Chapter 20

VEGAS Integration

The backbone integrator of WHIZARD is an object-oriented implemetation of the VEGAS algorithm.

```
<vegas.f90>≡  
  <File header>  
  
  module vegas  
    <Use kinds>  
    <Vegas: modules>  
  
    <Standard module head>  
  
    <Vegas: public>  
  
    <Vegas: parameters>  
  
    <Vegas: types>  
  
    <Vegas: interfaces>  
  
    interface  
      <Vegas: sub interfaces>  
    end interface  
  
    contains  
  
    <Vegas: main procedures>  
  
  end module vegas  
<vegas_sub.f90>≡  
  <File header>  
  
  submodule (vegas) vegas_s  
  
    implicit none  
  
    contains
```

```
⟨Vegas: procedures⟩
```

```
end submodule vegas_s
```

```
⟨Vegas: modules⟩≡
  use diagnostics
  use io_units
  use format_utils, only: write_indent
  use format_defs, only: FMT_17
  use rng_base, only: rng_t
  use rng_stream, only: rng_stream_t
```

MPI Module.

```
⟨MPI: Vegas: modules⟩≡
  use request_callback, only: request_handler_t
  use mpi_f08 !NODEP!
```

20.1 Integration modes

VEGAS operates in three different modes: `vegas_mode_importance_only`, `vegas_mode_importance` or `vegas_mode_stratified`. The default mode is `vegas_mode_importance`, where the algorithm decides whether if it is possible to use importance sampling or stratified sampling. In low dimensions VEGAS uses strict stratified sampling.

```
⟨Vegas: parameters⟩≡
  integer, parameter, public :: VEGAS_MODE_IMPORTANCE = 0, &
    & VEGAS_MODE_STRATIFIED = 1, VEGAS_MODE_IMPORTANCE_ONLY = 2
```

20.2 Type: `vegas_func_t`

We define a abstract `func` type which only gives an interface to an `evaluate` procedure. The inside of implementation and also the optimization of are not a concern of the `vegas` implementation.

```
⟨Vegas: public⟩≡
  public :: vegas_func_t

⟨Vegas: types⟩≡
  type, abstract :: vegas_func_t
  !
  contains
    procedure(vegas_func_evaluate), deferred, pass, public :: evaluate
  end type vegas_func_t
```

The only procedure called in `vegas` is `vegas_func_evaluate`. It takes a real value `x` and returns a real value `f`.

```
⟨Vegas: interfaces⟩≡
  abstract interface
    real(default) function vegas_func_evaluate (self, x) result (f)
    import :: default, vegas_func_t
    class(vegas_func_t), intent(inout) :: self
```

```

        real(default), dimension(:), intent(in) :: x
    end function vegas_func_evaluate
end interface

```

20.3 Type: vegas_config_t

We store the complete configuration in a transparent container. The `vegas_config_t` object inside VEGAS must not be directly accesible. We provide a get method which returns a copy of the `vegas_config_t` object.

Apart from the options which can be set by the constructor of `vegas_t` object, we store the run-time configuration `n_calls`, `calls_per_box`, `n_bins` and `n_boxes`. Those are calculated and set accordingly by VEGAS.

```

<Vegas: public>+≡
    public :: vegas_config_t

<Vegas: types>+≡
    type :: vegas_config_t
        integer :: n_dim = 0
        real(default) :: alpha = 1.5_default
        integer :: n_bins_max = 50
        integer :: iterations = 5
        integer :: mode = VEGAS_MODE_STRATIFIED
        integer :: calls_per_box = 0
        integer :: n_calls = 0
        integer :: n_calls_min = 20
        integer :: n_boxes = 1
        integer :: n_bins = 1
    contains
        <Vegas: vegas config: TBP>
    end type vegas_config_t

```

Write out the configuration of the grid.

```

<Vegas: vegas config: TBP>≡
    procedure, public :: write => vegas_config_write

<Vegas: sub interfaces>≡
    module subroutine vegas_config_write (self, unit, indent)
        class(vegas_config_t), intent(in) :: self
        integer, intent(in), optional :: unit
        integer, intent(in), optional :: indent
    end subroutine vegas_config_write

<Vegas: procedures>≡

```

Resize each bin accordingly to its corresponding weight w . Can be used to resize the grid to a new size of bins or refinement.

The procedure expects two arguments, firstly, `n_bins` and, secondly, the refinement weights w . If `n_bins` differs from the internally stored one, we resize the grid under consideration of w . If each element of w equals one, then the bins are resized preserving their original bin density.

Anytime else, we refine the grid accordingly to w .

Find the probability for a given x in the unit hypercube.

For the case $n_bins < N_BINARY_SEARCH$, we utilize linear search which is faster for short arrays. Else we make use of a binary search. Furthermore, we calculate the inverse of the probability and invert the result only at the end (saving some time on division).

Broadcast the grid information. As safety measure, we get the actual grid object from VEGAS (correctly allocated, but for non-root unfilled) and broadcast the root object. On success, we set grid into VEGAS.

We use the non-blocking broadcast routine, because we have to send quite a bunch of integers and reals.

We have to be very careful with `n_bins`, the number of bins can actually change during different iterations. If we reuse a grid, we have to take that, every grid uses the same `n_bins`. We expect, that the number of dimension does not change, which is in principle possible, but will be checked onto in `vegas_set_grid`.

20.5 Type: vegas_result_t

We store the result of the latest iteration(s) in a transparent container. The `vegas_result_t` object inside VEGAS must not be directly accessible. We export the a copy of the result via a get-method of the `vegas_t` object.

We store latest event weight in `evt_weight` and a (possible) event weight excess in `evt_weight_excess`, if the event weight is larger than `max_abs_f`.

Update results and efficiency.

We define

$$\max_x w(x) = \frac{f(x)}{p(x)} \Delta_{\text{jac}}. \quad (20.1)$$

In the implementation we have to factor out `n_calls` in the jacobian. Also, during event generation.

```

20.7 Type: vegas_t

The VEGAS object contains the methods for integration and grid resize- and refinement. We store the grid configuration and the (current) result in transparent containers alongside with the actual grid and the distribution.

The values of the distribution depend on the chosen mode whether the function value or the variance is stored. The distribution is used after each iteration to refine the grid.

```

< Vegas: public > +=
  public :: vegas_t

< Vegas: types > +=
  type :: vegas_t
    private
    type(vegas_config_t) :: config
    real(default) :: hypercube_volume = 0._default
    real(default) :: jacobian = 0._default
    real(default), dimension(:, :), allocatable :: d
    type(vegas_grid_t) :: grid
    integer, dimension(:), allocatable :: bin
    integer, dimension(:), allocatable :: box
    type(vegas_result_t) :: result
  < Vegas: vegas: type >
  contains
  < Vegas: vegas: TBP >
end type vegas_t

```

Add members for MPI communication and parallel mode. Must be set before calling to `vegas_integrate`, likewise `vegas_set_calls`.

```
(MPI: Vegas: vegas: type)≡
  type(MPI_COMM) :: comm
  logical :: parallel_mode = .false.
```

We overload the type constructor of `vegas_t` which initialises the mandatory argument `n_dim` and allocate memory for the grid.

```
(Vegas: interfaces)+≡
  interface vegas_t
    module procedure vegas_init
  end interface vegas_t

(Vegas: sub interfaces)+≡
  module function vegas_init &
    (n_dim, alpha, n_bins_max, iterations, mode) result (self)

        deallocate (self%box)
        deallocate (self%bin)
    end subroutine vegas_final

```

20.8 Get-/Set-methods

The VEGAS object prohibits direct access from outside. Communication is handle via get- or set-methods. Set the limits of integration. The defaults limits corresponsing the n -dimensional unit hypercube.

Remark: After setting the limits, the grid is initialised, again. Previous results are lost due to recalculation of the overall jacobian.

```

< Vegas: vegas: TBP >+≡
    procedure, public :: set_limits => vegas_set_limits

< Vegas: sub interfaces >+≡
    module subroutine vegas_set_limits (self, x_lower, x_upper)
        class(vegas_t), intent(inout) :: self
        real(default), dimension(:), intent(in) :: x_lower
        real(default), dimension(:), intent(in) :: x_upper
    end subroutine vegas_set_limits

< Vegas: procedures >+≡

        class(vegas_t), intent(inout) :: self
        real(default), dimension(:), intent(in) :: x_lower
        real(default), dimension(:), intent(in) :: x_upper
        if (size (x_lower) /= self%config%n_dim &
            & .or. size (x_upper) /= self%config%n_dim) then
            write (msg_buffer, "(A, I5, A, I5, A, I5)") &
                "VEGAS: [set_limits] n_dim of new lower/upper integration limit&
                & does not match previously set n_dim. ", self%config%n_dim, " /=&
                & ", size (x_lower), " /= ", size (x_upper)
            call msg_fatal ()
        end if
        if (any(x_upper < x_lower)) then

```

```

        call msg_fatal ("VEGAS: [set_limits] upper limits are smaller than lower limits.")
    end if
    if (any((x_upper - x_lower) > huge(0._default))) then
        call msg_fatal ("VEGAS: [set_limits] upper and lower limits exceed rendering.")
    end if
    self%grid%x_upper = x_upper
    self%grid%x_lower = x_lower
    self%grid%delta_x = self%grid%x_upper - self%grid%x_lower
    self%hypercube_volume = product (self%grid%delta_x)
    call self%reset_result ()
end subroutine vegas_set_limits

```

Set the number of calls. If the number of calls changed during different passes, we resize the grid preserving the probability density. We should reset the results after changing the number of calls which change the size of the grid and the running mode of VEGAS. But, this is a set method only for the number of calls.

```

< Vegas: vegas: TBP > +=
    procedure, public :: set_calls => vegas_set_n_calls
< Vegas: sub interfaces > +=
    module subroutine vegas_set_n_calls (self, n_calls)

    end subroutine vegas_set_n_calls
< Vegas: procedures > +=
    module subroutine vegas_set_n_calls (self, n_calls)
        class(vegas_t), intent(inout) :: self
        integer, intent(in) :: n_calls
        if (.not. (n_calls > 0)) then
            write (msg_buffer, "(A, I5)") &
                "VEGAS: [set_calls] number of calls must be a positive number. Keep&
                & number of calls = ", self%config%n_calls
            call msg_warning ()
        else
            self%config%n_calls = max (n_calls, self%config%n_calls_min)
            if (self%config%n_calls /= n_calls) then
                write (msg_buffer, "(A,I5)") &
                    "VEGAS: [set calls] number of calls is too few, reset to ", self%config%n_calls
                call msg_warning ()
            end if
            call self%init_grid ()
        end if
    end subroutine vegas_set_n_calls

```

Get the grid object and set `n_bins`, `n_dim` inside grid container.

```

< Vegas: vegas: TBP > +=
    procedure, public :: get_grid => vegas_get_grid
< Vegas: sub interfaces > +=
    module function vegas_get_grid (self) result (grid)
        class(vegas_t), intent(in) :: self
        type(vegas_grid_t) :: grid
    end function vegas_get_grid

```

```

<Vegas: procedures>+≡
  module function vegas_get_grid (self) result (grid)
    class(vegas_t), intent(in) :: self
    type(vegas_grid_t) :: grid
    grid = self%grid
    grid%n_dim = self%config%n_dim
    grid%n_bins = self%config%n_bins
  end function vegas_get_grid

```

Set grid. We need a set method for the parallelisation. We do some additional checks before copying the object. Be careful, we do not check on `n_bins`, because the number of bins can change after setting `n_calls`. We remind you, that you will loose all your current progress, if you use set the grid. Hence, it will only be used when compiled with MPI.

```

<MPI: Vegas: vegas: TBP>≡
  procedure, public :: set_grid => vegas_set_grid

<MPI: Vegas: sub interfaces>+≡
  module subroutine vegas_set_grid (self, grid)
    class(vegas_t), intent(inout) :: self
    type(vegas_grid_t), intent(in) :: grid
  end subroutine vegas_set_grid

<MPI: Vegas: procedures>+≡

        call handler%init (handler_id, result = self%result, d = self%d)
    end select
  end subroutine vegas_allocate_handler

```

20.9 Grid resize- and refinement

Before integration the grid itself must be initialised. Given the number of `n_calls` and `n_dim` we prepare the grid for the integration.

The grid is binned according to the VEGAS mode and `n_calls`. If the mode is not set to `vegas_importance_only`, the grid is divided in to equal boxes. We

try for 2 calls per box

$$boxes = \sqrt[n_{dim}]{\frac{calls}{2}}. \quad (20.2)$$

If the numbers of boxes exceeds the number of bins, which is the case for low dimensions, the algorithm switches to stratified sampling. Otherwise, we are still using importance sampling, but keep the boxes for book keeping. If the number of bins changes from the previous invocation, bins are expanded or contracted accordingly, while preserving bin density.

```

    self%grid%xi(1, :) = 0._default
    self%grid%xi(2, :) = 1._default
    call self%reset_result ()
  end subroutine vegas_reset_grid

```

Refine the grid to match the distribution `d`.

Average the distribution over neighbouring bins, then contract or expand the bins. The averaging dampens high fluctuations among the integrand or the variance.

We make the type-bound procedure public accessible because the multi-channel integration refines each grid after integration over all grids.

```

<Vegas: vegas: TBP>+≡
  procedure, public :: refine => vegas_refine_grid

```

```

<Vegas: sub interfaces>+≡
  module subroutine vegas_refine_grid (self, average)
    class(vegas_t), intent(inout) :: self
    logical, intent(in), optional :: average
    end subroutine vegas_refine_grid

```

```

<Vegas: procedures>+≡
  module subroutine vegas_refine_grid (self, average)
    class(vegas_t), intent(inout) :: self
    logical, intent(in), optional :: average
    logical :: opt_average
    opt_average = .true.; if (present (average)) opt_average = average

```

```

    if (opt_average) call self%average_distribution ()
    call self%grid%resize (self%config%n_bins, self%d(:self%config%n_bins, :))
end subroutine vegas_refine_grid

```

We average the collected values *d* of the (sq.) weighted *f* over neighbouring bins. The averaged *d* are then again damped by a logarithm to enhance numerical stability. The results are then the refinement weights *w*.

We have to take care of the special case where we have a very low sampling rate. In those cases we can not be sure that the distribution is satisfying filled, although we have already averaged over neighbouring bins. This will lead to a squashing of the unfilled bins and such the boundaries of those will be pushed together. We circumvent this problem by setting those unfilled bins to the smallest representable value of a default real.

The problem becomes very annoying in the multi-channel formulae where have to look up via binary search the corresponding probability of *x* and if the width is zero, the point will be neglected.

Another issue arises when NaNs appear during sampling. A single NaN may spoil the complete adaption as the refinement depends on all weights for a single axis, c.f. `vegas_grid_resize` for the details of the mechanism. Therefore, if we find a single (or more) NaNs in the distribution of an axis, then we won't adapt that specific axis by setting the weights to one. Hence, we skip the adaption for parts of the grid, where NaN appeared during evaluation.

20.10 Integration

Integrate `func`, in the previous set bounds `x_lower` to `x_upper`, with `n_calls`. Use results from previous invocations of `integrate` with `opt_reset_result = .false.` and better with subsequent calls.

Before we walk through the hybercube, we initialise the grid (at a central position).

We step through the (equidistant) boxes which ensure we do not miss any place in the n -dim. hypercube. In each box we sample `calls_per_box` random points and transform them to bin coordinates. The total integral and the total (sample) variance over each box i is then calculated by

$$E(I)_i = \sum_j^{\text{calls per box}} I_{i,j},$$

$$V(I)_i = \text{calls per box} \frac{\sum_j^{\text{calls per box}} I_{i,j}^2}{I} - \left(\sum_j^{\text{calls per box}} I_{i,j} \right)^2 * 2 \frac{\text{calls per box}}{\text{calls per box} - 1}.$$

The stratification of the n -dimensional hybercube allows a simple parallelisation of the algorithm (R. Kreckel, "Parallelization of adaptive MC integrators", Computer Physics Communications, vol. 106, no. 3, pp. 258–266, Nov. 1997.). We have to ensure that all boxes are sampled, but the number of boxes to distribute is too large. We allow each thread to sample a fraction r of all boxes k such that $r \ll k$. Furthermore, we constrain that the number of process p is much smaller than r .

The overall constraint is

$$p \ll r \ll k. \quad (20.3)$$

We divide the integration into a parallel and a perpendicular subspace. The number of parallel dimensions is $D_{\parallel} = \lfloor \frac{D}{2} \rfloor$.

We define additional chunk, which will be used later on for inserting MPI/general MPI code. The code is then removed by additional noweb filter if not compiled with the correspondig compiler flag.

Overall variables, some additionally introduced due to the MPI parallelization and needed in sequentiell verison.

```

< Vegas: vegas integrate: variables >≡

```

Overall initialization.

```

< Vegas: vegas integrate: init >≡

```

Reset all last-iteration results before sampling.

```

< Vegas: vegas integrate: presampling >≡

```

Adjust rng between parallel and perpendicular loops.

```

< Vegas: vegas integrate: loop >≡

```

<Vegas: vegas integrate: postsampling>≡

Increment the box coordinates by 1. If we reach the largest value for the current axis (starting with the largest dimension number), we reset the counter to 1 and increment the next axis counter by 1. And so on, until we reach the maximum counter value of the axis with the lowest dimension, then we set **success** to false and the box coord is set to 1.

<Vegas: vegas integrate: procedures>+≡

```
subroutine increment_box_coord (box, success)
  integer, dimension(:), intent(inout) :: box
  logical, intent(out) :: success
  integer :: j
  success = .true.
  do j = size (box), 1, -1
    box(j) = box(j) + 1
    if (box(j) <= self%config%n_boxes) return
    box(j) = 1
  end do
  success = .false.
end subroutine increment_box_coord
```

We parallelize VEGAS in simple forward manner. The hyper-cube is dissambled in to equidistant boxes in which we sample the integrand **calls_per_box** times. The workload of calculating those boxes is distributed along the worker.

The number of dimensions which will be parallelised are $\lfloor \frac{D}{2} \rfloor$, such MPI Variables for **vegas_integrate**. We have to duplicate all buffers for **MPI_Ireduce**, because we cannot use the same send or receive buffer.

We temporarily store a (empty) grid, before communicating.

<MPI: Vegas: vegas integrate: variables>≡

```
integer :: rank
logical :: parallel_mode
type(vegas_grid_t) :: grid
```

MPI procedure-specific initialization.

Allow for (external) veto on parallel mode.

<MPI: Vegas: vegas integrate: init>≡

```
parallel_mode = self%parallel_mode .and. self%is_parallelizable ()
if (parallel_mode) then
  call MPI_Comm_size (self%comm, n_size)
  call MPI_Comm_rank (self%comm, rank)
else
  n_size = 1
  rank = 0
end if
```

Pre-sampling communication.

We make a copy of the (actual) grid, which is unfilled when non-root. The actual grid is then broadcasted among the workers and inserted into the VEGAS object.

<MPI: Vegas: vegas integrate: presampling>≡

```
if (parallel_mode) then
  grid = self%get_grid ()
  call grid%broadcast (self%comm)
  call self%set_grid (grid)
```

Start index of the boxes for different ranks. If the random number generator is RngStream, we can advance the current stream in such a way, that we will get matching numbers. If `n_boxes` is larger than 2, otherwise parallelization is useless.

  end module vegas_ut

<vegas_util.f90>≡
  <File header>

  module vegas_util
    <Use kinds>
    use io_units
    use constants, only: pi
    use format_defs, only: FMT_10, FMT_12
    use rng_base
    use rng_stream
    use vegas

    <Standard module head>

    <Vegas: test declaration>

    <Vegas: test types>

    contains
    <Vegas: tests>
  end module vegas_util
API: driver for the unit tests below.
<Vegas: public test>≡
  public :: vegas_test
<Vegas: test driver>≡
  subroutine vegas_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Vegas: execute tests>
  end subroutine vegas_test

```

Test function

We use the example from the Monte Carlo Examples of the GSL library

$$I = \int_{-pi}^{+pi} dk_x / (2pi) \int_{-pi}^{+pi} dk_y / (2pi) \int_{-pi}^{+pi} dk_z / (2pi) 1 / (1 - \cos(k_x) \cos(k_y) \cos(k_z)). \quad (20.6)$$

The integral is reduced to region $(0,0,0) \rightarrow (\pi, \pi, \pi)$ and multiplied by 8.

```

<Vegas: test types>≡
  type, extends (vegas_func_t) :: vegas_test_func_t
  !
  contains
    <Vegas: vegas test func: TBP>
  end type vegas_test_func_t

```

Evaluate the integrand.

```

<Vegas: vegas test func: TBP>≡
  procedure, public :: evaluate => vegas_test_func_evaluate

<Vegas: tests>≡
  real(default) function vegas_test_func_evaluate (self, x) result (f)
    class(vegas_test_func_t), intent(inout) :: self
    real(default), dimension(:), intent(in) :: x
    f = 1.0 / (pi**3)
    f = f / ( 1.0 - cos (x(1)) * cos (x(2)) * cos (x(3)))
  end function vegas_test_func_evaluate

```

The second test function is the normalised n-dim. gaussian distribution.

```

<Vegas: test types>+≡
  type, extends (vegas_func_t) :: vegas_gaussian_test_func_t
  !
  contains
    <Vegas: vegas gaussian test func: TBP>
  end type vegas_gaussian_test_func_t

```

Evaluate the integrand.

```

<Vegas: vegas gaussian test func: TBP>≡
  procedure, public :: evaluate => vegas_gaussian_evaluate

<Vegas: tests>+≡
  real(default) function vegas_gaussian_evaluate (self, x) result (f)
    class(vegas_gaussian_test_func_t), intent(inout) :: self
    real(default), dimension(:), intent(in) :: x
    real(default), parameter :: inv_sqrt_pi = 1._default / sqrt(pi)
    f = inv_sqrt_pi**size (x)
    f = f * exp (- dot_product(x, x))
  end function vegas_gaussian_evaluate

```

The third test function is a three-dimensional polynomial function which factorises. The function is defined in such a way that the integral in the unit range is normalised to zero.

$$f(x) = -\frac{8}{3}(x+1)*(y-1)*z \quad (20.7)$$

```

<Vegas: test types>+≡
  type, extends (vegas_func_t) :: vegas_polynomial_func_t
  !
  contains
    <Vegas: vegas polynomial func: TBP>
  end type vegas_polynomial_func_t

```

```

<Vegas: vegas polynomial func: TBP>≡
  procedure, public :: evaluate => vegas_polynomial_evaluate

<Vegas: tests>+≡
  real(default) function vegas_polynomial_evaluate (self, x) result (f)
    class(vegas_polynomial_func_t), intent(inout) :: self
    real(default), dimension(:), intent(in) :: x
    f = - 8. / 3. * (x(1) + 1.) * (x(2) - 1.) * x(3)
  end function vegas_polynomial_evaluate

```

MC Integrator check

20.13.1 Type: vamp2_func_t

We extend `vegas_func_t` with the multi-channel weights and the `vegas_grid_t`, such that, the overall multi-channel weight can be calculated by the function itself.

