<Template matrix elements: procedures>+≡
    module function template_me_driver_type_name () result (string)
        type(string_t) :: string
        string = "template"
    end function template_me_driver_type_name

```

17.3.4 High-level process definition

This procedure wraps the details filling a process-component definition entry as appropriate for an template matrix element. Gfortran 7/8/9 bug, remains in main module.

```

<Template matrix elements: public>+≡
    public :: template_me_make_process_component
<Template matrix elements: main procedures>+≡
    subroutine template_me_make_process_component (entry, component_index, &
        model, model_name, prt_in, prt_out, unity)
        class(process_def_entry_t), intent(inout) :: entry
        integer, intent(in) :: component_index
        type(string_t), intent(in) :: model_name
        class(model_data_t), intent(in), target :: model
        type(string_t), dimension(:), intent(in) :: prt_in
        type(string_t), dimension(:), intent(in) :: prt_out
        logical, intent(in) :: unity
        class(prc_core_def_t), allocatable :: def
        allocate (template_me_def_t :: def)
        select type (def)
        type is (template_me_def_t)
            call def%init (model, prt_in, prt_out, unity)
        end select
        call entry%import_component (component_index, &
            n_out = size (prt_out), &
            prt_in = new_prt_spec (prt_in), &
            prt_out = new_prt_spec (prt_out), &
            method = var_str ("template"), &
            variant = def)
    end subroutine template_me_make_process_component

```

17.3.5 The prc_template_me_t wrapper

This is an instance of the generic prc_core_t object. It contains a pointer to the process definition (template_me_def_t), a data component (process_constants_t), and the matrix-element driver (template_me_driver_t).

```

<Template matrix elements: public>+≡
    public :: prc_template_me_t

```

```

<Template matrix elements: types>+≡
  type, extends (prc_core_t) :: prc_template_me_t
    real(default), dimension(:), allocatable :: par
    integer :: scheme = 0
  contains
    <Template matrix elements: prc template ME: TBP>
  end type prc_template_me_t

```

The workspace associated to a `prc_template_me_t` object contains a single flag. The flag is used to suppress re-evaluating the matrix element for each quantum-number combination, after the first amplitude belonging to a given kinematics has been computed.

We can also store the value of a running coupling once it has been calculated for an event. The default value is negative, which indicates an undefined value in this context.

```

<Template matrix elements: types>+≡
  type, extends (prc_core_state_t) :: template_me_state_t
    logical :: new_kinematics = .true.
    real(default) :: alpha_qcd = -1
    real(default) :: alpha_qed = -1
  contains
    procedure :: write => template_me_state_write
    procedure :: reset_new_kinematics => template_me_state_reset_new_kinematics
  end type template_me_state_t

```

```

<Template matrix elements: sub interfaces>+≡
  module subroutine template_me_state_write (object, unit)
    class(template_me_state_t), intent(in) :: object
    integer, intent(in), optional :: unit
  end subroutine template_me_state_write

```

```

<Template matrix elements: procedures>+≡
  module subroutine template_me_state_write (object, unit)
    class(template_me_state_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(3x,A,L1)") "Template ME state: new kinematics = ", &
      object%new_kinematics
  end subroutine template_me_state_write

```

```

<Template matrix elements: sub interfaces>+≡
  module subroutine template_me_state_reset_new_kinematics (object)
    class(template_me_state_t), intent(inout) :: object
  end subroutine template_me_state_reset_new_kinematics

```

```

<Template matrix elements: procedures>+≡
  module subroutine template_me_state_reset_new_kinematics (object)
    class(template_me_state_t), intent(inout) :: object
  end subroutine template_me_state_reset_new_kinematics

```

Allocate the workspace with the above specific type. Gfortran 7/8/9 bug, has to remain in the main module.

```

<Template matrix elements: prc template ME: TBP>≡
    procedure :: allocate_workspace => prc_template_me_allocate_workspace

<Template matrix elements: main procedures>+≡
    subroutine prc_template_me_allocate_workspace (object, core_state)
        class(prc_template_me_t), intent(in) :: object
        class(prc_core_state_t), intent(inout), allocatable :: core_state
        allocate (template_me_state_t :: core_state)
    end subroutine prc_template_me_allocate_workspace

```

The following procedures are inherited from the base type as deferred, thus must be implemented. The corresponding unit tests are skipped here; the procedures are tested when called from the `processes` module.

Output: print just the ID of the associated matrix element. Then display any stored parameters.

```

<Template matrix elements: prc template ME: TBP>+≡
    procedure :: write => prc_template_me_write

```

To fully initialize the process core, we perform base initialization, then initialize the external matrix element code.

This procedure overrides the `init` method of the base type, which we nevertheless can access via its binding `base_init`. When done, we have an allocated driver. The driver will call the `init` procedure for the external matrix element, and thus transfer the parameter set to where it finally belongs.

```

<Template matrix elements: prc template ME: TBP>+≡
  procedure :: init => prc_template_me_init

```

Compute the amplitude. For the tree-level process, we can ignore the scale settings. The term index j is also irrelevant.

We first call `new_event` for the given momenta (which we must unpack), then retrieve the amplitude value for the given quantum numbers.

If the `core_state` status flag is present, we can make sure that we call `new_event` only once for a given kinematics. After the first call, we unset the `new_kinematics` flag.

```

```

Generate, compile and load a simple process matrix element

The process is $e^+e^- \rightarrow \mu^+\mu^-$ for vanishing masses and $e = 0.3$. We initialize the process, build the library, and compute a particular matrix element for momenta of unit energy and right-angle scattering. The matrix element, as it happens, is equal to e^2 . (Note that are no conversion factors applied, so this result is exact.)

For GNU make, makeflags is set to -j1. This eliminates a potential clash with a -j<n> flag if this test is called from a parallel make.

```

17.4 O’MEGA Interface

The standard method for process computation with WHIZARD is the O’MEGA matrix element generator.

This section implements the interface to the code generator (via the makefile) and the driver for the features provided by the O’MEGA matrix element.

There are actually two different methods steered by this interface, the traditional one which delivers compiled Fortran code, while the O’MEGA virtual machine (OVM) produces bytecode with look-up tables.

```
<prc_omega.f90>≡
  <File header>

  module prc_omega

    use, intrinsic :: iso_c_binding !NODEP!

    use kinds
    <Use strings>
    use constants, only: one
    use os_interface
    use diagnostics
    use lorentz
    use sm_qcd
    use sm_qed
    use interactions
    use model_data

    use particle_specifiers, only: new_prt_spec
    use process_constants
    use prclib_interfaces
    use prc_core_def
    use process_libraries
    use prc_core

    <Omega interface: types>

    <Omega interface: interfaces>

    interface
    <Omega interface: sub interfaces>
    end interface

    contains

    <Omega interface: main procedures>

  end module prc_omega

<prc_omega_sub.f90>≡
  <File header>
```

```

submodule (prc_omega) prc_omega_s

  use io_units
  use system_defs, only: TAB

  implicit none

contains

  <Omega interface: procedures>

end submodule prc_omega_s

```

17.4.1 Process definition

For the process definition we implement an extension of the `prc_core_def_t` abstract type.

```

<Omega interface: public>≡
  public :: omega_def_t

<Omega interface: types>≡
  type, extends (prc_core_def_t) :: omega_def_t
    logical :: ufo = .false.
    logical :: ovm = .false.
  contains
    <Omega interface: omega def: TBP>
  end type omega_def_t

<Omega interface: omega def: TBP>≡
  procedure, nopass :: type_string => omega_def_type_string

<Omega interface: sub interfaces>≡
  module function omega_def_type_string () result (string)
    type(string_t) :: string
  end function omega_def_type_string

<Omega interface: procedures>≡
  module function omega_def_type_string () result (string)
    type(string_t) :: string
    string = "omega"
  end function omega_def_type_string

```

Initialization: allocate the writer for the O'MEGA matrix element. The writer type depends on the settings of the `ufo` and `ovm` flags. Also set any data for this process that the writer needs. Gfortran 7/8/9 bug, has to remain in the main module.

```

<Omega interface: omega def: TBP>+≡
  procedure :: init => omega_def_init

```

```

<Omega interface: main procedures>≡
  subroutine omega_def_init (object, &
    model_name, prt_in, prt_out, &

```

17.4.5 The prc_omega_t wrapper

This is an instance of the generic prc_core_t object. It contains a pointer to the process definition (omega_def_t), a data component (process_constants_t), and the matrix-element driver (omega_driver_t).

```

<Omega interface: public>+≡
    public :: prc_omega_t

<Omega interface: types>+≡
    type, extends (prc_core_t) :: prc_omega_t
        real(default), dimension(:), allocatable :: par

```

```

integer :: scheme = 0
type(helicity_selection_t) :: helicity_selection
type(qcd_t) :: qcd
type(qed_t) :: qed
contains
  <Omega interface: prc omega: TBP>
end type prc_omega_t

```

The workspace associated to a `prc_omega_t` object contains a single flag. The flag is used to suppress re-evaluating the matrix element for each quantum-number combination, after the first amplitude belonging to a given kinematics has been computed.

We can also store the value of a running coupling once it has been calculated for an event. The default value is negative, which indicates an undefined value in this context.

```

<Omega interface: public>+≡
  public :: omega_state_t

<Omega interface: types>+≡
  type, extends (prc_core_state_t) :: omega_state_t
    logical :: new_kinematics = .true.

```

To fully initialize the process core, we perform base initialization, then initialize the external matrix element code.

This procedure overrides the `init` method of the base type, which we nevertheless can access via its binding `base_init`. When done, we have an allocated driver. The driver will call the `init` procedure for the external matrix element, and thus transfer the parameter set to where it finally belongs.

If requested, we initialize the helicity selection counter.

```

<Omega interface: prc omega: TBP>+≡
    procedure :: init => prc_omega_init

    else
        call driver%reset_helicity_selection &
            (0._c_default_float, 0_c_int)
    end if
end if
end select
end subroutine prc_omega_reset_helicity_selection

```

Compute the amplitude. For the tree-level process, we can ignore the scale settings. The term index j is also irrelevant.

We first call `new_event` for the given momenta (which we must unpack), then retrieve the amplitude value for the given quantum numbers.

If the `core_state` status flag is present, we can make sure that we call `new_event` only once for a given kinematics. After the first call, we unset the `new_kinematics` flag.

The core objects computes the appropriate α_s value via the `qcd` subobject, taking into account the provided `ren_scale` value. However, if the extra parameter `alpha_qcd_forced` is allocated, it overrides this setting.

The `is_allowed` query is not redundant, since the status may change during the run if helicities are switched off.

Generate, compile and load a simple process matrix element

The process is $e^+e^- \rightarrow \mu^+\mu^-$ for vanishing masses and $e = 0.3$. We initialize the process, build the library, and compute a particular matrix element for momenta of unit energy and right-angle scattering. The matrix element, as it happens, is equal to e^2 . (Note that are no conversion factors applied, so this result is exact.)

For GNU make, makeflags is set to -j1. This eliminates a potential clash with a -j<n> flag if this test is called from a parallel make.

```

<Omega interface: execute tests>≡

Check prc_omega_t wrapper and options

The process is $e^-e^+ \rightarrow e^-e^+$ for vanishing masses and $e = 0.3$. We build the library using the high-level procedure `omega_make_process_component` and the “black box” `prc_omega_t` object. Two variants with different settings for restrictions and OpenMP.

For GNU make, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

```

QCD coupling

The process is $u\bar{u} \rightarrow d\bar{d}$ for vanishing masses. We compute the amplitude for a fixed configuration once, then reset α_s , then compute again.

For GNU make, makeflags is set to -j1. This eliminates a potential clash with a -j<n> flag if this test is called from a parallel make.

UFO model file support

Again, the process is $e^-e^+ \rightarrow e^-e^+$ for vanishing masses and $e = 0.3$. We build the library using the high-level procedure `omega_make_process_component` and the “black box” `prc_omega_t` object. OMega must be able to digest the specified UFO file and provide use with a fresh model file that can be read after producing the process code.

For GNU make, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

17.5 External matrix elements (squared)

This defines an abstract framework that can handle matrix elements which are computed outside of WHIZARD. Such matrix elements typically (i) require extra code or libraries to be configured linked at execution time, and (ii) provide only plain or correlated squared matrix elements instead of amplitudes.

In particular, matrix-element libraries that conform to the BLHA standard belong to this class. They have their own (also abstract) extension of the abstract `prc_external_t` type introduced here. `prc_external_t`-type.

```

17.5.2 Abstract interface to external matrix elements

This process class allows us to factor out common necessities of processes that involve external code or libraries.

Workspace

This is the workspace that is available for external matrix elements.

```

<Prc external: public>≡
  public :: prc_external_state_t

<Prc external: types>+≡
  type, abstract, extends (prc_core_state_t) :: prc_external_state_t
    logical :: new_kinematics = .true.
    real(default) :: alpha_qcd = -1
    real(default) :: alpha_qed = -1
  contains
    <Prc external: external state: TBP>
  end type prc_external_state_t

<Prc external: external state: TBP>≡
  procedure :: reset_new_kinematics => prc_external_state_reset_new_kinematics

<Prc external: sub interfaces>+≡
  module subroutine prc_external_state_reset_new_kinematics (object)
    class(prc_external_state_t), intent(inout) :: object
  end subroutine prc_external_state_reset_new_kinematics

<Prc external: procedures>+≡
  module subroutine prc_external_state_reset_new_kinematics (object)
    class(prc_external_state_t), intent(inout) :: object
    object%new_kinematics = .true.
  end subroutine prc_external_state_reset_new_kinematics

```

Driver

We have to add two O'Mega-routines to the external matrix-element driver to ensure proper process setup. The problem is that during the setup of the real component, the particle and flavor data are taken from the Born component to set up the subtraction terms. However, the Born component expects this data to be obtained from the Omega code, accessed by the driver.

```
<Prc external: public>+≡
  public :: prc_external_driver_t

<Prc external: types>+≡
  type, abstract, extends (prc_core_driver_t) :: prc_external_driver_t
    procedure(omega_update_alpha_s), nopass, pointer :: &
      update_alpha_s => null ()
    procedure(omega_is_allowed), nopass, pointer :: &
      is_allowed => null ()
  end type prc_external_driver_t
```

Core

```
<Prc external: public>+≡
  public :: prc_external_t

<Prc external: types>+≡
  type, abstract, extends (prc_core_t) :: prc_external_t
    type(qcd_t) :: qcd
    type(qed_t) :: qed
    integer :: n_flv = 1
    real(default), dimension(:), allocatable :: par
    integer :: scheme = 0
    type(sf_handler_t) :: sf_handler
    real(default) :: maximum_accuracy = 10000.0
  contains
    <Prc external: prc external: TBP>
  end type prc_external_t
```

By definition, this class of process-core types require extra code.

```

Chapter 18

Generic Event Handling

Event records allow the MC to communicate with the outside world. The event record should exhibit the observable contents of a physical event. We should be able to read and write events. The actual implementation of the event need not be defined yet, for that purpose.

We have the following basic modules:

event_base Abstract base type for event records. The base type contains a reference to a **particle_set_t** object as the event core, and it holds some data that we should always expect, such as the squared matrix element and event weight.

eio_data Transparent container for the metadata of an event sample.

eio_base Abstract base type for event-record input and output. The implementations of this base type represent specific event I/O formats.

These are the implementation modules:

eio_checkpoints Auxiliary output format. The only purpose is to provide screen diagnostics during event output.

eio_callback Auxiliary output format. The only purpose is to execute a callback procedure, so we have a hook for external access during event output.

eio_weights Print some event summary data, no details. The main use is for testing purposes.

Figure 18.1: Module dependencies in **src/events**.

eio_dump Dump the contents of WHIZARD's `particle_set` internal record, using the `write` method of that record as-is. The main use is for testing purposes.

hep_common Implements traditional HEP common blocks that are (still) used by some of the event I/O formats below.

hepmc_interface Access particle objects of the HepMC package. Functional only if this package is linked. The interface is working both for HepMC2 and HepMC3.

lcio_interface Access objects of the LCIO package. Functional only if this package is linked.

hep_events Interface between the event record and the common blocks.

eio_ascii Collection of event output formats that write ASCII files.

eio_lhef LHEF for input and output.

eio_stdhep Support for the StdHEP format (binary, machine-independent).

eio_hepmc Support for the HepMC format (C++).

eio_lcio Support for the LCIO format (C++).

18.1 Generic Event Handling

We introduce events first in form of an abstract type, together with some utilities. Abstract events can be used by other modules, in particular event I/O, without introducing an explicit dependency on the event implementation.

```

<event_base.f90>≡
  <File header>

  module event_base

    <Use kinds>
    use kinds, only: i64
    <Use strings>
    use model_data
    use particles

    <Standard module head>

    <Event base: public>

    <Event base: parameters>

    <Event base: types>

    <Event base: interfaces>

    interface
    <Event base: sub interfaces>

```

```

        end interface

    end module event_base

    <event_base_sub.f90>≡
    <File header>

    submodule (event_base) event_base_s

        use io_units

    end submodule event_base_s

```

18.1.1 generic event type

```

    <Event base: public>≡
        public :: generic_event_t

    <Event base: types>≡
        type, abstract :: generic_event_t
            !private
            logical :: particle_set_is_valid = .false.
            type(particle_set_t), pointer :: particle_set => null ()
            logical :: sqme_ref_known = .false.
            real(default) :: sqme_ref = 0
            logical :: sqme_prc_known = .false.
            real(default) :: sqme_prc = 0
            logical :: weight_ref_known = .false.
            real(default) :: weight_ref = 0
            logical :: weight_prc_known = .false.
            real(default) :: weight_prc = 0
            logical :: excess_prc_known = .false.
            real(default) :: excess_prc = 0
            logical :: n_dropped_known = .false.
            integer :: n_dropped = 0
            integer :: n_alt = 0
            logical :: sqme_alt_known = .false.
            real(default), dimension(:), allocatable :: sqme_alt
            logical :: weight_alt_known = .false.
            real(default), dimension(:), allocatable :: weight_alt
        contains
        <Event base: generic event: TBP>
    end type generic_event_t

```

18.1.2 Initialization

This determines the number of alternate weights and some values.

```
<Event base: generic event: TBP>≡
  procedure :: base_init => generic_event_init

<Event base: sub interfaces>≡
  module subroutine generic_event_init (event, n_alt)
    class(generic_event_t), intent(out) :: event
    integer, intent(in) :: n_alt
  end subroutine generic_event_init

<Event base: procedures>≡
  module subroutine generic_event_init (event, n_alt)
    class(generic_event_t), intent(out) :: event
    integer, intent(in) :: n_alt
    event%n_alt = n_alt
    allocate (event%sqme_alt (n_alt))
    allocate (event%weight_alt (n_alt))
  end subroutine generic_event_init
```

18.1.3 Access particle set

The particle set is the core of the event. We allow access to it via a pointer, and we maintain the information whether the particle set is valid, i.e., has been filled with meaningful data.

```
<Event base: generic event: TBP>+≡
  procedure :: has_valid_particle_set => generic_event_has_valid_particle_set
  procedure :: accept_particle_set => generic_event_accept_particle_set
  procedure :: discard_particle_set => generic_event_discard_particle_set

<Event base: sub interfaces>+≡
  module function generic_event_has_valid_particle_set (event) result (flag)
    class(generic_event_t), intent(in) :: event
    logical :: flag
  end function generic_event_has_valid_particle_set

  module subroutine generic_event_accept_particle_set (event)
    class(generic_event_t), intent(inout) :: event
  end subroutine generic_event_accept_particle_set

  module subroutine generic_event_discard_particle_set (event)
    class(generic_event_t), intent(inout) :: event
  end subroutine generic_event_discard_particle_set

<Event base: procedures>+≡
  module function generic_event_has_valid_particle_set (event) result (flag)
    class(generic_event_t), intent(in) :: event
    logical :: flag
    flag = event%particle_set_is_valid
  end function generic_event_has_valid_particle_set

  module subroutine generic_event_accept_particle_set (event)
    class(generic_event_t), intent(inout) :: event
```

```

        event%particle_set_is_valid = .true.
    end subroutine generic_event_accept_particle_set

    module subroutine generic_event_discard_particle_set (event)
        class(generic_event_t), intent(inout) :: event
        event%particle_set_is_valid = .false.
    end subroutine generic_event_discard_particle_set

```

These procedures deal with the particle set directly. Return the pointer:

```

(Event base: generic event: TBP)+≡
    procedure :: get_particle_set_ptr => generic_event_get_particle_set_ptr

(Event base: sub interfaces)+≡
    module function generic_event_get_particle_set_ptr (event) result (ptr)
        class(generic_event_t), intent(in) :: event
        type(particle_set_t), pointer :: ptr
    end function generic_event_get_particle_set_ptr

(Event base: procedures)+≡
    module function generic_event_get_particle_set_ptr (event) result (ptr)
        class(generic_event_t), intent(in) :: event
        type(particle_set_t), pointer :: ptr
        ptr => event%particle_set
    end function generic_event_get_particle_set_ptr

```

Let it point to some existing particle set:

```

(Event base: generic event: TBP)+≡
    procedure :: link_particle_set => generic_event_link_particle_set

(Event base: sub interfaces)+≡
    module subroutine generic_event_link_particle_set (event, particle_set)
        class(generic_event_t), intent(inout) :: event
        type(particle_set_t), intent(in), target :: particle_set
    end subroutine generic_event_link_particle_set

(Event base: procedures)+≡
    module subroutine generic_event_link_particle_set (event, particle_set)
        class(generic_event_t), intent(inout) :: event
        type(particle_set_t), intent(in), target :: particle_set
        event%particle_set => particle_set
        call event%accept_particle_set ()
    end subroutine generic_event_link_particle_set

```

18.1.4 Access sqme and weight

There are several incarnations: the current value, a reference value, alternate values.

```

(Event base: generic event: TBP)+≡
    procedure :: sqme_prc_is_known => generic_event_sqme_prc_is_known
    procedure :: sqme_ref_is_known => generic_event_sqme_ref_is_known
    procedure :: sqme_alt_is_known => generic_event_sqme_alt_is_known
    procedure :: weight_prc_is_known => generic_event_weight_prc_is_known
    procedure :: weight_ref_is_known => generic_event_weight_ref_is_known

```

```

procedure :: weight_alt_is_known => generic_event_weight_alt_is_known
procedure :: excess_prc_is_known => generic_event_excess_prc_is_known

(Event base: sub interfaces)+≡

```

18.1.5 Pure Virtual Methods

These procedures can only be implemented in the concrete implementation.

Output (verbose, depending on parameters).

(Event base: generic event: TBP)+≡
 procedure (generic_event_write), deferred :: write

(Event base: interfaces)≡
 abstract interface
 subroutine generic_event_write (object, unit, &
 show_process, show_transforms, &
 show_decay, verbose, testflag)
 import
 class(generic_event_t), intent(in) :: object
 integer, intent(in), optional :: unit
 logical, intent(in), optional :: show_process
 logical, intent(in), optional :: show_transforms
 logical, intent(in), optional :: show_decay
 logical, intent(in), optional :: verbose
 logical, intent(in), optional :: testflag
 end subroutine generic_event_write
end interface

Generate an event, based on a selector index `i_mci`, and optionally on an extra set of random numbers `r`. For the main bunch of random numbers that the generator needs, the event object should contain its own generator.

(Event base: generic event: TBP)+≡
 procedure (generic_event_generate), deferred :: generate

(Event base: interfaces)+≡
 abstract interface

```

subroutine generic_event_generate (event, i_mci, r, i_nlo)
  import
  class(generic_event_t), intent(inout) :: event
  integer, intent(in) :: i_mci
  real(default), dimension(:), intent(in), optional :: r
  integer, intent(in), optional :: i_nlo
end subroutine generic_event_generate
end interface

```

Alternative : inject a particle set that is supposed to represent the hard process.
How this determines the event, is dependent on the event structure, therefore
this is a deferred method.

<Event base: generic event: TBP>+≡

```

  procedure (generic_event_set_hard_particle_set), deferred :: &
    set_hard_particle_set

```

<Event base: interfaces>+≡

```

  abstract interface
    subroutine generic_event_set_hard_particle_set (event, particle_set)
      import
      class(generic_event_t), intent(inout) :: event
      type(particle_set_t), intent(in) :: particle_set
    end subroutine generic_event_set_hard_particle_set
  end interface

```

Event index handlers.

<Event base: generic event: TBP>+≡

```

  procedure (generic_event_set_index), deferred :: set_index
  procedure (generic_event_handler), deferred :: reset_index
  procedure (generic_event_increment_index), deferred :: increment_index

```

        end select
    end function factor
end subroutine event_normalization_update

```

18.1.8 Callback container

This derived type contains a callback procedure that can be executed during event I/O. The callback procedure is given the event object (with class `generic_event`) and an event index.

This is a simple wrapper. The object is abstract, so the the actual procedure is introduced by overriding the deferred one. We use the PASS attribute, so we may supplement runtime data in the callback object if desired.

```

<Event base: public>+≡
    public :: event_callback_t

<Event base: types>+≡
    type, abstract :: event_callback_t
    private
    contains
        procedure(event_callback_write), deferred :: write
        procedure(event_callback_proc), deferred :: proc
    end type event_callback_t

```

Identify the callback procedure in output

```

<Event base: interfaces>+≡
    abstract interface
        subroutine event_callback_write (event_callback, unit)
            import
            class(event_callback_t), intent(in) :: event_callback
            integer, intent(in), optional :: unit
        end subroutine event_callback_write
    end interface

```

This is the procedure interface.

```

<Event base: interfaces>+≡
    abstract interface
        subroutine event_callback_proc (event_callback, i, event)
            import

```

```

        class(event_callback_t), intent(in) :: event_callback
        integer(i64), intent(in) :: i
        class(generic_event_t), intent(in) :: event
    end subroutine event_callback_proc
end interface

```

A dummy implementation for testing and fallback.

```

<Event base: public>+≡
    public :: event_callback_nop_t

<Event base: types>+≡
    type, extends (event_callback_t) :: event_callback_nop_t
    private
    contains
        procedure :: write => event_callback_nop_write
        procedure :: proc => event_callback_nop
    end type event_callback_nop_t

<Event base: sub interfaces>+≡
    module subroutine event_callback_nop_write (event_callback, unit)
        class(event_callback_nop_t), intent(in) :: event_callback
        integer, intent(in), optional :: unit
    end subroutine event_callback_nop_write
    module subroutine event_callback_nop (event_callback, i, event)
        class(event_callback_nop_t), intent(in) :: event_callback
        integer(i64), intent(in) :: i
        class(generic_event_t), intent(in) :: event
    end subroutine event_callback_nop

<Event base: procedures>+≡
    module subroutine event_callback_nop_write (event_callback, unit)
        class(event_callback_nop_t), intent(in) :: event_callback
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)
        write (u, "(1x,A)") "NOP"
    end subroutine event_callback_nop_write

    module subroutine event_callback_nop (event_callback, i, event)
        class(event_callback_nop_t), intent(in) :: event_callback
        integer(i64), intent(in) :: i
        class(generic_event_t), intent(in) :: event
    end subroutine event_callback_nop

```

18.2 Event Handle

This module defines an abstract base type that allows us to communicate any type of event record within the program. The concrete extensions are expected to consist of pointers, such as the C pointers for HepMC or LCIO events, so the communication object is a very light-weight one.

```

<event_handles.f90>≡

```

```

    <File header>

    module event_handles

    <Standard module head>

    <Event handle: public>

    <Event handle: types>

    end module event_handles

```

There is only one abstract type.

```

<Event handle: public>≡
    public :: event_handle_t

<Event handle: types>≡
    type, abstract :: event_handle_t
    end type event_handle_t

```

18.3 Event Sample Data

We define a simple and transparent container for (meta)data that are associated with an event sample.

```

<eio_data.f90>≡
    <File header>

    module eio_data

    <Use kinds>
    <Use strings>

    use event_base

    <Standard module head>

    <EIO data: public>

    <EIO data: types>

    interface
    <EIO data: sub interfaces>
    end interface

    end module eio_data

    <eio_data_sub.f90>≡
    <File header>

    submodule (eio_data) eio_data_s

    use io_units
    use numeric_utils

```

```

    use diagnostics

    implicit none

contains

    <EIO data: procedures>

end submodule eio_data_s

```

18.3.1 Event Sample Data

These are data that apply to an event sample as a whole. They are given in an easily portable form (no fancy structure) and are used for initializing event formats.

There are two MD5 sums here. `md5sum_proc` depends only on the definition of the contributing processes. A sample with matching checksum can be rescanned with modified model parameters, beam structure etc, to recalculate observables. `md5sum_config` includes all relevant data. Rescanning a sample with matching checksum will produce identical observables. (A third checksum might be added which depends on the event sample itself. This is not needed, so far.)

If alternate weights are part of the event sample (`n_alt` nonzero), there is a configuration MD5 sum for each of them.

```

<EIO data: public>≡
    public :: event_sample_data_t

<EIO data: types>≡
    type :: event_sample_data_t
        character(32) :: md5sum_prc = ""
        character(32) :: md5sum_cfg = ""
        logical :: unweighted = .true.
        logical :: negative_weights = .false.
        integer :: norm_mode = NORM_UNDEFINED
        integer :: n_beam = 0
        integer, dimension(2) :: pdg_beam = 0
        real(default), dimension(2) :: energy_beam = 0
        integer :: n_proc = 0
        integer :: n_evt = 0
        integer :: nlo_multiplier = 1
        integer :: split_n_evt = 0
        integer :: split_n_kbytes = 0
        integer :: split_index = 0
        real(default) :: total_cross_section = 0
        integer, dimension(:), allocatable :: proc_num_id
        integer :: n_alt = 0
        character(32), dimension(:), allocatable :: md5sum_alt
        real(default), dimension(:), allocatable :: cross_section
        real(default), dimension(:), allocatable :: error
    contains
        <EIO data: event sample data: TBP>
end type event_sample_data_t

```

18.4 Abstract I/O Handler

This module defines an abstract object for event I/O and the associated methods.

There are `output` and `input` methods which write or read a single event from/to the I/O stream, respectively. The I/O stream itself may be a file, a common block, or an externally linked structure, depending on the concrete implementation.

A `write` method prints the current content of the implementation-dependent event record in human-readable form.

The `init_in/init_out` and `final` prepare and finalize the I/O stream, respectively. There is also a `switch_inout` method which turns an input stream into an output stream where events can be appended.

Optionally, output files can be split in chunks of well-defined size. The `split_out` method takes care of this.

```
<eio_base.f90>≡

```

18.4.1 Type

We can assume that most implementations will need the file extension as a fixed string and, if they support file splitting, the current file index.

The fallback model is useful for implementations that are able to read unknown files which may contain hadrons etc., not in the current hard-interaction model.

```

<EIO base: public>≡
    public :: eio_t

<EIO base: types>≡
    type, abstract :: eio_t
        type(string_t) :: sample
        type(string_t) :: extension
        type(string_t) :: filename
        logical :: has_file = .false.
        logical :: split = .false.
        integer :: split_n_evt = 0
        integer :: split_n_kbytes = 0
        integer :: split_index = 0
        integer :: split_count = 0
        class(model_data_t), pointer :: fallback_model => null ()
    contains
        <EIO base: eio: TBP>
    end type eio_t

```

Write to screen. If possible, this should display the contents of the current event, i.e., the last one that was written or read.

```

<EIO base: eio: TBP>≡
    procedure (eio_write), deferred :: write

<EIO base: interfaces>≡
    abstract interface
        subroutine eio_write (object, unit)
            import

            logical, intent(out), optional :: success
            type(string_t), intent(in), optional :: extension

```

```

        end subroutine eio_init_out
    end interface

```

Initialize for input. We provide process names. This should open an event file if appropriate and read header data. The `md5sum` can be used to check the integrity of the configuration, it provides a checksum to compare with. In case the extension has changed the extension is also given as an argument.

The `data` argument is `intent(inout)`: we may read part of it and keep other parts and/or check them against the data in the file.

```

<EIO base: eio: TBP>+≡
    procedure (eio_init_in), deferred :: init_in

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_init_in (eio, sample, data, success, extension)
            import
            class(eio_t), intent(inout) :: eio
            type(string_t), intent(in) :: sample
            type(event_sample_data_t), intent(inout), optional :: data
            logical, intent(out), optional :: success
            type(string_t), intent(in), optional :: extension
        end subroutine eio_init_in
    end interface

```

Re-initialize for output. This should change the status of any event file from input to output and position it for appending new events.

```

<EIO base: eio: TBP>+≡
    procedure (eio_switch_inout), deferred :: switch_inout

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_switch_inout (eio, success)
            import
            class(eio_t), intent(inout) :: eio
            logical, intent(out), optional :: success
        end subroutine eio_switch_inout
    end interface

```

This is similar: split the output, i.e., close the current file and open a new one. The default implementation does nothing. For the feature to work, an implementation must override this.

