iteratively for  $p_T$ . If the current emission is not accepted, in the next step it is  $\log \Delta^{(U)}(p_T^{\max}) = \log r_1$ , so that we have to solve the equation

$$\log \Delta^{(U)}(p_T) = \log r_1 + \log r_2$$

using the second random number  $r_2$ .

## Simple FSR

This corresponds to Appendix C of 1002.2581

```

<POWHEG matching: public>+≡
  public :: sudakov_simple_fsr_t
<POWHEG matching: types>+≡
  type, extends (sudakov_t) :: sudakov_simple_fsr_t
  contains
    <POWHEG matching: sudakov simple fsr: TBP>
  end type sudakov_simple_fsr_t

```

The simplest upper bounding function for final-state radiation is

$$\text{upper\_bound\_func} = \frac{U(\xi, y)}{N} = \frac{\alpha_s}{\xi(1-y)} \quad (31.4)$$

```

<POWHEG matching: sudakov simple fsr: TBP>≡
  procedure :: upper_bound_func => sudakov_simple_fsr_upper_bound_func
<POWHEG matching: procedures>+≡
  pure function sudakov_simple_fsr_upper_bound_func (sudakov, xi, y, alpha_s) result (u)
    real(default) :: u
    class(sudakov_simple_fsr_t), intent(in) :: sudakov
    real(default), intent(in) :: xi, y, alpha_s
    u = alpha_s / (xi * (1 - y))
  end function sudakov_simple_fsr_upper_bound_func

```

The above upper bounding function corresponds to the transverse momentum scale

$$k_T^2 = \frac{s}{2} \xi^2 (1-y). \quad (31.5)$$

```

<POWHEG matching: sudakov simple fsr: TBP>+≡

## Massive FSR

```

<POWHEG matching: public>+≡
  public :: sudakov_massive_fsr_t

```

```

<POWHEG matching: types>+≡
  type, extends (sudakov_t) :: sudakov_massive_fsr_t
    real(default) :: z, z1, z2 = 0._default
    real(default) :: xi_1, xi_min, xi_m = 0._default
    real(default) :: xi_max_extended = 1._default
  contains
  <POWHEG matching: sudakov massive fsr: TBP>
  end type sudakov_massive_fsr_t

```

During the radiation generation, an alternative expression for  $\xi_{\max}$ ,

$$\xi_{\max} = 1 - \frac{(m + m_{\text{rec}})^2}{q^2},$$

is used, which corresponds to an extended Dalitz region. Phase space points outside of the original Dalitz region will be vetoed afterwards.

```

<POWHEG matching: sudakov massive fsr: TBP>≡
  procedure :: compute_xi_max_extended &
    => sudakov_massive_fsr_compute_xi_max_extended

<POWHEG matching: procedures>+≡
  subroutine sudakov_massive_fsr_compute_xi_max_extended (sudakov, i_phs)
    class(sudakov_massive_fsr_t), intent(inout) :: sudakov
    integer, intent(in) :: i_phs
    real(default) :: m, mrec
    real(default) :: q0
    type(vector4_t) :: p
    q0 = sqrt(sudakov%event_deps%s_hat)
    p = sudakov%event_deps%p_born_lab%get_momentum (1, sudakov%associated_emitter())
    m = p**1
    mrec = sqrt ((q0 - p%p(0))**2 - p%p(1)**2 - p%p(2)**2 - p%p(3)**2)
    sudakov%xi_max_extended = one - (m + mrec)**2 / q0**2
  end subroutine sudakov_massive_fsr_compute_xi_max_extended

```

For massive emitters, the radiation variable  $\xi$  is constructed as follows. First,

$$\xi_{\min}(k_T^2) = \frac{\sqrt{k_T^2(k_T^2 z_2^2 + 8\bar{p}^0 q(1 - z_2)) - k_T^2 z_2}}{2q^2(1 - z_2)} \quad (31.7)$$

is computed. Then  $\xi_1$  is computed according to the same equation with  $z_2 \leftrightarrow z_1$ . Finally,  $\xi$  is generated according to

$$\xi = \frac{1}{q^2} \exp \left[ \log(\xi_{\min} q^2 - k_T^2) + r \log \frac{\xi_m q^2 - k_T^2}{\xi_{\min} q^2 - k_T^2} + k_T^2 \right], \quad (31.8)$$

where  $\xi_m = \min(\xi_{\max}, \xi_1)$ .