We add an additional logical `valid_x`, if it is set to `.false.`, we do not compute weighted function and just set the weighted integrand to zero. This behavior is in particular very useful, if a mapping is prohibited or fails. Or in the case of WHIZARD, a phase cut is applied.

Evaluate mappings. We defer this method to be implemented by the user. The result must be written to `xi` and `det`.

The mapping is defined by $\phi : U \rightarrow M$. We map $x \in M$ to the different mappings of the hypercube U_i , such that $x_i \in U_i$.

The mapping should determine, whether `x` is a valid point, e.g. can be mapped, or is restricted otherwise.

20.13.2 Type: `vamp2_config_t`

This is a transparent container which incorporates and extends the definitions in `vegas_config`. The parent object can then be used to parametrise the VEGAS grids directly, where the new parameters are exclusively used in the multi-channel implementation of VAMP2. `n_calls_min` is calculated by

`n_calls_min_per_channel` and `n_channel`. The channels weights (and the result `n_calls` for each channel) are calculated regarding `n_calls_threshold`.

```

Adapt. We adapt the weights due the contribution of variances with $\beta > 0$.

$$\alpha_i = \frac{\alpha_i V_i^\beta}{\sum_i \alpha_i V_i^\beta} \quad (20.9)$$

If `n_calls_threshold` is set, we rescale the weights in such a way, that the `n_calls` for each channel are greater than `n_calls_threshold`. We calculate

the distance of the weights to the `weight_min` and reset those weights which are less than `weight_mins` to this value. The other values are accordingly resized to fit the boundary condition of the partition of unity.

Integrate. We integrate each channel separately and combine the results

$$I = \sum_i \alpha_i I_i, \quad (20.10)$$

$$\sigma^2 = \sum_i \alpha_i^2 \sigma_i^2. \quad (20.11)$$

Although, the (population) variance is given by

$$\begin{aligned}
\sigma^2 &= \frac{1}{N} \left(\sum_i \alpha_i I_i^2 - I^2 \right) \\
&= \frac{1}{N-1} \left(\sum_i (N_i \sigma_i^2 + I_i^2) - I^2 \right) \\
&= \frac{1}{N-1} \left(\sum_i \alpha_i \sigma_i^2 + \alpha_i I_i^2 - I^2 \right),
\end{aligned} \quad (20.12)$$

where we used $\sigma_i^2 = \frac{1}{N} (\langle I_i^2 \rangle - \langle I_i \rangle^2)$, we use the approximation for numeric stability. The population variance relates to sample variance

$$s^2 = \frac{n}{n-1} \sigma^2, \quad (20.13)$$

which gives an unbiased error estimate.

Beside those adaption to multichannel, the overall processing of `total_integral`, `total_sq_integral` and `total_variance` is the same as in `vegas_integrate`.

    end select
  end if

```

Conditional handling for the MPI-version of sampling.

We have a request object and an advanced `channel_iterator` and have to consider three cases:

1. `channel_iterator` drained,
2. request terminated,
3. request received.

When the `channel_iterator` is drained by `update_iter_and_rng`, we send a terminate request to the master and await in the next cycle of channel loop the terminated request. When the request is terminated, we can gracefully exit the channel loop as `channel_iterator` and `rng` are already advanced by `update_iter_and_rng`. When we received a genuine request, then, we proceed as prophesied.

```

Generate unweighted events.

After selecting a channel ch by the inversion method using a random number $r \in [0, 1]$

$$F^{-1}(r) := \inf\{c \in \{1, \dots, N_c\} | F(c) \geq r\}, F(c) = \sum_{c' \leq c} \alpha'_c, \quad (20.14)$$

we try for an event from the previously selected channel. If the event is rejected, we also reject the selected channel.

The inversion method is implemented as a loop over the channel weights α_i until $\sum_c^{c^{prime}} \alpha_c - r \leq 0$, the last value of the loop index `ch` is then c' .

Prepare event generation. We have to set the channel weights and the grids for the integrand's object.

We use an ansatz proposed by T. Ohl in the original VAMP code where we do not have to accept on

$$\frac{w_i(x)}{\sum_i \alpha_i \max_x w_i(x)},$$

after we have selected a channel by the weights α_i . But rather, we use a more efficient way where we rescale the channel weights α_i

$$\alpha_i \rightarrow \alpha_i \frac{\max_x w_i(x)}{\sum_i \alpha_i \max_x w_i(x)}.$$

The overall magic is to insert a "1" and to move the uneasy part into the channel selection, such that we can generate events likewise in the single channel mode. We generate an unweighted event by

$$\frac{w_i(x)}{\max_x w_i x},$$

after we have selected a channel by the rescaled event channel weights. The overall normalization $\max_{i,x}$ is not needed because we normalize the event channel weights to one and therefore the overall normalization cancels.

```

API: driver for the unit tests below.

<VAMP2: public test>≡
  public :: vamp2_test

<VAMP2: test driver>≡
  subroutine vamp2_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <VAMP2: execute tests>
  end subroutine vamp2_test

```

Test function

We use the example from the Monte Carlo Examples of the GSL library

$$I = \int_{-pi}^{+pi} dk_x / (2pi) \int_{-pi}^{+pi} dk_y / (2pi) \int_{-pi}^{+pi} dk_z / (2pi) 1 / (1 - \cos(k_x) \cos(k_y) \cos(k_z)). \quad (20.15)$$

The integral is reduced to region $(0,0,0) \rightarrow (\pi, \pi, \pi)$ and multiplied by 8.

```

<VAMP2: test types>≡
  type, extends (vamp2_func_t) :: vamp2_test_func_t
  !
  contains
  <VAMP2: vamp2 test func: TBP>
end type vamp2_test_func_t

<VAMP2: vamp2 test func: TBP>≡
  procedure, public :: evaluate_maps => vamp2_test_func_evaluate_maps

```

```

<VAMP2: tests>≡
  subroutine vamp2_test_func_evaluate_maps (self, x)
    class(vamp2_test_func_t), intent(inout) :: self
    real(default), dimension(:), intent(in) :: x
    self%xi(:, 1) = x

20.15 MPI Request

Request Direct interface for requests.

Balancer Subliary interfaces and types for implementation into **request**.

Callback Direct interface for non-blocking communication in callback fashion used in subsidiary in **request**.

20.15.1 Request Base

request Container type for current request, contains handler index and status of request.

request group cache Caching for communicator groups, tries to reduce the costly calls to `MPI_CREATE_COMM_GROUP`.

request base Base type for request handling, defines procedures and basic request scheme for direct implementation into **VAMP2**.

When a data type has an associated communicator field, it always must duplicate the communicator in order to ensure communication encapsulation. Only in special case (e.g. outside of object communication is required) the parent communicator should be directly used. For example, that is the case for the group cache, as it exports its newly created communicator to the outside of the request library.

```

```

Base type for requesting and back calling.

A short remark on the semantics of point-to-point communication (as its intended use in this implementation): MPI is strict regarding the order of the messages (for blocking communication), as those can not overtake each other, p. 41. For non-blocking communication, the standard extends it such that the order depends on "the execution order of the calls that initiate the communication". The non-overtaking requirement is then extended to this definition of order.

Color method for tracking communication? We restrict each slave to a single callback (at once), which can communicate during the next request computation. Before handling the next (current) callback, the former one has to finish (with a wait call on the client-side). On the server-side, we only test on the finishing, reporting a communication failure.

Furthermore, the implementation has to take care that the order of the communication calls on the master and slave code always matches!

Therefore, we need to secure the order of communication calls. First, we let the master initiate all callback communication **before** polling. This fixates the order. Second, we require that the implementation of the polling honors this order.

        subroutine allocate_balancer ()
            class(balancer_base_t), allocatable :: balancer
            allocate (balancer_simple_t :: balancer)
            select type (balancer)
            type is (balancer_simple_t)
                call balancer%init (n_workers = req%n_workers, n_resources = req%n_channels)
            end select
            call req%add_balancer (balancer)
        end subroutine allocate_balancer
    end subroutine request_simple_init

```

Update number of channels and parallel grids. The simple request object does not utilize the request balancer, as the complexity of the request balancer is not required for the simple approach. The simple approach assigns each worker several channel by a modular mapping from the set of workers $\{0, \dots, N\}$ to the set of channels $\{1, \dots, N_c\}$. Vetoing on those channel which have a parallel grid (check the definition in `vegas.f90`), where all workers are assigned.

$$w = \phi(c) = (c - 1) \mod N, \text{ if not } P(c), \text{ else } \forall w \rightarrow c.$$

The information is stored in a dynamic-sized array list, which is filled, reversed and then used in a stack-like manner keeping track of the unassigned channels. Assigned and finished channels are then moved to the finished stack.

```

  end subroutine balancer_base_assign_worker
end interface

```

Free assignment of worker. If the worker is not assigned, this procedure is idempotent. If the worker is assigned, alter state correspondingly. In order to correctly free a worker from a resource, we have to explicitly keep track of the association status of a worker and a resource. This feature is mostly relevant for resources with a worker group. The resource may be disassociated from their worker by earlier calls or the former worker may be already assigned to a new resource. In the latter case, we are not allowed to free them (as the new resource is still active). Therefore, each call must check if a worker and resource are still associated and the resource is still active. Only, in this case, disassociating workers and resource is allowed.

Add partition of workers and link with workers. We move the allocated partition object into the balancer. We then assign each partition its respective number of workers in a incrementing linear fashion. However, we postpone the linking of the resources to the partition, which can be either done dynamically with the balancer state or directly with the appropriate type-bound procedure.

Is a worker unassigned, or is a worker assigned, but already assigned to an active resource? This is a fence for the `assign_worker` TBP. The `assign_worker` TBP must call `is_assignable` in order to retrieve the worker status. The input is the worker ID, the return flag tells: if the worker is NOT assigned, return `.true.` if

state has resources. If worker is assigned, return `.true.` if associated resource is active.

20.15.5 Balancer Simple

This module is the simple balancer. The simple balancer distribute the channel among the N workers using a modulo prescription. However, it does assign all workers to a channel capable of grid with parallelizable structure. The balancer use local, non-communicative approach; each worker allocates an own instance of the balancer and fills it with the respecting resources. We defer possible checks (or sentinels) to the request module, e.g. such as checking whether all channels are computed globally.

Free worker from associated resource. Idempotent. Depending on state association, given resource must equal worker's resource (check) for single state. For all state, the *current* resource of the worker may differ (grouping behavior!), only in case, that the older resource is inactive, return as idempotent. Else, free all worker from resource group.

20.15.7 Request Callback

request handler Base type and interface for providing two-sided communication in a callback fashion.

request handler manager Manages handler with a binary tree.

This module constitutes the request handler. A request handler allows to dispatch an object for communication a priori for a slave and a master. Typically, each slave register its own request handles, whereas the master requests all possible requests handles matching those of the slaves. The requests can then be used later on, e.g. during a computation, a slave may add a request to the master worker and starts sending an object. The master worker looks up the appropriate request handler, which then closes the communication, i.e. by a receive call. Most important: Only a pointer to the buffer object is stored, therefore, the calling function has to ensure, that the communication object (buffer) will not be changed during a request handle (receive or send).

Remark: The handler allows for a tag offset which allows to unify the the communication. The problem occurs when multiple callback need to handled simultaneously and MPI needs to connect the communication calls accordingly. Each message has a tuple of (source, tag, comm) associated, we can unify this tuple by a unique tag. $\text{tag} = \text{tag_offset} + \{1, \dots, \text{N_requests}\}$ where tag_offsets are multiple of N_requests . The latter condition should be checked by a modulo. What happens if the communication is out of order (is this a problem? check with standard)?

end subroutine request_handler_manager_client_callback
```

Chapter 21

Multi-Channel Integration

The abstract representation of multi-channel Monte Carlo algorithms for integration and event generation.

Module `mci_base`: The abstract types and their methods. It provides a test integrator that is referenced in later unit tests.

iterations Container for defining integration call and pass settings.

integration_results This module handles results from integrating processes. It records passes and iterations, calculates statistical averages, and provides the user output of integration results.

These are the implementations:

Module `mci_midpoint`: A simple integrator that uses the midpoint rule to sample the integrand uniformly over the unit hypercube. There is only one integration channel, so this can be matched only to single-channel phase space.

Module `mci_vamp`: Interface for the VAMP package.

Figure 21.1: Module dependencies in `src/mci`.

21.1 Generic Integrator

This module provides a multi-channel integrator (MCI) base type, a corresponding configuration type, and methods for integration and event generation.

21.1.1 MCI: integrator

The MCI object contains the methods for integration and event generation. For the actual work and data storage, it spawns an MCI instance object.

The base object contains the number of integration dimensions and the number of channels as configuration data. Further configuration data are stored in

the concrete extensions.

The MCI sum contains all relevant information about the integrand. It can be used for comparing the current configuration against a previous one. If they match, we can skip an actual integration. (Implemented only for the VAMP version.)

There is a random-number generator (its state with associated methods) available as `rng`. It may or may not be used for integration. It will be used for event generation.

```

<MCI base: public>≡
  public :: mci_t

            class(mci_results_t), intent(inout), optional :: results
        end subroutine mci_integrate
    end interface

```

Event generation. Depending on the implementation, event generation may or may not require a previous integration pass.

Instead of a black-box **simulate** method, we require an initializer, a finalizer, and procedures for generating a single event. This allows us to interface simulation event by event from the outside, and it facilitates the further processing of an event after successful generation. For integration, this is not necessary.

The initializer has **intent(inout)** for the **mci** passed object. The reason is that the initializer can read integration results and grids from file, where the results can modify the **mci** record.

```

<MCI base: mci: TBP>+≡
    procedure (mci_prepare_simulation), deferred :: prepare_simulation
<MCI base: interfaces>+≡
    abstract interface
        subroutine mci_prepare_simulation (mci)
            import
            class(mci_t), intent(inout) :: mci
        end subroutine mci_prepare_simulation
    end interface

```

The generated event will reside in in the **instance** object (overall results and weight) and in the **sampler** object (detailed data). In the real application, we can subsequently call methods of the **sampler** in order to further process the generated event.

The **target** attributes are required by the VAMP implementation, which uses pointers to refer to the instance and sampler objects from within the integration function.

```

<MCI base: mci: TBP>+≡
    procedure (mci_generate), deferred :: generate_weighted_event
    procedure (mci_generate), deferred :: generate_unweighted_event
<MCI base: interfaces>+≡

```

21.1.2 MCI instance

The base type contains an array of channel weights. The value `mci_weight` is the combined MCI weight that corresponds to a particular sampling point.

For convenience, we also store the `x` and Jacobian values for this sampling point.

```

<MCI base: public>+≡
    public :: mci_instance_t
<MCI base: types>+≡
    type, abstract :: mci_instance_t
        logical :: valid = .false.
        real(default), dimension(:), allocatable :: w
        real(default), dimension(:), allocatable :: f
        real(default), dimension(:,:), allocatable :: x
        integer :: selected_channel = 0
        real(default) :: mci_weight = 0
        real(default) :: integrand = 0
        logical :: negative_weights = .false.
        integer :: n_dropped = 0
    contains
        <MCI base: mci instance: TBP>
    end type mci_instance_t

```

Output: deferred

```

<MCI base: mci instance: TBP>≡
    procedure (mci_instance_write), deferred :: write
<MCI base: interfaces>+≡
    abstract interface
        subroutine mci_instance_write (object, unit, pacify)

    mci%n_dropped = mci%n_dropped + 1
  end subroutine mci_instance_record_event_dropped

```

21.1.3 MCI state

This object can hold the relevant information that allows us to reconstruct the MCI instance without re-evaluating the sampler completely.

We store the `x_in` MC input parameter set, which coincides with the section of the complete `x` array that belongs to a particular channel. We also store the MC function value. When we want to reconstruct the state, we can use the input array to recover the complete `x` and `f` arrays (i.e., the kinematics), but do not need to recompute the MC function value (the dynamics).

The `mci_state_t` may be extended, to allow storing/recalling more information. In that case, we would override the type-bound procedures. However, the base type is also a concrete type and self-contained.

```

<MCI base: public>+≡
    public :: mci_state_t

<MCI base: types>+≡
    type :: mci_state_t
        integer :: selected_channel = 0
        real(default), dimension(:), allocatable :: x_in
        real(default) :: val
    contains
        <MCI base: mci state: TBP>
    end type mci_state_t

```

Output:

```

<MCI base: mci state: TBP>≡
    procedure :: write => mci_state_write

<MCI base: sub interfaces>+≡
    module subroutine mci_state_write (object, unit)
        class(mci_state_t), intent(in) :: object
        integer, intent(in), optional :: unit
    end subroutine mci_state_write

<MCI base: procedures>+≡
    module subroutine mci_state_write (object, unit)
        class(mci_state_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)
        write (u, "(1x,A)") "MCI state:"
        write (u, "(3x,A,I0)") "Channel   = ", object%selected_channel
        write (u, "(3x,A,999(1x,F12.10))") "x (in)     = ", object%x_in
        write (u, "(3x,A,ES19.12)") "Integrand = ", object%val
    end subroutine mci_state_write

```

To store the object, we take the relevant section of the `x` array. The channel used for storing data is taken from the `instance` object, but it could be arbitrary in principle.

```

<MCI base: mci instance: TBP>+≡
    procedure :: store => mci_instance_store

```

```

<MCI base: sub interfaces>+≡
  module subroutine mci_instance_store (mci, state)
    class(mci_instance_t), intent(in) :: mci
    class(mci_state_t), intent(out) :: state
  end subroutine mci_instance_store

```

```

<MCI base: procedures>+≡
  module subroutine mci_instance_store (mci, state)
    class(mci_instance_t), intent(in) :: mci
    class(mci_state_t), intent(out) :: state
    state%selected_channel = mci%selected_channel
    allocate (state%x_in (size (mci%x, 1)))
    state%x_in = mci%x(:,mci%selected_channel)
    state%val = mci%integrand
  end subroutine mci_instance_store

```

Recalling the state, we must consult the sampler in order to fully reconstruct the x and f arrays. The integrand value is known, and we also give it to the sampler, bypassing evaluation.

