31.4 POWHEG

This module generates radiation according to the POWHEG Sudakov form factor

$$\Delta^{f_b}(\Phi_n, p_T) = \prod_{\alpha_r \in \{\alpha_r | f_b\}} \Delta_{\alpha_r}^{f_b}(\Phi_n, p_T), \quad (31.1)$$

with

$$\Delta_{\alpha_r}^{f_b}(\Phi_n, p_T) = \exp \left\{ - \left[\int d\Phi_{\text{rad}} \frac{R(\Phi_{n+1})}{B^{f_b}(\Phi_n)} \theta(k_T(\Phi_{n+1}) - p_T) \right]_{\alpha_r}^{\bar{\Phi}_n^{\alpha_r} = \Phi_n} \right\} \quad (31.2)$$

We expect that an underlying Born flavor structure f_b has been generated with a probability proportional to its contribution to the \tilde{B} at the given kinematic point.

To generate the transverse momentum, we have to solve the equation

$$\frac{\Delta^{(U)}(p_T)}{\Delta^{(U)}(p_T^{\max})} = r_1$$

iteratively for p_T . In log space and with initially $\Delta^{(U)}(p_T^{\max}) = 1$, this is

$$\log \Delta^{(U)}(p_T) = \log r_1$$

If no solution is found, we set $p_T = p_T^{\min}$ to exit the event generation loop and generate an emissionless event. If a solution is found but the current emission is not accepted, we set $p_T = p_T^{\max}$ and thus in the next step it is $\Delta^{(U)}(p_T^{\max}) = r_1$, so that we have to solve the equation

$$\log \Delta^{(U)}(p_T) = \log r_1 + \log r_2$$

using another random number r_2 . We use `sum_log_rands` to remember the sum of the logarithms of all previous random numbers used for this event.

Generates the FKS variables (ξ, y, ϕ) and sets the emission hardness scale. In debug mode, we assert that the `pt2` saved in the `radiation_t` and the massive hardness scale are equal. This should hold as we compute `kt2` with the `y` we got from generating `pt2` so that this is a full circle. It then initiates the generation of the transverse momentum followed by a sequence of veto steps to get the

correct distribution.

The logarithmic integrated UBF in the eeqq case as explained in [0709.2092], eq. (7.98), is given by

$$\begin{aligned}
-\frac{1}{N} \log [\Delta^U(p_T)] &= 2\pi \int_0^{k_{\max}} \alpha_s(k_T) \log \left[\frac{4k_{\max}^2}{k_T^2} \right] \theta(k_T - p_T) \frac{dk_T}{k_T} \\
&= \frac{\pi}{b_0} \left(\log \left[\frac{4k_{\max}^2}{k_T^2} \right] \log \left[\frac{\log(k_{\max}^2/\Lambda^2)}{\log(p_T^2/\Lambda^2)} \right] - \log \left[\frac{k_{\max}^2}{p_T^2} \right] \right)
\end{aligned} \tag{31.7}$$

with $k_{\max} = \frac{q^0}{2}$. We see that for these logarithms to be well defined, we need to set a lower bound for the transverse momentum $p_{T,\min} > \Lambda = \text{lambda2_gen}$.

```

<POWHEG matching: sudakov eeqq fsr: TBP>+≡

  real(default) :: log_sudakov
  class(sudakov_eeqq_fsr_t), intent(in) :: sudakov
  real(default), intent(in) :: pt2
  real(default) :: kt2_max, Lambda2
  logical :: within_boundaries
  kt2_max = sudakov%kt2_max ()
  within_boundaries = pt2 >= sudakov%powheg_settings%pt2_min &
    .and. pt2 <= kt2_max
  if (within_boundaries) then
    Lambda2 = sudakov%process_deps%lambda2_gen
    log_sudakov = pi / b0rad () * ( log (4 * kt2_max / Lambda2) * &
      log (log (kt2_max/Lambda2) / log (pt2/Lambda2)) - log(kt2_max/pt2) )
  else
    log_sudakov = 0
  end if
end function sudakov_eeqq_fsr_log_integrated_ubf

```

In order to arrive at the log integrated Sudakov implemented in `sudakov_eeqq_fsr_log_integrated_ubf`, we overestimated

$$\log \left[\frac{1 + \sqrt{1 - (k_T/k_{\max})^2}}{1 - \sqrt{1 - (k_T/k_{\max})^2}} \right] \leq \log \left[\frac{4k_{\max}^2}{k_T^2} \right]. \quad (31.8)$$

We correct for this in this veto step. Additionally, we correct for overestimating α_s .

  end subroutine sudakov_massive_fsr_compute_xi_max_extended

```

As described in 1202.0465, App. A.5., for massive emitters, the radiation variable ξ is constructed as follows. First,

$$\xi_{\min}(K_T^2) = \frac{\sqrt{K_T^2 (K_T^2 z_2^2 + 8\bar{p}^0 q(1 - z_2)) - K_T^2 z_2}}{2q^2(1 - z_2)} \quad (31.12)$$

is computed where K_T is a hardness scale for the radiation that determines the upper limit of the integral for the Sudakov form factor and coincides with the usual one, i.e. the transverse momentum of the radiated particle, in the massless

limit. Then ξ_1 is computed according to the same equation with $z_2 \leftrightarrow z_1$. Finally, ξ is generated according to

$$\xi = \frac{1}{q^2} \left(\exp \left[\log (\xi_{\min} q^2 - K_T^2) + r \log \frac{\xi_m q^2 - K_T^2}{\xi_{\min} q^2 - K_T^2} \right] + K_T^2 \right), \quad (31.13)$$

where $\xi_m = \min (\xi_{\max}, \xi_1)$.

```

In order to arrive at the log integrated Sudakov implemented in `sudakov_isr_log_integrated_ubf`, we overestimated

$$\log \left[\frac{\sqrt{x_+ - \rho} + \sqrt{x_- - \rho}}{\sqrt{x_+ - \rho} - \sqrt{x_- - \rho}} \right] \leq \log \left[\frac{\sqrt{x_+} + \sqrt{x_-}}{\sqrt{x_+} - \sqrt{x_-}} \right] = \frac{1}{2} \log \left[\frac{k_T^2 + s_b}{k_T^2} \right] \leq \frac{1}{2} \log \left[\frac{q^2}{k_T^2} \right] \quad (31.18)$$

with

$$x_{\pm} = \left(\sqrt{1 + \frac{k_T^2}{s_b}} \pm \frac{k_T}{\sqrt{s_b}} \right)^2, \quad \rho = \frac{s_b}{S} \quad \text{and} \quad q^2 = k_{T,\max}^2 + s_b. \quad (31.19)$$

We correct for this in this veto step. Additionally, we correct for overestimating α_s .

```

We want to generate $x := 1 - \xi$ for the ISR UBF with probability density

$$f(x) = \frac{1}{\sqrt{(x_+ - x)(x_- - x)}}. \quad (31.21)$$

within the limits

$$\frac{s_b}{S} = x_{b,\oplus} x_{b,\ominus} = \rho \leq x \leq x_- = x_+ = \left(\sqrt{1 + \frac{k_T^2}{s_b}} - \frac{k_T}{\sqrt{s_b}} \right)^2. \quad (31.22)$$

To generate x according to the distribution

$$F(x) = \int f(x) dx = 2 \sinh^{-1} \left(\sqrt{\frac{x_- - x}{x_+ - x_-}} \right) \quad (31.23)$$

we use

$$x = x_- + (x_- - x_+) \sinh^2 \left(\frac{r_x}{2} \right) \quad (31.24)$$

with a random number $r_x \in \text{Unif}[F(x_-), F(\rho)] = \text{Unif} \left[0, 2 \sinh^{-1} \left(\sqrt{\frac{x_- - \rho}{x_+ - x_-}} \right) \right]$. Alternatively, an implementation making extended use of rejection sampling is available.

This is the last step of the Sudakov veto algorithm removing the dependence on the normalization factor $N(\xi_i, y_i)$ and the upper bounding function $U(\xi, y, \alpha_s)$ from the final result.

In cases where the Born kinematic failed the cuts, \mathcal{B} was artificially set to zero, so we cannot use it in a denominator. We assume that the generator cuts applied for parton showering are weak cuts to avoid divergent phase space regions, thus \mathcal{B} would have been large and the reweighting would have failed. Here, we can compute `sqme_real` directly with scale p_T but we still need to

correct sqme_born.

This routine implements the Sudakov veto algorithm as explained in [1002.2581], Sec. 7.1 and Bijans thesis, Sec. 3.3 and B.2. Here, we veto in order to correct for

1. an overestimation of parts of the upper bounding function for complicated UBFs in `reweight_ubf` as well as the usage of α_s^{rad} instead of α_s^{true} .
2. the usage of `xi_max_extended` instead of `xi_max` in `reweight_xi_max` which is only non-trivial for massive FSR and ISR.
3. using the maximum of the entire POWHEG normalization grid N_{max} when generating p_T instead of the correct bin value $N(\xi_i, y_i)$ in `reweight_norm`.
4. the normalization grid and the upper bounding function in the first place in `reweight_matrix_elements` to retrieve the correct fraction $\frac{\mathcal{R}(\xi, y) \mathcal{J}(\xi, y)}{\mathcal{B}}$.

By looping over all ALRs and in the end choosing the ALR with the largest `pt2`, we are effectively implementing the highest bid procedure. To save some time generating equivalent phase spaces again and again, we could instead loop over all radiation regions `i_phs`, take the sum of all real matrix elements in the Sudakov and in the end pick the ALR with probability proportional to the corresponding \mathcal{R}_{α_r} . We might implement this optimization in the future.

We need to compute `xi2_max` before `kt2_max` here. In the simple case, it is given by $\xi_{\text{max}} = \frac{s - M_{\text{rec}}^2}{s}$ but we can also take the ξ_{max} from the phase space computed before; they coincide. This is possible already at this point because in the simple case, ξ_{max} only depends on the Born momentum of the emitter and not on the real kinematics. In the eeqq case, $M_{\text{rec}} = 0$, so $\xi_{\text{max}} = 1$ and in the massive case as well as in the ISR case, we compute an extended $\xi_{\text{max}}^{\text{ext}}$ because the actual ξ_{max} depends on the real kinematics.

Retrieves the value of the norm for given ξ and y from the pre-computed POWHEG grid. To find the correct bin we need to map (ξ, y) in some way to $[0, 1]^2$. This mapping is to the most extend arbitrary. We choose $y \mapsto |y|$ and $\xi \mapsto \log(1 - \xi) / \log(1 - \xi_{max})$. It may be possible to improve these mappings to tune the performance for processes with expensive matrix elements.

31.4.4 α_s and its reweighting

The main point to ensure here is that the simple fixed-flavor-1-loop expression α_s^{rad} is larger than the more accurate α_s such that we can use a reweighting veto and use α_s^{rad} for the generation of the emission. This can be done by setting

$$\alpha_s^{\text{rad}}(\mu_0) = \alpha_s(\mu_0) \quad (31.25)$$

whereby μ_0^2 is the `scale_to_relate2` that is taken to be $(2\Lambda_{\overline{MS}}^{(5)})^2$.

```

31.4.5 POWHEG hook

We provide a POWHEG hook to be called by `process_instance_evaluate` to prefill the adaptation grid.

We store the actual `powheg` object, which does the computations.

```

<POWHEG matching: public>+≡
    public :: powheg_matching_hook_t

<POWHEG matching: types>+≡
    type, extends(process_instance_hook_t) :: powheg_matching_hook_t
    type(string_t) :: process_name
    type(powheg_matching_t) :: powheg
contains
    <POWHEG matching: powheg matching hook: TBP>
end type powheg_matching_hook_t

```

Init the hook. The init procedure will be called in `setup_process`, after everything is set up.

Additionally, we have to include `var_list` in order to retrieve the grid size in `xi` and `y`.

```

(POWHEG matching: powheg matching hook: TBP)≡
  procedure :: init => powheg_matching_hook_init

(POWHEG matching: sub interfaces)+≡
  module subroutine powheg_matching_hook_init (hook, var_list, &
    instance, pdf_data)
    class(powheg_matching_hook_t), intent(inout), target :: hook
    type(var_list_t), intent(in) :: var_list
    class(process_instance_t), intent(in), target :: instance
    type(pdf_data_t), intent(in), optional :: pdf_data
  end subroutine powheg_matching_hook_init

(POWHEG matching: procedures)+≡
  module subroutine powheg_matching_hook_init (hook, var_list, &
    instance, pdf_data)
    class(powheg_matching_hook_t), intent(inout), target :: hook
    type(var_list_t), intent(in) :: var_list
    class(process_instance_t), intent(in), target :: instance
    type(pdf_data_t), intent(in), optional :: pdf_data
    if (debug_on) call msg_debug (D_MATCHING, "powheg_matching_hook_init")
    hook%process_name = instance%get_process_name ()
    call hook%powheg%init (var_list, hook%process_name)
    hook%powheg%qcd = instance%get_qcd ()
    call hook%powheg%connect (instance)
    hook%powheg%process_deps%lab_is_cm = &
      hook%powheg%process_instance%lab_is_cm (1)

  end subroutine powheg_matching_hook_final

```

(POWHEG matching: powheg matching hook final: reduce)≡

Reduce all grids to a single grid by using MPI_MAX on each element.

(MPI: POWHEG matching: powheg matching hook final: reduce)≡

call hook%powheg%grid%mpi_reduce (MPI_MAX)

This routine fills each bin of the POWHEG normalization grid $\{\tilde{\xi}, \tilde{y}\}$ such that

$$N(\{\tilde{\xi}, \tilde{y}\}) = \max_{\forall \xi, y \in \{\tilde{\xi}, \tilde{y}\}} \frac{\mathcal{R}(\xi, y) \mathcal{J}(\xi, y)}{\mathcal{B} U(\xi, y, \alpha_s^{\text{true}})} \quad (31.26)$$

where $\mathcal{R}(\xi, y)$ is the real cross section `sqme_real`, \mathcal{B} is the Born cross section `sqme_born`, \mathcal{J} is the Jacobian and U the upper bounding function `ubf`.

For each underlying Born f_b , there is a number of radiation regions. A radiation region `rr` may correspond to multiple α_r s. The phase space only depends upon the radiation region kinematics `rr` and not on the specific α_r . α_r can be picked in the set $\{\alpha_r | f_b, rr\}$ proportional to their R_{α_r} . For now, we simplify things though and just work with the α_r .

References:

- [1002.2581], Sec. 7.1
- Bijans Thesis, Sec. 3.3 and B.2

In cases where just the Born kinematic failed the cuts, \mathcal{B} was artificially set to zero. Unfortunately, we lost information about the value of `sqme_born` in these cases but we assume that the generator cuts applied for parton showering are weak cuts to avoid divergent phase space regions, thus \mathcal{B} is large and does not influence N so we can skip these phase space points.

A more appropriate way to solve this problem of Born zeroes is given by the real partition. With real partition, there are two possible cases if $\mathcal{B} = 0$: if the real phase space point belongs to the real singular, the real kinematic is Born-like and very likely also fails the cuts. If the real kinematic is not Born-like, it belongs to the real finite. In both cases, it is $\mathcal{R} = \mathcal{B} = 0$ and we can safely skip the phase space point.

In cases where just the real kinematic failed the cuts, \mathcal{R} was artificially set to zero and we have no way to recover it. We skip these phase space points too. If we apply the same cuts during integration and event generation, these points are not relevant. We also skip points where either matrix element is negative. If just one of both is negative, their ratio is negative and thus cannot possibly be relevant for the grid. If both are negative, we are in an unphysical region for the PDFs. We also need to correct all scale dependences of `sqme_born` and `sqme_real` from the process' scale to p_T as this is the scale of the entire Sudakov. This affects the PDFs and also α_s .

In some phase space point, the quark PDF may vanish although the gluon PDF does not. This may lead to very large ratios \mathcal{R}/\mathcal{B} which may spoil the reweighting performance of the POWHEG grid. Excluding these values when filling the grid is a minor approximation with a huge performance gain. The PDF veto we perform is independent on the actual emitter to not artificially favor specific ALRs.

There are no Powheg unit tests so far.

Compare generated emission with Sudakov form factor

This is a nontrivial test of the generation algorithm and should be independent of the used upper bounding function (as long as all singularities are included).

It runs for an extensive amount of time generating a file `sudakov.dat` containing a histogram for the Sudakov factor in bins of the radiation's transverse momentum p_T^2 .

So far, it is only designed to work for lepton collisions without beam spectra and cuts. In its current state however, it fills the histogram with either 1 or NaN as the `p_hard` received in `term_instance_evaluate_interaction` is identically zero.

Chapter 32

Event Implementation

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

event_transforms Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

resonance_insertion Insert a resonance history into an event record, based on kinematical and matrix-element information.

recoil_kinematics Common kinematics routines for the ISR and EPA handlers.

isr_photon_handler Transform collinear kinematics, as it results from applying ISR radiation, to non-collinear kinematics with a reasonable transverse-momentum distribution of the radiated photons, and also of the recoiling partonic event.

epa_beam_handler For photon-initiated processes where the effective photon approximation is used in integration, to add in beam-particle recoil. Analogous to the ISR handler.

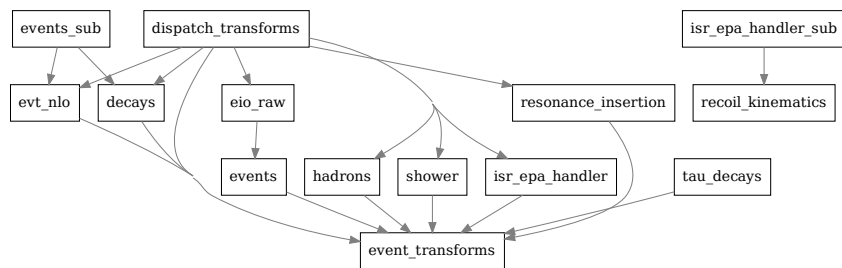

Figure 32.1: Module dependencies in `src/transforms`.

decays Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

showers Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

tau_decays (not implemented yet) Let τ leptons decay taking full spin correlations into account.

evt_nlo Handler for fixed-order NLO events.

events Combine all pieces to generate full events.

eio_raw Raw I/O for complete events.

32.1 Abstract Event Transforms

```

(event_transforms.f90)≡
  <File header>

  module event_transforms

    <Use kinds>
    <Use strings>
    use quantum_numbers, only: quantum_numbers_t
    use interactions
    use particles
    use model_data
    use rng_base
    use process, only: process_t
    use instances, only: process_instance_t
    use process_stacks

    <Standard module head>

    <Event transforms: public>

    <Event transforms: types>

    <Event transforms: interfaces>

    interface
    <Event transforms: sub interfaces>
    end interface

  end module event_transforms

```

```

<event_transforms_sub.f90>≡
  <File header>

  submodule (event_transforms) event_transforms_s

    use io_units
    use format_utils, only: write_separator
    use diagnostics
    use subevents

    implicit none

  contains

  <Event transforms: procedures>

  end submodule event_transforms_s

```

32.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified settings that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include `previous` and `next` pointers.

```

<Event transforms: public>≡
  public :: evt_t

<Event transforms: types>≡
  type, abstract :: evt_t
    type(process_t), pointer :: process => null ()
    type(process_instance_t), pointer :: process_instance => null ()
    class(model_data_t), pointer :: model => null ()
    class(rng_t), allocatable :: rng
    integer :: rejection_count = 0
    logical :: particle_set_exists = .false.
    type(particle_set_t) :: particle_set
    class(evt_t), pointer :: previous => null ()
    class(evt_t), pointer :: next => null ()
    logical :: only_weighted_events = .false.
  contains
  <Event transforms: evt: TBP>
  end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡

```

```

    procedure :: final => evt_final
    procedure :: base_final => evt_final
  <Event transforms: sub interfaces>≡
    module subroutine evt_final (evt)
      class(evt_t), intent(inout) :: evt
    end subroutine evt_final
  <Event transforms: procedures>≡
    module subroutine evt_final (evt)
      class(evt_t), intent(inout) :: evt
      if (allocated (evt%rng)) call evt%rng%final ()
      if (evt%particle_set_exists) &
        call evt%particle_set%final ()
    end subroutine evt_final

```

Print out the type of the evt.

```

  <Event transforms: evt: TBP>+≡
    procedure (evt_write_name), deferred :: write_name
  <Event transforms: interfaces>≡
    abstract interface
      subroutine evt_write_name (evt, unit)
        import
        class(evt_t), intent(in) :: evt
        integer, intent(in), optional :: unit
      end subroutine evt_write_name
    end interface
  <Event transforms: evt: TBP>+≡
    procedure (evt_write), deferred :: write
  <Event transforms: interfaces>+≡
    abstract interface
      subroutine evt_write (evt, unit, verbose, more_verbose, testflag)
        import
        class(evt_t), intent(in) :: evt
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: verbose, more_verbose, testflag
      end subroutine evt_write
    end interface

```

Output. We can print r.n.g. info.

```

  <Event transforms: evt: TBP>+≡
    procedure :: base_write => evt_base_write
  <Event transforms: sub interfaces>+≡
    module subroutine evt_base_write (evt, unit, testflag, show_set)
      class(evt_t), intent(in) :: evt
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: testflag, show_set
    end subroutine evt_base_write

```

<Event transforms: procedures>+≡

```

module subroutine evt_base_write (evt, unit, testflag, show_set)
  class(evt_t), intent(in) :: evt
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: testflag, show_set
  integer :: u
  logical :: show
  u = given_output_unit (unit)
  show = .true.; if (present (show_set)) show = show_set
  if (associated (evt%process)) then
    write (u, "(3x,A,A,A)") "Associated process: '", &
      char (evt%process%get_id ()), "'"
  end if
  if (allocated (evt%rng)) then
    call evt%rng%write (u, 1)
    write (u, "(3x,A,I0)") "Number of tries = ", evt%rejection_count
  end if
  if (show) then
    if (evt%particle_set_exists) then
      call write_separator (u)
      call evt%particle_set%write (u, testflag = testflag)
    end if
  end if
end subroutine evt_base_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

<Event transforms: evt: TBP>+≡

```

procedure :: connect => evt_connect
procedure :: base_connect => evt_connect

```

<Event transforms: sub interfaces>+≡

```

module subroutine evt_connect (evt, process_instance, model, process_stack)
  class(evt_t), intent(inout), target :: evt
  type(process_instance_t), intent(in), target :: process_instance
  class(model_data_t), intent(in), target :: model
  type(process_stack_t), intent(in), optional :: process_stack
end subroutine evt_connect

```

<Event transforms: procedures>+≡

```

module subroutine evt_connect (evt, process_instance, model, process_stack)
  class(evt_t), intent(inout), target :: evt
  type(process_instance_t), intent(in), target :: process_instance
  class(model_data_t), intent(in), target :: model
  type(process_stack_t), intent(in), optional :: process_stack
  evt%process => process_instance%process
  evt%process_instance => process_instance
  evt%model => model
  call evt%process%make_rng (evt%rng)
end subroutine evt_connect

```

Reset internal state.