```

<EIO base: eio: TBP>+≡
    procedure :: split_out => eio_split_out

<EIO base: sub interfaces>+≡
    module subroutine eio_split_out (eio)
        class(eio_t), intent(inout) :: eio
    end subroutine eio_split_out

<EIO base: procedures>+≡
    module subroutine eio_split_out (eio)
        class(eio_t), intent(inout) :: eio
    end subroutine eio_split_out

```

Determine the file size in kilobytes. More exactly, determine the size in units of 1024 storage units, as returned by the INQUIRE statement.

The implementation returns zero if there is no file. The `has_file` flag is set by the `set_filename` method, so we can be confident that the `inquire` call is meaningful. If this algorithm doesn't apply for a particular format, we still can override the procedure.

```

(EIO base: eio: TBP)+≡
    procedure :: file_size_kbytes => eio_file_size_kbytes

(EIO base: sub interfaces)+≡
    module function eio_file_size_kbytes (eio) result (kbytes)
        class(eio_t), intent(in) :: eio
        integer :: kbytes
    end function eio_file_size_kbytes

(EIO base: procedures)+≡
    module function eio_file_size_kbytes (eio) result (kbytes)
        class(eio_t), intent(in) :: eio
        integer :: kbytes
        integer(i64) :: bytes
        if (eio%has_file) then
            inquire (file = char (eio%filename), size = bytes)
            if (bytes > 0) then
                kbytes = bytes / 1024
            else
                kbytes = 0
            end if
        else
            kbytes = 0
        end if
    end function eio_file_size_kbytes

```

Output an event. All data can be taken from the `event` record. The index `i_prc` identifies the process among the processes that are contained in the current sample. The `reading` flag, if present, indicates that the event was read from file, not generated.

The `passed` flag tells us that this event has passed the selection criteria. Depending on the event format, we may choose to skip events that have not passed.

```

(EIO base: eio: TBP)+≡
    procedure (eio_output), deferred :: output

(EIO base: interfaces)+≡
    abstract interface
        subroutine eio_output &
            (eio, event, i_prc, reading, passed, pacify, event_handle)
        import
        class(eio_t), intent(inout) :: eio
        class(generic_event_t), intent(in), target :: event
        integer, intent(in) :: i_prc
        logical, intent(in), optional :: reading, passed, pacify
        class(event_handle_t), intent(inout), optional :: event_handle
    end subroutine eio_output
    end interface

```

Input an event. This should fill all event data that cannot be inferred from the associated process.

The input is broken down into two parts. First we read the `i_prc` index. So we know which process to expect in the subsequent event. If we have reached end of file, we also will know. Then, we read the event itself.

The parameter `iostat` is supposed to be set as the Fortran standard requires, negative for EOF and positive for error.

```

<EIO base: eio: TBP>+≡

    logical, intent(in), optional :: unweighted
    integer, intent(in), optional :: n_alt
    type(string_t), intent(in), optional :: sample_norm
  end subroutine eio_prepare_event
end interface

abstract interface
  subroutine eio_cleanup_event (event)
    import
    class(generic_event_t), intent(inout), pointer :: event
  end subroutine eio_cleanup_event
end interface

```

We store pointers to the test-environment handlers as module variables. This allows us to call them from the test routines themselves, which don't allow for extra arguments.

```

<EIO base: public test auxiliary>≡
public :: eio_prepare_test, eio_cleanup_test

<EIO base: test types>+≡
procedure(eio_prepare_event), pointer :: eio_prepare_test => null ()
procedure(eio_cleanup_event), pointer :: eio_cleanup_test => null ()

```

Similarly, for the fallback (hadron) model that some eio tests require:

```

<EIO base: test types>+≡
abstract interface
  subroutine eio_prepare_model (model)
    import
    class(model_data_t), intent(inout), pointer :: model
  end subroutine eio_prepare_model
end interface

abstract interface
  subroutine eio_cleanup_model (model)
    import
    class(model_data_t), intent(inout), target :: model
  end subroutine eio_cleanup_model
end interface

```

```

<EIO base: public test auxiliary>+≡
    public :: eio_prepare_fallback_model, eio_cleanup_fallback_model

<EIO base: test variables>≡
    procedure(eio_prepare_model), pointer :: eio_prepare_fallback_model => null ()
    procedure(eio_cleanup_model), pointer :: eio_cleanup_fallback_model => null ()

```

Test type for event I/O

The contents simulate the contents of an external file. We have the `sample` string as the file name and the array of momenta `event_p` as the list of events. The second index is the event index. The `event_i` component is the pointer to the current event, `event_n` is the total number of stored events.

```

<EIO base: test types>+≡
    type, extends (eio_t) :: eio_test_t
        integer :: event_n = 0
        integer :: event_i = 0
        integer :: i_prc = 0
        type(vector4_t), dimension(:,,:), allocatable :: event_p
    contains
        <EIO base: eio test: TBP>
    end type eio_test_t

```

Write to screen. Pretend that this is an actual event format.

```

<EIO base: eio test: TBP>≡
    procedure :: write => eio_test_write

<EIO base: test auxiliary>≡
    subroutine eio_test_write (object, unit)
        class(eio_test_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Test event stream"
        if (object%event_i /= 0) then
            write (u, "(1x,A,I0,A)") "Event #", object%event_i, ":"
            do i = 1, size (object%event_p, 1)
                call vector4_write (object%event_p(i, object%event_i), u)
            end do
        end if
    end subroutine eio_test_write

```

Finalizer. For the test case, we just reset the event count, but keep the stored “events”. For the real implementations, the events would be stored on an external medium, so we would delete the object contents.

```

<EIO base: eio test: TBP>+≡
    procedure :: final => eio_test_final

<EIO base: test auxiliary>+≡
    subroutine eio_test_final (object)
        class(eio_test_t), intent(inout) :: object
        object%event_i = 0
    end subroutine eio_test_final

```

```
end subroutine eio_test_final
```

Initialization: We store the process IDs and the energy from the beam-data object. We also allocate the momenta (i.e., the simulated event record) for a fixed maximum size of 10 events, 2 momenta each. There is only a single process.

```
<EIO base: eio test: TBP>+≡
  procedure :: init_out => eio_test_init_out

<EIO base: test auxiliary>+≡
  subroutine eio_test_init_out (eio, sample, data, success, extension)
    class(eio_test_t), intent(inout) :: eio
    type(string_t), intent(in) :: sample
    type(event_sample_data_t), intent(in), optional :: data
    logical, intent(out), optional :: success
    type(string_t), intent(in), optional :: extension
    eio%sample = sample
    eio%event_n = 0
    eio%event_i = 0
    allocate (eio%event_p (2, 10))
    if (present (success)) success = .true.
  end subroutine eio_test_init_out
```

Initialization for input. Nothing to do for the test type.

```
<EIO base: eio test: TBP>+≡
  procedure :: init_in => eio_test_init_in

<EIO base: test auxiliary>+≡
  subroutine eio_test_init_in (eio, sample, data, success, extension)
    class(eio_test_t), intent(inout) :: eio
    type(string_t), intent(in) :: sample
    type(event_sample_data_t), intent(inout), optional :: data
    logical, intent(out), optional :: success
    type(string_t), intent(in), optional :: extension
    if (present (success)) success = .true.
  end subroutine eio_test_init_in
```

Switch from output to input. Again, nothing to do for the test type.

```
<EIO base: eio test: TBP>+≡
  procedure :: switch_inout => eio_test_switch_inout

<EIO base: test auxiliary>+≡
  subroutine eio_test_switch_inout (eio, success)
    class(eio_test_t), intent(inout) :: eio
    logical, intent(out), optional :: success
    if (present (success)) success = .true.
  end subroutine eio_test_switch_inout
```

Output. Increment the event counter and store the momenta of the current event.

```
<EIO base: eio test: TBP>+≡
  procedure :: output => eio_test_output
```

```

(EIO base: test auxiliary)+≡
  subroutine eio_test_output &
    (eio, event, i_prc, reading, passed, pacify, event_handle)

```

18.5 Direct Event Access

As a convenient application of the base type, we construct an event handler that allows us of setting and retrieving events just in the same way as an file I/O format, but directly dealing with particle data and momenta. This is an input and output format, but we do not care about counting events.

`<eio_direct.f90>`≡

<File header>

module eio_direct

<Use kinds>

<Use strings>

```

use lorentz, only: vector4_t
use particles, only: particle_set_t
use model_data, only: model_data_t
use event_base
use event_handles, only: event_handle_t
use eio_data
use eio_base

```

```

    <Standard module head>

    <EIO direct: public>

    <EIO direct: types>

    interface
    <EIO direct: sub interfaces>
    end interface

    end module eio_direct

(eio_direct_sub.f90)≡
    <File header>

    submodule (eio_direct) eio_direct_s

        use io_units
        use diagnostics
        use cputime

        implicit none

    contains

    <EIO direct: procedures>

    end submodule eio_direct_s

```

18.5.1 Type

```

    <EIO direct: public>≡
        public :: eio_direct_t

    <EIO direct: types>≡
        type, extends (eio_t) :: eio_direct_t
            private
            logical :: i_evt_set = .false.
            integer :: i_evt = 0

18.8 Event Weight Output

This is an output-only format. For each event, we print the indices that identify process, process part (MCI group), and term. As numerical information we print the squared matrix element (trace) and the event weight.

```

```
end subroutine eio_weights_switch_inout
```

Output an event. Write first the event indices, then weight and two values of the squared matrix element: `sqme_ref` is the value stored in the event record, and `sqme_prc` is the one stored in the process instance. (They can differ: when recalculating, the former is read from file and the latter is the result of the new calculation.)

For the alternative entries, the `sqme` value is always obtained by a new calculation, and thus qualifies as `sqme_prc`.

Don't write the file if the `passed` flag is set and false.

18.9 Event Dump Output

This is an output-only format. We simply dump the contents of the `particle_set`, using the `write` method of that type. The event-format options are the options of that procedure.

```

18.11 HEP Common Blocks

Long ago, to transfer data between programs one had to set up a common block and link both programs as libraries to the main executable. The HEP community standardizes several of those common blocks.

The modern way of data exchange uses data files with standard formats. However, the LHEF standard data format derives from a common block (actually, two).

WHIZARD used to support those common blocks, and LHEF was implemented via writing/reading blocks. We still keep this convention, but intend to eliminate common blocks (or any other static storage) from the workflow in the future. This will gain flexibility towards concurrent running of program images.

We encapsulate everything here in a module. The module holds the variables which are part of the common block. To access the common block variables, we just have to `use` this module. (They are nevertheless in the common block, since external software may access it in this way.)

Note: This code is taken essentially unchanged from WHIZARD 2.1 and does not (yet) provide unit tests.

18.11.1 Event characteristics

The maximal number of particles in an event record.

```

<HEP common: parameters>≡
    integer, parameter, public :: MAXNUP = 500

```

The number of particles in this event.

```

<HEP common: variables>≡
    integer, public :: NUP

```

The process ID for this event.

```

<HEP common: variables>+≡
    integer, public :: IDPRUP

```

The weight of this event (± 1 for unweighted events).

```

<HEP common: variables>+≡
    double precision, public :: XWGTUP

```

The factorization scale that is used for PDF calculation (-1 if undefined).

```

<HEP common: variables>+≡
    double precision, public :: SCALUP

```

The QED and QCD couplings α used for this event (-1 if undefined).

```
<HEP common: variables>+≡  
  double precision, public :: AQEDUP  
  double precision, public :: AQCDUP
```

18.11.2 Particle characteristics

The PDG code:

```
<HEP common: variables>+≡  
  integer, dimension(MAXNUP), public :: IDUP
```

The status code. Incoming: -1 , outgoing: $+1$. Intermediate t-channel propagator: -2 (currently not used by WHIZARD). Intermediate resonance whose mass should be preserved: 2 . Intermediate resonance for documentation: 3 (currently not used). Beam particles: -9 .

```
<HEP common: variables>+≡  
  integer, dimension(MAXNUP), public :: ISTUP
```

Index of first and last mother.

```
<HEP common: variables>+≡  
  integer, dimension(2,MAXNUP), public :: MOTHUP
```

Color line index of the color and anticolor entry for the particle. The standard recommends using large numbers; we start from $\text{MAXNUP}+1$.

```
<HEP common: variables>+≡  
  integer, dimension(2,MAXNUP), public :: ICOLUP
```

Momentum, energy, and invariant mass: (p_x, p_y, p_z, E, M) . For space-like particles, M is the negative square root of the absolute value of the invariant mass.

```
<HEP common: variables>+≡  
  double precision, dimension(5,MAXNUP), public :: PUP
```

Invariant lifetime (distance) from production to decay in mm.

```
<HEP common: variables>+≡  
  double precision, dimension(MAXNUP), public :: VTIMUP
```

Cosine of the angle between the spin-vector and a particle and the 3-momentum of its mother, given in the lab frame. If undefined/unpolarized: 9 .

```
<HEP common: variables>+≡  
  double precision, dimension(MAXNUP), public :: SPINUP
```

18.11.3 The HEPRUP common block

This common block is filled once per run.

Run characteristics

The maximal number of different processes.

```
<HEP common: parameters>+≡  
  integer, parameter, public :: MAXPUP = 100
```

The beam PDG codes.

```
<HEP common: variables>+≡  
  integer, dimension(2), public :: IDBMUP
```

The beam energies in GeV.

```
<HEP common: variables>+≡  
    double precision, dimension(2), public :: EBMUP
```

The PDF group and set for the two beams. (Undefined: use -1; LHAPDF: use group = 0).

```
<HEP common: variables>+≡  
    integer, dimension(2), public :: PDFGUP  
    integer, dimension(2), public :: PDFSUP
```

The (re)weighting model. 1: events are weighted, the shower generator (SHG) selects processes according to the maximum weight (in pb) and unweights events. 2: events are weighted, the SHG selects processes according to their cross section (in pb) and unweights events. 3: events are unweighted and simply run through the SHG. 4: events are weighted, and the SHG keeps the weight. Negative numbers: negative weights are allowed (and are reweighted to ± 1 by the SHG, if allowed).

WHIZARD only supports modes 3 and 4, as the SHG is not given control over process selection. This is consistent with writing events to file, for offline showering.

```
<HEP common: variables>+≡  
    integer, public :: IDWTUP
```

The number of different processes.

```
<HEP common: variables>+≡  
    integer, public :: NPRUP
```

Process characteristics

Cross section and error in pb. (Cross section is needed only for IDWTUP = 2, so here both values are given for informational purposes only.)

```
<HEP common: variables>+≡  
    double precision, dimension(MAXPUP), public :: XSECUP  
    double precision, dimension(MAXPUP), public :: XERRUP
```

Maximum weight, i.e., the maximum value that XWGTUP can take. Also unused for the supported weighting models. It is ± 1 for unweighted events.

```
<HEP common: variables>+≡  
    double precision, dimension(MAXPUP), public :: XMAXUP
```

Internal ID of the selected process, matches IDPRUP below.

```
<HEP common: variables>+≡  
    integer, dimension(MAXPUP), public :: LPRUP
```

The common block

```
<HEP common: common blocks>≡  
    common /HEPRUP/ &  
        IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP, &  
        XSECUP, XERRUP, XMAXUP, LPRUP  
    save /HEPRUP/
```

Fill the run characteristics of the common block. The initialization sets the beam properties, number of processes, and weighting model.

```

<HEP common: public>≡
    public :: heprup_init

<HEP common: sub interfaces>≡
    module subroutine heprup_init &
        (beam_pdg, beam_energy, n_processes, unweighted, negative_weights)
        integer, dimension(2), intent(in) :: beam_pdg

        if (unweighted) then
            IDWTUP = 3
        else
            IDWTUP = 4
        end if
        if (negative_weights) IDWTUP = - IDWTUP
        NPRUP = n_processes
    end subroutine heprup_init

```

The HEPRUP (event) common block is needed for the interface to the shower. Filling of it is triggered by some output file formats. If these are not present, the common block is filled with some dummy information. Be generous with the number of processes in HEPRUP so that PYTHIA only rarely needs to be reinitialized in case events with higher process ids are generated.

```

```

Read in the LHE file opened in unit u and add the final particles to the `particle_set`, the outgoing particles of the existing `particle_set` are compared to the particles that are read in. When they are equal in flavor and momenta, they are erased and their mother-daughter relations are transferred to the existing particles.

18.11.5 Run parameter output (other formats)

This routine writes the initialization block according to the LHEF standard. It uses the current contents of the HEPRUP block.

```

<HEP common: public>+≡
public :: heprup_write_lhef

<HEP common: sub interfaces>+≡
module subroutine heprup_write_lhef (unit)
integer, intent(in), optional :: unit
end subroutine heprup_write_lhef

<HEP common: procedures>+≡
module subroutine heprup_write_lhef (unit)
integer, intent(in), optional :: unit
integer :: u, i
u = given_output_unit (unit); if (u < 0) return
write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
do i = 1, NPRUP
write (u, "(3(1x,ES17.10),1x,I0)") &
XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
end do
end subroutine heprup_write_lhef

```

This routine is a complete dummy at the moment. It uses the current contents of the HEPRUP block. At the end, it should depend on certain input flags for the different ASCII event formats.

```

<HEP common: public>+≡
public :: heprup_write_ascii

<HEP common: sub interfaces>+≡
module subroutine heprup_write_ascii (unit)
integer, intent(in), optional :: unit
end subroutine heprup_write_ascii

<HEP common: procedures>+≡
module subroutine heprup_write_ascii (unit)
integer, intent(in), optional :: unit
integer :: u, i
u = given_output_unit (unit); if (u < 0) return

```

```

write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
      IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
do i = 1, NPRUP
  write (u, "(3(1x,ES17.10),1x,I0)") &
        XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
end do
end subroutine heprup_write_ascii

```

Run parameter input (LHEF)

In a LHEF file, the parameters are written in correct order on separate lines, but we should not count on the precise format. List-directed input should just work.

```

<HEP common: public>+≡
  public :: heprup_read_lhef

<HEP common: sub interfaces>+≡
  module subroutine heprup_read_lhef (u)
    integer, intent(in) :: u
  end subroutine heprup_read_lhef

<HEP common: procedures>+≡
  module subroutine heprup_read_lhef (u)
    integer, intent(in) :: u
    integer :: i
    read (u, *) &
      IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
    do i = 1, NPRUP
      read (u, *) &
        XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
    end do
  end subroutine heprup_read_lhef

```

18.11.6 The HEPEUP common block

```

<HEP common: common blocks>+≡
  common /HEPEUP/ &
    NUP, IDPRUP, XWGTUP, SCALUP, AQEDUP, AQCDUP, &
    IDUP, ISTUP, MOTHUP, ICOLUP, PUP, VTIMUP, SPINUP
  save /HEPEUP/

```

Initialization

Fill the event characteristics of the common block. The initialization sets only the number of particles and initializes the rest with default values. The other routine sets the optional parameters.

```

<HEP common: public>+≡
  public :: hepeup_init
  public :: hepeup_set_event_parameters

```

```

<HEP common: sub interfaces>+≡
  module subroutine hepeup_init (n_tot)

        real(default), intent(in) :: lifetime
        VTIMUP(i) = lifetime
    end subroutine hepeup_set_particle_lifetime

```

Set the particle spin entry. We need the cosine of the angle of the spin axis with respect to the three-momentum of the parent particle.

If the particle has a full polarization density matrix given, we need the particle momentum and polarization as well as the mother-particle momentum. The polarization is transformed into a spin vector (which is sensible only for spin-1/2 or massless particles), which then is transformed into the lab frame (by a rotation of the 3-axis to the particle momentum axis). Finally, we compute the scalar product of this vector with the mother-particle three-momentum.

This puts severe restrictions on the applicability of this definition, and Lorentz invariance is lost. Unfortunately, the Les Houches Accord requires this computation.

```

<HEP common: public>+≡

18.11.7 The HEPEVT and HEPEV4 common block

For the LEP Monte Carlos, a standard common block has been proposed in AKV89. We strongly recommend its use. (The description is an abbreviated transcription of AKV89, Vol. 3, pp. 327-330).

NMXHEP is the maximum number of entries:

```

<HEP common: variables>+≡
integer, parameter :: NMXHEP = 4000

```

NEVHEP is normally the event number, but may take special values as follows:

0 the program does not keep track of event numbers. -1 a special initialization record. -2 a special final record.

```

<HEP common: variables>+≡
integer :: NEVHEP

```

NHEP holds the number of entries for this event.

```
<HEP common: variables>+≡
integer, public :: NHEP
```

The entry ISTHEP(N) gives the status code for the Nth entry, with the following semantics: 0 a null entry. 1 an existing entry, which has not decayed or fragmented. 2 a decayed or fragmented entry, which is retained for event history information. 3 documentation line. 4- 10 reserved for future standards. 11-200 at the disposal of each model builder. 201- at the disposal of users.

```
<HEP common: variables>+≡
integer, dimension(NMXHEP), public :: ISTHEP
```

The Particle Data Group has proposed standard particle codes, which are to be stored in IDHEP(N).

```
<HEP common: variables>+≡
integer, dimension(NMXHEP), public :: IDHEP
```

JMOHEP(1,N) points to the mother of the Nth entry, if any. It is set to zero for initial entries. JMOHEP(2,N) points to the second mother, if any.

```
<HEP common: variables>+≡
integer, dimension(2, NMXHEP), public :: JMOHEP
```

JDAHEP(1,N) and JDAHEP(2,N) point to the first and last daughter of the Nth entry, if any. These are zero for entries which have not yet decayed. The other daughters are stored in between these two.

```
<HEP common: variables>+≡
integer, dimension(2, NMXHEP), public :: JDAHEP
```

In PHEP we store the momentum of the particle, more specifically this means that PHEP(1,N), PHEP(2,N), and PHEP(3,N) contain the momentum in the x , y , and z direction (as defined by the machine people), measured in GeV/c. PHEP(4,N) contains the energy in GeV and PHEP(5,N) the mass in GeV/ c^2 . The latter may be negative for spacelike partons.

```
<HEP common: variables>+≡
double precision, dimension(5, NMXHEP), public :: PHEP
```

Finally VHEP is the place to store the position of the production vertex. VHEP(1,N), VHEP(2,N), and VHEP(3,N) contain the x , y , and z coordinate (as defined by the machine people), measured in mm. VHEP(4,N) contains the production time in mm/c.

```
<HEP common: variables>+≡
double precision, dimension(4, NMXHEP) :: VHEP
```

As an amendment to the proposed standard common block HEPEVT, we also have a polarisation common block HEPSPN, as described in AKV89. SHEP(1,N), SHEP(2,N), and SHEP(3,N) give the x , y , and z component of the spinvector s of a fermion in the fermions restframe.

Furthermore, we add the polarization of the corresponding outgoing particles:

```
<HEP common: variables>+≡
    integer, dimension(NMXHEP) :: hepevt_pol
```

By this variable the identity of the current process is given, defined via the LPRUP codes.

```
<HEP common: variables>+≡
    integer, public :: idruplh
```

This is the event weight, i.e. the cross section divided by the total number of generated events for the output of the parton shower programs.

```
<HEP common: variables>+≡
    double precision, public :: eventweightlh
```

There are the values for the electromagnetic and the strong coupling constants, α_{em} and α_s .

```
<HEP common: variables>+≡
    double precision, public :: alphaqedlh, alphaqcdlh
```

This is the squared scale Q of the event.

```
<HEP common: variables>+≡
    double precision, dimension(10), public :: scalelh
```

Finally, these variables contain the spin information and the color/anticolor flow of the particles.

```
<HEP common: variables>+≡
    double precision, dimension (3,NMXHEP), public :: spinlh
    integer, dimension (2,NMXHEP), public :: icolorflowlh
```

By convention, SHEP(4,N) is always 1. All this is taken from StdHep 4.06 manual and written using Fortran90 conventions.

```
<HEP common: common blocks>+≡
    common /HEPEVT/ &
        NEVHEP, NHEP, ISTHEP, IDHEP, &
        JMOHEP, JDAHEP, PHEP, VHEP
    save /HEPEVT/
```

Here we store HEPEVT parameters of the WHIZARD 1 realization which are not part of the HEPEVT common block.

```
<HEP common: variables>+≡
    integer :: hepevt_n_out, hepevt_n_remnants

<HEP common: variables>+≡
    double precision :: hepevt_weight, hepevt_function_value
    double precision :: hepevt_function_ratio
```

The HEPEV4 common block is an extension of the HEPEVT common block to allow for partonic colored events, including especially the color flow etc.

```
<HEP common: common blocks>+≡
common /HEPEV4/ &
    eventweightlh, alphaqedlh, alphaqcdlh, scalelh, &
    spinlh, icolorflowlh, idruplh
save /HEPEV4/
```

Filling HEPEVT: If the event count is not provided, set NEVHEP to zero. If the event count is -1 or -2, the record corresponds to initialization and finalization, and the event is irrelevant.

Note that the event count may be larger than 2^{31} (2 GEvents). In that case, cut off the upper bits since NEVHEP is probably limited to default integer.

For the HEPEV4 common block, it is unclear why the `scalelh` variable is 10-dimensional. We choose to only set the first value of the array.

```
<HEP common: public>+≡
public :: hepevt_init
public :: hepevt_set_event_parameters

<HEP common: sub interfaces>+≡
module subroutine hepevt_init (n_tot, n_out)
    integer, intent(in) :: n_tot, n_out
end subroutine hepevt_init
module subroutine hepevt_set_event_parameters &
    (proc_id, weight, function_value, function_ratio, &
    alpha_qcd, alpha_qed, scale, i_evt)
    integer, intent(in), optional :: proc_id
    integer, intent(in), optional :: i_evt
    real(default), intent(in), optional :: weight, function_value, &
    function_ratio, alpha_qcd, alpha_qed, scale
end subroutine hepevt_set_event_parameters

<HEP common: procedures>+≡
module subroutine hepevt_init (n_tot, n_out)
    integer, intent(in) :: n_tot, n_out
    NHEP = n_tot
    NEVHEP = 0
    idruplh = 0
    hepevt_n_out = n_out
    hepevt_n_remnants = 0
    hepevt_weight = 1
    eventweightlh = 1
    hepevt_function_value = 0
    hepevt_function_ratio = 1
    alphaqcdlh = -1
    alphaqedlh = -1
    scalelh = -1
end subroutine hepevt_init

module subroutine hepevt_set_event_parameters &
    (proc_id, weight, function_value, function_ratio, &
    alpha_qcd, alpha_qed, scale, i_evt)
    integer, intent(in), optional :: proc_id
    integer, intent(in), optional :: i_evt

```

This routine writes event output according to the HEPEVT standard. It uses the current contents of the HEPEVT block and some additional parameters according to the standard in WHIZARD 1. For the long ASCII format, the value of the sample function (i.e. the product of squared matrix element, structure functions and phase space factor is printed out). The option of reweighting matrix elements with respect to some reference cross section is not implemented in WHIZARD 2 for this event format, therefore the second entry in the long ASCII format (the function ratio) is always one. The ATHENA format is an implementation of the HEPEVT format that is readable by the ATLAS ATHENA software framework. It is very similar to the WHIZARD 1 HEPEVT format, except that it contains an event counter, a particle counter inside the event, and has the HEPEVT ISTHEP status before the PDG code. The MOKKA format is a special ASCII format that contains the information to be parsed to the MOKKA LC fast simulation software.

18.11.11 Data Transfer: particle sets

The WHIZARD format for handling particle data in events is `particle_set_t`. We have to interface this to the common blocks.

We first create a new particle set that contains only the particles that are supported by the LHEF format. These are: beam, incoming, resonant, outgoing. We drop particles with unknown, virtual or beam-remnant status.

From this set we fill the common block. Event information such as process ID and weight is not transferred here; this has to be done by the caller. The spin information is set only if the particle has a unique mother, and if its polarization is fully defined.

We use this routine also to hand over information to Pythia which lets Tauola access SPINUP. Tauola expects in SPINUP the helicity and not the LHA convention. We switch to this mode with `tauola_convention`.

```

Input. The particle set should be allocated properly, but we replace the particle contents.

If there are no beam particles in the event, we try to reconstruct beam particles and beam remnants. We assume for simplicity that the beam particles, if any, are the first two particles. If they are absent, the first two particles should be the incoming partons.

18.12 HepMC events

This section provides the interface to the HepMC C++ library for handling Monte-Carlo events.

Each C++ class of HepMC that we use is mirrored by a Fortran type, which contains as its only component the C pointer to the C++ object.

Each C++ method of HepMC that we use has a C wrapper function. This function takes a pointer to the host object as its first argument. Further arguments are either C pointers, or in the case of simple types (integer, real), interoperable C/Fortran objects.

The C wrapper functions have explicit interfaces in the Fortran module. They are called by Fortran wrapper procedures. These are treated as methods of the corresponding Fortran type.

```
<hepmc_interface.f90>≡  
  <File header>

    implicit none

contains

    <HepMC interface: procedures>

end submodule hepmc_interface_s

```

18.12.1 Interface check

This function can be called in order to verify that we are using the actual HepMC library, and not the dummy version.

```

<HepMC interface: interfaces>≡
    interface
        logical(c_bool) function hepmc_available () bind(C)
        import
        end function hepmc_available
    end interface

<HepMC interface: public>≡
    public :: hepmc_is_available

<HepMC interface: sub interfaces>≡
    module function hepmc_is_available () result (flag)
        logical :: flag
    end function hepmc_is_available

<HepMC interface: procedures>≡
    module function hepmc_is_available () result (flag)
        logical :: flag
        flag = hepmc_available ()
    end function hepmc_is_available

```

18.12.2 FourVector

The C version of four-vectors is often transferred by value, and the associated procedures are all inlined. The wrapper needs to transfer by reference, so we create FourVector objects on the heap which have to be deleted explicitly. The input is a `vector4_t` or `vector3_t` object from the `lorentz` module.

```

<HepMC interface: public>+≡
    public :: hepmc_four_vector_t

<HepMC interface: types>≡
    type :: hepmc_four_vector_t
    private
    type(c_ptr) :: obj

```

```
end type hepmc_four_vector_t
```

In the C constructor, the zero-component (fourth argument) is optional; if missing, it is set to zero. The Fortran version has initializer form and takes either a three-vector or a four-vector. A further version extracts the four-vector from a HepMC particle object.

```
<HepMC interface: interfaces>+≡
  interface
    type(c_ptr) function new_four_vector_xyz (x, y, z) bind(C)

```

18.12.3 Polarization

Polarization objects are temporarily used for assigning particle polarization. We add a flag `polarized`. If this is false, the polarization is not set and should not be transferred to `hepmc_particle` objects.

```

<HepMC interface: public>+≡
    public :: hepmc_polarization_t
<HepMC interface: types>+≡
    type :: hepmc_polarization_t
        private
        logical :: polarized = .false.
        type(c_ptr) :: obj

```

```
end type hepmc_polarization_t
```

Constructor. The C wrapper takes polar and azimuthal angle as arguments. The Fortran version allows for either a complete polarization density matrix, or for a definite (diagonal) helicity.

HepMC does not allow to specify the degree of polarization, therefore we have to map it to either 0 or 1. We choose 0 for polarization less than 0.5 and 1 for polarization greater than 0.5. Even this simplification works only for spin-1/2 and for massless particles; massive vector bosons cannot be treated this way. In particular, zero helicity is always translated as unpolarized.

For massive vector bosons, we arbitrarily choose the convention that the longitudinal (zero) helicity state is mapped to the theta angle $\pi/2$. This works under the condition that helicity is projected onto one of the basis states.

```
<HepMC interface: interfaces>+≡
```

```
interface

18.12.6 Vertex-particle-in iterator

This iterator iterates over all incoming particles in an vertex. We store a pointer to the vertex in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

```
<HepMC interface: public>+≡
    public :: hepmc_vertex_particle_in_iterator_t

<HepMC interface: types>+≡
    type :: hepmc_vertex_particle_in_iterator_t
    private
        type(c_ptr) :: obj
        type(c_ptr) :: v_obj
    end type hepmc_vertex_particle_in_iterator_t
```

Constructor. The iterator is initialized at the first particle in the vertex.

```
<HepMC interface: interfaces>+≡
    interface
        type(c_ptr) function &
            new_vertex_particles_in_const_iterator (v_obj) bind(C)
        import
            type(c_ptr), value :: v_obj
        end function new_vertex_particles_in_const_iterator
    end interface

<HepMC interface: public>+≡
    public :: hepmc_vertex_particle_in_iterator_init

<HepMC interface: sub interfaces>+≡
    module subroutine hepmc_vertex_particle_in_iterator_init (it, v)
        type(hepmc_vertex_particle_in_iterator_t), intent(out) :: it
        type(hepmc_vertex_t), intent(in) :: v
    end subroutine hepmc_vertex_particle_in_iterator_init

<HepMC interface: procedures>+≡
    module subroutine hepmc_vertex_particle_in_iterator_init (it, v)
        type(hepmc_vertex_particle_in_iterator_t), intent(out) :: it
        type(hepmc_vertex_t), intent(in) :: v
        it%obj = new_vertex_particles_in_const_iterator (v%obj)
        it%v_obj = v%obj
    end subroutine hepmc_vertex_particle_in_iterator_init
```

Destructor. Necessary because the iterator is allocated on the heap.