The final steps are equivalent to the `evaluate` method above.

```

<MCI base: mci instance: TBP>+≡
  procedure :: recall => mci_instance_recall

```

```

<MCI base: sub interfaces>+≡
  module subroutine mci_instance_recall (mci, sampler, state)
    class(mci_instance_t), intent(inout) :: mci
    class(mci_sampler_t), intent(inout) :: sampler
    class(mci_state_t), intent(in) :: state
  end subroutine mci_instance_recall

```

```

<MCI base: procedures>+≡
  module subroutine mci_instance_recall (mci, sampler, state)
    class(mci_instance_t), intent(inout) :: mci
    class(mci_sampler_t), intent(inout) :: sampler
    class(mci_state_t), intent(in) :: state
    if (size (state%x_in) == size (mci%x, 1) &
        .and. state%selected_channel <= size (mci%x, 2)) then
      call sampler%rebuild (state%selected_channel, &
        state%x_in, state%val, mci%x, mci%f)
      call mci%compute_weight (state%selected_channel)
      call mci%record_integrand (state%val)
    else
      call msg_fatal ("Recalling event: mismatch in channel or dimension")
    end if
  end subroutine mci_instance_recall

```

21.1.4 MCI sampler

A sampler is an object that implements a multi-channel parameterization of the unit hypercube. Specifically, it is able to compute, given a channel and a set of x MC parameter values, the complete set of x values and associated Jacobian factors f for all channels.

Furthermore, the sampler should return a single real value, the integrand, for the given point in the hypercube.

It must implement a method `evaluate` for performing the above computations.

```

<MCI base: public>+≡
  public :: mci_sampler_t
<MCI base: types>+≡
  type, abstract :: mci_sampler_t
  contains
    <MCI base: mci_sampler: TBP>
  end type mci_sampler_t

```

Output, deferred to the implementation.

```

<MCI base: mci_sampler: TBP>≡
  procedure (mci_sampler_write), deferred :: write
<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_sampler_write (object, unit, testflag)
      import
      class(mci_sampler_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: testflag
    end subroutine mci_sampler_write
  end interface

```

The evaluation routine. Input is the channel index `c` and the one-dimensional parameter array `x_in`. Output are the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

```

<MCI base: mci_sampler: TBP>+≡
  procedure (mci_sampler_evaluate), deferred :: evaluate
<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_sampler_evaluate (sampler, c, x_in, val, x, f)
      import
      class(mci_sampler_t), intent(inout) :: sampler
      integer, intent(in) :: c
      real(default), dimension(:), intent(in) :: x_in
      real(default), intent(out) :: val
      real(default), dimension(:,:), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_evaluate
  end interface

```

Query the validity of the sampling point. Can be called after `evaluate`.

```

<MCI base: mci_sampler: TBP>+≡
  procedure (mci_sampler_is_valid), deferred :: is_valid
<MCI base: interfaces>+≡
  abstract interface
    function mci_sampler_is_valid (sampler) result (valid)

```

```

import
class(mci_sampler_t), intent(in) :: sampler
logical :: valid
end function mci_sampler_is_valid
end interface

```

The shortcut. Again, the channel index `c` and the parameter array `x_in` are input. However, we also provide the integrand value `val`, and we just require that the complete parameter array `x` and Jacobian array `f` are recovered.

```

⟨MCI base: mci_sampler: TBP⟩+≡
  procedure (mci_sampler_rebuild), deferred :: rebuild
⟨MCI base: interfaces⟩+≡
  abstract interface
    subroutine mci_sampler_rebuild (sampler, c, x_in, val, x, f)
      import
      class(mci_sampler_t), intent(inout) :: sampler
      integer, intent(in) :: c
      real(default), dimension(:), intent(in) :: x_in
      real(default), intent(in) :: val
      real(default), dimension(:, :), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_rebuild
  end interface

```

This routine should extract the important data from a sampler that has been filled by other means. We fetch the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

```

⟨MCI base: mci_sampler: TBP⟩+≡
  procedure (mci_sampler_fetch), deferred :: fetch
⟨MCI base: interfaces⟩+≡
  abstract interface
    subroutine mci_sampler_fetch (sampler, val, x, f)
      import
      class(mci_sampler_t), intent(in) :: sampler

      real(default), dimension(:, :), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_fetch
  end interface

```

21.1.5 Results record

This is an abstract type which allows us to implement callback: each integration results can optionally be recorded to an instance of this object. The actual object may store a new result, average results, etc. It may also display a result on-line or otherwise, whenever the `record` method is called.

```

⟨MCI base: public⟩+≡
  public :: mci_results_t

```

```

<MCI base: types>+≡
  type, abstract :: mci_results_t
  contains
    <MCI base: mci results: TBP>
  end type mci_results_t

```

The output routine is deferred. We provide an extra `verbose` flag, which could serve any purpose.

```

<MCI base: mci results: TBP>≡
  procedure (mci_results_write), deferred :: write
  procedure (mci_results_write_verbose), deferred :: write_verbose

```

```

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_results_write (object, unit, suppress)
      import
        class(mci_results_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: suppress
    end subroutine mci_results_write

    subroutine mci_results_write_verbose (object, unit)
      import
        class(mci_results_t), intent(in) :: object
        integer, intent(in), optional :: unit
    end subroutine mci_results_write_verbose
  end interface

```

This is the generic `record` method, which can be called directly from the integrator. The `record_extended` procedure store additionally the valid calls, positive and negative efficiency.

```

<MCI base: mci results: TBP>+≡

      call instance%recall (sampler, state)
    end select
  end subroutine mci_test_rebuild_event

```

Instance of the test MCI type

This instance type simulates the VAMP approach. We implement the VAMP multi-channel formula, but keep the channel-specific probability functions g_i smooth and fixed. We also keep the weights fixed.

The setup is as follows: we have n mappings of the unit hypercube

$$x = x(x^{(k)}) \quad \text{where } x = (x_1, \dots). \quad (21.1)$$

The Jacobian factors are the determinants

$$f^{(k)}(x^{(k)}) = \left| \frac{\partial x}{\partial x^{(k)}} \right| \quad (21.2)$$

We introduce arbitrary probability functions

$$g^{(k)}(x^{(k)}) \quad \text{with} \quad \int dx^{(k)} g^{(k)}(x^{(k)}) = 1 \quad (21.3)$$

and weights

$$w_k \quad \text{with} \quad \sum_k w_k = 1 \quad (21.4)$$

and construct the joint probability function

$$g(x) = \sum_k w_k \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \quad (21.5)$$

which also satisfies

$$\int g(x) dx = 1. \quad (21.6)$$

The algorithm implements a resolution of unity as follows

$$\begin{aligned}
1 &= \int dx = \int \frac{g(x)}{g(x)} dx \\
&= \sum w_k \int \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \frac{dx}{g(x)} \\
&= \sum w_k \int g^{(k)}(x^{(k)}) \frac{dx^{(k)}}{g(x(x^{(k)}))}
\end{aligned} \tag{21.7}$$

where each of the integrals in the sum is evaluated using the channel-specific variables $x^{(k)}$.

We provide two examples: (1) trivial with one channel, one dimension, and all functions unity and (2) two channels and two dimensions with

$$\begin{aligned}
x(x^{(1)}) &= (x_1^{(1)}, x_2^{(1)}) \\
x(x^{(2)}) &= (x_1^{(2)2}, x_2^{(2)})
\end{aligned} \tag{21.8}$$

hence

$$f^{(1)} \equiv 1, \quad f^{(2)}(x^{(2)}) = 2x_1^{(2)} \tag{21.9}$$

The probability functions are

$$g^{(1)} \equiv 1, \quad g^{(2)}(x^{(2)}) = 2x_2^{(2)} \tag{21.10}$$

In the concrete implementation of the integrator instance we store values for the channel probabilities g_i and the accumulated probability g .

We also store the result (product of integrand and MCI weight), the expected maximum for the result in each channel.

```

```

```
end function mci_test_instance_get_event_excess
```

Test sampler

The test sampler implements a fixed configuration, either trivial (one-channel, one-dimension), or slightly nontrivial (two-channel, two-dimension). In the second channel, the first parameter is mapped according to $x_1 = x_1^{(2)2}$, so we have $f^{(2)}(x^{(2)}) = 2x_1^{(2)}$.

For display purposes, we store the return values inside the object. This is not strictly necessary.

```
<MCI base: test types>+≡
type, extends (mci_sampler_t) :: test_sampler_t
  real(default) :: integrand = 0
  integer :: selected_channel = 0
  real(default), dimension(:,:), allocatable :: x

21.2 Iterations

This module defines a container for the list of iterations and calls, to be submitted to integration.

```

<iterations.f90>≡
  <File header>

  module iterations

    <Use kinds>
    <Use strings>

    <Standard module head>

    <Iterations: public>

    <Iterations: types>

    interface
    <Iterations: sub interfaces>
    end interface

  end module iterations

<iterations_sub.f90>≡
  <File header>

  submodule (iterations) iterations_s

    use io_units
    use diagnostics

    implicit none

  contains

    <Iterations: procedures>

```

```
end submodule iterations_s
```

21.2.1 The iterations list

Each integration pass has a number of iterations and a number of calls per iteration. The last pass produces the end result; the previous passes are used for adaptation.

The flags `adapt_grid` and `adapt_weight` are used only if `custom_adaptation` is set. Otherwise, default settings are used that depend on the integration pass.

```
<Iterations: types>≡
  type :: iterations_spec_t
    private
    integer :: n_it = 0
    integer :: n_calls = 0
    logical :: custom_adaptation = .false.
    logical :: adapt_grids = .false.
    logical :: adapt_weights = .false.
  end type iterations_spec_t
```

We build up a list of iterations.

```
<Iterations: public>≡
  public :: iterations_list_t

<Iterations: types>+≡
  type :: iterations_list_t
    private
    integer :: n_pass = 0
    type(iterations_spec_t), dimension(:), allocatable :: pass
  contains
    <Iterations: iterations list: TBP>
  end type iterations_list_t
```

Initialize an iterations list. For each pass, we have to specify the number of iterations and calls. We may provide the adaptation conventions explicitly, either as character codes or as logicals.

For passes where the adaptation conventions are not specified, we use the following default setting: adapt weights and grids for all passes except the last one.

```
<Iterations: iterations list: TBP>≡
  procedure :: init => iterations_list_init

<Iterations: sub interfaces>≡
  module subroutine iterations_list_init &
    (it_list, n_it, n_calls, adapt, adapt_code, adapt_grids, adapt_weights)
    class(iterations_list_t), intent(inout) :: it_list
    integer, dimension(:), intent(in) :: n_it, n_calls
    logical, dimension(:), intent(in), optional :: adapt
    type(string_t), dimension(:), intent(in), optional :: adapt_code
    logical, dimension(:), intent(in), optional :: adapt_grids, adapt_weights
  end subroutine iterations_list_init
```

<Iterations: procedures>+≡

```

module subroutine iterations_list_init &
    (it_list, n_it, n_calls, adapt, adapt_code, adapt_grids, adapt_weights)
    class(iterations_list_t), intent(inout) :: it_list
    integer, dimension(:), intent(in) :: n_it, n_calls
    logical, dimension(:), intent(in), optional :: adapt
    type(string_t), dimension(:), intent(in), optional :: adapt_code
    logical, dimension(:), intent(in), optional :: adapt_grids, adapt_weights
    integer :: i
    it_list%n_pass = size (n_it)
    if (allocated (it_list%pass)) deallocate (it_list%pass)
    allocate (it_list%pass (it_list%n_pass))

    use diagnostics
    use md5

    implicit none

  contains

    <Integration results: procedures>

  end submodule integration_results_s
```

21.3.1 Integration results entry

This object collects the results of an integration pass and makes them available to the outside.

The results object has to distinguish the process type:

We store the process type, the index of the integration pass and the absolute iteration index, the number of iterations contained in this result (for averages), and the integral (cross section or partial width), error estimate, efficiency.

For intermediate results, we set a flag if this result is an improvement w.r.t. previous ones.

The process type indicates decay or scattering. Dummy entries (skipped iterations) have a process type of PRC_UNKNOWN.

The additional information `n_calls_valid`, `efficiency_pos` and `efficiency_neg` are stored, but only used in verbose mode.

```

<Integration results: public>≡
    public :: integration_entry_t

<Integration results: types>≡
    type :: integration_entry_t
        private
        integer :: process_type = PRC_UNKNOWN
        integer :: pass = 0
        integer :: it = 0
        integer :: n_it = 0
        integer :: n_calls = 0
        integer :: n_calls_valid = 0
        logical :: improved = .false.
        real(default) :: integral = 0
        real(default) :: error = 0
        real(default) :: efficiency = 0
        real(default) :: efficiency_pos = 0
        real(default) :: efficiency_neg = 0
        real(default) :: chi2 = 0
        real(default), dimension(:), allocatable :: chain_weights
    contains

21.3.2 Combined integration results

We collect a list of results which grows during the execution of the program. This is implemented as an array which grows if necessary; so we can easily compute averages.

We implement this as an extension of the `mci_results_t` which is defined in `mci_base` as an abstract type. We thus decouple the implementation of the integrator from the implementation of the results display, but nevertheless can record intermediate results during integration. This implies that the present extension implements a `record` method.

```

<Integration results: public>+≡
  public :: integration_results_t

<Integration results: types>+≡
  type, extends (mci_results_t) :: integration_results_t
    private
    integer :: process_type = PRC_UNKNOWN
    integer :: current_pass = 0
    integer :: n_pass = 0
    integer :: n_it = 0
    logical :: screen = .false.
    integer :: unit = 0
    integer :: verbosity = 0
    real(default) :: error_threshold = 0
    type(integration_entry_t), dimension(:), allocatable :: entry
    type(integration_entry_t), dimension(:), allocatable :: average
  contains
    <Integration results: integration results: TBP>
  end type integration_results_t

```

The array is extended in chunks of 10 entries.

```

<Integration results: parameters>+≡
  integer, parameter :: RESULTS_CHUNK_SIZE = 10

<Integration results: integration results: TBP>≡
  procedure :: init => integration_results_init

<Integration results: sub interfaces>+≡
  module subroutine integration_results_init (results, process_type)
    class(integration_results_t), intent(out) :: results

```

During integration, we do not want to print all results at once, but each intermediate result as soon as we get it. Thus, the previous procedure is chopped in pieces. First piece: store the output unit and a flag whether we want to print to standard output as well. Then write the header if the results are still empty, i.e., before integration has started. The second piece writes a single result to the saved output channels. We call this from the `record` method, which can be called from the integrator directly. The third piece writes the average result, once a pass has been completed. The fourth piece writes a footer (if any), assuming that this is the final result.

```

Compute the average for all entries in the specified integration pass. The integrals are weighted w.r.t. their individual errors.

The quoted error of the result is the expected error, computed from the weighted average of the given individual errors.

This should be compared to the actual distribution of the results, from which we also can compute an error estimate if there is more than one iteration. The ratio of the distribution error and the averaged error, is the χ^2 value.

All error distributions are assumed Gaussian, of course. The χ^2 value is a partial check for this assumption. If it is significantly greater than unity, there is something wrong with the individual errors.

The efficiency returned is the one of the last entry in the integration pass.

If any error vanishes, averaging by this algorithm would fail. In this case, we simply average the entries and use the deviations from this average (if any) to estimate the error.

```

21.3.3 Access results

Return true if the results object has entries.

```

<Integration results: integration results: TBP>+≡
    procedure :: exist => integration_results_exist

<Integration results: sub interfaces>+≡
    module function integration_results_exist (results) result (flag)
        logical :: flag
        class(integration_results_t), intent(in) :: results
    end function integration_results_exist

<Integration results: procedures>+≡
    module function integration_results_exist (results) result (flag)
        logical :: flag
        class(integration_results_t), intent(in) :: results
        flag = results%n_pass > 0
    end function integration_results_exist

```

Retrieve information from the results record. If **last** is set and true, take the last iteration. If it is set instead, take this iteration. If **pass** is set, take this average. If none is set, take the final average.

If the result would be invalid, the entry is not assigned. Due to default initialization, this returns a null entry.

```

<Integration results: integration results: TBP>+≡

  end submodule mci_none_s
```

21.4.1 Integrator

The object contains the methods for integration and event generation. For the actual work and data storage, it spawns an instance object.

After an integration pass, we update the `max` parameter to indicate the maximum absolute value of the integrand that the integrator encountered. This

is required for event generation.

```
<MCI none: public>≡

```

21.5 Simple midpoint integration

This is a most simple implementation of an integrator. The algorithm is the straightforward multi-dimensional midpoint rule, i.e., the integration hypercube is binned uniformly, the integrand is evaluated at the midpoints of each bin, and the result is the average. The binning is equivalent for all integration dimensions.

This rule is accurate to the order h^2 , where h is the bin width. Given that $h = N^{-1/d}$, where d is the integration dimension and N is the total number of sampling points, we get a relative error of order $N^{-2/d}$. This is superior to MC integration if $d < 4$, and equivalent if $d = 4$. It is not worse than higher-order formulas (such as Gauss integration) if the integrand is not smooth, e.g., if it contains cuts.

The integrator is specifically single-channel. However, we do not limit the dimension.

```
<mci_midpoint.f90>≡
  <File header>

  module mci_midpoint

    <Use kinds>
    use phs_base

    use mci_base

<mci_midpoint_sub.f90>≡
  <File header>

  submodule (mci_midpoint) mci_midpoint_s

    use io_units
    use diagnostics

    implicit none

    contains

    <MCI midpoint: procedures>
```

```
end submodule mci_midpoint_s
```

21.5.1 Integrator

The object contains the methods for integration and event generation. For the actual work and data storage, it spawns an instance object.

After an integration pass, we update the `max` parameter to indicate the maximum absolute value of the integrand that the integrator encountered. This is required for event generation.

```
<MCI midpoint: public>≡

        allocate (mci_midpoint_instance_t :: mci_instance)
    end subroutine mci_midpoint_allocate_instance

```

Integrate. The number of dimensions is arbitrary. We make sure that the number of calls is evenly distributed among the dimensions. The actual number of calls will typically be smaller than the requested number, but never smaller than 1.

The sampling over a variable number of dimensions implies a variable number of nested loops. We implement this by a recursive subroutine, one loop in each recursion level.

The number of iterations `n_it` is ignored. Also, the error is set to zero in the current implementation.

With this integrator, we allow the calculation to abort immediately when forced by a signal. There is no state that we can save, hence we do not catch an interrupt.

For unweighted events, we generate weighted events and apply a simple rejection step to the relative event weight, until an event passes.

Note that we use the `max_abs` value stored in the configuration record, not the one stored in the instance. The latter may change during event generation. After an event generation pass is over, we may update the value for a subsequent pass.

```

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

This is the function $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

Mimicking the behavior of a process object, we store the argument and result inside the sampler, so we can `fetch` results.

```

<MCI midpoint: test types>≡
    type, extends (mci_sampler_t) :: test_sampler_1_t
        real(default), dimension(:), allocatable :: x
        real(default) :: val
    contains
    <MCI midpoint: test sampler 1: TBP>
    end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

<MCI midpoint: test sampler 1: TBP>≡
    procedure :: write => test_sampler_1_write

<MCI midpoint: tests>≡
    subroutine test_sampler_1_write (object, unit, testflag)
        class(test_sampler_1_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: testflag
        integer :: u
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Test sampler: f(x) = 3 x^2"
    end subroutine test_sampler_1_write

```

Evaluation: compute the function value. The output x parameter (only one channel) is identical to the input x , and the Jacobian is 1.

```

<MCI midpoint: test sampler 1: TBP>+≡
    procedure :: evaluate => test_sampler_1_evaluate

21.6 VAMP interface

The standard method for integration is **VAMP**: the multi-channel version of the VEGAS algorithm. Each parameterization (channel) of the hypercube is binned in each dimension. The binning is equally equidistant, but an iteration of the integration procedure, the binning is updated for each dimension, according to the variance distribution of the integrand, summed over all other dimension. In the next iteration, the binning approximates (hopefully) follows the integrand more closely, and the accuracy of the result is increased. Furthermore, the relative weight of the individual channels is also updated after an iteration.

The bin distribution is denoted as the grid for a channel, which we can write to file and reuse later.

In our implementation we specify the generic **VAMP** algorithm more tightly: the number of bins is equal for all dimensions, the initial weights are all equal. The user controls whether to update bins and/or weights after each iteration. The integration is organized in passes, each one consisting of several iterations with a common number of calls to the integrand. The first passes are intended as warmup, so the results are displayed but otherwise discarded. In the final pass, the integration estimates for the individual iterations are averaged for the final result.

```

Given two pass objects, compare them. All parameters must match. Where integrations are done in both (number of calls nonzero), the results must be equal (up to numerical noise).

The allocated array sizes might be different, but should match up to the common `n_it` value.

```

end if
end function pass_matches

```

Update a pass object, given a reference. The parameters must match, except for the `n_it` entry. The number of complete iterations must be less or equal to the reference, and the number of complete iterations in the reference must be no larger than `n_it`. Where results are present in both passes, they must match. Where results are present in the reference only, the pass is updated accordingly.

Update the MCI record (i.e., the integration passes) by reading from input stream. The stream should contain a `write` output from a previous run. We first check the MD5 sum of the configuration parameters. If that matches, we proceed directly to the stored integration passes. If successful, we may continue to read the file; the position will be after a blank line that must follow the MCI record.