```

## Generation algorithm and grid initialization

`compute_sqme_real` is the projected real matrix element  $R_{\alpha_r} = S_{\alpha_r} R$  whereby the current  $\alpha_r$  is implied by the `emitter`. Furthermore, it is multiplied by the Jacobian.

```

For each underlying Born  $f_b$ , there is a number of radiation regions. A radiation region  $rr$  may correspond multiple  $\alpha_r$ s. The phase space only depends upon the radiation region kinematics  $rr$  and not on the specific  $\alpha_r$ .  $\alpha_r$  can be picked in the set  $\{\alpha_r|f_b, rr\}$  proportional to their  $R_{\alpha_r}$ . For now, we simplify things though and just work with the  $\alpha_r$ .

The following is valid for one underlying Born.

```

### 31.4.4 $\alpha_s$ and its reweighting

The main point to ensure here is that the simple fixed-flavor-1-loop expression  $\alpha_s^{\text{rad}}$  is larger than the more accurate  $\alpha_s$  such that we can use a reweighting veto and use  $\alpha_s^{\text{rad}}$  for the generation of the emission. This can be done by setting

$$\alpha_s^{\text{rad}}(\mu_0) = \alpha_s(\mu_0) \quad (31.13)$$

whereby  $\mu_0^2$  is the `scale_to_relate2` that is taken to be  $p_{T,\text{min}}^2$ .

### 31.4.5 POWHEG hook

We provide a POWHEG hook to be called by `process_instance_evaluate` to prefill the adaptation grid.

We store the actual `powheg` object, which does the computations.

*<POWHEG matching: public>+≡*

```

public :: powheg_matching_hook_t

```

*<POWHEG matching: types>+≡*

```

type, extends(process_instance_hook_t) :: powheg_matching_hook_t
  type(string_t) :: process_name
  type(powheg_matching_t) :: powheg
contains
  <POWHEG matching: powheg matching hook: TBP>
end type powheg_matching_hook_t

```

Init the hook. The init procedure will be called in `setup_process`, after everything is set up.

Additionally, we have to include `var_list` in order to retrieve the grid size in `xi` and `y`.

```

<POWHEG matching: powheg matching hook: TBP>≡
  procedure :: init => powheg_matching_hook_init

<POWHEG matching: procedures>+≡
  subroutine powheg_matching_hook_init (hook, var_list, instance)

## Chapter 32

# Event Implementation

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

**event\_transforms** Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

**resonance\_insertion** Insert a resonance history into an event record, based on kinematical and matrix-element information.

**recoil\_kinematics** Common kinematics routines for the ISR and EPA handlers.

**isr\_photon\_handler** Transform collinear kinematics, as it results from applying ISR radiation, to non-collinear kinematics with a reasonable transverse-momentum distribution of the radiated photons, and also of the recoiling partonic event.

**epa\_beam\_handler** For photon-initiated processes where the effective photon approximation is used in integration, to add in beam-particle recoil. Analogous to the ISR handler.

**decays** Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

**showers** Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

**hadrons** (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

**tau\_decays** (not implemented yet) Let  $\tau$  leptons decay taking full spin correlations into account.

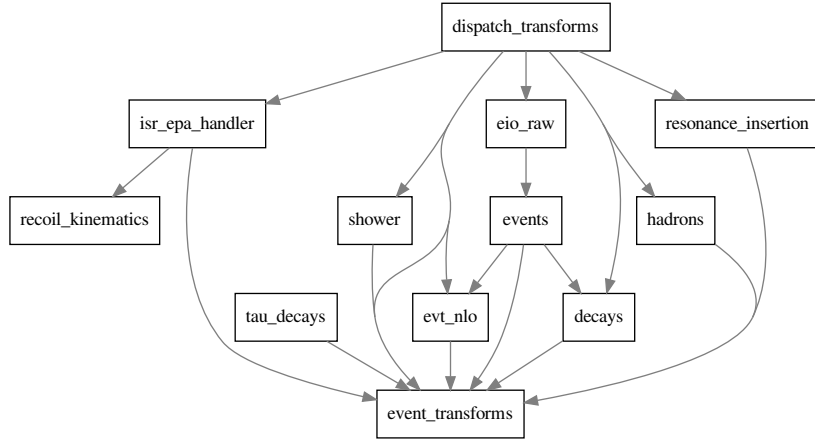

Figure 32.1: Module dependencies in `src/transforms`.

**evt\_nlo** Handler for fixed-order NLO events.

**events** Combine all pieces to generate full events.

**eio\_raw** Raw I/O for complete events.

## 32.1 Abstract Event Transforms