```
<HepMC interface: interfaces>+≡
    interface
        subroutine vertex_particles_in_const_iterator_delete (it_obj) bind(C)
        import

```

18.12.7 Vertex-particle-out iterator

This iterator iterates over all incoming particles in an vertex. We store a pointer to the vertex in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

```

<HepMC interface: public>+≡
    public :: hepmc_vertex_particle_out_iterator_t

<HepMC interface: types>+≡
    type :: hepmc_vertex_particle_out_iterator_t
    private
    type(c_ptr) :: obj
    type(c_ptr) :: v_obj
    end type hepmc_vertex_particle_out_iterator_t

```

Constructor. The iterator is initialized at the first particle in the vertex.

```

<HepMC interface: interfaces>+≡
    interface
        type(c_ptr) function &
            new_vertex_particles_out_const_iterator (v_obj) bind(C)
        import
        type(c_ptr), value :: v_obj
        end function new_vertex_particles_out_const_iterator
    end interface

<HepMC interface: public>+≡
    public :: hepmc_vertex_particle_out_iterator_init

<HepMC interface: sub interfaces>+≡
    module subroutine hepmc_vertex_particle_out_iterator_init (it, v)
        type(hepmc_vertex_particle_out_iterator_t), intent(out) :: it
        type(hepmc_vertex_t), intent(in) :: v
    end subroutine hepmc_vertex_particle_out_iterator_init

<HepMC interface: procedures>+≡
    module subroutine hepmc_vertex_particle_out_iterator_init (it, v)
        type(hepmc_vertex_particle_out_iterator_t), intent(out) :: it
        type(hepmc_vertex_t), intent(in) :: v
        it%obj = new_vertex_particles_out_const_iterator (v%obj)
        it%v_obj = v%obj
    end subroutine hepmc_vertex_particle_out_iterator_init

```

Destructor. Necessary because the iterator is allocated on the heap.

```

<HepMC interface: interfaces>+≡
    interface
        subroutine vertex_particles_out_const_iterator_delete (it_obj) bind(C)
        import
        type(c_ptr), value :: it_obj
        end subroutine vertex_particles_out_const_iterator_delete
    end interface

<HepMC interface: public>+≡
    public :: hepmc_vertex_particle_out_iterator_final

<HepMC interface: sub interfaces>+≡

    prt%obj = vertex_particles_out_const_iterator_get (it%obj)
  end function hepvc_vertex_particle_out_iterator_get

```

18.12.8 GenEvent

The main object of HepMC is a GenEvent. The object is filled by GenVertex objects, which in turn contain GenParticle objects.

This is an extension of the abstract `event_handle_t`, so we can use the according communicator features.

```
<HepMC interface: public>+≡
    public :: hepmc_event_t

<HepMC interface: types>+≡
    type, extends (event_handle_t) :: hepmc_event_t
    private
        type(c_ptr) :: obj = c_null_ptr
    end type hepmc_event_t
```

Constructor. Arguments are process ID (integer) and event ID (integer).

The Fortran version has initializer form.

```
<HepMC interface: interfaces>+≡
    interface
        type(c_ptr) function new_gen_event (proc_id, event_id) bind(C)
            import
                integer(c_int), value :: proc_id, event_id
        end function new_gen_event
    end interface

<HepMC interface: public>+≡
    public :: hepmc_event_init

<HepMC interface: sub interfaces>+≡
    module subroutine hepmc_event_init (evt, proc_id, event_id)
        type(hepmc_event_t), intent(out) :: evt
        integer, intent(in), optional :: proc_id, event_id
    end subroutine hepmc_event_init

<HepMC interface: procedures>+≡
    module subroutine hepmc_event_init (evt, proc_id, event_id)
        type(hepmc_event_t), intent(out) :: evt
        integer, intent(in), optional :: proc_id, event_id
        integer(c_int) :: pid, eid
        pid = 0; if (present (proc_id)) pid = proc_id
        eid = 0; if (present (event_id)) eid = event_id
        evt%obj = new_gen_event (pid, eid)
    end subroutine hepmc_event_init
```

Destructor.

```
<HepMC interface: interfaces>+≡
    interface
        subroutine gen_event_delete (evt_obj) bind(C)
            import
                type(c_ptr), value :: evt_obj
        end subroutine gen_event_delete
    end interface
```

Finalize: use the HepMC destructor. Also nullify the pointer explicitly, to be on the safe side.

```

<HepMC interface: public>+≡
    public :: hepmc_event_final

<HepMC interface: sub interfaces>+≡
    module subroutine hepmc_event_final (evt)
        type(hepmc_event_t), intent(inout) :: evt
    end subroutine hepmc_event_final

<HepMC interface: procedures>+≡
    module subroutine hepmc_event_final (evt)
        type(hepmc_event_t), intent(inout) :: evt
        if (c_associated (evt%obj)) then
            call gen_event_delete (evt%obj)
            evt%obj = c_null_ptr
        end if
    end subroutine hepmc_event_final

```

Nullify: do not call the destructor, just nullify the C pointer. There should be another pointer associated with the object.

```

<HepMC interface: public>+≡
    public :: hepmc_event_nullify

<HepMC interface: sub interfaces>+≡
    module subroutine hepmc_event_nullify (evt)
        type(hepmc_event_t), intent(inout) :: evt
    end subroutine hepmc_event_nullify

<HepMC interface: procedures>+≡
    module subroutine hepmc_event_nullify (evt)
        type(hepmc_event_t), intent(inout) :: evt
        evt%obj = c_null_ptr
    end subroutine hepmc_event_nullify

```

Return the actual object as a C pointer. For use in the native C++ interface only.

```

<HepMC interface: public>+≡
    public :: hepmc_event_get_c_ptr

<HepMC interface: sub interfaces>+≡
    module function hepmc_event_get_c_ptr (evt) result (p)
        type(hepmc_event_t), intent(in) :: evt
        type(c_ptr) :: p
    end function hepmc_event_get_c_ptr

<HepMC interface: procedures>+≡
    module function hepmc_event_get_c_ptr (evt) result (p)
        type(hepmc_event_t), intent(in) :: evt
        type(c_ptr) :: p
        p = evt%obj
    end function hepmc_event_get_c_ptr

```

Screen output. Printing to file is possible in principle (using a C++ output channel), by allowing an argument. Printing to an open Fortran unit is obviously not possible.

```
<HepMC interface: interfaces>+≡
  interface
    subroutine gen_event_print (evt_obj) bind(C)
      import
      type(c_ptr), value :: evt_obj
    end subroutine gen_event_print
  end interface
```

```
<HepMC interface: public>+≡
  public :: hepmc_event_print
```

```
<HepMC interface: sub interfaces>+≡
  module subroutine hepmc_event_print (evt)
    type(hepmc_event_t), intent(in) :: evt
  end subroutine hepmc_event_print
```

```

    end subroutine gen_event_set_cross_section
end interface

```

18.12.9 Event-particle iterator

This iterator iterates over all particles in an event. We store a pointer to the event in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

(HepMC interface: public)+≡

```

    public :: hepmc_event_particle_iterator_t

```

(HepMC interface: types)+≡

```

    type :: hepmc_event_particle_iterator_t
    private
    type(c_ptr) :: obj
    type(c_ptr) :: evt_obj
    end type hepmc_event_particle_iterator_t

```

Constructor. The iterator is initialized at the first particle in the event.

(HepMC interface: interfaces)+≡

```

interface
    type(c_ptr) function new_event_particle_const_iterator (evt_obj) bind(C)
        import
        type(c_ptr), value :: evt_obj
    end function new_event_particle_const_iterator
end interface

```

(HepMC interface: public)+≡

```

    public :: hepmc_event_particle_iterator_init

```

(HepMC interface: sub interfaces)+≡

```

module subroutine hepmc_event_particle_iterator_init (it, evt)
    type(hepmc_event_particle_iterator_t), intent(out) :: it
    type(hepmc_event_t), intent(in) :: evt
    end subroutine hepmc_event_particle_iterator_init

```

(HepMC interface: procedures)+≡

```

module subroutine hepmc_event_particle_iterator_init (it, evt)
    type(hepmc_event_particle_iterator_t), intent(out) :: it
    type(hepmc_event_t), intent(in) :: evt
    it%obj = new_event_particle_const_iterator (evt%obj)
    it%evt_obj = evt%obj
    end subroutine hepmc_event_particle_iterator_init

```

Destructor. Necessary because the iterator is allocated on the heap.

```
<HepMC interface: interfaces>+≡
  interface
    subroutine event_particle_const_iterator_delete (it_obj) bind(C)
    import
      type(c_ptr), value :: it_obj
    end subroutine event_particle_const_iterator_delete
  end interface

<HepMC interface: public>+≡
  public :: hepmc_event_particle_iterator_final

<HepMC interface: sub interfaces>+≡
  module subroutine hepmc_event_particle_iterator_final (it)
    type(hepmc_event_particle_iterator_t), intent(inout) :: it
  end subroutine hepmc_event_particle_iterator_final

  end subroutine hepmc_interface_test

```

This test example is an abridged version from the build-from-scratch example in the HepMC distribution. We create two vertices for $p \rightarrow q$ PDF splitting, then a vertex for a $qq \rightarrow W^- g$ hard-interaction process, and finally a vertex for $W^- \rightarrow qq$ decay. The setup is for LHC kinematics.

Extending the original example, we set color flow for the incoming quarks and polarization for the outgoing photon. For the latter, we have to define a particle-data object for the photon, so a flavor object can be correctly initialized.

18.13 LCIO events

This section provides the interface to the LCIO C++ library for handling Monte-Carlo events.

Each C++ class of LCIO that we use is mirrored by a Fortran type, which contains as its only component the C pointer to the C++ object.

Each C++ method of LCIO that we use has a C wrapper function. This function takes a pointer to the host object as its first argument. Further arguments are either C pointers, or in the case of simple types (integer, real), interoperable C/Fortran objects.

The C wrapper functions have explicit interfaces in the Fortran module. They are called by Fortran wrapper procedures. These are treated as methods of the corresponding Fortran type.

```

(lcio_interface.f90)≡
  <File header>

```

```

module lcio_interface

  use, intrinsic :: iso_c_binding !NODEP!

  <Use kinds>
  <Use strings>
  use lorentz
  use flavors
  use colors
  use helicities

```

```

        type(string_t), intent(in) :: filename
    end subroutine write_lcio_event

<LCIO interface: procedures>+≡
    module subroutine write_lcio_event (evt, filename)
        type(lcio_event_t), intent(in) :: evt
        type(string_t), intent(in) :: filename
        call lcio_event_to_file (evt%obj, char (filename) // c_null_char)
    end subroutine write_lcio_event

```

Finalize: use the LCIO destructor. Also nullify the pointer explicitly, to be on the safe side.

```

<LCIO interface: public>+≡
    public :: lcio_event_final

<LCIO interface: sub interfaces>+≡
    module subroutine lcio_event_final (evt, delete)
        type(lcio_event_t), intent(inout) :: evt
        logical, intent(in) :: delete
    end subroutine lcio_event_final

```

```

<LCIO interface: procedures>+≡
  module subroutine lcio_event_final (evt, delete)
    type(lcio_event_t), intent(inout) :: evt
    logical, intent(in) :: delete
    if (c_associated (evt%obj)) then
      if (delete) call lcio_event_delete (evt%obj)
      evt%obj = c_null_ptr
      evt%lccoll%obj = c_null_ptr
    end if
  end subroutine lcio_event_final

```

Nullify: do not call the destructor, just nullify the C pointer. There should be another pointer associated with the object.

```

<LCIO interface: public>+≡
  public :: lcio_event_nullify

<LCIO interface: sub interfaces>+≡
  module subroutine lcio_event_nullify (evt)
    type(lcio_event_t), intent(inout) :: evt

```

18.13.5 Polarization

For polarization there is a three-component float entry foreseen in the LCIO format. Completely generic density matrices can in principle be attached to events as float vectors added to `LCCollection` of the `LCEvent`. This is not yet implemented currently. Here, we restrict ourselves to the same implementation as in HepMC format: we use two entries as the polarization angles, while the first entry gives the degree of polarization (something not specified in the HepMC

format). For massive vector bosons, we arbitrarily choose the convention that the longitudinal (zero) helicity state is mapped to the theta angle $\pi/2$. This works under the condition that helicity is projected onto one of the basis states.

```

```

18.13.7 LCIO Reader type

There is a specific LCIO Reader type for handling the input of LCEventImpl objects (i.e., Monte Carlo event samples) from file. Opening the file is done by the constructor, closing by the destructor.

```

<LCIO interface: public>+≡
  public :: lcio_reader_t

<LCIO interface: types>+≡
  type :: lcio_reader_t
  private
  type(c_ptr) :: obj
end type lcio_reader_t

```

Constructor for an output associated to a file.

```

<LCIO interface: interfaces>+≡
  interface
    type(c_ptr) function open_lcio_reader (filename) bind(C)
      import
      character(c_char), dimension(*), intent(in) :: filename
    end function open_lcio_reader
  end interface

```

```

<LCIO interface: public>+≡
    public :: lcio_open_file

<LCIO interface: sub interfaces>+≡
    module subroutine lcio_open_file (lcio_reader, filename)
        type(lcio_reader_t), intent(out) :: lcio_reader
        type(string_t), intent(in) :: filename
    end subroutine lcio_open_file

<LCIO interface: procedures>+≡
    module subroutine lcio_open_file (lcio_reader, filename)
        type(lcio_reader_t), intent(out) :: lcio_reader
        type(string_t), intent(in) :: filename
        lcio_reader%obj = open_lcio_reader (char (filename) // c_null_char)
    end subroutine lcio_open_file

```

Destructor:

```

<LCIO interface: interfaces>+≡
    interface
        subroutine lcio_reader_delete (io_obj) bind(C)
            import
            type(c_ptr), value :: io_obj
        end subroutine lcio_reader_delete
    end interface

<LCIO interface: public>+≡
    public :: lcio_reader_close

<LCIO interface: sub interfaces>+≡
    module subroutine lcio_reader_close (lcioreader)
        type(lcio_reader_t), intent(inout) :: lcioreader
    end subroutine lcio_reader_close

<LCIO interface: procedures>+≡
    module subroutine lcio_reader_close (lcioreader)
        type(lcio_reader_t), intent(inout) :: lcioreader
        call lcio_reader_delete (lcioreader%obj)
    end subroutine lcio_reader_close

```

Read a single event from the event file. Return true if successful.

```

<LCIO interface: interfaces>+≡
    interface
        type(c_ptr) function read_lcio_event (io_obj) bind(C)
            import
            type(c_ptr), value :: io_obj
        end function read_lcio_event
    end interface

<LCIO interface: public>+≡
    public :: lcio_read_event

<LCIO interface: sub interfaces>+≡
    module subroutine lcio_read_event (lcrdr, evt, ok)
        type(lcio_reader_t), intent(inout) :: lcrdr
        type(lcio_event_t), intent(out) :: evt
        logical, intent(out) :: ok
    end subroutine lcio_read_event

```

```

<LCIO interface: procedures>+≡
  module subroutine lcio_read_event (lcrdr, evt, ok)
    type(lcio_reader_t), intent(inout) :: lcrdr

18.14 HEP Common and Events

This is a separate module that manages data exchange between the common blocks and `event_t` objects. We separate this from the previous module in order to avoid a circular module dependency. It also contains the functions necessary

for communication between `hepmc_event_t` and `event_t` or `lcio_event_t` and `event_t` as well as `particle_set_t` and `particle_t` objects.

            end if
            if (event%weight_prc_is_known ()) then
                call hepeup_set_event_parameters (weight = event%get_weight_prc ())
            end if
        else
            call msg_bug ("HEPEUP: event incomplete")
        end if
    end subroutine hepeup_from_event

```

Reverse.

Note: The current implementation sets the particle set of the hard process and is therefore not useful if the event on file is dressed. This should be reconsidered.

Note: setting of scale or alpha is not yet supported by the `event_t` object. Ticket #628.

HepMC format

The master output function fills a HepMC GenEvent object that is already initialized, but has no vertices in it.

We first set up the vertex lists and enter the vertices into the HepMC event. Then, we assign first all incoming particles and then all outgoing particles to their associated vertices. Particles which have neither parent nor children entries (this should not happen) are dropped.

Finally, we insert the beam particles. If there are none, use the incoming particles instead. Transform a particle into a `hepmc_particle` object, including color and polarization. The HepMC status is equivalent to the HEPEVT status, in particular: 0 = null entry, 1 = physical particle, 2 = decayed/fragmented SM hadron, tau or muon, 3 = other unphysical particle entry, 4 = incoming particles, 11 = intermediate resonance such as squarks. The use of 11 for intermediate resonances is as done by HERWIG, see <http://herwig.hepforge.org/trac/wiki/FaQs>.

```

Initialize a particle from a HepMC particle object. The model is necessary for making a fully qualified flavor component. We have the additional flag `polarized` which tells whether the polarization information should be interpreted or ignored, and the lookup array of barcodes. Note that the lookup array is searched linearly, a possible bottleneck for large particle arrays. If necessary, the barcode array could be replaced by a hash table.

If a particle set is initialized from a HepMC event record, we have to specify the treatment of polarization (unpolarized or density matrix) which is common to all particles. Correlated polarization information is not available.

There is some complication in reconstructing incoming particles and beam remnants. First of all, they all will be tagged as virtual. We then define an incoming particle as

```

LCIO event format

The master output function fills a LCIO event object that is already initialized, but has no particles in it.

In contrast to HepMC in LCIO there are no vertices (except for tracker and other detector specifications). So we assign first all incoming particles and then all outgoing particles to LCIO particle types. Particles which have neither parent nor children entries (this should not happen) are dropped. Finally, we insert the beam particles. If there are none, use the incoming particles instead.

Transform a particle into a `lcio_particle` object, including color and polarization. The LCIO status is equivalent to the HepMC status, in particular: 0 = null entry, 1 = physical particle, 2 = decayed/fragmented SM hadron, tau or muon, 3 = other unphysical particle entry, 4 = incoming particles, 11 = intermediate resonance such as squarks. The use of 11 for intermediate resonances is as done by HERWIG, see <http://herwig.hepforge.org/trac/wiki/FaQs>.

A beam-remnant particle (e.g., ISR photon) that has no children is tagged as outgoing, otherwise unphysical.

Input an event. Upon input of `i_prc`, we can just read in the whole HEPEUP common block. These data are known to come first. The `i_prc` value can be deduced from the IDPRUP value by a table lookup.

Reading the common block bypasses the `cstream` which accesses the input unit. This is consistent with the LHEF specification. After the common-block data have been swallowed, we can resume reading from stream.

We don't catch actual I/O errors. However, we return a negative value in `iostat` if we reached the terminating `</LesHouchesEvents>` tag.

Since we have already read the event information from file, this input routine can transfer the common-block contents to the event record. Also, we read any further information in the event record.

Since LHEF does not give this information, we must assume that the MCI group, term, and channel can all be safely set to 1. This works if there is only one MCI group and term. The channel doesn't matter for the matrix element.

The event index is incremented, as if the event was generated. The LHEF format does not support event indices.

18.15.5 Version-Specific Code: 1.0

In version 1.0, the init tag contains just HEPUP data. While a `cstream` is connected to the input unit, we bypass it temporarily for the purpose of reading the HEPUP contents. This is consistent with the LHEF standard.

This routine does not read the closing tag of the init block.

```

<EIO LHEF: eio lhef: TBP>+≡

        cross_section = data%cross_section(i), &
        error = data%error(i), &
        is_width = is_width)
    end do
  end subroutine eio_lhef_read_init_10

```

18.15.6 Version-Specific Code: 2.0

This is the init information for the 2.0 format, after the HEPRUP data. We have the following tags:

- **generator** Generator name and version.
- **xsecinfo** Cross section and weights data. We have the total cross section and number of events (assuming that the event file is intact), but

information on minimum and maximum weights is not available before the file is complete. We just write the mandatory tags. (Note that the default values of the other tags describe a uniform unit weight, but we can determine most values only after the sample is complete.)

- **cutsinfo** This optional tag is too specific to represent the possibilities of WHIZARD, so we skip it.
- **procinfo** This optional tag is useful for giving details of NLO calculations. Skipped.
- **mergetype** Optional, also not applicable.

```

<EIO LHEF: eio_lhef: TBP>+≡
  procedure :: write_init_20 => eio_lhef_write_init_20

<EIO LHEF: sub interfaces>+≡
  module subroutine eio_lhef_write_init_20 (eio, data)

18.15.7 Version-Specific Code: 3.0

This is the init information for the 3.0 format, after the HEPUP data. We have the following tags:

- **generator** Generator name and version.
- **xsecinfo** Cross section and weights data. We have the total cross section and number of events (assuming that the event file is intact), but information on minimum and maximum weights is not available before the file is complete. We just write the mandatory tags. (Note that the default values of the other tags describe a uniform unit weight, but we can determine most values only after the sample is complete.)
- **cutsinfo** This optional tag is too specific to represent the possibilities of WHIZARD, so we skip it.
- **procinfo** This optional tag is useful for giving details of NLO calculations. Skipped.
- **weightinfo** Determine the meaning of optional weights, whose values are given in the event record.

```

<EIO LHEF: eio_lhef: TBP>+≡
    procedure :: write_init_30 => eio_lhef_write_init_30
<EIO LHEF: sub interfaces>+≡
    module subroutine eio_lhef_write_init_30 (eio, data)

This is additional event-specific information for the 3.0 format, after the HEP-EUP data. We can specify weights, starting from the master weight and adding alternative weights. The weight tags are already allocated, so we just have to transfer the weight values to strings, assemble them and write them to file. All weights are collected in a single tag.

Note: If efficiency turns out to be an issue, we may revert to traditional character buffer writing. However, we need to know the maximum length.

```

<EIO LHEF: eio_lhef: TBP>+≡

Version 3.0 Output

Version 3.0 is an update which removes some tags (which we didn't use anyway) and suggests a new treatment of weights.

```

18.16 STDHEP File Formats

Here, we implement the two existing STDHEP file formats, one based on the HEPRUP/HEPEUP common blocks, the other based on the HEPEVT common

block. The second one is actually the standard STDHEP format.

```

<eio_stdhep.f90>≡
  <File header>

  module eio_stdhep

    use kinds, only: i32, i64
  <Use strings>
    use event_base
    use event_handles, only: event_handle_t
    use eio_data
    use eio_base

  <Standard module head>

  <EIO stdhep: public>

  <EIO stdhep: types>

    interface
  <EIO stdhep: sub interfaces>
    end interface

  end module eio_stdhep
<eio_stdhep_sub.f90>≡
  <File header>

  submodule (eio_stdhep) eio_stdhep_s

    use io_units
    use string_utils
    use diagnostics
    use hep_common
    use hep_events

    implicit none

  <EIO stdhep: variables>

  contains

  <EIO stdhep: procedures>

  end submodule eio_stdhep_s

```

18.16.1 Type

```

<EIO stdhep: public>≡
  public :: eio_stdhep_t

<EIO stdhep: types>≡
  type, abstract, extends (eio_t) :: eio_stdhep_t
    logical :: writing = .false.

```

```

        logical :: reading = .false.
        integer :: unit = 0
        logical :: keep_beams = .false.
        logical :: keep_remnants = .true.
        logical :: ensure_order = .false.
        logical :: recover_beams = .false.
        logical :: use_alphas_from_file = .false.
        logical :: use_scale_from_file = .false.

18.17.1 Type

A type `hepmc_event` is introduced as container to store HepMC event data, particularly for splitting the reading into read out of the process index and the proper event data.

Note: the `keep_beams` flag is not supported. Beams will always be written. Tools like `Rivet` can use the cross section information of a HepMC file for scaling plots. As there is no header in HepMC and this is written for every event, we make it optional with `output_cross_section`.

```
(EIO HepMC: public)≡
    public :: eio_hepmc_t

```

18.18 LCIO Output

The LCIO event record is standardized for the use with Linear e^+e^- colliders. It is a binary event format. We try our best at using it for both input and output.

```
<eio_lcio.f90>≡  
  <File header>  
  
  module eio_lcio  
  
    <Use kinds>  
    <Use strings>  
    use event_base  
    use event_handles, only: event_handle_t  
    use eio_data  
    use eio_base  
    use lcio_interface  
  
    <Standard module head>  
  
    <EIO LCIO: public>  
  
    <EIO LCIO: types>  
  
    interface  
    <EIO LCIO: sub interfaces>  
    end interface  
  
  end module eio_lcio  
  
<eio_lcio_sub.f90>≡  
  <File header>  
  
  submodule (eio_lcio) eio_lcio_s  
  
    use io_units  
    use string_utils  
    use diagnostics  
    use particles  
    use hep_events  
  
    implicit none  
  
    contains  
  
    <EIO LCIO: procedures>  
  
  end submodule eio_lcio_s
```

18.18.1 Type

A type `lcio_event` is introduced as container to store LCIO event data, particularly for splitting the reading into read out of the process index and the proper

event data.

Note: the `keep_beams` flag is not supported.

```
<EIO LCIO: public>≡
  public :: eio_lcio_t

<EIO LCIO: types>≡
  type, extends (eio_t) :: eio_lcio_t
    logical :: writing = .false.
    logical :: reading = .false.
    type(event_sample_data_t) :: data
    logical :: recover_beams = .false.
    logical :: use_alphas_from_file = .false.
    logical :: use_scale_from_file = .false.
    logical :: proc_as_run_id = .true.
    integer :: n_alt = 0
    integer :: lcio_run_id = 0
    type(lcio_writer_t) :: lcio_writer
    type(lcio_reader_t) :: lcio_reader
    type(lcio_run_header_t) :: lcio_run_hdr
    type(lcio_event_t) :: lcio_event
    integer, dimension(:), allocatable :: proc_num_id
  contains
    <EIO LCIO: eio lcio: TBP>
  end type eio_lcio_t
```

18.18.2 Specific Methods

Set parameters that are specifically used with LCIO.

```
<EIO LCIO: eio lcio: TBP>≡
  procedure :: set_parameters => eio_lcio_set_parameters

<EIO LCIO: sub interfaces>≡
  module subroutine eio_lcio_set_parameters &

Chapter 19

Phase Space

The abstract representation of a type that parameterizes phase space, with methods for construction and evaluation.

phs_base Abstract phase-space representation.

A simple implementation:

phs_none This implements a non-functional dummy module for the phase space. A process which uses this module cannot be integrated. The purpose of this module is to provide a placeholder for processes which do not require phase-space evaluation. They may still allow for evaluating matrix elements.

phs_single Parameterize the phase space of a single particle, i.e., the solid angle. This is useful only for very restricted problems, but it avoids the complexity of a generic approach in those trivial cases.

The standard implementation is called *wood* phase space. It consists of several auxiliary modules and the actual implementation module.

mappings Generate invariant masses and decay angles from given random numbers (or the inverse operation). Each mapping pertains to a particular node in a phase-space tree. Different mappings account for uniform distributions, resonances, zero-mass behavior, and so on.

phs_trees Phase space parameterizations for scattering processes are defined recursively as if there was an initial particle decaying. This module sets up a representation in terms of abstract trees, where each node gets a unique binary number. Each tree is stored as an array of branches, where integers indicate the connections. This emulates pointers in a transparent way. Real pointers would also be possible, but seem to be less efficient for this particular case.

phs_forests The type defined by this module collects the decay trees corresponding to a given process and the applicable mappings. To set this up, a file is read which is either written by the user or by the **cascades** module functions. The module also contains the routines that evaluate phase space, i.e., generate momenta from random numbers and back.

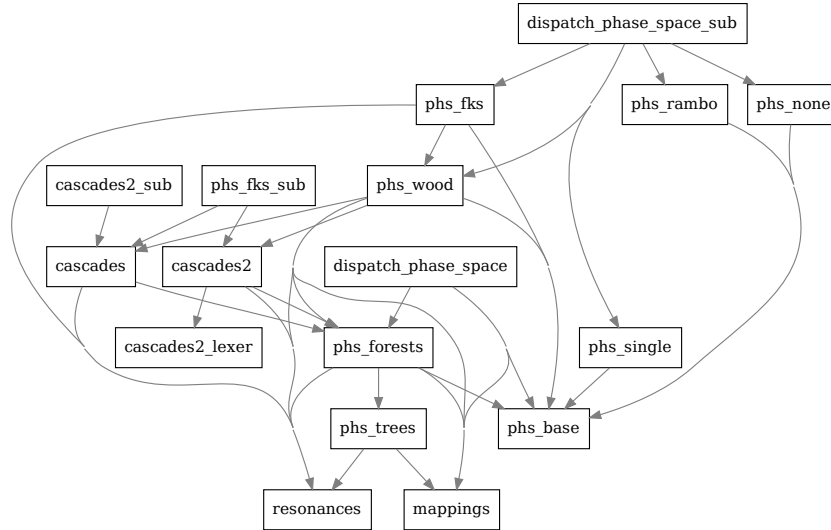

Figure 19.1: Module dependencies in `src/phase_space`.

cascades This module is a pseudo Feynman diagram generator with the particular purpose of finding the phase space parameterizations best suited for a given process. It uses a model file to set up the possible vertices, generates all possible diagrams, identifies resonances and singularities, and simplifies the list by merging equivalent diagrams and dropping irrelevant ones. This process can be controlled at several points by user-defined parameters. Note that it depends on the particular values of particle masses, so it cannot be done before reading the input file.

phs_wood Make the functionality available in form of an implementation of the abstract phase-space type.

phs_fks Phase-space parameterization with modifications for the FKS scheme.

19.1 Abstract phase-space module

In this module we define an abstract base type (and a trivial test implementation) for multi-channel phase-space parameterizations.

```

  <PHS base: procedures>
```

```
end submodule phs_base_s
```

19.1.1 Phase-space channels

The kinematics configuration may generate multiple parameterizations of phase space. Some of those have specific properties, such as a resonance in the s channel.

Channel properties

This is the abstract type for the channel properties. We need them as a data transfer container, so everything is public and transparent.

```
⟨PHS base: public⟩≡
  public :: channel_prop_t

⟨PHS base: types⟩≡
  type, abstract :: channel_prop_t
  contains
    procedure (channel_prop_to_string), deferred :: to_string
    generic :: operator (==) => is_equal
    procedure (channel_eq), deferred :: is_equal
  end type channel_prop_t

⟨PHS base: interfaces⟩≡
  abstract interface
    function channel_prop_to_string (object) result (string)
      import
      class(channel_prop_t), intent(in) :: object
      type(string_t) :: string
    end function channel_prop_to_string
  end interface

⟨PHS base: interfaces⟩+≡
  abstract interface
    function channel_eq (prop1, prop2) result (flag)
      import
      class(channel_prop_t), intent(in) :: prop1, prop2
      logical :: flag
    end function channel_eq
  end interface
```

Here is a resonance as a channel property. Mass and width are stored here in physical units.

```
⟨PHS base: public⟩+≡
  public :: resonance_t

⟨PHS base: types⟩+≡
  type, extends (channel_prop_t) :: resonance_t
    real(default) :: mass = 0
    real(default) :: width = 0
  contains
```

```

    procedure :: to_string => resonance_to_string
    procedure :: is_equal => resonance_is_equal
end type resonance_t

```

Print mass and width.

```

<PHS base: sub interfaces>≡
    module function resonance_to_string (object) result (string)
        class(resonance_t), intent(in) :: object
        type(string_t) :: string
    end function resonance_to_string

<PHS base: procedures>≡
    module function resonance_to_string (object) result (string)
        class(resonance_t), intent(in) :: object
        type(string_t) :: string
        character(32) :: buffer
        string = "resonant: m ="
        write (buffer, "(" // FMT_19 // ")") object%mass
        string = string // trim (buffer) // " GeV, w ="
        write (buffer, "(" // FMT_19 // ")") object%width
        string = string // trim (buffer) // " GeV"
    end function resonance_to_string

```

Equality.

```

<PHS base: sub interfaces>+≡
    module function resonance_is_equal (prop1, prop2) result (flag)
        class(resonance_t), intent(in) :: prop1
        class(channel_prop_t), intent(in) :: prop2
        logical :: flag
    end function resonance_is_equal

<PHS base: procedures>+≡
    module function resonance_is_equal (prop1, prop2) result (flag)
        class(resonance_t), intent(in) :: prop1
        class(channel_prop_t), intent(in) :: prop2
        logical :: flag
        select type (prop2)
            type is (resonance_t)
                flag = prop1%mass == prop2%mass .and. prop1%width == prop2%width
            class default
                flag = .false.
        end select
    end function resonance_is_equal

```

This is the limiting case of a resonance, namely an on-shell particle. We just store the mass in physical units.