```

```

Integrate. Perform a new integration pass (possibly reusing previous results), which may consist of several iterations.

Note: we record the integral once per iteration. The integral stored in the `mci` record itself is the last integral of the current iteration, no averaging done. The `results` record may average results.

In case we read the integration from file and we added new iterations to the pass preserving number of calls, we need to reshape the grids in order to incorporate the correct number of calls. Else the grids would be sampled with the number of calls from the grids file, which does not need to coincide with the number of calls from the pass.

Note: recording the efficiency is not supported yet.

Prepare an event generation pass. Should be called before a sequence of events is generated, then we should call the corresponding finalizer.

The pass-specific data of the previous integration pass are retained, but we reset the number of iterations and calls to zero. The latter now counts the number of events (calls to the sampling function, actually).

21.6.5 Sampling function

The VAMP sampling function has a well-defined interface which we have to implement. The `data` argument allows us to pass pointers to the `sampler` and `instance` objects, so we can access configuration data and fill point-dependent contents within these objects.

The `weights` and `channel` argument must be present in the call.

Note: this is the place where we must look for external signals, i.e., interrupt from the OS. We would like to raise a VAMP exception which is then caught by `vamp_sample_grids` as the caller, so it dumps its current state and returns (with the signal still pending). WHIZARD will then terminate gracefully. Of course, VAMP should be able to resume from the dump.

In the current implementation, we handle the exception in place and terminate immediately. The incomplete current integration pass is lost.

```

<MCI vamp: main procedures>+≡
  function vamp_sampling_function &
    (xi, data, weights, channel, grids) result (f)
    real(default) :: f
    real(default), dimension(:), intent(in) :: xi
    class(vamp_data_t), intent(in) :: data

```

```

real(default), dimension(:), intent(in), optional :: weights
integer, intent(in), optional :: channel
type(vamp_grid), dimension(:), intent(in), optional :: grids
type(exception) :: exc
logical :: verbose
character(*), parameter :: FN = "WHIZARD sampling function"
class(mci_instance_t), pointer :: instance
select type (data)
type is (mci_workspace_t)
  instance => data%instance
  select type (instance)
  class is (mci_vamp_instance_t)
    verbose = instance%mci%verbose
    call instance%evaluate (data%sampler, channel, xi)
    if (signal_is_pending ()) then
      call raise_exception (exc, EXC_FATAL, FN, "signal received")
      call handle_vamp_exception (exc, verbose)
      call terminate_now_if_signal ()
    end if
    instance%calls = instance%calls + 1
    if (data%sampler%is_valid ()) &
      & instance%calls_valid = instance%calls_valid + 1
    f = instance%get_value ()
    call terminate_now_if_single_event ()
  class default
    call msg_bug("VAMP: " // FN // ": unknown MCI instance type")
  end select
end select
end function vamp_sampling_function

```

This is supposed to be the mapping between integration channels. The VAMP event generating procedures technically require it, but it is meaningless in our setup where all transformations happen inside the sampler object. So, this implementation is trivial: Gfortran 7/8/9 bug, has to remain in the main module:

```

<MCI vamp: main procedures>+=
pure function phi_trivial (xi, channel_dummy) result (x)
  real(default), dimension(:), intent(in) :: xi
  integer, intent(in) :: channel_dummy
  real(default), dimension(size(xi)) :: x
  x = xi
end function phi_trivial

```

Generate weighted event. Note that the event weight (`vamp_weight`) is not just the MCI weight. `vamp_next_event` selects a channel based on the channel weights multiplied by the (previously recorded) maximum integrand value of the channel. The MCI weight is renormalized accordingly, to cancel this effect on the result. Gfortran 7/8/9/ bug, has to remain in the main module:

```

<MCI vamp: mci vamp: TBP>+=
procedure :: generate_weighted_event => mci_vamp_generate_weighted_event

<MCI vamp: main procedures>+=
subroutine mci_vamp_generate_weighted_event (mci, instance, sampler)
  class(mci_vamp_t), intent(inout) :: mci

```

```

21.6.6 Sampler as Workspace

In the full setup, the sampling function requires the process instance object as workspace. We implement this by (i) implementing the process instance as a type extension of the abstract `sampler_t` object used by the MCI implementation and (ii) providing such an object as an extra argument to the sampling function that VAMP can call. To minimize cross-package dependencies, we use an abstract type `vamp_workspace` that VAMP declares and extend this by including a pointer to the `sampler` and `instance` objects. In the body of the

sampling function, we dereference this pointer and can then work with the contents.

```

<MCI vamp: types>+≡
  type, extends (vamp_data_t) :: mci_workspace_t
    class(mci_sampler_t), pointer :: sampler => null ()
    class(mci_vamp_instance_t), pointer :: instance => null ()
  end type mci_workspace_t

```

21.6.7 Integrator instance

The history entries should point to the corresponding history entry in the `pass_t` object. If there is none, we may allocate a local history, which is then just transient.

```

Prepare a new integration pass: write the pass-specific settings to the `instance` object. This should be called initially, together with the `create_grids` procedure, and whenever we start a new integration pass.

Set `reshape` if the number of calls is different than previously (unless it was zero, indicating the first pass).

We link VAMP histories to the allocated histories in the current pass object, so the recorded results are persistent. However, if there are no histories present there, we allocate them locally. In that case, the histories will disappear together with the MCI instance object.

    end if
end if
end subroutine mci_vamp_instance_adapt_grids

```

Adapt weights. Use the variance array returned by VAMP for recalculating the weight array. The parameter `channel_weights_power` dampens fluctuations.

If the number of calls in a given channel falls below a user-defined threshold, the weight is not lowered further but kept at this threshold. The other channel weights are reduced accordingly. Gfortran 7/8/9 bug, has to remain in the main module:

```

<MCI vamp: mci vamp instance: TBP>+≡

Integration: sample the VAMP grids. The number of calls etc. are already stored inside the grids. We provide the random-number generator, the sampling function, and a link to the workspace object, which happens to contain a pointer to the sampler object. The sampler object thus becomes the workspace of the sampling function.

Note: in the current implementation, the random-number generator must be the TAO generator. This explicit dependence should be removed from the VAMP implementation. Gfortran 7/8/9 bug, has to remain in the main module:

```

21.6.8 Integrator instance: evaluation

Here, we compute the multi-channel reweighting factor for the current channel, that accounts for the Jacobians of the transformations from/to all other channels.

The computation of the VAMP probabilities may consume considerable time, therefore we enable parallel evaluation. (Collecting the contributions to `mci%g` is a reduction, which we should also implement via OpenMP.)

```

<MCI vamp: mci vamp instance: TBP>+≡
    procedure :: compute_weight => mci_vamp_instance_compute_weight

<MCI vamp: sub interfaces>+≡
    module subroutine mci_vamp_instance_compute_weight (mci, c)

```

Get the event weight. The default routine returns the same value that we would use for integration. This is correct if we select the integration channel according to the channel weight. `vamp_next_event` does differently, so we should rather rely on the weight that VAMP returns. This is the value stored in `vamp_weight`.

We override the default TBP accordingly.

```

21.6.9 VAMP exceptions

A VAMP routine may have raised an exception. Turn this into a WHIZARD error message.

An external signal could raise a fatal exception, but this should be delayed and handled by the correct termination routine. Gfortran 7/8/9 bug, has to remain in the main module:

```

<MCI vamp: main procedures>+≡
  subroutine handle_vamp_exception (exc, verbose)
    type(exception), intent(in) :: exc
    logical, intent(in) :: verbose
    integer :: exc_level
    if (verbose) then
      exc_level = EXC_INFO
    else
      exc_level = EXC_ERROR
    end if

```

```

    if (exc%level >= exc_level) then
        write (msg_buffer, "(A,':',1x,A)" trim (exc%origin), trim (exc%message)
        select case (exc%level)
            case (EXC_INFO); call msg_message ()
            case (EXC_WARN); call msg_warning ()
            case (EXC_ERROR); call msg_error ()
            case (EXC_FATAL)
                if (signal_is_pending ()) then
                    call msg_message ()
                else
                    call msg_fatal ()
                end if
            end select
        end if
    end subroutine handle_vamp_exception

```

```

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is $11x^{10}$, also with integral 1.

Mode 4 includes ranges of zero and negative function value, the integral is negative. The results should be identical to the results of `mci_midpoint_4`, where the same function is evaluated. The function is $f(x) = (1 - 3x^2) \theta(x - 1/2)$ with integral $\int_0^1 f(x) dx = -3/8$, minimum $f(1) = -2$ and maximum $f(1/2) = 1/4$.

```

<MCI vamp: test types>≡
    type, extends (mci_sampler_t) :: test_sampler_1_t
        real(default), dimension(:), allocatable :: x
        real(default) :: val
        integer :: mode = 1
    contains
    <MCI vamp: test sampler 1: TBP>
    end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

<MCI vamp: test sampler 1: TBP>≡
    procedure :: write => test_sampler_1_write
<MCI vamp: tests>≡
    subroutine test_sampler_1_write (object, unit, testflag)
        class(test_sampler_1_t), intent(in) :: object

```

```

integer, intent(in), optional :: unit
logical, intent(in), optional :: testflag
integer :: u
u = given_output_unit (unit)
select case (object%mode)
case (1)
  write (u, "(1x,A)") "Test sampler: f(x) = 3 x^2"
case (2)
  write (u, "(1x,A)") "Test sampler: f(x) = 11 x^10"
case (3)
  write (u, "(1x,A)") "Test sampler: f(x) = 11 x^10 * 2 * cos^2 (2 pi y)"
case (4)
  write (u, "(1x,A)") "Test sampler: f(x) = (1 - 3 x^2) theta(x - 1/2)"
end select
end subroutine test_sampler_1_write

```

Evaluation: compute the function value. The output x parameter (only one channel) is identical to the input x , and the Jacobian is 1.

Two-channel, two dimension test sampler

This sampler implements the function

$$f(x, y) = 4 \sin^2(\pi x) \sin^2(\pi y) + 2 \sin^2(\pi v) \quad (21.11)$$

where

$$x = u^v \quad u = xy \quad (21.12)$$

$$y = u^{(1-v)} \quad v = \frac{1}{2} \left(1 + \frac{\log(x/y)}{\log xy} \right) \quad (21.13)$$

Each term contributes 1 to the integral. The first term in the function is peaked along a cross aligned to the coordinates x and y , while the second term is peaked along the diagonal $x = y$.

The Jacobian is

$$\frac{\partial(x,y)}{\partial(u,v)} = |\log u| \quad (21.14)$$

```

Two-channel, one dimension test sampler

This sampler implements the function

$$f(x, y) = a * 5x^4 + b * 5(1 - x)^4 \quad (21.15)$$

Each term contributes 1 to the integral, multiplied by a or b , respectively. The first term is peaked at $x = 1$, the second one at $x = 0$.

We implement the two mappings

$$x = u^{1/5} \quad \text{and} \quad x = 1 - v^{1/5}, \quad (21.16)$$

with Jacobians

$$\frac{\partial(x)}{\partial(u)} = u^{-4/5}/5 \quad \text{and} \quad v^{-4/5}/5, \quad (21.17)$$

respectively. The first mapping concentrates points near $x = 1$, the second one near $x = 0$.

One-dimensional integration

Construct an integrator and use it for a one-dimensional sampler.

Note: We would like to check the precise contents of the grid allocated during integration, but the output format for reals is very long (for good reasons), so the last digits in the grid content display are numerical noise. So, we just check the integration results.

```

Update a pass object, given a reference. The parameters must match, except for the `n_it` entry. The number of complete iterations must be less or equal to

the reference, and the number of complete iterations in the reference must be no larger than `n_it`. Where results are present in both passes, they must match. Where results are present in the reference only, the pass is updated accordingly.

```

21.7.4 Integrator

We store the different passes of integration, adaptation and actual sampling, in a linked list.

We store the total number of calls `n_calls` and the minimal number of calls `n_calls_min`. The latter is calculated based on `n_channel` and `min_calls_per_channel`. If `n_calls` is smaller than `n_calls_min`, then we replace `n_calls` with `n_min_calls`.

Update the MCI record (i.e., the integration passes) by reading from input stream. The stream should contain a write output from a previous run. We first check the MD5 sum of the configuration parameters. If that matches, we proceed directly to the stored integration passes. If successful, we may continue to read the file; the position will be after a blank line that must follow the MCI record.

```

Read / write grids from / to file.

We split the reading process in two parts. First, we check on the header where we check (and update) all relevant pass data using `mci_vamp2_update`. In the second part we only read the integrator data. We implement `mci_vamp2_read` for completeness.

The writing of the MCI object is split into two parts, a header with the relevant process configuration regarding the integration and the results of the different passes and their iterations. The other part is the actual grid. The header will always be written in ASCII format, including a md5 hash, in order to testify against unwilling changes to the setup. The grid part can be either added to the ASCII file, or to an additional binary file.

```

```

Integrate. Perform a new integration pass (possibly reusing previous results), which may consist of several iterations. We reinitialise the sampling new each time and set the workspace again. Note: we record the integral once per iteration. The integral stored in the mci record itself is the last integral of the current iteration, no averaging done. The results record may average results. Note: recording the efficiency is not supported yet.

Write grids to `grid_filename` at a given checkpoint.

We qualify each iteration and pass as possible checkpoint. However, we allow the user to alter the checkpoint behavior:

- after every iteration,
- after every pass,
- after a N iterations and every pass.

The user sets the Sindarin variable `vamp_grid_checkpoint` to an integer value where the value 0 represents each pass, value 1 each iteration, and a value > 1 means after N iterations (or at the last iteration of a pass).

```

21.7.6 Integrator instance

We store all information relevant for simulation. The event weight is stored, when a weighted event is generated, and the event excess, when a larger weight occurs than actual stored max. weight.

We give the possibility to rescale the `f_max` within the integrator object with `event_rescale_f_max`.

```

<MCI vamp2: public>+≡
public :: mci_vamp2_instance_t

<MCI vamp2: types>+≡
type, extends (mci_instance_t) :: mci_vamp2_instance_t
class(mci_vamp2_func_t), allocatable :: func
real(default), dimension(:), allocatable :: gi
integer :: n_events = 0
logical :: event_generated = .false.
real(default) :: event_weight = 0._default
real(default) :: event_excess = 0._default
real(default) :: event_rescale_f_max = 1._default
real(default), dimension(:), allocatable :: event_x
contains
<MCI vamp2: mci vamp2 instance: TBP>
end type mci_vamp2_instance_t

```

Output.

Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is $f(x) = 3x^2$ with integral $\int_0^1 f(x) dx = 1$ and maximum $f(1) = 3$. If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is $11x^{10}$, also with integral 1.

Mode 4 includes ranges of zero and negative function value, the integral is negative. The results should be identical to the results of `mci_midpoint_4`, where the same function is evaluated. The function is $f(x) = (1 - 3x^2) \theta(x - 1/2)$ with integral $\int_0^1 f(x) dx = -3/8$, minimum $f(1) = -2$ and maximum $f(1/2) = 1/4$.

```

<MCI vamp2: test types>≡
    type, extends (mci_sampler_t) :: test_sampler_1_t
        real(default), dimension(:), allocatable :: x
        real(default) :: val
        integer :: mode = 1
    contains
    <MCI vamp2: test sampler 1: TBP>
end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

Two-channel, two dimension test sampler

This sampler implements the function

$$f(x, y) = 4 \sin^2(\pi x) \sin^2(\pi y) + 2 \sin^2(\pi v) \quad (21.19)$$

where

$$x = u^v \quad u = xy \quad (21.20)$$

$$y = u^{(1-v)} \quad v = \frac{1}{2} \left(1 + \frac{\log(x/y)}{\log xy} \right) \quad (21.21)$$

Each term contributes 1 to the integral. The first term in the function is peaked along a cross aligned to the coordinates x and y , while the second term is peaked along the diagonal $x = y$.

The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = |\log u| \quad (21.22)$$

```

Chapter 22

Parton shower and interface to PYTHIA6

This is the code for the WHIZARD QCD parton shower for final state radiation (FSR) and initial state radiation (ISR) as well as the interface to the PYTHIA module for showering and hadronization.

22.1 Basics of the shower

```
<shower_base.f90>≡  
<File header>  
  
module shower_base  
  
  <Use kinds>  
  <Use strings>  
  use lorentz  
  use particles  
  use os_interface  
  use rng_base  
  use variables  
  use model_data  
  use pdf  
  use tauola_interface  
  
  <Standard module head>  
  
  <Shower base: public>  
  
  <Shower base: parameters>  
  
  <Shower base: types>  
  
  <Shower base: interfaces>  
  
  interface  
  <Shower base: sub interfaces>
```

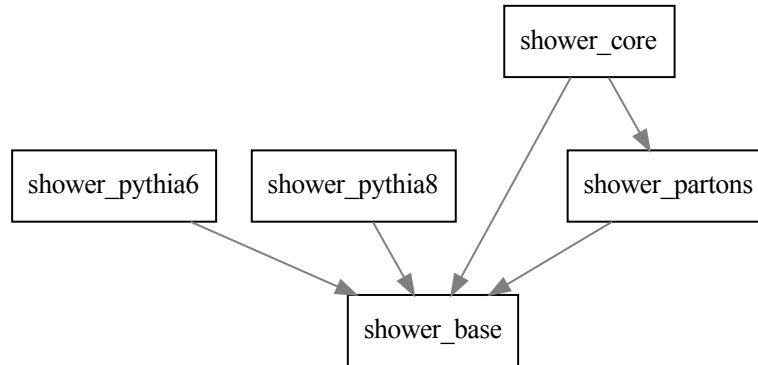

Figure 22.1: Module dependencies in `src/shower`.

```

    end interface

    end module shower_base

    (shower_base_sub.f90)≡
    <File header>

    submodule (shower_base) shower_base_s

        use io_units
        use constants
        use diagnostics
        use format_utils, only: write_separator
        use physics_defs
        use sm_physics, only: running_as_lam

        implicit none

    contains

    <Shower base: procedures>

    end submodule shower_base_s
  
```

22.1.1 Shower implementations

```

    (Shower base: public)≡
    public :: PS_WHIZARD, PS_PYTHIA6, PS_PYTHIA8, PS_UNDEFINED

    (Shower base: parameters)≡
    integer, parameter :: PS_UNDEFINED = 0
    integer, parameter :: PS_WHIZARD = 1
  
```

```
integer, parameter :: PS_PYTHIA6 = 2
integer, parameter :: PS_PYTHIA8 = 3
```

A dictionary

<Shower base: public>+≡

```
public :: shower_method_of_string
```

<Shower base: sub interfaces>≡

```
elemental module function shower_method_of_string (string) result (i)
  integer :: i
  type(string_t), intent(in) :: string
end function shower_method_of_string

  case (PS_PYTHIA8)
    string = "PYTHIA8"
  case default
    string = "UNDEFINED"
  end select
end function shower_method_to_string
```

22.1.2 Shower settings

These the general shower settings, the settings and parameters for the matching are defined in the corresponding matching modules. The width and the cutoff of the Gaussian primordial k_t distribution, PARP(91) and PARP(93), in GeV, are called `isr_primordial_kt_width` and `isr_primordial_kt_cutoff` in WHIZARD. The parameter MSTJ(45) gives the maximum number of flavors in gluon decay to quarks, and is here called `max_n_flavors`.

The two parameters `isr_alphas_running` and `fsr_alphas_running` decide whether to use constant or running α_s in the form of the function $D_{\alpha_s}(t)$ for the FSR and ISR (MSTJ(44), MSTP(64)), respectively. The next parameter, `fixed_alpha_s` is the parameter PARU(111), which sets the value for constant α_s , and the flag whether to use P_t -ordered ISR is `isr_pt_ordered`. From the entry `min_voirtuality` on, parameters have meanings both for the PYTHIA and WHIZARD parton shower(s), where PYTHIA values are denoted at the end of the line.

```

Mass and mass squared selection functions. All masses are in GeV. Light quarks are assumed to be ordered, $m_1 < m_2 < m_3 \dots$, and they get current masses, not elementary ones. Mesons and baryons other than proton and neutron are needed as beam-remnants. Particles with PDG number zero are taken massless, as well as proper beam remnants and any other particles.

```

22.2.1 The basic type defintions

The type `parton_t` defines a parton for the shower. The `x` value of the parton is only needed for spacelike showers. The pointer `initial` is only needed for partons in initial showers, it points to the hadron the parton is coming from. An auxiliary value for the P_t -ordered ISR is `aux_pt`. Then, there are two auxiliary entries for the clustering of CKKW pseudo weights and CKKW matching, `ckkwlabel` and `ckkwscale`. In order to make shower settings available to all operations on the shower partons, we endow the `parton_t` type with a pointer to `shower_settings_t`.