```

<event_transforms.f90>≡
  <File header>

  module event_transforms

    <Use kinds>
    <Use strings>
    use io_units
    use format_utils, only: write_separator
    use diagnostics
    use model_data
    use interactions
    use particles
    use subevents
    use rng_base
    use quantum_numbers, only: quantum_numbers_t
    use process, only: process_t
    use instances, only: process_instance_t
    use process_stacks

    <Standard module head>

```

```

    <Event transforms: public>

    <Event transforms: types>

    <Event transforms: interfaces>

contains

    <Event transforms: procedures>

end module event_transforms

```

### 32.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified setting that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include `previous` and `next` pointers.

```

<Event transforms: public>≡
    public :: evt_t

<Event transforms: types>≡
    type, abstract :: evt_t
        type(process_t), pointer :: process => null ()
        type(process_instance_t), pointer :: process_instance => null ()
        class(model_data_t), pointer :: model => null ()
        class(rng_t), allocatable :: rng
        integer :: rejection_count = 0
        logical :: particle_set_exists = .false.
        type(particle_set_t) :: particle_set
        class(evt_t), pointer :: previous => null ()
        class(evt_t), pointer :: next => null ()
        real(default) :: weight = 0._default
        logical :: only_weighted_events = .false.
    contains
        <Event transforms: evt: TBP>
    end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡
    procedure :: final => evt_final
    procedure :: base_final => evt_final

<Event transforms: procedures>≡
    subroutine evt_final (evt)
        class(evt_t), intent(inout) :: evt
    end subroutine

```

```

    if (allocated (evt%rng)) call evt%rng%final ()
    if (evt%particle_set_exists) &
        call evt%particle_set%final ()
end subroutine evt_final

```

Print out the type of the evt.

```

<Event transforms: evt: TBP>+≡
    procedure (evt_write_name), deferred :: write_name

```

```

<Event transforms: interfaces>≡
    abstract interface
        subroutine evt_write_name (evt, unit)
            import
            class(evt_t), intent(in) :: evt
            integer, intent(in), optional :: unit
        end subroutine evt_write_name
    end interface

```

```

<Event transforms: evt: TBP>+≡
    procedure (evt_write), deferred :: write

```

```

<Event transforms: interfaces>+≡
    abstract interface
        subroutine evt_write (evt, unit, verbose, more_verbose, testflag)
            import
            class(evt_t), intent(in) :: evt
            integer, intent(in), optional :: unit
            logical, intent(in), optional :: verbose, more_verbose, testflag
        end subroutine evt_write
    end interface

```

Output. We can print r.n.g. info.

```

<Event transforms: evt: TBP>+≡
    procedure :: base_write => evt_base_write

```

```

<Event transforms: procedures>+≡
    subroutine evt_base_write (evt, unit, testflag, show_set)
        class(evt_t), intent(in) :: evt
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: testflag, show_set
        integer :: u
        logical :: show
        u = given_output_unit (unit)
        show = .true.; if (present (show_set)) show = show_set
        if (associated (evt%process)) then
            write (u, "(3x,A,A,A)") "Associated process: '", &
                char (evt%process%get_id ()), "'"
        end if
        if (allocated (evt%rng)) then
            call evt%rng%write (u, 1)
            write (u, "(3x,A,I0)") "Number of tries = ", evt%rejection_count
        end if
        if (show) then
            if (evt%particle_set_exists) then

```

```

        call write_separator (u)
        call evt%particle_set%write (u, testflag = testflag)
    end if
end if
end subroutine evt_base_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

```

<Event transforms: evt: TBP>+≡
    procedure :: connect => evt_connect
    procedure :: base_connect => evt_connect

<Event transforms: procedures>+≡
    subroutine evt_connect (evt, process_instance, model, process_stack)
        class(evt_t), intent(inout), target :: evt
        type(process_instance_t), intent(in), target :: process_instance
        class(model_data_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        evt%process => process_instance%process
        evt%process_instance => process_instance
        evt%model => model
        call evt%process%make_rng (evt%rng)
    end subroutine evt_connect