```

(Event transforms: evt: TBP)+≡
  procedure :: reset => evt_reset
  procedure :: base_reset => evt_reset

(Event transforms: sub interfaces)+≡
  module subroutine evt_reset (evt)
    class(evt_t), intent(inout) :: evt
  end subroutine evt_reset

(Event transforms: procedures)+≡
  module subroutine evt_reset (evt)
    class(evt_t), intent(inout) :: evt
    evt%rejection_count = 0
    call evt%particle_set%final ()
    evt%particle_set_exists = .false.
  end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_prepare_new_event), deferred :: prepare_new_event

(Event transforms: interfaces)+≡
  interface
    subroutine evt_prepare_new_event (evt, i_mci, i_term)
      import
      class(evt_t), intent(inout) :: evt
      integer, intent(in) :: i_mci, i_term
    end subroutine evt_prepare_new_event
  end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)
      import
      class(evt_t), intent(inout) :: evt
      real(default), intent(inout) :: probability
    end subroutine evt_generate_weighted
  end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted

```

```

(Event transforms: sub interfaces)+≡
  module subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
  end subroutine evt_generate_unweighted

```

```

(Event transforms: procedures)+≡
  module subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set

```

```

(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_make_particle_set
  end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

(Event transforms: evt: TBP)+≡
  procedure :: set_particle_set => evt_set_particle_set

```

```

(Event transforms: sub interfaces)+≡
  module subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
    class(evt_t), intent(inout) :: evt
    type(particle_set_t), intent(in) :: particle_set
    integer, intent(in) :: i_term, i_mci
  end subroutine evt_set_particle_set

```

(Event transforms: procedures)+≡

```

module subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
  class(evt_t), intent(inout) :: evt
  type(particle_set_t), intent(in) :: particle_set
  integer, intent(in) :: i_term, i_mci
  call evt%prepare_new_event (i_mci, i_term)
  evt%particle_set = particle_set
  evt%particle_set_exists = .true.
end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. We need two interactions, one with color summed over, the `int_matrix`, and one with the probability distributed among flows, the `int_flows`.

We use the two values from the random number generator saved in `r` for factorizing the state. For testing purposes, we can provide those numbers explicitly.

The optional `qn_select` allows to limit the number of quantum numbers to choose from when factorizing. If only a single set of quantum numbers is given, it effectively dictates the quantum numbers chosen for the event.

(Event transforms: evt: TBP)+≡

```

procedure :: factorize_interactions => evt_factorize_interactions

```

(Event transforms: sub interfaces)+≡

```

module subroutine evt_factorize_interactions &
  (evt, int_matrix, int_flows, factorization_mode, &
   keep_correlations, r, qn_select)
  class(evt_t), intent(inout) :: evt

    call evt%tag_incoming ()
else
    call msg_bug ("Event factorization: event is incomplete")
end if
end subroutine make_factorized_particle_set

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event

transforms. If this is not true for a transform (say, MPI), it should override this method.

```

<Event transforms: evt: TBP>+≡
    procedure :: tag_incoming => evt_tag_incoming

<Event transforms: sub interfaces>+≡
    module subroutine evt_tag_incoming (evt)
        class(evt_t), intent(inout) :: evt

        call evt%particle_set%reset_status (in_index, PRT_INCOMING)
    end subroutine evt_tag_incoming

```

32.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The **generate** methods do nothing.

```

<Event transforms: public>+≡
    public :: evt_trivial_t

<Event transforms: types>+≡
    type, extends (evt_t) :: evt_trivial_t
    contains
    <Event transforms: evt trivial: TBP>
    end type evt_trivial_t

<Event transforms: evt trivial: TBP>≡
    procedure :: write_name => evt_trivial_write_name

<Event transforms: sub interfaces>+≡
    module subroutine evt_trivial_write_name (evt, unit)
        class(evt_trivial_t), intent(in) :: evt
        integer, intent(in), optional :: unit
    end subroutine evt_trivial_write_name

<Event transforms: procedures>+≡
    module subroutine evt_trivial_write_name (evt, unit)
        class(evt_trivial_t), intent(in) :: evt
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Event transform: trivial (hard process)"
    end subroutine evt_trivial_write_name

```

```
end subroutine evt_trivial_write_name
```

The finalizer is trivial. Some output:

```
<Event transforms: evt trivial: TBP>+≡
  procedure :: write => evt_trivial_write

<Event transforms: sub interfaces>+≡
  module subroutine evt_trivial_write &
    (evt, unit, verbose, more_verbose, testflag)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, more_verbose, testflag
  end subroutine evt_trivial_write

<Event transforms: procedures>+≡
  module subroutine evt_trivial_write &
    (evt, unit, verbose, more_verbose, testflag)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, more_verbose, testflag
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    call evt%write_name (u)
    call write_separator (u)
    call evt%base_write (u, testflag = testflag)
    !!! More readable but wider output; in line with evt_resonance_write
    !   if (verbose .and. evt%particle_set_exists) then
    !     call evt%particle_set%write &
    !       (u, summary = .true., compressed = .true., testflag = testflag)
    !     call write_separator (u)
    !   end if
  end subroutine evt_trivial_write
```

Nothing to do here:

```
<Event transforms: evt trivial: TBP>+≡
  procedure :: prepare_new_event => evt_trivial_prepare_new_event

<Event transforms: sub interfaces>+≡
  module subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
  end subroutine evt_trivial_prepare_new_event

<Event transforms: procedures>+≡
  module subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
  end subroutine evt_trivial_prepare_new_event
```

The weighted generator is, surprisingly, trivial.

```
<Event transforms: evt trivial: TBP>+≡
  procedure :: generate_weighted => evt_trivial_generate_weighted
```

```

<Event transforms: sub interfaces>+≡
  module subroutine evt_trivial_generate_weighted (evt, probability)
    class(evt_trivial_t), intent(inout) :: evt
    real(default), intent(inout) :: probability
  end subroutine evt_trivial_generate_weighted

```

```

<Event transforms: procedures>+≡
  module subroutine evt_trivial_generate_weighted (evt, probability)
    class(evt_trivial_t), intent(inout) :: evt
    real(default), intent(inout) :: probability
    probability = 1
  end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is. Note that it is a potential risk to tolerate a non-existent particle set at this point. We should remove it once the flavors are determined correctly in all cases. It is currently necessary if we are keeping failed events `?keep_failed_events = .true.` For these events, we do not compute the matrix elements, so the factorization fails trying to determine the quantum numbers. Additionally, it is necessary for the trivial event transformation preceding the event transformations required for POWHEG matching.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: make_particle_set => evt_trivial_make_particle_set

```

```

<Event transforms: sub interfaces>+≡
  module subroutine evt_trivial_make_particle_set &
    (evt, factorization_mode, keep_correlations, r)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_trivial_make_particle_set

```

```

<Event transforms: procedures>+≡
  module subroutine evt_trivial_make_particle_set &
    (evt, factorization_mode, keep_correlations, r)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    call make_factorized_particle_set (evt, factorization_mode, &
      keep_correlations, r)
    evt%particle_set_exists = .true.
  end subroutine evt_trivial_make_particle_set

```

```

Here we take the particle set from the previous event transform and apply the hadronization. The result is stored in the `evt%hadrons` object. We always return a probability of unity as we don't have the analytic weight of the hadronization. Invalid events have to be discarded by the caller which is why we mark the particle set as invalid.

```

32.3.2 Set contained data

Insert the resonance data, in form of a pre-generated resonance history set. Accumulate the number of histories for each set, to initialize an array of index offsets for lookup.

```

<Resonance insertion: evt resonance: TBP>+≡
    procedure :: set_resonance_data => evt_resonance_set_resonance_data

<Resonance insertion: sub interfaces>+≡
    module subroutine evt_resonance_set_resonance_data (evt, res_history_set)
        class(evt_resonance_t), intent(inout) :: evt
        type(resonance_history_set_t), dimension(:), intent(in) :: res_history_set
    end subroutine evt_resonance_set_resonance_data

<Resonance insertion: procedures>+≡
    module subroutine evt_resonance_set_resonance_data (evt, res_history_set)
        class(evt_resonance_t), intent(inout) :: evt
        type(resonance_history_set_t), dimension(:), intent(in) :: res_history_set
        integer :: i
        evt%res_history_set = res_history_set
        allocate (evt%index_offset (size (evt%res_history_set)), source = 0)
        do i = 2, size (evt%res_history_set)
            evt%index_offset(i) = &
                evt%index_offset(i-1) + evt%res_history_set(i-1)%get_n_history ()
        end do
    end subroutine evt_resonance_set_resonance_data

```

Set the library that contains the resonant subprocesses.

```

<Resonance insertion: evt resonance: TBP>+≡
    procedure :: set_library => evt_resonance_set_library

<Resonance insertion: sub interfaces>+≡
    module subroutine evt_resonance_set_library (evt, libname)
        class(evt_resonance_t), intent(inout) :: evt
        type(string_t), intent(in) :: libname
    end subroutine evt_resonance_set_library

<Resonance insertion: procedures>+≡
    module subroutine evt_resonance_set_library (evt, libname)
        class(evt_resonance_t), intent(inout) :: evt
        type(string_t), intent(in) :: libname
        evt%libname = libname
    end subroutine evt_resonance_set_library

```

Assign pointers to subprocess instances. Once a subprocess has been selected, the instance is used for generating the particle set with valid quantum-number assignments, ready for resonance insertion.

```

<Resonance insertion: evt resonance: TBP>+≡
    procedure :: set_subprocess_instances &
        => evt_resonance_set_subprocess_instances

<Resonance insertion: sub interfaces>+≡
    module subroutine evt_resonance_set_subprocess_instances (evt, instance)
        class(evt_resonance_t), intent(inout) :: evt
        type(process_instance_ptr_t), dimension(:), intent(in) :: instance
    end subroutine evt_resonance_set_subprocess_instances

```

```

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_set_subprocess_instances (evt, instance)
    class(evt_resonance_t), intent(inout) :: evt
    type(process_instance_ptr_t), dimension(:), intent(in) :: instance
    evt%instance = instance
  end subroutine evt_resonance_set_subprocess_instances

```

Set the on-shell limit, the relative distance from a resonance that is still considered to be on-shell. The probability for being considered on-shell can be reduced by the turnoff parameter below. For details, see the `resonances` module.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_on_shell_limit => evt_resonance_set_on_shell_limit

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_set_on_shell_limit (evt, on_shell_limit)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_limit
  end subroutine evt_resonance_set_on_shell_limit

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_set_on_shell_limit (evt, on_shell_limit)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_limit
    evt%on_shell_limit = on_shell_limit
  end subroutine evt_resonance_set_on_shell_limit

```

Set the Gaussian on-shell turnoff parameter, the width of the weighting factor for the resonance squared matrix element. If the resonance is off shell, this factor reduces the weight of the matrix element in the selector, such that the probability for considered resonant is reduced. The factor is applied only if the offshellness is less than the `on_shell_limit` above. For details, see the `resonances` module.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_on_shell_turnoff => evt_resonance_set_on_shell_turnoff

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_set_on_shell_turnoff (evt, on_shell_turnoff)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_turnoff
  end subroutine evt_resonance_set_on_shell_turnoff

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_set_on_shell_turnoff (evt, on_shell_turnoff)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_turnoff
    evt%on_shell_turnoff = on_shell_turnoff
  end subroutine evt_resonance_set_on_shell_turnoff

```

Reweight (suppress) the background contribution if there is a resonance history that applies. The event will be registered as background if there is no applicable resonance history, or if the background configuration has been selected based on (reweighted) squared matrix elements.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_background_factor => evt_resonance_set_background_factor

```

```

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_set_background_factor &
    (evt, background_factor)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: background_factor
  end subroutine evt_resonance_set_background_factor

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_set_background_factor (evt, background_factor)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: background_factor
    evt%background_factor = background_factor
  end subroutine evt_resonance_set_background_factor

```

32.3.3 Selector

Manually import a random-number generator object. This should be done only for testing purposes. The standard procedure is to `connect` a process to an event transform; this will create an appropriate `rng` from the RNG factory in the process object.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: import_rng => evt_resonance_import_rng

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_import_rng (evt, rng)
    class(evt_resonance_t), intent(inout) :: evt
    class(rng_t), allocatable, intent(inout) :: rng
  end subroutine evt_resonance_import_rng

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_import_rng (evt, rng)
    class(evt_resonance_t), intent(inout) :: evt
    class(rng_t), allocatable, intent(inout) :: rng
    call move_alloc (from = rng, to = evt%rng)
  end subroutine evt_resonance_import_rng

We use a standard selector object to choose from the available resonance histories. If the selector is inactive, we do not insert resonances.

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: write_selector => evt_resonance_write_selector

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_write_selector (evt, unit, testflag)
    class(evt_resonance_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
  end subroutine evt_resonance_write_selector

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_write_selector (evt, unit, testflag)
    class(evt_resonance_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: u

```

```

u = given_output_unit (unit)
if (evt%selector_active) then
    call evt%selector%write (u, testflag)
else
    write (u, "(1x,A)") "Selector: [inactive]"
end if
end subroutine evt_resonance_write_selector

```

The selector is initialized with relative weights of histories which need not be normalized. Channels with weight zero are ignored.

The `offset` will normally be -1 , so we count from zero, and zero is a valid result from the selector. Selecting the zero entry implies no resonance insertion. However, this behavior is not hard-coded here (without offset, no resonance is not possible as a result).

```

<Resonance insertion: evt resonance: TBP>+≡
    procedure :: init_selector => evt_resonance_init_selector

<Resonance insertion: sub interfaces>+≡
    module subroutine evt_resonance_init_selector (evt, weight, offset)
        class(evt_resonance_t), intent(inout) :: evt
        real(default), dimension(:), intent(in) :: weight
        integer, intent(in), optional :: offset
    end subroutine evt_resonance_init_selector

<Resonance insertion: procedures>+≡
    module subroutine evt_resonance_init_selector (evt, weight, offset)
        class(evt_resonance_t), intent(inout) :: evt
        real(default), dimension(:), intent(in) :: weight
        integer, intent(in), optional :: offset
        if (any (weight > 0)) then
            call evt%selector%init (weight, offset = offset)
            evt%selector_active = .true.
        else
            evt%selector_active = .false.
        end if
    end subroutine evt_resonance_init_selector

```

Return all selector weights, for inspection. Note that the index counts from zero.

```

<Resonance insertion: evt resonance: TBP>+≡
    procedure :: get_selector_weights => evt_resonance_get_selector_weights

<Resonance insertion: sub interfaces>+≡

```

32.3.4 Runtime calculations

Use the associated master process instance and the subprocess instances to distribute the current momentum set, then compute the squared matrix elements weights for all subprocesses.

NOTE: Procedures in this subsection are not covered by unit tests in this module, but by unit tests of the `restricted_subprocesses` module.

Fill the particle set, so the momentum configuration can be used by the subprocess instances. The standard workflow is to copy from the previous particle set.

```

<Resonance insertion: evt resonance: TBP>+≡
    procedure :: fill_momenta => evt_resonance_fill_momenta

<Resonance insertion: sub interfaces>+≡
    module subroutine evt_resonance_fill_momenta (evt)
        class(evt_resonance_t), intent(inout) :: evt
    end subroutine evt_resonance_fill_momenta

<Resonance insertion: procedures>+≡
    module subroutine evt_resonance_fill_momenta (evt)
        class(evt_resonance_t), intent(inout) :: evt
        integer :: i, n
        if (associated (evt%previous)) then
            evt%particle_set = evt%previous%particle_set
        else if (associated (evt%process_instance)) then
            ! this branch only for unit test
            call evt%process_instance%get_trace &
                (evt%particle_set, i_term=1, n_incoming=evt%process%get_n_in ())
        end if
    end subroutine evt_resonance_fill_momenta

```

Return the indices of those subprocesses which can be considered on-shell. The result depends on the stored particle set (outgoing momenta) and on the on-shell limit value.

The index `evt%selected_component` identifies the particular history set that corresponds to the given process component. Recall that process components may have different external particles, so they have distinct history sets.

```

end subroutine evt_resonance_apply_turnoff_factor

```

We use the calculations of resonant matrix elements to determine probabilities for all applicable resonance configurations. This method combines the steps implemented above.

First, we determine the selected process component.

TODO: the version below selects the first component which is found active. This make sense only for standard LO process components, where exactly one component corresponds to a MCI set.

For the selected process component, we query the kinematics and determine the applicable resonance histories. We collect squared matrix elements for those resonance histories and compare them to the master-process squared matrix element.

The result is the probability for each resonance history together with the probability for non-resonant background (zeroth entry). The latter is defined as the difference between the complete process result and the sum of the resonances, ignoring the possibility for interference. If the complete process result is actually undershooting the sum of resonances, we nevertheless count the background with positive probability.

When looking up the subprocess sqme, we must add the `index_offset` to the resulting array, since the indices returned by the individual history set all count from one, while the subprocess instances that belong to process components are collected in one flat array.

After determining matrix elements and background, we may reduce the weight of the matrix elements in the selector by applying a turnoff factor.

The factor `background_factor` indicates whether to include the background contribution at all, as long as there is a nonvanishing resonance contribution. Note that instead of setting background to zero, we just multiply it by a very small number. This ensures that indices are assigned correctly, and that background will eventually be selected if smooth turnoff is chosen.

```

  end subroutine evt_resonance_generate_weighted

```

Here take the current particle set and insert resonance intermediate states if applicable. The resonance history has already been chosen by the generator above. If no resonance history applies, just retain the particle set.

If a resonance history applies, we factorize the exclusive interaction of the selected (resonance-process) process instance. With a temporary particle set `pvt_set` as workspace, we then insert the resonances, reinstate parent-child relations and set colors and momenta for the resonances. The temporary is then copied back.

Taking the event data from the resonant subprocess instead of the master process, guarantees that all flavor, helicity, and color assignments are valid for the selected resonance history. Note that the transform may thus choose a quantum-number combination that is different from the one chosen by the master process.

The `i_term` value for the selected subprocess instance is always 1. We support only LO process. For those, the master process may have several terms (= components) that correspond to different external states. The subprocesses are distinct, each one corresponds to a definite master component, and by itself it consists of a single component/term.

However, if the selector chooses resonance history #0, i.e., no resonance, we just copy the particle set from the previous (i.e., trivial) event transform and ignore all subprocess data.

32.4.1 ϕ sampler

This is trivial. Generate an azimuthal angle, given a $(0,1)$ RNG parameter.

```

    <Recoil kinematics: procedures>≡
    elemental subroutine generate_phi_recoil (r, phi)
        real(default), intent(in) :: r
        real(default), intent(out) :: phi

        phi = r * twopi

    end subroutine generate_phi_recoil

```

32.4.2 Q^2 sampler

The dynamics of factorization suggests to generate a flat Q^2 distribution from a (random) number, event by event.

At the lowest momentum transfer values, the particle (electron) mass sets a smooth cutoff. The formula can produce Q values below the electron mass, down to zero, but with a power distribution that eventually evolves into the expected logarithmic distribution for $Q^2 > m^2$.

We are talking about the absolute value here, so all Q^2 values are positive. For the actual momentum transfer, $q^2 = -Q^2$.