```

<Shower partons: public>≡
    public :: parton_t

<Shower partons: types>≡
    type :: parton_t

The parameters of the shower module:

```

<Shower core: parameters>≡
    real(default), save :: alphaspdfmax = 12._default

```

In this routine, *y* and *ymin* are the jet measures, *w* and *wmax* are weights, *s* is the kinematic energy squared of the interaction. The flag *isr_is_possible_and_allowed* checks whether the initial parton is set, lepton-hadron collisions are not implemented (yet).

As a workaround: as WHIZARD can treat partons as massless, there might be partons with $E < m$: if such a parton is found, quarks will be treated massless.

We combine the `particle_set` from the hard interaction with the partons of the shower. For simplicity, we do not maintain the mother-daughter-relations of the shower. Hadronic beam_remnants of the old `particle_set` are removed as they are provided, including proper flavor information, by the ISR shower.

K(I,1) pythia status code
 1 = undecayed particle or unfragmented parton
 (single or last of parton system)
 2 = unfragmented parton
 (followed by more partons in the same color singlet)
 3 = unfragmented parton (color info in K(I,4), K(I,5))
 11 = decayed particle or fragmented parton
 12 = fragmented parton
 13 = fragmented parton that has been removed The first two
 14 = branched parton with color info like 3
 21 = documentation lines

K(I,2) PDG code

K(I,3) Parent where known else 0. Unphysical to assign
 particles partons as parents

K(I,4) Normally first daughter

K(I,5) Normally last daughter

particles are always the beams, in Pythia and Whizard. We remove all beam
 remnants (including the ISR photons) since those are added back in by Pythia.

!C      KTCLUS: written by Mike Seymour, July 1992.
!C      Last modified November 2000.
!C      Please send comments or suggestions to Mike.Seymour@rl.ac.uk
!C

```

```

!C      This is a general-purpose kt clustering package.
!C      It can handle ee, ep and pp collisions.
!C      It is loosely based on the program of Siggi Bethke.
!C
!C      The time taken (on a 10MIP machine) is (0.2microsec)*N**3
!C      where N is the number of particles.
!C      Over 90 percent of this time is used in subroutine KTPMIN, which
!C      simply finds the minimum member of a one-dimensional array.
!C      It is well worth thinking about optimization: on the SPARCstation
!C      a factor of two increase was obtained simply by increasing the
!C      optimization level from its default value.
!C
!C      The approach is to separate the different stages of analysis.
!C      KTCLUS does all the clustering and records a merging history.
!C      It returns a simple list of the y values at which each merging
!C      occurred. Then the following routines can be called to give extra
!C      information on the most recently analysed event.
!C      KTCLUR is identical but includes an R parameter, see below.
!C      KTYCUT gives the number of jets at each given YCUT value.
!C      KTYSUB gives the number of sub-jets at each given YCUT value.
!C      KTBEAM gives same info as KTCLUS but only for merges with the beam
!C      KTJOIN gives same info as KTCLUS but for merges of sub-jets.
!C      KTRECO reconstructs the jet momenta at a given value of YCUT.
!C      It also gives information on which jets at scale YCUT belong to
!C      which macro-jets at scale YMAC, for studying sub-jet properties.
!C      K TINCL reconstructs the jet momenta according to the inclusive jet
!C      definition of Ellis and Soper.
!C      KTISUB, KTIJOI and KTIREC are like KTYSUB, KTJOIN and KTRECO,
!C      except that they only apply to one inclusive jet at a time,
!C      with the pt of that jet automatically used for ECUT.
!C      KTWICH gives a list of which particles ended up in which jets.
!C      KTWCHS gives the same thing, but only for subjets.
!C      Note that the numbering of jets used by these two routines is
!C      guaranteed to be the same as that used by KTRECO.
!C
!C      The collision type and analysis type are indicated by the first
!C      argument of KTCLUS. IMODE=<TYPE><ANGLE><MONO><RECOM> where
!C      TYPE:  1=>ee, 2=>ep with p in -z direction, 3=>pe, 4=>pp
!C      ANGLE: 1=>angular kt def., 2=>DeltaR, 3=>f(DeltaEta,DeltaPhi)
!C              where f() $=2(\cosh(\eta)-\cos(\phi))$  is the QCD emission metric
!C      MONO:  1=>derive relative pseudoparticle angles from jets
!C              2=>monotonic definitions of relative angles
!C      RECOM: 1=>E recombination scheme, 2=>pt scheme, 3=>pt**2 scheme
!C
!C      There are also abbreviated forms for the most common combinations:
!C      IMODE=1 => E scheme in e+e-                      (=1111)
!C              2 => E scheme in ep                      (=2111)
!C              3 => E scheme in pe                      (=3111)
!C              4 => E scheme in pp                      (=4111)
!C              5 => covariant E scheme in pp            (=4211)
!C              6 => covariant pt-scheme in pp           (=4212)
!C              7 => covariant monotonic pt**2-scheme in pp (=4223)
!C
!C      KTRECO no longer needs to reconstruct the momenta according to the

```

!C same recombination scheme in which they were clustered. Its first
!C argument gives the scheme, taking the same values as RECOM above.
!C

!C Note that unlike previous versions, all variables which hold y
!C values have been named in a consistent way:
!C Y() is the output scale at which jets were merged,
!C YCUT is the input scale at which jets should be counted, and
!C jet-momenta reconstructed etc,
!C YMAC is the input macro-jet scale, used in determining whether
!C or not each jet is a sub-jet.
!C The original scheme defined in our papers is equivalent to always
!C setting YMAC=1.
!C Whenever a YCUT or YMAC variable is used, it is rounded down
!C infinitesimally, so that for example, setting YCUT=Y(2) refers
!C to the scale where the event is 2-jet, even if rounding errors
!C have shifted its value slightly.
!C

!C An R parameter can be used in hadron-hadron collisions by
!C calling KTCLUR instead of KTCLUS. This is as suggested by
!C Ellis and Soper, but implemented slightly differently,
!C as in M.H. Seymour, LU TP 94/2 (submitted to Nucl. Phys. B.).
!C R**2 multiplies the single Kt everywhere it is used.
!C Calling KTCLUR with R=1 is identical to calling KTCLUS.
!C R plays a similar role to the jet radius in a cone-type algorithm,
!C but is scaled up by about 40% (ie R=0.7 in a cone algorithm is
!C similar to this algorithm with R=1).
!C Note that R.EQ.1 must be used for the e+e- and ep versions,
!C and is strongly recommended for the hadron-hadron version.
!C However, R values smaller than 1 have been found to be useful for
!C certain applications, particularly the mass reconstruction of
!C highly-boosted colour-singlets such as high-pt hadronic Ws,
!C as in M.H. Seymour, LU TP 93/8 (to appear in Z. Phys. C.).
!C Situations in which R<1 is useful are likely to also be those in
!C which the inclusive reconstruction method is more useful.
!C

!C Also included is a set of routines for doing Lorentz boosts:
!C KTLBST finds the boost matrix to/from the cm frame of a 4-vector
!C KTRROT finds the rotation matrix from one vector to another
!C KTMUL multiplies together two matrices
!C KTMUL multiplies a vector by a matrix
!C KTINVT inverts a transformation matrix (nb NOT a general 4 by 4)
!C KTFRAM boosts a list of vectors between two arbitrary frames
!C KTBREI boosts a list of vectors between the lab and Breit frames
!C KTHADR boosts a list of vectors between the lab and hadronic cmf
!C The last two need the momenta in the +z direction of the lepton
!C and hadron beams, and the 4-momentum of the outgoing lepton.
!C

!C The main reference is:
!C S. Catani, Yu.L. Dokshitzer, M.H. Seymour and B.R. Webber,
!C Nucl.Phys.B406(1993)187.
!C The ep version was proposed in:
!C S. Catani, Yu.L. Dokshitzer and B.R. Webber,
!C Phys.Lett.285B(1992)291.
!C The inclusive reconstruction method was proposed in:

```

!C      S.D. Ellis and D.E. Soper,
!C      Phys.Rev.D48(1993)3160.

Setup the user process for the LHA interface.

We fill the user process with the correct information on the beams, and set the strategy of the user process to weighted events. `process_id` and `n_processes` are not used by LHA user process for weighted (or unweighted) events, but required by the LHA user process interface. Therefore, we choose arbitrary defaults.

Chapter 23

Multiple Interactions (MPI) Code

23.1 The Multiple Interactions main module

This file contains the module `muli` which is the multiple parton interactions interface module to `WHIZARD`. `muli` is supposed to run together with initial state radiation. Both share a momentum evolution variable and compete for beam momentum, so the generation of this scale variable must be fully transparent to `WHIZARD`. This here is a stub as long as there is no working `WHIZARD` implementation for multiple interactions. It gives an interface for the necessary routines.

```

Chapter 24

BLHA Interface

The code in this chapter implements support for the BLHA record that communicates data for NLO processes.

These are the modules:

blha_config

blha_olp_interfaces

The module is split into a configuration interface which manages configuration and handles the request and contract files, a module which interfaces the OLP matrix elements and a driver.

```
(blha_config.f90)≡  
  <File header>  
  
  module blha_config  
  
    use kinds  
    <Use strings>  
    use variables, only: var_list_t  
    use model_data  
    use beam_structures, only: beam_structure_t  
  
    <Standard module head>  
  
    <BLHA config: public>  
  
    <BLHA config: parameters>  
  
    <BLHA config: types>  
  
    <BLHA config: variables>  
  
    <BLHA config: interfaces>  
  
    interface  
    <BLHA config: sub interfaces>  
    end interface
```

Figure 24.1: Module dependencies in `src/blha`.

```

end module blha_config

⟨blha_config_sub.f90⟩≡
⟨File header⟩

submodule (blha_config) blha_config_s

  ⟨Use mpi f08⟩
  use io_units
  use constants
  use string_utils
  use physics_defs, only: PHOTON, PHOTON_OFFSHELL
  use diagnostics
  use flavors
  use pdg_arrays

  implicit none

contains

  ⟨BLHA config: procedures⟩

end submodule blha_config_s

```

24.1 Configuration

Parameters to enumerate the different options in the order.

```

⟨BLHA config: parameters⟩≡
  integer, public, parameter :: &
    BLHA_CT_QCD = 1, BLHA_CT_EW = 2, BLHA_CT_OTHER = 3
  integer, public, parameter :: &
    BLHA_IRREG_CDR = 1, BLHA_IRREG_DRED = 2, BLHA_IRREG_THV = 3, &
    BLHA_IRREG_MREG = 4, BLHA_IRREG_OTHER = 5
  integer, public, parameter :: &
    BLHA_MPS_ONSHELL = 1, BLHA_MPS_OTHER = 2
  integer, public, parameter :: &
    BLHA_MODE_GOSAM = 1, BLHA_MODE_FEYNARTS = 2, BLHA_MODE_GENERIC = 3, &
    BLHA_MODE_OPENLOOPS = 4
  integer, public, parameter :: &
    BLHA_VERSION_1 = 1, BLHA_VERSION_2 = 2
  integer, public, parameter :: &
    BLHA_AMP_LOOP = 1, BLHA_AMP_COLOR_C = 2, BLHA_AMP_SPIN_C = 3, &
    BLHA_AMP_TREE = 4, BLHA_AMP_LOOPINDUCED = 5
  integer, public, parameter :: &
    BLHA_EW_INTERNAL = 0, &
    BLHA_EW_GF = 1, BLHA_EW_MZ = 2, BLHA_EW_MSBAR = 3, &
    BLHA_EW_0 = 4, BLHA_EW_RUN = 5
  integer, public, parameter :: &
    BLHA_WIDTH_COMPLEX = 1, BLHA_WIDTH_FIXED = 2, &
    BLHA_WIDTH_RUNNING = 3, BLHA_WIDTH_POLE = 4, &
    BLHA_WIDTH_DEFAULT = 5

```

Those are the default pdg codes for massive particles in BLHA programs

```
<BLHA config: parameters>+=
  integer, parameter, public :: OLP_N_MASSIVE_PARTICLES = 12
  integer, dimension(OLP_N_MASSIVE_PARTICLES), public :: &
    OLP_MASSIVE_PARTICLES = [5, -5, 6, -6, 13, -13, 15, -15, 23, 24, -24, 25]
  integer, parameter :: OLP_HEL_UNPOLARIZED = 0
```

The user might provide an extra command string for OpenLoops to apply special libraries instead of the default ones, such as signal-only amplitudes for off-shell top production. We check in this subroutine that the provided string is valid and print out the possible options to ease the user's memory.

```
<BLHA config: parameters>+=
  integer, parameter :: N_KNOWN_SPECIAL_OL_METHODS = 3

<BLHA config: procedures>=
  subroutine check_extra_cmd (extra_cmd)
    type(string_t), intent(in) :: extra_cmd
    type(string_t), dimension(N_KNOWN_SPECIAL_OL_METHODS) :: known_methods
    integer :: i
    logical :: found
    known_methods(1) = 'top'
    known_methods(2) = 'not'
    known_methods(3) = 'stop'
    if (extra_cmd == var_str("")) return
    found = .false.
    do i = 1, N_KNOWN_SPECIAL_OL_METHODS
      found = found .or. &
        (extra_cmd == var_str ('extra approx ')) // known_methods(i))
    end do
    if (.not. found) &
      call msg_fatal ("The given extra OpenLoops method is not kown ", &
        [var_str ("Available commands are: "), &
        var_str ("extra approx top (only WbWb signal),"), &
        var_str ("extra approx stop (only WbWb singletop),"), &
        var_str ("extra approx not (no top in WbWb).")])
    end subroutine check_extra_cmd
```

This type contains the pdg code of the particle to be written in the process specification string and an optional additional information about the polarization of the particles. Note that the output can only be processed by OpenLoops.

```
<BLHA config: types>=

Write the BLHA file. Internal mode is intended for md5summing only.

Special cases of external photons in **OpenLoops**:

For electroweak corrections the particle ID (PID) of photons is a crucial input for the computation of matrix elements by **OpenLoops**. According to "arXiv: 1907.13071", section 3.2, external photons are classified by the following types:

- PID = -2002: off-shell photons, that undergo $\gamma \rightarrow f\bar{f}$ splittings at NLO EW, or initial state photons from QED PDFs
- PID = 2002: on-shell photons, that do not undergo $\gamma \rightarrow f\bar{f}$ splittings at NLO EW, or initial state photons for example at photon colliders
- PID = 22: unresolved photons, representing radiated photons at NLO EW, absent at LO

For the first two types scattering amplitudes for processes with external photons at NLO EW get renormalisation factors containing photon-coupling and wave function counterterms. Logarithmic mass singularities arising due to the renormalisation of off-shell external photon wave functions are cancelled by collinear singularities of photon PDF counterterms or analogous terms in virtual contributions originating from $\gamma \rightarrow f\bar{f}$ splittings of final state photons.

The finite remainders of the renormalisation factors are thus dictated by the specific photon PID stated above. As consequence, we have to adjust the input PIDs written into the BLHA file which will be read by **OpenLoops**.

Concretely, for the case of electroweak corrections initial state photons associated with photon PDFs and final state photons (if existent at LO) are labeled as off-shell photons with PID "-2002". On-shell photons with PID "2002" are neglected for now since to include them for processes at NLO EW is non-trivial from the phenomenological point of view. Processes at NLO EW typically are studied at high energy scales for which photon-induced sub-processes in most cases can not be neglected. However, on-shell, e. g. tagged, photons are defined at low energy scales and thus the process has to be described with external photon fields and couplings at two different scales.

Another issue which has to be addressed if various photon PIDs are taken into account is that real and virtual amplitudes have to be computed at the same order in α at a specific scale for the subtraction scheme to be consistent. The complication comes by the fact that the EW coupling α of each external photon in the amplitudes will automatically be rescaled by **OpenLoops** corresponding to the specific photon type. Following eq. (3.30) of "arXiv: 1907.13071", by default the coupling of an on-shell photon will be changed to $\alpha(0)$ and that of an off-shell photon to α_{G_μ} if not chosen already at a high scale, e. g. $\alpha(M_Z)$. In order to not spoil the IR cancellation **OpenLoops** supplies to register unresolved photons with PID "22" describing a radiated photon at NLO EW for which the photon-coupling α is left unchanged at the value which is computed with the

electroweak input scheme chosen by the user. This is adopted here by labeling each emitted photon as unresolved with PID "22" if no photons are present at LO.

For EW corrections the freedom to choose an electroweak input scheme is restricted, however, since the number of external photons present at LO is not conserved for the corresponding real flavor structures due to possible $\gamma \rightarrow f\bar{f}$ splittings. This forbids to choose $\alpha = \alpha(0)$ since otherwise the order in $\alpha(0)$ is not conserved in the real amplitudes corresponding to the factorizing Born process. Consequently, for FKS the NLO components are not of the same order in $\alpha(0)$. The option `$blha_ew_scheme = "alpha_0"` is thus refused for the case if EW corrections are activated and photons are present at LO.

24.2 Module definition

These modules implement the communication with one loop matrix element providers according to the Binoth LesHouches Accord Interface. The actual matrix element(s) are loaded as a dynamic library.

This module defines the common OLP-interfaces defined through the Binoth Les-Houches accord.

```

Computes a virtual matrix element from an interface to an external one-loop provider. The output of `blha_olp_eval2` is an array of `dimension(4)`, corresponding to the ϵ^2 -, ϵ^1 - and ϵ^0 -poles of the virtual matrix element at position `r(1:3)` and the Born matrix element at position `r(4)`. The matrix element is rejected if its accuracy is larger than the maximal allowed accuracy. OpenLoops includes a factor of $1 / n_{\text{hel}}$ in the amplitudes, which we have to undo if polarized matrix elements are requested (GoSam does not support polarized matrix elements).

For the color correlated matrix the standard is to compute the diagonal entries from the born amplitudes and corresponding casimirs. However, if EW corrections are activated, the thus derived entries can be computed with born amplitudes of wrong coupling powers if the flavor structure potentially induces QCD-EW interference amplitudes. For this purpose a second possibility, to compute the diagonal from the off-diagonal elements is implemented as a special case.

Computes a color-correlated matrix element from an interface to an external one-loop provider. The output of `blha_olp_eval2` is an array of dimension($n * (n - 1) / 2$). The matrix element is rejected if its accuracy is larger than the maximal allowed accuracy. OpenLoops includes a factor of $1 / n_{\text{hel}}$ in the amplitudes, which we have to undo if polarized matrix elements are requested (GoSam does not support polarized matrix elements).

In general, the BLHA consists of a virtual matrix element and n_{sub} subtraction terms. The subtraction terms can be pure Born matrix elements (to be used in collinear subtraction or in internal color-correlation), color-correlated matrix elements or spin-correlated matrix elements. The numbers should be ordered in such a way that \mathcal{V}_{fin} is first, followed by the pure Born, the color-correlated and the spin-correlated matrix elements. This repeats n_{flv} times. Let ν_i be

the position of the i th virtual matrix element. The next \mathcal{V}_{fin} is at position $\nu_i = \nu_{i-1} + n_{\text{sub}} + 1$. Obviously, $\nu_1 = 1$. This allows us to determine the virtual matrix element positions using the recursive function implemented below.

Chapter 25

GoSam Interface

The code in this chapter makes amplitudes accessible to **WHIZARD** that are generated and computed by the GoSam package.

These are the modules:

loop_archive Provide some useful extra functionality.

prc_gosam The actual interface, following the **WHIZARD** conventions for matrix-element generator methods.

No internal dependencies

Figure 25.1: Module dependencies in `src/gosam`.

```

The BLHA-interface conventions require the quantity $S_{ij} = \langle M_{i,+} | T_i T_j | M_{i,-} \rangle$ to be produced, where i is the position of the splitting gluon. However, $\bar{M} = \langle M_{i,-} | M_{i,+} \rangle$ is needed. This can be obtained using color conservation, $\sum_j T_j |M\rangle = 0$, so that

$$\sum_{j \neq i} S_{ij} = -\langle M_{i,+} | T_i^2 | M_{i,-} \rangle = -C_A \langle M_{i,+} | M_{i,-} \rangle = -C_A \bar{M}^*$$

According to BLHA conventions, the real part of S_{ij} is located at positions $2i + 2nj$ in the output array, where n denotes the number of external particles and the enumeration of particles starts at zero. The subsequent position, i.e. $2i + 2nj + 1$ is designated to the imaginary part of S_{ij} . Note that, since the first array position is 1, the implemented position association deviates from the above one in the addition of 1.

Computes a spin-correlated matrix element from an interface to an external one-loop provider. The output of `blha_olp_eval2` is an array of dimension(16). The current interface does not give out an accuracy, so that `bad_point` is always `.false..` OpenLoops includes a factor of $1 / n_{\text{hel}}$ in the amplitudes, which we have to undo if polarized matrix elements are requested.