```

Reset internal state.

```

<Event transforms: evt: TBP>+≡
    procedure :: reset => evt_reset
    procedure :: base_reset => evt_reset

<Event transforms: procedures>+≡
    subroutine evt_reset (evt)
        class(evt_t), intent(inout) :: evt
        evt%rejection_count = 0
        call evt%particle_set%final ()
        evt%particle_set_exists = .false.
    end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

<Event transforms: evt: TBP>+≡
    procedure (evt_prepare_new_event), deferred :: prepare_new_event

<Event transforms: interfaces>+≡
    interface
        subroutine evt_prepare_new_event (evt, i_mci, i_term)
            import
            class(evt_t), intent(inout) :: evt
            integer, intent(in) :: i_mci, i_term
        end subroutine evt_prepare_new_event
    end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)
      import
      class(evt_t), intent(inout) :: evt
      real(default), intent(inout) :: probability
    end subroutine evt_generate_weighted
  end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted

(Event transforms: procedures)+≡
  subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set

(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
  end interface

```

```

        integer, intent(in) :: factorization_mode
        logical, intent(in) :: keep_correlations
        real(default), dimension(:), intent(in), optional :: r
    end subroutine evt_make_particle_set
end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

<Event transforms: evt: TBP>+≡
    procedure :: set_particle_set => evt_set_particle_set

<Event transforms: procedures>+≡
    subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
        class(evt_t), intent(inout) :: evt
        type(particle_set_t), intent(in) :: particle_set
        integer, intent(in) :: i_term, i_mci
        call evt%prepare_new_event (i_mci, i_term)
        evt%particle_set = particle_set
        evt%particle_set_exists = .true.
    end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. (We need two interactions, one with color summed over, and one with the probability distributed among flows.)

We use the two values from the random number generator for factorizing the state. For testing purposes, we can provide those numbers explicitly.

```

<Event transforms: evt: TBP>+≡
    procedure :: factorize_interactions => evt_factorize_interactions

<Event transforms: procedures>+≡
    subroutine evt_factorize_interactions &
        (evt, int_matrix, int_flows, factorization_mode, &
         keep_correlations, r, qn_select)

        if (present (ii_term)) then
            i_term = ii_term
        else
            i_term = evt%process_instance%select_i_term ()
        end if
        int_matrix => evt%process_instance%get_matrix_int_ptr (i_term)
        int_flows => evt%process_instance%get_flows_int_ptr (i_term)
        call evt%factorize_interactions (int_matrix, int_flows, &
            factorization_mode, keep_correlations, r, qn_select)
        call evt%tag_incoming ()
    else
        call msg_bug ("Event factorization: event is incomplete")
    end if
end subroutine make_factorized_particle_set

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

```

<Event transforms: evt: TBP>+≡
procedure :: tag_incoming => evt_tag_incoming

<Event transforms: procedures>+≡
subroutine evt_tag_incoming (evt)
    class(evt_t), intent(inout) :: evt
    integer :: i_term, n_in
    integer, dimension(:), allocatable :: beam_index, in_index
    n_in = evt%process%get_n_in ()
    i_term = 1
    allocate (beam_index (n_in))
    call evt%process_instance%get_beam_index (i_term, beam_index)
    call evt%particle_set%reset_status (beam_index, PRT_BEAM)

```

```

allocate (in_index (n_in))
call evt%process_instance%get_in_index (i_term, in_index)
call evt%particle_set%reset_status (in_index, PRT_INCOMING)
end subroutine evt_tag_incoming

```

### 32.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

<Event transforms: public>+≡
  public :: evt_trivial_t

<Event transforms: types>+≡
  type, extends (evt_t) :: evt_trivial_t
  contains
  <Event transforms: evt trivial: TBP>
  end type evt_trivial_t

<Event transforms: evt trivial: TBP>≡
  procedure :: write_name => evt_trivial_write_name

<Event transforms: procedures>+≡
  subroutine evt_trivial_write_name (evt, unit)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event transform: trivial (hard process)"
  end subroutine evt_trivial_write_name

```

The finalizer is trivial. Some output:

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: write => evt_trivial_write

<Event transforms: procedures>+≡
  subroutine evt_trivial_write (evt, unit, verbose, more_verbose, testflag)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, more_verbose, testflag
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    call evt%write_name (u)
    call write_separator (u)
    call evt%base_write (u, testflag = testflag)
    !!! More readable but wider output; in line with evt_resonance_write
    !   if (verbose .and. evt%particle_set_exists) then
    !     call evt%particle_set%write &
    !       (u, summary = .true., compressed = .true., testflag = testflag)
    !     call write_separator (u)
    !   end if
  end subroutine evt_trivial_write

