDITIONAL
    node%tag = "cond"
    node%result_type = result_type
    call eval_node_allocate_value (node)
    node%arg0 => cond
    node%arg1 => arg1
    node%arg2 => arg2
end subroutine eval_node_init_conditional

```

Initialize a recording command (which evaluates to a logical constant). The first branch is the ID of the analysis object to be filled, the optional branches 1 to 4 are the values to be recorded.

If the event-weight pointer is null, we record values with unit weight. Otherwise, we use the value pointed to as event weight.

There can be up to four arguments which represent x , y , Δy , Δx . Therefore, this is the only node type that may fill four sub-nodes.

(Eval trees: procedures)+≡

```

subroutine eval_node_init_record_cmd &
    (node, event_weight, id, arg1, arg2, arg3, arg4)
    type(eval_node_t), intent(out) :: node
    real(default), pointer :: event_weight
    type(eval_node_t), intent(in), target :: id

```

```

type(eval_node_t), intent(in), optional, target :: arg1, arg2, arg3, arg4
call eval_node_init_log (node, .true.)
node%type = EN_RECORD_CMD
node%rval => event_weight
node%tag = "record_cmd"
node%arg0 => id
if (present (arg1)) then
  node%arg1 => arg1
  if (present (arg2)) then

end subroutine eval_node_init_real_fun_cum

```

Initialize a node for a string formatting function (sprintf).

<Eval trees: procedures>+≡

```

subroutine eval_node_init_format_string (node, fmt, arg, name, n_args)
    type(eval_node_t), intent(out) :: node
    type(eval_node_t), pointer :: fmt, arg
    type(string_t), intent(in) :: name
    integer, intent(in) :: n_args
    node%type = EN_FORMAT_STR
    node%tag = name

```

```

node%result_type = V_STR
call eval_node_allocate_value (node)
node%arg0 => fmt
node%arg1 => arg
allocate (node%ival)
node%ival = n_args
end subroutine eval_node_init_format_string

```

If particle functions depend upon a condition (or an expression is evaluated), the observables that can be evaluated for the given particles have to be thrown on the local variable stack. This is done here. Each observable is initialized with the particle pointers which have been allocated for the node.

The integer variable that is referred to by the `Index` pseudo-observable is always known when it is referred to.

```

<Eval trees: procedures>+≡
subroutine eval_node_set_observables (node, var_list)
  type(eval_node_t), intent(inout) :: node
  type(var_list_t), intent(in), target :: var_list
  logical, save, target :: known = .true.
  allocate (node%var_list)
  call node%var_list%link (var_list)
  allocate (node%index, source = 0)
  call node%var_list%append_int_ptr &
    (var_str ("Index"), node%index, known, intrinsic=.true.)
  if (.not. associated (node%prt2)) then
    call var_list_set_observables_unary &
      (node%var_list, node%prt1)
    if (associated (node%pval)) then
      call var_list_set_observables_sev &
        (node%var_list, node%pval)
    end if
  else
    call var_list_set_observables_binary &
      (node%var_list, node%prt1, node%prt2)
  end if
end subroutine eval_node_set_observables

```

Output

```

28.3.2 Operation types

For the operations associated to evaluation tree nodes, we define abstract interfaces for all cases.

Particles/subevents are transferred by-reference, to avoid unnecessary copying. Therefore, subroutines instead of functions.

(Eval trees: interfaces)≡

```

abstract interface
    logical function unary_log (arg)
        import eval_node_t
        type(eval_node_t), intent(in) :: arg
    end function unary_log
end interface
abstract interface
    integer function unary_int (arg)
        import eval_node_t
        type(eval_node_t), intent(in) :: arg
    end function unary_int
end interface

```

```

abstract interface
  real(default) function unary_real (arg)
    import default
    import eval_node_t
    type(eval_node_t), intent(in) :: arg
  end function unary_real
end interface
abstract interface
  complex(default) function unary_cmplx (arg)
    import default
    import eval_node_t
    type(eval_node_t), intent(in) :: arg
  end function unary_cmplx
end interface
abstract interface
  subroutine unary_pdg (pdg_array, arg)
    import pdg_array_t
    import eval_node_t
    type(pdg_array_t), intent(out) :: pdg_array
    type(eval_node_t), intent(in) :: arg
  end subroutine unary_pdg

28.3.3 Specific operators

Our expression syntax contains all Fortran functions that make sense. These functions have to be provided in a form that they can be used in procedures pointers, and have the abstract interfaces above. For some intrinsic functions, we could use specific versions provided by Fortran directly. However, this has two drawbacks: (i) We should work with the values instead of the eval-nodes as argument, which complicates the interface; (ii) more importantly, the **default** real type need not be equivalent to double precision. This would, at least, introduce system dependencies. Finally, for operators there are no specific versions.

Therefore, we write wrappers for all possible functions, at the expense of some overhead.

Binary numerical functions

```

<Eval trees: procedures>+≡
integer function add_ii (en1, en2) result (y)
    type(eval_node_t), intent(in) :: en1, en2
    y = en1%ival + en2%ival

Binary particle-list functions

This joins two subevents, stored in the evaluation nodes **en1** and **en2**. If **en0** is also present, it amounts to a logical test returning true or false for every pair of particles. A particle of the second list gets a mask entry only if it passes the test for all particles of the first list.

(Eval trees: procedures)+≡

```

subroutine join_pp (subevt, en1, en2, en0)
type(subevt_t), intent(inout) :: subevt
type(eval_node_t), intent(in) :: en1, en2
type(eval_node_t), intent(inout), optional :: en0
logical, dimension(:), allocatable :: mask2
integer :: i, j, n1, n2
n1 = en1%pval%get_length ()
n2 = en2%pval%get_length ()
allocate (mask2 (n2))
mask2 = .true.
if (present (en0)) then
do i = 1, n1
    en0%index = i

```

Binary string functions

Currently, the only string operation is concatenation.

(Eval trees: procedures)+≡

```

subroutine concat_ss (string, en1, en2)
  type(string_t), intent(out) :: string
  type(eval_node_t), intent(in) :: en1, en2
  string = en1%sval // en2%sval
end subroutine concat_ss

```

28.3.4 Compiling the parse tree

The evaluation tree is built recursively by following a parse tree. Evaluate an expression. The requested type is given as an optional argument; default is numeric (integer or real).

(Eval trees: procedures)+≡

```
recursive subroutine eval_node_compile_genexpr &
    (en, pn, var_list, result_type)
    type(eval_node_t), pointer :: en
    type(parse_node_t), intent(in) :: pn
    type(var_list_t), intent(in), target :: var_list
    integer, intent(in), optional :: result_type
    if (debug_active (D_MODEL_F)) then
        print *, "read genexpr"; call parse_node_write (pn)
    end if
    if (present (result_type)) then
        select case (result_type)
            case (V_INT, V_REAL, V_CMPLX)
                call eval_node_compile_expr (en, pn, var_list)
            case (V_LOG)

    end if
    if (debug_active (D_MODEL_F)) then
        call eval_node_write (en)
        print *, "done genexpr"
    end if
end subroutine eval_node_compile_genexpr
```

Numeric expressions

This procedure compiles a numerical expression. This is a single term or a sum or difference of terms. We have to account for all combinations of integer and real arguments. If both are constant, we immediately do the calculation and allocate a constant node.

(Eval trees: procedures)+≡

```
recursive subroutine eval_node_compile_expr (en, pn, var_list)
    type(eval_node_t), pointer :: en
    type(parse_node_t), intent(in) :: pn
    type(var_list_t), intent(in), target :: var_list
    type(parse_node_t), pointer :: pn_term, pn_addition, pn_op, pn_arg
```

```

type(eval_node_t), pointer :: en1, en2

```

Real, complex and integer values are numeric literals with an optional unit attached. In case of an integer, the unit actually makes it a real value in disguise. The signed version of real values is not possible in generic expressions; it is a special case for numeric constants in model files (see below). We do not introduce signed versions of complex values.

```

Compile a variable, with or without a specified type. Take the list of variables, look for the name and make a node with a pointer to the value. If no type is provided, the variable is numeric, and the stored value determines whether it is real or integer.

We explicitly demand that the variable is defined, so we do not accidentally point to variables that are declared only later in the script but have come into existence in a previous compilation pass.

Variables may actually be anonymous, these are expressions in disguise. In that case, the expression replaces the variable name in the parse tree, and we

allocate an ordinary expression node in the eval tree.

Variables of type V_PDG (pdg-code array) are not treated here. They are handled by eval_node_compile_cvariable.

```

Retrieve the result of an integration. If the requested process has been integrated, the results are available as special variables. (The variables cannot be accessed in the usual way since they contain brackets in their names.)

Since this compilation step may occur before the processes have been loaded, we have to initialize the required variables before they are used.

Variable definition

A block expression contains a variable definition (first argument) and an expression where the definition can be used (second argument). The `result_type` decides which type of expression is expected for the second argument. For numeric variables, if there is a mismatch between real and integer type, insert an extra node for type conversion.

Conditionals

A conditional has the structure `if lexpr then expr else expr`. So we first evaluate the logical expression, then depending on the result the first or second expression. Note that the second expression is mandatory.

The `result_type`, if present, defines the requested type of the `then` and `else` clauses. Default is numeric (int/real). If there is a mismatch between real and integer result types, insert conversion nodes.

(Eval trees: procedures)+≡

Comparisons

Up to the loop, this is easy. There is always at least one comparison. This is evaluated, and the result is the logical node **en**. If it is constant, we keep its second sub-node as **en2**. (Thus, at the very end **en2** has to be deleted if **en** is (still) constant.)

If there is another comparison, we first check if the first comparison was constant. In that case, there are two possibilities: (i) it was true. Then, its right-hand side is compared with the new right-hand side, and the result replaces the previous one which is deleted. (ii) it was false. In this case, the result of the whole comparison is false, and we can exit the loop without evaluating anything else.

Now assume that the first comparison results in a valid branch, its second sub-node kept as **en2**. We first need a copy of this, which becomes the new left-hand side. If **en2** is constant, we make an identical constant node **en1**. Otherwise, we make **en1** an appropriate pointer node. Next, the first branch is saved as **en0** and we evaluate the comparison between **en1** and the a right-hand side. If this turns out to be constant, there are again two possibilities: (i) true, then we revert to the previous result. (ii) false, then the wh

end subroutine eval_node_compile_compared_expr

```

This takes two extra arguments: **en1**, the left-hand-side of the comparison, is already allocated and evaluated. **en2** (the right-hand side) and **en** (the result) are allocated by the routine. **pn** is the parse node which contains the operator and the right-hand side as subnodes.

If the result of the comparison is constant, **en1** is deleted but **en2** is kept, because it may be used in a subsequent comparison. **en** then becomes a constant. If the result is variable, **en** becomes a branch node which refers to **en1** and **en2**.

```

A particle-list value is a PDG-code array, a particle identifier, a variable, a (grouped) pexpr, a block pexpr, a conditional, or a particle-list function.

The `cexpr` node is responsible for transforming a constant PDG-code array into a subevent. It takes the code array as its first argument, the event subevent as its second argument, and the requested particle type (incoming/outgoing) as its zero-th argument. The result is the list of particles in the event that match the code array.

Particle functions

This combines the treatment of 'join', 'combine', 'collect', 'cluster', 'select', and 'extract', as well as the functions for b , c and light jet selection and photon recombination which all have the same syntax. The one or two argument nodes are allocated. If there is a condition, the condition node is also allocated as a logical expression, for which the variable list is augmented by the appropriate (unary/binary) observables.

The `eval` expression is similar, but here the expression `arg0` is mandatory, and the whole thing evaluates to a numeric value. To guarantee initialization of

variables defined on subevents instead of a single (namely the first) particle of a subevent, we make sure that `en` points to the subevent stored in `en1`.

(Eval trees: procedures)+≡

```

28.3.5 Auxiliary functions for the compiler

Issue an error that the current node could not be compiled because of type mismatch:

(Eval trees: procedures)+≡

```

subroutine eval_type_error (pn, string, t)
    type(parse_node_t), intent(in) :: pn
    character(*), intent(in) :: string
    integer, intent(in) :: t
    type(string_t) :: type
    select case (t)
        case (V_NONE); type = "(none)"
        case (V_LOG); type = "'logical'"
        case (V_INT); type = "'integer'"
        case (V_REAL); type = "'real'"
        case (V_CMPLX); type = "'complex'"
        case default; type = "(unknown)"
    end select
    call parse_node_write (pn)
    call msg_fatal (" The " // string // &
        " operation is not defined for the given argument type " // &
        char (type))
end subroutine eval_type_error

```

If two numerics are combined, the result is integer if both arguments are integer, if one is integer and the other real or both are real, than its argument is real, otherwise complex.

(Eval trees: procedures)+≡

```

function numeric_result_type (t1, t2) result (t)
    integer, intent(in) :: t1, t2
    integer :: t
    if (t1 == V_INT .and. t2 == V_INT) then
        t = V_INT
    else if (t1 == V_INT .and. t2 == V_REAL) then

```

```

        t = V_REAL
    else if (t1 == V_REAL .and. t2 == V_INT) then
        t = V_REAL
    else if (t1 == V_REAL .and. t2 == V_REAL) then
        t = V_REAL
    else
        t = V_CMPLX
    end if
end function numeric_result_type

```

28.3.6 Evaluation

Evaluation is done recursively. For leaf nodes nothing is to be done.

Evaluating particle-list functions: First, we evaluate the particle lists. If a condition is present, we assign the particle pointers of the condition node to the allocated particle entries in the parent node, keeping in mind that the observables in the variable stack used for the evaluation of the condition also contain pointers to these entries. Then, the assigned procedure is evaluated, which sets the subevent in the parent node. If required, the procedure evaluates the condition node once for each (pair of) particles to determine the result.

(Eval trees: procedures)+≡

```

    end subroutine eval_node_test_obs

```

28.3.7 Evaluation syntax

We have two different flavors of the syntax: with and without particles.

```

<Eval trees: public>+≡
    public :: syntax_expr
    public :: syntax_pexpr

```

```

<Eval trees: variables>+=
  type(syntax_t), target, save :: syntax_expr
  type(syntax_t), target, save :: syntax_pexpr

```

These are for testing only and may be removed:

```

<Eval trees: public>+=
  public :: syntax_expr_init
  public :: syntax_pexpr_init

<Eval trees: sub interfaces>+=
  module subroutine syntax_expr_init ()
  end subroutine syntax_expr_init
  module subroutine syntax_pexpr_init ()
  end subroutine syntax_pexpr_init

<Eval trees: procedures>+=
  module subroutine syntax_expr_init ()
    type(ifile_t) :: ifile
    call define_expr_syntax (ifile, particles=.false., analysis=.false.)
    call syntax_init (syntax_expr, ifile)
    call ifile_final (ifile)
  end subroutine syntax_expr_init

  module subroutine syntax_pexpr_init ()
    type(ifile_t) :: ifile
    call define_expr_syntax (ifile, particles=.true., analysis=.false.)
    call syntax_init (syntax_pexpr, ifile)
    call ifile_final (ifile)
  end subroutine syntax_pexpr_init

<Eval trees: public>+=
  public :: syntax_expr_final
  public :: syntax_pexpr_final

<Eval trees: sub interfaces>+=
  module subroutine syntax_expr_final ()
  end subroutine syntax_expr_final
  module subroutine syntax_pexpr_final ()
  end subroutine syntax_pexpr_final

<Eval trees: procedures>+=
  module subroutine syntax_expr_final ()
    call syntax_final (syntax_expr)
  end subroutine syntax_expr_final

  module subroutine syntax_pexpr_final ()
    call syntax_final (syntax_pexpr)
  end subroutine syntax_pexpr_final

<Eval trees: public>+=
  public :: syntax_pexpr_write

<Eval trees: sub interfaces>+=
  module subroutine syntax_pexpr_write (unit)
    integer, intent(in), optional :: unit
  end subroutine syntax_pexpr_write

```

<Eval trees: procedures>+≡

```
module subroutine syntax_pexpr_write (unit)
  integer, intent(in), optional :: unit
  call syntax_write (syntax_pexpr, unit)
end subroutine syntax_pexpr_write
```

<Eval trees: public>+≡

```
public :: define_expr_syntax
```

28.3.10 Direct evaluation

These procedures create an eval tree and evaluate it on-the-fly, returning only the final value. The evaluation must yield a well-defined value, unless the `is_known` flag is present, which will be set accordingly.

```

    call msg_error ("Evaluation yields an undefined result, inserting default")
  end subroutine eval_tree_unknown

```

28.3.11 Factory Type

Since `eval_tree_t` is an implementation of `expr_t`, we also need a matching factory type and build method.

```

<Eval trees: public>+≡
  public :: eval_tree_factory_t

<Eval trees: types>+≡
  type, extends (expr_factory_t) :: eval_tree_factory_t
  private
    type(parse_node_t), pointer :: pn => null ()
  contains
    <Eval trees: eval tree factory: TBP>
  end type eval_tree_factory_t

```

Output: delegate to the output of the embedded parse node.

```

<Eval trees: eval tree factory: TBP>≡
  procedure :: write => eval_tree_factory_write

<Eval trees: sub interfaces>+≡
  module subroutine eval_tree_factory_write (expr_factory, unit)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    integer, intent(in), optional :: unit
  end subroutine eval_tree_factory_write

<Eval trees: procedures>+≡
  module subroutine eval_tree_factory_write (expr_factory, unit)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    integer, intent(in), optional :: unit
    if (associated (expr_factory%pn)) then
      call parse_node_write_rec (expr_factory%pn, unit)
    end if
  end subroutine eval_tree_factory_write

```

Initializer: take a parse node and hide it thus from the environment.

```

<Eval trees: eval tree factory: TBP>+≡
  procedure :: init => eval_tree_factory_init

<Eval trees: sub interfaces>+≡
  module subroutine eval_tree_factory_init (expr_factory, pn)
    class(eval_tree_factory_t), intent(out) :: expr_factory
    type(parse_node_t), intent(in), pointer :: pn
  end subroutine eval_tree_factory_init

```

```

<Eval trees: procedures>+≡
  module subroutine eval_tree_factory_init (expr_factory, pn)
    class(eval_tree_factory_t), intent(out) :: expr_factory
    type(parse_node_t), intent(in), pointer :: pn
    expr_factory%pn => pn
  end subroutine eval_tree_factory_init

```

Factory method: allocate expression with correct eval tree type. If the stored parse node is not associate, don't allocate. Gfortran 7/8/9 bug, has to remain in the module.

```

<Eval trees: eval tree factory: TBP>+≡
  procedure :: build => eval_tree_factory_build

<Eval trees: main procedures>≡
  subroutine eval_tree_factory_build (expr_factory, expr)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    class(expr_t), intent(out), allocatable :: expr
    if (associated (expr_factory%pn)) then
      allocate (eval_tree_t :: expr)
      select type (expr)
        type is (eval_tree_t)
          expr%pn => expr_factory%pn
        end select
      end if
    end subroutine eval_tree_factory_build

```

28.4 Physics Models

A model object represents a physics model. It contains a table of particle data, a list of parameters, and a vertex table. The list of parameters is a variable list which includes the real parameters (which are pointers to the particle data table) and PDG array variables for the particles themselves. The vertex list is used for phase-space generation, not for calculating the matrix element.

The actual numeric model data are in the base type `model_data_t`, as part of the `qft` section. We implement the `model_t` as an extension of this, for convenient direct access to the base-type methods via inheritance. (Alternatively, we could delegate these calls explicitly.) The extension contains administrative additions, such as the methods for recalculating derived data and keeping the parameter set consistent. It thus acts as a proxy of the actual model-data object towards the WHIZARD package. There are further proxy objects, such as the `parameter_t` array which provides the interface to the actual numeric parameters.

Model definitions are read from model files. Therefore, this module contains a parser for model files. The parameter definitions (derived parameters) are Sindarin expressions.

The models, as read from file, are stored in a model library which is a simple list of model definitions. For setting up a process object we should make a copy (an instance) of a model, which gets the current parameter values from the global variable list.

28.4.1 Module

```
<models.f90>≡  
<File header>  
  
module models  
  
    use, intrinsic :: iso_c_binding !NODEP!  
  
    <Use kinds>  
    use kinds, only: c_default_float  
    <Use strings>  
    use os_interface  
    use model_data  
  
    use syntax_rules  
    use parser  
    use variables  
    use expr_base  
    use eval_trees  
  
    <Standard module head>  
  
    <Models: public>  
  
    <Models: parameters>  
  
    <Models: types>
```

```

    <Models: interfaces>

    <Models: variables>

    interface
    <Models: sub interfaces>
    end interface

contains

    <Models: main procedures>

end module models

<models_sub.f90>≡
    <File header>

submodule (models) models_s

    use io_units
    use diagnostics
    use md5
    use physics_defs, only: UNDEFINED

    use ifiles
    use lexers
    use pdg_arrays
    use ttv_formfactors, only: init_parameters

    implicit none

contains

    <Models: procedures>

end submodule models_s

```

28.4.2 Physics Parameters

A parameter has a name, a value. Derived parameters also have a definition in terms of other parameters, which is stored as an `eval_tree`. External parameters are set by an external program.

This parameter object should be considered as a proxy object. The parameter name and value are stored in a corresponding `modelpar_data_t` object which is located in a `model_data_t` object. The latter is a component of the `model_t` handler. Methods of `parameter_t` can be delegated to the `par_data_t` component.

The `block_name` and `block_index` values, if nonempty, indicate the possibility of reading this parameter from a SLHA-type input file. (Within the `parameter_t` object, this info is just used for I/O, the actual block register is located in the parent `model_t` object.)

The `pn` component is a pointer to the parameter definition inside the model parse tree. It allows us to recreate the `eval_tree` when making copies (instances) of the parameter object.