Chapter 27

FKS Subtraction Scheme

The code in this chapter implements the FKS subtraction scheme for use with WHIZARD.

These are the modules:

fks_regions Given a process definition, identify singular regions in the associated phase space.

virtual Handle the virtual correction matrix element.

real_subtraction Handle the real-subtraction matrix element.

nlo_data Manage the subtraction objects.

dglap_remnant Handle the DGLAP Remnant matrix element.

This chapter deals with next-to-leading order contributions to cross sections. Basically, there are three major issues to be addressed: The creation of the $N + 1$ -particle flavor structure, the construction of the $N + 1$ -particle phase space and the actual calculation of the real- and virtual-subtracted matrix elements. The first is dealt with using the **auto_components** class, and it will be shown that the second and third issue are connected in FKS subtraction.

27.1 Brief outline of FKS subtraction

In the current state, this discussion is only concerned with lepton collisions. For hadron collisions, renormalization of parton distributions has to be taken into account. Further, for QCD corrections, initial-state radiation is necessarily present.

The aim is to calculate the next-to-leading order cross section according to

$$d\sigma_{\text{NLO}} = \mathcal{B} + \mathcal{V} + \mathcal{R}d\Phi_{\text{rad}}.$$

Analytically, the divergences, in terms of poles in the complex quantity $\varepsilon = 2 - d/2$, cancel. However, this is in general only valid in an arbitrary, complex number of dimensions. This is, roughly, the content of the KLN-theorem. WHIZARD, as any other numerical program, is confined to four dimensions. We

Figure 27.1: Module dependencies in `src/fks`.

will assume that the KLN-theorem is valid and that there exist subtraction terms \mathcal{C} such that

$$d\sigma_{\text{NLO}} = \mathcal{B} + \underbrace{\mathcal{V} + \mathcal{C}}_{\text{finite}} + \underbrace{\mathcal{R} - \mathcal{C}}_{\text{finite}},$$

i.e. the subtraction terms correspond to the divergent limits of the real and virtual matrix element.

Because \mathcal{C} subtracts the divergences of \mathcal{R} as well as those of \mathcal{V} , it suffices to consider one of them, so we focus on \mathcal{R} . For this purpose, \mathcal{R} is rewritten as

$$\mathcal{R} = \frac{1}{\xi^2} \frac{1}{1-y} (\xi^2(1-y)\mathcal{R}) = \frac{1}{\xi^2} \frac{1}{1-y} \tilde{\mathcal{R}},$$

with $\xi = (2k_{\text{rad}}^0)/\sqrt{s}$ and $y = \cos\theta$, where k_{rad}^0 denotes the energy of the radiated parton and θ is the angle between emitter and radiated parton. $\tilde{\mathcal{R}}$ is finite, therefore the whole singularity structure is contained in the prefactor $\xi^{-2}(1-y)^{-1}$. Combined with the d -dimensional phase space element,

$$\frac{d^{d-1}k}{2k^0(2\pi)^{d-1}} = \frac{s^{1-\varepsilon}}{(4\pi)^{d-1}} \xi^{1-2\varepsilon} (1-y^2)^{-\varepsilon} d\xi dy d\Omega^{d-2},$$

this yields

$$d\Phi_{\text{rad}} \mathcal{R} = dy(1-y)^{-1-\varepsilon} d\xi \xi^{-1-2\varepsilon} \tilde{\mathcal{R}}.$$

This can further be rewritten in terms of plus-distributions,

$$\begin{aligned} \xi^{-1-2\varepsilon} &= -\frac{1}{2\varepsilon} \delta(\xi) + \left(\frac{1}{\xi}\right)_+ - 2\varepsilon \left(\frac{\log \xi}{\xi}\right)_+ + \mathcal{O}(\varepsilon^2), \\ (1-y)^{-1-\varepsilon} &= -\frac{2^{-\varepsilon}}{\varepsilon} \delta(1-y) + \left(\frac{1}{1-y}\right)_+ - \varepsilon \left(\frac{1}{1-y}\right)_+ \log(1-y) + \mathcal{O}(\varepsilon^2), \end{aligned}$$

(imagine that all this is written inside of integrals, which are spared for ease of notation) such that

$$d\Phi_{\text{rad}}\mathcal{R} = -\frac{1}{2\varepsilon}dy(1-y)^{-1-\varepsilon}\tilde{R}(0,y) - d\xi \left[\frac{2^{-\varepsilon}}{\varepsilon} \left(\frac{1}{\xi}\right)_+ - 2 \left(\frac{\log \xi}{\xi}\right)_+ \right] \tilde{R}(\xi,1) \\ + dyd\xi \left(\frac{1}{\xi}\right)_+ \left(\frac{1}{1-y}\right)_+ \tilde{R}(\xi,y) + \mathcal{O}(\varepsilon).$$

The summand in the second line is of order $\mathcal{O}(1)$ and is the only one to reproduce $\mathcal{R}(\xi,y)$. It thus constitutes the sum of the real matrix element and the corresponding counterterms. The first summand consequently consists of the subtraction terms to the virtual matrix elements. Above formula thus allows to calculate all quantities to render the matrix elements finite.

alr	flst_alr	emitter	ftuple_list
1	[-11,11,2,-2,21,21]	3	(3,5), (3,6), (4,5), (4,6), (5,6)

3	[-11,11,2,-2,21,21]	5	(3,5), (3,6), (4,5), (4,6), (5,6)
4	[-11,11,2,-2,2,-2]	5	(3,4), (3,6), (4,5), (5,6)

Table 27.1: List of singular regions. The particles are represented by their PDG codes. The third column contains the emitter for the specific singular region. For the process involving an additional gluon, the gluon can either be emitted from one of the quarks or from the first gluon. Each emitter yields the same list of fundamental tuples, five in total. The last singular region corresponds to the process where the gluon splits up into two quarks. As the matrix element for this process has no information on which quarks originate from a gluon splitting, there are ftuples for all the quark pairs and not just those involving the emitter.

27.2 Identifying singular regions

In the FKS subtraction scheme, the phase space is decomposed into disjoint singular regions, such that

$$\sum_i \mathcal{S}_i + \sum_{ij} \mathcal{S}_{ij} = 1. \quad (27.1)$$

The quantities \mathcal{S}_i and \mathcal{S}_{ij} are functions of phase space corresponding to a pair of particles indices which can make up a divergent phase space region. We call such an index pair a fundamental tuple. For example, the process $e^+ e^- \rightarrow u \bar{u} g$ has two singular regions, (3, 5) and (4, 5), indicating that the gluon can be soft or collinear with respect to either the quark or the anti-quark. Therefore, the functions \mathcal{S}_{ij} have to be chosen in such a way that their contribution makes up most of (27.1) in phase-space configurations where (final-state) particle j is collinear to particle i or/and particle j is soft. The functions \mathcal{S}_i is the corresponding quantity for initial-state divergences.

As a singular region we understand the collection of real flavor structures associated with an emitter and a list of all possible fundamental tuples. As an example, consider the process $e^+ e^- \rightarrow u \bar{u} g$. At next-to-leading order, processes with an additionally radiated particle have to be considered. In this case, these are $e^+ e^- \rightarrow u \bar{u}, g g$, and $e^+ e^- \rightarrow u \bar{u} u \bar{u}$ (or the same process with any other quark). Table 27.1 sums up all possible singular regions for this problem.

Thus, during the preparation of a NLO-calculation, the possible singular regions have to be identified. `fk_regions.f90` deals with this issue.

alr	ftuple	emitter	flst_alr
1	(3, 5)	5	[-11,11,-2,21,2,21]
2	(4, 5)	5	[-11,11,2,21,-2,21]

Determines the splitting type for FSR. There are three different types of splittings relevant here: $g \rightarrow gg$ tagged V_T0_VV, $g \rightarrow qq$ tagged V_T0_FF and $q \rightarrow qq$ tagged F_T0_FV. For FSR, there is no need to differentiate between $q \rightarrow qq$ and $q \rightarrow gq$ splittings.

Determines the splitting type for ISR. There are four different types of splittings relevant here: $g \rightarrow gg$ tagged V_TO_VV, $g \rightarrow qq$ tagged V_TO_FF, $q \rightarrow qq$ tagged F_TO_FV and $q \rightarrow gq$ tagged F_TO_VF. The latter two need to be considered separately for ISR as they differ with respect to which particle enters the hard process. A splitting F_TO_FV may lead to soft divergences while F_TO_VF does not.

We also want to emphasize that the splitting type naming convention for ISR names the splittings considering backwards evolution. So in the splitting V_TO_FF, it is the *gluon* that enters the hard process.

Special treatment here is required if emitter 0 is assigned. This is the case only when a gluon was radiated from any of the IS particles. In this case, both splittings are soft divergent so we can equivalently choose 1 or 2 as the emitter here even if both have different flavors.

Returns **true** if the two particles at position *i* and *j* in the flavor array can originate from the same splitting. For this purpose, the function first checks whether the splitting is allowed at all. If this is the case, the emitter is removed from the flavor array. If the resulting array is equivalent to the Born flavor structure **flv_born**, the pair is accepted as a valid splitting.

We first check whether the splitting is possible. The array **flv_orig** contains all particles which share a vertex with the particles at position *i* and *j*. If any of these particles belongs to the initial state, a PDG-ID flip is necessary to correctly recognize the vertex. If its size is equal to zero, no splitting is possible and the subroutine is exited. Otherwise, we loop over all possible underlying Born flavor structures and check if any of them equals the actual underlying Born flavor structure. For a quark emitting a gluon, **flv_orig** contains the PDG code of the anti-quark. To be on the safe side, a second array is created, which contains both the positively and negatively signed PDG codes. Then, the original tuple (*i, j*) is removed from the real flavor structure and the particles in **flv_orig2** are inserted. If the resulting Born configuration is equal to the

underlying Born configuration, up to a permutation of final-state particles, the tuple (i, j) is accepted as valid.

A singular region is a partition of phase space which is associated with an individual emitter and, if relevant, resonance. It is associated with an α_r - and resonance-index, with a real flavor structure and its underlying Born flavor structure. To compute the FKS weights, it is relevant to know all the other particle indices which can result in a divergent phase space configuration, which are collected in the `ftuples`-array.

Some singular regions might behave physically identical. E.g. a real flavor structure associated with three-jet production is $[11, -11, 2, -2, 21, 21]$. Here, there are two possible `ftuples` which contribute to the same $u \rightarrow ug$ splitting, namely (3,5) and (3,6). The resulting singular regions will be identical. To

avoid this, one singular region is associated with the multiplicity factor `mult`. When computing the subtraction terms for each singular region, the result is then simply multiplied by this factor.

The `double_fsr`-flag indicates whether the singular region should also be supplied by a symmetry factor, explained below.

In case of a $g \rightarrow gg$ splitting, the factor

$$\frac{2E_{\text{em}}}{E_{\text{em}} + E_{\text{rad}}}$$

is multiplied to the real matrix element. This way, the symmetry of the splitting is used and only one singular region has to be taken into account. However, the factor ensures that there is only a soft singularity if the radiated parton becomes soft.

So far, we have only created singular regions for a non-resonant case. When resonance mappings are required, we have more singular regions, since they must now be identified by their emitter-resonance pair index, where the emitter must be compatible with the resonance.

```

This subroutine splits up the ftuple-list of the singular regions into interference-free lists, i.e. lists which only contain the same emitter. This is relevant for factorized NLO calculations. In the current implementation, it is hand-tailored

for the threshold computation, but should be generalized further in the future.

This subroutine starts with a specification of N - and $N + 1$ -particle configurations, `flst_born` and `flst_real`, saved in `reg_data`. From these, it creates a list of fundamental tuples, a list of emitters and a list containing the $N + 1$ -particle configuration, rearranged in such a way that the emitter-radiation pair is last (`flst_alr`). For the $e^+ e^- \rightarrow u \bar{u} g$ - example, the generated objects are shown in table 27.2. Note that at this point, `flst_alr` is arranged in such a way that the emitter can only be equal to $n_{legs} - 1$ for final-state radiation or 0, 1,

or 2 for initial-state radiation. Further, it occurs that regions can be equivalent. For example in table 27.2 the regions corresponding to $\text{alr} = 1$ and $\text{alr} = 3$ as well as $\text{alr} = 2$ and $\text{alr} = 4$ describe the same physics and are therefore equivalent.

We transfer the mapping of flavor structures that lead to the same ampli-

tude (with structure functions already accounted for!) to the Born and real flv_structure of each singular_region. We then use this information, besides other data of each singular_region, to determine which produce the same amplitude for the non-subtracted real and real subtraction terms and set up the equivalence index mapping for each region.

```

In the soft limit, our treatment of the divergencies requires a modification of the mapping functions. Recall that there, the ratios of the d -functions must approach either 1 or 0. This means

$$\frac{d_{lm}}{d_{0m}} = \frac{(2k_l \cdot k_m) [E_l E_m / (E_l + E_m)^2]}{E_m^2 (1 - y^2)} \Big|_{k_m = E_m \hat{k}} \frac{E_l E_m^2}{(E_l + E_m)^2} \frac{2k_l \cdot \hat{k}}{E_m^2 (1 - y^2)} \xrightarrow{E_m \rightarrow 0} \frac{2k_l \cdot \hat{k}}{E_l} (1 - y^2),$$

where we have written the gluon momentum in terms of the soft momentum \hat{k} . In the same limit

$$\frac{d_{lm}}{d_{nm}} = \frac{k_l \cdot \hat{k}}{k_n \cdot \hat{k}} \frac{E_n}{E_l}.$$

From these equations we can deduce the soft limit of d :

$$\begin{aligned}d_0^{\text{soft}} &= 1 - y^2, \\d_1^{\text{soft}} &= 2(1 - y), \\d_2^{\text{soft}} &= 2(1 + y), \\d_i^{\text{soft}} &= \frac{2k_i \cdot \hat{k}}{E_i}.\end{aligned}$$

Computes the sum of all soft dijs required to normalize the soft S functions `s_alpha_soft` similar to `fks_mapping_default_compute_sumdij`. In the soft limit however, we need to skip all ftuples (i, j) in which j does not correspond to the emitted particle because those d_{ij} s are finite and thus their contribution to the soft S function vanishes in the limit of soft radiation. Technically, they would not vanish if computed here because the fixed `p_soft` at this point would not fit their actual emitter.

  end subroutine fks_mapping_default_assign

```

The $d_{ij,k}$ -functions for the resonance mapping are basically the same as in the default case, but the kinematical values here must be evaluated in the resonance frame of reference. The energy of parton i in a given resonance frame with momentum p_{res} is

$$E_i = \frac{p_i^0 \cdot p_{res}}{m_{res}}.$$

However, since the expressions only depend on ratios of four-momenta, we leave out the denominator because it will cancel out anyway.

```

```

The virtual subtraction terms contain Casimir operators and derived constants, listed below:

$$C(q) = C(\bar{q}) = C_F, \quad (27.2)$$

$$C(g) = C_A, \quad (27.3)$$

$$\gamma(q) = \gamma(\bar{q}) = \frac{3}{2}C_F, \quad (27.4)$$

$$\gamma(g) = \frac{11}{6}C_A - \frac{2}{3}T_F N_f, \quad (27.5)$$

$$\gamma'(q) = \gamma'(\bar{q}) = \left(\frac{13}{2} - \frac{2\pi^2}{3} \right) C_F, \quad (27.6)$$

$$\gamma'(g) = \left(\frac{67}{9} - \frac{2\pi^2}{3} \right) C_A - \frac{23}{9}T_F N_f. \quad (27.7)$$

For uncolored particles, `virtual_init_constants` sets C , γ and γ' to zero.

The virtual-subtracted matrix element is given by the equation

$$\mathcal{V} = \frac{\alpha_s}{2\pi} \left(\mathcal{QB} + \sum \mathcal{I}_{ij} \mathcal{B}_{ij} + \mathcal{V}_{fin} \right), \quad (27.8)$$

The expressions for \mathcal{Q} can be found in equations 27.9 and 27.11. The expressions for \mathcal{I}_{ij} can be found in equations (27.13), (27.14), (27.29), depending on whether the particles involved in the radiation process are massive or massless.

If two or more flavor structures would produce the same amplitude we only compute one and use the `eqv_index` to copy the result to the others (if `reuse_amplitudes_fks` is true).

The Ellis-Sexton scale is set when explicitly allocated; if not it first is set to the renormalization scale; if that it is not set it will be set to the factorization scale which is the scale used for the virtual corrections.

```

The collinear limit of $\tilde{\mathcal{R}}$ can be integrated over the radiation degrees of freedom, giving the collinear contribution to the virtual component. Its general structure is $\mathcal{Q} \cdot \mathcal{B}$. The initial-state contribution to \mathcal{Q} is simply given by

$$\mathcal{Q} = -\log \frac{\mu_F^2}{Q^2} (\gamma(\mathcal{I}_1) + 2C(\mathcal{I}_1) \log(\xi_{\text{cut}}) + \gamma(\mathcal{I}_2) + 2C(\mathcal{I}_2) \log(\xi_{\text{cut}})), \quad (27.9)$$