```

Nothing to do here:

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: prepare_new_event => evt_trivial_prepare_new_event

<Event transforms: procedures>+≡
  subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
  end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: generate_weighted => evt_trivial_generate_weighted

<Event transforms: procedures>+≡
  subroutine evt_trivial_generate_weighted (evt, probability)
    class(evt_trivial_t), intent(inout) :: evt
    real(default), intent(inout) :: probability
    probability = 1
  end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: make_particle_set => evt_trivial_make_particle_set

<Event transforms: procedures>+≡
  subroutine evt_trivial_make_particle_set &
    (evt, factorization_mode, keep_correlations, r)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    call make_factorized_particle_set (evt, factorization_mode, &
      keep_correlations, r)
    evt%particle_set_exists = .true.
  end subroutine evt_trivial_make_particle_set

```

### 32.1.3 Unit tests

Test module, followed by the corresponding implementation module.

```

### 32.3.2 Set contained data

Insert the resonance data, in form of a pre-generated resonance history set. Accumulate the number of histories for each set, to initialize an array of index offsets for lookup.

```

<Resonance insertion: evt_resonance: TBP>+≡
  procedure :: set_resonance_data => evt_resonance_set_resonance_data

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_set_resonance_data (evt, res_history_set)
    class(evt_resonance_t), intent(inout) :: evt
    type(resonance_history_set_t), dimension(:), intent(in) :: res_history_set
    integer :: i
    evt%res_history_set = res_history_set
    allocate (evt%index_offset (size (evt%res_history_set)), source = 0)
    do i = 2, size (evt%res_history_set)
      evt%index_offset(i) = &
        evt%index_offset(i-1) + evt%res_history_set(i-1)%get_n_history ()
    end do
  end subroutine evt_resonance_set_resonance_data

```

Set the library that contains the resonant subprocesses.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_library => evt_resonance_set_library

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_set_library (evt, libname)
    class(evt_resonance_t), intent(inout) :: evt
    type(string_t), intent(in) :: libname
    evt%libname = libname
  end subroutine evt_resonance_set_library

```

Assign pointers to subprocess instances. Once a subprocess has been selected, the instance is used for generating the particle set with valid quantum-number assignments, ready for resonance insertion.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_subprocess_instances &
    => evt_resonance_set_subprocess_instances

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_set_subprocess_instances (evt, instance)
    class(evt_resonance_t), intent(inout) :: evt
    type(process_instance_ptr_t), dimension(:), intent(in) :: instance
    evt%instance = instance
  end subroutine evt_resonance_set_subprocess_instances

```

Set the on-shell limit, the relative distance from a resonance that is still considered to be on-shell. The probability for being considered on-shell can be reduced by the turnoff parameter below. For details, see the **resonances** module.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_on_shell_limit => evt_resonance_set_on_shell_limit

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_set_on_shell_limit (evt, on_shell_limit)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_limit
    evt%on_shell_limit = on_shell_limit
  end subroutine evt_resonance_set_on_shell_limit

```

Set the Gaussian on-shell turnoff parameter, the width of the weighting factor for the resonance squared matrix element. If the resonance is off shell, this factor reduces the weight of the matrix element in the selector, such that the probability for considered resonant is reduced. The factor is applied only if the offshellness is less than the **on\_shell\_limit** above. For details, see the **resonances** module.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_on_shell_turnoff => evt_resonance_set_on_shell_turnoff

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_set_on_shell_turnoff (evt, on_shell_turnoff)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_turnoff
    evt%on_shell_turnoff = on_shell_turnoff
  end subroutine evt_resonance_set_on_shell_turnoff

```

Reweight (suppress) the background contribution if there is a resonance history that applies. The event will be registered as background if there is no applicable resonance history, or if the background configuration has been selected based on (reweighted) squared matrix elements.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_background_factor => evt_resonance_set_background_factor