```

<Models: parameters>≡
  integer, parameter :: PAR_NONE = 0, PAR_UNUSED = -1
  integer, parameter :: PAR_INDEPENDENT = 1, PAR_DERIVED = 2
  integer, parameter :: PAR_EXTERNAL = 3

<Models: types>≡
  type :: parameter_t
    private
    integer :: type = PAR_NONE
    class(modelpar_data_t), pointer :: data => null ()
    type(string_t) :: block_name
    integer, dimension(:), allocatable :: block_index
    type(parse_node_t), pointer :: pn => null ()
    class(expr_t), allocatable :: expr
  contains
    <Models: parameter: TBP>
  end type parameter_t

```

Initialization depends on parameter type. Independent parameters are initialized by a constant value or a constant numerical expression (which may contain a unit). Derived parameters are initialized by an arbitrary numerical expression, which makes use of the current variable list. The expression is evaluated by the function `parameter_reset`.

This implementation supports only real parameters and real values.

```

<Models: parameter: TBP>≡
  procedure :: init_independent_value => parameter_init_independent_value
  procedure :: init_independent => parameter_init_independent
  procedure :: init_derived => parameter_init_derived
  procedure :: init_external => parameter_init_external
  procedure :: init_unused => parameter_init_unused

<Models: sub interfaces>≡
  module subroutine parameter_init_independent_value &
    (par, par_data, name, value)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    real(default), intent(in) :: value
  end subroutine parameter_init_independent_value
  module subroutine parameter_init_external (par, par_data, name)

    par%data => par_data
    call par%data%init (name, value)
end subroutine parameter_init_independent_value

module subroutine parameter_init_external (par, par_data, name)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    par%type = PAR_EXTERNAL
    par%data => par_data
    call par%data%init (name, 0._default)
end subroutine parameter_init_external

module subroutine parameter_init_unused (par, par_data, name)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    par%type = PAR_UNUSED
    par%data => par_data
    call par%data%init (name, 0._default)
end subroutine parameter_init_unused

```

Gfortran 7/8/9 bug: these have to remain in the main module.

<Models: main procedures>≡

```

subroutine parameter_init_independent (par, par_data, name, pn)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    type(parse_node_t), intent(in), target :: pn
    par%type = PAR_INDEPENDENT
    par%pn => pn
    allocate (eval_tree_t :: par%expr)
    select type (expr => par%expr)
    type is (eval_tree_t)
        call expr%init_numeric_value (pn)
    end select
    par%data => par_data
    call par%data%init (name, par%expr%get_real ())
end subroutine parameter_init_independent

subroutine parameter_init_derived (par, par_data, name, pn, var_list)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    type(parse_node_t), intent(in), target :: pn

```

```

    type(var_list_t), intent(in), target :: var_list
    par%type = PAR_DERIVED
    par%pn => pn
    allocate (eval_tree_t :: par%expr)
    select type (expr => par%expr)
    type is (eval_tree_t)
        call expr%init_expr (pn, var_list=var_list)
    end select
    par%data => par_data
!    call par%expr%evaluate ()
    call par%data%init (name, 0._default)
end subroutine parameter_init_derived

```

The finalizer is needed for the evaluation tree in the definition.

```

<Models: parameter: TBP>+≡
    procedure :: final => parameter_final

<Models: sub interfaces>+≡
    module subroutine parameter_final (par)
        class(parameter_t), intent(inout) :: par
    end subroutine parameter_final

<Models: procedures>+≡
    module subroutine parameter_final (par)
        class(parameter_t), intent(inout) :: par
        if (allocated (par%expr)) then
            call par%expr%final ()
        end if
    end subroutine parameter_final

```

All derived parameters should be recalculated if some independent parameters have changed:

```

<Models: parameter: TBP>+≡
    procedure :: reset_derived => parameter_reset_derived

<Models: sub interfaces>+≡
    module subroutine parameter_reset_derived (par)
        class(parameter_t), intent(inout) :: par
    end subroutine parameter_reset_derived

<Models: procedures>+≡
    module subroutine parameter_reset_derived (par)
        class(parameter_t), intent(inout) :: par
        select case (par%type)
        case (PAR_DERIVED)
            call par%expr%evaluate ()
            par%data = par%expr%get_real ()
        end select
    end subroutine parameter_reset_derived

```

Output. [We should have a formula format for the eval tree, suitable for input and output!]

```

<Models: parameter: TBP>+≡
    procedure :: write => parameter_write

```

```

<Models: sub interfaces>+≡
    module subroutine parameter_write (par, unit, write_defs)
        class(parameter_t), intent(in) :: par
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: write_defs
    end subroutine parameter_write

<Models: procedures>+≡
    module subroutine parameter_write (par, unit, write_defs)
        class(parameter_t), intent(in) :: par

        case (PAR_UNUSED)
            write (u, "(3x,A)", advance="no") "unused"
            write (u, "(1x,A)", advance="no") char (par%data%get_name ())
        end select
        select case (par%type)
        case (PAR_INDEPENDENT)
            if (allocated (par%block_index)) then
                write (u, "(1x,A,1x,A,*(1x,IO))" &
                    "slha_entry", char (par%block_name), par%block_index)
            else
                write (u, "(A)")
            end if
        case (PAR_DERIVED)
            if (defs) then
                call par%expr%write (unit)
            else
                write (u, "(A)")
            end if
        case default
            write (u, "(A)")
        end select
    end subroutine parameter_write

```

Screen output variant. Restrict output to the given parameter type.

```

<Models: parameter: TBP>+≡
    procedure :: show => parameter_show

<Models: sub interfaces>+≡
    module subroutine parameter_show (par, l, u, party)

```

```

        class(parameter_t), intent(in) :: par
        integer, intent(in) :: l, u
        integer, intent(in) :: partype
    end subroutine parameter_show
<Models: procedures>+≡
module subroutine parameter_show (par, l, u, partype)
    class(parameter_t), intent(in) :: par
    integer, intent(in) :: l, u
    integer, intent(in) :: partype
    if (par%type == partype) then
        call par%data%show (l, u)
    end if
end subroutine parameter_show

```

28.4.3 SLHA block register

For the optional SLHA interface, the model record contains a register of SLHA-type block names together with index values, which point to a particular parameter. These are private types:

```

<Models: types>+≡
    type :: slha_entry_t
        integer, dimension(:), allocatable :: block_index
        integer :: i_par = 0
    end type slha_entry_t

<Models: types>+≡
    type :: slha_block_t
        type(string_t) :: name
        integer :: n_entry = 0
        type(slha_entry_t), dimension(:), allocatable :: entry
    end type slha_block_t

```

28.4.4 Model Object

A model object holds all information about parameters, particles, and vertices. For models that require an external program for parameter calculation, there is the pointer to a function that does this calculation, given the set of independent and derived parameters.

As explained above, the type inherits from `model_data_t`, which is the actual storage for the model data.

When reading a model, we create a parse tree. Parameter definitions are available via parse nodes. Since we may need those later when making model instances, we keep the whole parse tree in the model definition (but not in the instances).

```

<Models: public>≡
    public :: model_t

```

```

<Models: types>+=
  type, extends (model_data_t) :: model_t
  private
    character(32) :: md5sum = ""
    logical :: ufo_model = .false.
    type(string_t) :: ufo_path
    type(string_t), dimension(:), allocatable :: schemes
    type(string_t), allocatable :: selected_scheme
    type(parameter_t), dimension(:), allocatable :: par
    integer :: n_slha_block = 0
    type(slha_block_t), dimension(:), allocatable :: slha_block
    integer :: max_par_name_length = 0
    integer :: max_field_name_length = 0
    type(var_list_t) :: var_list
    type(string_t) :: dlname
    procedure(model_init_external_parameters), nopass, pointer :: &
      init_external_parameters => null ()
    type(dlaccess_t) :: dlaccess
    type(parse_tree_t) :: parse_tree
  contains
    <Models: model: TBP>
  end type model_t

```

This is the interface for a procedure that initializes the calculation of external parameters, given the array of all parameters.

```

<Models: interfaces>=
  abstract interface
    subroutine model_init_external_parameters (par) bind (C)
      import
      real(c_default_float), dimension(*), intent(inout) :: par
    end subroutine model_init_external_parameters
  end interface

```

Initialization: Specify the number of parameters, particles, vertices and allocate memory. If an associated DL library is specified, load this library.

The model may already carry scheme information, so we have to save and restore the scheme number when actually initializing the `model_data_t` base.

```

<Models: model: TBP>=
  generic :: init => model_init
  procedure, private :: model_init

<Models: sub interfaces>+=
  module subroutine model_init &
    (model, name, libname, os_data, n_par, n_prt, n_vtx, ufo)

Make a copy of a parameter. We assume that the `model_data_t` parameter arrays have already been copied, so names and values are available in the current model, and can be used as targets. The eval tree should not be copied, since it should refer to the new variable list. The safe solution is to make use of the above initializers, which also take care of the building a new variable list.

28.4.5 Model Access via Variables

Write the model variable list.

```

<Models: model: TBP>+≡
    procedure :: write_var_list => model_write_var_list

<Models: sub interfaces>+≡
    module subroutine model_write_var_list (model, unit, follow_link)
        class(model_t), intent(in) :: model
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: follow_link
    end subroutine model_write_var_list

<Models: procedures>+≡
    module subroutine model_write_var_list (model, unit, follow_link)
        class(model_t), intent(in) :: model
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: follow_link
        call model%var_list%write (unit, follow_link)
    end subroutine model_write_var_list

```

Link a variable list to the model variables.

```

<Models: model: TBP>+≡
    procedure :: link_var_list => model_link_var_list

<Models: sub interfaces>+≡
    module subroutine model_link_var_list (model, var_list)
        class(model_t), intent(inout) :: model
        type(var_list_t), intent(in), target :: var_list
    end subroutine model_link_var_list

<Models: procedures>+≡
    module subroutine model_link_var_list (model, var_list)
        class(model_t), intent(inout) :: model
        type(var_list_t), intent(in), target :: var_list
        call model%var_list%link (var_list)
    end subroutine model_link_var_list

```

```
end subroutine model_link_var_list
```

Check if the model contains a named variable.

```
<Models: model: TBP>+≡
```

```
procedure :: var_exists => model_var_exists
```

```
<Models: sub interfaces>+≡
```

```
module function model_var_exists (model, name) result (flag)
  class(model_t), intent(in) :: model
  type(string_t), intent(in) :: name
  logical :: flag
end function model_var_exists
```

```
<Models: procedures>+≡
```

```
module function model_var_exists (model, name) result (flag)
  class(model_t), intent(in) :: model
  type(string_t), intent(in) :: name

```

28.4.6 UFO models

A single flag identifies a model as a UFO model. There is no other distinction, but the flag allows us to handle built-in and UFO models with the same name in parallel.

```

<Models: model: TBP>+≡

```

```

        procedure :: is_ufo_model => model_is_ufo_model
<Models: sub interfaces>+≡
        module function model_is_ufo_model (model) result (flag)
            class(model_t), intent(in) :: model
            logical :: flag
        end function model_is_ufo_model
<Models: procedures>+≡
        module function model_is_ufo_model (model) result (flag)
            class(model_t), intent(in) :: model
            logical :: flag
            flag = model%ufo_model
        end function model_is_ufo_model

```

Return the UFO path used for fetching the UFO source.

```

<Models: model: TBP>+≡
        procedure :: get_ufo_path => model_get_ufo_path
<Models: sub interfaces>+≡
        module function model_get_ufo_path (model) result (path)
            class(model_t), intent(in) :: model
            type(string_t) :: path
        end function model_get_ufo_path
<Models: procedures>+≡
        module function model_get_ufo_path (model) result (path)
            class(model_t), intent(in) :: model
            type(string_t) :: path
            if (model%ufo_model) then
                path = model%ufo_path
            else
                path = ""
            end if
        end function model_get_ufo_path

```

Call OMega and generate a model file from an UFO source file. We start with a file name; the model name is expected to be the base name, stripping extensions.

The path search either takes `ufo_path_requested`, or searches first in the working directory, then in a hard-coded UFO model directory.

```

<Models: procedures>+≡
        subroutine model_generate_ufo (filename, os_data, ufo_path, &
            ufo_path_requested)

    string = filename
    call split (string, model_name, ".")
  end subroutine get_model_name
end subroutine model_generate_ufo

```

28.4.7 Scheme handling

A model can specify a set of allowed schemes that steer the setup of model variables. The model file can contain scheme-specific declarations that are selected by a `select scheme` clause. Scheme support is optional.

If enabled, the model object contains a list of allowed schemes, and the model reader takes the active scheme as an argument. After the model has been read, the scheme is fixed and can no longer be modified.

The model supports schemes if the scheme array is allocated.

```
<Models: model: TBP>+≡
    procedure :: has_schemes => model_has_schemes

<Models: sub interfaces>+≡
    module function model_has_schemes (model) result (flag)
        logical :: flag
        class(model_t), intent(in) :: model
    end function model_has_schemes

<Models: procedures>+≡
    module function model_has_schemes (model) result (flag)
        logical :: flag
        class(model_t), intent(in) :: model
        flag = allocated (model%schemes)
    end function model_has_schemes
```

Enable schemes: fix the list of allowed schemes.

```
<Models: model: TBP>+≡
    procedure :: enable_schemes => model_enable_schemes

<Models: sub interfaces>+≡
    module subroutine model_enable_schemes (model, scheme)
        class(model_t), intent(inout) :: model
        type(string_t), dimension(:), intent(in) :: scheme
    end subroutine model_enable_schemes

<Models: procedures>+≡
    module subroutine model_enable_schemes (model, scheme)
        class(model_t), intent(inout) :: model
        type(string_t), dimension(:), intent(in) :: scheme
        allocate (model%schemes (size (scheme)), source = scheme)
    end subroutine model_enable_schemes
```

Find the scheme. Check if the scheme is allowed. The numeric index of the selected scheme is stored in the `model_data_t` base object.

If no argument is given, select the first scheme. The numeric scheme ID will then be 1, while a model without schemes retains 0.

```
<Models: model: TBP>+≡
    procedure :: set_scheme => model_set_scheme

<Models: sub interfaces>+≡
    module subroutine model_set_scheme (model, scheme)
        class(model_t), intent(inout) :: model
        type(string_t), intent(in), optional :: scheme
    end subroutine model_set_scheme
```

<Models: procedures>+≡

```

module subroutine model_set_scheme (model, scheme)
  class(model_t), intent(inout) :: model
  type(string_t), intent(in), optional :: scheme
  logical :: ok
  integer :: i
  if (model%has_schemes ()) then
    if (present (scheme)) then
      ok = .false.
      CHECK_SCHEME: do i = 1, size (model%schemes)
        if (scheme == model%schemes(i)) then
          allocate (model%selected_scheme, source = scheme)
          call model%set_scheme_num (i)
          ok = .true.
          exit CHECK_SCHEME
        end if
      end do CHECK_SCHEME
      if (.not. ok) then
        call msg_fatal &
          ("Model '" // char (model%get_name ()) &
           // "': scheme '" // char (scheme) // "' not supported")
      end if
    else
      allocate (model%selected_scheme, source = model%schemes(1))
      call model%set_scheme_num (1)
    end if
  else
    if (present (scheme)) then
      call msg_error &
        ("Model '" // char (model%get_name ()) &
         // "' does not support schemes")
    end if
  end if
end subroutine model_set_scheme

```

Get the scheme. Note that the base `model_data_t` provides a `get_scheme_num` getter function.

<Models: model: TBP>+≡

```

procedure :: get_scheme => model_get_scheme

```

<Models: sub interfaces>+≡

```

module function model_get_scheme (model) result (scheme)
  class(model_t), intent(in) :: model
  type(string_t) :: scheme
end function model_get_scheme

```

<Models: procedures>+≡

```

module function model_get_scheme (model) result (scheme)
  class(model_t), intent(in) :: model
  type(string_t) :: scheme
  if (allocated (model%selected_scheme)) then
    scheme = model%selected_scheme
  else
    scheme = ""
  end if
end function

```

```
end function model_get_scheme
```

Check if a model has been set up with a specific name and (if applicable) scheme. This helps in determining whether we need a new model object.

A UFO model is considered to be distinct from a non-UFO model. We assume that if `ufo` is asked for, there is no scheme argument. Furthermore, if there is an `ufo_path` requested, it must coincide with the `ufo_path` of the model. If not, the model `ufo_path` is not checked.

```
<Models: model: TBP>+≡
```

```
procedure :: matches => model_matches
```

```
<Models: sub interfaces>+≡
```

```
module function model_matches &
    (model, name, scheme, ufo, ufo_path) result (flag)
    logical :: flag
    class(model_t), intent(in) :: model

        flag = .false.
    else if (ufo_model .neqv. model%is_ufo_model ()) then
        flag = .false.
    else if (ufo_model) then
        if (present (ufo_path)) then
            flag = model%get_ufo_path () == ufo_path
        else
            flag = .true.
        end if
    else if (model%has_schemes ()) then
        if (present (scheme)) then
            flag = model%get_scheme () == scheme
        else
            flag = model%get_scheme_num () == 1
        end if
    else if (present (scheme)) then
        flag = .false.
    else
        flag = .true.
    end if
```

```
end function model_matches
```

28.4.8 SLHA-type interface

Abusing the original strict SUSY Les Houches Accord (SLHA), we support reading parameter data from some custom SLHA-type input file. To this end, the `model` object stores a list of model-specific block names together with information how to find a parameter in the model record, given a block name and index vector.

Check if the model supports custom SLHA block info. This is the case if `n_slha_block` is nonzero, i.e., after SLHA block names have been parsed and registered.

```
<Models: model: TBP>+≡
  procedure :: supports_custom_slha => model_supports_custom_slha

<Models: sub interfaces>+≡
  module function model_supports_custom_slha (model) result (flag)
    class(model_t), intent(in) :: model
    logical :: flag
  end function model_supports_custom_slha

<Models: procedures>+≡
  module function model_supports_custom_slha (model) result (flag)
    class(model_t), intent(in) :: model
    logical :: flag

    flag = model%n_slha_block > 0

  end function model_supports_custom_slha
```

Return the block names for all SLHA block references.

```
<Models: model: TBP>+≡
  procedure :: get_custom_slha_blocks => model_get_custom_slha_blocks

<Models: sub interfaces>+≡
  module subroutine model_get_custom_slha_blocks (model, block_name)
    class(model_t), intent(in) :: model
    type(string_t), dimension(:), allocatable :: block_name
  end subroutine model_get_custom_slha_blocks

<Models: procedures>+≡
  module subroutine model_get_custom_slha_blocks (model, block_name)
    class(model_t), intent(in) :: model
    type(string_t), dimension(:), allocatable :: block_name

    integer :: i

    allocate (block_name (model%n_slha_block))
    do i = 1, size (block_name)
      block_name(i) = model%slha_block(i)%name
    end do

  end subroutine model_get_custom_slha_blocks
```

This routine registers a SLHA block reference. We have the index of a (new) parameter entry and a parse node from the model file which specifies a block name and an index array.

```

<Models: procedures>+≡
subroutine model_record_slha_block_entry (model, i_par, node)
  class(model_t), intent(inout) :: model
  integer, intent(in) :: i_par
  type(parse_node_t), intent(in), target :: node

  type(parse_node_t), pointer :: node_block_name, node_index
  type(string_t) :: block_name
  integer :: n_index, i, i_block
  integer, dimension(:), allocatable :: block_index

  node_block_name => node%get_sub_ptr (2)
  select case (char (node_block_name%get_rule_key ()))
  case ("block_name")
    block_name = node_block_name%get_string ()

  n_index = node%get_n_sub () - 2
  allocate (block_index (n_index))
  node_index => node_block_name%get_next_ptr ()
  do i = 1, n_index
    block_index(i) = node_index%get_integer ()
    node_index => node_index%get_next_ptr ()
  end do
  i_block = 0
  FIND_BLOCK: do i = 1, model%n_slha_block
    if (model%slha_block(i)%name == block_name) then
      i_block = i
      exit FIND_BLOCK
    end if
  end do FIND_BLOCK
  if (i_block == 0) then
    call model_add_slha_block (model, block_name)
    i_block = model%n_slha_block
  end if
  associate (b => model%slha_block(i_block))
    call add_slha_block_entry (b, block_index, i_par)
  end associate
  model%par(i_par)%block_name = block_name
  model%par(i_par)%block_index = block_index
end subroutine model_record_slha_block_entry

```

Add a new entry to the SLHA block register, increasing the array size if necessary

```

<Models: procedures>+≡
subroutine model_add_slha_block (model, block_name)
  class(model_t), intent(inout) :: model
  type(string_t), intent(in) :: block_name

```

```

    if (.not. allocated (model%slha_block)) allocate (model%slha_block (1))
    if (model%n_slha_block == size (model%slha_block)) call grow
    model%n_slha_block = model%n_slha_block + 1
    associate (b => model%slha_block(model%n_slha_block))
        b%name = block_name
        allocate (b%entry (1))
    end associate

contains

    subroutine grow
        type(slha_block_t), dimension(:), allocatable :: b_tmp
        call move_alloc (model%slha_block, b_tmp)
        allocate (model%slha_block (2 * size (b_tmp)))
        model%slha_block(:size (b_tmp)) = b_tmp(:)
    end subroutine grow

end subroutine model_add_slha_block

```

Add a new entry to a block-register record. The entry establishes a pointer-target relation between an index array within the SLHA block and a parameter-data record. We increase the entry array as needed.

(Models: procedures)+≡

```

subroutine add_slha_block_entry (b, block_index, i_par)
    type(slha_block_t), intent(inout) :: b
    integer, dimension(:), intent(in) :: block_index
    integer, intent(in) :: i_par

    if (b%n_entry == size (b%entry)) call grow
    b%n_entry = b%n_entry + 1
    associate (entry => b%entry(b%n_entry))
        entry%block_index = block_index
        entry%i_par = i_par
    end associate

contains

    subroutine grow
        type(slha_entry_t), dimension(:), allocatable :: entry_tmp
        call move_alloc (b%entry, entry_tmp)
        allocate (b%entry (2 * size (entry_tmp)))
        b%entry(:size (entry_tmp)) = entry_tmp(:)
    end subroutine grow

end subroutine add_slha_block_entry

```

The lookup routine returns a pointer to the appropriate `par_data` record, if `block_name` and `block_index` are valid. The latter point to the `slha_block_t` register within the `model_t` object, if it is allocated.