```

<PHS base: public>+≡
    public :: on_shell_t

<PHS base: types>+≡
    type, extends (channel_prop_t) :: on_shell_t
        real(default) :: mass = 0
    contains

```

```

    procedure :: to_string => on_shell_to_string
    procedure :: is_equal => on_shell_is_equal
end type on_shell_t

```

Print mass and width.

```

<PHS base: sub interfaces>+≡
    module function on_shell_to_string (object) result (string)
        class(on_shell_t), intent(in) :: object
        type(string_t) :: string
    end function on_shell_to_string

<PHS base: procedures>+≡
    module function on_shell_to_string (object) result (string)
        class(on_shell_t), intent(in) :: object
        type(string_t) :: string
        character(32) :: buffer
        string = "on shell: m ="
        write (buffer, "(" // FMT_19 // ")") object%mass
        string = string // trim (buffer) // " GeV"
    end function on_shell_to_string

```

Equality.

```

<PHS base: sub interfaces>+≡
    module function on_shell_is_equal (prop1, prop2) result (flag)
        class(on_shell_t), intent(in) :: prop1
        class(channel_prop_t), intent(in) :: prop2
        logical :: flag
    end function on_shell_is_equal

<PHS base: procedures>+≡
    module function on_shell_is_equal (prop1, prop2) result (flag)
        class(on_shell_t), intent(in) :: prop1
        class(channel_prop_t), intent(in) :: prop2
        logical :: flag
        select type (prop2)
        type is (on_shell_t)
            flag = prop1%mass == prop2%mass
        class default
            flag = .false.
        end select
    end function on_shell_is_equal

```

Channel equivalences

This type describes an equivalence. The current channel is equivalent to channel `c`. The equivalence involves a permutation `perm` of integration dimensions and, within each integration dimension, a mapping `mode`.

```

<PHS base: types>+≡
    type :: phs_equivalence_t
        integer :: c = 0
        integer, dimension(:), allocatable :: perm
        integer, dimension(:), allocatable :: mode

```

```

contains
  <PHS base: phs equivalence: TBP>
end type phs_equivalence_t

```

The mapping modes are

```

<PHS base: types>+≡
  integer, parameter, public :: &
    EQ_IDENTITY = 0, EQ_INVERT = 1, EQ_SYMMETRIC = 2, EQ_INVARIANT = 3

```

In particular, if a channel is equivalent to itself in the EQ_SYMMETRIC mode, the integrand can be assumed to be symmetric w.r.t. a reflection $x \rightarrow 1 - x$ of the corresponding integration variable.

These are the associated tags, for output:

```

<PHS base: types>+≡
  character, dimension(0:3), parameter :: TAG = ["+", "-", ":", "x"]

```

Write an equivalence.

```

<PHS base: phs equivalence: TBP>≡
  procedure :: write => phs_equivalence_write

<PHS base: sub interfaces>+≡
  module subroutine phs_equivalence_write (object, unit)
    class(phs_equivalence_t), intent(in) :: object
    integer, intent(in), optional :: unit
  end subroutine phs_equivalence_write

<PHS base: procedures>+≡
  module subroutine phs_equivalence_write (object, unit)
    class(phs_equivalence_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, j
    u = given_output_unit (unit)
    write (u, "(5x,'= ',1x,I0,1x)", advance = "no") object%c
    if (allocated (object%perm)) then
      write (u, "(A)", advance = "no") "("
      do j = 1, size (object%perm)

Channel objects

The channel entry holds (optionally) specific properties.

`sf_channel` is the structure-function channel that corresponds to this phase-space channel. The structure-function channel may be set up with a specific mapping that depends on the phase-space channel properties. (The default setting is to leave the properties empty.)

```

<PHS base: public>+≡
    public :: phs_channel_t

<PHS base: types>+≡
    type :: phs_channel_t
        class(channel_prop_t), allocatable :: prop

19.1.3 Kinematics configuration

Here, we store the universal information that is specifically relevant for phase-space generation. It is a subset of the process data, supplemented by basic information on phase-space parameterization channels.

A concrete implementation will contain more data, that describe the phase space in detail.

MD5 sums: the phase space setup depends on the process, it depends on the model parameters (the masses, that is), and on the configuration parameters. (It does not depend on the QCD setup.)

```

<PHS base: public>+≡
    public :: phs_config_t

```

Set incoming momenta. Assume that array shapes match. If requested, compute the Lorentz transformation from the c.m. to the lab frame and apply that transformation to the incoming momenta.

In the c.m. frame, the sum of three-momenta is zero. In a scattering process, the z axis is the direction of the first beam, the second beam is along the negative z axis. The transformation from the c.m. to the lab frame is a rotation from the z axis to the boost axis followed by a boost, such that the c.m. momenta are transformed into the lab-frame momenta. In a decay process, we just boost along the flight direction, without rotation.

    real(default) :: f
    f = phs%flux * phs%volume
  end function phs_get_overall_factor

```

Compute flux factor. We do this during initialization (when the incoming momenta \mathbf{p} are undefined), unless `sqrts` is variable. We do this again once for each phase-space point, but then we skip the calculation if `sqrts` is fixed.

There are three different flux factors.

1. For a decaying massive particle, the factor is

$$f = (2\pi)^4/(2M) \quad (19.1)$$

2. For a $2 \rightarrow n$ scattering process with $n > 1$, the factor is

$$f = (2\pi)^4/(2\sqrt{\lambda}) \quad (19.2)$$

where for massless incoming particles, $\sqrt{\lambda} = s$.

3. For a $2 \rightarrow 1$ on-shell production process, the factor includes an extra $1/(2\pi)^3$ factor and a $1/m^2$ factor from the phase-space delta function $\delta(x_1x_2 - m^2/s)$, which originate from the one-particle phase space that we integrate out.

$$f = 2\pi/(2sm^2) \quad (19.3)$$

The delta function is handled by the structure-function parameterization.

    sqrts = phs%config%sqrts
  end function phs_get_sqrts

```

Uniform angular distribution

These procedures implement the uniform angular distribution, generated from two parameters x_1 and x_2 :

$$\cos \theta = 1 - 2x_1, \quad \phi = 2\pi x_2 \quad (19.4)$$

We generate a rotation (Lorentz transformation) which rotates the positive z axis into this point on the unit sphere. This rotation is applied to the \mathbf{p} momenta, which are assumed to be back-to-back, on-shell, and with the correct mass.

We do not compute a Jacobian (constant). The uniform distribution is assumed to be normalized.

```

<PHS base: public>+≡
  public :: compute_kinematics_solid_angle

<PHS base: sub interfaces>+≡
  module subroutine compute_kinematics_solid_angle (p, q, x)
    type(vector4_t), dimension(2), intent(in) :: p
    type(vector4_t), dimension(2), intent(out) :: q
    real(default), dimension(2), intent(in) :: x
  end subroutine compute_kinematics_solid_angle

<PHS base: procedures>+≡
  module subroutine compute_kinematics_solid_angle (p, q, x)
    type(vector4_t), dimension(2), intent(in) :: p
    type(vector4_t), dimension(2), intent(out) :: q
    real(default), dimension(2), intent(in) :: x
    real(default) :: ct, st, phi
    type(lorentz_transformation_t) :: rot
    integer :: i

```

```

ct = 1 - 2*x(1)
st = sqrt (1 - ct**2)
phi = twopi * x(2)
rot = rotation (phi, 3) * rotation (ct, st, 2)
do i = 1, 2
    q(i) = rot * p(i)
end do
end subroutine compute_kinematics_solid_angle

```

This is the inverse transformation. We assume that the outgoing momenta are rotated versions of the incoming momenta, back-to-back. Thus, we determine the angles from $q(1)$ alone. p is unused.

```

```

Test kinematics implementation

This implementation of kinematics generates a simple two-particle configuration from the incoming momenta. The incoming momenta must be in the c.m. system, all masses equal.

There are two channels: one generates $\cos\theta$ and ϕ uniformly, in the other channel we map the r_1 parameter which belongs to $\cos\theta$.

We should store the mass parameter that we need.

```

(PHS base: public test auxiliary)+≡
  public :: phs_test_t

    write (u, "(A)")  "* Test output end: phs_none_1"

  end subroutine phs_none_1
```

19.3 Single-particle phase space

This module implements the phase space for a single particle, i.e., the solid angle, in a straightforward parameterization with a single channel. The phase-space implementation may be used either for $1 \rightarrow 2$ decays or for $2 \rightarrow 2$ scattering processes, so the number of incoming particles is the only free parameter in the configuration. In the latter case, we should restrict its use to non-resonant s-channel processes, because there is no mapping of the scattering angle.

(We might extend this later to account for generic $2 \rightarrow 2$ situations, e.g., account for a Coulomb singularity or detect an s-channel resonance structure that requires matching structure-function mappings.)

This is derived from the `phs_test` implementation in the `phs_base` module above, even more simplified, but intended for actual use.

```
<phs_single.f90>≡  
  <File header>  
  
  module phs_single  
  
    <Use kinds>  
    <Use strings>  
    use lorentz  
    use phs_base

    class(phs_single_t), intent(inout) :: object
  end subroutine phs_single_final

```

Initialization. We allocate arrays (`base_init`) and adjust the phase-space volume. The massless two-particle phase space volume is

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.55294034614 \times 10^{-5} \quad (19.5)$$

For a decay with nonvanishing masses (m_3, m_4), there is a correction factor

$$\Phi_2(m)/\Phi_2(0) = \frac{1}{\hat{s}} \lambda^{1/2}(\hat{s}, m_3^2, m_4^2). \quad (19.6)$$

For a scattering process with nonvanishing masses, the correction factor is

$$\Phi_2(m)/\Phi_2(0) = \frac{1}{\hat{s}^2} \lambda^{1/2}(\hat{s}, m_1^2, m_2^2) \lambda^{1/2}(\hat{s}, m_3^2, m_4^2). \quad (19.7)$$

If the energy is fixed, this is constant. Otherwise, we have to account for varying \hat{s} .

```

<PHS single: phs single: TBP>+≡
  procedure :: init => phs_single_init
<PHS single: sub interfaces>+≡
  module subroutine phs_single_init (phs, phs_config)

19.4 Flat RAMBO phase space

This module implements the flat **RAMBO** phase space for massless and massive particles using the minimal d.o.f $3n - 4$ in a straightforward parameterization with a single channel. We generate n mass systems M_i with $M_0 = \sqrt{s}$ and $M_n = 0$. We let each mass system decay $1 \rightarrow 2$ in a four-momentum conserving way. The four-momenta of the two particles are generated back-to-back where we map the d.o.f. to energy, azimuthal and polar angle. The particle momenta are then boosted to CMS by an appropriate boost using the kinematics of the parent mass system.

19.5 Resonance Handler

For various purposes (e.g., shower histories), we should extract the set of resonances and resonant channels from a phase-space tree set. A few methods do kinematics calculations specifically for those resonance data.

```
<resonances.f90>≡  
  <File header>  
  
  module resonances  
  
    <Use kinds>  
    <Use strings>

  do i = 1, res_hist%n_resonances
    call res_hist%resonances(i)%evaluate_distance (p, dist(i))
  end do
end subroutine resonance_history_evaluate_distances

```

Use the distance to determine a Gaussian turnoff factor for a resonance. The factor is given by a Gaussian function e^{-d^2/σ^2} , where σ is the gw parameter multiplied by the resonance width, and d is the distance (see above). So, for $d = \sigma$, the factor is 0.37, and for $d = 2\sigma$ we get 0.018.

If the gw factor is less or equal to zero, return 1.

      child(nr+1:nr+no) = branch%o_child + offset_o
    end associate
  end function resonance_tree_get_children

```

Transform a resonance history into a resonance tree. Algorithm:

1. Determine a mapping of the resonance array, such that in the new array the resonances are ordered by decreasing number of contributors.
2. Copy the flavor entries to the mapped array.
3. Scan all resonances and, for each one, find a resonance that is its parent. Since the resonances are ordered, later matches overwrite earlier ones. The last match is the correct one. Then scan again and, for each resonance,

collect the resonances that have it as parent. This is the set of child resonances.

4. Analogously, scan all outgoing particles that appear in any of the contributors list. Determine their immediate parent as above, and set the child outgoing parents for the resonances, as above.

19.5.7 Resonance history set

This is an array of resonance histories. The elements are supposed to be unique. That is, entering a new element is successful only if the element does not already exist.

The current implementation uses a straightforward linear search for comparison. If this should become an issue, we may change the implementation to a hash table. To keep this freedom, the set should be an opaque object. In fact, we expect to use it as a transient data structure. Once the set is complete, we transform it into a contiguous array.

```

<Resonances: public>+≡
    public :: resonance_history_set_t

end subroutine resonance_history_set_freeze

```

Determine the histories (in form of their indices in the array) that can be considered on-shell, given a set of momenta and a maximum distance. The distance from the resonance is measured in multiples of the resonance width.

Note that the momentum array must only contain the outgoing particles.

If a particular history is on-shell, but there is another history which contains this and also is on-shell, only the latter is retained.

<Resonances: resonance history set: TBP>+≡

19.6 Mappings

Mappings are objects that encode the transformation of the interval $(0,1)$ to a physical variable m^2 or $\cos\theta$ (and back), as it is used in the phase space parameterization. The mapping objects contain fixed parameters, the associated methods implement the mapping and inverse mapping operations, including the computation of the Jacobian (phase space factor).

```
<mappings.f90>≡
  <File header>

  module mappings

    <Use kinds>
    use kinds, only: TC
    <Use strings>
    use model_data
    use flavors

```

19.6.2 The Mapping type

Each mapping has a type (e.g., s-channel, infrared), a binary code (redundant, but useful for debugging), and a reference particle. The flavor code of this particle is stored for bookkeeping reasons, what matters are the mass and width of this particle. Furthermore, depending on the type, various mapping parameters can be set and used.

The parameters **a1** to **a3** (for m^2 mappings) and **b1** to **b3** (for $\cos\theta$ mappings) are values that are stored once to speed up the calculation, if **variable_limits** is false. The exact meaning of these parameters depends on the mapping type. The limits are fixed if there is a fixed c.m. energy.

```

```

19.6.7 Mappings of the invariant mass

Inserting an x value between 0 and 1, we want to compute the corresponding invariant mass $m^2(x)$ and the jacobian, aka phase space factor $f(x)$. We also need the reverse operation.

In general, the phase space factor f is defined by

$$\frac{1}{s} \int_{m_{\min}^2}^{m_{\max}^2} dm^2 g(m^2) = \int_0^1 dx \frac{1}{s} \frac{dm^2}{dx} g(m^2(x)) = \int_0^1 dx f(x) g(x), \quad (19.8)$$

where thus

$$f(x) = \frac{1}{s} \frac{dm^2}{dx}. \quad (19.9)$$

With this mapping, a function of the form

$$g(m^2) = c \frac{dx(m^2)}{dm^2} \quad (19.10)$$

is mapped to a constant:

$$\frac{1}{s} \int_{m_{\min}^2}^{m_{\max}^2} dm^2 g(m^2) = \int_0^1 dx f(x) g(m^2(x)) = \int_0^1 dx \frac{c}{s}. \quad (19.11)$$

Here is the mapping routine. Input are the available energy squared s , the limits for m^2 , and the x value. Output are the m^2 value and the phase space factor f .

```

Trivial mapping

We simply map the boundaries of the interval (m_{\min}, m_{\max}) to $(0, 1)$:

$$m^2 = (1 - x)m_{\min}^2 + xm_{\max}^2; \quad (19.12)$$

the inverse is

$$x = \frac{m^2 - m_{\min}^2}{m_{\max}^2 - m_{\min}^2}. \quad (19.13)$$

Hence

$$f(x) = \frac{m_{\max}^2 - m_{\min}^2}{s}, \quad (19.14)$$

and we have, as required,

$$f(x) \frac{dx}{dm^2} = \frac{1}{s}. \quad (19.15)$$

We store the constant parameters the first time the mapping is called – or, if limits vary, recompute them each time.

```

<Constants for trivial msq mapping>≡
    if (map%variable_limits .or. map%a_unknown) then
        map%a1 = 0
        map%a2 = msq_max - msq_min
        map%a3 = map%a2 / s
        map%a_unknown = .false.
    end if

```

```

⟨Apply trivial msq mapping⟩≡
  msq = (1-x) * msq_min + x * msq_max
  f = map%a3
⟨Apply inverse trivial msq mapping⟩≡
  if (map%a2 /= 0) then
    x = (msq - msq_min) / map%a2
  else
    x = 0
  end if
  f = map%a3

```

Resonance or step mapping does not make much sense if the resonance mass is outside the kinematical bounds. If this is the case, revert to `NO_MAPPING`. This is possible even if the kinematical bounds vary from event to event.

```

⟨Modify mapping type if necessary⟩≡
  select case (type)
  case (S_CHANNEL, STEP_MAPPING_E, STEP_MAPPING_H)
    msq0 = map%mass**2
    if (msq0 < msq_min .or. msq0 > msq_max) type = NO_MAPPING
  end select

```

Breit-Wigner mapping

A Breit-Wigner resonance with mass M and width Γ is flattened by the following mapping:

This mapping does not make much sense if the resonance mass is too low. If this is the case, revert to `NO_MAPPING`. There is a tricky point with this if the mass is too high: `msq_max` is not a constant if structure functions are around. However, switching the type depending on the overall energy does not change the integral, it is just another branching point.

$$m^2 = M(M + t\Gamma), \quad (19.16)$$

where

$$t = \tan \left[(1-x) \arctan \frac{m_{\min}^2 - M^2}{M\Gamma} + x \arctan \frac{m_{\max}^2 - M^2}{M\Gamma} \right]. \quad (19.17)$$

The inverse:

$$x = \frac{\arctan \frac{m^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma}}{\arctan \frac{m_{\max}^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma}} \quad (19.18)$$

The phase-space factor of this transformation is

$$f(x) = \frac{M\Gamma}{s} \left(\arctan \frac{m_{\max}^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma} \right) (1 + t^2). \quad (19.19)$$

This maps any function proportional to

$$g(m^2) = \frac{M\Gamma}{(m^2 - M^2)^2 + M^2\Gamma^2} \quad (19.20)$$

to a constant times $1/s$.

  f = map%a3 * (1 + tmp**2)

```

Mapping for massless splittings

This mapping accounts for approximately scale-invariant behavior where $\ln M^2$ is evenly distributed.

$$m^2 = m_{\min}^2 + M^2 (\exp(xL) - 1) \quad (19.21)$$

where

$$L = \ln \left(\frac{m_{\max}^2 - m_{\min}^2}{M^2} + 1 \right). \quad (19.22)$$

The inverse:

$$x = \frac{1}{L} \ln \left(\frac{m^2 - m_{\min}^2}{M^2} + 1 \right) \quad (19.23)$$

The constant M is a characteristic scale. Above this scale ($m^2 - m_{\min}^2 \gg M^2$), this mapping behaves like $x \propto \ln m^2$, while below the scale it reverts to a linear mapping.

The phase-space factor is

$$f(x) = \frac{M^2}{s} \exp(xL) L. \quad (19.24)$$

A function proportional to

$$g(m^2) = \frac{1}{(m^2 - m_{\min}^2) + M^2} \quad (19.25)$$

is mapped to a constant, i.e., a simple pole near m_{\min} with a regulator mass M .

This type of mapping is useful for massless collinear and infrared singularities, where the scale is stored as the mass parameter. In the radiation case

(IR radiation off massive particle), the heavy particle width is the characteristic scale.

```

⟨Constants for s-channel pole mapping⟩≡

  f = map%a3 * msq1

```

Mapping for t-channel poles

This is also approximately scale-invariant, and we use the same type of mapping as before. However, we map $1/x$ singularities at both ends of the interval; again, the mapping becomes linear when the distance is less than M^2 :

$$m^2 = \begin{cases} m_{\min}^2 + M^2 (\exp(xL) - 1) & \text{for } 0 < x < \frac{1}{2} \\ m_{\max}^2 - M^2 (\exp((1-x)L) - 1) & \text{for } \frac{1}{2} \leq x < 1 \end{cases} \quad (19.26)$$

where

$$L = 2 \ln \left(\frac{m_{\max}^2 - m_{\min}^2}{2M^2} + 1 \right). \quad (19.27)$$

The inverse:

$$x = \begin{cases} \frac{1}{L} \ln \left(\frac{m^2 - m_{\min}^2}{M^2} + 1 \right) & \text{for } m^2 < (m_{\max}^2 - m_{\min}^2)/2 \\ 1 - \frac{1}{L} \ln \left(\frac{m_{\max}^2 - m^2}{M^2} + 1 \right) & \text{for } m^2 \geq (m_{\max}^2 - m_{\min}^2)/2 \end{cases} \quad (19.28)$$

The phase-space factor is

$$f(x) = \begin{cases} \frac{M^2}{s} \exp(xL) L. & \text{for } 0 < x < \frac{1}{2} \\ \frac{M^2}{s} \exp((1-x)L) L. & \text{for } \frac{1}{2} \leq x < 1 \end{cases} \quad (19.29)$$

A (continuous) function proportional to

$$g(m^2) = \begin{cases} 1/(m^2 - m_{\min}^2) + M^2 & \text{for } m^2 < (m_{\max}^2 - m_{\min}^2)/2 \\ 1/((m_{\max}^2 - m^2) + M^2) & \text{for } m^2 \geq (m_{\max}^2 - m_{\min}^2)/2 \end{cases} \quad (19.30)$$

is mapped to a constant by this mapping, i.e., poles near both ends of the interval.

```

  end if
  f = map%a3 * msq1

```

19.6.8 Step mapping

Step mapping is useful when the allowed range for a squared-mass variable is large, but only a fraction at the lower end is populated because the particle in question is an (off-shell) decay product of a narrow resonance. I.e., if the resonance was forced to be on-shell, the upper end of the range would be the resonance mass, minus the effective (real or resonance) mass of the particle(s) in the sibling branch of the decay.

The edge of this phase space section has a width which is determined by the width of the parent, plus the width of the sibling branch. (The widths might be added in quadrature, but this precision is probably not important.)

Fermi function

A possible mapping is derived from the Fermi function which has precisely this behavior. The Fermi function is given by

$$f(x) = \frac{1}{1 + \exp \frac{x-\mu}{\gamma}} \quad (19.31)$$

where x is taken as the invariant mass squared, μ is the invariant mass squared of the edge, and γ is the effective width which is given by the widths of the

parent and the sibling branch. (Widths might be added in quadrature, but we do not require this level of precision.)

$$x = \frac{m^2 - m_{\min}^2}{\Delta m^2} \quad (19.32)$$

$$\mu = \frac{m_{\max, \text{eff}}^2 - m_{\min}^2}{\Delta m^2} \quad (19.33)$$

$$\gamma = \frac{2m_{\max, \text{eff}}\Gamma}{\Delta m^2} \quad (19.34)$$

with

$$\Delta m^2 = m_{\max}^2 - m_{\min}^2 \quad (19.35)$$

m^2 is thus given by

$$m^2(x) = xm_{\max}^2 + (1-x)m_{\min}^2 \quad (19.36)$$

For the mapping, we compute the integral $g(x)$ of the Fermi function, normalized such that $g(0) = 0$ and $g(1) = 1$. We introduce the abbreviations

$$\alpha = 1 - \gamma \ln \frac{1 + \beta e^{1/\gamma}}{1 + \beta} \quad (19.37)$$

$$\beta = e^{-\mu/\gamma} \quad (19.38)$$

and obtain

$$g(x) = \frac{1}{\alpha} \left(x - \gamma \ln \frac{1 + \beta e^{x/\gamma}}{1 + \beta} \right) \quad (19.39)$$

The actual mapping is the inverse function $h(y) = g^{-1}(y)$,

$$h(y) = -\gamma \ln \left(e^{-\alpha y/\gamma} (1 + \beta) - \beta \right) \quad (19.40)$$

The Jacobian is

$$\frac{dh}{dy} = \alpha \left(1 - e^{\alpha y/\gamma} \frac{\beta}{1 + \beta} \right)^{-1} \quad (19.41)$$

which is equal to $1/(dg/dx)$, namely

$$\frac{dg}{dx} = \frac{1}{\alpha} \frac{1}{1 + \beta e^{x/\gamma}} \quad (19.42)$$

The final result is

$$\int_{m_{\min}^2}^{m_{\max}^2} dm^2 F(m^2) = \Delta m^2 \int_0^1 dx F(m^2(x)) \quad (19.43)$$

$$= \Delta m^2 \int_0^1 dy F(m^2(h(y))) \frac{dh}{dy} \quad (19.44)$$

Here is the implementation. We fill **a1**, **a2**, **a3** with α, β, γ , respectively.

```

    / map%a1
  f = map%a1 * tmp * (msq_max - msq_min) / s

```

Hyperbolic mapping

The Fermi function has the drawback that it decreases exponentially. It might be preferable to take a function with a power-law decrease, such that the high-mass region is not completely depopulated.

Here, we start with the actual mapping which we take as

$$h(y) = \frac{b}{a-y} - \frac{b}{a} + \mu y \quad (19.45)$$

with the abbreviation

$$a = \frac{1}{2} \left(1 + \sqrt{1 + \frac{4b}{1-\mu}} \right) \quad (19.46)$$

This is a hyperbola in the xy plane. The derivative is

$$\frac{dh}{dy} = \frac{b}{(a-y)^2} + \mu \quad (19.47)$$

The constants correspond to

$$\mu = \frac{m_{\text{max,eff}}^2 - m_{\text{min}}^2}{\Delta m^2} \quad (19.48)$$

$$b = \frac{1}{\mu} \left(\frac{2m_{\text{max,eff}}\Gamma}{\Delta m^2} \right)^2 \quad (19.49)$$

The inverse function is the solution of a quadratic equation,

$$g(x) = \frac{1}{2} \left[\left(a + \frac{x}{\mu} + \frac{b}{a\mu} \right) - \sqrt{\left(a - \frac{x}{\mu} \right)^2 + 2\frac{b}{a\mu} \left(a + \frac{x}{\mu} \right) + \left(\frac{b}{a\mu} \right)^2} \right] \quad (19.50)$$

The constants $a_{1,2,3}$ are identified with a, b, μ .

```

⟨Constants for hyperbolic step mapping⟩≡

  x = ((map%a1 + z / map%a3 + tmp) &
        - sqrt((map%a1 - z / map%a3)**2 + 2 * tmp * (map%a1 + z / map%a3) &
              + tmp**2)) / 2
  f = (map%a2 / (map%a1 - x)**2 + map%a3) * (msq_max - msq_min) / s

```

19.6.9 Mappings of the polar angle

The other type of singularity, a simple pole just outside the integration region, can occur in the integration over $\cos\theta$. This applies to exchange of massless (or light) particles.

Double poles (Coulomb scattering) are also possible, but only in certain cases. These are also handled by the single-pole mapping.

The mapping is analogous to the previous m^2 pole mapping, but with a different normalization and notation of variables:

$$\frac{1}{2} \int_{-1}^1 d\cos\theta g(\theta) = \int_0^1 dx \frac{d\cos\theta}{dx} g(\theta(x)) = \int_0^1 dx f(x) g(x), \quad (19.51)$$

where thus

$$f(x) = \frac{1}{2} \frac{d\cos\theta}{dx}. \quad (19.52)$$

With this mapping, a function of the form

$$g(\theta) = c \frac{dx(\cos\theta)}{d\cos\theta} \quad (19.53)$$

is mapped to a constant:

$$\int_{-1}^1 d\cos\theta g(\theta) = \int_0^1 dx f(x) g(\theta(x)) = \int_0^1 dx c. \quad (19.54)$$

```

Trivial mapping

This is just the mapping of the interval $(-1, 1)$ to $(0, 1)$:

$$\cos \theta = -1 + 2x \quad (19.55)$$

and

$$f(x) = 1 \quad (19.56)$$

with the inverse

$$x = \frac{1 + \cos \theta}{2} \quad (19.57)$$

```

⟨Apply trivial ct mapping⟩≡
    tmp = 2 * (1-x)
    ct = 1 - tmp
    st = sqrt (tmp * (2-tmp))
    f = 1

⟨Apply inverse trivial ct mapping⟩≡
    x = (ct + 1) / 2
    f = 1

```

Pole mapping

As above for m^2 , we simultaneously map poles at both ends of the $\cos \theta$ interval. The formulae are completely analogous:

$$\cos \theta = \begin{cases} \frac{M^2}{s} [\exp(xL) - 1] - 1 & \text{for } x < \frac{1}{2} \\ -\frac{M^2}{s} [\exp((1-x)L) - 1] + 1 & \text{for } x \geq \frac{1}{2} \end{cases} \quad (19.58)$$

where

$$L = 2 \ln \frac{M^2 + s}{M^2}. \quad (19.59)$$

Inverse:

$$x = \begin{cases} \frac{1}{2L} \ln \frac{1 + \cos \theta + M^2/s}{M^2/s} & \text{for } \cos \theta < 0 \\ 1 - \frac{1}{2L} \ln \frac{1 - \cos \theta + M^2/s}{M^2/s} & \text{for } \cos \theta \geq 0 \end{cases} \quad (19.60)$$

The phase-space factor:

$$f(x) = \begin{cases} \frac{M^2}{s} \exp(xL) L & \text{for } x < \frac{1}{2} \\ \frac{M^2}{s} \exp((1-x)L) L & \text{for } x \geq \frac{1}{2} \end{cases} \quad (19.61)$$

```

```

19.7 Phase-space trees

The phase space evaluation is organized in terms of trees, where each branch corresponds to three integrations: m^2 , $\cos\theta$, and ϕ . The complete tree thus makes up a specific parameterization of the multidimensional phase-space integral. For the multi-channel integration, the phase-space tree is a single channel.

The trees imply mappings of formal Feynman tree graphs into arrays of integer numbers: Each branch, corresponding to a particular line in the graph, is assigned an integer code c (with kind value $\text{TC} = \text{tree code}$).

In this integer, each bit determines whether a particular external momentum flows through the line. The external branches therefore have codes 1, 2, 4, 8, ... An internal branch has those bits ORed corresponding to the momenta flowing through it. For example, a branch with momentum $p_1 + p_4$ has code $2^0 + 2^3 = 1 + 8 = 9$.

There is a two-fold ambiguity: Momentum conservation implies that the branch with code

$$c_0 = \sum_{i=1}^{n(\text{ext})} 2^{i-1} \quad (19.62)$$

i.e. the branch with momentum $p_1 + p_2 + \dots p_n$ has momentum zero, which is equivalent to tree code 0 by definition. Correspondingly,

$$c \quad \text{and} \quad c_0 - c = c \text{ XOR } c_0 \quad (19.63)$$

are equivalent. E.g., if there are five externals with codes $c = 1, 2, 4, 8, 16$, then $c = 9$ and $\bar{c} = 31 - 9 = 22$ are equivalent.

This ambiguity may be used to assign a direction to the line: If all momenta are understood as outgoing, $c = 9$ in the example above means $p_1 + p_4$, but $c = 22$ means $p_2 + p_3 + p_5 = -(p_1 + p_4)$.

Here we make use of the ambiguity in a slightly different way. First, the initial particles are singled out as those externals with the highest bits, the IN-bits. (Here: 8 and 16 for a $2 \rightarrow 3$ scattering process, 16 only for a $1 \rightarrow 4$ decay.) Then we invert those codes where all IN-bits are set. For a decay process this maps each tree of an equivalence class onto a unique representative (that one with the smallest integer codes). For a scattering process we proceed further:

The ambiguity remains in all branches where only one IN-bit is set, including the initial particles. If there are only externals with this property, we have an s -channel graph which we leave as it is. In all other cases, an internal with only one IN-bit is a t -channel line, which for phase space integration should be associated with one of the initial momenta as a reference axis. We take that one whose bit is set in the current tree code. (E.g., for branch $c = 9$ we use the initial particle $c = 8$ as reference axis, whereas for the same branch we would take $c = 16$ if it had been assigned $\bar{c} = 31 - 9 = 22$ as tree code.) Thus, different ways of coding the same t -channel graph imply different phase space parameterizations.

s -channel graphs have a unique parameterization. The same sets of parameterizations are used for t -channel graphs, except for the reference frames of their angular parts. We map each t -channel graph onto an s -channel graph as follows:

Working in ascending order, for each t -channel line (whose code has exactly one IN-bit set) the attached initial line is flipped upstream, while the outgoing

line is flipped downstream. (This works only if t -channel graphs are always parameterized beginning at their outer vertices, which we require as a restriction.) After all possible flips have been applied, we have an s -channel graph. We only have to remember the initial particle a vertex was originally attached to.

19.7.2 The phase-space tree type

Definition

In the concrete implementation, each branch c may have two *daughters* c_1 and c_2 such that $c_1 + c_2 = c$, a *sibling* c_s and a *mother* c_m such that $c + c_s = c_m$, and a *friend* which is kept during flips, such that it can indicate a fixed reference frame. Absent entries are set $c = 0$.