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_set_background_factor (evt, background_factor)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: background_factor
    evt%background_factor = background_factor
  end subroutine evt_resonance_set_background_factor

```

### 32.3.3 Selector

Manually import a random-number generator object. This should be done only for testing purposes. The standard procedure is to `connect` a process to an event transform; this will create an appropriate `rng` from the RNG factory in the process object.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: import_rng => evt_resonance_import_rng

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_import_rng (evt, rng)
    class(evt_resonance_t), intent(inout) :: evt
    class(rng_t), allocatable, intent(inout) :: rng
    call move_alloc (from = rng, to = evt%rng)
  end subroutine evt_resonance_import_rng

```

We use a standard selector object to choose from the available resonance histories. If the selector is inactive, we do not insert resonances.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: write_selector => evt_resonance_write_selector

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_write_selector (evt, unit, testflag)
    class(evt_resonance_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: u
    u = given_output_unit (unit)
    if (evt%selector_active) then
      call evt%selector%write (u, testflag)
    else
      write (u, "(1x,A)") "Selector: [inactive]"
    end if
  end subroutine evt_resonance_write_selector

```

The selector is initialized with relative weights of histories which need not be normalized. Channels with weight zero are ignored.

The **offset** will normally be  $-1$ , so we count from zero, and zero is a valid result from the selector. Selecting the zero entry implies no resonance insertion. However, this behavior is not hard-coded here (without offset, no resonance is not possible as a result).

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: init_selector => evt_resonance_init_selector

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_init_selector (evt, weight, offset)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), dimension(:), intent(in) :: weight
    integer, intent(in), optional :: offset
    if (any (weight > 0)) then
      call evt%selector%init (weight, offset = offset)
      evt%selector_active = .true.
    else
      evt%selector_active = .false.
    end if
  end subroutine evt_resonance_init_selector

```

Return all selector weights, for inspection. Note that the index counts from zero.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: get_selector_weights => evt_resonance_get_selector_weights

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_get_selector_weights (evt, weight)
    class(evt_resonance_t), intent(in) :: evt
    real(default), dimension(0:), intent(out) :: weight
    integer :: i
    do i = 0, ubound (weight,1)
      weight(i) = evt%selector%get_weight (i)
    end do
  end subroutine evt_resonance_get_selector_weights

```

### 32.3.4 Runtime calculations

Use the associated master process instance and the subprocess instances to distribute the current momentum set, then compute the squared matrix elements weights for all subprocesses.

NOTE: Procedures in this subsection are not covered by unit tests in this module, but by unit tests of the **restricted\_subprocesses** module.

Fill the particle set, so the momentum configuration can be used by the subprocess instances. The standard workflow is to copy from the previous particle set.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: fill_momenta => evt_resonance_fill_momenta

```

```

<Resonance insertion: procedures>+≡
subroutine evt_resonance_fill_momenta (evt)
  class(evt_resonance_t), intent(inout) :: evt
  integer :: i, n
  if (associated (evt%previous)) then
    evt%particle_set = evt%previous%particle_set
  else if (associated (evt%process_instance)) then
    ! this branch only for unit test
    call evt%process_instance%get_trace &
      (evt%particle_set, i_term=1, n_incoming=evt%process%get_n_in ())
  end if
end subroutine evt_resonance_fill_momenta

```

Return the indices of those subprocesses which can be considered on-shell. The result depends on the stored particle set (outgoing momenta) and on the on-shell limit value.

The index `evt%selected_component` identifies the particular history set that corresponds to the given process component. Recall that process components may have different external particles, so they have distinct history sets.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: determine_on_shell_histories &
    => evt_resonance_determine_on_shell_histories

<Resonance insertion: procedures>+≡
subroutine evt_resonance_determine_on_shell_histories &
  (evt, index_array)
  class(evt_resonance_t), intent(in) :: evt
  integer, dimension(:), allocatable, intent(out) :: index_array
  integer :: i
  i = evt%selected_component
  call evt%res_history_set(i)%determine_on_shell_histories &
    (evt%particle_set%get_outgoing_momenta (), &
     evt%on_shell_limit, &
     index_array)
end subroutine evt_resonance_determine_on_shell_histories

```

Evaluate selected subprocesses. (In actual operation, the ones that have been tagged as on-shell.)

We assume that the MCI, term, and channel indices for the subprocesses can all be set to 1.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: evaluate_subprocess => evt_resonance_evaluate_subprocess

<Resonance insertion: procedures>+≡
subroutine evt_resonance_evaluate_subprocess (evt, index_array)
  class(evt_resonance_t), intent(inout) :: evt
  integer, dimension(:), intent(in) :: index_array
  integer :: k, i
  if (allocated (evt%instance)) then
    do k = 1, size (index_array)
      i = index_array(k)
      associate (instance => evt%instance(i)%p)
        call instance%choose_mci (1)
      end associate
    end do
  end if
end subroutine evt_resonance_evaluate_subprocess