```

    <Recoil kinematics: public>≡
    public :: generate_q2_recoil

    <Recoil kinematics: sub interfaces>≡
    elemental module subroutine generate_q2_recoil (s, x_bar, q2_max, m2, r, q2)
        real(default), intent(in) :: s
        real(default), intent(in) :: q2_max
        real(default), intent(in) :: x_bar
        real(default), intent(in) :: m2
        real(default), intent(in) :: r
        real(default), intent(out) :: q2
    end subroutine generate_q2_recoil

    <Recoil kinematics: procedures>+≡
    elemental module subroutine generate_q2_recoil (s, x_bar, q2_max, m2, r, q2)
        real(default), intent(in) :: s
        real(default), intent(in) :: q2_max
        real(default), intent(in) :: x_bar
        real(default), intent(in) :: m2

```

```

real(default), intent(in) :: r
real(default), intent(out) :: q2

real(default) :: q2_max_evt

q2_max_evt = q2_max_event (s, x_bar, q2_max)

q2 = m2 * (exp (r * log (1 + (q2_max_evt / m2))) - 1)

end subroutine generate_q2_recoil

```

The Q distribution is cut off from above by the kinematic limit, which depends on the energy that is available for the radiated photon, or by a user-defined cutoff – whichever is less. The kinematic limit fits the formulas for recoil momenta (see below), and it also implicitly enters the ISR collinear structure function, so the normalization of the distribution should be correct.

(Recoil kinematics: procedures)+≡

```

elemental function q2_max_event (s, x_bar, q2_max) result (q2)
  real(default), intent(in) :: s
  real(default), intent(in) :: x_bar
  real(default), intent(in) :: q2_max
  real(default) :: q2

  q2 = min (x_bar * s, q2_max)

end function q2_max_event

```

32.4.3 Kinematics functions

Given values for energies, $Q_{1,2}^2$, azimuthal angle, compute the matching polar angle of the radiating particle. The subroutine returns $\sin\theta$ and $\cos\theta$.

(Recoil kinematics: procedures)+≡

```

subroutine polar_angles (s, xb, rho, ee, q2, sin_th, cos_th, ok)
  real(default), intent(in) :: s
  real(default), intent(in) :: xb
  real(default), intent(in) :: rho

    end subroutine scaled_x

```

32.4.4 Iterative solution of kinematics constraints

Find a solution of the kinematics constraints. We know the parameters appropriate for collinear kinematics \sqrt{s} , $x_{1,2}^c$. We have picked values vor the momentum transfer $Q_{1,2}$ and the azimuthal angles $\phi_{1,2}$. The solution consists of modified energy fractions $x_{1,2}$ and polar angles $\theta_{1,2}$.

If the computation fails, which can happen for large momentum transfer, the flag `ok` will indicate this.

32.4.5 Generate recoil event

Combine the above kinematics calculations. First generate azimuthal angles and momentum transfer, solve kinematics and compute momenta for the radiated photons and the on-shell projected, recoiling partons.

The `mo` masses are used for the on-shell projection of the partons after radiation. They may be equal to `m`, or set to zero.

If `ok` is false, the data point has failed and we should repeat the procedure for a new set of RNG parameters `r`.

Transformation after recoil with on-shell momenta

Given a solution to recoil kinematics, compute the Lorentz transformation that transforms the old collinear parton momenta into the new parton momenta.

Compare the results for massless and massive on-shell projection.

32.5 Transverse momentum for the ISR and EPA approximations

The ISR and EPA handler takes an event with a single radiated collinear particle (photon for ISR, beam particle for EPA) for each beam, respectively, and inserts transverse momentum for both. The four-particle kinematics allows us to generate Q^2 and azimuthal angles independently, without violating energy-momentum conservation. The Q^2 distribution is logarithmic, as required by the effective particle approximation, and reflected in the inclusive ISR/EPA structure functions. We also conserve the invariant mass of the partonic system after radiation. The total transverse-momentum kick is applied in form of a Lorentz transformation to the elementary process, both in- and out-particles. In fact, the incoming partons (beam particle for ISR, photon for EPA) which would be virtual space-like in the exact kinematics configuration, are replaced by on-shell incoming partons, such that energy, momentum, and invariant mass \sqrt{s} are conserved.

Regarding kinematics, we treat all particles as massless. The beam-particle mass only appears as the parameter `isr_mass` or `epa_mass`, respectively, and cuts off the logarithmic distribution. The upper cutoff is `isr_q_max` (`epa_q_max`), which defaults to the available energy \sqrt{s} .

The only differences between ISR and EPA, in this context, are the particle types, and an extra \bar{x} factor in the lower cutoff for EPA, see below.

32.5.1 Event transform type

Convention: **beam** are the incoming partons before ISR – not necessarily the actual beams, need not be in c.m. frame. **radiated** are the radiated particles (photon for ISR), and **parton** are the remainders which initiate the elementary process. These particles are copied verbatim from the event record, and must be collinear.

The kinematical parameters are **sqrts** = invariant mass of the **beam** particles, **q_max** and **m** determining the Q^2 distribution, and **xc/xcb** as the energy fraction (complement) of the partons, relative to the beams.

Transformations: **lti** is the Lorentz transformation that would boost **pi** (c.m. frame) back to the original **beam** momenta (lab frame). **lto** is the recoil transformation, transforming the partons after ISR from the collinear frame to the recoiling frame. **lt** is the combination of both, which is to be applied to all particles after the hard interaction.

Momenta: **pi** are the beams transformed to their common c.m. frame. **ki** and **qi** are the photon/parton momenta in the **pi** c.m. frame. **km** and **qm** are the photon/parton momenta with the Q distribution applied, and finally **qo** are the partons **qm** projected on-shell.

32.5.5 Initialization

Manually import a random-number generator object. This should be done only for testing purposes. The standard procedure is to **connect** a process to an event transform; this will create an appropriate **rng** from the RNG factory in the process object.

```

<ISR/EPA handler: evt_isr: TBP>+≡
    procedure :: import_rng => evt_isr_epa_import_rng

<ISR/EPA handler: sub interfaces>+≡
    module subroutine evt_isr_epa_import_rng (evt, rng)
        class(evt_isr_epa_t), intent(inout) :: evt
        class(rng_t), allocatable, intent(inout) :: rng
    end subroutine evt_isr_epa_import_rng

<ISR/EPA handler: procedures>+≡
    module subroutine evt_isr_epa_import_rng (evt, rng)
        class(evt_isr_epa_t), intent(inout) :: evt
        class(rng_t), allocatable, intent(inout) :: rng
        call move_alloc (from = rng, to = evt%rng)
    end subroutine evt_isr_epa_import_rng

```

Set constant kinematics limits and initialize for ISR. Note that **sqrts** is used only as the fallback value for **q_max**. The actual **sqrts** value for the transform

object is inferred from the incoming particles, event by event.

```

<ISR/EPA handler: evt_isr: TBP>+≡
  procedure :: set_data_isr => evt_isr_epa_set_data_isr

<ISR/EPA handler: sub interfaces>+≡
  module subroutine evt_isr_epa_set_data_isr (evt, sqrts, q_max, m, keep_mass)
    class(evt_isr_epa_t), intent(inout) :: evt
    real(default), intent(in) :: sqrts
    real(default), intent(in) :: q_max
    real(default), intent(in) :: m

```

32.5.7 Two-parton recoil

For transforming partons into recoil momenta, we make use of the routines in the `recoil_kinematics` module. In addition to the collinear momenta, we use the x energy fractions, and four numbers from the RNG.

There is one subtle difference w.r.t. ISR case: the EPA mass parameter is multiplied by the energy fraction x , separately for each beam. This is the effective lower Q cutoff.

For certain kinematics, close to the Q_{\max} endpoint, this may fail, and `ok` is set to false. In that case, we should generate new recoil momenta for the same event. This is handled by the generic unweighting procedure.

```

<ISR/EPA handler: evt isr: TBP>+≡
    procedure, private :: generate_recoil => evt_generate_recoil
<ISR/EPA handler: sub interfaces>+≡
    module subroutine evt_generate_recoil (evt, ok)

  call evt%rng%generate (r)
  m = 0
  mo = 0
  do i = 1, 2
    select case (evt%rad_mode(i))
    case (BEAM_RAD_ISR)
      m(i) = evt%m(i)
      if (evt%isr_keep_mass) mo(i) = m(i)
    case (BEAM_RAD_EPA)
      m(i) = evt%xc(i) * evt%m(i)
    end select
  end do
  call generate_recoil (evt%sqrts, evt%q_max, m, mo, evt%xc, evt%xcb, r, &
    evt%km, evt%qm, evt%qo, ok)
end subroutine evt_generate_recoil

```

Replace the collinear radiated (incoming) parton momenta by the momenta that we have generated, respectively. Recall that the recoil has been applied in the c.m. system of the partons before ISR, so we apply the stored Lorentz transformation to boost them to the lab frame.

        call prt%set_momentum (evt%lti * evt%qo(i))
    end associate
end do
end subroutine replace_partons

```

32.5.8 Transform the event

Knowing the new incoming partons for the elementary process, we can make use of another procedure in `recoil_kinematics` to determine the Lorentz transformation that transforms the collinear frame into the frame with transverse momentum. We apply this transformation, recursively, to all particles that originate from those incoming partons in the original particle set.

We have to allow for the pre-ISR partons being not in their common c.m. frame. Taking into account non-commutativity, we actually have to first transform the outgoing particles to that c.m. frame, then apply the recoil transformation, then boost back to the lab frame.

The `mask` keep track of particles that we transform, just in case the parent-child tree is multiply connected.

```

<ISR/EPA handler: evt_isr: TBP>+≡
    procedure :: transform_outgoing => evt_transform_outgoing

<ISR/EPA handler: sub interfaces>+≡
    module subroutine evt_transform_outgoing (evt)
        class(evt_isr_epa_t), intent(inout) :: evt
    end subroutine evt_transform_outgoing

32.6.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

<Decays: types>≡
  type, abstract :: any_config_t
    private
    contains
    <Decays: any config: TBP>
  end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
  procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
  interface
    subroutine any_config_final (object)
      import
      class(any_config_t), intent(inout) :: object
    end subroutine any_config_final
  end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
  procedure (any_config_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_config_write (object, unit, indent, verbose)
      import
      class(any_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
    end subroutine any_config_write
  end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_config_t
  private
    class(any_config_t), allocatable :: c
  end type particle_config_t

```

32.6.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above.

```

<Decays: types>+≡
  type, abstract :: any_t
  private
    contains
    <Decays: any: TBP>
  end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final

<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
      class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write

```

```

<Decays: interfaces>+=
  interface
    subroutine any_write (object, unit, indent)
      import
      class(any_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
    end subroutine any_write
  end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+=
  type :: particle_out_t
  private
    class(any_t), allocatable :: c
  end type particle_out_t

```

32.6.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+=
  type :: decay_term_config_t
  private
    type(particle_config_t), dimension(:), allocatable :: prt
  contains
    <Decays: decay term config: TBP>
  end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>=
  procedure :: final => decay_term_config_final

<Decays: sub interfaces>=
  recursive module subroutine decay_term_config_final (object)
    class(decay_term_config_t), intent(inout) :: object
  end subroutine decay_term_config_final

<Decays: procedures>=
  recursive module subroutine decay_term_config_final (object)
    class(decay_term_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%prt)) then
      do i = 1, size (object%prt)
        if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
      end do
    end if
  end subroutine decay_term_config_final

```

Output, with optional indentation

```

<Decays: decay term config: TBP>+≡
    procedure :: write => decay_term_config_write

<Decays: sub interfaces>+≡
    recursive module subroutine decay_term_config_write &
        (object, unit, indent, verbose)
        class(decay_term_config_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent

        end do
    end subroutine decay_term_generate

```

32.6.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```
<Decays: public>≡
    public :: decay_root_config_t

<Decays: types>+≡
    type :: decay_root_config_t
    private
        type(string_t) :: process_id
        type(process_t), pointer :: process => null ()
        class(model_data_t), pointer :: model => null ()
        type(decay_term_config_t), dimension(:), allocatable :: term_config
    contains
        <Decays: decay root config: TBP>
    end type decay_root_config_t
```

The finalizer is recursive since there may be cascade decays.

```
<Decays: decay root config: TBP>≡
    procedure :: final => decay_root_config_final

<Decays: sub interfaces>+≡
    recursive module subroutine decay_root_config_final (object)
        class(decay_root_config_t), intent(inout) :: object
    end subroutine decay_root_config_final

<Decays: procedures>+≡
    recursive module subroutine decay_root_config_final (object)
        class(decay_root_config_t), intent(inout) :: object
        integer :: i
        if (allocated (object%term_config)) then
            do i = 1, size (object%term_config)
                call object%term_config(i)%final ()
            end do
        end if
    end subroutine decay_root_config_final
```

The output routine is also recursive, and it contains an adjustable indentation.

```

        call decay%term_config(i)%init (flv, stable, model, process_stack, var_list)
    end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore `intent(out)`.

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

For the unstable particles, we have to check whether their masses match between the production and the decay. Fortunately, both versions are available for comparison.

The optional `var_list` argument may override integral/error values for decay processes.

```

```

32.6.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```

<Decays: types>+≡
  type, abstract :: decay_gen_t
  private
    type(decay_term_t), dimension(:), allocatable :: term
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
  contains
    <Decays: decay gen: TBP>
  end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

<Decays: public>+≡
  public :: decay_root_t

<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_root_t
  private
    type(decay_root_config_t), pointer :: config => null ()
  contains
    <Decays: decay root: TBP>
  end type decay_root_t

```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```

<Decays: decay gen: TBP>≡
  procedure :: base_final => decay_gen_final

<Decays: sub interfaces>+≡
  recursive module subroutine decay_gen_final (object)
    class(decay_gen_t), intent(inout) :: object
  end subroutine decay_gen_final

<Decays: procedures>+≡
  recursive module subroutine decay_gen_final (object)
    class(decay_gen_t), intent(inout) :: object
    integer :: i
    if (allocated (object%term)) then
      do i = 1, size (object%term)
        call object%term(i)%final ()
      end do
    end if
  end subroutine decay_gen_final

```

```
end subroutine decay_gen_final
```

No extra finalization for the decay root.

```
<Decays: decay root: TBP>≡
  procedure :: final => decay_root_final

<Decays: sub interfaces>+≡
  module subroutine decay_root_final (object)
    class(decay_root_t), intent(inout) :: object

    end if
  end subroutine decay_root_generate

```

32.6.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

The flavor component should be identical to the flavor component of the parent particle (`unstable` object).

```

<Decays: types>+≡
  type, extends (decay_root_config_t) :: decay_config_t
  private
    type(flavor_t) :: flv
    real(default) :: weight = 0
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: mci_selector
  contains
    <Decays: decay config: TBP>
  end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
  procedure :: write => decay_config_write

<Decays: sub interfaces>+≡
  recursive module subroutine decay_config_write &
    (object, unit, indent, verbose)
    class(decay_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
  end subroutine decay_config_write

<Decays: procedures>+≡
  recursive module subroutine decay_config_write (object, unit, indent, verbose)
    class(decay_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent

    call write_indent (u, ind)
    write (u, 2) "branching ratio =", object%weight * 100
    call write_indent (u, ind)
    write (u, 1) "partial width   =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs)      =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel)     =", object%rel_error
  end subroutine decay_config_write

```

```

1  format (3x,A,ES19.12)
2  format (3x,A,F11.6,1x,'%')
   call object%write_terms (unit, indent, verbose)
end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should be used instead.

If there is an optional `var_list`, check if the stored values for the decay partial width and error have been overridden there.

```

<Decays: decay config: TBP>+≡
  procedure :: connect => decay_config_connect

<Decays: sub interfaces>+≡
  recursive module subroutine decay_config_connect &
    (decay, process, model, process_stack, process_instance, var_list)
    class(decay_config_t), intent(out) :: decay
    type(process_t), intent(in), target :: process

    else
      decay%rel_error = 0
    end if
  end subroutine decay_config_compute

```

32.6.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```
<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_t
  private
    type(decay_config_t), pointer :: config => null ()
    class(rng_t), allocatable :: rng
  contains
    <Decays: decay: TBP>
  end type decay_t
```

The finalizer is recursive.

```
<Decays: decay: TBP>≡
  procedure :: final => decay_final

<Decays: sub interfaces>+≡
  recursive module subroutine decay_final (object)
    class(decay_t), intent(inout) :: object
  end subroutine decay_final

<Decays: procedures>+≡
  recursive module subroutine decay_final (object)
    class(decay_t), intent(inout) :: object
    integer :: i
    call object%base_final ()
    do i = 1, object%config%process%get_n_mci ()
      call object%process_instance%final_simulation (i)
    end do
    call object%process_instance%final ()
    deallocate (object%process_instance)
  end subroutine decay_final
```

Output.

```
<Decays: decay: TBP>+≡
  procedure :: write => decay_write

<Decays: sub interfaces>+≡
  recursive module subroutine decay_write (object, unit, indent, recursive)
    class(decay_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent, recursive
  end subroutine decay_write

<Decays: procedures>+≡
  recursive module subroutine decay_write (object, unit, indent, recursive)
    class(decay_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent, recursive
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call object%config%write (unit, indent, verbose = .false.)
```

```

if (allocated (object%rng)) then
  call object%rng%write (u, ind + 1)
end if
call write_indent (u, ind)
if (object%selected_mci > 0) then
  write (u, "(3x,A,I0)") "Selected MCI    = ", object%selected_mci
else
  write (u, "(3x,A)") "Selected MCI    = [undefined]"
end if
call write_indent (u, ind)
if (object%selected_term > 0) then
  write (u, "(3x,A,I0)") "Selected term  = ", object%selected_term
  call object%term(object%selected_term)%write (u, ind + 1)
else
  write (u, "(3x,A)") "Selected term  = [undefined]"
end if
end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
  procedure :: init => decay_init

<Decays: sub interfaces>+≡
  recursive module subroutine decay_init (decay, config)
    class(decay_t), intent(out) :: decay
    type(decay_config_t), intent(in), target :: config
  end subroutine decay_init

<Decays: procedures>+≡
  recursive module subroutine decay_init (decay, config)

    end do
    call decay%config%process%make_rng (decay%rng)
    call decay%make_term_rng (decay%config%process)
  end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
  procedure :: link_interactions => decay_link_interactions

```

```

<Decays: sub interfaces>+≡
    recursive module subroutine decay_link_interactions (decay, i_prt, trace)
        class(decay_t), intent(inout) :: decay
        integer, intent(in) :: i_prt
        type(interaction_t), intent(in), target :: trace
    end subroutine decay_link_interactions

<Decays: procedures>+≡
    recursive module subroutine decay_link_interactions (decay, i_prt, trace)
        class(decay_t), intent(inout) :: decay
        integer, intent(in) :: i_prt
        type(interaction_t), intent(in), target :: trace
        type(interaction_t), pointer :: beam_int
        integer :: n_in, n_vir
        beam_int => decay%process_instance%get_beam_int_ptr ()
        n_in = trace%get_n_in ()
        n_vir = trace%get_n_vir ()
        call beam_int%set_source_link (1, trace, &
            n_in + n_vir + i_prt)
        call decay%link_term_interactions ()
    end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
    procedure :: select_chain => decay_select_chain

<Decays: sub interfaces>+≡
    recursive module subroutine decay_select_chain (decay)
        class(decay_t), intent(inout) :: decay
    end subroutine decay_select_chain

<Decays: procedures>+≡
    recursive module subroutine decay_select_chain (decay)
        class(decay_t), intent(inout) :: decay
        real(default) :: x
        integer :: i
        call decay%rng%generate (x)
        decay%selected_mci = decay%config%mc_selector%select (x)
        call decay%process_instance%choose_mci (decay%selected_mci)
        decay%selected_term = decay%process_instance%select_i_term ()
        do i = 1, size (decay%term)
            call decay%term(i)%select_chain ()
        end do
    end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account

for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

<Decays: decay: TBP>+≡
    procedure :: generate => decay_generate

<Decays: sub interfaces>+≡
    recursive module subroutine decay_generate (decay)
        class(decay_t), intent(inout) :: decay
    end subroutine decay_generate

<Decays: procedures>+≡
    recursive module subroutine decay_generate (decay)
        class(decay_t), intent(inout) :: decay
        type(isolated_state_t), pointer :: isolated_state
        integer :: i
        call decay%process_instance%receive_beam_momenta ()
        call decay%process_instance%generate_unweighted_event (decay%selected_mci)
        if (signal_is_pending ()) return
        call decay%process_instance%evaluate_event_data ()
        isolated_state => &
            decay%process_instance%get_isolated_state_ptr (decay%selected_term)
        call isolated_state%normalize_matrix_by_trace ()
        do i = 1, size (decay%term)
            call decay%term(i)%generate ()
            if (signal_is_pending ()) return
        end do
    end subroutine decay_generate

```

32.6.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```

<Decays: types>+≡
    type, extends (any_config_t) :: stable_config_t
    private
        type(flavor_t), dimension(:), allocatable :: flv
    contains
        <Decays: stable config: TBP>
    end type stable_config_t

```

The finalizer is empty:

```

<Decays: stable config: TBP>≡
    procedure :: final => stable_config_final

<Decays: sub interfaces>+≡
    module subroutine stable_config_final (object)
        class(stable_config_t), intent(inout) :: object
    end subroutine stable_config_final

<Decays: procedures>+≡
    module subroutine stable_config_final (object)
        class(stable_config_t), intent(inout) :: object
    end subroutine stable_config_final

```

Output.

```

<Decays: stable config: TBP>+=
  procedure :: write => stable_config_write

<Decays: sub interfaces>+=
  recursive module subroutine stable_config_write &
    (object, unit, indent, verbose)
    class(stable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
  end subroutine stable_config_write

<Decays: procedures>+=
  recursive module subroutine stable_config_write &
    (object, unit, indent, verbose)
    class(stable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"
    write (u, "(1x,A)", advance = "no") char (object%flv(1)%get_name ())
    do i = 2, size (object%flv)
      write (u, "(:',A)", advance = "no") &
        char (object%flv(i)%get_name ())
    end do
    write (u, *)
  end subroutine stable_config_write

```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```

<Decays: stable config: TBP>+=
  procedure :: init => stable_config_init

<Decays: sub interfaces>+=
  module subroutine stable_config_init (config, flv)

        type(stable_config_t), intent(in), target :: config
    end subroutine stable_init

```

```

<Decays: procedures>+≡
  module subroutine stable_init (stable, config)
    class(stable_t), intent(out) :: stable
    type(stable_config_t), intent(in), target :: config
    stable%config => config
  end subroutine stable_init

```

32.6.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: public>+≡
  public :: unstable_config_t

<Decays: types>+≡
  type, extends (any_config_t) :: unstable_config_t
    private
    type(flavor_t) :: flv
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: selector
    type(decay_config_t), dimension(:), allocatable :: decay_config
  contains
    <Decays: unstable config: TBP>
  end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
  procedure :: final => unstable_config_final

<Decays: sub interfaces>+≡
  recursive module subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
  end subroutine unstable_config_final

<Decays: procedures>+≡
  recursive module subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%final ()
      end do
    end if
  end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
  procedure :: write => unstable_config_write

<Decays: sub interfaces>+≡
  recursive module subroutine unstable_config_write &

  end subroutine unstable_generate
```