First, declare the branch type. There is some need to have this public. Give initializations for all components, so no `init` routine is necessary. The branch has some information about the associated coordinates and about connections.

```

(PHS trees: types)+≡
  type :: phs_branch_t
  private
    logical :: set = .false.
    logical :: inverted_decay = .false.
    logical :: inverted_axis = .false.
    integer(TC) :: mother = 0
    integer(TC) :: sibling = 0
    integer(TC) :: friend = 0
    integer(TC) :: origin = 0
    integer(TC), dimension(2) :: daughter = 0
    integer :: firstborn = 0
    logical :: has_children = .false.
    logical :: has_friend = .false.
    logical :: is_real = .false.
  end type phs_branch_t

```

The tree type: No initialization, this is done by `phs_tree_init`. In addition to the branch array which

The branches are collected in an array which holds all possible branches, of which only a few are set. After flips have been applied, the branch $c_M = \sum_{i=1}^{n(\text{fin})} 2^{i-1}$ must be there, indicating the mother of all decay products. In addition, we should check for consistency at the beginning.

`n_branches` is the number of those actually set. `n externals` defines the number of significant bit, and `mask` is a code where all bits are set. Analogous: `n_in` and `mask_in` for the incoming particles.

The mapping array contains the mappings associated to the branches (corresponding indices). The array `mass_sum` contains the sum of the real masses of the external final-state particles associated to the branch. During phase-space evaluation, this determines the boundaries.

```

(PHS trees: public)+≡
  public :: phs_tree_t

(PHS trees: types)+≡
  type :: phs_tree_t
  private
    integer :: n_branches, n externals, n_in, n_msq, n_angles
    integer(TC) :: n_branches_tot, n_branches_out
    integer(TC) :: mask, mask_in, mask_out
    type(phs_branch_t), dimension(:), allocatable :: branch
    type(mapping_t), dimension(:), allocatable :: mapping
    real(default), dimension(:), allocatable :: mass_sum

```

```

    real(default), dimension(:), allocatable :: effective_mass
    real(default), dimension(:), allocatable :: effective_width
    logical :: real_phsp = .false.
    integer, dimension(:), allocatable :: momentum_link
contains
  <PHS trees: phs tree: TBP>
end type phs_tree_t

```

The maximum number of external particles that can be represented is related to the bit size of the integer that stores binary codes. With the default integer of 32 bit on common machines, this is more than enough space. If TC is actually the default integer kind, there is no need to keep it separate, but doing so marks this as a special type of integer. So, just state that the maximum number is 32:

```

<Limits: public parameters>≡
  integer, parameter, public :: MAX_EXTERNAL = 32

```

Constructor and destructor

Allocate memory for a phase-space tree with given number of externals and incoming. The number of allocated branches can easily become large, but appears manageable for realistic cases, e.g., for $n_{in}=2$ and $n_{out}=8$ we get $2^{10} - 1 = 1023$. Here we set the masks for incoming and for all externals.

```

19.7.3 PHS tree setup

Transformation into an array of branch codes and back

Assume that the tree/array has been created before with the appropriate length and is empty.

```

<PHS trees: public>+≡
public :: phs_tree_from_array

<PHS trees: phs tree: TBP>+≡
procedure :: from_array => phs_tree_from_array

<PHS trees: sub interfaces>+≡
module subroutine phs_tree_from_array (tree, a)
class(phs_tree_t), intent(inout) :: tree
integer(TC), dimension(:), intent(in) :: a
end subroutine phs_tree_from_array

<PHS trees: procedures>+≡
module subroutine phs_tree_from_array (tree, a)
class(phs_tree_t), intent(inout) :: tree
integer(TC), dimension(:), intent(in) :: a
integer :: i
integer(TC) :: k
<Set branches from array a>
<Set external branches if necessary>
<Check number of branches>
<Determine the connections>
contains
<Subroutine: set relatives>
end subroutine phs_tree_from_array

```

First, set all branches specified by the user. If all IN-bits are set, we invert the branch code.

```

<Set branches from array a>+≡
do i=1, size(a)
k = a(i)
if (iand(k, tree%mask_in) == tree%mask_in) k = ieor(tree%mask, k)
tree%branch(k)%set = .true.
tree%n_branches = tree%n_branches+1
end do

```

The external branches are understood, so set them now if not yet done. In all cases ensure that the representative with one bit set is used, except for decays where the in-particle is represented by all OUT-bits set instead.

```

<Set external branches if necessary>+≡

```

```

do i=0, tree%n_externals-1
  k = ibset(0,i)
  if (iand(k, tree%mask_in) == tree%mask_in) k = ieor(tree%mask, k)
  if (tree%branch(ieor(tree%mask, k))%set) then
    tree%branch(ieor(tree%mask, k))%set = .false.
    tree%branch(k)%set = .true.
  else if (.not.tree%branch(k)%set) then
    tree%branch(k)%set = .true.
    tree%n_branches = tree%n_branches+1
  end if
end do

```

Now the number of branches set can be checked. Here we assume that the tree is binary. For three externals there are three branches in total, and for each additional external branch we get another internal one.

```

<Check number of branches>≡
  if (tree%n_branches /= tree%n_externals*2-3) then
    call phs_tree_write (tree)
    call msg_bug &
      & (" Wrong number of branches set in phase space tree")
  end if

```

For all branches that are set, except for the externals, we try to find the daughter branches:

```

<Determine the connections>≡
  do k=1, size (tree%branch)
    if (tree%branch(k)%set .and. tc_decay_level (k) /= 1) then
      call branch_set_relatives(k)
    end if
  end do

```

To this end, we scan all codes less than the current code, whether we can find two branches which are set and which together give the current code. After that, the tree may still not be connected, but at least we know if a branch does not have daughters: This indicates some inconsistency.

The algorithm ensures that, at this stage, the first daughter has a smaller code value than the second one.

```

<Subroutine: set relatives>≡
  subroutine branch_set_relatives (k)
    integer(TC), intent(in) :: k
    integer(TC) :: m,n
    do m=1, k-1

    end subroutine branch_set_relatives

```

The inverse: this is trivial, fortunately.

Flip t -channel into s -channel

Flipping the tree is done upwards, beginning from the decay products. First we select a t -channel branch k : one which is set, which does have an IN-bit, and which is not an external particle.

Next, we determine the adjacent in-particle (called the 'friend' f here, since it will provide the reference axis for the angular integration). In addition, we look for the 'mother' and 'sibling' of this particle. If the latter field is empty, we select the (unique) other out-particle which has no mother, calling the internal subroutine `find_orphan`.

The flip is done as follows: We assume that the first daughter d is an s -channel line, which is true if the daughters are sorted. This will stay the first daughter. The second one is a t -channel line; it is exchanged with the 'sibling' s . The new line which replaces the branch k is just the sum of s and d . In addition, we have to rearrange the relatives of s and d , as well of f .

Finally, we flip 'sibling' and 'friend' and set the new s -channel branch n which replaces the t -channel branch k . After this is complete, we are ready to execute another flip.

[Although the friend is not needed for the final flip, since it would be an initial particle anyway, we need to know whether we have t - or u -channel.]

```

```

After the tree has been flipped, one may need to determine what has become of a particular *t*-channel branch. This function gives the bincode of the flipped tree. If the original bincode does not contain IN-bits, we leave it as it is.

(PHS trees: procedures)+≡

```

function tc_flipped (tree, kt) result (ks)
    type(phs_tree_t), intent(in) :: tree
    integer(TC), intent(in) :: kt
    integer(TC) :: ks
    if (iand (kt, tree%mask_in) == 0) then
        ks = kt
    else
        ks = tree%branch(iand (kt, tree%mask_out))%mother
    end if
end function tc_flipped

```

Scan a tree and make sure that the first daughter has always a smaller code than the second one. Furthermore, delete any `friend` entry in the root branch – this branching has the incoming particle direction as axis anyway. Keep track of reordering by updating `inverted_axis`, `inverted_decay` and `firstborn`.

```

Kinematics

Fill the mass sum array, starting from the external particles and working down to the tree root. For each bincode k we scan the bits in k ; if only one is set, we

take the physical mass of the corresponding external particle; if more then one is set, we sum up the two masses (which we know have already been set).

```

<PHS trees: phs tree: TBP>+=
  procedure :: set_mass_sum => phs_tree_set_mass_sum

<PHS trees: sub interfaces>+=
  module subroutine phs_tree_set_mass_sum (tree, flv)

  end if
end subroutine set_masses_x
end subroutine phs_tree_set_effective_masses

```

Define step mappings, recursively, for the decay products of all intermediate resonances. Step mappings account for the fact that a branch may originate from a resonance, which almost replaces the upper limit on the possible invariant mass. The step mapping implements a smooth cutoff that interpolates between the resonance and the real kinematic limit. The mapping width determines the sharpness of the cutoff.

Step mappings are inserted only for branches that are not mapped otherwise.

At each branch, we record the mass that is effectively available for phase space, by taking the previous limit and subtracting the effective mass of the sibling branch. Widths are added, not subtracted.

If we encounter a resonance decay, we discard the previous limit and replace it by the mass and width of the resonance, also subtracting the sibling branch.

Initially, the limit is zero, so it becomes negative at any branch. Only if there is a resonance, the limit becomes positive. Whenever the limit is positive, and the current branch decays, we activate a step mapping for the current branch.

As a result, step mappings are implemented for all internal lines that originate from an intermediate resonance decay.

The flag `variable_limits` applies to the ultimate limit from the available energy, not to the intermediate resonances whose masses are always fixed.

This routine requires `phs_tree_set_effective_masses`

    end subroutine phs_tree_extract_resonance_history

```

Structural comparison

This function allows to check whether one tree is the permutation of another one. The permutation is applied to the second tree in the argument list. We do not make up a temporary permuted tree, but compare the two trees directly. The branches are scanned recursively, where for each daughter we check the friend and the mapping as well. Once a discrepancy is found, the recursion is exited immediately.

19.7.4 Phase-space evaluation

Phase-space volume

We compute the phase-space volume recursively, following the same path as for computing other kinematical variables. However, the volume depends just on $\sqrt{\hat{s}}$, not on the momentum configuration.

Note: counting branches, we may replace this by a simple formula.

```
<PHS trees: phs tree: TBP>+≡
  procedure :: compute_volume => phs_tree_compute_volume

<PHS trees: sub interfaces>+≡
  module subroutine phs_tree_compute_volume (tree, sqrts, volume)

      else
        v2 = 1
      end if
      if (initial) then
        volume = v1 * v2 / (4 * twopi5)
```

```

        else
            volume = v1 * v2 * sqrts**2 / (4 * twopi2)
        end if
    end subroutine compute_volume_x
end subroutine phs_tree_compute_volume

```

Determine momenta

This is done in two steps: First the masses are determined. This step may fail, in which case `ok` is set to false. If successful, we generate angles and the actual momenta. The array `decay_p` serves for transferring the individual three-momenta of the daughter particles in their mother rest frame from the mass generation to the momentum generation step.

(PHS trees: phs tree: TBP)+≡

```

    procedure :: compute_momenta_from_x => phs_tree_compute_momenta_from_x

```

(PHS trees: sub interfaces)+≡

            (tree, prt, factor, decay_p, sqrts, x(n1+1:n2))
    end subroutine phs_tree_compute_momenta_from_x

```

Mass generation is done recursively. The `ok` flag causes the filled tree to be discarded if set to `.false.` This happens if a three-momentum turns out to be imaginary, indicating impossible kinematics. The index `ix` tells us how far we have used up the input array `x`.

```

The heart of phase space generation: Now we have the invariant masses, let us generate angles. At each branch, we take a Lorentz transformation and augment it by a boost to the current particle rest frame, and by rotations ϕ and θ around the z and y axis, respectively. This transformation is passed down to the daughter particles, if present.

19.8 The phase-space forest

Simply stated, a phase-space forest is a collection of phase-space trees. More precisely, a `phs_forest` object contains all parameterizations of phase space that WHIZARD will use for a single hard process, prepared in the form of `phs_tree` objects. This is suitable for evaluation by the VAMP integration package: each parameterization (tree) is a valid channel in the multi-channel adaptive integration, and each variable in a tree corresponds to an integration dimension, defined by an appropriate mapping of the $(0, 1)$ interval to the allowed range of the integration variable.

The trees are grouped in groves. The trees (integration channels) within a grove share a common weight, assuming that they are related by some approximate symmetry.

Trees/channels that are related by an exact symmetry are connected by an array of equivalences; each equivalence object holds the data that relate one channel to another.

The phase-space setup, i.e., the detailed structure of trees and forest, are read from a file. Therefore, this module also contains the syntax definition and the parser needed for interpreting this file.

19.8.1 Phase-space setup parameters

This transparent container holds the parameters that the algorithm needs for phase-space setup, with reasonable defaults.

The threshold mass (for considering a particle as effectively massless) is specified separately for s- and t-channel. The default is to treat W and Z bosons as massive in the s-channel, but as massless in the t-channel. The b -quark is treated always massless, the t -quark always massive.

```

```

19.8.2 Equivalences

This type holds information about equivalences between phase-space trees. We make a linked list, where each node contains the two trees which are equivalent and the corresponding permutation of external particles. Two more arrays are to be filled: The permutation of mass variables and the permutation of angular variables, where the signature indicates a necessary exchange of daughter branches.

```

<PHS forests: types>+≡

19.8.3 Groves

A grove is a group of trees (phase-space channels) that share a common weight in the integration. Within a grove, channels can be declared equivalent, so they also share their integration grids (up to symmetries). The grove contains a list of equivalences. The `tree_count_offset` is the total number of trees of the preceding groves; when the trees are counted per forest (integration channels), the offset has to be added to all tree indices.

```

<PHS forests: types>+≡
type :: phs_grove_t
private
integer :: tree_count_offset
type(phs_tree_t), dimension(:), allocatable :: tree
type(equivalence_list_t) :: equivalence_list
end type phs_grove_t

```

Call `phs_tree_init` which is also elemental:

```

<PHS forests: procedures>+≡
elemental subroutine phs_grove_init &
  (grove, n_trees, n_in, n_out, n_masses, n_angles)
type(phs_grove_t), intent(inout) :: grove
integer, intent(in) :: n_trees, n_in, n_out, n_masses, n_angles
grove%tree_count_offset = 0
allocate (grove%tree (n_trees))
call grove%tree%init (n_in, n_out, n_masses, n_angles)
end subroutine phs_grove_init

```

The trees do not have pointer components, thus no call to `phs_tree_final`:

```

<PHS forests: procedures>+≡
elemental subroutine phs_grove_final (grove)
type(phs_grove_t), intent(inout) :: grove
deallocate (grove%tree)
call equivalence_list_final (grove%equivalence_list)
end subroutine phs_grove_final

```

Deep copy. This triggers double free corruption with the Intel compiler and hence has to remain in the main module.

```

<PHS forests: interfaces>+≡

```

```

interface assignment(=)
  module procedure phs_grove_assign0
  module procedure phs_grove_assign1
end interface

```

(PHS forests: main procedures)+≡

```

subroutine phs_grove_assign0 (grove_out, grove_in)
  type(phs_grove_t), intent(out) :: grove_out
  type(phs_grove_t), intent(in) :: grove_in
  grove_out%tree_count_offset = grove_in%tree_count_offset
  if (allocated (grove_in%tree)) then
    allocate (grove_out%tree (size (grove_in%tree)))
    grove_out%tree = grove_in%tree
  end if
  grove_out%equivalence_list = grove_in%equivalence_list
end subroutine phs_grove_assign0

subroutine phs_grove_assign1 (grove_out, grove_in)
  type(phs_grove_t), dimension(:), intent(out) :: grove_out
  type(phs_grove_t), dimension(:), intent(in) :: grove_in
  integer :: i
  do i = 1, size (grove_in)
    call phs_grove_assign0 (grove_out(i), grove_in(i))
  end do
end subroutine phs_grove_assign1

```

Get the global (s-channel) mappings. Implemented as a subroutine which returns an array (slice).

(PHS forests: procedures)+≡

```

subroutine phs_grove_assign_s_mappings (grove, mapping)
  type(phs_grove_t), intent(in) :: grove
  type(mapping_t), dimension(:), intent(out) :: mapping
  integer :: i
  if (size (mapping) == size (grove%tree)) then
    do i = 1, size (mapping)
      call grove%tree(i)%assign_s_mapping (mapping(i))
    end do
  else
    call msg_bug ("phs_grove_assign_s_mappings: array size mismatch")
  end if
end subroutine phs_grove_assign_s_mappings

```

19.8.4 The forest type

This is a collection of trees and associated particles. In a given tree, each branch code corresponds to a particle in the `prt` array. Furthermore, we have an array of mass sums which is independent of the decay tree and of the particular event. The mappings directly correspond to the decay trees, and the decay groves collect the trees in classes. The permutation list consists of all permutations of outgoing particles that map the decay forest onto itself.

The particle codes `flv` (one for each external particle) are needed for determining masses and such. The trees and associated information are collected in the `grove` array, together with a lookup table that associates tree indices to groves. Finally, the `prt` array serves as workspace for phase-space evaluation.

The `prt_combination` is a list of index pairs, namely the particle momenta pairs that need to be combined in order to provide all momentum combinations that the phase-space trees need to know.

```

<PHS forests: public>+≡
  public :: phs_forest_t

<PHS forests: types>+≡
  type :: phs_forest_t
    private
    integer :: n_in, n_out, n_tot
    integer :: n_masses, n_angles, n_dimensions
    integer :: n_trees, n_equivalences
    type(flavor_t), dimension(:), allocatable :: flv
    type(phs_grove_t), dimension(:), allocatable :: grove
    integer, dimension(:), allocatable :: grove_lookup
    type(phs_prt_t), dimension(:), allocatable :: prt_in
    type(phs_prt_t), dimension(:), allocatable :: prt_out
    type(phs_prt_t), dimension(:), allocatable :: prt
    integer(TC), dimension(:,:), allocatable :: prt_combination
    type(mapping_t), dimension(:), allocatable :: s_mapping
  contains
    <PHS forests: phs forest: TBP>
  end type phs_forest_t

```

The initialization merely allocates memory. We have to know how many trees there are in each grove, so we can initialize everything. The number of groves is the size of the `n_tree` array.

In the `grove_lookup` table we store the grove index that belongs to each absolute tree index. The difference between the absolute index and the relative (to the grove) index is stored, for each grove, as `tree_count_offset`.

The particle array is allocated according to the total number of branches each tree has, but not filled.

```

<PHS forests: phs forest: TBP>≡
  procedure :: init => phs_forest_init

<PHS forests: sub interfaces>+≡
  module subroutine phs_forest_init (forest, n_tree, n_in, n_out)
    class(phs_forest_t), intent(inout) :: forest
    integer, dimension(:), intent(in) :: n_tree
    integer, intent(in) :: n_in, n_out
  end subroutine phs_forest_init

<PHS forests: procedures>+≡
  module subroutine phs_forest_init (forest, n_tree, n_in, n_out)
    class(phs_forest_t), intent(inout) :: forest
    integer, dimension(:), intent(in) :: n_tree
    integer, intent(in) :: n_in, n_out
    integer :: g, count, k_root
    forest%n_in = n_in
    forest%n_out = n_out

```

```

forest%n_tot = n_in + n_out
forest%n_masses = max (n_out - 2, 0)
forest%n_angles = max (2*n_out - 2, 0)
forest%n_dimensions = forest%n_masses + forest%n_angles
forest%n_trees = sum (n_tree)
forest%n_equivalences = 0
allocate (forest%grove (size (n_tree)))
call phs_grove_init &
    (forest%grove, n_tree, n_in, n_out, forest%n_masses, &
    forest%n_angles)
allocate (forest%grove_lookup (forest%n_trees))

19.8.7 Read the phase space setup from file

The phase space setup is stored in a file. The file may be generated by the `cascades` module below, or by other means. This file has to be read and parsed to create the PHS forest as the internal phase-space representation.

Create lexer and syntax:

```

(PHS forests: procedures)+≡
subroutine define_phs_forest_syntax (ifile)
    type(ifile_t) :: ifile
    call ifile_append (ifile, "SEQ phase_space_list = process_phase_space*")
    call ifile_append (ifile, "SEQ process_phase_space = " &
        // "process_def process_header phase_space")
    call ifile_append (ifile, "SEQ process_def = process process_list")
    call ifile_append (ifile, "KEY process")
    call ifile_append (ifile, "LIS process_list = process_tag*")
    call ifile_append (ifile, "IDE process_tag")
    call ifile_append (ifile, "SEQ process_header = " &
        // "md5sum_process = md5sum " &
        // "md5sum_model_par = md5sum " &
        // "md5sum_phs_config = md5sum " &
        // "sqrts = real " &
        // "m_threshold_s = real " &
        // "m_threshold_t = real " &
        // "off_shell = integer " &
        // "t_channel = integer " &
        // "keep_nonresonant = logical")
    call ifile_append (ifile, "KEY '='")
    call ifile_append (ifile, "KEY '-'")
    call ifile_append (ifile, "KEY md5sum_process")
    call ifile_append (ifile, "KEY md5sum_model_par")
    call ifile_append (ifile, "KEY md5sum_phs_config")
    call ifile_append (ifile, "KEY sqrts")
    call ifile_append (ifile, "KEY m_threshold_s")
    call ifile_append (ifile, "KEY m_threshold_t")
    call ifile_append (ifile, "KEY off_shell")
    call ifile_append (ifile, "KEY t_channel")
    call ifile_append (ifile, "KEY keep_nonresonant")
    call ifile_append (ifile, "QUO md5sum = '""' ... '""'")
    call ifile_append (ifile, "REA real")
    call ifile_append (ifile, "INT integer")
    call ifile_append (ifile, "IDE logical")
    call ifile_append (ifile, "SEQ phase_space = grove_def+")
end subroutine

```

```

call ifile_append (ifile, "SEQ grove_def = grove tree_def+")
call ifile_append (ifile, "KEY grove")
call ifile_append (ifile, "SEQ tree_def = tree bincodes mapping*")
call ifile_append (ifile, "KEY tree")
call ifile_append (ifile, "SEQ bincodes = bincodes*")
call ifile_append (ifile, "INT bincodes")
call ifile_append (ifile, "SEQ mapping = map bincodes channel signed_pdg")
call ifile_append (ifile, "KEY map")
call ifile_append (ifile, "ALT channel = &
    &s_channel | t_channel | u_channel | &
    &collinear | infrared | radiation | on_shell")
call ifile_append (ifile, "KEY s_channel")
! call ifile_append (ifile, "KEY t_channel")    !!! Key already exists
call ifile_append (ifile, "KEY u_channel")
call ifile_append (ifile, "KEY collinear")
call ifile_append (ifile, "KEY infrared")
call ifile_append (ifile, "KEY radiation")
call ifile_append (ifile, "KEY on_shell")
call ifile_append (ifile, "ALT signed_pdg = &
    &pdg | negative_pdg")
call ifile_append (ifile, "SEQ negative_pdg = '-' pdg")
call ifile_append (ifile, "INT pdg")
end subroutine define_phs_forest_syntax

```

The model-file syntax and lexer are fixed, therefore stored as module variables:

        integer, intent(in), optional :: unit
        call syntax_write (syntax_phs_forest, unit)
    end subroutine syntax_phs_forest_write

```

The concrete parser and interpreter. Generate an input stream for the external `unit`, read the parse tree (with given `syntax` and `lexer`) from this stream, and transfer the contents of the parse tree to the PHS forest.

We look for the matching `process` tag, count groves and trees for initializing the forest, and fill the trees.

If the optional parameters are set, compare the parameters stored in the file to those. Set `match` true if everything agrees.

```

19.8.8 Preparation

The trees that we read from file do not carry flavor information. This is set separately:

The flavor list must be unique for a unique set of masses; if a given particle can have different flavor, the mass must be degenerate, so we can choose one of the possible flavor combinations.

(PHS forests: phs forest: TBP)+≡

```

Once the parameter set is fixed, the masses and the widths of the particles are known and the `mass_sum` arrays as well as the mapping parameters can be computed. Note that order is important: we first compute the mass sums, then the ordinary mappings. The resonances obtained here determine the effective masses, which in turn are used to implement step mappings for resonance decay products that are not mapped otherwise.

```

Generate the particle combination table. Scan all trees and merge their individual combination tables. At the end, valid entries are non-zero, and they indicate the indices of a pair of particles to be combined to a new particle. If a particle is accessible by more than one tree (this is usual), only keep the first possibility.

19.8.10 Find equivalences among phase-space trees

Scan phase space for equivalences. We generate the complete set of unique permutations for the given list of outgoing particles, and use this for scanning equivalences within each grove. We scan all pairs of trees, using all permutations. This implies that trivial equivalences are included, and equivalences between different trees are recorded twice. This is intentional.

(PHS forests: procedures)+≡

```

19.8.12 Phase-space evaluation

Given one row of the **x** parameter array and the corresponding channel index, compute first all relevant momenta and then recover the remainder of the **x**

array, the Jacobians `phs_factor`, and the phase-space volume.

The output argument `ok` indicates whether this was successful.

19.9 Finding phase space parameterizations

If the phase space configuration is not found in the appropriate file, we should generate one.

The idea is to construct all Feynman diagrams subject to certain constraints which eliminate everything that is probably irrelevant for the integration. These Feynman diagrams (cascades) are grouped in groves by finding equivalence classes related by symmetry and ordered with respect to their importance (resonances). Finally, the result (or part of it) is written to file and used for the integration.

This module may eventually disappear and be replaced by CAML code. In particular, we need here a set of Feynman rules (vertices with particle codes, but not the factors). Thus, the module works for the Standard Model only.

Note that this module is stand-alone, it communicates to the main program only via the generated ASCII phase-space configuration file.

19.9.1 The mapping modes

The valid mapping modes, to be used below. We will make use of the convention that mappings of internal particles have a positive value. Only for positive values, the flavor code is propagated when combining cascades.

```

⟨Mapping modes⟩≡
    integer, parameter :: &
        & EXTERNAL_PRT = -1, &
        & NO_MAPPING = 0, S_CHANNEL = 1, T_CHANNEL = 2, U_CHANNEL = 3, &
        & RADIATION = 4, COLLINEAR = 5, INFRARED = 6, &
        & STEP_MAPPING_E = 11, STEP_MAPPING_H = 12, &
        & ON_SHELL = 99

⟨Cascades: parameters⟩≡
    ⟨Mapping modes⟩

```

19.9.2 The cascade type

A cascade is essentially the same as a decay tree (both definitions may be merged in a later version). It contains a linked tree of nodes, each of which representing an internal particle. In contrast to decay trees, each node has a definite particle code. These nodes need not be modified, therefore we can use pointers and do not have to copy them. Thus, physically each cascades has only a single node, the mother particle. However, to be able to compare trees quickly, we store in addition an array of binary codes which is always sorted in ascending order. This is accompanied by a corresponding list of particle codes. The index is the location of the corresponding cascade in the cascade set, this may be used to access the daughters directly.

The real mass is the particle mass belonging to the particle code. The minimal mass is the sum of the real masses of all its daughters; this is the kinematical cutoff. The effective mass may be zero if the particle mass is below a certain threshold; it may be the real mass if the particle is resonant; or it may be some other value.

The logical `t_channel` is set if this a t -channel line, while `initial` is true only for an initial particle. Note that both initial particles are also `t_channel` by definition, and that they are distinguished by the direction of the tree: One of them decays and is the root of the tree, while the other one is one of the leaves.

The cascade is a list of nodes (particles) which are linked via the `daughter` entries. The node is the mother particle of the decay cascade. Much of the information in the nodes is repeated in arrays, to be accessible more easily. The arrays will be kept sorted by binary codes.

The counter `n_off_shell` is increased for each internal line that is neither resonant nor log-enhanced. It is set to zero if the current line is resonant, since this implies on-shell particle production and subsequent decay.

The counter `n_t_channel` is non-negative once an initial particle is included in the tree: then, it counts the number of t -channel lines.

The `multiplicity` is the number of branchings to follow until all daughters are on-shell. A resonant or non-decaying particle has multiplicity one. Merging nodes, the multiplicities add unless the mother is a resonance. An initial or final node has multiplicity zero.

The arrays correspond to the subnode tree **tree** of the current cascade. PDG codes are stored only for those positions which are resonant, with the exception of the last entry, i.e., the current node. Other positions, in particular external legs, are assigned undefined PDG code.

A cascade is uniquely identified by its tree, the tree of PDG codes, and the tree of mappings. The tree of resonances is kept only to mask the PDG tree as described above.

19.9.3 Creating new cascades

This initializes a single-particle cascade (external, final state). The PDG entry in the tree is set undefined because the cascade is not resonant. However, the flavor entry is set, so the cascade flavor is identified nevertheless.

(Cascades: procedures)+≡

```

subroutine cascade_init_outgoing (cascade, flv, pos, m_thr)
    type(cascade_t), intent(out) :: cascade
    type(flavor_t), intent(in) :: flv
    integer, intent(in) :: pos
    real(default), intent(in) :: m_thr
    call cascade_init (cascade, 1)
    cascade%bincode = ibset (0_TC, pos-1)
    cascade%flv = flv
    cascade%pdg = cascade%flv%get_pdg ()
    cascade%is_vector = flv%get_spin_type () == VECTOR
    cascade%m_min = flv%get_mass ()
    cascade%m_rea = cascade%m_min
    if (cascade%m_rea >= m_thr) then
        cascade%m_eff = cascade%m_rea
    end if
    cascade%on_shell = .true.
    cascade%multiplicity = 1
    cascade%tree(1) = cascade%bincode
    cascade%tree_pdg(1) = cascade%pdg

```

```

        cascade%tree_mapping(1) = EXTERNAL_PRT
        cascade%tree_resonant(1) = .false.
    end subroutine cascade_init_outgoing

```

The same for an incoming line:

```

<Cascades: procedures>+=
    subroutine cascade_init_incoming (cascade, flv, pos, m_thr)
        type(cascade_t), intent(out) :: cascade
        type(flavor_t), intent(in) :: flv
        integer, intent(in) :: pos
        real(default), intent(in) :: m_thr
        call cascade_init (cascade, 1)
        cascade%incoming = .true.
        cascade%bincode = ibset (0_TC, pos-1)
        cascade%flv = flv%anti ()
        cascade%pdg = cascade%flv%get_pdg ()
        cascade%is_vector = flv%get_spin_type () == VECTOR
        cascade%m_min = flv%get_mass ()
        cascade%m_rea = cascade%m_min
        if (cascade%m_rea >= m_thr) then
            cascade%m_eff = cascade%m_rea
        end if
        cascade%on_shell = .true.
        cascade%n_t_channel = 0
        cascade%n_off_shell = 0
        cascade%tree(1) = cascade%bincode
        cascade%tree_pdg(1) = cascade%pdg
        cascade%tree_mapping(1) = EXTERNAL_PRT
        cascade%tree_resonant(1) = .false.
    end subroutine cascade_init_incoming

```

19.9.4 Tools

This function returns true if the two cascades share no common external particle. This is a requirement for joining them.

```

<Cascades: interfaces>=
    interface operator(.disjunct.)
        module procedure cascade_disjunct
    end interface

<Cascades: sub interfaces>=
    module function cascade_disjunct (cascade1, cascade2) result (flag)
        logical :: flag
        type(cascade_t), intent(in) :: cascade1, cascade2
    end function cascade_disjunct

<Cascades: procedures>+=
    module function cascade_disjunct (cascade1, cascade2) result (flag)
        logical :: flag
        type(cascade_t), intent(in) :: cascade1, cascade2
        flag = iand (cascade1%bincode, cascade2%bincode) == 0
    end function cascade_disjunct

```

Compute a hash code for the resonance pattern of a cascade. We count the number of times each particle appears as a resonance.

We pack the PDG codes of the resonances in two arrays (s-channel and t-channel), sort them both, concatenate the results, transfer to `i8` integers, and compute the hash code from this byte stream.