This should only be needed during I/O (i.e., while reading the SLHA file), so a simple linear search for each parameter should not be a performance problem.

(Models: model: TBP)+≡

```

Read a model from file. Handle all syntax and respect the provided scheme.

The `ufo` flag just says that the model object should be tagged as being derived from an UFO model. The UFO model path may be requested by the caller. If not, we use a standard path search for UFO models. There is no difference in the contents of the file or the generated model object.

```

    end if
end subroutine model_list_add

```

Read a new model from file and add to the list, if it does not yet exist. Finalize the model by allocating the vertex table. Return a pointer to the new model. If unsuccessful, return the original pointer.

The model is always inserted in the last link of a chain of model lists. This way, we avoid loading models twice from different contexts. When a model is modified, we should first allocate a local copy.

28.4.12 Model instances

A model instance is a copy of a model object. The parameters are true copies. The particle data and the variable list pointers should point to the copy, so modifying the parameters has only a local effect. Hence, we build them up explicitly. The vertex array is also rebuilt, it contains particle pointers. Finally, the vertex hash table can be copied directly since it contains no pointers.

The `multiplicity` entry depends on the association of the `mass_data` entry and therefore has to be set at the end.

The instance must carry the `target` attribute.

Parameters: the `copy_parameter` method essentially copies the parameter decorations (parse node, expression etc.). The current parameter values are part of the `model_data_t` base type and are copied afterwards via its `copy_from` method.

Note: the parameter set is initialized for real parameters only.

In order for the local model to be able to use the correct UFO model setup, UFO model information has to be transferred.

```

<Models: model: TBP>+≡
    procedure :: init_instance => model_copy

<Models: sub interfaces>+≡
    module subroutine model_copy (model, orig)

```

28.5.1 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

A name clash occurs if the block name is identical to a keyword. This can happen for custom SLHA models and files. In that case, we prepend an underscore, which will be silently suppressed where needed.

```

end subroutine slha_preprocess

```

Return the mode that we should treat this block with. We add the `custom_block_name` array to the set of supported blocks, which otherwise includes only hard-coded block names. Those custom blocks are data blocks.

Unknown blocks will be skipped altogether. The standard does not specify their internal format at all, so we must not parse their content.

If the name of a (custom) block clashes with a keyword of the SLHA syntax, we append an underscore to the block name, modifying the current line string. This should be silently suppressed when actually parsing block names.

```

<SLHA: procedures> +=
subroutine check_block_handling (line, custom_block_name, mode)
    type(string_t), intent(inout) :: line
    type(string_t), dimension(:), intent(in) :: custom_block_name
    integer, intent(out) :: mode
    type(string_t) :: buffer, key, block_name
    integer :: i
    buffer = trim (line)
    call split (buffer, key, " ")
    buffer = adjustl (buffer)
    call split (buffer, block_name, " ")
    buffer = adjustl (buffer)
    block_name = trim (adjustl (upper_case (block_name)))
    select case (char (block_name))
    case ("MODSEL", "MINPAR", "SMINPUTS")
        mode = MODE_DATA
    case ("MASS")
        mode = MODE_DATA
    case ("NMIX", "UMIX", "VMIX", "STOPMIX", "SBOTMIX", "STAUMIX")
        mode = MODE_DATA
    case ("NMHMIX", "NMAMIX", "NMNMIX", "NMSSMRUN")
        mode = MODE_DATA
    case ("ALPHA", "HMIX")
        mode = MODE_DATA
    case ("AU", "AD", "AE")
        mode = MODE_DATA
    case ("SPINFO", "DCINFO")
        mode = MODE_INFO
    end select
end subroutine

```

```

case default
  mode = MODE_SKIP

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

<SLHA: public>+≡

```

The concrete SLHA interpreter

SLHA codes for particular physics models

```
<SLHA: parameters>+≡
  integer, parameter :: MDL_MSSM = 0
  integer, parameter :: MDL_NMSSM = 1
```

Take the parse tree and extract relevant data. Select the correct model and store all data that is present in the appropriate variable list. Finally, update the variable record.

We assume that if the model contains custom SLHA block names, we just have to scan those to get complete information. Block names could coincide with the SLHA standard block names, but we do not have to assume this. This will be the situation for an UFO-generated file. In particular, an UFO file should contain all expressions necessary for computing dependent parameters, so we can forget about the strict SLHA standard and its hard-coded conventions.

If there are no custom SLHA block names, we should assume that the model is a standard SUSY model, and the parameters and hard-coded blocks can be read as specified by the original SLHA standard. There are hard-coded block names and parameter calculations.

Public for use in unit test.

MODSEL

Handle the overall model definition. Only certain models are recognized. The soft-breaking model templates that determine the set of input parameters.

This block used to be required, but for generic UFO model support we should allow for its absence. In that case, `mssm_type` will be set to a negative value. If the block is present, the model must be one of the following, or parsing ends with an error.

SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is not defined in the block, we use the previous value from the model variable list. For the basic parameters we have to do a small recalculation, since SLHA uses the G_F - α - m_Z scheme, while WHIZARD derives them from G_F , m_W , and m_Z .

  end do
end subroutine slha_handle_decays
```

Mixing matrices

Read mixing matrices. We can treat all matrices by a single procedure if we just know the block name, variable prefix, and matrix dimension. The matrix dimension must be less than 10. For the pseudoscalar Higgses in NMSSM-type models we need off-diagonal matrices, so we generalize the definition.

(*SLHA: procedures*) +=

```
subroutine slha_handle_matrix_block &
  (parse_tree, block_name, var_prefix, dim1, dim2, model)
  type(parse_tree_t), intent(in) :: parse_tree
  character(*), intent(in) :: block_name, var_prefix
  integer, intent(in) :: dim1, dim2
  type(model_t), intent(inout), target :: model
  type(parse_node_t), pointer :: pn_block
  type(var_list_t), pointer :: var_list

call set_data_item (pn_block, 5, var_str ("nmu"), var_list)
end subroutine slha_handle_NMSSMRUN

```

28.5.5 Parsing custom SLHA files

With the introduction of UFO models, we support custom files in generic SLHA format that reset model parameters. In contrast to strict SLHA files, the order and naming of blocks is arbitrary.

We scan the complete file (i.e., preprocessed parse tree), parsing all blocks that contain data lines. For each data line, we identify index array and associated value. Then we set the model parameter that is associated with that block name and index array, if it exists.

```

<SLHA: procedures>+=
subroutine slha_handle_custom_file (parse_tree, model)
  type(parse_tree_t), intent(in) :: parse_tree
  type(model_t), intent(inout), target :: model

  type(parse_node_t), pointer :: pn_root, pn_block

! FB: -replaced tabs by 2 whitespaces
!      -reduced hardcoded default stepsize for subroutine 'odeint'
!      called by hypgeo, cf. line 4751
!      -added explicit interface for function 'qgaus' to main module 'nr'

```

```
!      -renamed function 'locate' to 'locatenr' to avoid segfault (???)
!  
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

```

c   xcutn    : numerical UV cutoff on all momenta
c              (UV cutoff of the Gauss-Legendre grid)
c   xcutv    : renormalization cutoff on the
c              delta-, the  $(p^2+q^2)/(p-q)^2$ -, and the
c               $1/r^2 - [1/|p-q|]$ -potential:
c              if  $(\max(p,q) \geq \text{xcutv})$  then the three potentials
c              are set to zero in the Lippmann-Schwinger equation
c   xc0      : 0th order coefficient for the Coulomb potential,
c              see calling example above
c   xc1      : 1st order coefficient for the Coulomb potential
c   xc2      : 2nd order coefficient for the Coulomb potential
c   xcdeltc  : constant of the delta(r)-
c              [= constant in momentum space-] potential
c   xcdeltl  : constant for the additional  $\log(q^2/\mu^2)$ -part of the
c              delta-potential:
c               $\text{xcdeltc} * 1 + \text{xcdeltl} * \log(q^2/\mu^2)$ 
c   xcfullc  : constant of the  $(p^2+q^2)/(p-q)^2$ -potential
c   xcfulll  : constant for the additional  $\log(q^2/\mu^2)$ -part of the
c               $(p^2+q^2)/(p-q)^2$ -potential
c   xcrm2    : constant of the  $1/r^2 - [1/|p-q|]$ -potential
c   xkincm   : } kinetic corrections in the 0th order Green-function:
c   xkinca   : }  $G_0(p) := 1/[E + i\Gamma_t - p^2/m_t] * (1 + xkincm) + xkinca$ 
c              !!! WATCH THE SIGN IN  $G_0$  !!!
c   jknflg   : flag for these kinetic corrections:
c              0 : no kinetic corrections applied
c              1 : kinetic corrections applied with cutoff xcutv
c                  for xkinca only
c              2 : kinetic corrections applied with cutoff xcutv
c                  for xkinca AND xkincm
c   jgcflg   : flag for  $G_0(p)$  in the LS equation:
c              0 (standard choice) :  $G_0(p)$  as given above
c              1 (for TIPT)         :  $G_0(p) = G_c^{\{0\}}(p)$  the 0th
c                                      order Coulomb-Green-function
c                                      in analytical form; not for
c                                      momenta  $p > 1000 \cdot \text{topmass}$ 
c   xkincv   : additional kinematic vertexcorrection in  $G_0$ , see below:
c   jvflg    : flag for the additional vertexcorrection xkincv in the
c              "zeroth order"  $G_0(p)$  in the LS-equation:
c              0 : no correction, means  $G = G_0 + G_0 \text{ int } V G$ 
c                  with  $G_0 = 1/[E + i\Gamma_t - p^2/m_t] * (1 + xkincm) + xkinca$ 
c              1 : apply the correction in the LS equation as
c                   $G = G_0 + xkincv * p^2/m_t^2 / [E + i\Gamma_t - p^2/m_t] +$ 
c                   $G_0 \text{ int } V G$ 
c                  and correct the integral over  $\text{Im}[G(p)]$  to get  $\text{sigma}_{\text{tot}}$ 

```

```

c          from the optical theorem by the same factor.
c          The cutoff xcutv is applied for these corrections.
c
c - Output:
c
c   xim      : R_{ttbar} from the imaginary part of the green
c              function
c   xdi      : R_{ttbar} form the integral over the momentum
c              distribution (no cutoff but the numerical one here!!)
c   np       : number of points used for the grid; fixed in tttoppik
c   xpp      : 1-dim array (max. 900 elements) giving the momenta of
c              the Gauss-Legendre grid (pp(i) in the code)
c   xww      : 1-dim array (max. 900 elements) giving the corresponding
c              Gauss-Legendre weights for the grid
c   xdsdp    : 1-dim array (max. 900 elements) giving the
c              momentum distribution of top: d\sigma/dp,
c              normalized to R,
c              at the momenta of the Gauss-Legendre grid xpp(i)
c   zvfct    : 1-dim array (max. 900 elements) of COMPLEX*16 numbers
c              giving the vertex function K(p), G(p)=K(p)*G_0(p)
c              at the momenta of the grid

c Cut for divergent potential-terms for large momenta in the function vhat
c and in the integrals a(p):
        dcut=xcutv
c
c Numerical Cutoff of all momenta (maximal momenta of the grid):

```

```

        xpmx=xcutn
        if (dcut.gt.xpmx) then
            write(*,*) ' dcut > xpmx  makes no sense! Stop.'
            stop
        endif
c
c Not needed for the fixed order potentials:
        alamb5=0.2d0
c
c        WRITE(*,*) 'INPUT TGAMMA=',TGAMMA
c Needed in subroutine GAMMAT:
        GFERMI=1.16637d-5
c        CALL GAMMAT
c        WRITE(*,*) 'CALCULATED TGAMMA=',TGAMMA
c
        etot=2.d0*tmass+energy
c
        if ((npot.eq.1).or.(npot.eq.3).or.(npot.eq.4).or.
            u      (npot.eq.5)) then
c For pure coulomb and fixed order potentials there is no delta-part:
            consde = 0.d0
            else if (npot.eq.2) then
c Initialize QCD-potential common-blocks and calculate constant multiplying
c the delta-part of the 'qcutted' potential in momentum-space:
                call iniphc(1)
                call vqdelt(consde)
            else
                write (*,*) ' Potential not implemented! Stop.'
                stop
            endif
c Delta-part of potential is absorbed by subtracting vzero from the
c original energy (shift from the potential to the free Hamiltonian):
            vzero = consde / (2.d0*pi)**3
c            write (*,*) 'vzero=', vzero
c
c Find x-values pp(i) and weights w1(i) for the gaussian quadrature;
c care about large number of points in the important intervals:
c        if (energy-vzero.le.0.d0) then
cc            call gauleg(0.d0, 1.d0, pp, w1, n/3)
cc            call gauleg(1.d0, 5.d0, pp(n/3+1), w1(n/3+1), n/3)
cc            call gauleg(0.d0, 0.2d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c            call gauleg(0.d0, 5.d0, pp, w1, n/3)
c            call gauleg(5.d0, 20.d0, pp(n/3+1), w1(n/3+1), n/3)
c            call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c        else
cc Avoid numerical singular points in the inner of the intervals:
c            critp = dsqrt((energy-vzero)*tmass)
c            if (critp.le.1.d0) then
cc Gauss-Legendre is symmetric => automatically principal-value prescription:
c                call gauleg(0.d0, 2.d0*critp, pp, w1, n/3)
c                call gauleg(2.d0*critp, 20.d0, pp(n/3+1),
c                    u      w1(n/3+1), n/3)
c                call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c            else

```

```

cc Better behaviour at the border of the intervals:
c      call gauleg(0.d0, critp, pp, w1, n/3)
c      call gauleg(critp, 2.d0*critp, pp(n/3+1),
c      u      w1(n/3+1), n/3)
c      call gauleg(0.d0, 1.d0/(2.d0*critp), pp(2*n/3+1),
c      u      w1(2*n/3+1), n/3)
c      endif
c      endif
c
c Or different (simpler) method, good for V_JKT:
c      if (energy.le.0.d0) then
c          critp=tmass/3.d0
c      else
c          critp=max(tmass/3.d0,2.d0*dsqrt(energy*tmass))
c      endif
c      call gauleg(0.d0, critp, pp, w1, 2*n/3)
c      call gauleg(1.d0/xpmax, 1.d0/critp, pp(2*n/3+1),
c      u      w1(2*n/3+1), n/3)
c
c Do substitution  $p \Rightarrow 1/p$  for the last interval explicitly:
c      do 10 i=2*n/3+1,n
c          pp(i) = 1.d0/pp(i)
10      continue
c
c Reorder the arrays for the third interval:
c      do 20 i=1,n/3
c          xx(i) = pp(2*n/3+i)
c          w2(i) = w1(2*n/3+i)
20      continue
c      do 30 i=1,n/3
c          pp(n-i+1) = xx(i)
c          w1(n-i+1) = w2(i)
30      continue
c
c Calculate the integrals  $a(p)$  for the given momenta  $pp(i)$ 
c and store weights and momenta for the output arrays:
c      do 40 i=1,n
c          a1(i) = a(pp(i)) !!! FB: can get stuck in original Toppik!
c          !!! FB: abuse 'np' as a flag to communicate unstable runs
c          if ( abs(a1(i)) .gt. 1d10 ) then
c              np = -1
c              return
c          endif
c          xpp(i)=pp(i)
c          xww(i)=w1(i)
40      continue
c      do 41 i=n+1,nmax
c          xpp(i)=0.d0
c          xww(i)=0.d0
41      continue
c
c Solve the integral-equation by solving a system of algebraic equations:
c      call sae(pp, w1, bb, a1, n)
c

```

```

c (The substitution for the integration to infinity pp => 1/pp
c is done already.)
      do 50 i=1,n

c      Correction function for non-constant (energy and momentum dependent) width:
c          FUNCTION GTPCOR1(TOPP,ETOT)
c
c          TOPP - momentum of t quark = - momentum of tbar
c          ETOT - total energy of t-tbar system
c          calls: GENWDS, RAN2
c
c          Evaluates a correction factor to the width of t-tbar system.
c          in future has to be replaced by a function evaluating
c          width including radiative corrections and GTPCOR.
c          I include two factors reducing the width:
c          a - time dilatation: for decay in flight lifetime
c              increased accordingly to relativistic kinematics
c          b - overall energy-momentum conservation: I assume that
c              t and tbar decay in flight and in this decays energies
c              of Ws follow from 2-body kinematics. Then I calculate
c              effective mass squared of b-bar system (it may be
c              negative!) from en-momentum conservation.
c              If effective mass is < 2*Mb + 2 GeV configuration
c              is rejected. The weight is acceptance.

C *****

```

```

c      Version tuned to provide 0(1%) relative accuracy for Coulomb axial
c      vertex function at first and second order (search for 'cctt'):
c      - integrals A(p), Vhat, Vhhat provided analytically w/out cut-off
c      - grid range fixed to 0.1 ... 10**6 absolut
c      - and grid size enhanced to 600 points (900 foreseen in arrays).
c
c      This provides a compromise between stability and accuracy:
c      We need a relatively high momentum resolution and large maximal
c      momenta to achieve a ~1 percent accuracy, but the method of
c      direct inversion of the discretised integral equation for objects
c      whose integral is divergent induces instabilities at small
c      momenta. As the behaviour there is known, they can be cut off and
c      the vertex function fixed by hand; but limiting the grid
c      further would impact on the accuracy.
c      22.3.2017, tt
c *****
c
c Working version with all the different original potentials
c like (p^2+q^2)/|p-q|^2, not transformed in terms of delta and 1/r^2;
c accuracy eps=1.d-3 possible (only), but should be save, 13.8.'98, tt.
c cleaned up a bit, 24.2.1999, tt.
c
c *****

c !!! Only P wave result given as output!!! 9.4.1999, tt.
c
c - Calculation of the Green function in momentum space by solving the
c   Lippmann-Schwinger equation
c   
$$F(p) = G_0(p) + G_0(p) \int_0^{\text{xcutn}} V(p,q) q.p/p^2 F(q) dq$$

c
c - Written by Thomas Teubner, Hamburg, November 1998
c   * Based on TOPPIK Version 1.1
c     from M. Jezabek and TT, Karlsruhe, June 1992
c   * Version originally for non-constant top-width
c   * Constant width supplied here
c   * No generator included
c
c - Use of double precision everywhere
c
c - All masses, momenta, energies, widths in GeV
c
c - Input parameters:
c

```

```

c   xenergy : E=Sqrt[s]-2*topmass
c   xtm      : topmass (in the Pole scheme)
c   xtg      : top-width
c   xalphas  : alpha_s^{MSbar,n_f=5}(xscale)
c   xscale   : soft scale mu_{soft}
c   xcutn    : numerical UV cutoff on all momenta
c              (UV cutoff of the Gauss-Legendre grid)
c   xcutv    : renormalization cutoff on the
c              delta-, the (p^2+q^2)/(p-q)^2-, and the
c              1/r^2-[1/|p-q|]-potential:
c              if (max(p,q).ge.xcutv) then the three potentials
c              are set to zero in the Lippmann-Schwinger equation
c   xc0      : 0th order coefficient for the Coulomb potential,
c              see calling example above
c   xc1      : 1st order coefficient for the Coulomb potential
c   xc2      : 2nd order coefficient for the Coulomb potential
c   xcdeltc  : constant of the delta(r)-
c              [= constant in momentum space-] potential
c   xcdeletl : constant for the additional log(q^2/mu^2)-part of the
c              delta-potential:
c              xcdeltc*1 + xcdeletl*log(q^2/mu^2)
c   xcfullc  : constant of the (p^2+q^2)/(p-q)^2-potential
c   xcfulll  : constant for the additional log(q^2/mu^2)-part of the
c              (p^2+q^2)/(p-q)^2-potential
c   xcrm2    : constant of the 1/r^2-[1/|p-q|]-potential
c   xkincm   : } kinetic corrections in the 0th order Green function:
c   xkinca   : } G_0(p):=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c             !!! WATCH THE SIGN IN G_0 !!!
c   jknflg   : flag for these kinetic corrections:
c               0 : no kinetic corrections applied
c               1 : kinetic corrections applied with cutoff xcutv
c                   for xkinca only
c               2 : kinetic corrections applied with cutoff xcutv
c                   for xkinca AND xkincm
c   jgcflg   : flag for G_0(p) in the LS equation:
c               0 (standard choice) : G_0(p) as given above
c               1 (for TIPT)         : G_0(p) = G_c^{0}(p) the 0th
c                                       order Coulomb Green function
c                                       in analytical form; not for
c                                       momenta p > 1000*topmass
c   xkincv   : additional kinematic vertexcorrection in G_0, see below:
c   jvflg    : flag for the additional vertexcorrection xkincv in the
c               "zeroth order" G_0(p) in the LS-equation:
c               0 : no correction, means G = G_0 + G_0 int V G
c                   with G_0=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c               1 : apply the correction in the LS equation as
c                   G = G_0 + xkincv*p^2/m_t^2/[E+iGamma_t-p^2/m_t] +
c                   G_0 int V G
c               and correct the integral over Im[G(p)] to get sigma_tot
c               from the optical theorem by the same factor.
c               The cutoff xcutv is applied for these corrections.
c
c - Output:
c

```

```

c      xim      : R^{P wave}_{ttbar} from the imaginary part of the Green
c                function
c      xdi      : R^{P wave}_{ttbar} from the integral over the momentum
c                distribution:  $\int_0^{x_{cutv}} dp p^3/m_t * |F(p,E)|^2$ 
c      np       : number of points used for the grid; fixed in tttoppik
c      xpp      : 1-dim array (max. 900 elements) giving the momenta of
c                the Gauss-Legendre grid (pp(i) in the code)
c      xww      : 1-dim array (max. 900 elements) giving the corresponding
c                Gauss-Legendre weights for the grid
c      xdsdp    : 1-dim array (max. 900 elements) giving the
c                momentum distribution of top:  $d\sigma^{P \text{ wave}}/dp$ ,
c                normalized to R,
c                at the momenta of the Gauss-Legendre grid xpp(i)
c      zftild   : 1-dim array (max. 900 elements) of COMPLEX*16 numbers
c                giving the vertex function K_A for the P-wave
c                at the momenta of the grid.
c                Then  $F(p)=K_A(p)*G_0(p)$  corresponding to  $G=K_V*G_0$ .

c      u          w1(2*n/3+1), n/3)
c      endif
c  endif
c
c Or different (simpler) method, good for V_JKT:
c      if (energy.le.0.d0) then
c          critp=tmass/3.d0
c      else
c          critp=max(tmass/3.d0,2.d0*sqrt(energy*tmass))
c      endif
c      call gauleg(0.d0, critp, pp, w1, 2*n/3)
c      call gauleg(1.d0/xpmax, 1.d0/critp, pp(2*n/3+1),
c      u          w1(2*n/3+1), n/3)
cctt Tuned March 2017 for best possible numerical behaviour of P-wave
c      call gauleg(0.1d0, 2.d0, pp, w1, 10)
c      call gauleg(2.d0, critp, pp(11), w1(11), 2*n/3-10)
c      call gauleg(1.d-6, 1.d0/critp, pp(2*n/3+1),
c      u          w1(2*n/3+1), n/3)
c
c Do substitution  $p \Rightarrow 1/p$  for the last interval explicitly:
c      do 10 i=2*n/3+1,n
c          pp(i) = 1.d0/pp(i)
10      continue
c
c Reorder the arrays for the third interval:
c      do 20 i=1,n/3
c          xx(i) = pp(2*n/3+i)
c          w2(i) = w1(2*n/3+i)
20      continue
c      do 30 i=1,n/3
c          pp(n-i+1) = xx(i)
c          w1(n-i+1) = w2(i)
30      continue
c
c Calculate the integrals aax(p) for the given momenta pp(i)
c and store weights and momenta for the output arrays:
c      do 40 i=1,n
c          a1(i) = aax(pp(i)) !!! FB: can get stuck in original Toppik!
c          !!! FB: abuse 'np' as a flag to communicate unstable runs
c          if ( abs(a1(i)) .gt. 1d10 ) then
c              np = -1
c              return
c          endif
c          xpp(i)=pp(i)
c          xww(i)=w1(i)
40      continue
c      do 41 i=n+1,nmax
c          xpp(i)=0.d0
c          xww(i)=0.d0
41      continue
c

```

```

Chapter 30

Integration and Process Objects

This is the central part of the **WHIZARD** package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

subevt_expr This enables process observables as (abstract) expressions, to be evaluated for each process call.

parton_states A **parton_state_t** object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

process Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: **prc_core** for matrix-element evaluation, **prc_core_def** for the associated configuration and driver, **sf_base** for beams and structure-functions, **phs_base** for phase space, and **mci_base** for integration and event generation.

process_config

process_counter Very simple object for statistics

process_mci

pcm

kinematics

instances While the above modules set up all static information, the instances have the changing event data. There are term and process instances but no component instances.

process_stacks Process stacks collect process objects.