32.6.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```
<Decays: types>+≡
  type, extends (connected_state_t) :: decay_chain_entry_t
  private
  integer :: index = 0
  type(decay_config_t), pointer :: config => null ()
  integer :: selected_mci = 0
  integer :: selected_term = 0
  type(decay_chain_entry_t), pointer :: previous => null ()
end type decay_chain_entry_t
```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that

all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: public>+≡
    public :: decay_chain_t

<Decays: types>+≡
    type :: decay_chain_t
    private
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_term = 0
    type(evaluator_t) :: correlated_trace
    type(decay_chain_entry_t), pointer :: last => null ()
    contains
    <Decays: decay chain: TBP>
end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay chain: TBP>≡
    procedure :: final => decay_chain_final

<Decays: sub interfaces>+≡
    module subroutine decay_chain_final (object)
        class(decay_chain_t), intent(inout) :: object
    end subroutine decay_chain_final

<Decays: procedures>+≡
    module subroutine decay_chain_final (object)
        class(decay_chain_t), intent(inout) :: object
        type(decay_chain_entry_t), pointer :: entry
        do while (associated (object%last))
            entry => object%last
            object%last => entry%previous
            call entry%final ()
            deallocate (entry)
        end do
        call object%correlated_trace%final ()
    end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

<Decays: decay chain: TBP>+≡
    procedure :: write => decay_chain_write

<Decays: sub interfaces>+≡
    module subroutine decay_chain_write (object, unit)
        class(decay_chain_t), intent(in) :: object
        integer, intent(in), optional :: unit
    end subroutine decay_chain_write

```

```

<Decays: procedures>+≡

  end if
  int_last_decay => chain%last%get_matrix_int_ptr ()
  allocate (qn_mask (int_last_decay%get_n_tot ()))

```

```

    call qn_mask%init (mask_f = .true., mask_c = .true., mask_h = .true.)
    call chain%correlated_trace%init_qn_sum (int_last_decay, qn_mask)
end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable particles.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: sub interfaces>+≡
  recursive module subroutine decay_chain_build_term_entries (chain, term)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_term_t), intent(in) :: term
  end subroutine decay_chain_build_term_entries

<Decays: procedures>+≡
  recursive module subroutine decay_chain_build_term_entries (chain, term)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_term_t), intent(in) :: term
    integer :: i
    do i = 1, size (term%particle_out)
      select type (unstable => term%particle_out(i)%c)
        type is (unstable_t)
          if (unstable%selected_decay > 0) then
            call chain%build_decay_entries &
              (unstable%decay(unstable%selected_decay))
          end if
        end select
      end do
    end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

        resonant=.true.)
  end if
  chain%last => entry
  call chain%build_term_entries (decay%term(decay%selected_term))
end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

```

<Decays: decay chain: TBP>+≡
  procedure :: evaluate => decay_chain_evaluate

<Decays: sub interfaces>+≡

        call entry%evaluate_trace ()
        call entry%evaluate_event_data ()
      end if
    end subroutine evaluate
  end subroutine decay_chain_evaluate

```

Return the probability of a decay chain. This is given as the trace of the density matrix with intermediate helicity correlations, normalized by the product of the uncorrelated density matrix traces. This works only if an event has been evaluated and the `correlated_trace` evaluator is filled. By definition, this evaluator has only one matrix element, and this must be real.

```

<Decays: decay chain: TBP>+≡
  procedure :: get_probability => decay_chain_get_probability

<Decays: sub interfaces>+≡
  module function decay_chain_get_probability (chain) result (x)

    real(default) :: x
    x = real (chain%correlated_trace%get_matrix_element (1))
  end function decay_chain_get_probability

```

32.6.12 Decay as Event Transform

The `evt_decay` object combines decay configuration, decay tree, and chain in a single object, as an implementation of the `evt` (event transform) abstract type.

The `var_list` may be a pointer to the user variable list, which could contain overridden parameters for the decay processes.

```

<Decays: public>+≡

```

```

    public :: evt_decay_t

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations is under construction. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid. This procedure directly

takes the (MLM) matching into account.

32.9 Fixed Order NLO Events

This section deals with the generation of weighted event samples which take into account next-to-leading order corrections. An approach generating unweighted events is not possible here, because negative weights might occur due to subtraction. Note that the events produced this way are not physical in the sense

that they will not keep NLO-accuracy when interfaced to a parton shower. They are rather useful for theoretical consistency checks and a fast estimate of NLO effects.

We generate NLO events in the following way: First, the integration is carried out using the complete divergence-subtracted NLO matrix element. In the subsequent simulation, N -particle kinematics are generated using $\mathcal{B} + \mathcal{V} + \mathcal{C}$ as weight. After that, the program loops over all singular regions and for each of them generates an event with $N + 1$ -particle kinematics. The weight for those events corresponds to the real matrix element \mathcal{R}^α evaluated at the α -region's emitter's phase space point, multiplied with S_α . This procedure is implemented using the `evt_nlo` transform.

```

This event transformation is for the generation of fixed-order NLO events. It takes an event with Born kinematics and creates $N_\alpha + 1$ modified weighted events. The first one has Born kinematics and its weight is the sum of Born, virtual, subtraction and, if present, also DGLAP matrix elements. The other N_α events have a weight which is equal to the real matrix element, evaluated with the phase space corresponding to the emitter of the α -region.

As the NLO event transforms have different kinematics, they also differ in their `particle_sets`. The `NLO event_t` object carries a single pointer to a `particle_set`. To avoid interference between the different NLO `particle_sets`, we save the `particle_set` of the current α -region in the array `particle_set_nlo`. Otherwise it would be unretrievable if the usual particle set of the event object was used.

The event transform has a variable which counts the number of times it has already been called for one generation point. If this variable, `i_evaluation`, is zero, this means that `evt_nlo_generate_weighted` is called for the first time, so that the generation of an N -particle event is required. In all other cases, emission events are generated.

During a separate integration of the real component, the first event of each event group will become the counterevent. In this case, we return the sum of all subtraction matrix elements.

During a combined integration, the first event will be a combination of all Born-like events. To get the sum of their matrix elements, we subtract the sum of all real emissions from the sum of all matrix elements as the real contribution is the only non-Born contribution.

Note that the argument named `probability`, the use of the routine `generate_weighted` and the procedure we use to generate NLO events via an event transformation is an abuse of the interface which should be refactored.

The routine `make_factorized_particle_set` will setup the subevent momenta from the `connected%matrix`. Its initial state momenta correspond to the Born process without IS splitting and thus need to be updated with the real momenta from the `int_hard` to get correct momenta in the events with real radiation.

Ideally the `int_hard` and the `connected` would be setup with correct `source_links` to real momenta so that we would not need to replace momenta of the `connected` here.

The parameter `n_in` from the `int_matrix` is still 0 as it has been shifted to `n_vir`. We thus take `n_in` from the `particle_set`.

Boosts the given four vector `p_lab` to the Born or real CMS depending on the number of given momenta. Unfortunately, all boosts available via `get_boost_to_cms` are Born-like, so we need to compute the boost to the real CMS here manually. We cannot rely on `i_term` in order to determine whether to apply a Born-like or a real boost as we also need a real boost to compute the weights of the Born-like subevents as implemented in `evt_nlo_generate_weighted`.

Selects a flavor structure for Born subevents, such that each possible flavor structure is as probable as its portion of the sum of Born matrix elements over all flavors. For non-Born Born-like subevents, no Born matrix elements are available. We always choose `i_flv = 1` in this case. If all terms are active, i.e. in a full NLO calculation, the flavors of Born-like subevents will be distributed according to the Born matrix elements only, to avoid issues with matrix elements of different sign and assure a LO flavor distribution.

Likewise, the real-like event flavors are distributed according to the real matrix elements. Here, we need to make sure to not mix matrix elements from different real terms and instead determine the flavor for each subevent based on just the matrix elements for one of the terms. The implementation below assumes that in the sequence of NLO terms, the Born term is immediately followed by all the real terms which are again followed by the subtraction, the virtual and the DGLAP term.

Both flavor structures can be determined without correlation as the flavors will only become important for events to be matched to a parton shower and in this case we will only generate either a single Born-like or a single real-like event which are not part of an event group.

In case all subevents failed the cuts, all `sqmes` were set to 0 so we cannot determine the flavor in this way. In this case, we always choose the first flavor structure given by the matrix-element generator with `i_flv = 1`.

Ideally, having to choose a particle set here would not be necessary as it is also chosen in `particle_set_init_interaction` which in the current approach is disabled by supplying `qn_select` explicitly based on the flavors chosen here.

32.10.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The **safety_factor** reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The **sigma** and **n** values, if nontrivial, allow for reweighting the events according to the requested **norm_mode**.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the `event_expr_t` objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

```

32.10.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event_base` module. The core manages the main (dressed) particle set pointer and the current values for weights and `sqme`. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

The `sqme` and `weight` values mirror corresponding values in the `expr` sub-object. The idea is that when generating or reading events, the event record is filled first, then the `expr` object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the `expr` subobject. In particular, evaluating the event-selection expression sets the `passed` flag. Furthermore, the `expr` subobject collects data that can be used in the analysis and should be written to file, including copies of `sqme` and `weight`.

```

Output.

The event index is written in the header, it should coincide with the `event_index` variable that can be used in selection and analysis.

Particle set: this is a pointer to one of the event transforms, so it should suffice to print the latter.

32.10.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one. Gfortran 7/8/9 bug, has to remain in the main module:

```

<Events: event: TBP>+≡
    procedure :: basic_init => event_init

<Events: main procedures>≡
    subroutine event_init (event, var_list, n_alt)
        class(event_t), intent(out) :: event
        type(var_list_t), intent(in), optional :: var_list
        integer, intent(in), optional :: n_alt
        type(string_t) :: norm_string, mode_string
        logical :: polarized_events
        if (present (n_alt)) then
            call event%base_init (n_alt)
            call event%expr%init (n_alt)
        else
            call event%base_init (0)
        end if
        if (present (var_list)) then
            event%config%unweighted = var_list%get_lval (&
                var_str ("?unweighted"))
            norm_string = var_list%get_sval (&
                var_str ("sample_normalization"))
            event%config%norm_mode = &
                event_normalization_mode (norm_string, event%config%unweighted)
            polarized_events = &
                var_list%get_lval (var_str ("?polarized_events"))
            if (polarized_events) then
                mode_string = &
                    var_list%get_sval (var_str ("polarization_mode"))
                select case (char (mode_string))
                case ("ignore")
                    event%config%factorization_mode = FM_IGNORE_HELICITY
                case ("helicity")

```

```

        event%config%factorization_mode = FM_SELECT_HELICITY
    case ("factorized")
        event%config%factorization_mode = FM_FACTOR_HELICITY
    case ("correlated")
        event%config%factorization_mode = FM_CORRELATED_HELICITY
    case default
        call msg_fatal ("Polarization mode " &
            // char (mode_string) // " is undefined")
    end select
else
    event%config%factorization_mode = FM_IGNORE_HELICITY
end if
event%config%colorize_subevt = &
    var_list%get_lval (var_str ("?colorize_subevt"))
if (event%config%unweighted) then
    event%config%safety_factor = var_list%get_rval (&
        var_str ("safety_factor"))
end if
else
    event%config%norm_mode = NORM_SIGMA
end if
allocate (evt_trivial_t :: event%transform_first)
event%transform_last => event%transform_first
end subroutine event_init

```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

(Events: event: TBP)+≡

```

    procedure :: set_sigma => event_set_sigma
    procedure :: set_n => event_set_n

```

(Events: sub interfaces)+≡

```

    elemental module subroutine event_set_sigma (event, sigma)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: sigma
    end subroutine event_set_sigma
    elemental module subroutine event_set_n (event, n)
        class(event_t), intent(inout) :: event
        integer, intent(in) :: n
    end subroutine event_set_n

```

(Events: procedures)+≡

```

    elemental module subroutine event_set_sigma (event, sigma)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: sigma
        event%config%sigma = sigma
    end subroutine event_set_sigma

    elemental module subroutine event_set_n (event, n)
        class(event_t), intent(inout) :: event
        integer, intent(in) :: n
        event%config%n = n
    end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
  procedure :: import_transform => event_import_transform

<Events: sub interfaces>+≡
  module subroutine event_import_transform (event, evt)
    class(event_t), intent(inout) :: event
    class(evt_t), intent(inout), pointer :: evt
  end subroutine event_import_transform

<Events: procedures>+≡
  module subroutine event_import_transform (event, evt)
    class(event_t), intent(inout) :: event
    class(evt_t), intent(inout), pointer :: evt
    event%transform_last%next => evt
    evt%previous => event%transform_last
    event%transform_last => evt
    evt => null ()
  end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to **event** subobjects, therefore the **target** attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

<Events: sub interfaces>+≡
  module subroutine event_connect &
    (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
  end subroutine event_connect

<Events: procedures>+≡
  module subroutine event_connect &
    (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack

```

```

type(string_t) :: id
integer :: num_id
class(evt_t), pointer :: evt
event%process => process_instance%process
event%instance => process_instance
id = event%process%get_id ()
if (id /= "") call event%expr%set_process_id (id)
num_id = event%process%get_num_id ()
if (num_id /= 0) call event%expr%set_process_num_id (num_id)
call event%expr%setup_vars (event%process%get_sqrts ())
call event%expr%link_var_list (event%process%get_var_list_ptr ())
call event%process%make_rng (event%rng)
evt => event%transform_first
do while (associated (evt))
    call evt%connect (process_instance, model, process_stack)
    evt => evt%next
end do
end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

(Events: event: TBP)+≡

```

procedure :: set_selection => event_set_selection
procedure :: set_reweight => event_set_reweight
procedure :: set_analysis => event_set_analysis

```

(Events: sub interfaces)+≡

```

module subroutine event_set_selection (event, ef_selection)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_selection
end subroutine event_set_selection
module subroutine event_set_reweight (event, ef_reweight)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_reweight
end subroutine event_set_reweight
module subroutine event_set_analysis (event, ef_analysis)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_analysis
end subroutine event_set_analysis

```

(Events: procedures)+≡

```

module subroutine event_set_selection (event, ef_selection)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_selection
    allocate (event%config%ef_selection, source = ef_selection)
end subroutine event_set_selection

module subroutine event_set_reweight (event, ef_reweight)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_reweight
    allocate (event%config%ef_reweight, source = ef_reweight)
end subroutine event_set_reweight

module subroutine event_set_analysis (event, ef_analysis)
    class(event_t), intent(inout) :: event

```

```

class(expr_factory_t), intent(in) :: ef_analysis
allocate (event%config%ef_analysis, source = ef_analysis)
end subroutine event_set_analysis

```

Create evaluation trees from the parse trees. The `target` attribute is required because the expressions contain pointers to event subobjects.

```

<Events: event: TBP>+≡
  procedure :: setup_expressions => event_setup_expressions

<Events: sub interfaces>+≡
  module subroutine event_setup_expressions (event)
    class(event_t), intent(inout), target :: event
  end subroutine event_setup_expressions

<Events: procedures>+≡
  module subroutine event_setup_expressions (event)
    class(event_t), intent(inout), target :: event
    call event%expr%setup_selection (event%config%ef_selection)
    call event%expr%setup_analysis (event%config%ef_analysis)
    call event%expr%setup_reweight (event%config%ef_reweight)
    call event%expr%colorize (event%config%colorize_subevt)
  end subroutine event_setup_expressions

```

32.10.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

<Events: event: TBP>+≡
  procedure :: evaluate_transforms => event_evaluate_transforms

<Events: sub interfaces>+≡
  module subroutine event_evaluate_transforms (event, r)
    class(event_t), intent(inout) :: event
    real(default), dimension(:), intent(in), optional :: r
  end subroutine event_evaluate_transforms

<Events: procedures>+≡
  module subroutine event_evaluate_transforms (event, r)
    class(event_t), intent(inout) :: event
    real(default), dimension(:), intent(in), optional :: r
    class(evt_t), pointer :: evt
    real(default) :: weight_over_sqme
    integer :: i_term, emitter, n_in

```

```

    end if
  end subroutine event_check

```

32.10.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we accept the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
  procedure :: generate => event_generate

```

```

<Events: sub interfaces>+≡
  module subroutine event_generate (event, i_mci, r, i_nlo)

      event%selected_i_term = 0
      event%selected_channel = 0
    end if
  end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. The event reader may either read in the transformed event separately, or apply all event transforms to the hard particle set to (re)generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
  procedure :: set_hard_particle_set => event_set_hard_particle_set

<Events: sub interfaces>+≡
  module subroutine event_set_hard_particle_set (event, particle_set)

        else
            allocate (event%scale_forced, source = scale)
        end if
    end subroutine event_set_scale_forced

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have a `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

If `recover_phs` is set (and false), do not attempt any phase-space calculation, including MCI evaluation. Useful if we need only matrix elements.

(Events: event: TBP)+≡

32.11 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the `events` module which provides the concrete implementation of `event_base`. The other I/O formats access only the methods that are defined in `event_base`.

```
(eio_raw.f90)≡
  <File header>

  module eio_raw

    <Use kinds>
    <Use strings>
    use event_base
    use event_handles, only: event_handle_t
    use eio_data
    use eio_base
    use events

    <Standard module head>

    use particles

    implicit none

  contains
```

```
⟨EIO raw: procedures⟩
```

```
end submodule eio_raw_s
```

32.11.1 File Format Version

This is the current default file version.

```
⟨EIO raw: parameters⟩≡
```

```
integer, parameter :: CURRENT_FILE_VERSION = 2
```

The user may change this number; this should force some compatibility mode for reading and writing. In any case, the file version stored in a event file that we read has to match the expected file version.

History of version numbers:

1. Format for WHIZARD 2.2.0 to 2.2.3. No version number stored in the raw file.
2. Format from 2.2.4 on. File contains version number. The file contains the transformed particle set (if applicable) after the hard-process particle set.

32.11.2 Type

Note the file version number. The default may be reset during initialization, which should enforce some compatibility mode.

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

The `passed` flag is not written. This allow us to apply different selection criteria upon rereading.

```

Input an event.

Note: the particle set is physically copied. If there is a performance issue, we might choose to pointer-assign it instead, with a different version of `event%set_hard_particle_set`.

32.12 Dispatch

An event transform is responsible for dressing a partonic event. Since event transforms are not mutually exclusive but are concatenated, we provide individual dispatchers for each of them.

Due to the gfortran 7/8/9 bug that leads to segmentation violation if polymorphic user-defined derived types are allocated in routines within submodules, this module remains without submodule until we can switch to gfortran v10 or newer.

Initialize the ISR/EPA handler, depending on active settings.

The activation is independent for both handlers, since only one may be needed at a time. However, if both handlers are active, the current implementation requires the handler modes of ISR and EPA to coincide.

Chapter 33

Integration and Simulation

33.1 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```
(user_files.f90)≡  
  File header  
  
  module user_files  
  
    Use strings  
    use ifiles  
  
    Standard module head  
  
    User files: public  
  
    User files: types  
  
    User files: interfaces  
  
    interface  
    User files: sub interfaces  
    end interface  
  
  end module user_files  
  
(user_files_sub.f90)≡  
  File header  
  
  submodule (user_files) user_files_s  
  
    use io_units  
    use diagnostics  
    use analysis
```

```

        implicit none

contains

    <User files: procedures>

end submodule user_files_s

```

33.1.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```

<User files: types>≡
    type :: file_t
    private
    type(string_t) :: name
    integer :: unit = -1
    logical :: reading = .false.
    logical :: writing = .false.
    type(file_t), pointer :: prev => null ()
    type(file_t), pointer :: next => null ()
end type file_t

```

The initializer opens the file.

```

<User files: procedures>≡
    subroutine file_init (file, name, action, status, position)
    type(file_t), intent(out) :: file
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    file%unit = free_unit ()
    file%name = name
    open (unit = file%unit, file = char (file%name), &
        action = action, status = status, position = position)
    select case (action)
    case ("read")
        file%reading = .true.
    case ("write")
        file%writing = .true.
    case ("readwrite")
        file%reading = .true.
        file%writing = .true.
    end select
end subroutine file_init

```

The finalizer closes it.

```

<User files: procedures>+≡
    subroutine file_final (file)
    type(file_t), intent(inout) :: file
    close (unit = file%unit)
    file%unit = -1
end subroutine file_final

```

Check if a file is open with correct status.

<User files: procedures>+≡

```
function file_is_open (file, action) result (flag)
  logical :: flag
  type(file_t), intent(in) :: file
  character(*), intent(in) :: action
  select case (action)
  case ("read")
    flag = file%reading
  case ("write")
    flag = file%writing
  case ("readwrite")
    flag = file%reading .and. file%writing
  case default
    call msg_bug ("Checking file '" // char (file%name) &
      // "': illegal action specifier")
  end select
end function file_is_open
```

Return the unit number of a file for direct access. It should be checked first whether the file is open.

<User files: procedures>+≡

```
function file_get_unit (file) result (unit)
  integer :: unit
  type(file_t), intent(in) :: file
  unit = file%unit
end function file_get_unit
```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the **advancing** option.