For t/u-channel, we remove the sign for antiparticles since this is not well-defined.

```

<Cascades: procedures> +=
  subroutine cascade_assign_resonance_hash (cascade)
    type(cascade_t), intent(inout) :: cascade
    integer(i8), dimension(1) :: mold
    cascade%res_hash = hash (transfer &
      ([sort (pack (cascade%tree_pdg, &
        cascade%tree_resonant)), &
        sort (pack (abs (cascade%tree_pdg), &
          cascade%tree_mapping == T_CHANNEL .or. &
          cascade%tree_mapping == U_CHANNEL))], &
        mold))
  end subroutine cascade_assign_resonance_hash

```

19.9.5 Hash entries for cascades

We will set up a hash array which contains keys of and pointers to cascades. We hold a list of cascade (pointers) within each bucket. This is not for collision resolution, but for keeping similar, but unequal cascades together.

```

<Cascades: types> +=
  type :: cascade_p
    type(cascade_t), pointer :: cascade => null ()
    type(cascade_p), pointer :: next => null ()
  end type cascade_p

```

Here is the bucket or hash entry type:

```

<Cascades: types> +=
  type :: hash_entry_t
    integer(i32) :: hashval = 0
    integer(i8), dimension(:), allocatable :: key
    type(cascade_p), pointer :: first => null ()
    type(cascade_p), pointer :: last => null ()
  end type hash_entry_t

```

```

<Cascades: public> =
  public :: hash_entry_init

```

```

<Cascades: sub interfaces> +=
  module subroutine hash_entry_init (entry, entry_in)
    type(hash_entry_t), intent(out) :: entry
    type(hash_entry_t), intent(in) :: entry_in
  end subroutine hash_entry_init

```

```

<Cascades: procedures>+=
module subroutine hash_entry_init (entry, entry_in)
  type(hash_entry_t), intent(out) :: entry
  type(hash_entry_t), intent(in) :: entry_in
  type(cascade_p), pointer :: casc_iter, casc_copy
  entry%hashval = entry_in%hashval
  entry%key = entry_in%key
  casc_iter => entry_in%first
  do while (associated (casc_iter))
    allocate (casc_copy)
    casc_copy = casc_iter
    casc_copy%next => null ()
    if (associated (entry%first)) then
      entry%last%next => casc_copy
    else
      entry%first => casc_copy
    end if
    entry%last => casc_copy
    casc_iter => casc_iter%next
  end do
end subroutine hash_entry_init

```

Finalize: just deallocate the list; the contents are just pointers.

```

<Cascades: procedures>+=
subroutine hash_entry_final (hash_entry)
  type(hash_entry_t), intent(inout) :: hash_entry
  type(cascade_p), pointer :: current
  do while (associated (hash_entry%first))
    current => hash_entry%first
    hash_entry%first => current%next
    deallocate (current)
  end do
end subroutine hash_entry_final

```

Output: concise format for debugging, just list cascade indices.

```

<Cascades: procedures>+=
subroutine hash_entry_write (hash_entry, unit)
  type(hash_entry_t), intent(in) :: hash_entry
  integer, intent(in), optional :: unit
  type(cascade_p), pointer :: current
  integer :: u, i
  u = given_output_unit (unit); if (u < 0) return
  write (u, "(1x,A)", advance="no") "Entry:"
  do i = 1, size (hash_entry%key)
    write (u, "(1x,I0)", advance="no") hash_entry%key(i)
  end do
  write (u, "(1x,A)", advance="no") "->"
  current => hash_entry%first
  do while (associated (current))
    write (u, "(1x,I7)", advance="no") current%cascade%index
    current => current%next
  end do
  write (u, *)

```

```
end subroutine hash_entry_write
```

This function adds a cascade pointer to the bucket. If `ok` is present, check first if it is already there and return failure if yes. If `cascade_ptr` is also present, set it to the current cascade if successful. If not, set it to the cascade that is already there.

(Cascades: procedures)+≡

```
subroutine hash_entry_add_cascade_ptr (hash_entry, cascade, ok, cascade_ptr)
  type(hash_entry_t), intent(inout) :: hash_entry
  type(cascade_t), intent(in), target :: cascade
  logical, intent(out), optional :: ok
  type(cascade_t), optional, pointer :: cascade_ptr
  type(cascade_p), pointer :: current
  if (present (ok)) then
    call hash_entry_check_cascade (hash_entry, cascade, ok, cascade_ptr)
    if (.not. ok) return
  end if
  allocate (current)
  current%cascade => cascade
  if (associated (hash_entry%last)) then
    hash_entry%last%next => current
  else
    hash_entry%first => current
  end if
  hash_entry%last => current
end subroutine hash_entry_add_cascade_ptr
```

This function checks whether a cascade is already in the bucket. For incomplete cascades, we look for an exact match. It should suffice to verify the tree, the PDG codes, and the mapping modes. This is the information that is written to the phase space file.

For complete cascades, we ignore the PDG code at positions with mappings infrared, collinear, or t/u-channel. Thus a cascade which is distinguished only by PDG code at such places, is flagged existent. If the convention is followed that light particles come before heavier ones (in the model definition), this ensures that the lightest particle is kept in the appropriate place, corresponding to the strongest peak.

For external cascades (incoming/outgoing) we take the PDG code into account even though it is zeroed in the PDG-code tree.

(Cascades: procedures)+≡

```
subroutine hash_entry_check_cascade (hash_entry, cascade, ok, cascade_ptr)
  type(hash_entry_t), intent(in), target :: hash_entry
  type(cascade_t), intent(in), target :: cascade
  logical, intent(out) :: ok
  type(cascade_t), optional, pointer :: cascade_ptr
  type(cascade_p), pointer :: current
  integer, dimension(:), allocatable :: tree_pdg
  ok = .true.
  allocate (tree_pdg (size (cascade%tree_pdg)))
  if (cascade%complete) then

19.9.6 The cascade set

The cascade set will later be transformed into the decay forest. It is set up as a linked list. In addition to the usual `first` and `last` pointers, there is a `first_t` pointer which points to the first t-channel cascade (after all s-channel cascades), and a `first_k` pointer which points to the first final cascade (with a keystone).

As an auxiliary device, the object contains a hash array with associated parameters where an additional pointer is stored for each cascade. The keys are made from the relevant cascade data. This hash is used for fast detection (and thus avoidance) of double entries in the cascade list.

```

19.9.7 Adding cascades

Add a deep copy of a cascade to the set. The copy has all content of the original, but the pointers are nullified. We do not care whether insertion was successful or not. The pointer argument, if present, is assigned to the input cascade, or to the hash entry if it is already present.

The procedure is recursive: any daughter or mother entries are also deep-copied and added to the cascade set before the current copy is added.

(Cascades: procedures) +=

```

recursive subroutine cascade_set_add_copy &
  (cascade_set, cascade_in, cascade_ptr)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in) :: cascade_in

```

```

type(cascade_t), optional, pointer :: cascade_ptr
type(cascade_t), pointer :: cascade
logical :: ok
allocate (cascade)
cascade = cascade_in
if (associated (cascade_in%daughter1)) call cascade_set_add_copy &
    (cascade_set, cascade_in%daughter1, cascade%daughter1)
if (associated (cascade_in%daughter2)) call cascade_set_add_copy &
    (cascade_set, cascade_in%daughter2, cascade%daughter2)
if (associated (cascade_in%mother)) call cascade_set_add_copy &
    (cascade_set, cascade_in%mother, cascade%mother)
cascade%next => null ()
call cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
if (.not. ok) deallocate (cascade)
end subroutine cascade_set_add_copy

```

Add a cascade to the set. This does not deep-copy. We first try to insert it in the hash array. If successful, add it to the list. Failure indicates that it is already present, and we drop it.

The hash key is built solely from the tree array, so neither particle codes nor resonances count, just topology.

Technically, hash and list receive only pointers, so the cascade can be considered as being in either of both. We treat it as part of the list.

```

<Cascades: procedures>+=
subroutine cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
type(cascade_set_t), intent(inout), target :: cascade_set
type(cascade_t), intent(in), target :: cascade
logical, intent(out) :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i8), dimension(1) :: mold
call cascade_set_hash_insert &
    (cascade_set, transfer (cascade%tree, mold), cascade, ok, cascade_ptr)
if (ok) call cascade_set_list_add (cascade_set, cascade)
end subroutine cascade_set_add

```

Add a new cascade to the list:

```

<Cascades: procedures>+=
subroutine cascade_set_list_add (cascade_set, cascade)
type(cascade_set_t), intent(inout) :: cascade_set
type(cascade_t), intent(in), target :: cascade
if (associated (cascade_set%last)) then
    cascade_set%last%next => cascade
else
    cascade_set%first => cascade
end if
cascade_set%last => cascade
end subroutine cascade_set_list_add

```

Add a cascade entry to the hash array:

```

<Cascades: procedures>+=
subroutine cascade_set_hash_insert &
    (cascade_set, key, cascade, ok, cascade_ptr)

```

```

type(cascade_set_t), intent(inout), target :: cascade_set
integer(i8), dimension(:), intent(in) :: key
type(cascade_t), intent(in), target :: cascade
logical, intent(out) :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i32) :: h
if (cascade_set%n_entries >= cascade_set%n_entries_max) &
    call cascade_set_hash_expand (cascade_set)
h = hash (key)
call cascade_set_hash_insert_rec &
    (cascade_set, h, h, key, cascade, ok, cascade_ptr)
end subroutine cascade_set_hash_insert

```

Double the hashtable size when necessary:

```

<Cascades: procedures>+=
subroutine cascade_set_hash_expand (cascade_set)
type(cascade_set_t), intent(inout), target :: cascade_set
type(hash_entry_t), dimension(:), allocatable, target :: table_tmp
type(cascade_p), pointer :: current
integer :: i, s
allocate (table_tmp (0:cascade_set%mask))
table_tmp = cascade_set%entry
deallocate (cascade_set%entry)
s = 2 * size (table_tmp)
cascade_set%n_entries = 0
cascade_set%n_entries_max = s * cascade_set%fill_ratio
cascade_set%mask = s - 1
allocate (cascade_set%entry (0:cascade_set%mask))
do i = 0, ubound (table_tmp, 1)
    current => table_tmp(i)%first
    do while (associated (current))
        call cascade_set_hash_insert_rec &
            (cascade_set, table_tmp(i)%hashval, table_tmp(i)%hashval, &
                table_tmp(i)%key, current%cascade)
        current => current%next
    end do
end do
end subroutine cascade_set_hash_expand

```

Insert the cascade at the bucket determined by the hash value. If the bucket is filled, check first for a collision (unequal keys). In that case, choose the following bucket and repeat. Otherwise, add the cascade to the bucket.

If the bucket is empty, record the hash value, allocate and store the key, and then add the cascade to the bucket.

If ok is present, before insertion we check whether the cascade is already stored, and return failure if yes.

```

<Cascades: procedures>+=
recursive subroutine cascade_set_hash_insert_rec &
    (cascade_set, h, hashval, key, cascade, ok, cascade_ptr)
type(cascade_set_t), intent(inout) :: cascade_set
integer(i32), intent(in) :: h, hashval
integer(i8), dimension(:), intent(in) :: key

```

```

type(cascade_t), intent(in), target :: cascade
logical, intent(out), optional :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i32) :: i
i = iand (h, cascade_set%mask)
if (allocated (cascade_set%entry(i)%key)) then
  if (size (cascade_set%entry(i)%key) /= size (key)) then
    call cascade_set_hash_insert_rec &
      (cascade_set, h + 1, hashval, key, cascade, ok, cascade_ptr)
  else if (any (cascade_set%entry(i)%key /= key)) then
    call cascade_set_hash_insert_rec &
      (cascade_set, h + 1, hashval, key, cascade, ok, cascade_ptr)
  else
    call hash_entry_add_cascade_ptr &
      (cascade_set%entry(i), cascade, ok, cascade_ptr)
  end if
else
  cascade_set%entry(i)%hashval = hashval
  allocate (cascade_set%entry(i)%key (size (key)))
  cascade_set%entry(i)%key = key
  call hash_entry_add_cascade_ptr &
    (cascade_set%entry(i), cascade, ok, cascade_ptr)
  cascade_set%n_entries = cascade_set%n_entries + 1
end if
end subroutine cascade_set_hash_insert_rec

```

19.9.8 External particles

We want to initialize the cascade set with the outgoing particles. In case of multiple processes, initial cascades are prepared for all of them. The hash array check ensures that no particle appears more than once at the same place.

```

<Cascades: interfaces>+≡
  interface cascade_set_add_outgoing
    module procedure cascade_set_add_outgoing1
    module procedure cascade_set_add_outgoing2
  end interface

<Cascades: sub interfaces>+≡
  module subroutine cascade_set_add_outgoing1 (cascade_set, flv)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(flavor_t), dimension(:), intent(in) :: flv
  end subroutine cascade_set_add_outgoing1
  module subroutine cascade_set_add_outgoing2 (cascade_set, flv)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(flavor_t), dimension(:,,:), intent(in) :: flv
  end subroutine cascade_set_add_outgoing2

<Cascades: procedures>+≡
  module subroutine cascade_set_add_outgoing2 (cascade_set, flv)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(flavor_t), dimension(:,,:), intent(in) :: flv
    integer :: pos, prc, n_out, n_prc

```

```

type(cascade_t), pointer :: cascade
logical :: ok
n_out = size (flv, dim=1)
n_prc = size (flv, dim=2)
do prc = 1, n_prc
  do pos = 1, n_out
    allocate (cascade)
    call cascade_init_outgoing &
      (cascade, flv(pos,prc), pos, cascade_set%m_threshold_s)
    call cascade_set_add (cascade_set, cascade, ok)
    if (.not. ok) then
      deallocate (cascade)
    end if
  end do
end do
end subroutine cascade_set_add_outgoing2

```

```

else
    deallocate (cascade)
end if
end subroutine cascade_set_add_incoming0

```

19.9.9 Cascade combination I: flavor assignment

We have two disjunct cascades, now use the vertex table to determine the possible flavors of the combination cascade. For each possibility, try to generate a new cascade. The total cascade depth has to be one less than the limit, because this is reached by setting the keystone.

```

(Cascades: procedures) +=
subroutine cascade_match_pair (cascade_set, cascade1, cascade2, s_channel)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(cascade_t), intent(in), target :: cascade1, cascade2
    logical, intent(in) :: s_channel
    integer, dimension(:), allocatable :: pdg3
    integer :: i, depth_max
    type(flavor_t) :: flv
    if (s_channel) then
        depth_max = cascade_set%depth_out
    else
        depth_max = cascade_set%depth_tot
    end if
    if (cascade1%depth + cascade2%depth < depth_max) then
        call cascade_set%model%match_vertex ( &
            cascade1%flv%get_pdg (), &
            cascade2%flv%get_pdg (), &
            pdg3)
        do i = 1, size (pdg3)
            call flv%init (pdg3(i), cascade_set%model)
            if (s_channel) then
                call cascade_combine_s (cascade_set, cascade1, cascade2, flv)
            else
                call cascade_combine_t (cascade_set, cascade1, cascade2, flv)
            end if
        end do
        deallocate (pdg3)
    end if
end subroutine cascade_match_pair

```

The triplet version takes a third cascade, and we check whether this triplet has a matching vertex in the database. If yes, we make a keystone cascade.

```

(Cascades: procedures) +=
subroutine cascade_match_triplet &
    (cascade_set, cascade1, cascade2, cascade3, s_channel)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(cascade_t), intent(in), target :: cascade1, cascade2, cascade3
    logical, intent(in) :: s_channel
    integer :: depth_max
    depth_max = cascade_set%depth_tot

```

```

if (cascade1%depth + cascade2%depth + cascade3%depth == depth_max) then
  if (cascade_set%model%check_vertex ( &
    cascade1%flv%get_pdg (), &
    cascade2%flv%get_pdg (), &
    cascade3%flv%get_pdg ())) then
    call cascade_combine_keystone &
      (cascade_set, cascade1, cascade2, cascade3, s_channel)
  end if
end if
end subroutine cascade_match_triplet

```

19.9.10 Cascade combination II: kinematics setup and check

Having three matching flavors, we start constructing the combination cascade. We look at the mass hierarchies and determine whether the cascade is to be kept. In passing we set mapping modes, resonance properties and such.

If successful, the cascade is finalized. For a resonant cascade, we prepare in addition a copy without the resonance.

```

Here we complete a decay cascade. The third input is the single-particle cascade for the initial particle. There is no resonance or mapping assignment. The only condition for keeping the cascade is the mass sum of the final state, which must be less than the available energy.

Two modifications are necessary for scattering cascades: a pure s-channel diagram (cascade1 is the incoming particle) do not have a logarithmic mapping at top-level. And in a t-channel diagram, the last line exchanged is mapped t-channel, not u-channel. Finally, we can encounter the case of a $2 \rightarrow 1$ process, where cascade1 is incoming, and cascade2 is the outgoing particle. In all three cases we register a new cascade with the modified mapping.

19.9.11 Cascade combination III: node connections and tree fusion

Here we assign global tree properties. If the allowed number of off-shell lines is exceeded, discard the new cascade. Otherwise, assign the trees, sort them, and assign connections. Finally, append the cascade to the list. This may fail (because in the hash array there is already an equivalent cascade). On failure, discard the cascade.

(Cascades: procedures) +=

19.9.13 Groves

Before assigning groves, assign hashcodes to the resonance patterns, so they can easily be compared.

(Cascades: procedures)+≡

```

subroutine cascade_set_assign_resonance_hash (cascade_set)
    type(cascade_set_t), intent(inout) :: cascade_set
    type(cascade_t), pointer :: cascade
    cascade => cascade_set%first_k
    do while (associated (cascade))
        call cascade_assign_resonance_hash (cascade)
        cascade => cascade%next
    end do
end subroutine cascade_set_assign_resonance_hash

```

After all cascades are recorded, we group the complete cascades in groves. A grove consists of cascades with identical multiplicity, number of resonances, log-enhanced, t-channel lines, and resonance flavors.

(Cascades: procedures)+≡

```

subroutine cascade_set_assign_groves (cascade_set)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(cascade_t), pointer :: cascade1, cascade2
    integer :: multiplicity
    integer :: n_resonances, n_log_enhanced, n_t_channel, n_off_shell
    integer :: res_hash
    integer :: grove
    grove = 0
    cascade1 => cascade_set%first_k

      cascade2%grove = grove
    end if
  end if
  call terminate_now_if_signal ()
  cascade2 => cascade2%next
end do
end if
call terminate_now_if_signal ()
cascade1 => cascade1%next
end do
cascade_set%n_groves = grove
end subroutine cascade_set_assign_groves

```

19.9.14 Generate the phase space file

Generate a complete phase space configuration.

For each flavor assignment: First, all s-channel graphs that can be built up from the outgoing particles. Then we distinguish (1) decay, where we complete the s-channel graphs by connecting to the input line, and (2) scattering, where we now generate t-channel graphs by introducing an incoming particle, and complete this by connecting to the other incoming particle.

After all cascade sets have been generated, merge them into a common set. This eliminates redundancies between flavor assignments.

```

19.10 A lexer for O’Mega’s phase-space output

This module provides three data types. One of them is the type `dag_string_t` which should contain the information of all Feynman diagrams in the factorized form which is provided by O’Mega in its phase-space outout. This output is translated into a string of tokens (in the form of an a array of the type `dag_token_t`) which have a certain meaning. The purpose of this module is only to identify these tokens correctly and to provide some procedures and interfaces which allow us to use these strings in a similar way as variables of the basic character type or the type `iso_varying_string`. Both `character` and `iso_varying_string` have some disadvantages at least if one wants to keep support for some older compiler versions. These can be circumvented by the `dag_string_t` type. Finally the `dag_chain_t` type is used to create a larger string in several steps without always recreating the string, which is done in the form of a simple linked list. In the end one can create a single `dag_string` out of this list, which is more useful.

(cascades2_lexer.f90)≡

```

    <File header>

module cascades2_lexer

    <Cascades2 lexer: parameters>

    <Cascades2 lexer: types>

    <Cascades2 lexer: interfaces>

        interface
    <Cascades2 lexer: sub interfaces>
        end interface

end module cascades2_lexer

<cascades2_lexer_sub.f90>≡
    <File header>

    submodule (cascades2_lexer) cascades2_lexer_s

        implicit none

    contains

    <Cascades2 lexer: procedures>

end submodule cascades2_lexer_s

```

This is the token type. By default the variable `type` is `EMPTY_TK` but can obtain other values corresponding to the parameters defined below. The type of the token corresponds to a particular sequence of characters. When the token corresponds to a node of a tree, i.e. some particle in the Feynman diagram, the type is `NODE_TK` and the `particle_name` variable is holding the name of the particle. O'Megas output contains in addition to the particle name some numbers which indicate the external momenta that are flowing through this line. These numbers are translated into a binary code and saved in the variable `bincode`. In this case the number 1 corresponds to a bit set at position 0, 2 corresponds to a bit set at position 1, etc. Instead of numbers which are composed out of several digits, letters are used, i.e. A instead of 10 (bit at position 9), B instead of 11 (bit at position 10), etc.

When the DAG is reconstructed from a `dag_string` which was built from O'Mega's output, this string is modified such that a substring (a set of tokens) is replaced by a single token where the type variable is one of the three parameters `DAG_NODE_TK`, `DAG_OPTIONS_TK` and `DAG_COMBINATION_TK`. These

parameters correspond to the three types `dag_node_t`, `dag_options_t` and `dag_combination_t` (see `cascades2` for more information. In this case, since these objects are organized in arrays, the `index` variable holds the corresponding position in the array.

In any case, we want to be able to reproduce the character string from which a token (or a string) has been created. The variable `char_len` is the length of this string. For tokens with the type `DAG_NODE_TK`, `DAG_OPTIONS_TK` and `DAG_COMBINATION_TK` we use output of the form `<N23>`, `<O23>` or `<C23>` which is useful for debugging the parser. Here 23 is the `index` and N, O or C obviously corresponds to the `type`.

```

<Cascades2 lexer: parameters>≡
    integer, parameter :: PRT_NAME_LEN = 20

<Cascades2 lexer: public>≡
    public :: dag_token_t

<Cascades2 lexer: types>≡
    type :: dag_token_t
        integer :: type = EMPTY_TK
        integer :: char_len = 0
        integer(TC) :: bincode = 0
        character(len=PRT_NAME_LEN) :: particle_name=""
        integer :: index = 0
    contains
        <Cascades2 lexer: dag token: TBP>
    end type dag_token_t

```

This is the string type. It also holds the number of characters in the corresponding character string. It contains an array of tokens. If the `dag_string` is constructed using the type `dag_chain_t`, which creates a linked list, we also need the pointer `next`.

```

<Cascades2 lexer: public>+≡
    public :: dag_string_t

<Cascades2 lexer: types>+≡
    type :: dag_string_t
        integer :: char_len = 0
        type(dag_token_t), dimension(:), allocatable :: t
        type(dag_string_t), pointer :: next => null ()
    contains
        <Cascades2 lexer: dag string: TBP>
    end type dag_string_t

```

This is the chain of `dag_strings`. It allows us to construct a large string by appending new strings to the linked list, which can later be merged to a single string. This is very useful because the file written by O'Mega contains large strings where each string contains all Feynman diagrams in a factorized form, but these large strings are cut into several pieces and distributed over many lines. As the file can become large, rewriting a new `dag_string` (or `iso_varying_string`) would consume more and more time with each additional line. For recreating a single `dag_string` out of this chain, we need the total character length and the sum of all sizes of the `dag_token` arrays `t`.

```

<Cascades2 lexer: public>+≡

```

```

    public :: dag_chain_t
  <Cascades2 lexer: types>+≡
    type :: dag_chain_t
      integer :: char_len = 0
      integer :: t_size = 0
      type(dag_string_t), pointer :: first => null ()
      type(dag_string_t), pointer :: last => null ()
    contains
      <Cascades2 lexer: dag chain: TBP>
    end type dag_chain_t

```

We define two parameters holding the characters corresponding to a backslash and a blanc space.

```

  <Cascades2 lexer: parameters>+≡
    character(len=1), parameter, public :: BACKSLASH_CHAR = "\"
    character(len=1), parameter :: BLANC_CHAR = " "

```

These are the parameters which correspond to meaningful types of token.

```

  <Cascades2 lexer: parameters>+≡
    integer, parameter, public :: NEW_LINE_TK = -2
    integer, parameter :: BLANC_SPACE_TK = -1
    integer, parameter :: EMPTY_TK = 0
    integer, parameter, public :: NODE_TK = 1
    integer, parameter, public :: DAG_NODE_TK = 2
    integer, parameter, public :: DAG_OPTIONS_TK = 3
    integer, parameter, public :: DAG_COMBINATION_TK = 4
    integer, parameter, public :: COLON_TK = 11
    integer, parameter, public :: COMMA_TK = 12
    integer, parameter, public :: VERTICAL_BAR_TK = 13
    integer, parameter, public :: OPEN_PAR_TK = 21
    integer, parameter, public :: CLOSED_PAR_TK = 22
    integer, parameter, public :: OPEN_CURLY_TK = 31
    integer, parameter, public :: CLOSED_CURLY_TK = 32

```

Different sorts of assignment. This contains the conversion of a character variable into a dag_token or dag_string.

Compare strings/tokens/characters. Each character is relevant, including all blanc spaces. An exception is the `newline` character which is not treated by the types used in this module (not to confused with the type parameter `NEW_LINE_TK` which corresponds to the backslash character and simply tells us that the string continues on the next line in the file).

19.11 An alternative cascades module

This module might replace the module `cascades`, which generates suitable phase space parametrizations and generates the phase space file. The mappings, as well as the criteria to determine these, do not change.

The advantage of this module is that it makes use of the 0'Mega matrix element generator which provides the relevant Feynman diagrams (the ones

which can be constructed only from 3-vertices). In principle, the construction of these diagrams is also one of the tasks of the existing `cascades` module, in which the diagrams would correspond to a set of cascades. It starts by creating cascades which correspond to the outgoing particles. These are combined to a new cascade using the vertices of the model. In this way, since each cascade knows the daughter cascades from which it is built, complete Feynman diagrams are represented by sets of cascades, as soon as the existing cascades can be recombined with the incoming particle(s).

In this module, the Feynman diagrams are represented by the type `feyngraph_t`, which represents the Feynman diagrams as a tree of nodes. The object which contains the necessary kinematical information to determine mappings, and hence sensible phase space parametrizations is of another type, called `kingraph_t`, which is built from a corresponding `feyngraph` object.

There are two types of output which can be produced by `O'Mega` and are potentially relevant here. The first type contains all tree diagrams for the process under consideration, where each line of the output corresponds to one Feynman diagram. This output is easy to read, but can be very large, depending on the number of particles involved in the process. Moreover, it repeats substructures of the diagrams which are part of more than one diagram. One could in principle work with this output and construct a `feyngraph` from each line, if allowed, i.e. if there are only 3-vertices.

The other output contains also all of these Feynman diagrams, but in a factorized form. This means that the substructures which appear in several Feynman diagrams, are written only once, if possible. This leads to a much shorter input file, which speeds up the parsing process. Furthermore it makes it possible to reconstruct the `feyngraphs` in such a way that the calculations concerning subdiagrams which reappear in other `feyngraphs` have to be performed only once. This is already the case in the existing `cascades` module but can be exploited more efficiently here because the possible graphs are well known from the input file, whereas the `cascades` module would create a large number of `cascades` which do not lead to a complete Feynman diagram of the given process.

```

19.11.1 Particle properties

We define a type holding the properties of the particles which are needed for parsing and finding the phase space parametrizations and mappings. The properties of all particles which appear in the parsed Feynman diagrams for the given process will be stored in a central place, and only pointers to these objects are used.

```

<Cascades2: types>≡
    type :: part_prop_t
        character(len=LABEL_LEN) :: particle_label
        integer :: pdg = 0
        real(default) :: mass = 0.
        real :: width = 0.

```

```

integer :: spin_type = 0
logical :: is_vector = .false.
logical :: empty = .true.
type(part_prop_t), pointer :: anti => null ()
type(string_t) :: tex_name
contains
  <Cascades2: part prop: TBP>
end type part_prop_t

```

The `particle_label` in `part_prop_t` is simply the particle name (e.g. 'W+'). The corresponding variable in the type `f_node_t` contains some additional information related to the external momenta, see below. The length of the `character` variable is fixed as:

```

<Cascades2: parameters>≡
  integer, parameter :: LABEL_LEN=30

<Cascades2: part prop: TBP>≡
  procedure :: final => part_prop_final

<Cascades2: sub interfaces>≡
  module subroutine part_prop_final (part)
    class(part_prop_t), intent(inout) :: part
  end subroutine part_prop_final

<Cascades2: procedures>≡
  module subroutine part_prop_final (part)
    class(part_prop_t), intent(inout) :: part
    part%anti => null ()
  end subroutine part_prop_final

```

19.11.2 The mapping modes

The possible mappings are essentially the same as in `cascades`, but we introduce in addition the mapping constant `NON_RESONANT`, which does not refer to a new mapping; it corresponds to the nonresonant version of a potentially resonant particle (or `k_node`). This becomes relevant when we compare `k_nodes` to eliminate equivalences.

```

<Cascades2: parameters>+≡
  integer, parameter :: &
    & NONRESONANT = -2, EXTERNAL_PRT = -1, &
    & NO_MAPPING = 0, S_CHANNEL = 1, T_CHANNEL = 2, U_CHANNEL = 3, &
    & RADIATION = 4, COLLINEAR = 5, INFRARED = 6, &
    & STEP_MAPPING_E = 11, STEP_MAPPING_H = 12, &
    & ON_SHELL = 99

```

19.11.3 Grove properties

The channels or `kingraphs` will be grouped in groves, i.e. sets of channels, which share some characteristic numbers. These numbers are stored in the following type:

```

<Cascades2: types>+≡
  type :: grove_prop_t

```

```

integer :: multiplicity = 0
integer :: n_resonances = 0
integer :: n_log_enhanced = 0
integer :: n_off_shell = 0
integer :: n_t_channel = 0
integer :: res_hash = 0
end type grove_prop_t

```

19.11.4 The tree type

This type contains all the information which is needed to reconstruct a **feyngraph** or **kingraph**. We store bincodes, pdg codes and mappings for all nodes of a valid **kingraph**. If we label the external particles as given in the process definition with integer numbers representing their position in the process definition, the bincode would be the number that one obtains by setting the bit at the position that is given by this number. If we combine two particles/nodes to a third one (using a three-vertex of the given model), the bincode is the number which one obtains by setting all the bits which are set for the two particles. The **pdg** and **mapping** are simply the pdg-code and mapping at the position (i.e. propagator or external particle) which is specified by the corresponding bincode. We use **tree_t** not only for completed **kingraphs**, but also for all **k_nodes**, which are a subtree of a **kingraph**.

```

<Cascades2: types>+≡
type :: tree_t
integer(TC), dimension(:), allocatable :: bc
integer, dimension(:), allocatable :: pdg
integer, dimension(:), allocatable :: mapping
integer :: n_entries = 0
logical :: keep = .true.
logical :: empty = .true.
contains
<Cascades2: tree: TBP>
end type tree_t

<Cascades2: tree: TBP>≡
procedure :: final => tree_final

<Cascades2: sub interfaces>+≡
module subroutine tree_final (tree)
class(tree_t), intent(inout) :: tree
end subroutine tree_final

<Cascades2: procedures>+≡
module subroutine tree_final (tree)
class(tree_t), intent(inout) :: tree
if (allocated (tree%bc)) deallocate (tree%bc)
if (allocated (tree%pdg)) deallocate (tree%pdg)
if (allocated (tree%mapping)) deallocate (tree%mapping)
end subroutine tree_final

```

```

<Cascades2: interfaces>≡
  interface assignment (=)
    module procedure tree_assign
    end interface assignment (=)

<Cascades2: sub interfaces>+≡
  module subroutine tree_assign (tree1, tree2)
    type(tree_t), intent(inout) :: tree1
    type(tree_t), intent(in) :: tree2
  end subroutine tree_assign

<Cascades2: procedures>+≡
  module subroutine tree_assign (tree1, tree2)
    type(tree_t), intent(inout) :: tree1
    type(tree_t), intent(in) :: tree2
    if (allocated (tree2%bc)) then
      allocate (tree1%bc(size(tree2%bc)))
      tree1%bc = tree2%bc
    end if
    if (allocated (tree2%pdg)) then
      allocate (tree1%pdg(size(tree2%pdg)))
      tree1%pdg = tree2%pdg
    end if
    if (allocated (tree2%mapping)) then
      allocate (tree1%mapping(size(tree2%mapping)))
      tree1%mapping = tree2%mapping
    end if
    tree1%n_entries = tree2%n_entries
    tree1%keep = tree2%keep
    tree1%empty = tree2%empty
  end subroutine tree_assign

```

19.11.5 Add entries to the tree

The following procedures fill the arrays in `tree_t` with entries resulting from the bincode and mapping assignment.

```

<Cascades2: tree: TBP>+≡
  procedure :: add_entry_from_numbers => tree_add_entry_from_numbers
  procedure :: add_entry_from_node => tree_add_entry_from_node
  generic :: add_entry => add_entry_from_numbers, add_entry_from_node

```

Here we add a single entry to each of the arrays. This will exclusively be used for external particles.

```

<Cascades2: sub interfaces>+≡
  module subroutine tree_add_entry_from_numbers (tree, bincode, pdg, mapping)
    class(tree_t), intent(inout) :: tree
    integer(TC), intent(in) :: bincode
    integer, intent(in) :: pdg
    integer, intent(in) :: mapping
  end subroutine tree_add_entry_from_numbers

```

```

<Cascades2: procedures>+≡
module subroutine tree_add_entry_from_numbers (tree, bincode, pdg, mapping)
  class(tree_t), intent(inout) :: tree
  integer(TC), intent(in) :: bincode
  integer, intent(in) :: pdg
  integer, intent(in) :: mapping
  integer :: pos
  if (tree%empty) then
    allocate (tree%bc(1))
    allocate (tree%pdg(1))
    allocate (tree%mapping(1))
    pos = tree%n_entries + 1
    tree%bc(pos) = bincode
    tree%pdg(pos) = pdg
    tree%mapping(pos) = mapping
    tree%n_entries = pos
    tree%empty = .false.
  end if
end subroutine tree_add_entry_from_numbers

```

Here we merge two existing subtrees and a single entry (bc, pdg and mapping).