where Q^2 is the Ellis-Sexton scale and γ is as in eqns. 27.4 and 27.5. `virtual_evaluate_initial_state` computes this quantity. The loop over the initial-state particles is only executed if we are dealing with a scattering process, because for decays there are no virtual initial-initial interactions.

```

Same as above, but for final-state particles. The collinear limit for final-state particles follows from the integral

$$I_{+, \alpha_r} = \int d\Phi_{n+1} \frac{\xi_+^{-1-2\epsilon}}{\xi^{-1-2\epsilon}} \mathcal{R}_{\alpha_r}.$$

We can distinguish three situations:

1. α_r contains a massive emitter. In this case, no collinear subtraction term is required and the integral above is irrelevant.
2. α_r contains a massless emitter, but resonances are not taken into account in the subtraction. Here, $\xi_{max} = \frac{2E_{em}}{\sqrt{s}}$ is the upper bound on ξ .
3. α_r contains a massless emitter and resonance-aware subtraction is used. Here, $\xi_{max} = \frac{2E_{em}}{\sqrt{k_{res}^2}}$.

Before version 2.4, only situations 1 and 2 were covered. The difference between situation 2 and 3 comes from the expansion of the plus-distribution in the integral above,

$$\xi_+^{-1-2\epsilon} = \xi^{-1-2\epsilon} + \frac{1}{2\epsilon} \delta(\xi) = \xi_{max}^{-1-2\epsilon} \left[(1-z)^{-1-2\epsilon} + \frac{\xi_{max}^{2\epsilon}}{2\epsilon} \delta(1-z) \right].$$

The expression from the standard FKS literature is given by \mathcal{Q} is given by

$$\begin{aligned} \mathcal{Q} = \sum_{k=n_{in}}^{n_L^{(B)}} & \left[\gamma'(\mathcal{I}_k) - \log \frac{s\delta_o}{2Q^2} \left(\gamma(\mathcal{I}_k) - 2C(\mathcal{I}_k) \log \frac{2E_k}{\xi_{cut}\sqrt{s}} \right) \right. \\ & \left. + 2C(\mathcal{I}_k) \left(\log^2 \frac{2E_k}{\sqrt{s}} - \log^2 \xi_{cut} \right) - 2\gamma(\mathcal{I}_k) \log \frac{2E_k}{\sqrt{s}} \right]. \end{aligned} \quad (27.10)$$

$n_L^{(B)}$ is the number of legs at Born level. Here, ξ_{max} is implicitly present in the ratios in the logarithms. Using the resonance-aware ξ_{max} yields

$$\begin{aligned} \mathcal{Q} = \sum_{k=n_{in}}^{n_L^{(B)}} & \left[\gamma'(\mathcal{I}_k) + 2 \left(\log \frac{\sqrt{s}}{2E_{em}} + \log \xi_{max} \right) \left(\log \frac{\sqrt{s}}{2E_{em}} + \log \xi_{max} + \log \frac{Q^2}{s} \right) C(\mathcal{I}_k) \right. \\ & \left. + 2 \log \xi_{max} \left(\log \xi_{max} - \log \frac{Q^2}{k_{res}^2} \right) C(\mathcal{I}_k) + \left(\log \frac{Q^2}{k_{res}^2} - 2 \log \xi_{max} \right) \gamma(\mathcal{I}_k) \right]. \end{aligned} \quad (27.11)$$

Equation 27.11 leads to 27.10 with the substitutions $\xi_{max} \rightarrow \frac{2E_{em}}{\sqrt{s}}$ and $k_{res}^2 \rightarrow s$. `virtual_compute_collinear_contribution` only implements the second one.

The following code implements the \mathcal{I}_{ij} -function. The complete formulas can be found in arXiv:0908.4272 (A.1-A.17) and are also discussed in arXiv:1002.2581 in Appendix A. The implementation may differ in the detail from the formulas presented in the above paper. The parameter ξ_{cut} is unphysically and cancels with appropriate factors in the real subtraction. We keep the additional parameter for debug usage. The implemented formulas are then defined as follows:

massless-massless case $p^2 = 0, k^2 = 0$,

$$\begin{aligned} \mathcal{I}_{ij} = & \frac{1}{2} \log^2 \frac{\xi_{\text{cut}}^2 s}{Q^2} + \log \frac{\xi_{\text{cut}}^2 s}{Q^2} \log \frac{k_i k_j}{2E_i E_j} - \text{Li}_2 \left(\frac{k_i k_j}{2E_i E_j} \right) \\ & + \frac{1}{2} \log^2 \frac{k_i k_j}{2E_i E_j} - \log \left(1 - \frac{k_i k_j}{2E_i E_j} \right) \log \frac{k_i k_j}{2E_i E_j}. \end{aligned} \quad (27.13)$$

massive-massive case $p^2 \neq 0, k^2 \neq 0$,

$$\mathcal{I}_{ij} = \frac{1}{2} I_0(k_i, k_j) \log \frac{\xi_{\text{cut}}^2 s}{Q^2} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (27.14)$$

with

$$I_0(k_i, k_j) = \frac{1}{\beta} \log \frac{1 + \beta}{1 - \beta}, \quad \beta = \sqrt{1 - \frac{k_i^2 k_j^2}{(k_i \cdot k_j)^2}} \quad (27.15)$$

and a rather involved expression for I_ϵ :

$$I_\epsilon(k_i, k_j) = (K(z_j) - K(z_i)) \frac{1 - \vec{\beta}_i \cdot \vec{\beta}_j}{\sqrt{a(1-b)}}, \quad (27.16)$$

$$\vec{\beta}_i = \frac{\vec{k}_i}{k_i^0}, \quad (27.17)$$

$$a = \beta_i^2 + \beta_j^2 - 2\vec{\beta}_i \cdot \vec{\beta}_j, \quad (27.18)$$

$$x_i = \frac{\beta_i^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a}, \quad (27.19)$$

$$x_j = \frac{\beta_j^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a} = 1 - x_i, \quad (27.20)$$

$$b = \frac{\beta_i^2 \beta_j^2 - (\vec{\beta}_i \cdot \vec{\beta}_j)^2}{a}, \quad (27.21)$$

$$c = \sqrt{\frac{b}{4a}}, \quad (27.22)$$

$$z_+ = \frac{1 + \sqrt{1-b}}{\sqrt{b}}, \quad (27.23)$$

$$z_- = \frac{1 - \sqrt{1-b}}{\sqrt{b}}, \quad (27.24)$$

$$z_i = \frac{\sqrt{x_i^2 + 4c^2} - x_i}{2c}, \quad (27.25)$$

$$z_j = \frac{\sqrt{x_j^2 + 4c^2} + x_j}{2c}, \quad (27.26)$$

$$K(z) = -\frac{1}{2} \log^2 \frac{(z - z_-)(z_+ - z)}{(z_+ + z)(z_- + z)} - 2\text{Li}_2 \left(\frac{2z_-(z_+ - z)}{(z_+ - z_-)(z_- + z)} \right) \quad (27.27)$$

$$- 2\text{Li}_2 \left(-\frac{2z_+(z_- + z)}{(z_+ - z_-)(z_+ - z)} \right) \quad (27.28)$$

massless-massive case $p^2 = 0, k^2 \neq 0$,

$$\mathcal{I}_{ij} = \frac{1}{2} \left[\frac{1}{2} \log^2 \frac{\xi_{\text{cut}}^2 s}{Q^2} - \frac{\pi^2}{6} \right] + \frac{1}{2} I_0(k_i, k_j) \log \frac{\xi_{\text{cut}}^2 s}{Q^2} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (27.29)$$

with

$$I_0(p, k) = \log \frac{(\hat{p} \cdot \hat{k})^2}{\hat{k}^2}, \quad (27.30)$$

$$I_\epsilon(p, k) = -2 \left[\frac{1}{4} \log^2 \frac{1-\beta}{1+\beta} + \log \frac{\hat{p} \cdot \hat{k}}{1+\beta} \log \frac{\hat{p} \cdot \hat{k}}{1-\beta} + \text{Li}_2 \left(1 - \frac{\hat{p} \cdot \hat{k}}{1+\beta} \right) + \text{Li}_2 \left(1 - \frac{\hat{p} \cdot \hat{k}}{1-\beta} \right) \right], \quad (27.31)$$

using

$$\hat{p} = \frac{p}{p^0}, \quad \hat{k} = \frac{k}{k^0}, \quad \beta = \frac{|\vec{k}|}{k^0}, \quad (27.32)$$

$$\text{Li}_2(1-x) + \text{Li}_2(1-x^{-1}) = -\frac{1}{2} \log^2 x. \quad (27.33)$$

The treatment of the momentum k follows the discussion about the soft limit of the partition functions (see [1002.2581], p. 29 and C. Weiss' PhD Thesis, p. 24). The parton momentum is pulled out, $k = E\hat{k}$. In fact, we will substitute \hat{k} for k throughout the code, because the energy will factor out of the equation when the soft \mathcal{S} -function is multiplied. The momentum `p_soft` represents the soft

limit of the radiated particle divided by its energy. It is a unit vector, because $k^2 = (k^0)^2 - (\hat{k})^2 = 0$.

The soft momentum is constructed by first creating a unit vector parallel to the emitter's Born momentum. This unit vector is then rotated about the corresponding angles y and ϕ to match the direction of the real radiation in the soft limit.

```

The soft vector for the real mismatch is basically the same as for usual FSR, except for the scaling with the total gluon energy. Moreover, the resulting vector is rotated into the frame where the 3-axis points along the direction of the emitter. This is necessary because in the collinear limit, the approximation

$$k_i = \frac{k_i^0}{k_j^0} \bar{k}_j = \frac{\xi \sqrt{s}}{2k_j^0} \bar{k}_j$$

is used. The collinear limit is not included in the soft mismatch yet, but we keep the rotation for future usage here already (the performance loss is negligible).

Computation of the soft limit of R_α . Note that what we are actually integrating (in the case of final-state radiation) is the quantity $f(0, y)/\xi$, where

$$f(\xi, y) = \frac{J(\xi, y, \phi)}{\xi} \xi^2 R_\alpha.$$

J/ξ is computed by the phase space generator. The additional factor of ξ^{-1} is supplied in the `evaluate_region_fsr`-routine. Thus, we are left with a factor of ξ^2 . A look on the expression for the soft limit of R_α below reveals that we are factoring out the gluon energy E_i in the denominator. Therefore, we have a factor $\xi^2/E_i^2 = 4/q^2$.

Note that the same routine is used also for the computation of the soft mismatch. There, the gluon energy is not factored out from the soft vector, so that we are left with the ξ^2 -factor, which will eventually be cancelled out again. So, we just multiply with 1. Both cases are distinguished by the flag `xi2_expanded`.

Note that for the soft subtraction term, also the S functions are computed in the soft limit. The input momenta are thus the real momenta in the soft limit, i.e. the Born momenta given by `p_born`.

```

This subroutine computes the collinear limit of $g^\alpha(\xi, y)$ introduced in eq. 27.34. Care is given to also enable the usage for the soft-collinear limit. This, we write all formulas in terms of soft-finite quantities.

We have to compute

$$\frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1-y)\xi^2 \mathcal{R}^\alpha(\Phi_{n+1})] |_{y=1}.$$

The Jacobian J is proportional to ξ , due to the d^3k_{n+1}/k_{n+1}^0 factor in the integration measure. It cancels the factor of ξ in the denominator. The remaining part of the Jacobian is multiplied in `evaluate_region_fsr` and is not relevant here. Inserting the splitting functions exemplarily for $q \rightarrow qg$ yields

$$g^\alpha = \frac{8\pi\alpha_s}{k_{\text{em}}^2} C_F (1-y) \xi^2 \frac{1+(1-z)^2}{z} \mathcal{B},$$

where we have chosen $z = E_{\text{rad}}/\bar{E}_{\text{em}}$ and \bar{E}_{em} denotes the emitter energy in the Born frame. The collinear final state imposes $\bar{k}_n = k_n + k_{n+1}$ for the connection between Φ_n - and Φ_{n+1} -phasepace and we get $1-z = E_{\text{em}}/\bar{E}_{\text{em}}$. The denominator can be rewritten by the constraint $\bar{k}_n^2 = (k_n + k_{n+1})^2 = 0$ to

$$k_{\text{em}}^2 = 2E_{\text{rad}}E_{\text{em}}(1-y)$$

which cancels the $(1-y)$ factor in the numerator, thus showing that the whole expression is indeed collinear-finite. We can further transform

$$E_{\text{rad}}E_{\text{em}} = z(1-z)\bar{E}_{\text{em}}^2$$

so that in total we have

$$g^\alpha = \frac{4\pi\alpha_s}{1-z} \frac{1}{\bar{k}_{\text{em}}^2} C_F \left(\frac{\xi}{z} \right)^2 (1 + (1-z)^2) \mathcal{B}$$

Follow up calculations give us

$$g^{\alpha, g \rightarrow gg} = \frac{4\pi\alpha_s}{1-z} \frac{1}{\bar{k}_{\text{em}}^2} C_A \frac{\xi}{z} \left\{ 2 \left(\frac{z}{1-z} \xi + \frac{1-z}{\frac{z}{\xi}} \right) \mathcal{B} + 4\xi z(1-z) \hat{k}_\perp^\mu \hat{k}_\perp^\nu \mathcal{B}_{\mu\nu} \right\},$$

$$g^{\alpha, g \rightarrow qq} = \frac{4\pi\alpha_s}{1-z} \frac{1}{\bar{k}_{\text{em}}^2} T_R \frac{\xi}{z} \left\{ \xi \mathcal{B} - 4\xi z(1-z) \hat{k}_\perp^\mu \hat{k}_\perp^\nu \mathcal{B}_{\mu\nu} \right\}.$$

The ratio z/ξ is finite in the soft limit

$$\frac{z}{\xi} = \frac{q^0}{2E_{\text{em}}}$$

so that ξ does not appear explicitly in the computation.

The argumentation above is valid for $q \rightarrow qg$ -splittings, but the general factorization is valid for general splittings, also for those involving spin correlations and QED splittings. Note that care has to be given to the definition of z . Further, we have factored out a factor of z to include in the ratio z/ξ , which has to be taken into account in the implementation of the splitting functions.

```

Like in the context of `coll_subtraction_compute_fsr` we compute the quantity

$$\lim_{y \rightarrow \pm 1} \left\{ \frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1-y^2)\xi^2 \mathcal{R}^\alpha(\Phi_{n+1})] \right\},$$

where the $(1-y^2)$ accounts for both $y = \pm 1$. Again, the Jacobian is proportional to ξ , so we drop the J/ξ factor. Note that it is important to take into account this missing factor of ξ in the computation of the Jacobian during phase-space generation both for fixed-beam and structure ISR. We consider only a $q \rightarrow qq$ splitting arguing that other splittings are identical in terms of the factors which cancel. It is given by

$$g^\alpha = \frac{8\pi\alpha_s}{-k_{\text{em}}^2} C_F (1-y^2) \xi^2 \frac{1+z^2}{1-z} \mathcal{B},$$

where g^α is defined akin to the one for FSR in eq. 27.34. Note the negative sign of k_{em}^2 to compensate the negative virtuality of the initial-state emitter. For ISR, z is defined with respect to the emitter energy entering the hard interaction, i.e.

$$z = \frac{E_{\text{beam}} - E_{\text{rad}}}{E_{\text{beam}}} = 1 - \frac{E_{\text{rad}}}{E_{\text{beam}}}.$$

Because $E_{\text{rad}} = E_{\text{beam}} \cdot \xi$, it is $z = 1 - \xi$, thus one factor of ξ is cancelled by $(1-z)$ in the denominator of g^α . The factor k_{em}^2 in the denominator is rewritten as

$$k_{\text{em}}^2 = (p_{\text{beam}} - p_{\text{rad}})^2 = -2p_{\text{beam}} \cdot p_{\text{rad}} = -2E_{\text{beam}} E_{\text{rad}} (1 \pm y) = -2E_{\text{beam}}^2 (1-z)(1 \pm y),$$

where we used

$$E_{\text{beam}} E_{\text{rad}} = E_{\text{beam}}^2 (1-z).$$

This leads to the cancellation of the corresponding $(1 \pm y)$ factor in $(1 - y^2)$, with the other factor becoming a simple factor of 2, and the remaining factor of ξ in the numerator. We thus end up with

$$g^\alpha = \frac{8\pi\alpha_s}{E_{\text{beam}}^2} C_F (1 + z^2) \mathcal{B},$$

which is soft-finite.

Note that here in `compute_isr`, `sqme_born` is supposed to be the squared Born matrix element convoluted with the real PDF.

27.6.4 The real contribution to the cross section

In each singular region α , the real contribution to σ is given by the second summand of eqn. ??,

$$\sigma_{\text{real}}^{\alpha} = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 dy \int_0^{\xi_{\text{max}}} d\xi \left(\frac{1}{\xi} \right)_+ \left(\frac{1}{1-y} \right)_+ \underbrace{\frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1-y)\xi^2 \mathcal{R}^{\alpha}(\Phi_{n+1})]}_{g^{\alpha}(\xi, y)}. \quad (27.34)$$

Writing out the plus-distribution and introducing $\tilde{\xi} = \xi/\xi_{\text{max}}$ to set the upper integration limit to 1, this turns out to be equal to

$$\begin{aligned} \sigma_{\text{real}}^{\alpha} = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 \frac{dy}{1-y} \left\{ \int_0^1 d\tilde{\xi} \left[\frac{g^{\alpha}(\tilde{\xi}\xi_{\text{max}}, y)}{\tilde{\xi}} - \underbrace{\frac{g^{\alpha}(0, y)}{\tilde{\xi}}}_{\text{soft}} - \underbrace{\frac{g^{\alpha}(\tilde{\xi}\xi_{\text{max}}, 1)}{\tilde{\xi}}}_{\text{coll.}} + \underbrace{\frac{g^{\alpha}(0, 1)}{\tilde{\xi}}}_{\text{coll.+soft}} \right] \right. \\ \left. + [\log \xi_{\text{max}}(y) g^{\alpha}(0, y) - \log \xi_{\text{max}}(1) g^{\alpha}(0, 1)] \right\}. \end{aligned} \quad (27.35)$$

This formula is implemented in `compute_sqme_real_fin`

If two or more singular regions would produce the same amplitude we only compute one and use the `eqv_index` to copy the result to the others (if `reuse_amplitudes_fks` is true).

```

Sums up $\sum_{i_1, i_2} S_{i_1 i_2}$ for the given alr. The soft S functions take the real momenta in the soft limit, i.e. the Born momenta. For each summand of `sum_s_alpha_soft` we take `p_soft` constructed from the emitter of the given alpha region also for ftuples in which the first integer i1 does not coincide with the emitter. This is necessary because only if we keep `p_soft` fixed, all soft S functions are computed with the same denominator and thus add up to 1.

This subroutine computes the finite part of the real matrix element in an individual singular region. First, the radiation variables are fetched and \mathcal{R} is multiplied by the appropriate S_α -factors, region multiplicities and double-FSR factors. Then, it computes the soft, collinear, soft-collinear and remnant matrix elements and supplies the corresponding factor $1/\xi/(1-y)$ as well as the corresponding Jacobians.

Compares the real matrix element to the subtraction terms in the soft, the collinear or the soft-collinear limits. Used for debug purposes if ?test_anti_coll_limit,

?test_coll_limit and/or ?test_soft_limit are set in the Sindarin. sqme_soft and sqme_cs need to be provided if called for FSR and sqme_coll_plus, sqme_coll_minus, sqme_cs_plus as well as sqme_cs_minus need to be provided if called for ISR.

For final state radiation, the subtraction remnant cross section is

$$\sigma_{\text{remn}} = (\sigma_{\text{soft}} - \sigma_{\text{soft-coll}}) \log(\xi_{\text{max}}) \cdot \frac{\tilde{\xi}}{\xi_{\text{cut}}}. \quad (27.36)$$

There is only one factor of $\log(\xi_{\text{max}})$ for both limits as ξ_{max} does not depend on y in the case of FSR. We use the already computed `sqme_soft` and `sqme_cs` with a factor of $\tilde{\xi}$ which we have to compensate. We also need a factor $1/\xi_{\text{cut}}$ here to assure that the cross section is independent of this free cutoff parameter. However, it still remains to be motivated analytically.

```

Computes the soft remnant for ISR. The formulas can be found in arXiv:1002.2581, eq. 4.21. and arXiv:0709.2092, sec. 5.1.2. This results in

$$\sigma_{\text{remn}}^{\text{ISR}} = \log(\xi_{\text{max}}(y))\sigma_{\text{soft}} - \frac{1}{2}\log(\xi_{\text{max}}(1))\sigma_{\oplus}^{\text{soft-coll}} - \frac{1}{2}\log(\xi_{\text{max}}(-1))\sigma_{\ominus}^{\text{soft-coll}} \quad (27.37)$$

where for ISR, ξ_{max} does explicitly depend on y due to the rescaling of the x values from the Born to the real partonic system according to

$$x_{\oplus} = \frac{\bar{x}_{\oplus}}{\sqrt{1-\xi}} \sqrt{\frac{2-\xi(1-y)}{2-\xi(1+y)}}, \quad x_{\ominus} = \frac{\bar{x}_{\ominus}}{\sqrt{1-\xi}} \sqrt{\frac{2-\xi(1+y)}{2-\xi(1-y)}} \quad (27.38)$$

As ξ_{max} is determined by the fact that the real x_{\oplus}, x_{\ominus} have to stay in a physically

meaningful regime, i.e. $x_{\oplus}, x_{\ominus} < 1$, this leads to

$$\xi_{\max} = 1 - \max \left\{ \frac{2(1+y)\bar{x}_{\oplus}^2}{\sqrt{(1+\bar{x}_{\oplus}^2)^2(1-y)^2 + 16y\bar{x}_{\oplus}^2 + (1-y)(1-\bar{x}_{\oplus}^2)}}, \quad (27.39)$$

$$\frac{2(1-y)\bar{x}_{\oplus}^2}{\sqrt{(1+\bar{x}_{\oplus}^2)^2(1+y)^2 - 16y\bar{x}_{\oplus}^2 + (1+y)(1-\bar{x}_{\oplus}^2)}} \right\} \quad (27.40)$$

and thus

$$\xi_{\max}(y = 1) = 1 - \bar{x}_{\oplus} \quad (27.41)$$

$$\xi_{\max}(y = -1) = 1 - \bar{x}_{\ominus} \quad (27.42)$$

So we need to use the unrescaled $\bar{x}_{\oplus}, \bar{x}_{\ominus}$ here. Factors of $\frac{1}{2}$ and $\frac{1}{\xi}$ are already included in the matrix elements from `apply_kinematic_factors_subtraction_isr`. We keep the former and remove the latter by multiplying with $\tilde{\xi}$. The factor $1/\xi_{\text{cut}}$ is probably needed to assure that the cross section is independent of this free cutoff parameter in analogy to the FSR case. However, it still remains to be motivated analytically and to be validated.

Applies the kinematic dependent part of the Jacobian to the squared matrix element. During integration and when generating fixed order events, the non-kinematic part $\frac{s}{(4\pi)^3}$ is applied in `real_subtraction_compute` via `get_phs_factor`.

The additional factor $\frac{\xi}{\xi}$ comes from eq. (4.19f) in arXiv:1002.2581.

This subroutine evaluates the soft and collinear subtraction terms for ISR. References:

- arXiv:0709.2092, sec. 2.4.2
- arXiv:0908.4272, sec. 4.2

For the collinear terms, the procedure is as follows:

If the emitter is 0, then a gluon was radiated from one of the incoming partons. Gluon emissions require two counter terms: One for emission in the direction of the first incoming parton \oplus and a second for emission in the direction of the second incoming parton \ominus because in both cases, there are divergent diagrams contributing to the matrix element. So in this case both, `sqme_coll_plus` and `sqme_coll_minus`, are non-zero.

If the emitter is 1 or 2, then a quark was emitted instead of a gluon. This only leads to a divergence collinear to the emitter because for anti-collinear quark emission, there are simply no divergent diagrams in the same region as two collinear quarks that cannot originate in the same splitting are non-divergent. This means that in case the emitter is 1, we need non-zero `sqme_coll_plus` and in case the emitter is 2, we need non-zero `sqme_coll_minus`.