```

```

        call instance%set_trace (evt%particle_set, 1, check_match=.false.)
        call instance%recover (channel = 1, i_term = 1, &
            update_sqme = .true., recover_phs = .false.)
    end associate
end do
end if
end subroutine evt_resonance_evaluate_subprocess

```

Return the current squared matrix-element value of the master process, and of the selected resonant subprocesses, respectively.

*(Resonance insertion: evt\_resonance: TBP)+≡*

```

    procedure :: get_master_sqme => evt_resonance_get_master_sqme
    procedure :: get_subprocess_sqme => evt_resonance_get_subprocess_sqme

```

*(Resonance insertion: procedures)+≡*

```

    function evt_resonance_get_master_sqme (evt) result (sqme)

    & (evt%particle_set%get_outgoing_momenta (), &
    &   evt%on_shell_turnoff, index_array(k))
end do
end subroutine evt_resonance_apply_turnoff_factor

```

We use the calculations of resonant matrix elements to determine probabilities for all applicable resonance configurations. This method combines the steps implemented above.

First, we determine the selected process component.

TODO: the version below selects the first component which is found active. This make sense only for standard LO process components, where exactly one component corresponds to a MCI set.

For the selected process component, we query the kinematics and determine the applicable resonance histories. We collect squared matrix elements for those resonance histories and compare them to the master-process squared matrix element.

The result is the probability for each resonance history together with the probability for non-resonant background (zeroth entry). The latter is defined as the difference between the complete process result and the sum of the resonances, ignoring the possibility for interference. If the complete process result is actually undershooting the sum of resonances, we nevertheless count the background with positive probability.

When looking up the subprocess sqme, we must add the `index_offset` to the resulting array, since the indices returned by the individual history set all count from one, while the subprocess instances that belong to process components are collected in one flat array.

After determining matrix elements and background, we may reduce the weight of the matrix elements in the selector by applying a turnoff factor.

The factor `background_factor` indicates whether to include the background contribution at all, as long as there is a nonvanishing resonance contribution. Note that instead of setting background to zero, we just multiply it by a very small number. This ensures that indices are assigned correctly, and that background will eventually be selected if smooth turnoff is chosen.

*(Resonance insertion: evt resonance: TBP)+≡*

```

procedure :: compute_probabilities => evt_resonance_compute_probabilities

```

*(Resonance insertion: procedures)+≡*

```

subroutine evt_resonance_compute_probabilities (evt)
  class(evt_resonance_t), intent(inout) :: evt

end if
if (any (sqme_res > 0)) then
    sqme_bg = sqme_bg * evt%background_factor
end if
call evt%init_selector ([sqme_bg, sqme_res], offset = -1)
end subroutine evt_resonance_compute_probabilities

```

Set the selected component (unit tests).

```

<Resonance insertion: evt resonance: TBP>+≡
    procedure :: select_component => evt_resonance_select_component

<Resonance insertion: procedures>+≡
    subroutine evt_resonance_select_component (evt, i_component)
        class(evt_resonance_t), intent(inout) :: evt
        integer, intent(in) :: i_component
        evt%selected_component = i_component
    end subroutine evt_resonance_select_component

```

### 32.3.5 Sanity check

Check the color assignment, which may be wrong for the inserted resonances. Delegated to the particle-set component. Return offending particle indices and, optionally, particles as arrays.