```

<Cascades2: procedures>+≡
subroutine tree_merge (tree, tree1, tree2, bc, pdg, mapping)
  class(tree_t), intent(inout) :: tree
  type(tree_t), intent(in) :: tree1, tree2
  integer(TC), intent(in) :: bc
  integer, intent(in) :: pdg, mapping
  integer :: tree_size
  integer :: i1, i2
  if (tree%empty) then
    i1 = tree1%n_entries
    i2 = tree1%n_entries + tree2%n_entries
    !! Proof: tree_size > 0 (always)
    tree_size = tree1%n_entries + tree2%n_entries + 1
    allocate (tree%bc (tree_size))
    allocate (tree%pdg (tree_size))
    allocate (tree%mapping (tree_size))
    if (.not. tree1%empty) then
      tree%bc(:i1) = tree1%bc
      tree%pdg(:i1) = tree1%pdg
      tree%mapping(:i1) = tree1%mapping
    end if
    if (.not. tree2%empty) then
      tree%bc(i1+1:i2) = tree2%bc
      tree%pdg(i1+1:i2) = tree2%pdg
      tree%mapping(i1+1:i2) = tree2%mapping
    end if
    tree%bc(tree_size) = bc
    tree%pdg(tree_size) = pdg
    tree%mapping(tree_size) = mapping
    tree%n_entries = tree_size
    tree%empty = .false.
  end if
end subroutine tree_merge

```

```
end subroutine tree_merge
```

Here we add entries to a tree for a given `k_node`, which means that we first have to determine whether the node is external or internal. The arrays are sorted after the entries have been added (see below for details).

<Cascades2: sub interfaces>+≡

```
module subroutine tree_add_entry_from_node (tree, node)
  class(tree_t), intent(inout) :: tree
  type(k_node_t), intent(in) :: node
end subroutine tree_add_entry_from_node
```

<Cascades2: procedures>+≡

```
module subroutine tree_add_entry_from_node (tree, node)
  class(tree_t), intent(inout) :: tree
  type(k_node_t), intent(in) :: node
  integer :: pdg
  if (node%t_line) then
    pdg = abs (node%particle%pdg)
  else
    pdg = node%particle%pdg
  end if
  if (associated (node%daughter1) .and. &
      associated (node%daughter2)) then
    call tree_merge (tree, node%daughter1%subtree, &
                    node%daughter2%subtree, node%bincode, &
                    node%particle%pdg, node%mapping)
  else
    call tree_add_entry_from_numbers (tree, node%bincode, &
                                     node%particle%pdg, node%mapping)
  end if
  call tree%sort ()
end subroutine tree_add_entry_from_node
```

For a well-defined order of the elements of the arrays in `tree_t`, the elements can be sorted. The bincodes (entries of `bc`) are simply ordered by size, the `pdg` and `mapping` entries go to the positions of the corresponding `bc` values.

<Cascades2: tree: TBP>+≡

```
procedure :: sort => tree_sort
```

<Cascades2: sub interfaces>+≡

```
module subroutine tree_sort (tree)
  class(tree_t), intent(inout) :: tree
end subroutine tree_sort
```

<Cascades2: procedures>+≡

```
module subroutine tree_sort (tree)
  class(tree_t), intent(inout) :: tree
  integer(TC), dimension(size(tree%bc)) :: bc_tmp
  integer, dimension(size(tree%pdg)) :: pdg_tmp, mapping_tmp
  integer, dimension(1) :: pos
  integer :: i
  bc_tmp = tree%bc
  pdg_tmp = tree%pdg
  mapping_tmp = tree%mapping
```

```

do i = size(tree%bc),1,-1
  pos = maxloc (bc_tmp)
  tree%bc(i) = bc_tmp (pos(1))
  tree%pdg(i) = pdg_tmp (pos(1))
  tree%mapping(i) = mapping_tmp (pos(1))
  bc_tmp(pos(1)) = 0
end do
end subroutine tree_sort

```

19.11.6 Graph types

We define an abstract type which will give rise to two different types: The type `feyngraph_t` contains the pure information of the corresponding Feynman diagram, but also a list of objects of the `kingraph` type which contain the kinematically relevant data for the mapping calculation as well as the mappings themselves. Every graph should have an index which is unique. Graphs which are not needed any more can be disabled by setting the `keep` variable to `false`.

```

<Cascades2: types>+≡
type, abstract :: graph_t
  integer :: index = 0
  integer :: n_nodes = 0
  logical :: keep = .true.
end type graph_t

```

This is the type representing the Feynman diagrams which are read from an input file created by O'Mega. It is a tree of nodes, which we call `f_nodes`, so that `feyngraph_t` contains a pointer to the root of this tree, and each node can have two daughter nodes. The case of only one associated daughter should never appear, because in the method of phase space parametrization which is used here, we combine always two particle momenta to a third one. The `feyngraphs` will be arranged in a linked list. This is why we have a pointer to the next graph. The `kingraphs` on the other hand are arranged in linked lists which are attached to the corresponding `feyngraph`. In general, a `feyngraph` can give rise to more than one `kingraph` because we make a copy every time a particle can be resonant, so that in the copy we keep the particle nonresonant.

```

<Cascades2: types>+≡
type, extends (graph_t) :: feyngraph_t
  type(string_t) :: omega_feyngraph_output
  type(f_node_t), pointer :: root => null ()
  type(feyngraph_t), pointer :: next => null()
  type(kingraph_t), pointer :: kin_first => null ()
  type(kingraph_t), pointer :: kin_last => null ()
contains
  <Cascades2: feyngraph: TBP>
end type feyngraph_t

```

A container for a pointer of type `feyngraph_t`. This is used to realize arrays of these pointers.

```

<Cascades2: types>+≡
type :: feyngraph_ptr_t

```

```

    type(feyngraph_t), pointer :: graph => null ()
end type feyngraph_ptr_t

```

The length of a string describing a Feynman diagram which is produced by O'Mega is fixed by the parameter

```

<Cascades2: parameters>+≡
    integer, parameter :: FEYNGRAPH_LEN=300

<Cascades2: feyngraph: TBP>≡
    procedure :: final => feyngraph_final

<Cascades2: sub interfaces>+≡
    module subroutine feyngraph_final (graph)
        class(feyngraph_t), intent(inout) :: graph
    end subroutine feyngraph_final

<Cascades2: procedures>+≡
    module subroutine feyngraph_final (graph)
        class(feyngraph_t), intent(inout) :: graph
        type(kingraph_t), pointer :: current
        graph%root => null ()
        graph%kin_last => null ()
        do while (associated (graph%kin_first))
            current => graph%kin_first
            graph%kin_first => graph%kin_first%next
            call current%final ()
            deallocate (current)
        end do
    end subroutine feyngraph_final

```

This is the type of graph which is used to find the phase space channels, or in other words, each kingraph could correspond to a channel, if it is not eliminated for kinematical reasons or due to an equivalence. For the linked list which is attached to the corresponding `feyngraph`, we need the `next` pointer, whereas `grove_next` points to the next `kingraph` within a grove. The information which is relevant for the specification of a channel is stored in `tree`. We use `grove_prop` to sort the `kingraph` in a grove in which all `kingraphs` are characterized by the numbers contained in `grove_prop`. Later these groves are further subdivided using the resonance hash. A `kingraph` which is constructed directly from the output of O'Mega, is not `inverse`. In this case the first incoming particle is the root of the tree. In a scattering process, we can also construct a `kingraph` where the root of the tree is the second incoming particle. In this case the value of `inverse` is `.true.`.

```

<Cascades2: types>+≡
    type, extends (graph_t) :: kingraph_t
        type(k_node_t), pointer :: root => null ()
        type(kingraph_t), pointer :: next => null()
        type(kingraph_t), pointer :: grove_next => null ()
    type(tree_t) :: tree
    type(grove_prop_t) :: grove_prop
    logical :: inverse = .false.
    integer :: prc_component = 0
contains

```

```

    <Cascades2: kingraph: TBP>
end type kingraph_t

```

Another container for a pointer to emulate arrays of pointers:

```

<Cascades2: types>+≡
type :: kingraph_ptr_t
    type(kingraph_t), pointer :: graph => null ()
end type kingraph_ptr_t

<Cascades2: kingraph: TBP>≡
procedure :: final => kingraph_final

<Cascades2: sub interfaces>+≡
module subroutine kingraph_final (graph)
    class(kingraph_t), intent(inout) :: graph
end subroutine kingraph_final

<Cascades2: procedures>+≡
module subroutine kingraph_final (graph)
    class(kingraph_t), intent(inout) :: graph
    graph%root => null ()
    graph%next => null ()
    graph%grove_next => null ()
    call graph%tree%final ()
end subroutine kingraph_final

```

19.11.7 The node types

We define an abstract type containing variables which are needed for `f_node_t` as well as `k_node_t`. We say that a node is on the t-line if it lies between the two nodes which correspond to the two incoming particles. `incoming` and `tline` are used only for scattering processes and remain `.false.` in decay processes. The variable `n_subtree_nodes` holds the number of nodes (including the node itself) of the subtree of which the node is the root.

```

<Cascades2: types>+≡
type, abstract :: node_t
    type(part_prop_t), pointer :: particle => null ()
    logical :: incoming = .false.
    logical :: t_line = .false.
    integer :: index = 0
    logical :: keep = .true.
    integer :: n_subtree_nodes = 1
end type node_t

```

We use two different list types for the different kinds of nodes. We therefore start with an abstract type:

```

<Cascades2: types>+≡
type, abstract :: list_t
    integer :: n_entries = 0
end type list_t

```

Since the contents of the lists are different, we introduce two different entry types. Since the trees of nodes use pointers, the nodes should only be allocated by a type-bound procedure of the corresponding list type, such that we can keep track of all nodes, eventually reuse and in the end deallocate nodes correctly, without forgetting any nodes. Here is the type for the `k_nodes`. The list is a linked list. We want to reuse (recycle) the `k_nodes` which are neither incoming nor `t_line`.

```

<Cascades2: types>+≡
  type :: k_node_entry_t
    type(k_node_t), pointer :: node => null ()
    type(k_node_entry_t), pointer :: next => null ()
    logical :: recycle = .false.
  contains
    <Cascades2: k node entry: TBP>
  end type k_node_entry_t

<Cascades2: k node entry: TBP>≡
  procedure :: final => k_node_entry_final

<Cascades2: sub interfaces>+≡
  module subroutine k_node_entry_final (entry)
    class(k_node_entry_t), intent(inout) :: entry
  end subroutine k_node_entry_final

<Cascades2: procedures>+≡
  module subroutine k_node_entry_final (entry)
    class(k_node_entry_t), intent(inout) :: entry
    if (associated (entry%node)) then
      call entry%node%final
      deallocate (entry%node)
    end if
    entry%next => null ()
  end subroutine k_node_entry_final

<Cascades2: k node entry: TBP>+≡
  procedure :: write => k_node_entry_write

<Cascades2: sub interfaces>+≡
  module subroutine k_node_entry_write (k_node_entry, u)
    class(k_node_entry_t), intent(in) :: k_node_entry
    integer, intent(in) :: u
  end subroutine k_node_entry_write

<Cascades2: procedures>+≡
  module subroutine k_node_entry_write (k_node_entry, u)
    class(k_node_entry_t), intent(in) :: k_node_entry
    integer, intent(in) :: u
  end subroutine k_node_entry_write

```

Here is the list type for `k_nodes`. A `k_node_list` can be declared to be an observer. In this case it does not create any nodes by itself, but the entries set their pointers to existing nodes. In this way we can use the list structure and the type bound procedures for existing nodes.

```

<Cascades2: types>+≡

```

```

type, extends (list_t) :: k_node_list_t
  type(k_node_entry_t), pointer :: first => null ()
  type(k_node_entry_t), pointer :: last => null ()
  integer :: n_recycle
  logical :: observer = .false.
contains
  <Cascades2: k node list: TBP>
end type k_node_list_t

<Cascades2: k node list: TBP>≡
  procedure :: final => k_node_list_final

<Cascades2: sub interfaces>+≡
  module subroutine k_node_list_final (list)
    class(k_node_list_t), intent(inout) :: list
  end subroutine k_node_list_final

<Cascades2: procedures>+≡
  module subroutine k_node_list_final (list)
    class(k_node_list_t), intent(inout) :: list
    type(k_node_entry_t), pointer :: current
    do while (associated (list%first))
      current => list%first
      list%first => list%first%next
      if (list%observer) current%node => null ()
      call current%final ()
      deallocate (current)
    end do
  end subroutine k_node_list_final

```

The `f_node_t` type contains the `particle_label` variable which is extracted from the input file. It consists not only of the particle name, but also of some numbers in brackets. These numbers indicate which external particles are part of the subtree of this node. The `f_node` contains also a list of `k_nodes`. Therefore, if the nodes are not `incoming` or `t_line`, the mapping calculations for these `k_nodes` which can appear in several `kingraphs` have to be performed only once.

```

<Cascades2: types>+≡
  type, extends (node_t) :: f_node_t
    type(f_node_t), pointer :: daughter1 => null ()
    type(f_node_t), pointer :: daughter2 => null ()
    character(len=LABEL_LEN) :: particle_label
    type(k_node_list_t) :: k_node_list
  contains
    <Cascades2: f node: TBP>
  end type f_node_t

```

The finalizer nullifies the daughter pointers, since they are deallocated, like the `f_node` itself, with the finalizer of the `f_node_list`.

```

<Cascades2: f node: TBP>≡
  procedure :: final => f_node_final

```

```

<Cascades2: sub interfaces>+≡
    recursive module subroutine f_node_final (node)
        class(f_node_t), intent(inout) :: node
    end subroutine f_node_final

```

```

<Cascades2: procedures>+≡
    recursive module subroutine f_node_final (node)
        class(f_node_t), intent(inout) :: node
        call node%k_node_list%final ()
        node%daughter1 => null ()
        node%daughter2 => null ()
    end subroutine f_node_final

```

Finaliser for f_node_entry.

```

<Cascades2: f node entry: TBP>≡
    procedure :: final => f_node_entry_final

<Cascades2: sub interfaces>+≡
    module subroutine f_node_entry_final (entry)
        class(f_node_entry_t), intent(inout) :: entry
    end subroutine f_node_entry_final

<Cascades2: procedures>+≡
    module subroutine f_node_entry_final (entry)
        class(f_node_entry_t), intent(inout) :: entry
        if (associated (entry%node)) then
            call entry%node%final ()
            deallocate (entry%node)
        end if
        entry%next => null ()
    end subroutine f_node_entry_final

```

Set index if not yet done, i.e. if it is zero.

```

<Cascades2: f node: TBP>+≡
    procedure :: set_index => f_node_set_index

<Cascades2: sub interfaces>+≡
    module subroutine f_node_set_index (f_node)
        class(f_node_t), intent(inout) :: f_node
    end subroutine f_node_set_index

<Cascades2: procedures>+≡
    module subroutine f_node_set_index (f_node)
        class(f_node_t), intent(inout) :: f_node
        integer, save :: counter = 0
        if (f_node%index == 0) then
            counter = counter + 1
            f_node%index = counter
        end if
    end subroutine f_node_set_index

```

Type for the nodes of the tree (lines of the Feynman diagrams). We also need a type containing a pointer to a node, which is needed for creating arrays of pointers. This will be used for scattering processes where we can take either the first or the second particle to be the root of the tree. Since we need both

cases for the calculations and O'Mega only gives us one of these, we have to perform a transformation of the graph in which some nodes (on the line which we hereafter call t-line) need to know their mother and sister nodes, which become their daughters within this transformation.

```

<Cascades2: types>+≡
  type :: f_node_ptr_t
    type(f_node_t), pointer :: node => null ()

    end subroutine k_node_entry_assign

<Cascades2: procedures>+≡
    module subroutine k_node_entry_assign (entry1, entry2)
        type(k_node_entry_t), intent(out) :: entry1
        type(k_node_entry_t), intent(in)  :: entry2
        entry1%node => entry2%node
        entry1%recycle = entry2%recycle
    end subroutine k_node_entry_assign

```

Add an entry to the `k_node_list`. We have to specify if the node can be reused. The check for existing reusable nodes happens with `k_node_list_get_nodes` (see below).

```

<Cascades2: k node list: TBP>+≡
    procedure :: add_entry => k_node_list_add_entry

<Cascades2: sub interfaces>+≡
    recursive module subroutine k_node_list_add_entry &
        (list, ptr_to_node, recycle)
        class(k_node_list_t), intent(inout) :: list
        type(k_node_t), pointer, intent(out) :: ptr_to_node
        logical, intent(in) :: recycle
    end subroutine k_node_list_add_entry

<Cascades2: procedures>+≡
    recursive module subroutine k_node_list_add_entry &
        (list, ptr_to_node, recycle)
        class(k_node_list_t), intent(inout) :: list
        type(k_node_t), pointer, intent(out) :: ptr_to_node
        logical, intent(in) :: recycle
        if (list%n_entries == 0) then
            allocate (list%first)
            list%last => list%first
        else
            allocate (list%last%next)
            list%last => list%last%next
        end if
        list%n_entries = list%n_entries + 1
        list%last%recycle = recycle
        allocate (list%last%node)
        call list%last%node%set_index ()
        ptr_to_node => list%last%node
    end subroutine k_node_list_add_entry

```

We need a similar subroutine for adding only a pointer to a list. This is needed for a `k_node_list` which is only an observer, i.e. it does not create any nodes by itself.

```

<Cascades2: k node list: TBP>+≡
    procedure :: add_pointer => k_node_list_add_pointer

```

```

<Cascades2: sub interfaces>+≡
  module subroutine k_node_list_add_pointer (list, ptr_to_node, recycle)
    class(k_node_list_t), intent(inout) :: list
    type(k_node_t), pointer, intent(in) :: ptr_to_node
    logical, optional, intent(in) :: recycle
  end subroutine k_node_list_add_pointer

<Cascades2: procedures>+≡
  module subroutine k_node_list_add_pointer (list, ptr_to_node, recycle)
    class(k_node_list_t), intent(inout) :: list
    type(k_node_t), pointer, intent(in) :: ptr_to_node
    logical, optional, intent(in) :: recycle
    logical :: rec
    if (present (recycle)) then
      rec = recycle
    else
      rec = .false.
    end if
    if (list%n_entries == 0) then
      allocate (list%first)
      list%last => list%first
    else
      allocate (list%last%next)
      list%last => list%last%next
    end if
    list%n_entries = list%n_entries + 1
    list%last%recycle = rec
    list%last%node => ptr_to_node
  end subroutine k_node_list_add_pointer

```

The `k_node_list` can also be used to collect `k_nodes` which belong to different `f_nodes` in order to compare these. This is done only for nodes which have the same number of subtree nodes. We compare all nodes of the list with each other (as long as the node is not deactivated, i.e. if the `keep` variable is set to `.true.`) using the subroutine `subtree_select`. If it turns out that two nodes are equivalent, we keep only one of them. The term equivalent in this module refers to trees or subtrees which differ in the pdg codes at positions where the trivial mapping is used (`NO_MAPPING` or `NON_RESONANT`) so that the mass of the particle does not matter. Depending on the available couplings, two equivalent subtrees could eventually lead to the same phase space channels, which is why only one of them is kept.

```

<Cascades2: k node list: TBP>+≡
  procedure :: check_subtree_equivalences => &
    k_node_list_check_subtree_equivalences

<Cascades2: sub interfaces>+≡
  module subroutine k_node_list_check_subtree_equivalences (list, model)
    class(k_node_list_t), intent(inout) :: list
    type(model_data_t), intent(in) :: model
  end subroutine k_node_list_check_subtree_equivalences

<Cascades2: procedures>+≡
  module subroutine k_node_list_check_subtree_equivalences (list, model)
    class(k_node_list_t), intent(inout) :: list

```

```

type(model_data_t), intent(in) :: model
type(k_node_ptr_t), dimension (:), allocatable :: set
type(k_node_entry_t), pointer :: current
integer :: pos
integer :: i,j
if (list%n_entries == 0) return
allocate (set (list%n_entries))
current => list%first
pos = 0
do while (associated (current))
    pos = pos + 1
    set(pos)%node => current%node
    current => current%next
end do
do i=1, list%n_entries
    if (set(i)%node%keep) then
        do j=i+1, list%n_entries
            if (set(j)%node%keep) then
                if (set(i)%node%bincode == set(j)%node%bincode) then
                    call subtree_select (set(i)%node%subtree,set(j)%node%subtree, model)
                    if (.not. set(i)%node%subtree%keep) then
                        set(i)%node%keep = .false.
                        exit
                    else if (.not. set(j)%node%subtree%keep) then
                        set(j)%node%keep = .false.
                    end if
                end if
            end if
        end do
    end if
end do
deallocate (set)
end subroutine k_node_list_check_subtree_equivalences

```

This subroutine is used to obtain all `k_nodes` of a `k_node_list` which can be recycled and are not disabled for some reason. We pass an allocatable array of the type `k_node_ptr_t` which will be allocated if there are any such nodes in the list and the pointers will be associated with these nodes.

<Cascades2: k node list: TBP>+≡

```

end subroutine k_node_list_get_nodes

```

Gfortran 7/8/9 bug, has to remain in the main module:

```

<Cascades2: f node list: TBP>+≡
  procedure :: final => f_node_list_final

<Cascades2: main procedures>≡
  subroutine f_node_list_final (list)
    class(f_node_list_t) :: list
    type(f_node_entry_t), pointer :: current
    list%k_node_list => null ()
    do while (associated (list%first))
      current => list%first
      list%first => list%first%next
      call current%final ()
      deallocate (current)
    end do
  end subroutine f_node_list_final

```

19.11.8 The grove list

First a type is introduced in order to speed up the comparison of kingraphs with the purpose to quickly find the graphs that might be equivalent. This is done solely on the basis of a number (which is given by the value of `depth` in `compare_tree_t`) of bincodes, which are the highest ones that do not belong to external particles. The highest such value determines the index of the element in the `entry` array of the `compare_tree`. The next lower such value determines the index of the element in the `entry` array of this `entry`, and so on and so forth. This results in a tree structure where the number of levels is given by `depth` and should not be too large for reasons of memory. This is the entry type.

```

<Cascades2: types>+≡
  type :: compare_tree_entry_t
    type(compare_tree_entry_t), dimension(:), pointer :: entry => null ()
    type(kingraph_ptr_t), dimension(:), allocatable :: graph_entry
  contains
    <Cascades2: compare tree entry: TBP>
  end type compare_tree_entry_t

```

This is the tree type.

```

<Cascades2: types>+≡
  type :: compare_tree_t
    integer :: depth = 3
    type(compare_tree_entry_t), dimension(:), pointer :: entry => null ()
  contains
    <Cascades2: compare tree: TBP>
  end type compare_tree_t

```

Finalizers for both types. The one for the entry type has to be recursive.

```

<Cascades2: compare tree: TBP>≡
  procedure :: final => compare_tree_final

<Cascades2: sub interfaces>+≡
  module subroutine compare_tree_final (ctree)
    class(compare_tree_t), intent(inout) :: ctree
  end subroutine compare_tree_final

<Cascades2: procedures>+≡
  module subroutine compare_tree_final (ctree)
    class(compare_tree_t), intent(inout) :: ctree
    integer :: i
    if (associated (ctree%entry)) then
      do i=1, size (ctree%entry)
        call ctree%entry(i)%final ()
        deallocate (ctree%entry)
      end do
    end if
  end subroutine compare_tree_final

<Cascades2: compare tree entry: TBP>≡
  procedure :: final => compare_tree_entry_final

```

```

<Cascades2: sub interfaces>+≡
    recursive module subroutine compare_tree_entry_final (ct_entry)
        class(compare_tree_entry_t), intent(inout) :: ct_entry
    end subroutine compare_tree_entry_final

<Cascades2: procedures>+≡
    recursive module subroutine compare_tree_entry_final (ct_entry)
        class(compare_tree_entry_t), intent(inout) :: ct_entry
        integer :: i
        if (associated (ct_entry%entry)) then
            do i=1, size (ct_entry%entry)
                call ct_entry%entry(i)%final ()
            end do
            deallocate (ct_entry%entry)
        else
            deallocate (ct_entry%graph_entry)
        end if
    end subroutine compare_tree_entry_final

```

Check the presence of a graph which is considered as equivalent and select between the two. If there is no such graph, the current one is added to the list. First the entry has to be found:

```

<Cascades2: compare tree: TBP>+≡
    procedure :: check_kingraph => compare_tree_check_kingraph

<Cascades2: sub interfaces>+≡
    module subroutine compare_tree_check_kingraph &
        (ctree, kingraph, model, preliminary)
        class(compare_tree_t), intent(inout) :: ctree
        type(kingraph_t), intent(inout), pointer :: kingraph
        type(model_data_t), intent(in) :: model
        logical, intent(in) :: preliminary
    end subroutine compare_tree_check_kingraph

<Cascades2: procedures>+≡
    module subroutine compare_tree_check_kingraph &
        (ctree, kingraph, model, preliminary)
        class(compare_tree_t), intent(inout) :: ctree
        type(kingraph_t), intent(inout), pointer :: kingraph
        type(model_data_t), intent(in) :: model
        logical, intent(in) :: preliminary
        integer :: i
        integer :: pos
        integer(TC) :: sz
        integer(TC), dimension(:), allocatable :: identifier
        if (.not. associated (ctree%entry)) then
            sz = 0_TC
            do i = size(kingraph%tree%bc), 1, -1
                sz = ior (sz, kingraph%tree%bc(i))
            end do
            if (sz > 0) then
                allocate (ctree%entry (sz))
            else
                call msg_bug ("Compare tree could not be created")
            end if
        end if
    end subroutine compare_tree_check_kingraph

```

```

end if
allocate (identifier (ctree%depth))
pos = 0
do i = size(kingraph%tree%bc), 1, -1
  if (popcnt (kingraph%tree%bc(i)) /= 1) then
    pos = pos + 1
    identifier(pos) = kingraph%tree%bc(i)
    if (pos == ctree%depth) exit
  end if
end do
if (size (identifier) > 1) then
  call ctree%entry(identifier(1))%check_kingraph (kingraph, model, &
    preliminary, identifier(1), identifier(2:))
else if (size (identifier) == 1) then
  call ctree%entry(identifier(1))%check_kingraph &

        do i=1, pos
            ct_entry%graph_entry(i)%graph => tmp_ptr(i)%graph
        end do
        deallocate (tmp_ptr)
    end subroutine rebuild_graph_entry
end subroutine compare_tree_entry_check_kingraph

```

The grove to which a completed `kingraph` will be added is determined by the entries of `grove_prop`. We use another list type (linked list) to arrange the groves. Each `grove` contains again a linked list of `kingraphs`.

```

<Cascades2: types>+≡
  type :: grove_t
    type(grove_prop_t) :: grove_prop
    type(grove_t), pointer :: next => null ()
    type(kingraph_t), pointer :: first => null ()
    type(kingraph_t), pointer :: last => null ()
    type(compare_tree_t) :: compare_tree
  contains
    <Cascades2: grove: TBP>
  end type grove_t

```

Container for a pointer of type `grove_t`:

```

<Cascades2: types>+≡
  type :: grove_ptr_t
    type(grove_t), pointer :: grove => null ()
  end type grove_ptr_t

```

```

<Cascades2: grove: TBP>≡
  procedure :: final => grove_final

<Cascades2: sub interfaces>+≡
  module subroutine grove_final (grove)
    class(grove_t), intent(inout) :: grove
  end subroutine grove_final

<Cascades2: procedures>+≡
  module subroutine grove_final (grove)
    class(grove_t), intent(inout) :: grove
    grove%first => null ()
    grove%last  => null ()
    grove%next => null ()
  end subroutine grove_final

```

This is the list type:

```

<Cascades2: types>+≡
  type :: grove_list_t
    type(grove_t), pointer :: first => null ()
  contains
    <Cascades2: grove list: TBP>
  end type grove_list_t

```

Gfortran 7/8/9 bug, has to remain in the main module:

```

<Cascades2: grove list: TBP>≡
  procedure :: final => grove_list_final

<Cascades2: main procedures>+≡
  subroutine grove_list_final (list)
    class(grove_list_t), intent(inout) :: list

```

```

class(grove_t), pointer :: current
do while (associated (list%first))
  current => list%first
  list%first => list%first%next
  call current%final ()
  deallocate (current)
end do
end subroutine grove_list_final

```

19.11.9 The feyngraph set

The fundament of the module is the public type `feyngraph_set_t`. It is not only a linked list of all `feyngraphs` but contains an array of all particle properties (`particle`), an `f_node_list` and a pointer of the type `grove_list_t`, since several `feyngraph_sets` can share a common `grove_list`. In addition it keeps the data which unambiguously specifies the process, as well as the model which provides information which allows us to choose between equivalent subtrees or complete `kingraphs`.

```

<Cascades2: public>+≡
  public :: feyngraph_set_t

<Cascades2: types>+≡
  type :: feyngraph_set_t
    type(model_data_t), pointer :: model => null ()
    type(flavor_t), dimension(:, :), allocatable :: flv
    integer :: n_in = 0
    integer :: n_out = 0
    integer :: process_type = DECAY
    type(pbs_parameters_t) :: pbs_par
    logical :: fatal_beam_decay = .true.
    type(part_prop_t), dimension (:), pointer :: particle => null ()
    type(f_node_list_t) :: f_node_list
    type(feyngraph_t), pointer :: first => null ()
    type(feyngraph_t), pointer :: last => null ()
    integer :: n_graphs = 0
    type(grove_list_t), pointer :: grove_list => null ()
    logical :: use_dag = .true.
    type(dag_t), pointer :: dag => null ()
    type(feyngraph_set_t), dimension (:), pointer :: fset => null ()
    contains
    <Cascades2: feyngraph set: TBP>
  end type feyngraph_set_t

```

This final procedure contains calls to all other necessary final procedures. Gfortran 7/8/9 bug, has to remain in the main module:

```

<Cascades2: feyngraph set: TBP>≡
  procedure :: final => feyngraph_set_final

    deallocate (set%dag)
  end if
end if
end if
end subroutine feyngraph_set_final

```

19.11.10 Construct the feyngraph set

We construct the `feyngraph_set` from an input file. Therefore we pass a unit to `feyngraph_set_build`. The parsing subroutines are chosen depending on the value of `use_dag`. In the DAG output, which is the one that is produced by default, we have to work on a string of one line, where the length of this string becomes larger the more particles are involved in the process. The other output (which is now only used in a unit test) contains one Feynman diagram per line and each line starts with an open parenthesis so that we read the file line per line and create a `feyngraph` for every line. Only after this, nodes are created. In both decay and scattering processes the diagrams are represented like in a

decay process, i.e. in a scattering process one of the incoming particles appears as an outgoing particle.

```

```

Read the string from the file. The output which is produced by O'Mega contains the DAG in a factorised form as a long string, distributed over several lines (in addition, in the case of a scattering process, it contains a similar string for the same process, but with the other incoming particle as the root of the tree structure). In general, such a file can contain many of these strings, belonging to different process components. Therefore we first have to find the correct position of the string for the process in question. Therefore we look for a line containing a pair of colons, in which case the line contains a process string. Then we check if the process string describes the correct process, which is done by checking for all the incoming and outgoing particle names. If the process is correct, the dag output should start in the following line. As long as we do not find the correct process string, we continue searching. If we reach the end of the file, we rewind the unit once, and repeat searching. If the process is still not found, there must be some sort of error.

```

<Cascades2: dag: TBP>≡
    procedure :: read_string => dag_read_string

<Cascades2: sub interfaces>+≡
    module subroutine dag_read_string (dag, u_in, flv)
        class(dag_t), intent(inout) :: dag
        integer, intent(in) :: u_in
        type(flavor_t), dimension(:), intent(in) :: flv
    end subroutine dag_read_string

<Cascades2: procedures>+≡
    module subroutine dag_read_string (dag, u_in, flv)
        class(dag_t), intent(inout) :: dag
        integer, intent(in) :: u_in

```

```

type(flavor_t), dimension(:), intent(in) :: flv
character(len=BUFFER_LEN) :: process_string
logical :: process_found
logical :: rewound
!!! Find process string in file
process_found = .false.
rewound = .false.
do while (.not. process_found)

  if (len_trim(process_string) /= 0) then
    if (index (process_string, "::") > 0) then
      process_found = process_string_match (trim (process_string), flv)
    end if
  else if (.not. rewound) then
    rewind (u_in)
    rewound = .true.
  else
    call msg_bug ("Process string not found in O'Mega input file.")
  end if
end do
call fds_file_get_line (u_in, dag%string)
call dag%string%clean ()
if (.not. allocated (dag%string%t) .or. dag%string%char_len == 0) &
  call msg_bug ("Process string not found in O'Mega input file.")
end subroutine dag_read_string

```

The output of factorized Feynman diagrams which is created by O'Mega for a given process could in principle be written to a single line in the file. This can however lead to different problems with different compilers as soon as such lines become too long. This is the reason why the line is cut into smaller pieces. This means that a new line starts after each vertical bar. For this long string the type `dag_string_t` has been introduced. In order to read the file quickly into such a `dag_string` we use another type, `dag_chain_t` which is a linked list of such `dag_strings`. This has the advantage that we do not have to recreate a new `dag_string` for every line which has been read from file. Only in the end of this operation we compress the list of strings to a single string, removing useless `dag_tokens`, such as blanc space tokens. This subroutine reads all lines starting from the position in the file the unit is connected to, until no backslash character is found at the end of a line (the backslash means that the next line also belongs to the current string).