At this point, we want to remind ourselves that in case of initial state divergences, y is just the polar angle, so the `sqme_coll_minus` terms are there to counter emissions in the direction of the second incoming parton \ominus and *not* to counter in general anti-collinear divergences.

This is basically the global part of the real Jacobian corresponding to

$$\frac{q^2}{8(2\pi)^3}.$$

We interpret it as the additional phase space factor of the real component, to be more consistent with the evaluation of the Born phase space.

We specifically use the Born center-of-mass energy here. The real center-of-mass energy is only different from the Born center-of-mass energy in case of ISR. The missing factor $\frac{1}{1-\xi}$ for this conversion is supplied in `phs_fks_generator_generate_isr`.

Computes the soft subtraction term. If there is an initial state emission having a soft divergence, then a gluon has to have been emitted. A gluon can always be emitted from both IS partons and thus, we can take the `sf_factor` for emitter 0 in this case. Be aware that this approach will not work for *pe* collisions.

Computes the soft-collinear subtraction term. For alpha regions with emitter 0, this routine is called with `em == 1` and `em == 2` separately. To still be able to use the unrescaled pdf factors stored in `sf_factors(alr, 0)` in this case, we need to differentiate between `em` and `em_pdf = 0`.

27.7 Contribution of divergencies due to PDF Evolution

References:

- arXiv:hep-ph/9512328, (2.1)-(2.5), (4.29)-(4.53)
- arXiv:0709.2092, (2.102)-(2.106)

The parton distribution densities have to be evaluated at NLO, too. The NLO PDF evolution is given by

$$f(\bar{x}) = \int_0^1 \int_0^1 dx dz f(x) \Gamma(z) \delta(\bar{x} - xz), \quad (27.44)$$

where Γ are the DGLAP evolution kernels for an $a \rightarrow d$ splitting,

$$\Gamma_a^{(d)} = \delta_{ad} \delta(1-x) - \frac{\alpha_s}{2\pi} \left(\frac{1}{\epsilon} P_{ad}(x, 0) - K_{ad}(x) \right) + \mathcal{O}(\alpha_s^2). \quad (27.45)$$

K_{ad} is a renormalization scheme matching factor, which is exactly zero in $\overline{\text{MS}}$. Let the leading-order hadronic cross section be given by

$$d\sigma^{(0)}(s) = \int dx_{\oplus} dx_{\ominus} f_{\oplus}(x_{\oplus}) f_{\ominus}(x_{\ominus}) d\tilde{\sigma}^{(0)}(x_{\oplus} x_{\ominus} s), \quad (27.46)$$

then the NLO hadronic cross section is

$$d\sigma^{(1)}(s) = \int dx_{\oplus} dx_{\ominus} dz_{\oplus} dz_{\ominus} f_{\oplus}(x_{\oplus}) f_{\ominus}(x_{\ominus}) \underbrace{\Gamma_{\oplus}(z_{\oplus}) \Gamma_{\ominus}(z_{\ominus}) d\tilde{\sigma}^{(1)}(z_{\oplus} z_{\ominus} s)}_{d\hat{\sigma}^{(1)}}. \quad (27.47)$$

$d\hat{\sigma}$ is called the subtracted partonic cross section. Expanding in α_s we find

$$d\hat{\sigma}_{ab}^{(0)}(k_1, k_2) = d\tilde{\sigma}_{ab}^{(0)}(k_1, k_2), \quad (27.48)$$

$$d\hat{\sigma}_{ab}^{(1)}(k_1, k_2) = d\tilde{\sigma}_{ab}^{(1)}(k_1, k_2) \quad (27.49)$$

$$+ \frac{\alpha_s}{2\pi} \sum_d \int dx \left(\frac{1}{\epsilon} P_{da}(x, 0) - K_{da}(x) \right) d\tilde{\sigma}_{db}^{(0)}(xk_1, k_2) \quad (27.50)$$

$$+ \frac{\alpha_s}{2\pi} \sum_d \int \left(\frac{1}{\epsilon} P_{db}(x, 0) - K_{db}(x) \right) d\tilde{\sigma}_{ad}^{(0)}(k_1, xk_2). \quad (27.51)$$

$$= d\tilde{\sigma}_{ab}^{(1)} + d\tilde{\sigma}_{ab}^{(cnt,+)} + d\tilde{\sigma}_{ab}^{(cnt,-)} \quad (27.52)$$

Let us now turn to the soft-subtracted real part of the cross section. For ease of notation, it is constrained to one singular region,

$$d\sigma_{\alpha}^{(in)} = \left[\left(\frac{1}{\xi} \right)_c - 2\epsilon \left(\frac{\log \xi}{\xi} \right)_c \right] (1-y^2) \xi^2 \mathcal{R}_{\alpha} \mathcal{S}_{\alpha} \\ \times \frac{1}{2(2\pi)^{3-2\epsilon}} \left(\frac{\sqrt{s}}{2} \right)^{2-2\epsilon} (1-y^2)^{-1-\epsilon} d\phi d\xi dy d\Omega^{2-2\epsilon},$$

where we regularize collinear divergencies using the identity

$$(1-y^2)^{-1-\epsilon} = -\frac{2^{-\epsilon}}{2\epsilon} (\delta(1-y) + \delta(1+y)) + \underbrace{\frac{1}{2} \left[\left(\frac{1}{1-y} \right)_c + \left(\frac{1}{1+y} \right)_c \right]}_{\mathcal{P}(y)}.$$

This enables us to split the cross section into a finite and a singular part. The latter can further be separated into a contribution of the incoming and of the outgoing particles,

$$d\sigma_\alpha^{(in)} = d\sigma_\alpha^{(in,+)} + d\sigma_\alpha^{(in,-)} + d\sigma_\alpha^{(in,f)}.$$

They are given by

$$d\sigma_\alpha^{(in,f)} = \mathcal{P}(y) \left[\left(\frac{1}{\xi} \right)_c - 2\epsilon \left(\frac{\log \xi}{\xi} \right)_c \right] \frac{1}{2(2\pi)^{3-2\epsilon}} \left(\frac{\sqrt{s}}{2} \right)^{2-2\epsilon} \times (1-y^2) \xi^2 \mathcal{R}_\alpha \mathcal{S}_\alpha d\phi d\xi dy d\Omega^{2-2\epsilon} \quad (27.53)$$

and

$$d\sigma_\alpha^{(in,\pm)} = -\frac{2^{-\epsilon}}{2\epsilon} \delta(1 \mp y) \left[\left(\frac{1}{\xi} \right)_c - 2\epsilon \left(\frac{\log \xi}{\xi} \right)_c \right] \times \frac{1}{2(2\pi)^{3-2\epsilon}} \left(\frac{\sqrt{s}}{2} \right)^{2-2\epsilon} (1-y^2) \xi^2 \mathcal{R}_\alpha \mathcal{S}_\alpha d\phi d\xi dy d\Omega^{2-2\epsilon}. \quad (27.54)$$

Equation 27.53 is the contribution to the real cross section which is computed in `evaluate_region_isr`. It is regularized both in the soft and collinear limit via the plus distributions. Equation 27.54 is a different contribution. It is only present exactly in the collinear limit, due to the delta function. The divergences present in this term do not completely cancel out divergences in the virtual matrix element, because the beam axis is distinguished. Thus, the conditions in which the KLN theorem applies are not met. To see this, we carry out the collinear limit, obtaining

$$\lim_{y \rightarrow 1} (1-y^2) \xi^2 \mathcal{R}_\alpha = 8\pi\alpha_s \mu^{2\epsilon} \left(\frac{2}{\sqrt{s}} \right)^2 \xi P^<(1-\xi, \epsilon) \mathcal{R}_\alpha,$$

with the Altarelli-Parisi splitting kernel for $z < 1$, $P^<(z, \epsilon)$. Moreover, $\lim_{\vec{k} \parallel \vec{k}_1} d\phi = d\phi_3$ violates spatial averaging. The integration over the spherical angle $d\Omega$ can be carried out easily, yielding a factor of $2\pi^{1-\epsilon}/\Gamma(1-\epsilon)$. This allows us to redefine ϵ ,

$$\frac{1}{\epsilon} - \gamma_E + \log(4\pi) \rightarrow \frac{1}{\epsilon}. \quad (27.55)$$

Coming back to $d\tilde{\sigma}_{ab}^{(cnt,+)}$ in order to make a connection to $d\sigma_\alpha^{(in,+)}$, we relate $P_{ab}(z, 0)$ to $P_{ab}^<(z, 0)$ via the equation

$$P_{ab}(z, 0) = (1-z) P_{ab}^<(z, 0) \left(\frac{1}{1-z} \right)_+ + \gamma(a) \delta_{ab} \delta(1-z),$$

which yields

$$d\tilde{\sigma}_\alpha^{(cnt,+)} = \frac{\alpha_s}{2\pi} \sum_d \left\{ -K_{da}(1-\xi) + \frac{1}{\epsilon} \left[\left(\frac{1}{\xi} \right)_+ \xi P_{da}^<(1-\xi, 0) + \delta_{da} \delta(\xi) \gamma(d) \right] \right\} \mathcal{R}_\alpha \mathcal{S}_\alpha d\phi d\xi dy. \quad (27.56)$$

This term has the same pole structure as eqn. 27.54. This makes clear that the quantity

$$d\hat{\sigma}^{(in,+)} = d\tilde{\sigma}^{(in,+)} + d\tilde{\sigma}^{(cnt,+)} \quad (27.57)$$

has no collinear poles. Therefore, our task is to add up eqns. 27.54 and 27.56 in order to compute the finite remainder. This is the integrand which is evaluated in the `dglap_remnant` component.

So, we have to perform an expansion of $d\hat{\sigma}^{(in,+)}$ in ϵ . Hereby, we must not neglect the implicit ϵ -dependence of $P^<$, which leads to additional terms involving the first derivative,

$$P_{ab}^<(z, \epsilon) = P_{ab}^<(z, 0) + \epsilon \frac{\partial P_{ab}^<(z, \epsilon)}{\partial \epsilon} \Big|_{\epsilon=0} + \mathcal{O}(\alpha_s^2).$$

This finally gives us the equation for the collinear remnant. Note that there is still one soft $1/\epsilon$ -pole, which cancels out with the corresponding expression in the soft-virtual terms.

$$\begin{aligned} d\hat{\sigma}^{(in,+)} &= \frac{\alpha_s}{2\pi} \frac{1}{\epsilon} \gamma(a) \mathcal{R}_\alpha \mathcal{S}_\alpha \\ &+ \frac{\alpha_s}{2\pi} \sum_d \left\{ (1-z) P_{da}^<(z, 0) \left[\left(\frac{1}{1-z} \right)_c \log \frac{s\delta_I}{2\mu^2} + 2 \left(\frac{\log(1-z)}{1-z} \right)_c \right] \right. \\ &\quad \left. - (1-z) \frac{\partial P_{da}^<(z, \epsilon)}{\partial \epsilon} \left(\frac{1}{1-z} \right)_c - K_{da}(z) \right\} \mathcal{R}_\alpha \mathcal{S}_\alpha d\phi d\xi dy \end{aligned} \quad (27.58)$$

Evaluates formula 27.58. Note that, as also in the case for the real subtraction, we have to take into account an additional term, occuring because the integral the plus distribution is evaluated over is not constrained on the interval $[0, 1]$. Explicitly, this means (see JHEP 06(2010)043, (4.11)-(4.12))

$$\int_{\bar{x}_{\oplus}}^1 dz \left(\frac{1}{1-z} \right)_{\xi_{\text{cut}}} = \log \frac{1-\bar{x}_{\oplus}}{\xi_{\text{cut}}} f(1) + \int_{\bar{x}_{\oplus}}^1 \frac{f(z) - f(1)}{1-z}, \quad (27.59)$$

$$\int_{\bar{x}_{\oplus}}^1 dz \left(\frac{\log(1-z)}{1-z} \right)_{\xi_{\text{cut}}} f(z) = \frac{1}{2} (\log^2(1-\bar{x}_{\oplus}) - \log^2(\xi_{\text{cut}})) f(1) + \int_{\bar{x}_{\oplus}}^1 \frac{\log(1-z)[f(z) - f(1)]}{1-z}, \quad (27.60)$$

and the same of course for \bar{x}_{\ominus} . These two terms are stored in the `plus_dist_remnant` variable below.

The option `separate_uborns` allows to compute the contribution of the DGLAP remnant separately for each underlying Born flavor structure. We need this option during event generation to generate counter events with a specific Born flavor structure.

Chapter 28

Model Handling and Features

These modules deal with process definitions and physics models.

These modules use the `model_data` methods to automatically generate process definitions.

auto_components Generic process-definition generator. We can specify a basic process or initial particle(s) and some rules to extend this process, given a model definition with particle names and vertex structures.

radiation_generator Applies the generic generator to the specific problem of generating NLO corrections in a restricted setup.

Model construction:

eval_trees Implementation of the generic `expr_t` type for the concrete evaluation of expressions that access user variables.

This module is actually part of the Sindarin language implementation, and should be moved elsewhere. Currently, the `models` module relies on it.

models Extends the `model_data_t` structure by user-variable objects for easy access, and provides the means to read a model definition from file.

slha_interface Read/write a SUSY model in the standardized SLHA format. The format defines fields and parameters, but no vertices.

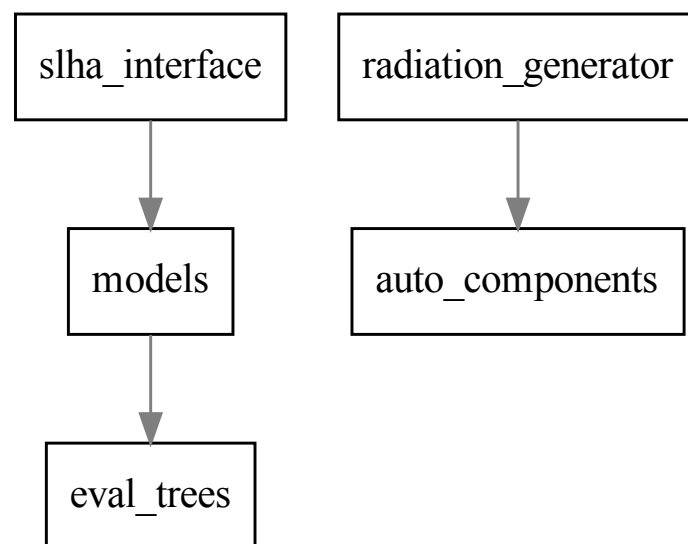

Figure 28.1: Module dependencies in `src/model_features`.

28.1 Automatic generation of process components

This module provides the functionality for automatically generating radiation corrections or decays, provided as lists of PDG codes.

28.1.1 Constraints: Abstract types

An abstract type that denotes a constraint on the automatically generated states. The concrete objects are applied as visitor objects at certain hooks during the splitting algorithm.

```
<Auto components: types>≡
  type, abstract :: split_constraint_t
  contains
  <Auto components: split constraint: TBP>
end type split_constraint_t
```

By default, all checks return true.

```
<Auto components: split constraint: TBP>≡
  procedure :: check_before_split => split_constraint_check_before_split
  procedure :: check_before_insert => split_constraint_check_before_insert
  procedure :: check_before_record => split_constraint_check_before_record

<Auto components: sub interfaces>≡
  module subroutine split_constraint_check_before_split (c, table, pl, k, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table

    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    passed = .true.
end subroutine split_constraint_check_before_record

```

A transparent wrapper, so we can collect constraints of different type.

```

<Auto components: types>+≡
    type :: split_constraint_wrap_t
        class(split_constraint_t), allocatable :: c
    end type split_constraint_wrap_t

```

A collection of constraints.

```

<Auto components: public>≡
    public :: split_constraints_t

<Auto components: types>+≡
    type :: split_constraints_t
        class(split_constraint_wrap_t), dimension(:), allocatable :: cc
    contains
        <Auto components: split constraints: TBP>
    end type split_constraints_t

```

Gfortran 7/8/9 bug: has to remain in the main module. Initialize the constraints set with a specific number of elements.

```

<Auto components: split constraints: TBP>≡
    procedure :: init => split_constraints_init

<Auto components: main procedures>≡
    subroutine split_constraints_init (constraints, n)
        class(split_constraints_t), intent(out) :: constraints
        integer, intent(in) :: n
        allocate (constraints%cc (n))
    end subroutine split_constraints_init

```

Set a constraint.

```

<Auto components: split constraints: TBP>+≡
    procedure :: set => split_constraints_set

<Auto components: sub interfaces>+≡
    module subroutine split_constraints_set (constraints, i, c)
        class(split_constraints_t), intent(inout) :: constraints
        integer, intent(in) :: i
        class(split_constraint_t), intent(in) :: c
    end subroutine split_constraints_set

```

<Auto components: procedures>+≡

```

module subroutine split_constraints_set (constraints, i, c)
  class(split_constraints_t), intent(inout) :: constraints
  integer, intent(in) :: i
  class(split_constraint_t), intent(in) :: c
  allocate (constraints%cc(i)%c, source = c)
end subroutine split_constraints_set

```

Apply checks.

`check_before_split` is applied to the particle list that we want to split.

`check_before_insert` is applied to the particle list `pl` that is to replace the particle `pa` that is split. This check may transform the particle list.

`check_before_record` is applied to the complete new particle list that results from splitting before it is recorded.

<Auto components: split constraints: TBP>+≡

```

procedure :: check_before_split => split_constraints_check_before_split
procedure :: check_before_insert => split_constraints_check_before_insert
procedure :: check_before_record => split_constraints_check_before_record

```

<Auto components: sub interfaces>+≡

```

28.1.2 Specific constraints

Number of particles

Specific constraint: The number of particles plus the number of loops, if any, must remain less than the given limit. Note that the number of loops is defined only when we are recording the entry.

(Auto components: types)+≡

```

    type, extends (split_constraint_t) :: constraint_n_tot
    private
    integer :: n_max = 0
    contains

  end subroutine constraint_n_loop_check_before_record

```

Particles allowed in splitting

Specific constraint: The entries in the particle list ready for insertion are matched to a given list of particle patterns. If a match occurs, the entry is replaced by the corresponding pattern. If there is no match, the check fails. If a massless gauge boson splitting is detected, the splitting partners are checked against a list of excluded particles. If a match occurs, the check fails.

```

<Auto components: types>+≡

Particles required in final state

Specific constraint: The entries in the recorded state must be a superset of the entries in the given list (for instance, the lowest-order state).

```

<Auto components: types>+≡

```

```

type, extends (split_constraint_t) :: constraint_require
  private
  type(pdg_list_t) :: pl
contains
  procedure :: check_before_record => constraint_require_check_before_record
end type constraint_require

```

We check the current state by matching all particle entries against the stored particle list, and crossing out the particles in the latter list when a match is found. The constraint passed if all entries have been crossed out.

For an `if_table` in particular, we check the final state only.

```

```

Mass sum

Specific constraint: The sum of masses within the particle list must be smaller than a given limit. For in/out state combinations, we check initial and final state separately.

If we specify `margin` in the initialization, the sum must be strictly less than the limit minus the given margin (which may be zero). If not, equality is allowed.

```

<Auto components: public>+≡

28.1.3 Tables of states

Automatically generate a list of possible process components for a given initial set (a single massive particle or a preset list of states).

The set of process components are generated by recursive splitting, applying constraints on the fly that control and limit the process. The generated states are accumulated in a table that we can read out after completion.

```

⟨Auto components: types⟩+≡
    type, extends (pdg_list_t) :: ps_entry_t
        integer :: n_loop = 0
        integer :: n_rad = 0
        type(ps_entry_t), pointer :: previous => null ()
        type(ps_entry_t), pointer :: next => null ()
    end type ps_entry_t

```

```

⟨Auto components: parameters⟩≡
    integer, parameter :: PROC_UNDEFINED = 0
    integer, parameter :: PROC_DECAY = 1
    integer, parameter :: PROC_SCATTER = 2

```

This is the wrapper type for the decay tree for the list of final states and the final array. First, an abstract base type:

```

⟨Auto components: public⟩+≡
    public :: ps_table_t

⟨Auto components: types⟩+≡
    type, abstract :: ps_table_t
        private
        class(model_data_t), pointer :: model => null ()
        logical :: loops = .false.
        type(ps_entry_t), pointer :: first => null ()
        type(ps_entry_t), pointer :: last => null ()
        integer :: proc_type
    contains
        ⟨Auto components: ps table: TBP⟩
    end type ps_table_t

```

The extensions: one for decay, one for generic final states. The decay-state table stores the initial particle. The final-state table is indifferent, and the initial/final state table treats the first two particles in its list as incoming antiparticles.

```

<Auto components: public>+≡
  public :: ds_table_t
  public :: fs_table_t
  public :: if_table_t

<Auto components: types>+≡
  type, extends (ps_table_t) :: ds_table_t
    private
      integer :: pdg_in = 0
    contains
      <Auto components: ds table: TBP>