<User files: procedures>+≡

```
subroutine file_write_string (file, string, advancing)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: string
  logical, intent(in), optional :: advancing
  if (file%writing) then
    if (present (string)) then
      if (present (advancing)) then
        if (advancing) then
          write (file%unit, "(A)") char (string)
        else
          write (file%unit, "(A)", advance="no") char (string)
        end if
      else
        write (file%unit, "(A)") char (string)
      end if
    else
      write (file%unit, *)
    end if
  else
    call msg_error ("Writing to file: File '" // char (file%name) &
```

```

        // " is not open for writing.")
    end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
subroutine file_write_ifile (file, ifile)
  type(file_t), intent(in) :: file
  type(ifile_t), intent(in) :: ifile
  type(line_p) :: line
  call line_init (line, ifile)
  do while (line_is_associated (line))
    call file_write_string (file, line_get_string_advance (line))
  end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
subroutine file_write_analysis (file, tag)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: tag
  if (file%writing) then
    if (present (tag)) then
      call analysis_write (tag, unit = file%unit)
    else
      call analysis_write (unit = file%unit)
    end if
  else
    call msg_error ("Writing analysis to file: File " // char (file%name) &
      // " is not open for writing.")
  end if
end subroutine file_write_analysis

```

33.1.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
  public :: file_list_t

<User files: types>+≡
  type :: file_list_t
    type(file_t), pointer :: first => null ()
    type(file_t), pointer :: last => null ()
  end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
  public :: file_list_final

```

```

<User files: sub interfaces>≡
    module subroutine file_list_final (file_list)
        type(file_list_t), intent(inout) :: file_list
    end subroutine file_list_final

```

```

<User files: procedures>+≡
    module subroutine file_list_final (file_list)
        type(file_list_t), intent(inout) :: file_list
        type(file_t), pointer :: current
        do while (associated (file_list%first))
            current => file_list%first
            file_list%first => current%next
            call file_final (current)
            deallocate (current)
        end do
        file_list%last => null ()
    end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```

<User files: procedures>+≡
    function file_list_get_file_ptr (file_list, name) result (current)
        type(file_t), pointer :: current
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        current => file_list%first
        do while (associated (current))
            if (current%name == name) return
            current => current%next
        end do
    end function file_list_get_file_ptr

```

Check if a file is open, public version:

```

<User files: public>+≡
    public :: file_list_is_open

<User files: sub interfaces>+≡
    module function file_list_is_open (file_list, name, action) result (flag)
        logical :: flag
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action
    end function file_list_is_open

<User files: procedures>+≡
    module function file_list_is_open (file_list, name, action) result (flag)
        logical :: flag
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action

33.2.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn, is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

33.2.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()

```

```

        type(parse_node_t), pointer :: fac_scale_expr => null ()
        type(parse_node_t), pointer :: ren_scale_expr => null ()
        type(parse_node_t), pointer :: weight_expr => null ()
        type(parse_node_t), pointer :: selection_lexpr => null ()
        type(parse_node_t), pointer :: reweight_expr => null ()
        type(parse_node_t), pointer :: analysis_lexpr => null ()
        type(parse_node_p), dimension(:), allocatable :: alt_setup
contains
  <RT data: rt parse nodes: TBP>
end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

  <RT data: rt parse nodes: TBP>≡
    procedure :: clear => rt_parse_nodes_clear

  <RT data: sub interfaces>≡
    module subroutine rt_parse_nodes_clear (rt_pn, name)

        call global%beam_structure%final_pol ()
        call global%beam_structure%final_mom ()
    end subroutine rt_data_clear_beams

```

33.2.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

```

<RT data: rt data: TBP>+≡
    procedure :: global_init => rt_data_global_init

<RT data: sub interfaces>+≡
    module subroutine rt_data_global_init (global, paths, logfile)
        class(rt_data_t), intent(out), target :: global
        type(paths_t), intent(in), optional :: paths
        type(string_t), intent(in), optional :: logfile
    end subroutine rt_data_global_init

<RT data: procedures>+≡
    module subroutine rt_data_global_init (global, paths, logfile)
        class(rt_data_t), intent(out), target :: global
        type(paths_t), intent(in), optional :: paths
        type(string_t), intent(in), optional :: logfile
        integer :: seed
        call global%os_data%init (paths)
    end subroutine rt_data_global_init

```

```

if (present (logfile)) then
  global%logfile = logfile
else
  global%logfile = ""
end if
allocate (global%out_files)
call system_clock (seed)
call global%var_list%init_defaults (seed, paths)
call global%init_pointer_variables ()
call global%process_stack%init_var_list (global%var_list)
end subroutine rt_data_global_init

```

33.2.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init

<RT data: sub interfaces>+≡
  module subroutine rt_data_local_init (local, global, env)
    class(rt_data_t), intent(inout), target :: local
    type(rt_data_t), intent(in), target :: global
    integer, intent(in), optional :: env
  end subroutine rt_data_local_init

<RT data: procedures>+≡
  module subroutine rt_data_local_init (local, global, env)
    class(rt_data_t), intent(inout), target :: local
    type(rt_data_t), intent(in), target :: global
    integer, intent(in), optional :: env
    local%context => global
    call local%process_stack%link (global%process_stack)
    call local%process_stack%init_var_list (local%var_list)
    call local%process_stack%link_var_list (global%var_list)
    call local%var_list%append_string (var_str ("model_name"), &
      var_str (""), intrinsic=.true.)
    call local%init_pointer_variables ()
    local%fallback_model => global%fallback_model
    local%os_data = global%os_data
    local%logfile = global%logfile
    call local%model_list%link (global%model_list)
    local%model => global%model
    if (associated (local%model)) then
      call local%model%link_var_list (local%var_list)
    end if
    if (allocated (global%event_callback)) then
      allocate (local%event_callback, source = global%event_callback)
    end if
  end subroutine rt_data_local_init

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
    procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: sub interfaces>+≡
    module subroutine rt_data_init_pointer_variables (local)
        class(rt_data_t), intent(inout), target :: local
    end subroutine rt_data_init_pointer_variables

<RT data: procedures>+≡
    module subroutine rt_data_init_pointer_variables (local)
        class(rt_data_t), intent(inout), target :: local
        logical, target, save :: known = .true.
        call local%var_list%append_string_ptr (var_str ("%fc"), &
            local%os_data%fc, known, intrinsic=.true., &
            description=var_str('This string variable gives the ' // &
                '\ttt{Fortran} compiler used within \whizard. It can ' // &
                'only be accessed, not set by the user. (cf. also ' // &
                '\ttt{\$fcflags}, \ttt{\$fclibs}'))))
        call local%var_list%append_string_ptr (var_str ("%fcflags"), &
            local%os_data%fcflags, known, intrinsic=.true., &
            description=var_str('This string variable gives the ' // &
                'compiler flags for the \ttt{Fortran} compiler used ' // &
                'within \whizard. It can only be accessed, not set by ' // &
                'the user. (cf. also \ttt{\$fc}, \ttt{\$fclibs}'))))
        call local%var_list%append_string_ptr (var_str ("%fclibs"), &
            local%os_data%fclibs, known, intrinsic=.true., &
            description=var_str('This string variable gives the ' // &
                'linked libraries for the \ttt{Fortran} compiler used ' // &
                'within \whizard. It can only be accessed, not set by ' // &
                'the user. (cf. also \ttt{\$fc}, \ttt{\$fcflags}'))))
    end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

Gfortran 7/8/9 bug, has to remain in the main module:

```

<RT data: rt data: TBP>+≡
    procedure :: activate => rt_data_activate

<RT data: main procedures>≡
    subroutine rt_data_activate (local)
        class(rt_data_t), intent(inout), target :: local

```

```

class(rt_data_t), pointer :: global
global => local%context
if (associated (global)) then
    local%lexer => global%lexer
    call global%copy_globals (local)
    local%os_data = global%os_data
    local%logfile = global%logfile
    if (associated (global%prclib)) then
        local%prclib => &
            local%prclib_stack%get_library_ptr (global%prclib%get_name ())
    end if
    call local%import_values ()
    call local%process_stack%link (global%process_stack)
    local%it_list = global%it_list
    local%beam_structure = global%beam_structure
    local%pn = global%pn
    if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
    if (allocated (global%sample_fmt)) then
        allocate (local%sample_fmt (size (global%sample_fmt)), &
            source = global%sample_fmt)
    end if
    local%out_files => global%out_files
    local%model => global%model
    local%model_is_copy = .false.
else if (.not. associated (local%model)) then
    local%model => local%preload_model
    local%model_is_copy = .false.
end if
if (associated (local%model)) then
    call local%model%link_var_list (local%var_list)
    call local%var_list%set_string (var_str ("model_name"), &
        local%model%get_name (), is_known = .true.)
else
    call local%var_list%set_string (var_str ("model_name"), &
        var_str (""), is_known = .false.)
end if
end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
    procedure :: deactivate => rt_data_deactivate

<RT data: sub interfaces>+≡
    module subroutine rt_data_deactivate (local, global, keep_local)
        class(rt_data_t), intent(inout), target :: local
        class(rt_data_t), intent(inout), optional, target :: global

        end if
        call global%restore_globals (local)
    else
        call local%unselect_model ()
    end if
end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
procedure :: copy_globals => rt_data_copy_globals

```

```

<RT data: sub interfaces>+≡
  module subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
  end subroutine rt_data_copy_globals

```

```

<RT data: procedures>+≡
  module subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
    local%prclib_stack = global%prclib_stack
  end subroutine rt_data_copy_globals

```

This restores global objects for which local modifications should be kept. May also modify (remove) the local objects.

```

<RT data: rt data: TBP>+≡
  procedure :: restore_globals => rt_data_restore_globals

<RT data: sub interfaces>+≡
  module subroutine rt_data_restore_globals (global, local)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(inout) :: local
  end subroutine rt_data_restore_globals

<RT data: procedures>+≡
  module subroutine rt_data_restore_globals (global, local)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(inout) :: local
    global%prclib_stack = local%prclib_stack
    call local%handle_exports (global)
  end subroutine rt_data_restore_globals

```

33.2.8 Exported objects

Exported objects are transferred to the global state when a local environment is closed. (For the top-level global data set, there is no effect.)

The current implementation handles only the **results** object, which resolves to the local process stack. The stack elements are appended to the global stack without modification, the local stack becomes empty.

Write names of objects to be exported:

```

<RT data: rt data: TBP>+≡
  procedure :: write_exports => rt_data_write_exports

<RT data: sub interfaces>+≡
  module subroutine rt_data_write_exports (rt_data, unit)
    class(rt_data_t), intent(in) :: rt_data
    integer, intent(in), optional :: unit
  end subroutine rt_data_write_exports

<RT data: procedures>+≡
  module subroutine rt_data_write_exports (rt_data, unit)
    class(rt_data_t), intent(in) :: rt_data
    integer, intent(in), optional :: unit
    integer :: u, i

```

```

    u = given_output_unit (unit)
    do i = 1, rt_data%get_n_export ()
        write (u, "(A)") char (rt_data%export(i))
    end do
end subroutine rt_data_write_exports

```

The number of entries in the export list.

```

<RT data: rt data: TBP>+≡
    procedure :: get_n_export => rt_data_get_n_export

<RT data: sub interfaces>+≡
    module function rt_data_get_n_export (rt_data) result (n)
        class(rt_data_t), intent(in) :: rt_data
        integer :: n
    end function rt_data_get_n_export

<RT data: procedures>+≡
    module function rt_data_get_n_export (rt_data) result (n)
        class(rt_data_t), intent(in) :: rt_data
        integer :: n
        if (allocated (rt_data%export)) then
            n = size (rt_data%export)
        else
            n = 0
        end if
    end function rt_data_get_n_export

```

Return a specific export Append new names to the export list. If a duplicate occurs, do not transfer it.

```

<RT data: rt data: TBP>+≡
    procedure :: append_exports => rt_data_append_exports

<RT data: sub interfaces>+≡
    module subroutine rt_data_append_exports (rt_data, export)
        class(rt_data_t), intent(inout) :: rt_data
        type(string_t), dimension(:), intent(in) :: export
    end subroutine rt_data_append_exports

<RT data: procedures>+≡
    module subroutine rt_data_append_exports (rt_data, export)
        class(rt_data_t), intent(inout) :: rt_data
        type(string_t), dimension(:), intent(in) :: export
        logical, dimension(:), allocatable :: mask
        type(string_t), dimension(:), allocatable :: tmp
        integer :: i, j, n
        if (.not. allocated (rt_data%export)) allocate (rt_data%export (0))
        n = size (rt_data%export)
        allocate (mask (size (export)), source=.false.)
        do i = 1, size (export)
            mask(i) = all (export(i) /= rt_data%export) &
                .and. all (export(i) /= export(:i-1))
        end do
        if (count (mask) > 0) then
            allocate (tmp (n + count (mask)))
            tmp(1:n) = rt_data%export(:)

```

```

                        call local%transfer_process_stack (global)
                    case default
                        call msg_bug ("handle exports: '" &
                            // char (export) // "' unsupported")
                end select
            end do
        end if
    end subroutine rt_data_handle_exports

```

Export the process stack. One-by-one, take the last process from the local stack and push it on the global stack. Also handle the corresponding result variables: append if the process did not exist yet in the global stack, otherwise update.

TODO: result variables do not work that way yet, require initialization in the global variable list.

```

<RT data: rt data: TBP>+≡
    procedure :: transfer_process_stack => rt_data_transfer_process_stack

<RT data: sub interfaces>+≡
    module subroutine rt_data_transfer_process_stack (local, global)

```

```

        class(rt_data_t), intent(inout), target :: local
        class(rt_data_t), intent(inout), target :: global
    end subroutine rt_data_transfer_process_stack

<RT data: procedures>+≡
module subroutine rt_data_transfer_process_stack (local, global)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), target :: global
    type(process_entry_t), pointer :: process
    type(string_t) :: process_id
    do
        call local%process_stack%pop_last (process)
        if (.not. associated (process)) exit
        process_id = process%get_id ()
        call global%process_stack%push (process)
        call global%process_stack%fill_result_vars (process_id)
        call global%process_stack%update_result_vars &
            (process_id, global%var_list)
    end do
end subroutine rt_data_transfer_process_stack

```

33.2.9 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
    procedure :: final => rt_data_global_final

<RT data: sub interfaces>+≡
    module subroutine rt_data_global_final (global)
        class(rt_data_t), intent(inout) :: global
    end subroutine rt_data_global_final

<RT data: procedures>+≡
module subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
    call global%model_list%final ()
    call global%var_list%final (follow_link=.false.)
    if (associated (global%out_files)) then
        call file_list_final (global%out_files)
        deallocate (global%out_files)
    end if
end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡
    procedure :: local_final => rt_data_local_final

```

```

<RT data: sub interfaces>+≡
    module subroutine rt_data_local_final (local)
        class(rt_data_t), intent(inout) :: local
    end subroutine rt_data_local_final

<RT data: procedures>+≡
    module subroutine rt_data_local_final (local)
        class(rt_data_t), intent(inout) :: local
        call local%process_stack%clear ()
        call local%model_list%final ()
        call local%var_list%final (follow_link=.false.)
    end subroutine rt_data_local_final

```

33.2.10 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
    procedure :: read_model => rt_data_read_model

<RT data: sub interfaces>+≡
    module subroutine rt_data_read_model (global, name, model, scheme)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name
        type(string_t), intent(in), optional :: scheme
        type(model_t), pointer, intent(out) :: model
    end subroutine rt_data_read_model

<RT data: procedures>+≡
    module subroutine rt_data_read_model (global, name, model, scheme)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name
        type(string_t), intent(in), optional :: scheme
        type(model_t), pointer, intent(out) :: model
        type(string_t) :: filename
        filename = name // ".mdl"
        call global%model_list%read_model &
            (name, filename, global%os_data, model, scheme)
    end subroutine rt_data_read_model

```

Read a UFO model. Create it on the fly if necessary.

```

<RT data: rt data: TBP>+≡
    procedure :: read_ufo_model => rt_data_read_ufo_model

<RT data: sub interfaces>+≡
    module subroutine rt_data_read_ufo_model (global, name, model, ufo_path)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name
        type(model_t), pointer, intent(out) :: model
        type(string_t), intent(in), optional :: ufo_path
    end subroutine rt_data_read_ufo_model

```

```

<RT data: procedures>+≡
module subroutine rt_data_read_ufo_model (global, name, model, ufo_path)
  class(rt_data_t), intent(inout) :: global
  type(string_t), intent(in) :: name
  type(model_t), pointer, intent(out) :: model
  type(string_t), intent(in), optional :: ufo_path
  type(string_t) :: filename
  filename = name // ".ufo.mdl"
  call global%model_list%read_model &
    (name, filename, global%os_data, model, ufo=.true., ufo_path=ufo_path)
end subroutine rt_data_read_ufo_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
  procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: sub interfaces>+≡
  module subroutine rt_data_init_fallback_model (global, name, filename)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name, filename
  end subroutine rt_data_init_fallback_model

```

```

<RT data: procedures>+≡

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

Local Model

Locally modify a model and restore the global one. We need an auxiliary function to determine the status of a model particle:

```

<RT data: test auxiliary>≡
function is_stable (pdg, global) result (flag)
  integer, intent(in) :: pdg
  type(rt_data_t), intent(in) :: global
  logical :: flag
  type(flavor_t) :: flv
  call flv%init (pdg, global%model)
  flag = flv%is_stable ()
end function is_stable

function is_polarized (pdg, global) result (flag)
  integer, intent(in) :: pdg
  type(rt_data_t), intent(in) :: global
  logical :: flag
  type(flavor_t) :: flv
  call flv%init (pdg, global%model)
  flag = flv%is_polarized ()
end function is_polarized

<RT data: execute tests>+≡
call test (rt_data_6, "rt_data_6", &
  "local model", &
  u, results)

<RT data: test declarations>+≡
public :: rt_data_6

33.3 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

We would like to put this in the `me_methods` folder but it also depends on `gosam` and `openloops`, so it is unclear where to put it.

```
<dispatch_me_methods.f90>≡  
  <File header>  
  
  module dispatch_me_methods  
  
    <Use strings>  
    <Use debug>  
    use physics_defs, only: BORN  
    use diagnostics  
    use sm_qcd  
    use variables, only: var_list_t  
    use models  
    use model_data  
  
    use prc_core_def  
    use prc_core  
    use prc_test_core  
    use prc_template_me  
    use prc_test  
    use prc_omega  
    use prc_external  
    use prc_gosam  
    use prc_openloops  
    use prc_recola  
    use prc_threshold  
  
    <Standard module head>  
  
    <Dispatch ME methods: public>  
  
    interface  
    <Dispatch ME methods: sub interfaces>  
    end interface  
  
    contains  
  
    <Dispatch ME methods: main procedures>  
  
  end module dispatch_me_methods  
  
<dispatch_me_methods_sub.f90>≡  
  <File header>  
  
  submodule (dispatch_me_methods) dispatch_me_methods_s  
  
    implicit none
```

contains

<Dispatch ME methods: procedures>

end submodule dispatch_me_methods_s

33.3.1 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable. Gfortran 7/8/9 bug, has to remain in the main module:

<Dispatch ME methods: public>≡

public :: dispatch_core_def

<Dispatch ME methods: main procedures>≡

33.3.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model. Gfortran 7/8/9 bug, has to remain in the main module:

```

<Dispatch ME methods: public>+≡
    public :: dispatch_core

<Dispatch ME methods: main procedures>+≡
    subroutine dispatch_core (core, core_def, model, &
                             helicity_selection, qcd, use_color_factors, has_beam_pol)
        class(prc_core_t), allocatable, intent(inout) :: core
        class(prc_core_def_t), intent(in) :: core_def
        class(model_data_t), intent(in), target, optional :: model
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        type(qcd_t), intent(in), optional :: qcd
        logical, intent(in), optional :: use_color_factors
        logical, intent(in), optional :: has_beam_pol
        select type (core_def)
        type is (prc_test_def_t)
            allocate (test_t :: core)
        type is (template_me_def_t)
            allocate (prc_template_me_t :: core)
            select type (core)
            type is (prc_template_me_t)
                call core%set_parameters (model)
            end select
        class is (omega_def_t)
            if (.not. allocated (core)) allocate (prc_omega_t :: core)
            select type (core)
            type is (prc_omega_t)
                call core%set_parameters (model, &
                                         helicity_selection, qcd, use_color_factors)
            end select
        type is (gosam_def_t)
            if (.not. allocated (core)) allocate (prc_gosam_t :: core)
            select type (core)
            type is (prc_gosam_t)
                call core%set_parameters (qcd)
            end select
        end select
    end subroutine dispatch_core

```

```

        end select
type is (openloops_def_t)
    if (.not. allocated (core)) allocate (prc_openloops_t :: core)
    select type (core)
    type is (prc_openloops_t)
        call core%set_parameters (qcd)

    end select
class default
    call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

33.3.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

(Dispatch ME methods: public) +≡

```

public :: dispatch_core_update
public :: dispatch_core_restore

```

(Dispatch ME methods: sub interfaces) ≡

```

module subroutine dispatch_core_update &
    (core, model, helicity_selection, qcd, saved_core)

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

end module process_configurations_util

```

API: driver for the unit tests below.

```

<Process configurations: public test>≡
  public :: process_configurations_test

<Process configurations: test driver>≡
  subroutine process_configurations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Process configurations: execute tests>
  end subroutine process_configurations_test