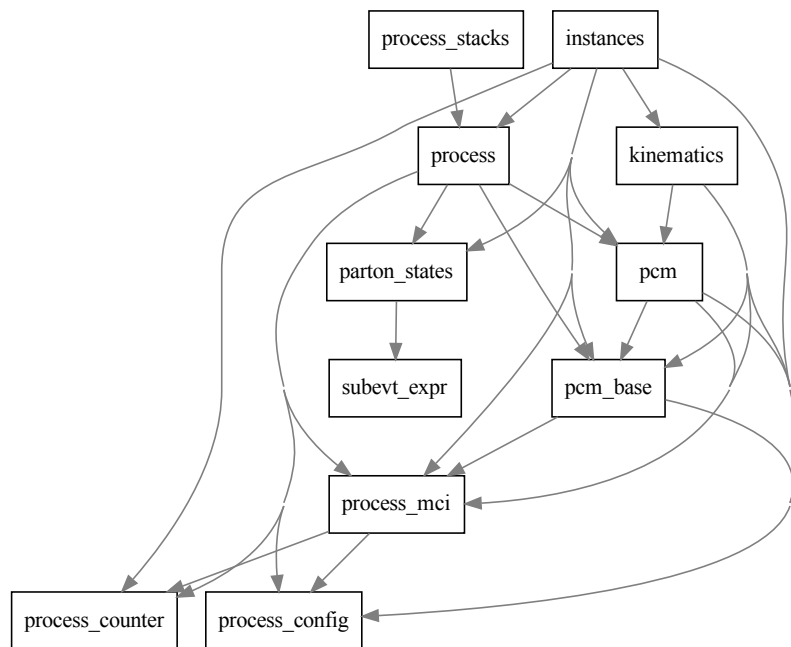

Figure 30.1: Module dependencies in `src/process_integration`.

We combine here hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the `computed` state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the `observed` state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible subsequent decay processes on the parton level, which are full-fledged process objects themselves.

30.1 Process observables

We define an abstract `subevt_expr_t` object as an extension of the `subevt_t` type. The object contains a local variable list, variable instances (as targets for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the `subevt`.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression `selection` which determines whether the object passes user-defined cuts.

The intention is that we fill the `subevt_t` base object and compute the variables once we have evaluated a kinematical phase space point (or a complete event). We then evaluate the expressions and can use the results in further calculations.

The `process_expr_t` extension contains furthermore scale and weight expressions. The `event_expr_t` extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the

variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

Note that there are unit tests, but they are deferred to the `expr_tests` module.

  end subroutine subevt_expr_final

```

30.1.2 Initialization

Initialization: define local variables and establish pointers.

The common variables are `sqrts` (the nominal beam energy, fixed), `sqrts_hat` (the actual energy), `n_in`, `n_out`, and `n_tot` for the subevt. With the exception of `sqrts`, all are implemented as pointers to subobjects.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure (subevt_expr_setup_vars), deferred :: setup_vars
  procedure :: base_setup_vars => subevt_expr_setup_vars

<Subevt expr: sub interfaces>+≡
  module subroutine subevt_expr_setup_vars (expr, sqrts)
    class(subevt_expr_t), intent(inout), target :: expr
    real(default), intent(in) :: sqrts
  end subroutine subevt_expr_setup_vars

<Subevt expr: procedures>+≡
  module subroutine subevt_expr_setup_vars (expr, sqrts)
    class(subevt_expr_t), intent(inout), target :: expr
    real(default), intent(in) :: sqrts
    call expr%var_list%final ()
    call expr%var_list%append_real (var_str ("sqrts"), sqrts, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call expr%var_list%append_real_ptr (var_str ("sqrts_hat"), &
      expr%sqrts_hat, is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call expr%var_list%append_int_ptr (var_str ("n_in"), expr%n_in, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)

      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call expr%var_list%append_int_ptr (var_str ("n_tot"), expr%n_tot, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)

```

```
end subroutine subevt_expr_setup_vars
```

Append the subevent expr (its base-type core) itself to the variable list, if it is not yet present.

```
<Subevt expr: subevt expr: TBP>+≡
  procedure :: setup_var_self => subevt_expr_setup_var_self

<Subevt expr: sub interfaces>+≡
  module subroutine subevt_expr_setup_var_self (expr)
    class(subevt_expr_t), intent(inout), target :: expr
  end subroutine subevt_expr_setup_var_self

<Subevt expr: procedures>+≡
  module subroutine subevt_expr_setup_var_self (expr)
    class(subevt_expr_t), intent(inout), target :: expr
    if (.not. expr%var_list%contains (var_str ("@evt"))) then
      call expr%var_list%append_subevt_ptr &
        (var_str ("@evt"), expr%subevt_t, &
          is_known = expr%subevt_filled, &
          locked = .true., verbose = .false., intrinsic=.true.)
    end if
  end subroutine subevt_expr_setup_var_self
```

Link a variable list to the local one. This could be done event by event, but before evaluating expressions.

```
<Subevt expr: subevt expr: TBP>+≡
  procedure :: link_var_list => subevt_expr_link_var_list

<Subevt expr: sub interfaces>+≡
  module subroutine subevt_expr_link_var_list (expr, var_list)
    class(subevt_expr_t), intent(inout) :: expr
    type(var_list_t), intent(in), target :: var_list
  end subroutine subevt_expr_link_var_list

<Subevt expr: procedures>+≡
  module subroutine subevt_expr_link_var_list (expr, var_list)
    class(subevt_expr_t), intent(inout) :: expr
    type(var_list_t), intent(in), target :: var_list
    call expr%var_list%link (var_list)
  end subroutine subevt_expr_link_var_list
```

Compile the selection expression. If there is no expression, the build method will not allocate the expression object.

```
<Subevt expr: subevt expr: TBP>+≡
  procedure :: setup_selection => subevt_expr_setup_selection

<Subevt expr: sub interfaces>+≡
  module subroutine subevt_expr_setup_selection (expr, ef_cuts)

    class(expr_factory_t), intent(in) :: ef_cuts
  end subroutine subevt_expr_setup_selection
```

```

<Subvt expr: procedures>+≡
  module subroutine subvt_expr_setup_selection (expr, ef_cuts)
    class(subvt_expr_t), intent(inout), target :: expr
    class(expr_factory_t), intent(in) :: ef_cuts
    call ef_cuts%build (expr%selection)
    if (allocated (expr%selection)) then
      call expr%setup_var_self ()
      call expr%selection%setup_lexpr (expr%var_list)
      expr%has_selection = .true.
    end if
  end subroutine subvt_expr_setup_selection

```

(De)activate color storage and evaluation for the expression. The subevent particles will have color information.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: colorize => subvt_expr_colorize

<Subvt expr: sub interfaces>+≡
  module subroutine subvt_expr_colorize (expr, colorize_subvt)
    class(subvt_expr_t), intent(inout), target :: expr
    logical, intent(in) :: colorize_subvt
  end subroutine subvt_expr_colorize

<Subvt expr: procedures>+≡
  module subroutine subvt_expr_colorize (expr, colorize_subvt)
    class(subvt_expr_t), intent(inout), target :: expr
    logical, intent(in) :: colorize_subvt
    expr%colorize_subvt = colorize_subvt
  end subroutine subvt_expr_colorize

```

30.1.3 Evaluation

Reset to initial state, i.e., mark the subvt as invalid.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: reset_contents => subvt_expr_reset_contents
  procedure :: base_reset_contents => subvt_expr_reset_contents

<Subvt expr: sub interfaces>+≡
  module subroutine subvt_expr_reset_contents (expr)
    class(subvt_expr_t), intent(inout) :: expr
  end subroutine subvt_expr_reset_contents

<Subvt expr: procedures>+≡
  module subroutine subvt_expr_reset_contents (expr)
    class(subvt_expr_t), intent(inout) :: expr
    expr%subvt_filled = .false.
  end subroutine subvt_expr_reset_contents

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: base_evaluate => subvt_expr_evaluate

```

```

<Subevt expr: sub interfaces>+≡
    module subroutine subevt_expr_evaluate (expr, passed)
        class(subevt_expr_t), intent(inout) :: expr
        logical, intent(out) :: passed
    end subroutine subevt_expr_evaluate

<Subevt expr: procedures>+≡
    module subroutine subevt_expr_evaluate (expr, passed)
        class(subevt_expr_t), intent(inout) :: expr
        logical, intent(out) :: passed
        if (expr%has_selection) then
            call expr%selection%evaluate ()
            if (expr%selection%is_known ()) then
                passed = expr%selection%get_log ()
            else

    end if
end subroutine parton_expr_setup_weight

```

Filling the partonic state consists of two parts. The first routine prepares the subevt without assigning momenta. It takes the particles from an `interaction_t`. It needs the indices and flavors for the beam, incoming, and outgoing particles.

We can assume that the particle content of the subevt does not change. Therefore, we set the event variables `n_in`, `n_out`, `n_tot` already in this initialization step.

```

30.1.5 Implementation for full events

This implementation contains the expressions that we can evaluate for the full event. It also contains data that pertain to the event, suitable for communication with external event formats. These data simultaneously serve as pointer targets for the variable lists hidden in the expressions (eval trees).

Squared matrix element and weight values: when reading events from file, the **ref** value is the number in the file, while the **prc** value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of **alt** values is copied from an array of alternative event records. These values should represent calculated values.

```

30.2 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states, depending on the the beam setup allows. The result is used for integration.

The `matrix` evaluator is the counterpart of `trace` which is kept exclusive in all observable quantum numbers. The `flows` evaluator is furthermore exclusive in colors, but neglecting all color interference. The `matrix` and `flows` evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. The extra `has_XXX` flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the `processes` module below.

```

    contains

    <Parton states: procedures>

    end submodule parton_states_s

```

30.2.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

    <Parton states: types>≡
    type, abstract :: parton_state_t
    logical :: has_trace = .false.
    logical :: has_matrix = .false.
    logical :: has_flows = .false.
    type(evaluator_t) :: trace
    type(evaluator_t) :: matrix
    type(evaluator_t) :: flows
    contains
    <Parton states: parton state: TBP>

```

```
end type parton_state_t
```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both are implemented as a pointer. The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```
<Parton states: public>≡
  public :: isolated_state_t

<Parton states: types>+≡
  type, extends (parton_state_t) :: isolated_state_t
    logical :: sf_chain_is_allocated = .false.
    type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()
    logical :: int_is_allocated = .false.
    type(interaction_t), pointer :: int_eff => null ()
  contains
    <Parton states: isolated state: TBP>
  end type isolated_state_t
```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

```
<Parton states: public>+≡
  public :: connected_state_t

<Parton states: types>+≡
  type, extends (parton_state_t) :: connected_state_t
    type(state_flv_content_t) :: state_flv
    logical :: has_flows_sf = .false.
    type(evaluator_t) :: flows_sf
    logical :: has_expr = .false.
    type(parton_expr_t) :: expr
  contains
    <Parton states: connected state: TBP>
  end type connected_state_t
```

Output: each evaluator is written only when it is active. The `sf_chain` is only written if it is explicitly allocated.

```
<Parton states: parton state: TBP>≡
  procedure :: write => parton_state_write

<Parton states: sub interfaces>≡

```

30.2.2 Common Initialization

Initialize the isolated parton state. In this version, the effective structure-function chain `sf_chain_eff` and the effective interaction `int_eff` both are trivial pointers to the seed structure-function chain and to the hard interaction, respectively.

```

(Parton states: isolated state: TBP)≡
  procedure :: init => isolated_state_init

(Parton states: sub interfaces)+≡
  module subroutine isolated_state_init (state, sf_chain, int)
    class(isolated_state_t), intent(out) :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(interaction_t), intent(in), target :: int
  end subroutine isolated_state_init

(Parton states: procedures)+≡
  module subroutine isolated_state_init (state, sf_chain, int)
    class(isolated_state_t), intent(out) :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(interaction_t), intent(in), target :: int
    state%sf_chain_eff => sf_chain
    state%int_eff => int
  end subroutine isolated_state_init

```

30.2.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask_in`.

There are two options: explicitly computing the color factor table (`use_cf` false; `nc` defined), or taking the color factor table from the hard matrix element data.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_square_trace => isolated_state_setup_square_trace

(Parton states: sub interfaces)+≡
  module subroutine isolated_state_setup_square_trace (state, core, &
    qn_mask_in, col, keep_fs_flavor)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), intent(in), dimension(:) :: qn_mask_in
    integer, intent(in), dimension(:), allocatable :: col
    logical, intent(in) :: keep_fs_flavor
  end subroutine isolated_state_setup_square_trace

(Parton states: procedures)+≡
  module subroutine isolated_state_setup_square_trace (state, core, &
    qn_mask_in, col, keep_fs_flavor)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), intent(in), dimension(:) :: qn_mask_in
    !!! Actually need allocatable attribute here for once because col might
    !!! enter the subroutine non-allocated.

```

```

integer, intent(in), dimension(:), allocatable :: col
logical, intent(in) :: keep_fs_flavor
type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
associate (data => core%data)
  allocate (qn_mask (data%n_in + data%n_out))
  qn_mask( : data%n_in) = &
    quantum_numbers_mask (.false., .true., .false.) &
    .or. qn_mask_in
  qn_mask(data%n_in + 1 : ) = &
    quantum_numbers_mask (.not. keep_fs_flavor, .true., .true.)
  if (core%use_color_factors) then
    call state%trace%init_square (state%int_eff, qn_mask, &
      col_flow_index = data%cf_index, &
      col_factor = data%color_factors, &
      col_index_hi = col, &
      nc = core%nc)
  else
    call state%trace%init_square (state%int_eff, qn_mask, nc = core%nc)
  end if
end associate
state%has_trace = .true.
end subroutine isolated_state_setup_square_trace

```

Set up an identity-evaluator for the trace. This implies that `me` is considered to be a squared amplitude, as for example for BLHA matrix elements.

(Parton states: isolated state: TBP)+≡

```

procedure :: setup_identity_trace => isolated_state_setup_identity_trace

```

    allocate (qn_mask (data%n_in + data%n_out))
    qn_mask( : data%n_in) = &
      quantum_numbers_mask (.false., col_flag, .false.) .or. qn_mask_in
    qn_mask(data%n_in + 1 : ) = &
      quantum_numbers_mask (fs_flg_flag, col_flag, .true.)
  end associate
end subroutine isolated_state_setup_identity_trace

```

```

end associate
call state%int_eff%set_mask (qn_mask)
call state%trace%init_identity (state%int_eff)
state%has_trace = .true.
end subroutine isolated_state_setup_identity_trace

```

Set up the evaluator for the transition matrix, exclusive in helicities where this is requested.

For all unstable final-state particles we keep polarization according to the applicable decay options. If the process is a decay itself, this applies also to the initial state.

For all polarized final-state particles, we keep polarization including off-diagonal entries. We drop helicity completely for unpolarized final-state particles.

For the initial state, if the particle has not been handled yet, we apply the provided `qn_mask_in` which communicates the beam properties.

```

30.2.4 Evaluator initialization: connected state

Set up a trace evaluator as a product of two evaluators (incoming state, effective interaction). In the result, all quantum numbers are summed over.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`.

The `resonant` flag applies if we want to construct a decay chain. The resonance property can propagate to the final event output.

If an extended structure function is required `requires_extended_sf`, we have to not consider `sub` as a quantum number.

    end subroutine connected_state_setup_connected_matrix

```

Set up a matrix evaluator as a product of two evaluators (incoming state, effective interaction). In the intermediate state, only helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`, after creating an intermediate interaction that includes a correlated color state. We assume that for a caller-provided `int`, this is not necessary.

For fixed-order NLO differential distribution, we are interested at the partonic level, no parton showering takes place as this would demand for a proper matching. So, the flows in the `connected_state` are not needed, and the color part will be masked for the interaction coming from the `sf_chain`. The squared matrix elements coming from the OLP provider at the moment do not come with flows anyhow. This needs to be revised once the matching to the shower is completed.

```

30.2.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

30.2.6 Evaluation

Transfer momenta to the trace evaluator and fill the `subevt` with this effective kinematics, if applicable.

Note: we may want to apply a boost for the `subevt`.

```

(Parton states: parton state: TBP)+≡
  procedure :: receive_kinematics => parton_state_receive_kinematics

(Parton states: sub interfaces)+≡
  module subroutine parton_state_receive_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
  end subroutine parton_state_receive_kinematics

(Parton states: procedures)+≡
  module subroutine parton_state_receive_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
    if (state%has_trace) then
      call state%trace%receive_momenta ()
      select type (state)
        class is (connected_state_t)
          if (state%has_expr) then
            call state%expr%fill_subevt (state%trace%interaction_t)
          end if
        end select
      end if
    end if
  end subroutine parton_state_receive_kinematics

```

Recover kinematics: We assume that the trace evaluator is filled with momenta. Send those momenta back to the sources, then fill the variables and subevent as above.

The incoming momenta of the connected state are not connected to the isolated state but to the beam interaction. Therefore, the incoming momenta within the isolated state do not become defined, yet. Instead, we reconstruct the beam (and ISR) momentum configuration.

```

(Parton states: parton state: TBP)+≡
  procedure :: send_kinematics => parton_state_send_kinematics

(Parton states: sub interfaces)+≡
  module subroutine parton_state_send_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
  end subroutine parton_state_send_kinematics

(Parton states: procedures)+≡
  module subroutine parton_state_send_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
    if (state%has_trace) then
      call state%trace%send_momenta ()
      select type (state)
        class is (connected_state_t)
          call state%expr%fill_subevt (state%trace%interaction_t)
        end select
      end if
    end if
  end subroutine parton_state_send_kinematics

```

Evaluate the expressions. The routine evaluates first the cut expression. If the event passes, it evaluates the other expressions. Where no expressions are defined, default values are inserted.

```

(Parton states: connected state: TBP)+≡
  procedure :: evaluate_expressions => connected_state_evaluate_expressions

(Parton states: sub interfaces)+≡

30.3.2 Core management

This object holds information about the cores used by the components and allocates the corresponding manager instance.

`i_component` is the index of the process component which this core belongs to. The pointer to the core definition is a convenient help in configuring the core itself.

We allow for a `blha_config` configuration object that covers BLHA cores. The BLHA standard is suitable generic to warrant support outside of specific type extension (i.e., applies to LO and NLO if requested). The BLHA configuration is allocated only if the core requires it.