```

<Cascades2: parameters>+≡
integer, parameter :: BUFFER_LEN = 1000
integer, parameter :: STACK_SIZE = 100

<Cascades2: procedures>+≡
subroutine fds_file_get_line (u, string)
  integer, intent(in) :: u
  type(dag_string_t), intent(out) :: string
  type(dag_chain_t) :: chain
  integer :: string_size, current_len
  character(len=BUFFER_LEN) :: buffer
  integer :: fragment_len

```

```

integer :: stat
current_len = 0
stat = 0
string_size = 0
do while (stat == 0)
  read (unit=u, fmt='(A)', iostat=stat) buffer
  if (stat /= 0) exit
  fragment_len = len_trim (buffer)
  if (fragment_len == 0) then
    exit
  else if (buffer (fragment_len:fragment_len) == BACKSLASH_CHAR) then
    fragment_len = fragment_len - 1
  end if
  call chain%append (buffer(:fragment_len))
  if (buffer(fragment_len+1:fragment_len+1) /= BACKSLASH_CHAR) exit
end do
if (associated (chain%first)) then
  call chain%compress ()
  string = chain%first
  call chain%final ()
end if
end subroutine fds_file_get_line

```

We check, if the process string which has been read from file corresponds to the process for which we want to extract the Feynman diagrams.

(Cascades2: procedures) +=

```

function process_string_match (string, flv) result (match)

Initialize a `part_prop` object by passing a `particle_label`, which is simply the particle name. `part_prop` should be part of the `particle` array of `feyngraph_set`. We use the model of `feyngraph_set` to obtain the relevant data of the particle which is needed to find `phase_space` parametrizations. When a `part_prop` is initialized, we add and initialize also the corresponding anti- particle `part_prop` if it is not yet in the array.

```

This subroutine assigns to a node the particle properties. Since these properties do not change and are simply read from the model file, we use pointers to the elements of the `particle` array of the `feyngraph_set`. If there is no corresponding array element, we have to initialize the first empty element of the array.

```

  !!! here. An exception is the first particle in the parsable DAG output
  node%particle => node%particle%anti
end subroutine f_node_assign_particle_properties

```

From the output of a Feynman diagram (in the non-factorized output) we need to find out how many daughter nodes would be required to reconstruct it correctly, to make sure that we keep only those **feyngraphs** which are constructed solely on the basis of the 3-vertices which are provided by the model. The number of daughter particles can easily be determined from the syntax of O'Mega's output: The particle which appears before the colon ':' is the mother particle. The particles or subtrees (i.e. whole parentheses) follow after the colon and are separated by commas.

```

<Cascades2: procedures>+=

```

19.11.12 Reconstruction of trees

The reconstruction of a tree or subtree with the non-factorized input can be done recursively, i.e. we first find the root of the tree in the string and create an `f_node`. Then we look for daughters, which in the string appear either as single particles or subtrees (which are of the same form as the tree which we want to reconstruct. Therefore the subroutine can simply be called again and again until there are no more daughter nodes to create. When we meet a vertex which requires more than two daughter particles, we stop the recursion and disable the node using its `keep` variable. Whenever a daughter node is not kept, we do not keep the mother node as well.

(Cascades2: procedures) +=

```

recursive subroutine node_construct_subtree_rec (feyngraph_set, &
    feyngraph, subtree_string, mother_node)
    type(feyngraph_set_t), intent(inout) :: feyngraph_set

end if
end subroutine node_construct_subtree_rec

```

When the non-factorized version of the O'Mega output is used, the feyngraph is reconstructed from the contents of its string_t variable omega_feyngraph_output. This can be used for the recursive reconstruction of the tree of k_nodes with node_construct_subtree_rec.

<Cascades2: procedures>+≡

```

subroutine feyngraph_construct (feyngraph_set, feyngraph)
  type(feyngraph_set_t), intent(inout) :: feyngraph_set
  type(feyngraph_t), pointer, intent(inout) :: feyngraph

```

```

call node_construct_subtree_rec (feyngraph_set, feyngraph, &
char(feyngraph%omega_feyngraph_output), feyngraph%root)
feyngraph%n_nodes = feyngraph%root%n_subtree_nodes
end subroutine feyngraph_construct

```

We introduce another node type, which is called `dag_node_t` and is used to reproduce the dag structure which is represented by the input. The `dag_nodes` can have several combinations of daughters 1 and 2. The `dag` type contains an array of `dag_nodes` and is only used for the reconstruction of `feyngraphs` which are factorized as well, but in the other direction as the original output. This means in particular that the outgoing particles in the output file (which there can appear many times) exist only once as `f_nodes`. To represent combinations of daughters and alternatives (options), we further use the types `dag_options_t` and `dag_combination_t`. The `dag_nodes`, `dag_options` and `dag_combinations` correspond to a substring of the string which has been read from file (and transformed into an object of type `dag_string_t`, which is simply another compact representation of this string), or a modified version of this substring. The aim is to create only one object for a given substring, even if it appears several times in the original string and then create trees of `f_nodes`, which build up the `feyngraph`, such that as many `f_nodes` as possible can be reused. An outgoing particle (always interpreting the input as a decay) is called a `leaf` in the context of a `dag`.

```

end subroutine dag_node_final

```

Whenever there are more than one possible subtrees (represented by a `dag_node`) or combinations of subtrees to daughters (represented by `dag_combination_t`), we use the type `dag_options_t`. In the syntax of the factorized output, options are listed within curly braces, separated by horizontal bars.

```

<Cascades2: types>+≡
type :: dag_options_t
    integer :: string_len
    type(dag_string_t) :: string
    type(f_node_ptr_t), dimension (:), allocatable :: f_node_ptr1
    type(f_node_ptr_t), dimension (:), allocatable :: f_node_ptr2
contains
    <Cascades2: dag options: TBP>
end type dag_options_t

<Cascades2: dag options: TBP>≡
procedure :: final => dag_options_final

<Cascades2: sub interfaces>+≡
module subroutine dag_options_final (dag_options)
    class(dag_options_t), intent(inout) :: dag_options
end subroutine dag_options_final

<Cascades2: procedures>+≡
module subroutine dag_options_final (dag_options)
    class(dag_options_t), intent(inout) :: dag_options
    integer :: i
    call dag_options%string%final ()
    if (allocated (dag_options%f_node_ptr1)) then
        do i=1, size (dag_options%f_node_ptr1)
            dag_options%f_node_ptr1(i)%node => null ()
        end do
        deallocate (dag_options%f_node_ptr1)
    end if
    if (allocated (dag_options%f_node_ptr2)) then
        do i=1, size (dag_options%f_node_ptr2)
            dag_options%f_node_ptr2(i)%node => null ()
        end do
        deallocate (dag_options%f_node_ptr2)
    end if
end subroutine dag_options_final

```

A pair of two daughters (which can be `dag_nodes` or `dag_options`) is represented by the type `dag_combination_t`. In the original string, a `dag_combination` appears between parentheses, which contain a comma, but not a colon. If we find a colon between these parentheses, it is a `dag_node` instead.

```

<Cascades2: types>+≡
type :: dag_combination_t
    integer :: string_len
    type(dag_string_t) :: string

```

```

        integer, dimension (2) :: combination
        type(f_node_ptr_t), dimension (:), allocatable :: f_node_ptr1

        call dag%combination(i)%final ()
      end do
      deallocate (dag%combination)
    end if
  end subroutine dag_final

```

We construct the DAG from the given `dag_string` which is modified several times so that in the end the remaining string corresponds to a simple `dag_node`, the root of the factorized tree. This means that we first identify the leaves, i.e. outgoing particles. Then we identify `dag_nodes`, `dag_combinations` and `options` until the number of these objects does not change any more. Identifying means that we add a corresponding object to the array (if not yet present), which can be identified with the corresponding substring, and replace the substring in the original `dag_string` by a `dag_token` of the corresponding type (in the char output of this token, this corresponds to a place holder like e.g. '<O23>' which in this particular case corresponds to an option and can be found at the position 23 in the array). The character output of the substrings turns out to be very useful for debugging.

Identify `dag_nodes` and `dag_combinations`. Leaves are simply nodes (i.e. of type `NODE_TK`) where only one bit in the bincode is set. The `dag_nodes` and `dag_combinations` have in common that they are surrounded by parentheses. There is however a way to distinguish between them because the corresponding substring contains a colon (or `dag_token` with type `COLON_TK`) if it is a `dag_node`. Otherwise it is a `dag_combination`. The string of the `dag_node` or `dag_combination` should not contain curly braces, because these correspond to `dag_options` and should be identified before.

```

<Cascades2: dag: TBP>+=

```

For a given `dag_node` we want to create all `f_nodes`. If the node is not a leaf, it contains in its string placeholders for options or combinations. For these objects there are similar subroutines which are needed here to obtain the sets of daughter nodes. If the `dag_node` is a leaf, it corresponds to an external particle and the token contains the particle name.

In `dag_options_make_f_nodes_single` we obtain all `f_nodes` for `dag_nodes` which correspond to a set of rival subtrees or nodes, which is the first possibility for which `dag_options` can appear. In `dag_options_make_f_nodes_pair` the options are rival pairs (`daughter1`, `daughter2`). Therefore we have to pass two allocatable arrays of type `f_node_ptr_t` to the subroutine.

We create all combinations of daughter `f_nodes` for a combination. In the combination each daughter can be either a single `dag_node` or `dag_options` which are a set of single `dag_nodes`. Therefore, we first create all possible `f_nodes` for daughter1, then all possible `f_nodes` for daughter2. In the end we combine all daughter1 nodes with all daughter2 nodes.

```

Here we create the **feyngraphs**. After the construction of the **dag** the remaining **dag_string** should contain a token for a single **dag_node** which corresponds to the roots of the **feyngraphs**. Therefore we make all **f_nodes** for this **dag_node** and create a **feyngraph** for each **f_node**. Note that only 3-vertices are accepted. All other vertices are rejected. The starting point is the last dag node which has been added to the list, since this corresponds to the root of the tree. It is important to understand that the structure of feyngraphs is not the same as the structure of the dag which is read from file, because for the calculations which are performed in this module we want to reuse the nodes for the outgoing particles, which means that they appear only once. In O'Mega's output, it is the first incoming particle which appears only once and the outgoing particles appear many times. This transition is incorporated in the subroutines which create **f_nodes** from the different dag objects.

```

For a given `feyngraph` we create all possible `kingraphs`. Here we use existing `k_nodes` which have already been created when the mapping calculations of the pure s-channel subgraphs are performed. The nodes for the incoming particles or the nodes on the t-line will have to be created in all cases because they are not used in several graphs. To obtain the existing `k_nodes`, we use the subroutine `k_node_init_from_f_node` which itself uses `f_node_list_get_nodes` to obtain all active `k_nodes` in the `k_node_list` of the `f_node`. The created `kingraphs` are attached to the linked list of the `feyngraph`. For scattering processes we have to split up the t-line, because since all graphs are represented as a decay, different nodes can share daughter nodes. This happens also for the t-line or the incoming particle which appears as an outgoing particle. For the `t_line` or `incoming` nodes we do not want to recycle nodes but rather create a copy of this line for each `kingraph`.

```

```

The graphs resulting from `k_node_init_from_f_node` are fine if they are used only in one direction. This is however not the case when one wants to invert the graphs, i.e. take the other incoming particle of a scattering process as the decaying particle, because the outgoing `f_nodes` (and hence also the `k_nodes`) exist only once. This problem is solved here by creating a distinct t-line for each of the graphs. The following subroutine disentangles the data structure by creating new nodes such that the different t-lines are not connected any more.

(*Cascades2: procedures*) +=

```

recursive subroutine split_up_t_lines (t_node)
    type(k_node_ptr_t), dimension(:), intent(inout) :: t_node
    type(k_node_t), pointer :: ref_node => null ()
    type(k_node_t), pointer :: ref_daughter => null ()

```

```

type(k_node_t), pointer :: new_daughter => null ()

        new_daughter%daughter2 => ref_daughter%daughter2
        if (ref_daughter_index == 1) then
          ref_node%daughter1 => new_daughter
        else if (ref_daughter_index == 2) then
          ref_node%daughter2 => new_daughter
        end if
        ref_daughter => new_daughter
      end if
    end do
  else
    return
  end if
end do
call split_up_t_lines (t_daughter)
deallocate (t_daughter)
end subroutine split_up_t_lines

```

This subroutine sets the `inverse_daughters` of a `k_node`. If we invert a `kingraph` such that not the first but the second incoming particle appears as the root of the tree, the `incoming` and `t_line` particles obtain other daughters. These are the former mother node and the sister node `s_daughter`. Here we set only the pointers for the `inverse_daughters`. The inversion happens in `kingraph_make_inverse_copy` and `node_inverse_deep_copy`.

(*Cascades2: procedures*) +=

```

subroutine kingraph_set_inverse_daughters (kingraph)
  type(kingraph_t), intent(inout) :: kingraph
  type(k_node_t), pointer :: mother
  type(k_node_t), pointer :: t_daughter

```

```

type(k_node_t), pointer :: s_daughter
mother => kingraph%root
do while (associated (mother))
  if (associated (mother%daughter1) .and. &
      associated (mother%daughter2)) then
    if (mother%daughter1%t_line .or. mother%daughter1%incoming) then
      t_daughter => mother%daughter1; s_daughter => mother%daughter2
    else if (mother%daughter2%t_line .or. mother%daughter2%incoming) then
      t_daughter => mother%daughter2; s_daughter => mother%daughter1
    else

    end if
    t_daughter%inverse_daughter1 => mother
    t_daughter%inverse_daughter2 => s_daughter
    mother => t_daughter
  else
    exit
  end if
end do
end subroutine kingraph_set_inverse_daughters

```

Set the bincode of an `f_node` which corresponds to an external particle. This is done on the basis of the `particle_label` which is a substring of the input file. Here it is not the particle name which is important, but the number(s) in brackets which in general indicate the external particles which are connected to the current node. This function is however only used for external particles, so there can either be one or `n_out + 1` particles in the brackets (in the DAG input file always one, because also for the root there is only a single number). In all cases we check the number of particles (in the DAG input the numbers are separated by a slash).

(*Cascades2: procedures*) \equiv

```

function f_node_get_external_bincode (feyngraph_set, f_node) result (bincode)
  type(feyngraph_set_t), intent(in) :: feyngraph_set
  type(f_node_t), intent(in) :: f_node

```

19.11.13 Mapping calculations

Once a `k_node` and its subtree nodes have been created, we can perform the kinematical calculations and assign mappings, depending on the particle properties and the results for the subtree nodes. This could in principle be done recursively, calling the procedure first for the daughter nodes and then perform the calculations for the actual node. But for parallization and comparing the nodes, this will be done simultaneously for all nodes with the same number of subtree nodes, and the number of subtree nodes increases, starting from one, in steps of two. The actual mapping calculations are done in complete analogy to cascades.

```

(Cascades2: procedures) +=

end subroutine kinggraph_compute_mappings_t_line

```

Perform the kinematical calculations and mapping assignment for a node which is either `incoming` or `t_line`. This is done recursively, going first to the daughter node which has this property. Therefore we first set the pointer `t_node` to this daughter node and `s_node` to the other one. The mapping determination happens again in the same way as in `cascades`.

(Cascades2: procedures) +=

```

After all pure s-channel subdiagrams have already been created from the corresponding `f_nodes` and mappings have been determined for their nodes, we complete the calculations here. In a first step, the `kingraphs` have to be created on the basis of the existing `k_nodes`, which means in particular that a `feyngraph` can give rise to several `kingraphs` which will all be attached to the linked list of the `feyngraph`. The calculations which remain are of different kinds for decay and scattering processes. In a decay process the kinematical calculations have to be done for the `root` node. In a scattering process, after the creation of `kingraphs` in the first step, there will be only `kingraphs` with the first incoming particle as the `root` of the tree. For these graphs the `inverse` variable has the value `.false..` Before performing any calculations on these graphs we make a so-called inverse copy of the graph (see below), which will also be attached to the linked list. Since the s-channel subgraph calculations have already been completed, only the t-line computations remain.

```

<Cascades2: feyngraph: TBP>+≡
  procedure :: make_inverse_kingraphs => feyngraph_make_inverse_kingraphs

```

Here we control the mapping calculations for the nodes of s-channel subgraphs. We start with the nodes with the smallest number of subtree nodes and always increase this number by two because nodes have exactly zero or two daughter nodes. We create the `k_nodes` using the `k_node_list` of each `f_node`. The number of nodes which have to be created depends of the number of existing daughter nodes, which means that we have to create a node for each combination of existing and valid (the ones which we keep) daughter nodes. If the node corresponds to an external particle, we create only one node, since there are no daughter nodes. If the particle is not external and the daughter `f_nodes` do not contain any valid `k_nodes`, we do not create a new `k_nodes` either. When the calculations for all nodes with the same number of subtree nodes have been completed, we compare the valid nodes to eliminate equivalences (see below).

```

19.11.14 Fill the grove list

Find the **grove** within the **grove_list** for a **kingraph** for which the kinematical calculations and mapping assignments have been completed. The **groves** are defined by the **grove_prop** entries and the value of the resonance hash (**res_hash**). Whenever a matching grove does not exist, we create one. In a first step we consider only part of the grove properties (see **grove_prop_match**) and the resonance hash is ignored, which leads to a preliminary grove list. In the end all numbers in **grove_prop** as well as the resonance hash are compared, i.e. we create a new **grove_list**.

```

```

19.11.15 Remove equivalent channels

Here we define the equivalence condition for completed **kingraphs**. The aim is to keep those **kingraphs** which describe the strongest peaks of the amplitude. The **bincodes** and **mappings** have to be the same for an equivalence, but the **pdgs** can be different. At the same time we check if the trees are exactly the same (up to the sign of **pdg** codes) in which case we do not keep both of them. This can be the case when the incoming particles are the same or their mutual anti-particles and there are no t-channel lines in the Feynman diagram to which the kingraph belongs.

```

<Cascades2: parameters>+≡

end function kinggraph_eqv

```

Select between two **kingraphs** which fulfill the equivalence condition above. This is done by comparing the **pdg** values of the **tree** for increasing bincode. If the particles are different at some place, we usually choose the one which would be returned first by the subroutine **match_vertex** of the model for the daughter **pdg** codes. Since we work here only on the basis of the **trees** of the completed **kingraphs**, we have to use the **bc** array to determine the positions of the daughter nodes' entries in the array. The graph which has to be kept should correspond to the stronger peak at the place which is compared.

(*Cascades2: procedures*) $\vdash\equiv$

```

```

At the beginning we do not care about the resonance hash, but only about part of the grove properties, which is defined in `grove_prop_match`. In these resulting preliminary groves the kingraphs can be equivalent, i.e. we do not have to compare all graphs with each other but only all graphs within each of these preliminary groves. In the end we create a new grove list where the grove properties of the `kingraphs` within a `grove` have to be exactly the same and in addition the groves are distinguished by the resonance hash values. Here the kingraphs are not compared any more, which means that the number of channels is not reduced any more.

19.11.17 Invert a graph

All Feynman diagrams given by O'Mega look like a decay. The `feyngraph` which is constructed from this output also looks like a decay, where one of the incoming particles is the decaying particle (or the root of the tree). The calculations can in principle be done on this data structure. However, it is also performed with the other incoming particle as the root. The first part of the calculation is the same for both cases. For the second part we need to transform/turn the graphs such that the other incoming particle becomes the root. This is done by identifying the incoming particles from the O'Mega output (the first one is simply the root of the existing tree, the second contains [2] in the `particle_label`) and the nodes/particles which connect both incoming particles (here we set `t_line`

= .true.). At the same time we set the pointers `inverse_daughter1` and `inverse_daughter2` for the corresponding node, which point to the mother node and the other daughter of the mother node; these will be the daughters of the node in the inverted `feyngraph`.

```

```

Find the phase space parametrizations. We start with the computation of pure s-channel subtrees, i.e. we determine mappings and compare subtrees in order to reduce the number of channels. This can be parallelized easily. When all s-channel `k_nodes` exist, the possible `kingraphs` are created using these nodes and we determine mappings for t-channel nodes.

(*Cascades2: procedures*) +=

19.12 WOOD phase space

This is the module that interfaces the `phs_forests` phase-space treatment and the `cascades` module for generating phase-space channels. As an extension of the `phs_base` abstract type, the phase-space configuration and instance implement the standard API.

(Currently, this is the only generic phase-space implementation of WHIZARD. For trivial two-particle phase space, there is `phs_wood` as an alternative.)

19.12.3 Phase-space configuration

We read the phase-space configuration from the stored I/O unit. If this is not set, we assume that we have to generate a phase space configuration. When done, we open a scratch file and write the configuration.

If `rebuild` is set, we should trash any existing phase space file and build a new one. Otherwise, we try to use an old one, which we check for existence and integrity. If `ignore_mismatch` is set, we reuse an existing file even if it does not match the current setup.

```

<PHS wood: phs wood config: TBP>+≡

```

```

The MD5 sum of the forest is computed in addition to the MD5 sum of the configuration. The reason is that the forest may depend on a user-provided external file. On the other hand, this MD5 sum encodes all information that is relevant for further processing. Therefore, the `get_md5sum` method returns this result, once it is available.

Create filenames according to standard conventions. The `id` is the process name including the suffix `_iX` where `X` stands for the component identifier (an integer). The `run_id` may be set or unset.

The convention for file names that include the run ID is to separate prefix, run ID, and any extensions by dots. We construct the file name by concatenating the individual elements accordingly. If there is no run ID, we nevertheless replace `_iX` by `.iX`.

```

19.12.5 Evaluation

We compute the outgoing momenta from the incoming momenta and the input parameter set `r_in` in channel `r_in`. We also compute the `r` parameters and Jacobians `f` for all other channels.

We do *not* need to apply a transformation from/to the c.m. frame, because in `phs_base` the momenta are already boosted to the c.m. frame before assigning them in the `phs` object, and inversely boosted when extracting them.

```

The boost to the center-of-mass system only has a reasonable meaning above the threshold. Below the threshold, we do not apply boost at all, so that the top quarks stay in the rest frame. However, with top quarks exactly at rest, problems arise in the matrix elements (e.g. in the computation of angles). Therefore, we apply a boost which is not exactly 1, but has a tiny value differing from that.

This routine computes the bounds of the Dalitz region for massive emitters. The corresponding derivation can be found in 1202.0465, App. A. It is also used for the POWHEG matching so the routine is public. The input parameter `m2` corresponds to the squared mass of the emitter.

```

```

Very soft or collinear phase-space points can become a problem for matrix elements providers, as some scalar products cannot be evaluated properly. Here, a nonsensical result can spoil the whole integration. We therefore check the scalar products appearing to be below a certain tolerance.

Naturally, this happens very rarely but for some processes, setting `?test_coll_limit = true` and/or `?test_soft_limit = true` leads to all phase space points being discarded by this routine.

The fks phase space type contains the wood phase space and separately the in- and outgoing momenta for the real process and the corresponding Born momenta. Additionally, there are the variables ξ, ξ_{max}, y and ϕ which are used to create the real phase space, as well as the jacobian and its corresponding soft and collinear limit. Lastly, the array `ch_to_em` connects each channel with an emitter.

19.13.1 Creation of the real phase space - FSR

At this point, the Born phase space has been generated, as well as the three random variables ξ , y and ϕ . The question is how the real phase space is generated for a final-state emission configuration. We work with two different sets of momenta, the Born configuration $\{\bar{k}_\oplus, \bar{k}_\ominus, \bar{k}_1, \dots, \bar{k}_n\}$ and the real configuration $\{k_\oplus, k_\ominus, k_1, \dots, k_n, k_{n+1}\}$. We define the momentum of the emitter to be on the n -th position and the momentum of the radiated particle to be at position $n+1$. The magnitude of the spatial component of \mathbf{k} is denoted by \underline{k} .

For final-state emissions, it is $\bar{k}_\oplus = k_\oplus$ and $\bar{k}_\ominus = k_\ominus$. Thus, the center-of-mass systems coincide and it is

$$q = \sum_{i=1}^n \bar{k}_i = \sum_{i=1}^{n+1} k_i, \quad (19.65)$$

with $\vec{q} = 0$ and $q^2 = (q^0)^2$.

We want to construct the real phase space from the Born phase space using three random numbers. They are defined as follows:

- $\xi = \frac{2k_{n+1}^0}{\sqrt{s}} \in [0, \xi_{max}]$, where k_{n+1} denotes the four-momentum of the radiated particle.
- $y = \cos \theta = \frac{\vec{k}_n \cdot \vec{k}_{n+1}}{\underline{k}_n \underline{k}_{n+1}}$ is the splitting angle.
- The angle between the two splitting particles in the transversal plane, $\phi \in [0, 2\pi]$.

Further, $k_{rec} = \sum_{i=1}^{n-1} k_i$ denotes the sum of all recoiling momenta.

```

The momentum of the radiated particle is computed according to

$$\underline{k}_n = \frac{q^2 - M_{\text{rec}}^2 - 2q^0 \underline{k}_{n+1}}{2(q^0 - \underline{k}_{n+1}(1 - y))}, \quad (19.66)$$

with $k = k_n + k_{n+1}$ and $M_{\text{rec}}^2 = k_{\text{rec}}^2 = (q - k)^2$. Because of $\bar{\mathbf{k}}_n \parallel \mathbf{k}_n + \mathbf{k}_{n+1}$ we find $M_{\text{rec}}^2 = (q - \bar{\mathbf{k}}_n)^2$. Equation 19.66 follows from the fact that $(\mathbf{k} - \mathbf{k}_n)^2 =$

\mathbf{k}_{n+1}^2 , which is equivalent to $\mathbf{k}_n \cdot \mathbf{k} = \frac{1}{2}(\underline{k}_n^2 + \underline{k}^2 - \underline{k}_{n+1}^2)$.
 \mathbf{k}_n and \mathbf{k}_{n+1} are obtained by first setting up vectors parallel to $\bar{\mathbf{k}}_n$,

$$\mathbf{k}'_n = \underline{k}_n \frac{\bar{\mathbf{k}}_n}{\underline{k}_n}, \quad \mathbf{k}'_{n+1} = \underline{k}_{n+1} \frac{\bar{\mathbf{k}}_n}{\underline{k}_n},$$

and then rotating these vectors by an amount of $\cos \psi_n = \frac{\mathbf{k}_n \cdot \mathbf{k}}{\underline{k}_n \underline{k}}$. The emitted particle cannot have more momentum than the emitter has in the Born phase space. Thus, there is an upper bound for ξ , determined by the condition $k_{n+1}^0 = \underline{k}_n$, which is equal to

$$\xi_{\max} = \frac{2}{\underline{k}_n} q^0.$$

end function get_xi_max_fsr_massless
```

The computation of ξ_{\max} for massive emitters is described in arXiv:1202.0465. Let's recapitulate it here.

We consider the Dalitz-domain created by k_{n+1}^0 , k_n^0 and k_{rec}^0 and introduce the parameterization

$$k_n^0 = \bar{k}_n^0 - z k_{n+1}^0$$

Then, for each value of z , there exists a maximum value of \underline{k}_{n+1} from which ξ_{\max} can be extracted via $\xi_{\max} = 2k_{n+1}^0/q$. It is determined by the condition

$$\underline{k}_{n+1} \pm \underline{k}_n \pm \underline{k}_{\text{rec}} = 0.$$

This can be manipulated to yield

$$(\underline{k}_{n+1}^2 + \underline{k}_n^2 - \underline{k}_{\text{rec}}^2)^2 = 4\underline{k}_{n+1}^2 \underline{k}_n^2.$$

Here we can use $\underline{k}_n^2 = (k_n^0)^2 - m^2$ and $\underline{k}_{\text{rec}}^2 = (q - k_n^0 - k_{n+1}^0)^2 - M_{\text{rec}}^2$, as well as the above parameterization of k_n^0 , to obtain

$$4\underline{k}_{n+1}^2 (2\underline{k}_{n+1} q z (1 - z) + q^2 z^2 - 2q \bar{k}_{\text{rec}}^0 z + M_{\text{rec}}^2) = 0.$$

Solving for k_{n+1}^0 gives

$$k_{n+1}^0 = \frac{2q \bar{k}_{\text{rec}}^0 z - q^2 z^2 - M_{\text{rec}}^2}{2q z (1 - z)}. \quad (19.67)$$

It is still open how to compute z . For this, consider that the right-hand-side of equation (19.67) vanishes for

$$z_{1,2} = \left(\bar{k}_{\text{rec}}^0 \pm \sqrt{(\bar{k}_{\text{rec}}^0)^2 - M_{\text{rec}}^2} \right) / q,$$

which corresponds to the borders of the Dalitz-region where the gluon momentum vanishes. Thus we define

$$z = z_2 - \frac{1}{2}(z_2 - z_1)(1 + y).$$

The real phase space for an initial-state emission involved in a decay process is generated by first setting the gluon momentum like in the scattering case by using its angular coordinates y and ϕ and then adjusting the gluon energy with ξ . The emitter momentum is kept identical to the Born case, i.e. $p_{\text{in}} = \bar{p}_{\text{in}}$, so that after the emission it has momentum $p_{\text{virt}} = p_{\text{in}} - p_g$ and invariant mass $m^2 = p_{\text{virt}}^2$. Note that the final state momenta have to remain on-shell, so that $p_1^2 = \bar{p}_1^2 = m_1^2$ and $p_2^2 = \bar{p}_2^2 = m_2^2$. Let Λ be the boost from into the rest frame of the emitter after emission, i.e. $\Lambda p_{\text{virt}} = (m, 0, 0, 0)$. In this reference frame, the spatial components of the final-state momenta sum up to zero, and their magnitude is

$$p = \frac{\sqrt{\lambda(m^2, m_1^2, m_2^2)}}{2m},$$

a fact already used in the evaluation of the phase space trees of `phs_forest`. Obviously, from this, the final-state energies can be deferred via $E_i^2 = m_i^2 - p^2$. In the next step, the $p_{1,2}$ are set up as vectors $(E, 0, 0, \pm p)$ along the z-axis and then rotated about the same azimuthal and polar angles as in the Born system. Finally, the momenta are boosted out of the rest frame by multiplying with Λ .

Construction of the real momenta `p_real` in case of ISR. Follows the discussion in [0709.2092] sec. 5.1. The sequence of Lorentz boosts required to construct `p_real` from `p_born` is as follows:

- We construct the IS momenta of `p_real` from the Born momenta via rescaling: $\mathbf{p_real}(1:2) = \frac{x}{\bar{x}} \cdot \mathbf{p_born}(1:2)$. If the Born momenta are imported in the lab frame, these will define the real lab frame.
- We construct the momentum of the radiated particle in the real CMS: $k_{n+1} = \frac{s\xi}{2} \cdot (1, \sin(\theta) \sin(\phi), \sin(\theta) \cos(\phi), \cos(\theta))$
- 0. We first boost the momentum of the radiated particle from the real CMS to the real lab frame determined from `p_real(1:2)`.
- 1. We initialize the non-radiated real FS momenta by a longitudinal boost of `p_born` to a system with zero rapidity, i.e. zero longitudinal momentum. This is \mathbb{B}_L .
- 2. We boost these momenta in a transverse direction to compensate the transverse momentum of the radiation. This is \mathbb{B}_T . Note: we switched \mathbb{B}_T and \mathbb{B}_T^{-1} in Eq. (5.16) and their definition w.r.t. [0709.2092].
- 3. We restore longitudinal momentum conservation by applying the inverse boost of \mathbb{B}_L to all non-radiated real FS momenta.

This way, all components of `p_real` are constructed in the real Lab frame.

```

Get xi and y from an external routine (e.g. powheg) and generate the ISR phase space. For this, we need to overwrite all variables of the real kinematics dependent on (ξ, y, ϕ) that we need to compute p_{real} . From the `isr_kinematics` we just need `sqme_born` and `x`. Both do not depend on the real radiation so we can leave them as they are.