```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.
The `procname` argument replaces the predefined `procname(s)`.
This is re-exported by the UT module.

```

33.6.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

<Integrations: public>≡
    public :: integration_t

<Integrations: types>≡
    type :: integration_t
    private
        type(string_t) :: process_id
        type(string_t) :: run_id
        type(process_t), pointer :: process => null ()
        logical :: rebuild_phs = .false.
        logical :: ignore_phs_mismatch = .false.
        logical :: phs_only = .false.
        logical :: process_has_me = .true.
        integer :: n_calls_test = 0
        logical :: vis_history = .true.
        type(string_t) :: history_filename
        type(string_t) :: log_filename
        type(helicity_selection_t) :: helicity_selection
        logical :: use_color_factors = .false.
        logical :: has_beam_pol = .false.
        logical :: combined_integration = .false.
        type(iteration_multipliers_t) :: iteration_multipliers
        type(nlo_settings_t) :: nlo_settings
    contains
        <Integrations: integration: TBP>
end type integration_t

```

33.6.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied. Gfortran7/8/9 bug, has to remain in the main module:

```

<Integrations: integration: TBP>≡
    procedure :: create_process => integration_create_process

<Integrations: main procedures>≡
    subroutine integration_create_process (intg, process_id, global)
        class(integration_t), intent(out) :: intg
        type(rt_data_t), intent(inout), optional, target :: global
        type(string_t), intent(in) :: process_id
        type(process_entry_t), pointer :: process_entry
        if (debug_on) call msg_debug (D_CORE, "integration_create_process")
        intg%process_id = process_id
        if (present (global)) then
            allocate (process_entry)
            intg%process => process_entry%process_t
            call global%process_stack%push (process_entry)
        else
            allocate (process_t :: intg%process)
        end if
    end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the local stack directly. The intent(inout) attribute for the local data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

```

<Integrations: integration: TBP>+≡
    procedure :: init_process => integration_init_process

<Integrations: sub interfaces>≡
    module subroutine integration_init_process (intg, local)
        class(integration_t), intent(inout) :: intg
        type(rt_data_t), intent(inout), target :: local
    end subroutine integration_init_process

<Integrations: procedures>≡
    module subroutine integration_init_process (intg, local)
        class(integration_t), intent(inout) :: intg
        type(rt_data_t), intent(inout), target :: local
        type(string_t) :: model_name

33.6.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

<Integrations: integration: TBP>+≡
  procedure :: evaluate => integration_evaluate

<Integrations: sub interfaces>+≡
  module subroutine integration_evaluate &
    (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
  end subroutine integration_evaluate

<Integrations: procedures>+≡
  module subroutine integration_evaluate &
    (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
    integer :: n_calls, n_it
    logical :: adapt_grids, adapt_weights, final
    n_it = it_list%get_n_it (pass)
    n_calls = it_list%get_n_calls (pass)
    adapt_grids = it_list%adapt_grids (pass)
    adapt_weights = it_list%adapt_weights (pass)
    final = pass == it_list%get_n_pass ()
    call process_instance%integrate ( &
      i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
      final, pacify)
  end subroutine integration_evaluate

```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

```

<Integrations: integration: TBP>+≡
  procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: sub interfaces>+≡
  module subroutine integration_make_iterations_list (intg, it_list)
    class(integration_t), intent(in) :: intg
    type(iterations_list_t), intent(out) :: it_list
  end subroutine integration_make_iterations_list

<Integrations: procedures>+≡
  module subroutine integration_make_iterations_list (intg, it_list)
    class(integration_t), intent(in) :: intg
    type(iterations_list_t), intent(out) :: it_list
    integer :: pass, n_pass
    integer, dimension(:), allocatable :: n_it, n_calls
    logical, dimension(:), allocatable :: adapt_grids, adapt_weights
    n_pass = intg%process%get_n_pass_default ()
    allocate (n_it (n_pass), n_calls (n_pass))

```

```

allocate (adapt_grids (n_pass), adapt_weights (n_pass))
do pass = 1, n_pass
  n_it(pass)      = intg%process%get_n_it_default (pass)
  n_calls(pass)   = intg%process%get_n_calls_default (pass)
  adapt_grids(pass) = intg%process%adapt_grids_default (pass)
  adapt_weights(pass) = intg%process%adapt_weights_default (pass)
end do
call it_list%init (n_it, n_calls, &
  adapt_grids = adapt_grids, adapt_weights = adapt_weights)
end subroutine integration_make_iterations_list

```

In NLO calculations, the individual components might scale very differently with the number of calls. This especially applies to the real-subtracted component, which usually fluctuates more than the Born and virtual component, making it a bottleneck of the calculation. Thus, the calculation is throttled twice, first by the number of calls for the real component, second by the number of surplus calls of computation-intense virtual matrix elements. Therefore, we want to set a different number of calls for each component, which is done by the subroutine `integration_apply_call_multipliers`.

        type(process_t), pointer :: ptr
    end function integration_get_process_ptr

<Integrations: procedures>+≡
    module function integration_get_process_ptr (intg) result (ptr)
        class(integration_t), intent(in) :: intg
        type(process_t), pointer :: ptr
        ptr => intg%process
    end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the `global` environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the process object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

```

<Integrations: public>+≡
    public :: integrate_process

<Integrations: sub interfaces>+≡
    module subroutine integrate_process &

Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (33.1)$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (33.2)$$

f is the flux of the incoming particles with mass $m = 125 \text{ GeV}$ and energy $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (33.3)$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (33.4)$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (33.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function $f(x) = x$ for both beams. Together with the $1/x_1x_2$ factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the m_s mass which we set to zero here.

```

Integration with sign change

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`. The weight that is applied changes the sign in half of phase space. The weight is -3 and 1 , respectively, so the total result is equal to the original, but negative sign.

The efficiency should (approximately) become the average of 1 and $1/3$, that is $2/3$.

33.7 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
(event_streams.f90)≡
  <File header>

  module event_streams

    <Use strings>
    use events
    use event_handles, only: event_handle_t
    use eio_data
    use eio_base
    use rt_data

    use dispatch_transforms, only: dispatch_eio

    <Standard module head>

    <Event streams: public>

    <Event streams: types>

    interface
    <Event streams: sub interfaces>
    end interface

  end module event_streams

(event_streams_sub.f90)≡
  <File header>

  submodule (event_streams) event_streams_s

    use io_units
    use diagnostics

    implicit none

  contains

    <Event streams: procedures>

  end submodule event_streams_s
```

33.7.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡
```

```

type :: event_stream_entry_t
  class(eio_t), allocatable :: eio
end type event_stream_entry_t

```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```

<Event streams: public>≡
  public :: event_stream_array_t

<Event streams: types>+≡
  type :: event_stream_array_t
    type(event_stream_entry_t), dimension(:), allocatable :: entry
    integer :: i_in = 0
  contains
    <Event streams: event stream array: TBP>
  end type event_stream_array_t

```

Output.

```

<Event streams: event stream array: TBP>≡
  procedure :: write => event_stream_array_write

<Event streams: sub interfaces>≡
  module subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
  end subroutine event_stream_array_write

<Event streams: procedures>≡
  module subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event stream array:"
    if (allocated (object%entry)) then
      select case (size (object%entry))
      case (0)
        write (u, "(3x,A)") "[empty]"
      case default
        do i = 1, size (object%entry)
          if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
          call object%entry(i)%eio%write (u)
        end do
      end select
    else
      write (u, "(3x,A)") "[undefined]"
    end if
  end subroutine event_stream_array_write

```

Check if there is content.

```

<Event streams: event stream array: TBP>+≡
  procedure :: is_valid => event_stream_array_is_valid

```

```

<Event streams: sub interfaces>+≡
    module function event_stream_array_is_valid (es_array) result (flag)
        class(event_stream_array_t), intent(in) :: es_array
        logical :: flag
    end function event_stream_array_is_valid

<Event streams: procedures>+≡
    module function event_stream_array_is_valid (es_array) result (flag)
        class(event_stream_array_t), intent(in) :: es_array
        logical :: flag

        flag = allocated (es_array%entry)

    end function event_stream_array_is_valid

```

Finalize all streams.

```

<Event streams: event stream array: TBP>+≡
    procedure :: final => event_stream_array_final

<Event streams: sub interfaces>+≡
    module subroutine event_stream_array_final (es_array)
        class(event_stream_array_t), intent(inout) :: es_array
    end subroutine event_stream_array_final

<Event streams: procedures>+≡
    module subroutine event_stream_array_final (es_array)
        class(event_stream_array_t), intent(inout) :: es_array
        integer :: i
        if (allocated (es_array%entry)) then
            do i = 1, size (es_array%entry)
                call es_array%entry(i)%eio%final ()
            end do
        end if
    end subroutine event_stream_array_final

```

Initialization. We use a generic sample name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

```

33.8 Restricted Subprocesses

This module provides an automatic means to construct restricted subprocesses of a current process object. A restricted subprocess has the same initial and final state as the current process, but a restricted set of Feynman graphs.

The actual application extracts the set of resonance histories that apply to the process and uses this to construct subprocesses that are restricted to one of those histories, respectively. The resonance histories are derived from the phase-space setup. This implies that the method is tied to the OMega matrix element generator and to the wood phase space method.

The processes are collected in a new process library that is generated on-the-fly.

The `resonant_subprocess_t` object is intended as a component of the event record, which manages all operations regarding resonance handling.

The run-time calculations are delegated to an event transform (`evt_resonance_t`), as a part of the event transform chain. The transform selects one (or none) of the resonance histories, given the momentum configuration, computes matrix elements and inserts resonances into the particle set.

33.8.1 Process configuration

We extend the `process_configuration_t` by another method for initialization that takes into account a resonance history.

```

<Restricted subprocesses: public>≡
  public :: restricted_process_configuration_t

<Restricted subprocesses: types>≡
  type, extends (process_configuration_t) :: restricted_process_configuration_t
  private
  contains
  <Restricted subprocesses: restricted process configuration: TBP>
  end type restricted_process_configuration_t

```

Resonance history as an argument. We use it to override the `restrictions` setting in a local variable list. Since we can construct the restricted process only by using OMega, we enforce it as the ME method. Other settings are taken from the variable list. The model will most likely be set, but we insert a safeguard just in case.

Also, the resonant subprocess should not itself spawn resonant subprocesses, so we unset `?resonance_history`.

We have to create a local copy of the model here, via pointer allocation. The reason is that the model as stored (via pointer) in the base type will be finalized and deallocated.

The current implementation will generate a LO process, the optional `nlo_process` is unset. (It is not obvious whether the construction makes sense beyond LO.)

```

<Restricted subprocesses: restricted process configuration: TBP>≡
  procedure :: init_resonant_process

```

```

<Restricted subprocesses: sub interfaces>≡

```

33.8.2 Resonant-subprocess set manager

This data type enables generation of a library of resonant subprocesses for a given master process, and it allows for convenient access. The matrix elements from the subprocesses can be used as channel weights to activate a selector, which then returns a preferred channel via some random number generator.

```

<Restricted subprocesses: public>+≡

```

33.8.4 Library for the resonance history set

The recommended library name: append `_R` to the process name.

<Restricted subprocesses: public>+≡

```

public :: get_libname_res

```

<Restricted subprocesses: sub interfaces>+≡

```

elemental module function get_libname_res (proc_id) result (libname)
type(string_t), intent(in) :: proc_id
type(string_t) :: libname
end function get_libname_res

```

<Restricted subprocesses: procedures>+≡

```

elemental module function get_libname_res (proc_id) result (libname)
type(string_t), intent(in) :: proc_id
type(string_t) :: libname
libname = proc_id // "_R"
end function get_libname_res

```

Here we scan the global process library whether any processes require resonant subprocesses to be constructed. If yes, create process objects with phase space and construct the process libraries as usual. Then append the library names to the array.

The temporary integration objects should carry the `phs_only` flag. We set this in the local environment.

Once a process object with resonance histories (derived from phase space) has been created, we extract the resonance histories and use them, together with the process definition, to create the new library.

Finally, compile the library.

```

33.8.5 Process objects and instances

Prepare process objects for all entries in the resonant-subprocesses library. The process objects are appended to the global process stack. A local environment can be used where we place temporary variable settings that affect process-object generation. We initialize the processes, such that we can evaluate matrix elements, but we do not need to integrate them.

The internal procedure `prepare_process` is an abridged version of the procedure with this name in the `simulations` module.

33.8.6 Event transform connection

The idea is that the resonance-insertion event transform has been allocated somewhere (namely, in the standard event-transform chain), but we maintain a link such that we can inject matrix-element results event by event. The event transform holds a selector, to choose one of the resonance histories (or none), and it manages resonance insertion for the particle set.

The data that the event transform requires can be provided here. The resonance history set has already been assigned with the `dispatch` initializer. Here, we supply the set of subprocess instances that we have generated (see above). The master-process instance is set when we `connect` the transform by the standard method.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: connect_transform => &
    resonant_subprocess_set_connect_transform

```

If events have been dropped during simulation of weighted events, issue a message here. If a fraction `n_dropped / n_total` of the events fail the cuts, we keep generating new ones until we have `n_total` events with `weight > 0`. Thus, the total sum of weights will be a fraction of `n_dropped / n_total` too large. However, we do not know how many events will pass or fail the cuts prior to generating them so we leave it to the user to correct for this factor.

Count an event. The weight and event source are optional; by default we assume that the event has been generated and has positive weight.

The optional integer `n_dropped` counts weighted events with weight zero that were encountered while generating the current event, but dropped (because of their zero weight). Accumulating this number allows for renormalizing event weight sums in histograms, after the generation step has been completed.

33.9.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

```

<Simulations: types>+=
  type :: core_safe_t
    class(prc_core_t), allocatable :: core
  end type core_safe_t

```

33.9.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. `use_process` implies that the process should already exist as an object in the process stack. If integration is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

```

<Simulations: procedures>+=
  subroutine prepare_process &

```

```

```

33.9.5 Simulation-entry object

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares an MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocates the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

For the purpose of NLO events, `entry_t` contains a pointer list to other simulation-entries. This is due to the fact that we have to associate an event for each component of the fixed order simulation, i.e. one N -particle event and N_{phs} $N + 1$ -particle events. However, all entries share the same event transforms.

```

Simulation-entry initialization

Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the `process_instance` pointer. Assign data by looking at the process object and at the environment.

If `n_alt` is set, we prepare for additional alternate sqme and weight entries.

The `compile` flag is only false if we do not need the Whizard process at all, just its definition. In that case, we skip process initialization.

Otherwise, and if the process object is not found initially: if `integrate` is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If `generate` is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

If `resonance_history` is set, we create a separate process library which contains all possible restricted subprocesses with distinct resonance histories. These processes will not be integrated, but their matrix element codes are used for determining probabilities of resonance histories. Note that this can work only if the process method is `OMega`, and the phase-space method is 'wood'.

When done, we assign the `instance` and `process` pointers of the base type by the `connect` method, so we can reference them later.

TODO: In case of NLO event generation, copying the configuration from the master process is rather intransparent. For instance, we override the process var list by the global var list.

Event-transform initialization

Part of simulation-entry initialization: dispatch event transforms (decay, shower) as requested. If a transform is not applicable or switched off via some variable, it will be skipped.

Regarding resonances/decays: these two transforms are currently mutually exclusive. Resonance insertion will not be applied if there is an unstable particle in the game.

The initial particle set is the output of the trivial transform; this has already been applied when the transforms listed here are encountered. Each transform takes a particle set and produces a new one, with one exception: the decay module takes its input from the process object, ignoring the trivial transform. (Reason: spin correlations.) Therefore, the decay module must be first in line.

Settings that we don't or can't support (yet) are rejected by the embedded call to `event_transforms_check`.

```

```

Update and restore the process core that this entry accesses, when parameters change. If explicit arguments `model`, `qcd`, or `helicity_selection` are provided, use those. Otherwise use the parameters stored in the process object.

These two procedures come with a caching mechanism which guarantees that the current core object is saved when calling `update_process`, and restored by calling `restore_process`. If the flag `saved` is unset, saving is skipped, and the `restore` procedure should not be called.

33.9.6 Handling resonant subprocesses

Resonant subprocesses are required if we want to determine resonance histories when generating events. The feature is optional, to be switched on by the user.

This procedure initializes a new, separate process library that contains copies of the current process, restricted to the relevant resonance histories. (If this library exists already, it is just kept.) The histories can be extracted from the process object.

The code has to match the assignments in `create_resonant_subprocess_library`. The library may already exist – in that case, here it will be recovered without recompilation.

```

33.9.7 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
  type, extends (entry_t) :: alt_entry_t
    contains
      <Simulations: alt entry: TBP>
    end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

Simulation-object initialization

We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If `integrate` is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If `integrate` is unset, we do not need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If `generate` is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

```

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the `luminosity` setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the `luminosity`, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

  integer :: n

  n = simulation%n_evt_requested

end function simulation_get_n_events_requested

```

Generate the number of events that has been set by `simulation_set_n_events_requested`. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

The `begin_it` and `end_it` limits are equal to 1 and the number of events, respectively, in serial mode, but differ for MPI mode.

TODO: When reading from file, event transforms cannot be applied because the process instance will not be complete. (?)

```

<Simulations: simulation: TBP>+≡
  procedure :: generate => simulation_generate

<Simulations: sub interfaces>+≡
  module subroutine simulation_generate (simulation, es_array)

  end subroutine simulation_generate

```

The header of the event loop: with all necessary information present in the `simulation` and `es_array` objects, and given a number of events `n` to generate, we prepare for actually generating/reading/writing events.

The procedure returns the real iteration bounds `begin_it` and `end_it` for the event loop. This is nontrivial only for MPI; in serial mode those are equal to 1 and to `n_events`, respectively.

Alternate environments

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

```

Rescan-Events Loop

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

```

Event index

Here we handle the event index that is kept in the simulation record. The event index is valid for the current sample. When generating or reading events, we initialize the index with the offset that the user provides (if any) and increment

it for each event that is generated or read from file. The event index is stored in the event-entry that is current for the event. If an event on file comes with its own index, that index overwrites the predefined one and also resets the index within the simulation record.

The event index is not connected to the `counter` object. The counter is supposed to collect statistical information. The event index is a user-level object that is visible in event records and analysis expressions.

(Simulations: simulation: TBP)+≡

```
procedure :: init_event_index => simulation_init_event_index
procedure :: increment_event_index => simulation_increment_event_index
procedure :: set_event_index => simulation_set_event_index

    end if
end function simulation_get_event_index

```

33.9.9 Direct event access

If we want to retrieve event information, we should expose the currently selected event `entry` within the simulation object. We recall that this is an extension of the (generic) `event` type. Assuming that we will restrict this to read access, we return a pointer.

```

<Simulations: simulation: TBP>+≡
    procedure :: get_process_index => simulation_get_process_index
    procedure :: get_event_ptr => simulation_get_event_ptr

<Simulations: sub interfaces>+≡
    module function simulation_get_process_index (simulation) result (i_prc)
        class(simulation_t), intent(in), target :: simulation
        integer :: i_prc
    end function simulation_get_process_index
    module function simulation_get_event_ptr (simulation) result (event)
        class(simulation_t), intent(in), target :: simulation
        class(event_t), pointer :: event
    end function simulation_get_event_ptr

<Simulations: procedures>+≡
    module function simulation_get_process_index (simulation) result (i_prc)
        class(simulation_t), intent(in), target :: simulation
        integer :: i_prc

        i_prc = simulation%i_prc

    end function simulation_get_process_index

    module function simulation_get_event_ptr (simulation) result (event)
        class(simulation_t), intent(in), target :: simulation
        class(event_t), pointer :: event

        event => simulation%entry(simulation%i_prc)

    end function simulation_get_event_ptr

```

33.9.10 Event Stream I/O

Write an event to a generic `eio` event stream. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+≡
    generic :: write_event => write_event_eio
    procedure :: write_event_eio => simulation_write_event_eio

```

<Simulations: sub interfaces>+≡

```

module subroutine simulation_write_event_eio (object, eio, i_prc)
  class(simulation_t), intent(in) :: object
  class(eio_t), intent(inout) :: eio
  integer, intent(in), optional :: i_prc
end subroutine simulation_write_event_eio

```

<Simulations: procedures>+≡

```

module subroutine simulation_write_event_eio (object, eio, i_prc)
  class(simulation_t), intent(in) :: object
  class(eio_t), intent(inout) :: eio
  integer, intent(in), optional :: i_prc
  logical :: increased
  integer :: current
  if (present (i_prc)) then
    current = i_prc
  else
    current = object%i_prc
  end if
  if (current > 0) then
    if (object%split_n_evt > 0 .and. object%counter%total > 1) then
      if (mod (object%counter%total, object%split_n_evt) == 1) then
        call eio%split_out ()
      end if
    else if (object%split_n_kbytes > 0) then
      call eio%update_split_count (increased)
      if (increased) call eio%split_out ()
    end if
    call eio%output (object%entry(current)%event_t, current, pacify = object%pacify)
  else
    call msg_fatal ("Simulation: write event: no process selected")
  end if
end subroutine simulation_write_event_eio

```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

<Simulations: simulation: TBP>+≡

```

generic :: read_event => read_event_eio
procedure :: read_event_eio => simulation_read_event_eio

```

<Simulations: sub interfaces>+≡

```

```

        event_index, &
        passed = passed, &
        pacify = object%pacify, &
        event_handle = event_handle)
    end do
else
    call msg_fatal ("Simulation: write event: no process selected")
end if
end subroutine simulation_write_event_es_array

```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

<Simulations: simulation: TBP>+≡

```

33.9.12 Recover event

Recalculate the process instance contents, given an event with known particle set. The indices for MC, term, and channel must be already set. The `recalculate` method of the selected entry will import the result into `sqme_prc` and `weight_prc`.