<PCM base: public>≡

public :: core_entry_t

<PCM base: types>≡

```
type :: core_entry_t
  integer :: i_component = 0
  logical :: active = .false.
  class(prc_core_def_t), pointer :: core_def => null ()
  type(blha_template_t), allocatable :: blha_config
  class(prc_core_t), allocatable :: core
contains
  <PCM base: core entry: TBP>
end type core_entry_t
```

<PCM base: core entry: TBP>≡

procedure :: get_core_ptr => core_entry_get_core_ptr

<PCM base: sub interfaces>≡

```
module function core_entry_get_core_ptr (core_entry) result (core)
  class(core_entry_t), intent(in), target :: core_entry
  class(prc_core_t), pointer :: core
end function core_entry_get_core_ptr
```

<PCM base: procedures>≡

```
module function core_entry_get_core_ptr (core_entry) result (core)
  class(core_entry_t), intent(in), target :: core_entry
  class(prc_core_t), pointer :: core
  if (allocated (core_entry%core)) then
    core => core_entry%core
  else
    core => null ()
  end if
end function core_entry_get_core_ptr
```

Configure the core object after allocation with correct type. The `core_def` object pointer and the index `i_component` of the associated process component are already there.

```

<PCM base: core entry: TBP>+=
  procedure :: configure => core_entry_configure

<PCM base: sub interfaces>+=
  module subroutine core_entry_configure (core_entry, lib, id)
    class(core_entry_t), intent(inout) :: core_entry
    type(process_library_t), intent(in), target :: lib
    type(string_t), intent(in) :: id
  end subroutine core_entry_configure

<PCM base: procedures>+=
  module subroutine core_entry_configure (core_entry, lib, id)
    class(core_entry_t), intent(inout) :: core_entry
    type(process_library_t), intent(in), target :: lib
    type(string_t), intent(in) :: id
    call core_entry%core%init &
      (core_entry%core_def, lib, id, core_entry%i_component)
  end subroutine core_entry_configure

```

30.3.3 Process component manager

The process-component manager `pcm` is the master component of the `process_t` object. It serves two purposes:

1. It holds configuration data which allow us to centrally manage the components, terms, etc. of the process object.
2. It implements the methods that realize the algorithm for constructing the process object and computing an integral. This algorithm makes use of the data stored within `pcm`.

To this end, the object is abstract and polymorphic. The two extensions that we support, implement (a) default tree-level calculation, optionally including a sum over sub-processes with different particle content, or (b) the FKS-NLO subtraction algorithm for QCD-corrected processes. In both cases, the type extensions may hold suitable further data.

Data included in the base type:

The number of components determines the `component_selected` array.

`i_phs_config` is a lookup table that holds the PHS configuration index for a given component index.

`i_core` is a lookup table that holds the core-entry index for a given component index.

`i_mci` is a lookup table that holds the integrator (MCI) index for a given component index.

```

<PCM base: public>+=
  public :: pcm_t

```

```

<PCM base: types>+≡
  type, abstract :: pcm_t
    logical :: initialized = .false.
    logical :: has_pdfs = .false.
    integer :: n_components = 0
    integer :: n_cores = 0
    integer :: n_mci = 0
    logical, dimension(:), allocatable :: component_selected
    logical, dimension(:), allocatable :: component_active
    integer, dimension(:), allocatable :: i_phs_config
    integer, dimension(:), allocatable :: i_core
    integer, dimension(:), allocatable :: i_mci
    type(blha_template_t) :: blha_defaults
    logical :: uses_blha = .false.
    type(os_data_t) :: os_data
  contains
    <PCM base: pcm: TBP>
  end type pcm_t

```

The factory method. We use the inout intent, so calling this again is an error.

```

<PCM base: pcm: TBP>≡
  procedure(pcm_allocate_workspace), deferred :: allocate_workspace
<PCM base: interfaces>≡
  abstract interface
    subroutine pcm_allocate_workspace (pcm, work)
      import
      class(pcm_t), intent(in) :: pcm
      class(pcm_workspace_t), intent(inout), allocatable :: work
    end subroutine pcm_allocate_workspace
  end interface

```

    subroutine pcm_final (pcm)
      import
      class(pcm_t), intent(inout) :: pcm
    end subroutine pcm_final
  end interface

```

30.3.4 Initialization methods

The PCM has the duty to coordinate and configure the process-object components.

Initialize the PCM configuration itself, using environment data.

```
<PCM base: pcm: TBP>+≡
  procedure(pcm_init), deferred :: init
<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_init (pcm, env, meta)
      import
      class(pcm_t), intent(out) :: pcm
      type(process_environment_t), intent(in) :: env
      type(process_metadata_t), intent(in) :: meta
    end subroutine pcm_init
  end interface
```

Initialize the BLHA configuration block, the component-independent default settings. This is to be called by `pcm_init`. We use the provided variable list.

This block is filled regardless of whether BLHA is actually used, because why not? We use a default value for the scheme (not set in unit tests).

```
<PCM base: pcm: TBP>+≡
  procedure :: set_blha_defaults => pcm_set_blha_defaults
<PCM base: sub interfaces>+≡
  module subroutine pcm_set_blha_defaults (pcm, polarized_beams, var_list)
    class(pcm_t), intent(inout) :: pcm
    type(var_list_t), intent(in) :: var_list
    logical, intent(in) :: polarized_beams
  end subroutine pcm_set_blha_defaults
<PCM base: procedures>+≡
  module subroutine pcm_set_blha_defaults (pcm, polarized_beams, var_list)
    class(pcm_t), intent(inout) :: pcm
    type(var_list_t), intent(in) :: var_list
    logical, intent(in) :: polarized_beams
    logical :: muon_yukawa_off
    real(default) :: top_yukawa
    type(string_t) :: ew_scheme
    muon_yukawa_off = &
      var_list%get_lval (var_str ("?openloops_switch_off_muon_yukawa"))
    top_yukawa = &
      var_list%get_rval (var_str ("blha_top_yukawa"))
    ew_scheme = &
      var_list%get_sval (var_str ("$blha_ew_scheme"))
    if (ew_scheme == "") ew_scheme = "Gmu"
    call pcm%blha_defaults%init &
      (polarized_beams, muon_yukawa_off, top_yukawa, ew_scheme)
  end subroutine pcm_set_blha_defaults
```

Read the method settings from the variable list and store them in the BLHA master. The details depend on the `pcm` concrete type.

```
<PCM base: pcm: TBP>+≡
  procedure(pcm_set_blha_methods), deferred :: set_blha_methods
```

```

<PCM base: interfaces>+=
  abstract interface
    subroutine pcm_set_blha_methods (pcm, blha_master, var_list)
      import
      class(pcm_t), intent(inout) :: pcm
      type(blha_master_t), intent(inout) :: blha_master
      type(var_list_t), intent(in) :: var_list
    end subroutine pcm_set_blha_methods
  end interface

```

Produce the LO and NLO flavor-state tables (as far as available), as appropriate for BLHA configuration. We may inspect either the PCM itself or the array of process cores.

```

<PCM base: pcm: TBP>+=
  procedure(pcm_get_blha_flv_states), deferred :: get_blha_flv_states
<PCM base: interfaces>+=
  abstract interface
    subroutine pcm_get_blha_flv_states (pcm, core_entry, flv_born, flv_real)
      import
      class(pcm_t), intent(in) :: pcm
      type(core_entry_t), dimension(:), intent(in) :: core_entry
      integer, dimension(:,:), allocatable, intent(out) :: flv_born
      integer, dimension(:,:), allocatable, intent(out) :: flv_real
    end subroutine pcm_get_blha_flv_states
  end interface

```

Allocate the right number of process components. The number is also stored in the process meta. Initially, all components are active but none are selected.

```

<PCM base: pcm: TBP>+=
  procedure :: allocate_components => pcm_allocate_components
<PCM base: sub interfaces>+=
  module subroutine pcm_allocate_components (pcm, comp, meta)
    class(pcm_t), intent(inout) :: pcm
    type(process_component_t), dimension(:), allocatable, intent(out) :: comp
    type(process_metadata_t), intent(in) :: meta
  end subroutine pcm_allocate_components
<PCM base: procedures>+=
  module subroutine pcm_allocate_components (pcm, comp, meta)
    class(pcm_t), intent(inout) :: pcm
    type(process_component_t), dimension(:), allocatable, intent(out) :: comp
    type(process_metadata_t), intent(in) :: meta
    pcm%n_components = meta%n_components
    allocate (comp (pcm%n_components))
    allocate (pcm%component_selected (pcm%n_components), source = .false.)
    allocate (pcm%component_active (pcm%n_components), source = .true.)
  end subroutine pcm_allocate_components

```

Each process component belongs to a category/type, which we identify by a universal integer constant. The categories can be taken from the process definition. For easy lookup, we store the categories in an array.

```

<PCM base: pcm: TBP>+=

```

```

        procedure(pcm_categorize_components), deferred :: categorize_components
    <PCM base: interfaces>+≡
    abstract interface
        subroutine pcm_categorize_components (pcm, config)
            import
            class(pcm_t), intent(inout) :: pcm
            type(process_config_data_t), intent(in) :: config
        end subroutine pcm_categorize_components
    end interface

```

Allocate the right number and type(s) of process-core objects, i.e., the interface object between the process and matrix-element code.

Within the `pcm` block, also associate cores with components and store relevant configuration data, including the `i_core` lookup table.

```

    <PCM base: pcm: TBP>+≡
        procedure(pcm_allocate_cores), deferred :: allocate_cores
    <PCM base: interfaces>+≡
    abstract interface
        subroutine pcm_allocate_cores (pcm, config, core_entry)
            import
            class(pcm_t), intent(inout) :: pcm
            type(process_config_data_t), intent(in) :: config
            type(core_entry_t), dimension(:), allocatable, intent(out) :: core_entry
        end subroutine pcm_allocate_cores
    end interface

```

Generate and interface external code for a single core, if this is required.

```

    <PCM base: pcm: TBP>+≡
        procedure(pcm_prepare_any_external_code), deferred :: &
            prepare_any_external_code
    <PCM base: interfaces>+≡
    abstract interface
        subroutine pcm_prepare_any_external_code &
            (pcm, core_entry, i_core, libname, model, var_list)
            import
            class(pcm_t), intent(in) :: pcm
            type(core_entry_t), intent(inout) :: core_entry
            integer, intent(in) :: i_core
            type(string_t), intent(in) :: libname
            type(model_data_t), intent(in), target :: model
            type(var_list_t), intent(in) :: var_list
        end subroutine pcm_prepare_any_external_code
    end interface

```

Prepare the BLHA configuration for a core object that requires it. This does not affect the core object, which may not yet be allocated.

```

    <PCM base: pcm: TBP>+≡
        procedure(pcm_setup_blha), deferred :: setup_blha

```

```

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_setup_blha (pcm, core_entry)
      import
      class(pcm_t), intent(in) :: pcm
      type(core_entry_t), intent(inout) :: core_entry
    end subroutine pcm_setup_blha
  end interface

```

Configure the BLHA interface for a core object that requires it. This is separate from the previous method, assuming that the pcm has to allocate the actual cores and acquire some data in-between.

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_prepare_blha_core), deferred :: prepare_blha_core

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_prepare_blha_core (pcm, core_entry, model)
      import
      class(pcm_t), intent(in) :: pcm
      type(core_entry_t), intent(inout) :: core_entry
      class(model_data_t), intent(in), target :: model
    end subroutine pcm_prepare_blha_core
  end interface

```

Allocate and configure the MCI (multi-channel integrator) records and their relation to process components, appropriate for the algorithm implemented by pcm.

Create a mci_t template: the procedure `dispatch_mci` is called as a factory method for allocating the mci_t object with a specific concrete type. The call may depend on the concrete pcm type.

```

<PCM base: public>+≡
  public :: dispatch_mci_proc

<PCM base: interfaces>+≡
  abstract interface
    subroutine dispatch_mci_proc (mci, var_list, process_id, is_nlo)
      import
      class(mci_t), allocatable, intent(out) :: mci
      type(var_list_t), intent(in) :: var_list
      type(string_t), intent(in) :: process_id
      logical, intent(in), optional :: is_nlo
    end subroutine dispatch_mci_proc
  end interface

```

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_setup_mci), deferred :: setup_mci
  procedure(pcm_call_dispatch_mci), deferred :: call_dispatch_mci

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_setup_mci (pcm, mci_entry)
      import

```

```

        class(pcm_t), intent(inout) :: pcm
        type(process_mci_entry_t), &
            dimension(:), allocatable, intent(out) :: mci_entry
    end subroutine pcm_setup_mci
end interface

abstract interface
    subroutine pcm_call_dispatch_mci (pcm, &
        dispatch_mci, var_list, process_id, mci_template)
    import
        class(pcm_t), intent(inout) :: pcm
        procedure(dispatch_mci_proc) :: dispatch_mci
        type(var_list_t), intent(in) :: var_list
        type(string_t), intent(in) :: process_id
        class(mci_t), intent(out), allocatable :: mci_template
    end subroutine pcm_call_dispatch_mci
end interface

```

Proceed with PCM configuration based on the core and component configuration data. Base version is empty.

```

<PCM base: pcm: TBP>+≡
    procedure(pcm_complete_setup), deferred :: complete_setup

<PCM base: interfaces>+≡
    abstract interface
        subroutine pcm_complete_setup (pcm, core_entry, component, model)
        import
            class(pcm_t), intent(inout) :: pcm
            type(core_entry_t), dimension(:), intent(in) :: core_entry
            type(process_component_t), dimension(:), intent(inout) :: component
            type(model_t), intent(in), target :: model
        end subroutine pcm_complete_setup
    end interface

```

Retrieve information

Return the core index that belongs to a particular component.

```

<PCM base: pcm: TBP>+≡
    procedure :: get_i_core => pcm_get_i_core

<PCM base: sub interfaces>+≡
    module function pcm_get_i_core (pcm, i_component) result (i_core)
        class(pcm_t), intent(in) :: pcm
        integer, intent(in) :: i_component
        integer :: i_core
    end function pcm_get_i_core

<PCM base: procedures>+≡
    module function pcm_get_i_core (pcm, i_component) result (i_core)
        class(pcm_t), intent(in) :: pcm
        integer, intent(in) :: i_component
        integer :: i_core
        if (allocated (pcm%i_core)) then

```

```

        i_core = pcm%i_core(i_component)
    else
        i_core = 0
    end if
end function pcm_get_i_core

```

Phase-space configuration

Allocate and initialize the right number and type(s) of phase-space configuration entries. The `i_phs_config` lookup table must be set accordingly.

```

<PCM base: pcm: TBP>+≡
    procedure(pcm_init_phs_config), deferred :: init_phs_config

<PCM base: interfaces>+≡
    abstract interface
        subroutine pcm_init_phs_config &
            (pcm, phs_entry, meta, env, phs_par, mapping_defs)
            import
            class(pcm_t), intent(inout) :: pcm
            type(process_phs_config_t), &
                dimension(:), allocatable, intent(out) :: phs_entry
            type(process_metadata_t), intent(in) :: meta
            type(process_environment_t), intent(in) :: env
            type(mapping_defaults_t), intent(in) :: mapping_defs
            type(phs_parameters_t), intent(in) :: phs_par
        end subroutine pcm_init_phs_config
    end interface

```

Initialize a single component. We require all process-configuration blocks, and specific templates for the phase-space and integrator configuration.

We also provide the current component index `i` and the `active` flag.

```

<PCM base: pcm: TBP>+≡
    procedure(pcm_init_component), deferred :: init_component

<PCM base: interfaces>+≡
    abstract interface
        subroutine pcm_init_component &

30.4.3 The process type

NOTE: The description below represents the intended structure after refactoring and disentangling the FKS-NLO vs. LO algorithm dependencies.

A **process** object is the internal representation of integration-run methods and data, as they are controlled by the user via a Sindarin script. The process object provides access to matrix elements (the actual “process” definitions that the user has provided before), it defines the separation into individually integrable components, and it manages phase-space construction, the actual integration over phase space, and the accumulation of results.

As a workspace for individual sampling calls, we introduce an associated **process_instance** object type elsewhere. The **process** object contains data that either define the configuration or accumulate results from a complete integration pass.

After successful phase-space integration, subsequent event generation is not actually represented by the **process** object. However, any event generation refers to an existing **process** object which represents a specific integration pass, and it uses a fresh **process_instance** workspace for calculations.

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The **meta** object describes the process globally. All contents become fixed when the object is initialized. Similarly, the **env** component captures the (Sindarin) environment at the point where the process object is initialized.

The **config** object holds physical and technical configuration data that are collected and derived from the environment during process initialization, and which are common to all process components.

The **pcm** object (process-component manager) is polymorphic. This is an object which holds data which represent the process-object structure and breakdown, and it contains the methods that implement the algorithm of managing this structure, accumulating partial results, and finally collecting the pieces. Depending on the generic process type, the contents of **pcm** do vary. In particular, there is some base-type data content and a simple (default) extension which is designed for traditional O’MEGA matrix elements and tree-level integration, possibly with several sub-processes to sum over. The second extension is designed for the FKS phase-space and subtraction algorithm for NLO QCD, which interfaces external one-loop providers.

The **component** subobjects are, first of all, interfaces to the original process-component definitions that have been provided by the user, which the program

has already taken to produce matrix-element code and interfaces. The management of those components is deferred by `pcm`, which contains the information that defines the role of each component. In particular, in the default (LO) version, process components correspond to distinct particle combinations which have been included in the original process definition. In the FKS-NLO version, the breakdown of a NLO process into Born, real, virtual, etc. components determines the setup.

The `phs_config` subobjects hold data that allow and implement the construction of phase-space configurations. The type `process_phs_config_t` is a wrapper type around the concrete polymorphic `phs_config_t` object type, which manages phase-space construction, including some bookkeeping required for setting up multi-channel integration. In the LO case, we expect a separate entry for each independent sub-process. For the FKS-NLO algorithm, we expect several entries: a default-type entry which implements the underlying Born phase space, and additional entries which enable the construction of various real-radiation and subtraction kinematics configurations.

A `core_entry` is the interface to existing matrix-element and interaction code. Depending on the process and its components, there may be various distinct matrix elements to compute.

The `mci_entry` objects configure distinct MC input parameter sets and their associated (multi-channel) integrators.

The `rng_factory` object is a single objects which constructs individual random-number generators for various tasks, in a uniform and well-defined way.

The `beam_config` object describes the incoming particles, either the decay mother or the scattering beams. It also contains the spectrum- and structure-function setup, which has to interact with the phase-space and integrator facilities.

The `term` subobjects break down the process in its smallest parts which appear in the calculation. For LO processes, the correspondence between terms and components is one-to-one. The FKS-NLO algorithm requires not just separation of Born, real, and virtual components but also subtraction terms, and a decomposition of the real phase space into singular regions. The general idea is that the integration results of distinct sets of terms are summed over to provide the results of individual components. This is also controlled by the `pcm` subobject.

The `process_status` object is a bookkeeping device that allows us to query the status of an ongoing calculation.

The `process_results` object collects the integration results for external use, including integration history information.

```

        logical, intent(in), optional :: pacify
        integer :: u, iostat
        character(0) :: iomsg
        integer, dimension(:), allocatable :: v_list
        u = given_output_unit (unit)
        allocate (v_list (0))
        call set_flag (v_list, F_SHOW_OS_DATA, show_os_data)
        call set_flag (v_list, F_SHOW_VAR_LIST, show_var_list)
        call set_flag (v_list, F_SHOW_RNG, show_rng)
        call set_flag (v_list, F_SHOW_EXPRESSIONS, show_expressions)
        call set_flag (v_list, F_PACIFY, pacify)
        if (screen) then
            call process%write_formatted (u, "LISTDIRECTED", v_list, iostat, iomsg)
        else
            call process%write_formatted (u, "DT", v_list, iostat, iomsg)
        end if
    end subroutine process_write

```

Standard DTIO procedure with binding.

For the particular application, the screen format is triggered by the LISTDIRECTED option for the iotype format editor string. The other options activate when the particular parameter value is found in v_list.

NOTE: The DTIO generic binding is supported by gfortran since 7.0.

TODO wk 2018: The default could be to show everything, and we should have separate switches for all major parts. Currently, there are only a few.

            write (u, "(1x,'(,F4.0,4x,')%')") err_percent
        end if
    else
        write (u, "(A)") "[integral undefined]"
    end if
end subroutine process_show

```

Finalizer. Explicitly iterate over all subobjects that may contain allocated pointers.

TODO wk 2018 (workaround): The finalizer for the `config_data` component is not called. The reason is that this deletes model data local to the process, but these could be referenced by pointers (flavor objects) from some persistent event record. Obviously, such side effects should be avoided, but this requires refactoring the event-handling procedures.

```

(Process: process: TBP)+≡
    procedure :: final => process_final

(Process: sub interfaces)+≡
    module subroutine process_final (process)
        class(process_t), intent(inout) :: process
    end subroutine process_final

            call process%pcm%final ()
            deallocate (process%pcm)
        end if
    end subroutine process_final

```

Process setup

Initialize a process. We need a process library `lib` and the process identifier `proc_id` (string). We will fetch the current run ID from the variable list `var_list`.

We collect all important data from the environment and store them in the appropriate places. OS data, model, and variable list are copied into `env` (true snapshot), also the process library (pointer only).

The `meta` subobject is initialized with process ID and attributes taken from the process library.

We initialize the `config` subobject with all data that are relevant for this run, using the settings from `env`. These data determine the MD5 sum for this run, which allows us to identify the setup and possibly skips in a later re-run.

We also allocate and initialize the embedded RNG factory. We take the seed from the `var_list`, and we should return the `var_list` to the caller with a new seed.

Finally, we allocate the process component manager `pcm`, which implements the chosen algorithm for process integration. The first task of the manager is to allocate the component array and to determine the component categories (e.g., Born/Virtual etc.).

TODO wk 2018: The `pcm` dispatcher should be provided by the caller, if we eventually want to eliminate dependencies on concrete `pcm_t` extensions.

Gfortran 7/8/9 bug, has to remain in the main module:

```
<Process: process: TBP>+≡
  procedure :: init => process_init

<Process: main procedures>≡
  subroutine process_init &
    (process, proc_id, lib, os_data, model, var_list, beam_structure)

      call config%init &
        (meta, env)
      call dispatch_rng_factory &
        (process%rng_factory, env%get_var_list_ptr (), next_rng_seed)
      call update_rng_seed_in_var_list (var_list, next_rng_seed)
      call dispatch_pcm &
        (process%pcm, config%process_def%is_nlo ())
    associate (pcm => process%pcm)
      call pcm%init (env, meta)
    end associate
  end subroutine
```

```

        call pcm%allocate_components (process%component, meta)
        call pcm%categorize_components (config)
    end associate
end associate
end subroutine process_init

```

30.4.6 Process component manager

The pcm (read: process-component manager) takes the responsibility of steering the actual algorithm of configuration and integration. Depending on the concrete type, different algorithms can be implemented.

The first version of this supports just two implementations: leading-order (tree-level) integration and event generation, and NLO (QCD/FKS subtraction). We thus can start with a single logical for steering the dispatcher.

TODO wk 2018: Eventually, we may eliminate all references to the extensions of pcm_t from this module and therefore move this outside the module as well. Gfortran 7/8/9 bug, has to be in the main module:

```

(Process: main procedures)+≡
subroutine dispatch_pcm (pcm, is_nlo)
  class(pcm_t), allocatable, intent(out) :: pcm
  logical, intent(in) :: is_nlo
  if (.not. is_nlo) then
    allocate (pcm_default_t :: pcm)
  else
    allocate (pcm_nlo_t :: pcm)
  end if
end subroutine dispatch_pcm

```

This step is performed after phase-space and core objects are done: collect all missing information and prepare the process component manager for the appropriate integration algorithm.

```

(Process: process: TBP)+≡
  procedure :: complete_pcm_setup => process_complete_pcm_setup

(Process: sub interfaces)+≡
  module subroutine process_complete_pcm_setup (process)
    class(process_t), intent(inout) :: process
  end subroutine process_complete_pcm_setup

(Process: procedures)+≡
  module subroutine process_complete_pcm_setup (process)
    class(process_t), intent(inout) :: process
    call process%pcm%complete_setup &
      (process%core_entry, process%component, process%env%get_model_ptr ())
  end subroutine process_complete_pcm_setup

```

30.4.7 Core management

Allocate cores (interface objects to matrix-element code).

The `dispatch_core` procedure is taken as an argument, so we do not depend on the implementation, and thus on the specific core types.

The `helicity_selection` object collects data that the matrix-element code needs for configuring the appropriate behavior.

After the cores have been allocated, and assuming the phs initial configuration has been done before, we proceed with computing the pcm internal data.

```

(Process: process: TBP)+≡
  procedure :: setup_cores => process_setup_cores

(Process: sub interfaces)+≡
  module subroutine process_setup_cores (process, dispatch_core, &
    helicity_selection, use_color_factors, has_beam_pol)

```

Initialize the process components, one by one. We require templates for the mci (integrator) and phs_config (phase-space) configuration data.

The active flag is set if the component has an associated matrix element, so we can compute it. The case of no core is a unit-test case.

The specifics depend on the algorithm and are delegated to the pcm process-component manager.

The optional `phs_config` overrides a pre-generated config array (for unit test).

```

```

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam_data_t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by extending the code in the `beams` module.

Set up index mapping for `region_data` for singular regions equivalent w.r.t. their amplitudes. Has to be called after `region_data` AND the `core` are fully set up. For processes with structure function, subprocesses which lead to the same amplitude for the hard interaction can differ if structure functions are applied. In this case we remap flavor structures to themselves if the equivalent hard interaction flavor structure has no identical initial state.

We complete the kinematics configuration after the beam setup, but before we configure the chain of structure functions. The reason is that we need the total energy `sqrts` for the kinematics, but the structure-function setup requires the number of channels, which depends on the kinematics configuration. For instance, the kinematics module may return the need for parameterizing an s-channel resonance.

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

```

Let us call the ratio of the NLO and the LO result $\iota = I_{NLO}/I_{LO}$. Then usual error propagation gives

$$\sigma_{\iota}^2 = \left(\frac{\partial \iota}{\partial I_{LO}} \right)^2 \sigma_{I_{LO}}^2 + \left(\frac{\partial \iota}{\partial I_{NLO}} \right)^2 \sigma_{I_{NLO}}^2 = \frac{I_{NLO}^2 \sigma_{I_{LO}}^2}{I_{LO}^4} + \frac{\sigma_{I_{NLO}}^2}{I_{LO}^2}.$$

30.4.8 Default iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

30.4.10 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```

<Process: process: TBP>+=

    integer, parameter, public :: COMP_DEFAULT = 0
    integer, parameter, public :: COMP_REAL_FIN = 1
    integer, parameter, public :: COMP_MASTER = 2
    integer, parameter, public :: COMP_VIRT = 3
    integer, parameter, public :: COMP_REAL = 4
    integer, parameter, public :: COMP_REAL_SING = 5
    integer, parameter, public :: COMP_MISMATCH = 6
    integer, parameter, public :: COMP_PDF = 7
    integer, parameter, public :: COMP_SUB = 8
    integer, parameter, public :: COMP_RESUM = 9
```

30.5.1 Output selection flags

We declare a number of identifiers for write methods, so they only displays selected parts. The identifiers can be supplied to the `vlist` array argument of the standard F2008 derived-type writer call.

```
⟨Process config: parameters⟩+≡
    integer, parameter, public :: F_PACIFY = 1
    integer, parameter, public :: F_SHOW_VAR_LIST = 11
    integer, parameter, public :: F_SHOW_EXPRESSIONS = 12
    integer, parameter, public :: F_SHOW_LIB = 13
    integer, parameter, public :: F_SHOW_MODEL = 14
    integer, parameter, public :: F_SHOW_QCD = 15
    integer, parameter, public :: F_SHOW_OS_DATA = 16
```

```
integer, parameter, public :: F_SHOW_RNG = 17
integer, parameter, public :: F_SHOW_BEAMS = 18
```

This is a simple function that returns true if a flag value is present in `v_list`, but not its negative. If neither is present, it returns default.

```
<Process config: public>≡
public :: flagged

<Process config: sub interfaces>≡
module function flagged (v_list, id, def) result (flag)
logical :: flag
integer, dimension(:), intent(in) :: v_list
integer, intent(in) :: id
logical, intent(in), optional :: def
end function flagged

<Process config: procedures>≡
module function flagged (v_list, id, def) result (flag)
logical :: flag
integer, dimension(:), intent(in) :: v_list
integer, intent(in) :: id
logical, intent(in), optional :: def
logical :: default_result
default_result = .false.; if (present (def)) default_result = def
if (default_result) then
flag = all (v_list /= -id)
else
flag = all (v_list /= -id) .and. any (v_list == id)
end if
end function flagged
```

Related: if flag is set (unset), append value (its negative) to the `v_list`, respectively. `v_list` must be allocated.

```
<Process config: public>+≡
public :: set_flag

<Process config: sub interfaces>+≡
module subroutine set_flag (v_list, value, flag)
integer, dimension(:), intent(inout), allocatable :: v_list
integer, intent(in) :: value
logical, intent(in), optional :: flag
end subroutine set_flag

<Process config: procedures>+≡
module subroutine set_flag (v_list, value, flag)
integer, dimension(:), intent(inout), allocatable :: v_list
integer, intent(in) :: value
logical, intent(in), optional :: flag
if (present (flag)) then
if (flag) then
v_list = [v_list, value]
else
v_list = [v_list, -value]
end if
end if
end subroutine set_flag
```

30.5.2 Generic configuration data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the variable list.

The number **n_in** is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number **n_components** is the number of components that constitute the current process.

The number **n_terms** is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number **n_mci** is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The **model** pointer identifies the physics model and its parameters. This is a pointer to an external object.

Various **parse_node_t** objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the **effective_state** subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The **md5sum** is taken and used to verify the process configuration when re-reading data from file.

end if
end subroutine process_config_data_write

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

The model pointer references the model data within the `env` record. That should be an instance of the global model.

We initialize the QCD object, unless the environment information is unavailable (unit tests).

The RNG factory object is imported by moving the allocation. Gfortran 7/8/9 bug: has to remain in the main module:

```

<Process config: process config data: TBP>+=
    procedure :: init => process_config_data_init

<Process config: main procedures>=
    subroutine process_config_data_init (config, meta, env)
        class(process_config_data_t), intent(out) :: config
        type(process_metadata_t), intent(in) :: meta
        type(process_environment_t), intent(in) :: env
        config%process_def => env%lib%get_process_def_ptr (meta%id)
        config%n_in = config%process_def%get_n_in ()
        config%n_components = size (meta%component_id)
        config%model => env%get_model_ptr ()
        config%model_name = config%model%get_name ()
        if (env%got_var_list ()) then
            call dispatch_qcd &
                (config%qcd, env%get_var_list_ptr (), env%get_os_data ())
        end if
    end subroutine process_config_data_init

```

Return a copy of the QCD data block.

```

(Process config: process config data: TBP)+≡
  procedure :: get_qcd => process_config_data_get_qcd

(Process config: sub interfaces)+≡
  module function process_config_data_get_qcd (config) result (qcd)

    type(qcd_t) :: qcd
  end function process_config_data_get_qcd

(Process config: procedures)+≡
  module function process_config_data_get_qcd (config) result (qcd)
    class(process_config_data_t), intent(in) :: config
    type(qcd_t) :: qcd
    qcd = config%qcd
  end function process_config_data_get_qcd

```

Compute the MD5 sum of the configuration data. This encodes, in particular, the model and the expressions for cut, scales, weight, etc. It should not contain the IDs and number of components, etc., since the MD5 sum should be useful for integrating individual components.

This is done only once. If the MD5 sum is nonempty, the calculation is skipped.

```

(Process config: process config data: TBP)+≡
  procedure :: compute_md5sum => process_config_data_compute_md5sum

(Process config: sub interfaces)+≡

  end function process_config_data_get_md5sum

```

30.5.3 Environment

This record stores a snapshot of the process environment at the point where the process object is created.

Model and variable list are implemented as pointer, so they always have the `target` attribute.

For unit-testing purposes, setting the var list is optional. If not set, the pointer is null.

```

<Process config: public>+≡
  public :: process_environment_t

<Process config: types>+≡
  type :: process_environment_t
    private
    type(model_t), pointer :: model => null ()
    type(var_list_t), pointer :: var_list => null ()
    logical :: var_list_is_set = .false.
    type(process_library_t), pointer :: lib => null ()
    type(beam_structure_t) :: beam_structure
    type(os_data_t) :: os_data
  contains
    <Process config: process environment: TBP>
  end type process_environment_t

```

Model and local var list are snapshots and need a finalizer.

```

<Process config: process environment: TBP>≡
  procedure :: final => process_environment_final

<Process config: sub interfaces>+≡
  module subroutine process_environment_final (env)
    class(process_environment_t), intent(inout) :: env
  end subroutine process_environment_final

<Process config: procedures>+≡
  module subroutine process_environment_final (env)
    class(process_environment_t), intent(inout) :: env
    if (associated (env%model)) then
      call env%model%final ()
      deallocate (env%model)
    end if
    if (associated (env%var_list)) then
      call env%var_list%final (follow_link=.true.)
      deallocate (env%var_list)
    end if
  end subroutine process_environment_final

```

Output, DTIO compatible.

```

```

Initialize: Make a snapshot of the provided model. Make a link to the current process library.

Also make a snapshot of the variable list, if provided. If none is provided,

there is an empty variable list nevertheless, so a pointer lookup does not return null.

If no beam structure is provided, the beam-structure member is empty and will yield a number of zero beams when queried.

(Process config: process environment: TBP)+≡

```

30.5.4 Metadata

This information describes the process. It is fixed upon initialization.

The `id` string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The `num_id` is meaningful if nonzero. It is used for communication with external programs or file standards which do not support string IDs.

The `run_id` string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The `lib_name` identifies the process library where the process definition and the process driver are located.

The `lib_index` is the index of entry in the process library that corresponds to the current process.

The `component_id` array identifies the individual process components.

The `component_description` is an array of human-readable strings that characterize the process components, for instance `a`, `b` => `c`, `d`.

The `active` mask array marks those components which are active. The others are skipped.

```

30.5.6 Beam configuration

The object `data` holds all details about the initial beam configuration. The allocatable array `sf` holds the structure-function configuration blocks. There are `n_strfun` entries in the structure-function chain (not counting the initial beam object). We maintain `n_channel` independent parameterizations of this

chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is `n_sfpar`.

The flag `azimuthal_dependence` tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag `lab_is_cm` is obvious.

```

(Process config: public)+≡
    public :: process_beam_config_t

(Process config: types)+≡
    type :: process_beam_config_t
        type(beam_data_t) :: data
        integer :: n_strfun = 0
        integer :: n_channel = 1
        integer :: n_sfpar = 0
        type(sf_config_t), dimension(:), allocatable :: sf
        type(sf_channel_t), dimension(:), allocatable :: sf_channel
        logical :: azimuthal_dependence = .false.
        logical :: lab_is_cm = .true.
        character(32) :: md5sum = ""
        logical :: sf_trace = .false.
        type(string_t) :: sf_trace_file
    contains
        (Process config: process beam config: TBP)
    end type process_beam_config_t

```

Here we write beam data only if they are actually used.

The `verbose` flag is passed to the beam-data writer.

```

30.5.7 Process components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components can have different types. In short, `process_component_t` is a wrapper for the actual process variants.

If the `active` flag is false, we should skip this component. This happens if the associated process has vanishing matrix element.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

<Process config: public>+≡
  public :: process_component_t

<Process config: types>+≡
  type :: process_component_t
    type(process_component_def_t), pointer :: config => null ()

30.5.8 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`.

In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`. This is the total number of independent entries in the density matrix. For each combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

This type is public only for use in a unit test.

```

(Process config: public)+≡
  public :: process_term_t

(Process config: types)+≡
  type :: process_term_t
    integer :: i_term_global = 0
    integer :: i_component = 0

        class(process_term_t), intent(inout) :: term
        call term%int%final ()
    end subroutine process_term_final

```

Initialize the term. We copy the process constants from the `core` object and set up the `int` hard interaction accordingly.

The `alpha_s` value is useful for writing external event records. This is the constant value which may be overridden by an event-specific running value. If the model does not contain the strong coupling, the value is zero.

The `rearrange` part is commented out; this or something equivalent could become relevant for NLO algorithms.

```

(Process config: process term: TBP)+≡

if (present (subtraction_method)) &
    use_internal_color = (char (subtraction_method) == 'omega') &
    .or. (char (subtraction_method) == 'threshold')
call term%setup_interaction (core, model, nlo_type = nlo_type, &
    pol_beams = use_beam_pol, use_internal_color = use_internal_color, &
    has_pdfs = has_pdfs, n_emitters = n_emitters)
end subroutine process_term_init

```

We fetch the process constants which determine the quantum numbers and use those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

Why are these four subtraction entries for structure-function aware interactions? Taking the soft or collinear limit of the real-emission matrix element, the behavior of the parton energy fractions has to be taken into account. In the pure real case, x_{\oplus} and x_{\ominus} are given by

$$x_{\oplus} = \frac{\bar{x}_{\oplus}}{\sqrt{1-\xi}} \sqrt{\frac{2-\xi(1-y)}{2-\xi(1+y)}}, \quad x_{\ominus} = \frac{\bar{x}_{\ominus}}{\sqrt{1-\xi}} \sqrt{\frac{2-\xi(1+y)}{2-\xi(1-y)}}.$$

In the soft limit, $\xi \rightarrow 0$, this yields $x_{\oplus} = \bar{x}_{\oplus}$ and $x_{\ominus} = \bar{x}_{\ominus}$. In the collinear limit, $y \rightarrow 1$, it is $x_{\oplus} = \bar{x}_{\oplus}/(1-\xi)$ and $x_{\ominus} = \bar{x}_{\ominus}$. Likewise, in the anti-collinear limit $y \rightarrow -1$, the inverse relation holds. We therefore have to distinguish four cases with the PDF assignments $f(x_{\oplus}) \cdot f(x_{\ominus})$, $f(\bar{x}_{\oplus}) \cdot f(\bar{x}_{\ominus})$, $f(\bar{x}_{\oplus}/(1-\xi)) \cdot f(\bar{x}_{\ominus})$ and $f(\bar{x}_{\oplus}) \cdot f(\bar{x}_{\ominus}/(1-\xi))$.

The `n_emitters` optional argument is provided by the caller if this term requires spin-correlated matrix elements, and thus involves additional subtractions.

    end subroutine process_term_get_process_constants

```

30.6 Process call statistics

Very simple object for statistics. Could be moved to a more basic chapter.

```

<process_counter.f90>≡
<File header>

    module process_counter

<Standard module head>

<Process counter: public>

<Process counter: parameters>

<Process counter: types>

        interface
<Process counter: sub interfaces>
        end interface

    end module process_counter

```

This object can record process calls, categorized by evaluation status. It is a part of the `mci_entry` component below.

```

<Process counter: public>≡
    public :: process_counter_t
<Process counter: types>≡
    type :: process_counter_t
        integer :: total = 0
        integer :: failed_kinematics = 0
        integer :: failed_cuts = 0
        integer :: has_passed = 0
        integer :: evaluated = 0
        integer :: complete = 0
    contains
        <Process counter: process counter: TBP>
    end type process_counter_t

```

Here are the corresponding numeric codes:

```

(Process counter: parameters)≡
  integer, parameter, public :: STAT_UNDEFINED = 0
  integer, parameter, public :: STAT_INITIAL = 1
  integer, parameter, public :: STAT_ACTIVATED = 2
  integer, parameter, public :: STAT_BEAM_MOMENTA = 3
  integer, parameter, public :: STAT_FAILED_KINEMATICS = 4
  integer, parameter, public :: STAT_SEED_KINEMATICS = 5
  integer, parameter, public :: STAT_HARD_KINEMATICS = 6
  integer, parameter, public :: STAT_EFF_KINEMATICS = 7
  integer, parameter, public :: STAT_FAILED_CUTS = 8
  integer, parameter, public :: STAT_PASSED_CUTS = 9
  integer, parameter, public :: STAT_EVALUATED_TRACE = 10
  integer, parameter, public :: STAT_EVENT_COMPLETE = 11

```

Output.

```

(Process counter: process counter: TBP)≡
  procedure :: write => process_counter_write

(Process counter: sub interfaces)≡
  module subroutine process_counter_write (object, unit)
    class(process_counter_t), intent(in) :: object
    integer, intent(in), optional :: unit
  end subroutine process_counter_write

(Process counter: procedures)≡
  module subroutine process_counter_write (object, unit)
    class(process_counter_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    if (object%total > 0) then
      write (u, "(1x,A)") "Call statistics (current run):"
      write (u, "(3x,A,I0)") "total          = ", object%total
      write (u, "(3x,A,I0)") "failed kin. = ", object%failed_kinematics
      write (u, "(3x,A,I0)") "failed cuts = ", object%failed_cuts
      write (u, "(3x,A,I0)") "passed cuts = ", object%has_passed
      write (u, "(3x,A,I0)") "evaluated   = ", object%evaluated
    else
      write (u, "(1x,A)") "Call statistics (current run): [no calls]"
    end if
  end subroutine process_counter_write

(process_counter_sub.f90)≡
  <File header>

  submodule (process_counter) process_counter_s

    use io_units

    implicit none

  contains

```

<Process counter: procedures>

end submodule process_counter_s

Reset. Just enforce default initialization.

<Process counter: process counter: TBP>+≡

procedure :: reset => process_counter_reset

<Process counter: sub interfaces>+≡

```
module subroutine process_counter_reset (counter)
  class(process_counter_t), intent(out) :: counter
end subroutine process_counter_reset
```

<Process counter: procedures>+≡

```
module subroutine process_counter_reset (counter)
  class(process_counter_t), intent(out) :: counter
  counter%total = 0
  counter%failed_kinematics = 0
  counter%failed_cuts = 0
  counter%has_passed = 0
  counter%evaluated = 0
  counter%complete = 0
end subroutine process_counter_reset
```

We record an event according to the lowest status code greater or equal to the actual status. This is actually done by the process instance; the process object just copies the instance counter.

<Process counter: process counter: TBP>+≡

procedure :: record => process_counter_record

<Process counter: sub interfaces>+≡

```
module subroutine process_counter_record (counter, status)
  class(process_counter_t), intent(inout) :: counter
  integer, intent(in) :: status
end subroutine process_counter_record
```

<Process counter: procedures>+≡

```
module subroutine process_counter_record (counter, status)
  class(process_counter_t), intent(inout) :: counter
  integer, intent(in) :: status
  if (status <= STAT_FAILED_KINEMATICS) then
    counter%failed_kinematics = counter%failed_kinematics + 1
  else if (status <= STAT_FAILED_CUTS) then
    counter%failed_cuts = counter%failed_cuts + 1
  else if (status <= STAT_PASSED_CUTS) then
    counter%has_passed = counter%has_passed + 1
  else
    counter%evaluated = counter%evaluated + 1
  end if
  counter%total = counter%total + 1
end subroutine process_counter_record
```

30.7 Multi-channel integration

```
<process_mci.f90>≡

    implicit none  
  
  contains  
  
    <Process mci: procedures>  
  
  end submodule process_mci_s
```

30.7.1 Process MCI entry

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly the values that apply to the current pass. Previous values are archived in the `results` object.

The `counter` receives the counter statistics from the associated process instance, for diagnostics.

The `results` object records results, broken down in passes and iterations.