If `recover_phs` is set (and false), do not attempt any phase-space calculation. Useful if we need only matrix elements (esp. testing); this flag is not stored in the simulation record.

```

<Simulations: simulation: TBP>+≡
    procedure :: recalculate => simulation_recalculate

Return data that may be useful for writing event files.

Usually we can refer to a previously integrated process, for which we can fetch a process pointer. Occasionally, we do not have this because we are just rescanning an externally generated file without calculation. For that situation,

we generate our local beam data object using the current environment, or, in simple cases, just fetch the necessary data from the process definition and environment.

Chapter 34

More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in `init`/`final` hooks that we can set at runtime.)

34.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
(expr_tests_ut.f90)≡
  <File header>
  module expr_tests_ut

    use unit_tests
    use expr_tests_util

    <Standard module head>

    <Expr tests: public test>

    contains

    <Expr tests: test driver>

  end module expr_tests_ut
(expr_tests_util.f90)≡
  <File header>

  module expr_tests_util

    <Use kinds>
    <Use strings>
    use format_defs, only: FMT_12
    use format_utils, only: write_separator
```

```

    use os_interface
    use sm_qcd
    use lorentz
    use ifiles
    use lexers
    use parser
    use model_data
    use interactions, only: reset_interaction_counter
    use process_libraries
    use subevents
    use subvt_expr
    use rng_base

Chapter 35

Top Level

The top level consists of

commands Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

whizard This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

main The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

whizard_c_interface Alternative top-level procedures, for use in the context of a C-compatible caller program.

35.1 Commands

This module defines the command language of the main input file.

```

35.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

<Commands: types>≡

```

type, abstract :: command_t
  type(parse_node_t), pointer :: pn => null ()
  class(command_t), pointer :: next => null ()
  type(parse_node_t), pointer :: pn_opt => null ()
  type(command_list_t), pointer :: options => null ()
  type(rt_data_t), pointer :: local => null ()

```

```

contains
  <Commands: command: TBP>
end type command_t

```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```

<Commands: command: TBP>≡
  procedure :: final => command_final

<Commands: sub interfaces>≡
  recursive module subroutine command_final (cmd)
    class(command_t), intent(inout) :: cmd
  end subroutine command_final

<Commands: procedures>≡
  recursive module subroutine command_final (cmd)
    class(command_t), intent(inout) :: cmd
    if (associated (cmd%options)) then
      call cmd%options%final ()
      deallocate (cmd%options)
      call cmd%local%local_final ()
      deallocate (cmd%local)
    else
      cmd%local => null ()
    end if
  end subroutine command_final

```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling. Gfortran 7/8/9 bug, has to remain in the main module:

```

<Commands: main procedures>≡
  subroutine dispatch_command (command, pn)
    class(command_t), intent(inout), pointer :: command
    type(parse_node_t), intent(in), target :: pn

case default
    print *, char (parse_node_get_rule_key (pn))
    call msg_bug ("Command not implemented")
end select
command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_write), deferred :: write

⟨Commands: interfaces⟩≡
    abstract interface
        subroutine command_write (cmd, unit, indent)
            import
            class(command_t), intent(in) :: cmd
            integer, intent(in), optional :: unit, indent
        end subroutine command_write
    end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_compile), deferred :: compile

```

```

<Commands: interfaces>+≡
  abstract interface
    subroutine command_compile (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_compile
  end interface

```

Execute a command. This will use and/or modify the runtime data set. If the `quit` flag is set, the caller should terminate command execution.

```

<Commands: command: TBP>+≡
  procedure (command_execute), deferred :: execute

```

```

<Commands: interfaces>+≡
  abstract interface
    subroutine command_execute (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_execute
  end interface

```

35.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```

<Commands: command: TBP>+≡
  procedure :: write_options => command_write_options

<Commands: sub interfaces>+≡
  recursive module subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine command_write_options

<Commands: procedures>+≡
  recursive module subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options

```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```

<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

```

```

<Commands: sub interfaces>+≡
    recursive module subroutine command_compile_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
    end subroutine command_compile_options

<Commands: procedures>+≡
    recursive module subroutine command_compile_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%pn_opt)) then
            allocate (cmd%local)
            call cmd%local%local_init (global)
            call global%copy_globals (cmd%local)
            allocate (cmd%options)
            call cmd%options%compile (cmd%pn_opt, cmd%local)
            call global%restore_globals (cmd%local)
            call cmd%local%deactivate ()
        else
            cmd%local => global
        end if
    end subroutine command_compile_options

```

Execute options. First prepare the local environment, then execute the command list.

```

<Commands: command: TBP>+≡
    procedure :: execute_options => cmd_execute_options

<Commands: sub interfaces>+≡
    recursive module subroutine cmd_execute_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
    end subroutine cmd_execute_options

<Commands: procedures>+≡
    recursive module subroutine cmd_execute_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call cmd%local%activate ()
            call cmd%options%execute (cmd%local)
        end if
    end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to global can become permanent.

```

<Commands: command: TBP>+≡
    procedure :: reset_options => cmd_reset_options

<Commands: sub interfaces>+≡
    module subroutine cmd_reset_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
    end subroutine cmd_reset_options

```

```

<Commands: procedures>+≡
module subroutine cmd_reset_options (cmd, global)
  class(command_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  if (associated (cmd%options)) then
    call cmd%local%deactivate (global)
  end if
end subroutine cmd_reset_options

```

35.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_model_t
  private
  type(string_t) :: name
  type(string_t) :: scheme
  logical :: ufo_model = .false.
  logical :: ufo_path_set = .false.
  type(string_t) :: ufo_path
contains
  <Commands: cmd model: TBP>
end type cmd_model_t

```

Output

```

<Commands: cmd model: TBP>≡
  procedure :: write => cmd_model_write

<Commands: sub interfaces>+≡
  module subroutine cmd_model_write (cmd, unit, indent)
    class(cmd_model_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_model_write

<Commands: procedures>+≡
  module subroutine cmd_model_write (cmd, unit, indent)
    class(cmd_model_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,1x,'"',A,'"',", advance='no") "model =", char (cmd%name)
    if (cmd%ufo_model) then
      if (cmd%ufo_path_set) then
        write (u, "(1x,A,A,A)") "(ufo (", char (cmd%ufo_path), ")")
      else
        write (u, "(1x,A)") "(ufo)"
      end if
    else if (cmd%scheme /= "") then
      write (u, "(1x,'(,A,')')") char (cmd%scheme)
    else

```

```

        write (u, *)
    end if
end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed. If the model has a scheme argument, take this into account.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

(Commands: cmd model: TBP)+≡

```

    procedure :: compile => cmd_model_compile

```

end subroutine cmd_library_execute

```

Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

<Commands: types>+=
    type, extends (command_t) :: cmd_process_t
    private
    type(string_t) :: id
    integer :: n_in = 0
    type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
    type(parse_node_t), pointer :: pn_out => null ()
    contains
    <Commands: cmd process: TBP>
end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

<Commands: cmd process: TBP>=
    procedure :: write => cmd_process_write

<Commands: sub interfaces>+=
    module subroutine cmd_process_write (cmd, unit, indent)
        class(cmd_process_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
    end subroutine cmd_process_write

<Commands: procedures>+=
    module subroutine cmd_process_write (cmd, unit, indent)
        class(cmd_process_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
    end subroutine cmd_process_write

```

```

integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A,A,A,I0,A)") "process: ", char (cmd%id), " (", &
      size (cmd%pn_pdg_in), " -> X)"
call cmd%write_options (u, indent)
end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

      pn_codes => parse_node_get_next_ptr (pn_codes)
    end do
  end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

There are two possibilities that a process contains more than one component: by an explicit component statement by the user for inclusive processes, or by having one process at NLO level. The first option is determined in the chunk

scan components, and determines n_components.

Command execution. Generate code, write driver, compile and link. Do this for all libraries in the list.

If no library names have been given and stored while compiling this command, we collect all libraries from the current stack and compile those.

As a bonus, a compiled library may be able to spawn new process libraries. For instance, a processes may ask for a set of resonant subprocesses which go into their own library, but this can be determined only after the process is available as a compiled object. Therefore, the compilation loop is implemented as a recursive internal subroutine.

We can compile static libraries (which actually just loads them). However, we can't incorporate in a generated executable.

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_var_t
  private
  type(string_t) :: name
  integer :: type = V_NONE
  type(parse_node_t), pointer :: pn_value => null ()
  logical :: is_intrinsic = .false.
  logical :: is_model_var = .false.
  contains
  ⟨Commands: cmd var: TBP⟩

```

```
end type cmd_var_t
```

Output. We know name, type, and properties, but not the value.

<Commands: cmd var: TBP>≡

```
procedure :: write => cmd_var_write
```

<Commands: sub interfaces>+≡

```
module subroutine cmd_var_write (cmd, unit, indent)
  class(cmd_var_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
end subroutine cmd_var_write
```

<Commands: procedures>+≡

```
module subroutine cmd_var_write (cmd, unit, indent)
  class(cmd_var_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,A,A)", advance="no") "var: ", char (cmd%name), " ("
  select case (cmd%type)
  case (V_NONE)
    write (u, "(A)", advance="no") "[unknown]"
  case (V_LOG)
    write (u, "(A)", advance="no") "logical"

    write (u, "(A)", advance="no") "int"
  case (V_REAL)
    write (u, "(A)", advance="no") "real"
  case (V_CMPLX)
    write (u, "(A)", advance="no") "complex"
  case (V_STR)
    write (u, "(A)", advance="no") "string"
  case (V_PDG)
    write (u, "(A)", advance="no") "alias"
  end select
  if (cmd%is_intrinsic) then
    write (u, "(A)", advance="no") ", intrinsic"
  end if
  if (cmd%is_model_var) then
    write (u, "(A)", advance="no") ", model"
  end if
  write (u, "(A)") ")"
end subroutine cmd_var_write
```

Compile the lhs and determine the variable name and type. Check whether this variable can be created or modified as requested, and append the value to the variable list, if appropriate. The value is initially undefined. The rhs is assigned to a pointer, to be compiled and evaluated when the command is executed.

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_expect_t
        private
            type(parse_node_t), pointer :: pn_lexpr => null ()
        contains
            <Commands: cmd expect: TBP>
        end type cmd_expect_t

```

Simply tell the status.

```

<Commands: cmd expect: TBP>≡

```

```

    procedure :: write => cmd_expect_write

```

Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

<Commands: types>+≡
    type :: sentry_expr_t
        type(parse_node_p), dimension(:), allocatable :: expr
        contains
        <Commands: sentry expr: TBP>
    end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

<Commands: sentry expr: TBP>≡
    procedure :: compile => sentry_expr_compile

<Commands: sub interfaces>+≡
    module subroutine sentry_expr_compile (sentry, pn)
        class(sentry_expr_t), intent(out) :: sentry
        type(parse_node_t), intent(in), target :: pn
    end subroutine sentry_expr_compile

<Commands: procedures>+≡
    module subroutine sentry_expr_compile (sentry, pn)
        class(sentry_expr_t), intent(out) :: sentry
        type(parse_node_t), intent(in), target :: pn
        type(parse_node_t), pointer :: pn_expr, pn_extra
        integer :: n_expr, i
        n_expr = parse_node_get_n_sub (pn)
        allocate (sentry%expr (n_expr))
        if (n_expr > 0) then

```

```

i = 0
pn_expr => parse_node_get_sub_ptr (pn)
pn_extra => parse_node_get_next_ptr (pn_expr)
do i = 1, n_expr
  sentry%expr(i)%ptr => pn_expr
  if (associated (pn_extra)) then
    pn_expr => parse_node_get_sub_ptr (pn_extra, 2)
    pn_extra => parse_node_get_next_ptr (pn_extra)
  end if
end do
end if
end subroutine sentry_expr_compile

```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

```

Weight

Define a weight expression. The weight is applied to a process to be integrated, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_weight_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()
contains
  <Commands: cmd weight: TBP>
end type cmd_weight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

⟨Commands: cmd weight: TBP⟩≡
  procedure :: write => cmd_weight_write

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_weight_write (cmd, unit, indent)
    class(cmd_weight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_weight_write

⟨Commands: procedures⟩+≡
  module subroutine cmd_weight_write (cmd, unit, indent)

  end subroutine cmd_selection_execute

<Commands: procedures>+≡
  module subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_reweight_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()
  contains
  <Commands: cmd reweight: TBP>
  end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd reweight: TBP>≡
  procedure :: write => cmd_reweight_write

<Commands: sub interfaces>+≡
  module subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_reweight_write

<Commands: procedures>+≡
  module subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd reweight: TBP⟩+≡
  procedure :: compile => cmd_reweight_compile

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_reweight_compile

⟨Commands: procedures⟩+≡
  module subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd reweight: TBP⟩+≡
  procedure :: execute => cmd_reweight_execute

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_reweight_execute (cmd, global)

    type(rt_data_t), intent(inout), target :: global
    global%pn%reweight_expr => cmd%pn_expr
  end subroutine cmd_reweight_execute

```

Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_alt_setup_t
  private
  type(parse_node_p), dimension(:), allocatable :: setup
  contains
  ⟨Commands: cmd alt setup: TBP⟩
  end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

⟨Commands: cmd alt setup: TBP⟩≡
  procedure :: write => cmd_alt_setup_write

```

```

<Commands: sub interfaces>+≡
    module subroutine cmd_alt_setup_write (cmd, unit, indent)
        class(cmd_alt_setup_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
    end subroutine cmd_alt_setup_write

<Commands: procedures>+≡
    module subroutine cmd_alt_setup_write (cmd, unit, indent)
        class(cmd_alt_setup_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
    end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

<Commands: cmd alt setup: TBP>+≡
    procedure :: compile => cmd_alt_setup_compile

<Commands: sub interfaces>+≡

    if (i > 1) write (u, "(A,1x)", advance="no") " ,"
    write (u, "(A)", advance="no") char (cmd%process_id(i))
  end do
  write (u, "(A)") ")"
end subroutine cmd_integrate_write

```

Compile.

```

<Commands: cmd integrate: TBP>+≡
procedure :: compile => cmd_integrate_compile

```

<Commands: sub interfaces>+≡

```
module subroutine cmd_integrate_compile (cmd, global)
  class(cmd_integrate_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
end subroutine cmd_integrate_compile
```

<Commands: procedures>+≡

```
module subroutine cmd_integrate_compile (cmd, global)
  class(cmd_integrate_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_proclist, pn_proc
  integer :: i
  pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
  call cmd%compile_options (global)
  cmd%n_proc = parse_node_get_n_sub (pn_proclist)
  allocate (cmd%process_id (cmd%n_proc))
  pn_proc => parse_node_get_sub_ptr (pn_proclist)
  do i = 1, cmd%n_proc
    cmd%process_id(i) = parse_node_get_string (pn_proc)
    call global%process_stack%init_result_vars (cmd%process_id(i))
    pn_proc => parse_node_get_next_ptr (pn_proc)
  end do
end subroutine cmd_integrate_compile
```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

<Commands: cmd integrate: TBP>+≡

```
procedure :: execute => cmd_integrate_execute
```

<Commands: sub interfaces>+≡

```

```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_graph_t
  private
  type(string_t) :: id
  integer :: n_elements = 0
  type(cmd_plot_t), dimension(:), allocatable :: el
  type(string_t), dimension(:), allocatable :: element_id
contains
  <Commands: cmd graph: TBP>
end type cmd_graph_t

```

Output. Just print the ID.

```

<Commands: cmd graph: TBP>≡
  procedure :: write => cmd_graph_write

<Commands: sub interfaces>+≡
  module subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_graph_write

<Commands: procedures>+≡
  module subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,A,I0,A)" "graph: ", char (cmd%id), &
      " (", cmd%n_elements, " entries)"
  end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

⟨Commands: cmd graph: TBP⟩+≡
    procedure :: compile => cmd_graph_compile

⟨Commands: sub interfaces⟩+≡
    module subroutine cmd_graph_compile (cmd, global)

            pn_app => parse_node_get_next_ptr (pn_app)
        end do

    end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
    type :: analysis_id_t
        type(string_t) :: tag

```

```

    type(parse_node_t), pointer :: pn_sexpr => null ()
end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_analysis_t
    private
    type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
    ⟨Commands: cmd analysis: TBP⟩
end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

⟨Commands: cmd analysis: TBP⟩≡
    procedure :: write => cmd_analysis_write

⟨Commands: sub interfaces⟩+≡
    module subroutine cmd_analysis_write (cmd, unit, indent)
        class(cmd_analysis_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
    end subroutine cmd_analysis_write

⟨Commands: procedures⟩+≡
    module subroutine cmd_analysis_write (cmd, unit, indent)
        class(cmd_analysis_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)") "analysis: [defined]"
    end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd analysis: TBP⟩+≡
    procedure :: compile => cmd_analysis_compile

⟨Commands: sub interfaces⟩+≡
    module subroutine cmd_analysis_compile (cmd, global)
        class(cmd_analysis_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
    end subroutine cmd_analysis_compile

      if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
        cmd%id(i)%tag = parse_node_get_string (pn_id)
      else
        cmd%id(i)%pn_sexpr => pn_id
      end if
    end do
  else
    allocate (cmd%id (0))
  end if
end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

<Commands: parameters>+≡
character(*), parameter, public :: &
  DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
  FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(6), parameter, public :: &
  FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "pg", "lo", "la" ]
character(len=3), dimension(20), parameter, public :: &
  FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
    "f95", "log", "ltp", "mod", "mpx", "olc", "olp", "pdf", "phs", &
    "sin", "sub", "tex", "vg2", "vgx" ]

```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: execute => cmd_write_analysis_execute

<Commands: sub interfaces>+≡
  module subroutine cmd_write_analysis_execute (cmd, global)
    class(cmd_write_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_write_analysis_execute

<Commands: procedures>+≡
  module subroutine cmd_write_analysis_execute (cmd, global)
    class(cmd_write_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global

```

```

type(var_list_t), pointer :: var_list
var_list => cmd%local%get_var_list_ptr ()
call write_analysis_wrap (var_list, global%out_files, &
    cmd%id, tag = cmd%tag)
end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

(Commands: procedures)+≡

```

  class(cmd_printf_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
end subroutine cmd_printf_execute

```

<Commands: procedures>+≡

```

module subroutine cmd_printf_execute (cmd, global)
  class(cmd_printf_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  type(string_t) :: string, file
  type(eval_tree_t) :: sprintf_expr
  logical :: advance
  var_list => cmd%local%get_var_list_ptr ()

```

```

advance = var_list%get_lval (&
    var_str ("?out_advance"))
file = var_list%get_sval (&
    var_str ("out_file"))
call sprintf_expr%init_sexpr (cmd%sexpr, var_list)
call sprintf_expr%evaluate ()
if (sprintf_expr%is_known ()) then
    string = sprintf_expr%get_string ()
    if (len (file) == 0) then
        call msg_result (char (string))
    else
        call file_list_write (global%out_files, file, string, advance)
    end if
end if
end subroutine cmd_printf_execute

```

Record data

The expression syntax already contains a **record** keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_record_t
    private
        type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
        ⟨Commands: cmd record: TBP⟩
    end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

⟨Commands: cmd record: TBP⟩≡
    procedure :: write => cmd_record_write

⟨Commands: sub interfaces⟩+≡
    module subroutine cmd_record_write (cmd, unit, indent)
        class(cmd_record_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
    end subroutine cmd_record_write

⟨Commands: procedures⟩+≡
    module subroutine cmd_record_write (cmd, unit, indent)
        class(cmd_record_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)") "record"
    end subroutine cmd_record_write

```

Compile. This is a hack which transforms the **record** command into a **record** expression, which we handle in the **expressions** module.

```

⟨Commands: cmd record: TBP⟩+≡
    procedure :: compile => cmd_record_compile

```

```

<Commands: sub interfaces>+≡
  module subroutine cmd_record_compile (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_record_compile

<Commands: procedures>+≡
  module subroutine cmd_record_compile (cmd, global)

    call parse_node_append_sub (pn_lsinglet, pn_lterm)
    pn_record => parse_node_get_sub_ptr (cmd%pn)
    call parse_node_append_sub (pn_lterm, pn_record)
    cmd%pn_lexpr => pn_lexpr
  end subroutine cmd_record_compile

```

Command execution. Again, transfer this to the embedded expression and just forget the logical result.

```

<Commands: cmd record: TBP>+≡
  procedure :: execute => cmd_record_execute

<Commands: sub interfaces>+≡
  module subroutine cmd_record_execute (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_record_execute

<Commands: procedures>+≡
  module subroutine cmd_record_execute (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    logical :: lval
    var_list => global%get_var_list_ptr ()
    lval = eval_log (cmd%pn_lexpr, var_list)
  end subroutine cmd_record_execute

```

Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_unstable_t
  private
  integer :: n_proc = 0

```

```

        type(string_t), dimension(:), allocatable :: process_id
        type(parse_node_t), pointer :: pn_prt_in => null ()
contains
    <Commands: cmd unstable: TBP>
end type cmd_unstable_t

```

Output: we know the process IDs.

```

<Commands: cmd unstable: TBP>≡
    procedure :: write => cmd_unstable_write

<Commands: sub interfaces>+≡
    module subroutine cmd_unstable_write (cmd, unit, indent)
        class(cmd_unstable_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
    end subroutine cmd_unstable_write

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

Range expressions

We need a special type for storing and evaluating range expressions.

<Commands: parameters>+≡

```

    integer, parameter :: STEP_NONE = 0
    integer, parameter :: STEP_ADD = 1
    integer, parameter :: STEP_SUB = 2
    integer, parameter :: STEP_MUL = 3

```

```

integer, parameter :: STEP_DIV = 4
integer, parameter :: STEP_COMP_ADD = 11
integer, parameter :: STEP_COMP_MUL = 13

```

There is an abstract base type and two implementations: scan over integers and scan over reals.