```

(Process mci: public)≡
    public :: process_mci_entry_t

(Process mci: types)≡

```

Configure the MCI entry. This is intent(inout) since some specific settings may be done before this. The actual mci_t object is an instance of the mci_template argument, which determines the concrete types.

In a unit-test context, the mci_template argument may be unallocated.

We obtain the number of channels and the number of parameters separately

for the structure-function chain and for the associated process component. We assume that the phase-space object has already been configured.

We assume that there is only one process component directly associated with an MCI entry.

Compute an MD5 sum that summarizes all information that could influence integration results, for the associated process components. We take the process-configuration MD5 sum which represents parameters, cuts, etc., the MD5 sums for the process component definitions and their phase space objects (which should be configured), and the beam configuration MD5 sum. (The QCD setup is included in the process configuration data MD5 sum.)

Done only once, when the MD5 sum is still empty.

Integrate.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

Generate an event. The instance should be initialized, otherwise event generation is directed by the mci integrator subobject. The integrator instance is contained in a mci_work subobject of the process instance, which simultaneously serves as the sampler object. (We avoid the anti-aliasing rules if we assume that the sampling itself does not involve the integrator instance contained in the process instance.)

Regarding weighted events, we only take events which are valid, which means that they have valid kinematics and have passed cuts. Therefore, we have a rejection loop. For unweighted events, the unweighting routine should already take care of this.

The `keep_failed` flag determines whether events which failed cuts are nevertheless produced, to be recorded with zero weight. Alternatively, failed events are dropped, and this fact is recorded by the counter `n_dropped`.

```

30.7.2 MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

```

<Process mci: public>+≡
    public :: mci_work_t

<Process mci: types>+≡
    type :: mci_work_t
        type(process_mci_entry_t), pointer :: config => null ()
        real(default), dimension(:), allocatable :: x
        class(mci_instance_t), pointer :: mci => null ()
        type(process_counter_t) :: counter
        logical :: keep_failed_events = .false.
        integer :: n_event_dropped = 0
    contains
        <Process mci: mci work: TBP>
    end type mci_work_t

```

First write configuration data, then the current values.

```

<Process mci: mci work: TBP>≡
    procedure :: write => mci_work_write

```

```

(Process mci: sub interfaces)+≡
    module subroutine mci_work_write (mci_work, unit, testflag)
        class(mci_work_t), intent(in) :: mci_work
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: testflag
    end subroutine mci_work_write

(Process mci: procedures)+≡
    module subroutine mci_work_write (mci_work, unit, testflag)
        class(mci_work_t), intent(in) :: mci_work
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: testflag
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A,I0,A)") "Active MCI instance #", &
            mci_work%config%i_mci, " ="
        write (u, "(2x)", advance="no")
        do i = 1, mci_work%config%n_par
            write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
            if (i == mci_work%config%n_par_sf) &
                write (u, "(1x,'|')", advance="no")
        end do
        write (u, *)
        if (associated (mci_work%mci)) then
            call mci_work%mci%write (u, pacify = testflag)
            call mci_work%counter%write (u)
        end if
    end subroutine mci_work_write

```

The mci component may require finalization.

```

(Process mci: mci work: TBP)+≡
    procedure :: final => mci_work_final

(Process mci: sub interfaces)+≡
    module subroutine mci_work_final (mci_work)
        class(mci_work_t), intent(inout) :: mci_work

```

As appropriate for the NLO/FKS algorithm, the category defined by the process, is called `nlo_type`. We refine this by setting the component category `component_type` separately.

The component types `COMP_MISMATCH`, `COMP_PDF`, `COMP_SUB` are set only if the algorithm uses combined integration. Otherwise, they are set to `COMP_DEFAULT`.

The component type `COMP_REAL` is further distinguished between `COMP_REAL_SING` or `COMP_REAL_FIN`, if the algorithm uses real partitions. The former acts as a reference component for the latter, and we always assume that it is the first real component.

Each component is assigned its own core. Exceptions: the finite-real component gets the same core as the singular-real component. The mismatch component gets the same core as the subtraction component.

TODO wk 2018: this convention for real components can be improved. Check whether all component types should be assigned, not just for combined integration.

```

```

Core management

Allocate the core (matrix-element interface) objects that we will need for evaluation. Every component gets an associated core, except for the real-finite and mismatch components (if any). Those components are associated with their previous corresponding real-singular and subtraction cores, respectively.

After cores are allocated, configure the region-data block that is maintained by the NLO process-component manager.

```
<PCM: pcm_nlo: TBP>+≡
  procedure :: allocate_cores => pcm_nlo_allocate_cores

<PCM: sub interfaces>+≡

```

Extra code is required for certain core types (threshold) or if BLHA uses an external OLP for getting its matrix elements. OMega matrix elements, by definition, do not need extra code. NLO-virtual or subtraction matrix elements always need extra code.

More precisely: for the Born and virtual matrix element, the extra code is accessed only if the component is active. The radiation (real) and the subtraction corrections (singular and finite), extra code is accessed in any case.

The flavor state is taken from the `region_data` table in the `pcm` record. We use the Born and real flavor-state tables as appropriate.

```

```

After phase-space configuration data and core entries are available, we fill tables and compute the remaining NLO data that will steer the integration and subtraction algorithm.

There are three parts: recognize a threshold-type process core (if it exists), prepare the region-data tables (always), and prepare for real partitioning (if requested).

The real-component phase space acts as the source for resonance-history information, required for the region data.

```

```

Allocate and configure the MCI (multi-channel integrator) records. The relation depends on the `combined_integration` setting. If we integrate components separately, each component gets its own record, except for the subtraction component. If we do the combination, there is one record for the master (Born) component and a second one for the real-finite component, if present.

Each entry acquires some NLO-specific initialization. Generic configuration follows later.

Second procedure: call the MCI dispatcher with NLO-setup arguments.

```

```

After region data are set up, we allocate and configure the `real_partition` objects, if requested. Gfortran 7/8/9 bug, has to remain in the main module:

```

<PCM: pcm_nlo: TBP>+≡
    procedure :: setup_real_partition => pcm_nlo_setup_real_partition

<PCM: main procedures>+≡
    subroutine pcm_nlo_setup_real_partition (pcm)
        class(pcm_nlo_t), intent(inout) :: pcm
        if (pcm%use_real_partition) then
            if (.not. allocated (pcm%real_partition)) then
                allocate (real_partition_fixed_order_t :: pcm%real_partition)
                select type (partition => pcm%real_partition)
                    type is (real_partition_fixed_order_t)
                        call pcm%region_data%get_all_ftuples (partition%fks_pairs)
                        partition%scale = pcm%real_partition_scale
                    end select
            end if
        end if
    end subroutine pcm_nlo_setup_real_partition

```

Initialize a single component. We require all process-configuration blocks, and specific templates for the phase-space and integrator configuration.

We also provide the current component index `i` and the `active` flag. For a subtraction component, the `active` flag is overridden.

In the nlo mode, the component types have been determined before.

TODO wk 2018: the component type need not be stored in the component; we may remove this when everything is controlled by `pcm`.

```

This routine modifies the kinematic factors applied to the real matrix element for use with POWHEG matching. We need to divide the real matrix element by `xi_max` to cancel a factor of `xi_max` applied in `apply_kinematic_factors_radiation`. It comes from the fact that we sample $\tilde{\xi} \in [0,1]$ when integrating but $\xi \in [p_T^2, \xi_{\max}]$ for POWHEG matching. Thus, we are taking into account that $d\xi = d\tilde{\xi} \frac{\xi}{\xi_{\max}} = d\tilde{\xi} \xi_{\max}$. Additionally, we need to cancel the Jacobian from the random number mapping. We only want the physical part of the Jacobian in our Sudakov splitting function. Furthermore, the real matrix element lacks its flux factor $\frac{1}{2s_R}$ and the real Jacobian lacks a factor of $\frac{1}{1-\xi}$. Together, this is a factor of $\frac{1}{2s_B}$, i.e. the same as the flux factor of the Born matrix element. We do not correct any of both here, as only the ratio of both will be relevant for the Sudakov.

30.9 Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

sf_chain is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

phs is an instance of the phase space for the elementary process.

The array **f** contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either **sf_chain** or **phs** are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component ('owned' by the object) or as a pointer.

Configure the kinematics object. This consists of several configuration steps which correspond to individual procedures. In essence, we configure the structure-function part, the partonic phase-space part, and various NLO items.

TODO wk 19-03-01: This includes some region-data setup within `pcm`, hence `pcm` is `intent(inout)`. This should be moved elsewhere, so `pcm` can become strictly `intent(in)`.

Generate kinematics, given a phase-space channel and a MC parameter set. The main result is the momentum array *p*, but we also fill the momentum entries in the structure-function chain and the Jacobian-factor array *f*. Regarding phase space, we fill only the parameter arrays for the selected channel.

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

30.10.1 Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The **amp** array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The **int_hard** interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The **isolated** object holds the effective parton state for the elementary interaction. The amplitude entries are computed from **int_hard**.

The **connected** evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The **checked** flag is set once we have applied cuts on this term. The result of this is stored in the **passed** flag.

Although each **term_instance** carries a **weight**, this currently always keeps the value 1 and is only used to be given to routines to fulfill their signature.

  integer, intent(in) :: nlo_type
  term_instance%pcm => pcm
  term_instance%pcm_work => pcm_work
  term_instance%nlo_type = nlo_type
end subroutine term_instance_init

```

The second part of term-instance configuration concerns dynamics, i.e., the interface to the matrix-element (interaction), and the parton-state objects that combine all kinematics and matrix-element data for evaluation.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (**rearrange**) as effective structure-function chain and interaction, respectively.

Finally, we set up the **subevt** component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

The **rearrange** parts are still commented out; they could become relevant for a NLO algorithm.

```

Set up beam polarisation quantum numbers, if beam polarisation is required.

We retrieve the full helicity information from `term%config%data` and reduce the information only to the initial state. Afterwards, we uniquify the initial state polarization by applying an index (hash) table.

The helicity information is fed into an array of quantum numbers to assign flavor, helicity and subtraction indices correctly to their matrix element.

Initialization of equivalent cut expression classes.

Each flavor index `i_flv` here is assigned to the corresponding one representative for an equivalent cut expression class. This class describes the set of flavor quantum numbers for which the phase space cut expression evaluation yield the same output. The representative `i_flv` for one class correspond to the first flavor quantum numbers of that kind occuring in the state matrix.

Compute the momenta in the hard interactions, one for each term that constitutes this process component. In simple cases this amounts to just copying momenta. In more advanced cases, we may generate distinct sets of momenta from the seed kinematics.

The interactions in the term instances are accessed individually. We may choose to calculate all terms at once together with the seed kinematics, use `component%core_state` for storage, and just fill the interactions here.

```

```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

Color-correlated matrix elements should be obtained from the external BLHA provider. According to the standard, the matrix elements output is a one-dimensional array. For FKS subtraction, we require the matrix B_{ij} . BLHA prescribes a mapping $(i, j) \rightarrow k$, where k is the index of the matrix element in the output array. It focusses on the off-diagonal entries, i.e. $i \neq j$. The subroutine `blha_color_c_fill_offdiag` realizes this mapping. The diagonal entries can simply be obtained as the product of the Born matrix element and either C_A or C_F , which is achieved by `blha_color_c_fill_diag`. For simple processes, i.e. those with only one color line, it is $B_{ij} = C_F \cdot B$. For those, we keep the possibility of computing color correlations by a multiplication of the Born matrix element with C_F . It is triggered by the `use_internal_color_correlations` flag and should be used only for testing purposes. However, it is also used for

the threshold computation where the process is well-defined and fixed.

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the

isolated parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain.

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

```

<Instances: term instance: TBP>+≡
  procedure :: compute_eff_kinematics => &

Evaluate the trace: first evaluate the hard interaction, then the trace evaluator. We use the `evaluate_interaction` method of the process component which generated this term. The `subevt` and cut expressions are not yet filled.

The `component` argument is `intent(inout)` because the `compute_amplitude` method may modify the `core_state` workspace object.

Retrieve the matrix elements from a matrix element provider and place them into `term%amp`.

For the handling of NLO calculations, FKS applies a book keeping handling flavor and/or particle type (e.g. for QCD: quark/gluon and quark flavor) in order to calculate the subtraction terms. Therefore, we have to insert the calculated matrix elements correctly into the state matrix where each entry corresponds to a set of quantum numbers. We apply a mapping `hard_qn_ind` from a list of quantum numbers provided by FKS to the hard process `int_hard`.

The calculated matrix elements are insert into `term%amp` in the following way. The first `n_born` particles are the matrix element of the hard process. In non-trivial beams, we store another `n_beams_rescaled` copies of these matrix elements as the first `n_beams_rescaled` subtractions. This is a remnant from times before the method `term_instance_set_sf_factors` and these entries are

not used anymore. However, eliminating these entries involves deeper changes in how the connection tables for the evaluator product are set up and should therefore be part of a larger refactoring of the interactions & state matrices. The next $n_{\text{born}} \times n_{\text{sub_color}}$ are color-correlated Born matrix elements, with then again the next $n_{\text{born}} \times n_{\text{emitters}} \times n_{\text{sub_spin}}$ being spin-correlated Born matrix elements.

If two or more flavor structures would produce the same amplitude we only compute one and use the `eqv_index` determined by the `prc_core` and just copy the result to improve performance.

Same as for `term_instance_evaluate_interaction_external_tree`, but for the integrated-subtraction and finite one-loop terms. We only need color-correlated Born matrix elements, but an additional entry per flavor structure for the finite one-loop contribution. We thus have $2 + n_{sub_color}$ entries in the `term%amp` for each `i_flv` and `i_hel` combination.

If two or more flavor structures would produce the same amplitude we only compute one and use the `eqv_index` determined by the `prc_core` and just copy the result to improve performance.

        term%amp(i_color_c) = term%amp(i_color_c_eqv)
    end do
end if
end do
end do
end subroutine term_instance_evaluate_interaction_external_loop

```

Evaluate the trace. First evaluate the structure-function chain (i.e., the density matrix of the incoming partons). Do this twice, in case the sf-chain instances within `kin` and `isolated` differ. Next, evaluate the hard interaction, then compute the convolution with the initial state.

<Instances: term instance: TBP>+≡

```
procedure :: evaluate_trace => term_instance_evaluate_trace
```

<Instances: sub interfaces>+≡

```
module subroutine term_instance_evaluate_trace (term, kin)
```

```

        class(term_instance_t), intent(inout) :: term
        type(kinematics_t), intent(inout) :: kin
    end subroutine term_instance_evaluate_trace

<Instances: procedures>+=
module subroutine term_instance_evaluate_trace (term, kin)

    call term%isolated%evaluate_trace ()
    call term%connected%evaluate_trace ()
end subroutine term_instance_evaluate_trace

```

Include rescaled structure functions due to NLO calculation. We rescale the structure function for the real subtraction `sf_rescale_collinear`, the collinear counter terms `sf_rescale_dglap_t` and for the case, in which we have an emitter in the initial state, we rescale the kinematics for it using `sf_rescale_real_t`. The references are arXiv:0709.2092, Eqs. (2.35)-(2.42).

Obviously, it is completely irrelevant, which beam is treated. It becomes problematic when handling *ep* collisions. Gfortran 7/8/9 bug, has to remain in the main module:

```

<Instances: term instance: TBP>+=
    procedure :: evaluate_scaled_sf_chains => &
        term_instance_evaluate_scaled_sf_chains

        end if
    end function term_instance_get_ren_scale

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

<Instances: term instance: TBP>+≡

```

```

```

30.10.2 The process instance

NOTE: The description below represents the intended structure after refactoring and disentangling the FKS-NLO vs. LO algorithm dependencies.

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `pcm` pointer is a shortcut to the `pcm` (process-component manager) component of the associated process, which we need wherever the calculation depends on the overall algorithm.

The `pcm_work` component is the workspace for the `pcm` object referenced above.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `count` object records process evaluations, broken down according to status.

The `sqme` value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The **weight** value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the **sqme** value times Jacobian weights from the integration, or unity, respectively.

The **i_mci** index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The **sf_chain** subobject is a realization of the beam and structure-function configuration in the **process** object. It is not used for calculation directly but serves as the template for the sf-chain instances that are contained in the **component** objects.

The **kinematics** array contains the set of phase-space points that are associated with the current calculation. The entries may correspond to different process components and terms. (TODO wk 19-02-22: Not implemented yet.)

TODO wk 19-02-22: May include extra arrays for storing (squared) amplitude data. The **term** data set may be reduced to just results, or be removed altogether.

The **term** subobjects are workspace for evaluating kinematics, matrix elements, cuts etc. The array entries correspond to the **term** configuration entries in the associated process object.

The **mci_work** subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the **mci_work** array is selected by the **i_mci** index above.

The **hook** pointer accesses a list of after evaluate objects which are evaluated after the matrix element.

```

<Instances: public>+≡
    public :: process_instance_t

<Instances: types>+≡
    type, extends (mci_sampler_t) :: process_instance_t
        type(process_t), pointer :: process => null ()
        class(pcm_t), pointer :: pcm => null ()
        class(pcm_workspace_t), allocatable :: pcm_work
        integer :: evaluation_status = STAT_UNDEFINED
        real(default) :: sqme = 0
        real(default) :: weight = 0
        real(default) :: excess = 0
        integer :: n_dropped = 0
        integer :: i_mci = 0
        integer :: selected_channel = 0
        type(sf_chain_t) :: sf_chain
        type(kinematics_t), dimension(:), allocatable :: kin
        type(term_instance_t), dimension(:), allocatable :: term
        type(mci_work_t), dimension(:), allocatable :: mci_work
        class(process_instance_hook_t), pointer :: hook => null ()
    contains
        <Instances: process instance: TBP>
    end type process_instance_t

```

Wrapper type for storing pointers to process instance objects in arrays.

```

<Instances: public>+≡
    public :: process_instance_ptr_t

```

```

<Instances: types>+≡
  type :: process_instance_ptr_t
  type(process_instance_t), pointer :: p => null ()
end type process_instance_ptr_t

```

The process hooks are first-in-last-out list of objects which are evaluated after the phase space and matrixelement are evaluated. It is possible to retrieve the sampler object and read the sampler information.

The hook object are part of the `process_instance` and therefore, share a common lifetime. A data transfer, after the usual lifetime of the `process_instance`, is not provided, as such the finalisation procedure has to take care of this! E.g. write the object to file from which later the collected information can then be retrieved.

```

<Instances: public>+≡
  public :: process_instance_hook_t

<Instances: types>+≡
  type, abstract :: process_instance_hook_t
  class(process_instance_hook_t), pointer :: next => null ()
  contains
    procedure(process_instance_hook_init), deferred :: init
    procedure(process_instance_hook_final), deferred :: final
    procedure(process_instance_hook_evaluate), deferred :: evaluate
end type process_instance_hook_t

```

We have to provide an `init`, a `final` procedure and, for after evaluation, the `evaluate` procedure.

The `init` procedures accesses `var_list` and current instance object.

```

<Instances: public>+≡
  public :: process_instance_hook_final, process_instance_hook_evaluate

<Instances: interfaces>≡
  abstract interface
    subroutine process_instance_hook_init (hook, var_list, instance, pdf_data)
      import :: process_instance_hook_t, var_list_t, process_instance_t, pdf_data_t
      class(process_instance_hook_t), intent(inout), target :: hook
      type(var_list_t), intent(in) :: var_list
      class(process_instance_t), intent(in), target :: instance
      type(pdf_data_t), intent(in), optional :: pdf_data
    end subroutine process_instance_hook_init

    subroutine process_instance_hook_final (hook)
      import :: process_instance_hook_t
      class(process_instance_hook_t), intent(inout) :: hook
    end subroutine process_instance_hook_final

    subroutine process_instance_hook_evaluate (hook, instance)
      import :: process_instance_hook_t, process_instance_t
      class(process_instance_hook_t), intent(inout) :: hook
      class(process_instance_t), intent(in), target :: instance
    end subroutine process_instance_hook_evaluate
  end interface

```

The output routine contains a header with the most relevant information about the process, copied from `process_metadata_write`. We mark the active components by an asterisk.

The next section is the MC parameter input. The following sections are written only if the evaluation status is beyond setting the parameters, or if the `verbose` option is set.

```

<Instances: process instance: TBP>≡
  procedure :: write_header => process_instance_write_header

```

Initialization connects the instance with a process. All initial information is transferred from the process object. The process object contains templates for the interaction subobjects (beam and term), but no evaluators. The initialization routine creates evaluators for the matrix element trace, other evaluators are left untouched.

Before we start generating, we double-check if the process library has been updated after the process was initialized (`check_library_sanity`). This may happen if between integration and event generation the library has been recompiled, so all links become broken.

The `instance` object must have the `target` attribute (also in any caller) since the initialization routine assigns various pointers to subobject of `instance`.

```

  integer, intent(in) :: i_mci
  integer, intent(in) :: n_calls
end subroutine process_instance_sampler_test
```

(Instances: procedures)+≡

```
module subroutine process_instance_sampler_test (instance, i_mci, n_calls)
  class(process_instance_t), intent(inout), target :: instance
  integer, intent(in) :: i_mci
  integer, intent(in) :: n_calls
  integer :: i_mci_work
  i_mci_work = instance%process%get_i_mci_work (i_mci)
  call instance%choose_mci (i_mci_work)
  call instance%reset_counter ()
  call instance%process%sampler_test (instance, n_calls, i_mci_work)
  call instance%process%set_counter_mci_entry (i_mci_work, instance%get_counter ())
end subroutine process_instance_sampler_test
```

Generate a weighted event. We select one of the available MCI integrators by its index `i_mci` and thus generate an event for the associated (group of) process component(s). The arguments exactly correspond to the initializer and finalizer above.

The resulting event is stored in the `process_instance` object, which also holds the workspace of the integrator.

Note: The `process` object contains the random-number state, which changes for each event. Otherwise, all volatile data are inside the `instance` object.

(Instances: process instance: TBP)+≡

```
procedure :: generate_weighted_event => &
  process_instance_generate_weighted_event
```

(Instances: sub interfaces)+≡

```
module subroutine process_instance_generate_weighted_event (instance, i_mci)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_mci
end subroutine process_instance_generate_weighted_event
```

(Instances: procedures)+≡

```
module subroutine process_instance_generate_weighted_event (instance, i_mci)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_mci
  integer :: i_mci_work
  i_mci_work = instance%process%get_i_mci_work (i_mci)
  call instance%choose_mci (i_mci_work)
  associate (mci_work => instance%mci_work(i_mci_work))
    call instance%process%generate_weighted_event &
      (i_mci_work, mci_work, instance, &
       instance%keep_failed_events ())
  end associate
end subroutine process_instance_generate_weighted_event
```

(Instances: process instance: TBP)+≡

```
procedure :: generate_unweighted_event => &
  process_instance_generate_unweighted_event
```

<Instances: sub interfaces>+≡

```

module subroutine process_instance_generate_unweighted_event &
  (instance, i_mci)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_mci
end subroutine process_instance_generate_unweighted_event

```

<Instances: procedures>+≡

```

module subroutine process_instance_generate_unweighted_event (instance, i_mci)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_mci
  integer :: i_mci_work
  i_mci_work = instance%process%get_i_mci_work (i_mci)
  call instance%choose_mci (i_mci_work)
  associate (mci_work => instance%mci_work(i_mci_work))
    call instance%process%generate_unweighted_event &
      (i_mci_work, mci_work, instance)
  end associate
end subroutine process_instance_generate_unweighted_event

```

This replaces the event generation methods for the situation that the process instance object has been filled by other means (i.e., reading and/or recalculating its contents). We just have to fill in missing MCI data, especially the event weight.

```

Subroutine of the initialization above: initialize the beam and structure-function chain template. We establish pointers to the configuration data, so `beam_config` must have a `target` attribute.

The resulting chain is not used directly for calculation. It will acquire instances which are stored in the process-component instance objects.

(Instances: process instance: TBP)+≡

```

procedure :: setup_sf_chain => process_instance_setup_sf_chain

```

(Instances: sub interfaces)+≡

```

module subroutine process_instance_setup_sf_chain (instance, config)
  class(process_instance_t), intent(inout) :: instance
  type(process_beam_config_t), intent(in), target :: config
end subroutine process_instance_setup_sf_chain

```

(Instances: procedures)+≡

```

module subroutine process_instance_setup_sf_chain (instance, config)
  class(process_instance_t), intent(inout) :: instance
  type(process_beam_config_t), intent(in), target :: config
  integer :: n_strfun
  n_strfun = config%n_strfun
  if (n_strfun /= 0) then
    call instance%sf_chain%init (config%data, config%sf)
  else
    call instance%sf_chain%init (config%data)
  end if
  if (config%sf_trace) then
    call instance%sf_chain%setup_tracing (config%sf_trace_file)
  end if
end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

<Instances: process instance: TBP>+≡
  procedure :: setup_event_data => process_instance_setup_event_data

<Instances: sub interfaces>+≡
  module subroutine process_instance_setup_event_data &
    (instance, model, i_core)
    class(process_instance_t), intent(inout), target :: instance
    class(model_data_t), intent(in), optional, target :: model
    integer, intent(in), optional :: i_core
  end subroutine process_instance_setup_event_data

<Instances: procedures>+≡
  module subroutine process_instance_setup_event_data (instance, model, i_core)
    class(process_instance_t), intent(inout), target :: instance
    class(model_data_t), intent(in), optional, target :: model

          call term%setup_event_data (kin, core, current_model)
        end if
      end associate
    end do
    core => null ()
  end subroutine process_instance_setup_event_data

```

Choose a MC parameter set and the corresponding integrator. The choice persists beyond calls of the `reset` method above. This method is automatically called here.

```

<Instances: process instance: TBP>+≡
  procedure :: choose_mci => process_instance_choose_mci

<Instances: sub interfaces>+≡
  module subroutine process_instance_choose_mci (instance, i_mci)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
  end subroutine process_instance_choose_mci

```

```

<Instances: procedures>+=
  module subroutine process_instance_choose_mci (instance, i_mci)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    instance%i_mci = i_mci
    call instance%reset ()
  end subroutine process_instance_choose_mci

```

Explicitly set a MC parameter set. Works only if we are in initial state. We assume that the length of the parameter set is correct.

After setting the parameters, activate the components and terms that correspond to the chosen MC parameter set.

The `warmup_flag` is used when a dummy phase-space point is computed for the warmup of e.g. OpenLoops helicities. The setting of the `evaluation_status` has to be avoided then.

```

<Instances: process instance: TBP>+=
  procedure :: set_mcpair => process_instance_set_mcpair

<Instances: sub interfaces>+=
  module subroutine process_instance_set_mcpair (instance, x, warmup_flag)
    class(process_instance_t), intent(inout) :: instance
    real(default), dimension(:), intent(in) :: x
    logical, intent(in), optional :: warmup_flag
  end subroutine process_instance_set_mcpair

<Instances: procedures>+=
  module subroutine process_instance_set_mcpair (instance, x, warmup_flag)
    class(process_instance_t), intent(inout) :: instance
    real(default), dimension(:), intent(in) :: x
    logical, intent(in), optional :: warmup_flag
    logical :: activate
    activate = .true.; if (present (warmup_flag)) activate = .not. warmup_flag
    if (instance%evaluation_status == STAT_INITIAL) then
      associate (mci_work => instance%mci_work(instance%i_mci))
        call mci_work%set (x)
      end associate
      if (activate) call instance%activate ()
    end if
  end subroutine process_instance_set_mcpair

```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The sf-chain instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```

<Instances: process instance: TBP>+=
  procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

<Instances: sub interfaces>+=
  module subroutine process_instance_receive_beam_momenta (instance)

```

```

        class(process_instance_t), intent(inout) :: instance
    end subroutine process_instance_receive_beam_momenta

<Instances: procedures>+≡
module subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
        call instance%sf_chain%receive_beam_momenta ()
        instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
end subroutine process_instance_receive_beam_momenta

```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```

<Instances: process instance: TBP>+≡
    procedure :: set_beam_momenta => process_instance_set_beam_momenta

<Instances: sub interfaces>+≡
    module subroutine process_instance_set_beam_momenta (instance, p)
        class(process_instance_t), intent(inout) :: instance
        type(vector4_t), dimension(:), intent(in) :: p
    end subroutine process_instance_set_beam_momenta

<Instances: procedures>+≡
module subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    if (instance%evaluation_status >= STAT_INITIAL) then
        call instance%sf_chain%set_beam_momenta (p)
        instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
end subroutine process_instance_set_beam_momenta

```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```

<Instances: process instance: TBP>+≡
    procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

<Instances: sub interfaces>+≡
    module subroutine process_instance_recover_beam_momenta (instance, i_term)

        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
            call instance%kin(i_term)%return_beam_momenta ()
        end if
    end if
end subroutine process_instance_recover_beam_momenta

```

```
end subroutine process_instance_recover_beam_momenta
```

Explicitly choose MC integration channel. We assume here that the channel count is identical for all active components.

```
<Instances: process instance: TBP>+≡
```

```
  procedure :: select_channel => process_instance_select_channel
```

```
<Instances: sub interfaces>+≡
```

```
  module subroutine process_instance_select_channel (instance, channel)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
  end subroutine process_instance_select_channel
```

```
<Instances: procedures>+≡
```

```
  module subroutine process_instance_select_channel (instance, channel)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    instance%selected_channel = channel
  end subroutine process_instance_select_channel
```

First step of process evaluation: set up seed kinematics. That is, for each active process component, compute a momentum array from the MC input parameters.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```
<Instances: process instance: TBP>+≡
```

```
  procedure :: compute_seed_kinematics => &
    process_instance_compute_seed_kinematics
```

```
<Instances: sub interfaces>+≡
```

```
  module subroutine process_instance_compute_seed_kinematics &

```

Fourth step of process evaluation: check cuts for all terms. Where successful, compute any scales and weights. Otherwise, deactivate the term. If any of the terms has passed, set the state to STAT_PASSED_CUTS.

The argument `scale_forced`, if present, will override the scale calculation in the term expressions.

```

Fifth step of process evaluation: fill the parameters for the non-selected chan-

nels, that have not been used for seeding. We should do this after evaluating cuts, since we may save some expensive calculations if the phase space point fails the cuts.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

Calculates and then saves the ratio of the value of the (rescaled) real structure function chain of each ISR alpha region over the value of the corresponding underlying born flavor structure. In the case of emitter 0 we also need the rescaled ratio for emitter 1 and 2 in that region for the (soft-)collinear limits. If the emitter is 1 or 2 in some cases, e. g. for EW corrections where a photon

in the proton is required, there can be the possibility of soft radiation off the initial state. For that purpose the unrescaled ratio is needed and as a default we always save these numbers in `sf_factors(:,0)`. Although this procedure is implying functionality for general structure functions, it should be reviewed for anything else besides PDFs, as there might be complications in the details. The general idea of getting the ratio in this way should hold up in these cases as well, however.

```

```

Final step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

If `weight` is provided, we already know the kinematical event weight (the MCI weight which depends on the kinematics sampling algorithm, but not on the matrix element), so we do not need to take it from the MCI record.

```

Computes the real-emission matrix element for externally supplied momenta for the term instance with index `i_term` and a phase space point set with index `i_phs`. In addition, for the real emission, each term instance corresponds to one emitter. There is the possibility to supply an external α_s as well as an external scale to override the scale set in the Sindarin, e.g. for POWHEG matching.

        end if
    end subroutine process_instance_normalize_weight

```

This is a convenience routine that performs the computations of the steps 1 to 5 in a single step. The arguments are the input for `set_mcp`. After this, the evaluation status should be either `STAT_FAILED_KINEMATICS`, `STAT_FAILED_CUTS` or `STAT_EVALUATED_TRACE`.

Before calling this, we should call `choose_mci`.

```

<Instances: process instance: TBP>+≡
    procedure :: evaluate_sqme => process_instance_evaluate_sqme

<Instances: sub interfaces>+≡
    module subroutine process_instance_evaluate_sqme (instance, channel, x)

  call instance%compute_eff_kinematics ()
  call instance%evaluate_expressions ()
  call instance%compute_other_channels ()
  call instance%evaluate_trace ()
end subroutine process_instance_evaluate_sqme

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

```

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the x array, and the f Jacobian array are exposed by the `sampler_t` object.

We allow for the additional hook to be called, if associated, for outlying object to access information from the current state of the `sampler`.

(Instances: process instance: TBP)+≡

```

procedure :: evaluate => process_instance_evaluate

Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

If `n_incoming` is provided, the status code of the first `n_incoming` particles will be reset to incoming. Otherwise, they would be classified as virtual.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

NB: The `recover_beams` option should be used only when the particle set originates from an external event file, and the user has asked for it. It should be switched off when reading from raw event file.

```

Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```
<Processes: execute tests>+≡
    call test (processes_8, "processes_8", &
               "process evaluation with structure functions", &

Complete events

For the purpose of simplifying further tests, we implement a convenience routine that initializes a process and prepares a single event. This is a wrapup of the test `processes_10`.

The procedure is re-exported by the `processes_ut` module.

(Processes: public test auxiliary)≡

```
public :: prepare_test_process
```

(Processes: test auxiliary)+≡

```

subroutine prepare_test_process &
    (process, process_instance, model, var_list, run_id)

Resonances in Phase Space

This test demonstrates the extraction of the resonance-history set from the generated phase space. We need a nontrivial process, but no matrix element. This is provided by the `prc_template` method, using the `SM` model. We also need the `phs_wood` method, otherwise we would not have resonances in the phase space configuration.

```

30.12 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually,

this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

```

<process_stacks.f90>≡
  <File header>

  module process_stacks

    <Use kinds>
    <Use strings>
    use variables
    use process

    <Standard module head>

    <Process stacks: public>

    <Process stacks: types>

    interface
    <Process stacks: sub interfaces>
    end interface

  end module process_stacks
<process_stacks_sub.f90>≡
  <File header>

  submodule (process_stacks) process_stacks_s

    use io_units
    use format_utils, only: write_separator
    use diagnostics
    use observables

    implicit none

  contains

  <Process stacks: procedures>

  end submodule process_stacks_s

```

30.12.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```

<Process stacks: public>≡
  public :: process_entry_t

<Process stacks: types>≡
  type, extends (process_t) :: process_entry_t
    type(process_entry_t), pointer :: next => null ()

```

```
end type process_entry_t
```

30.12.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

The process stack can be linked to another one. This allows us to work with stacks of local scope.

```
<Process stacks: public>+≡
  public :: process_stack_t

<Process stacks: types>+≡
  type :: process_stack_t
    integer :: n = 0
    type(process_entry_t), pointer :: first => null ()
    type(var_list_t), pointer :: var_list => null ()
    type(process_stack_t), pointer :: next => null ()
  contains
    <Process stacks: process stack: TBP>
  end type process_stack_t
```

Finalize partly: deallocate the process stack and variable list entries, but keep the variable list as an empty object. This way, the variable list links are kept.

```
<Process stacks: process stack: TBP>≡
  procedure :: clear => process_stack_clear

<Process stacks: sub interfaces>≡
  module subroutine process_stack_clear (stack)
    class(process_stack_t), intent(inout) :: stack
  end subroutine process_stack_clear

<Process stacks: procedures>≡
  module subroutine process_stack_clear (stack)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), pointer :: process
    if (associated (stack%var_list)) then
      call stack%var_list%final ()
    end if
    do while (associated (stack%first))
      process => stack%first
      stack%first => process%next
      call process%final ()
      deallocate (process)
    end do
    stack%n = 0
  end subroutine process_stack_clear
```

Finalizer. Clear and deallocate the variable list.

```
<Process stacks: process stack: TBP>+≡
  procedure :: final => process_stack_final
```

```

<Process stacks: sub interfaces>+≡
    module subroutine process_stack_final (object)
        class(process_stack_t), intent(inout) :: object
    end subroutine process_stack_final

```

```

<Process stacks: procedures>+≡
    module subroutine process_stack_final (object)
        class(process_stack_t), intent(inout) :: object
        call object%clear ()
        if (associated (object%var_list)) then
            deallocate (object%var_list)
        end if
    end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write => process_stack_write

<Process stacks: sub interfaces>+≡
    recursive module subroutine process_stack_write (object, unit, pacify)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: pacify
    end subroutine process_stack_write

<Process stacks: procedures>+≡
    recursive module subroutine process_stack_write (object, unit, pacify)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: pacify
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)
        call write_separator (u, 2)
        select case (object%n)
        case (0)
            write (u, "(1x,A)") "Process stack: [empty]"
            call write_separator (u, 2)
        case default
            write (u, "(1x,A)") "Process stack:"
            process => object%first
            do while (associated (process))
                call process%write (.false., u, pacify = pacify)
                process => process%next
            end do
        end select
        if (associated (object%next)) then
            write (u, "(1x,A)") "[Processes from context environment:]"
            call object%next%write (u, pacify)
        end if
    end subroutine process_stack_write

```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```

<Process stacks: process stack: TBP>+≡

```

```

    procedure :: write_var_list => process_stack_write_var_list
<Process stacks: sub interfaces>+≡
    module subroutine process_stack_write_var_list (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
    end subroutine process_stack_write_var_list
<Process stacks: procedures>+≡
    module subroutine process_stack_write_var_list (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        if (associated (object%var_list)) then
            call object%var_list%write (unit)
        end if
    end subroutine process_stack_write_var_list

```

Short output.

Since this is a stack, the default output ordering for each stack will be last-in, first-out. To enable first-in, first-out, which is more likely to be requested, there is an optional `fifo` argument.

```

<Process stacks: process stack: TBP>+≡

        type(process_stack_t), intent(in), target :: global_stack
        local_stack%next => global_stack
    end subroutine process_stack_link

```

Initialize the process variable list and link the main variable list to it.

```

<Process stacks: process stack: TBP>+≡
    procedure :: init_var_list => process_stack_init_var_list

<Process stacks: sub interfaces>+≡
    module subroutine process_stack_init_var_list (stack, var_list)
        class(process_stack_t), intent(inout) :: stack
        type(var_list_t), intent(inout), optional :: var_list
    end subroutine process_stack_init_var_list

<Process stacks: procedures>+≡
    module subroutine process_stack_init_var_list (stack, var_list)
        class(process_stack_t), intent(inout) :: stack
        type(var_list_t), intent(inout), optional :: var_list
        allocate (stack%var_list)
        if (present (var_list)) call var_list%link (stack%var_list)
    end subroutine process_stack_init_var_list

```

Link the process variable list to a global variable list.

```

<Process stacks: process stack: TBP>+≡
    procedure :: link_var_list => process_stack_link_var_list

<Process stacks: sub interfaces>+≡
    module subroutine process_stack_link_var_list (stack, var_list)
        class(process_stack_t), intent(inout) :: stack
        type(var_list_t), intent(in), target :: var_list
    end subroutine process_stack_link_var_list

```

```

<Process stacks: procedures>+≡
  module subroutine process_stack_link_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in), target :: var_list
    call stack%var_list%link (var_list)
  end subroutine process_stack_link_var_list

```

30.12.4 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

<Process stacks: process stack: TBP>+≡
  procedure :: push => process_stack_push

<Process stacks: sub interfaces>+≡
  module subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
  end subroutine process_stack_push

<Process stacks: procedures>+≡
  module subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    process%next => stack%first
    stack%first => process
    process => null ()
    stack%n = stack%n + 1
  end subroutine process_stack_push

```

Inverse: Remove the last process pointer in the list and return it.

```

<Process stacks: process stack: TBP>+≡
  procedure :: pop_last => process_stack_pop_last

<Process stacks: sub interfaces>+≡
  module subroutine process_stack_pop_last (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
  end subroutine process_stack_pop_last

<Process stacks: procedures>+≡
  module subroutine process_stack_pop_last (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    type(process_entry_t), pointer :: previous
    integer :: i
    select case (stack%n)
    case (:0)
      process => null ()
    case (1)
      process => stack%first
      stack%first => null ()
      stack%n = 0

```

```

case (2:)
  process => stack%first
  do i = 2, stack%n
    previous => process
    process => process%next
  end do
  previous%next => null ()
  stack%n = stack%n - 1
end select
end subroutine process_stack_pop_last

```

Initialize process variables for a given process ID, without setting values.

```

(Process stacks: process stack: TBP)+≡
  procedure :: init_result_vars => process_stack_init_result_vars

(Process stacks: sub interfaces)+≡
  module subroutine process_stack_init_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
  end subroutine process_stack_init_result_vars

(Process stacks: procedures)+≡
  module subroutine process_stack_init_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    call var_list_init_num_id (stack%var_list, id)
    call var_list_init_process_results (stack%var_list, id)
  end subroutine process_stack_init_result_vars

```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```

(Process stacks: process stack: TBP)+≡
  procedure :: fill_result_vars => process_stack_fill_result_vars

(Process stacks: sub interfaces)+≡
  module subroutine process_stack_fill_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack

    <Use debug>
    use diagnostics

    implicit none

    contains

    <Matching base: procedures>

    end submodule matching_base_s

```

31.1 Abstract Matching Type

A matching will need access to the `shower` as well as matrix elements that we currently get over `process_instace`. The `model` is intended for the backup `model_hadrons`.

```

    <Matching base: public>≡
    public :: matching_t

    <Matching base: types>≡
    type, abstract :: matching_t
    logical :: is_hadron_collision = .false.
    type(qcd_t) :: qcd
    class(shower_base_t), pointer :: shower => null ()
    type(process_instance_t), pointer :: process_instance => null ()
    class(model_data_t), pointer :: model => null ()
    class(rng_t), allocatable :: rng
    type(string_t) :: process_name
    contains
    <Matching base: matching: TBP>
    end type matching_t

    <Matching base: matching: TBP>≡
    procedure (matching_init), deferred :: init

```

```

<Matching base: interfaces>≡
  abstract interface
    subroutine matching_init (matching, var_list, process_name)
      import
      class(matching_t), intent(out) :: matching
      type(var_list_t), intent(in) :: var_list
      type(string_t), intent(in) :: process_name
    end subroutine matching_init
  end interface

```

If we use a polymorphic settings type, this boilerplate wouldn't be necessary but then we introduce `select type` statements all over the place.

```

<default matching init>≡
  type(var_list_t), intent(in) :: var_list
  type(string_t), intent(in) :: process_name
  if (debug_on) call msg_debug (D_MATCHING, "matching_init")
  call matching%settings%init (var_list)
  matching%process_name = process_name

<Matching base: matching: TBP>+≡
  procedure (matching_write), deferred :: write

31.3 CKKW matching

This module contains the CKKW matching.

The type `ckkw_pseudo_shower_weights_t` gives the (relative) weights for different clusterings of the final particles, as given in Eq. (2.7) of hep-ph/0503281v1. Each particle has a binary labelling (power of 2) (first particle = 1, second par-

ticle = 2, third particle = 4, ...). Each recombination therefore corresponds to an integer, that is not a power of 2. For multiple subsequent recombinations, no different weights for different sequences of clustering are stored. It is assumed that the weight of a multiply recombined state is a combination of the states with one fewer recombination and that these states' contributions are proportional to their weights. For a $2 > n$ event, the weights array thus has the size $2^{(2+n)-1}$. The `weights_by_type` array gives the weights depending on the type of the particle, the first index is the same as for weights, the second index gives the type of the new mother particle:

- 0: uncolored (γ , Z , W , Higgs)
- 1: colored (quark)
- 2: gluon
- 3: squark
- 4: gluino

`alphaS` gives the value for α_s used in the generation of the matrix element. This is needed for the reweighting using the values for a running α_s at the scales of the clusterings.

31.4 POWHEG

This module generates radiation according to the POWHEG Sudakov form factor

$$\Delta^{f_b}(\Phi_n, p_T) = \prod_{\alpha_r \in \{\alpha_r | f_b\}} \Delta_{\alpha_r}^{f_b}(\Phi_n, p_T), \quad (31.1)$$

with

$$\Delta_{\alpha_r}^{f_b}(\Phi_n, p_T) = \exp \left\{ - \left[\int d\Phi_{\text{rad}} \frac{R(\Phi_{n+1})}{Bf_b(\Phi_n)} \theta(k_T(\Phi_{n+1}) - p_T) \right]_{\alpha_r}^{\bar{\Phi}_n^{\alpha_r} = \Phi_n} \right\} \quad (31.2)$$

We expect that an underlying Born flavor structure f_b has been generated with a probability proportional to its contribution to the \tilde{B} at the given kinematic point.