```

⟨Commands: types⟩+=
  type, abstract :: range_t
    type(parse_node_t), pointer :: pn_expr => null ()
    type(parse_node_t), pointer :: pn_term => null ()
    type(parse_node_t), pointer :: pn_factor => null ()
    type(parse_node_t), pointer :: pn_value => null ()
    type(parse_node_t), pointer :: pn_literal => null ()
    type(parse_node_t), pointer :: pn_beg => null ()
    type(parse_node_t), pointer :: pn_end => null ()
    type(parse_node_t), pointer :: pn_step => null ()
    type(eval_tree_t) :: expr_beg
    type(eval_tree_t) :: expr_end
    type(eval_tree_t) :: expr_step
    integer :: step_mode = 0
    integer :: n_step = 0
  contains
    ⟨Commands: range: TBP⟩
  end type range_t

```

These are the implementations:

```

⟨Commands: types⟩+=
  type, extends (range_t) :: range_int_t
    integer :: i_beg = 0
    integer :: i_end = 0
    integer :: i_step = 0
  contains
    ⟨Commands: range int: TBP⟩
  end type range_int_t

  type, extends (range_t) :: range_real_t
    real(default) :: r_beg = 0
    real(default) :: r_end = 0
    real(default) :: r_step = 0
    real(default) :: lr_beg = 0
    real(default) :: lr_end = 0
    real(default) :: lr_step = 0
  contains
    ⟨Commands: range real: TBP⟩
  end type range_real_t

```

Finalize the allocated dummy node. The other nodes are just pointers.

```

⟨Commands: range: TBP⟩=
  procedure :: final => range_final

⟨Commands: sub interfaces⟩+=
  module subroutine range_final (object)
    class(range_t), intent(inout) :: object
  end subroutine range_final

```

```

<Commands: procedures>+≡
module subroutine range_final (object)
  class(range_t), intent(inout) :: object
  if (associated (object%pn_expr)) then
    call parse_node_final (object%pn_expr, recursive = .false.)
    call parse_node_final (object%pn_term, recursive = .false.)
    call parse_node_final (object%pn_factor, recursive = .false.)
    call parse_node_final (object%pn_value, recursive = .false.)
    call parse_node_final (object%pn_literal, recursive = .false.)
    deallocate (object%pn_expr)
    deallocate (object%pn_term)
    deallocate (object%pn_factor)
    deallocate (object%pn_value)
    deallocate (object%pn_literal)
  end if
end subroutine range_final

```

Output.

```

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

```

```

Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_scan_t
private
type(string_t) :: name
integer :: n_values = 0
type(parse_node_p), dimension(:), allocatable :: scan_cmd
class(range_t), dimension(:), allocatable :: range
contains
<Commands: cmd scan: TBP>
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

<Commands: cmd scan: TBP>≡
procedure :: final => cmd_scan_final

<Commands: sub interfaces>+≡
recursive module subroutine cmd_scan_final (cmd)
    class(cmd_scan_t), intent(inout) :: cmd
end subroutine cmd_scan_final

<Commands: procedures>+≡
recursive module subroutine cmd_scan_final (cmd)
    class(cmd_scan_t), intent(inout) :: cmd

```

```

type(parse_node_t), pointer :: pn_var_single, pn_decl_single
type(string_t) :: key
integer :: i
if (allocated (cmd%scan_cmd)) then
  do i = 1, size (cmd%scan_cmd)
    pn_var_single => parse_node_get_sub_ptr (cmd%scan_cmd(i)%ptr)
    key = parse_node_get_rule_key (pn_var_single)
    select case (char (key))
    case ("scan_string_decl", "scan_log_decl")
      pn_decl_single => parse_node_get_sub_ptr (pn_var_single, 2)
      call parse_node_final (pn_decl_single, recursive=.false.)
      deallocate (pn_decl_single)
    end select
    call parse_node_final (pn_var_single, recursive=.false.)
    deallocate (pn_var_single)
  end do
  deallocate (cmd%scan_cmd)
end if
if (allocated (cmd%range)) then
  do i = 1, size (cmd%range)
    call cmd%range(i)%final ()
  end do
end if
end subroutine cmd_scan_final

```

Output.

```

<Commands: cmd scan: TBP>+≡
  procedure :: write => cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node. Gfortran 7/8/9 bug, has to remain in the main module:

```

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of **else if** constructs. A `cmd_if_t` object can hold either an **else_if** clause which is another object of this type, or an **else_body**, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

<Commands: types>+≡

```

Export values

This command exports the current values of variables or other objects to the surrounding scope. By default, a scope enclosed by braces keeps all objects local to it. The `export` command exports the values that are generated within the scope to the corresponding object in the outer scope.

The allowed set of exportable objects is, in principle, the same as the set of objects that the `show` command supports. This includes some convenience abbreviations.

TODO: The initial implementation inherits syntax from `show`, but supports only the `results` pseudo-object. The results (i.e., the process stack) is appended to the outer process stack instead of being discarded. The behavior of

the `export` command for other object kinds is to be defined on a case-by-case basis. It may involve replacing the outer value or, instead, doing some sort of appending or reduction.

```

        call global%append_exports (cmd%name)
    end subroutine cmd_export_execute

```

Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_quit_t
    private
    logical :: has_code = .false.
    type(parse_node_t), pointer :: pn_code_expr => null ()
    contains
    <Commands: cmd quit: TBP>
    end type cmd_quit_t

```

Output.

```
<Commands: cmd quit: TBP>≡
  procedure :: write => cmd_quit_write

<Commands: sub interfaces>+≡
  module subroutine cmd_quit_write (cmd, unit, indent)
    class(cmd_quit_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_quit_write

<Commands: procedures>+≡
  module subroutine cmd_quit_write (cmd, unit, indent)
    class(cmd_quit_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,L1)") "quit: has_code = ", cmd%has_code
  end subroutine cmd_quit_write
```

Compile: allocate a quit object which serves as a placeholder.

```
<Commands: cmd quit: TBP>+≡
  procedure :: compile => cmd_quit_compile

<Commands: sub interfaces>+≡
  module subroutine cmd_quit_compile (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_quit_compile

<Commands: procedures>+≡

    pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
    if (associated (pn_arg)) then
      cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
      cmd%has_code = .true.
    end if
  end subroutine cmd_quit_compile
```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```
<Commands: cmd quit: TBP>+≡
  procedure :: execute => cmd_quit_execute

<Commands: sub interfaces>+≡
  module subroutine cmd_quit_execute (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_quit_execute
```

```

<Commands: procedures>+≡
module subroutine cmd_quit_execute (cmd, global)
  class(cmd_quit_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  logical :: is_known
  var_list => global%get_var_list_ptr ()
  if (cmd%has_code) then
    global%quit_code = eval_int (cmd%pn_code_expr, var_list, &
      is_known=is_known)
    if (.not. is_known) then
      call msg_error ("Undefined return code of quit/exit command")
    end if
  end if
  global%quit = .true.
end subroutine cmd_quit_execute

```

35.1.6 The command list

The command list holds a list of commands and relevant global data.

```

<Commands: public>+≡
  public :: command_list_t

<Commands: types>+≡
  type :: command_list_t
    ! not private anymore as required by the whizard-c-interface
    class(command_t), pointer :: first => null ()
    class(command_t), pointer :: last => null ()
  contains
    <Commands: command list: TBP>
  end type command_list_t

```

Output.

```

<Commands: command list: TBP>≡
  procedure :: write => command_list_write

<Commands: sub interfaces>+≡
  recursive module subroutine command_list_write (cmd_list, unit, indent)
    class(command_list_t), intent(in) :: cmd_list
    integer, intent(in), optional :: unit, indent
  end subroutine command_list_write

<Commands: procedures>+≡
  recursive module subroutine command_list_write (cmd_list, unit, indent)
    class(command_list_t), intent(in) :: cmd_list
    integer, intent(in), optional :: unit, indent
    class(command_t), pointer :: cmd
    cmd => cmd_list%first
    do while (associated (cmd))
      call cmd%write (unit, indent)
      cmd => cmd%next
    end do
  end subroutine command_list_write

```

Append a new command to the list and free the original pointer.

```

<Commands: command list: TBP>+≡
    procedure :: append => command_list_append

<Commands: sub interfaces>+≡
    module subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
    end subroutine command_list_append

<Commands: procedures>+≡
    module subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
        if (associated (cmd_list%last)) then
            cmd_list%last%next => command
        else
            cmd_list%first => command
        end if
        cmd_list%last => command
        command => null ()
    end subroutine command_list_append

```

Finalize.

```

<Commands: command list: TBP>+≡
    procedure :: final => command_list_final

<Commands: sub interfaces>+≡
    recursive module subroutine command_list_final (cmd_list)
        class(command_list_t), intent(inout) :: cmd_list
    end subroutine command_list_final

<Commands: procedures>+≡
    recursive module subroutine command_list_final (cmd_list)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), pointer :: command
        do while (associated (cmd_list%first))
            command => cmd_list%first
            cmd_list%first => cmd_list%first%next
            call command%final ()
            deallocate (command)
        end do
        cmd_list%last => null ()
    end subroutine command_list_final

```

35.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint. Gfortran 7/8/9 bug: has to remain in the main module:

```

<Commands: command list: TBP>+≡
    procedure :: compile => command_list_compile

```

```

<Commands: main procedures>+≡
recursive subroutine command_list_compile (cmd_list, pn, global)
  class(command_list_t), intent(inout), target :: cmd_list
  type(parse_node_t), intent(in), target :: pn
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_cmd
  class(command_t), pointer :: command
  integer :: i
  pn_cmd => parse_node_get_sub_ptr (pn)
  do i = 1, parse_node_get_n_sub (pn)
    call dispatch_command (command, pn_cmd)
    call command%compile (global)
    call cmd_list%append (command)
    call terminate_now_if_signal ()
    pn_cmd => parse_node_get_next_ptr (pn_cmd)
  end do
end subroutine command_list_compile

```

35.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```

<Commands: command list: TBP>+≡
procedure :: execute => command_list_execute

<Commands: sub interfaces>+≡
recursive module subroutine command_list_execute (cmd_list, global)
  class(command_list_t), intent(in) :: cmd_list
  type(rt_data_t), intent(inout), target :: global
end subroutine command_list_execute

<Commands: procedures>+≡
recursive module subroutine command_list_execute (cmd_list, global)
  class(command_list_t), intent(in) :: cmd_list
  type(rt_data_t), intent(inout), target :: global
  class(command_t), pointer :: command
  command => cmd_list%first
  COMMAND_COND: do while (associated (command))
    call command%execute_options (global)
    call command%execute (global)
    call command%reset_options (global)
    call terminate_now_if_signal ()
    if (global%quit) exit COMMAND_COND
    command => command%next
  end do COMMAND_COND
end subroutine command_list_execute

```

35.1.9 Command list syntax

```

<Commands: public>+≡
public :: syntax_cmd_list

```

```

<Commands: variables>+=
    type(syntax_t), target, save :: syntax_cmd_list

```

For this test, we invent a callback object which simply writes the analysis file, using the standard call for this. Here we rely on the fact that the analysis data are stored as a global entity, otherwise we would have to access them via the event object.

```

<Commands: test auxiliary types>≡
    type, extends (event_callback_t) :: event_callback_34_t
    private
    integer :: u = 0
    contains
    procedure :: write => event_callback_34_write
    procedure :: proc => event_callback_34
    end type event_callback_34_t

```

The output routine is unused. The actual callback should write the analysis data to the output unit that we have injected into the callback object.

```

    integer(i64), intent(in) :: i
    class(generic_event_t), intent(in) :: event
    call analysis_write (event_callback%u)
    end subroutine event_callback_34

```

35.2 Toplevel module WHIZARD

```
<whizard.f90>≡  
  <File header>  
  
  module whizard  
  
    use io_units  
    <Use strings>  
    use os_interface  
    use ifiles  
    use lexers  
    use parser  
    use rt_data  
  
    <Standard module head>  
  
    <WHIZARD: public>  
  
    <WHIZARD: types>  
  
    <WHIZARD: variables>  
  
    save  
  
    interface  
    <WHIZARD: sub interfaces>  
    end interface  
  
  end module whizard  
  
<whizard_sub.f90>≡  
  <File header>  
  
  submodule (whizard) whizard_s  
  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF, BACKSLASH  
    use diagnostics  
    use eval_trees  
    use models  
    use phs_forests  
    use prclib_stacks  
    use slha_interface  
    use commands  
  
    implicit none  
  
  contains  
  
    <WHIZARD: procedures>  
  
  end submodule whizard_s
```

35.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```
<WHIZARD: public>≡
    public :: whizard_options_t

<WHIZARD: types>≡
    type :: whizard_options_t
        type(string_t) :: job_id
        type(string_t), dimension(:), allocatable :: pack_args
        type(string_t), dimension(:), allocatable :: unpack_args
        type(string_t) :: preload_model
        type(string_t) :: default_lib
        type(string_t) :: preload_libraries
        logical :: rebuild_library = .false.
        logical :: recompile_library = .false.
        logical :: rebuild_phs = .false.
        logical :: rebuild_grids = .false.
        logical :: rebuild_events = .false.
    end type whizard_options_t
```

35.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```
<WHIZARD: types>+≡
    type, extends (parse_tree_t) :: pt_entry_t
        type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t
```

This is the stack. Since we always prepend, we just need the `last` pointer.

```
<WHIZARD: types>+≡
    type :: pt_stack_t
        type(pt_entry_t), pointer :: last => null ()
        contains
            <WHIZARD: pt_stack: TBP>
    end type pt_stack_t
```

The finalizer is called at the very end.

```
<WHIZARD: pt_stack: TBP>≡
    procedure :: final => pt_stack_final

<WHIZARD: sub interfaces>≡
    module subroutine pt_stack_final (pt_stack)
        class(pt_stack_t), intent(inout) :: pt_stack
    end subroutine pt_stack_final
```

```

<WHIZARD: procedures>+=
module subroutine pt_stack_final (pt_stack)
  class(pt_stack_t), intent(inout) :: pt_stack
  type(pt_entry_t), pointer :: current
  do while (associated (pt_stack%last))
    current => pt_stack%last
    pt_stack%last => current%previous
    call parse_tree_final (current%parse_tree_t)
    deallocate (current)
  end do
end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt_stack: TBP>+=
  procedure :: push => pt_stack_push

<WHIZARD: sub interfaces>+=
  module subroutine pt_stack_push (pt_stack, parse_tree)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(parse_tree_t), intent(out), pointer :: parse_tree
  end subroutine pt_stack_push

<WHIZARD: procedures>+=
  module subroutine pt_stack_push (pt_stack, parse_tree)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(parse_tree_t), intent(out), pointer :: parse_tree
    type(pt_entry_t), pointer :: current
    allocate (current)
    parse_tree => current%parse_tree_t
    current%previous => pt_stack%last
    pt_stack%last => current
  end subroutine pt_stack_push

```

35.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a WHIZARD instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+=
  public :: whizard_t

```

```

<WHIZARD: types>+=
  type :: whizard_t
    type(whizard_options_t) :: options
    type(rt_data_t) :: global
    type(pt_stack_t) :: pt_stack
  contains
    <WHIZARD: whizard: TBP>
  end type whizard_t

```

35.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>=
  procedure :: init => whizard_init

<WHIZARD: sub interfaces>+=
  module subroutine whizard_init (whizard, options, paths, logfile)
    class(whizard_t), intent(out), target :: whizard
    type(whizard_options_t), intent(in) :: options
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
  end subroutine whizard_init

<WHIZARD: procedures>+=
  module subroutine whizard_init (whizard, options, paths, logfile)
    class(whizard_t), intent(out), target :: whizard
    type(whizard_options_t), intent(in) :: options
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
    call init_syntax_tables ()
    whizard%options = options
    call whizard%global%global_init (paths, logfile)
    call whizard%init_job_id ()
    call whizard%init_rebuild_flags ()
    call whizard%unpack_files ()
    call whizard%preload_model ()
    call whizard%preload_library ()
    call whizard%global%init_fallback_model &
      (var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))
  end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+=
  procedure :: final => whizard_final

<WHIZARD: sub interfaces>+=
  module subroutine whizard_final (whizard)
    class(whizard_t), intent(inout), target :: whizard
  end subroutine whizard_final

<WHIZARD: procedures>+=
  module subroutine whizard_final (whizard)
    class(whizard_t), intent(inout), target :: whizard
    call whizard%global%final ()

```

```

    call whizard%pt_stack%final ()
    call whizard%pack_files ()
    call final_syntax_tables ()
end subroutine whizard_final

```

Set the job ID, if nonempty. If the ID string is empty, the value remains undefined.

```

<WHIZARD: whizard: TBP>+=
  procedure :: init_job_id => whizard_init_job_id

<WHIZARD: sub interfaces>+=
  module subroutine whizard_init_job_id (whizard)
    class(whizard_t), intent(inout), target :: whizard
  end subroutine whizard_init_job_id

<WHIZARD: procedures>+=
  module subroutine whizard_init_job_id (whizard)
    class(whizard_t), intent(inout), target :: whizard
    associate (var_list => whizard%global%var_list, options => whizard%options)
      if (options%job_id /= "") then
        call var_list%set_string (var_str ("$_job_id"), &
          options%job_id, is_known=.true.)
      end if
    end associate
  end subroutine whizard_init_job_id

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+=
  procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: sub interfaces>+=
  module subroutine whizard_init_rebuild_flags (whizard)
    class(whizard_t), intent(inout), target :: whizard
  end subroutine whizard_init_rebuild_flags

<WHIZARD: procedures>+=
  module subroutine whizard_init_rebuild_flags (whizard)
    class(whizard_t), intent(inout), target :: whizard
    associate (var_list => whizard%global%var_list, options => whizard%options)
      call var_list%append_log (var_str ("?rebuild_library"), &
        options%rebuild_library, intrinsic=.true.)
      call var_list%append_log (var_str ("?recompile_library"), &
        options%recompile_library, intrinsic=.true.)
      call var_list%append_log (var_str ("?rebuild_phase_space"), &
        options%rebuild_phs, intrinsic=.true.)
      call var_list%append_log (var_str ("?rebuild_grids"), &
        options%rebuild_grids, intrinsic=.true.)
      call var_list%append_log (var_str ("?rebuild_events"), &
        options%rebuild_events, intrinsic=.true.)
    end associate
  end subroutine whizard_init_rebuild_flags

```

Pack/unpack files in the working directory, if requested.

```

  end if
end do SCAN_LIBS
end subroutine whizard_preload_library

```

35.2.5 Initialization and finalization: syntax tables

Initialize/finalize the syntax tables used by WHIZARD. These are effectively singleton objects. We introduce a module variable that tracks the initialization status.

Without syntax tables, essentially nothing will work. Any initializer has to call this.

```

<WHIZARD: variables>≡
  logical :: syntax_tables_exist = .false.

<WHIZARD: public>+≡
  public :: init_syntax_tables
  public :: final_syntax_tables

<WHIZARD: sub interfaces>+≡
  module subroutine init_syntax_tables ()
  end subroutine init_syntax_tables
  module subroutine final_syntax_tables ()
  end subroutine final_syntax_tables

<WHIZARD: procedures>+≡
  module subroutine init_syntax_tables ()
    if (.not. syntax_tables_exist) then
      call syntax_model_file_init ()
      call syntax_phs_forest_init ()
      call syntax_pexpr_init ()
      call syntax_slha_init ()
      call syntax_cmd_list_init ()
      syntax_tables_exist = .true.
    end if
  end subroutine init_syntax_tables

  module subroutine final_syntax_tables ()
    if (syntax_tables_exist) then
      call syntax_model_file_final ()
    end if
  end subroutine final_syntax_tables

```

```

        call syntax_phs_forest_final ()
        call syntax_pexpr_final ()
        call syntax_slha_final ()
        call syntax_cmd_list_final ()
        syntax_tables_exist = .false.
    end if
end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
    public :: write_syntax_tables

<WHIZARD: sub interfaces>+≡
    module subroutine write_syntax_tables ()
    end subroutine write_syntax_tables

<WHIZARD: procedures>+≡
    module subroutine write_syntax_tables ()
        integer :: unit
        character(*), parameter :: file_model = "whizard.model_file.syntax"
        character(*), parameter :: file_phs = "whizard.phase_space_file.syntax"
        character(*), parameter :: file_pexpr = "whizard.prt_expressions.syntax"
        character(*), parameter :: file_slha = "whizard.slha.syntax"
        character(*), parameter :: file_sindarin = "whizard.sindarin.syntax"
        if (.not. syntax_tables_exist) call init_syntax_tables ()
        unit = free_unit ()
        print *, "Writing file '" // file_model // "'"
        open (unit=unit, file=file_model, status="replace", action="write")

35.3 Query Feature Support

This module accesses the various optional features (modules) that WHIZARD can support and reports on their availability.

```
<features.f90>≡
  module features

    <Standard module head>

    <Features: public>

    interface
    <Features: sub interfaces>
    end interface

  end module features

<features_sub.f90>≡
  <File header>

  submodule (features) features_s

    use string_utils, only: lower_case
    use system_dependencies, only: WHIZARD_VERSION
    <Features: dependencies>

    implicit none

    contains

    <Features: procedures>

  end submodule features_s
```

35.3.1 Output

```
<Features: public>≡
  public :: print_features

<Features: sub interfaces>≡
  module subroutine print_features ()
    end subroutine print_features

<Features: procedures>≡
  module subroutine print_features ()
    print "(A)", "WHIZARD " // WHIZARD_VERSION
    print "(A)", "Build configuration:"
    <Features: config>
    print "(A)", "Optional features available in this build:"
    <Features: print>
  end subroutine print_features
```

35.3.2 Query function

```
<Features: procedures>+≡
  subroutine check (feature, recognized, result, help)
    character(*), intent(in) :: feature
    logical, intent(out) :: recognized
    character(*), intent(out) :: result, help
    recognized = .true.
    result = "no"
    select case (lower_case (trim (feature)))