This is done in a unit test. The current algorithm, i.e., selecting the color assignment from the resonant-subprocess instance, should not generate invalid color assignments.

```

<Resonance insertion: evt resonance: TBP>+≡
    procedure :: find_prt_invalid_color => evt_resonance_find_prt_invalid_color

```

```

⟨Resonance insertion: procedures⟩+≡
  subroutine evt_resonance_find_prt_invalid_color (evt, index, prt)
    class(evt_resonance_t), intent(in) :: evt
    integer, dimension(:), allocatable, intent(out) :: index
    type(particle_t), dimension(:), allocatable, intent(out), optional :: prt
    if (evt%particle_set_exists) then
      call evt%particle_set%find_prt_invalid_color (index, prt)
    else
      allocate (prt (0))
    end if
  end subroutine evt_resonance_find_prt_invalid_color

```

### 32.3.6 API implementation

```

⟨Resonance insertion: evt resonance: TBP⟩+≡
  procedure :: prepare_new_event => evt_resonance_prepare_new_event

⟨Resonance insertion: procedures⟩+≡
  subroutine evt_resonance_prepare_new_event (evt, i_mci, i_term)
    class(evt_resonance_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
  end subroutine evt_resonance_prepare_new_event

```

Select one of the histories, based on the momentum array from the current particle set. Compute the probabilities for all resonant subprocesses and initialize the selector accordingly. Then select one resonance history, or none.

```

⟨Resonance insertion: evt resonance: TBP⟩+≡
  procedure :: generate_weighted => evt_resonance_generate_weighted

⟨Resonance insertion: procedures⟩+≡
  subroutine evt_resonance_generate_weighted (evt, probability)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(inout) :: probability
    call evt%fill_momenta ()
    call evt%compute_probabilities ()
    call evt%selector%generate (evt%rng, evt%selected_history)
    probability = 1
  end subroutine evt_resonance_generate_weighted

```

Here take the current particle set and insert resonance intermediate states if applicable. The resonance history has already been chosen by the generator above. If no resonance history applies, just retain the particle set.

If a resonance history applies, we factorize the exclusive interaction of the selected (resonance-process) process instance. With a temporary particle set `prt_set` as workspace, we insert the resonances, reinstate parent-child relations and set colors and momenta for the resonances. The temporary is then copied back.

Taking the event data from the resonant subprocess instead of the master process, guarantees that all flavor, helicity, and color assignments are valid for the selected resonance history. Note that the transform may thus choose

a quantum-number combination that is different from the one chosen by the master process.

The `i_term` value for the selected subprocess instance is always 1. We support only LO process. For those, the master process may have several terms (= components) that correspond to different external states. The subprocesses are distinct, each one corresponds to a definite master component, and by itself it consists of a single component/term.

However, if the selector chooses resonance history #0, i.e., no resonance, we just copy the particle set from the previous (i.e., trivial) event transform and ignore all subprocess data.

```

```

### 32.4.1 $\phi$ sampler

This is trivial. Generate an azimuthal angle, given a (0,1) RNG parameter.

```
<Recoil kinematics: procedures>≡
  elemental subroutine generate_phi_recoil (r, phi)
    real(default), intent(in) :: r
    real(default), intent(out) :: phi

    phi = r * twopi

  end subroutine generate_phi_recoil
```

### 32.4.2 $Q^2$ sampler

The dynamics of factorization suggests to generate a flat  $Q^2$  distribution from a (random) number, event by event.

At the lowest momentum transfer values, the particle (electron) mass sets a smooth cutoff. The formula can produce  $Q$  values below the electron mass, down to zero, but with a power distribution that eventually evolves into the expected logarithmic distribution for  $Q^2 > m^2$ .

We are talking about the absolute value here, so all  $Q^2$  values are positive. For the actual momentum transfer,  $q^2 = -Q^2$ .

```
<Recoil kinematics: public>≡
  public :: generate_q2_recoil

<Recoil kinematics: procedures>+≡
  elemental subroutine generate_q2_recoil (s, x_bar, q2_max, m2, r, q2)
    real(default), intent(in) :: s
    real(default), intent(in) :: q2_max
    real(default), intent(in) :: x_bar
    real(default), intent(in) :: m2
    real(default), intent(in) :: r
    real(default), intent(out) :: q2

    real(default) :: q2_max_evt

    q2_max_evt = q2_max_event (s, x_bar, q2_max)

    q2 = m2 * (exp (r * log (1 + (q2_max_evt / m2))) - 1)

  end subroutine generate_q2_recoil
```

The  $Q$  distribution is cut off from above by the kinematic limit, which depends on the energy that is available for the radiated photon, or by a user-defined cutoff – whichever is less. The kinematic limit fits the formulas for recoil momenta (see below), and it also implicitly enters the ISR collinear structure function, so the normalization of the distribution should be correct.

```

(Recoil kinematics: procedures)+≡
  elemental function q2_max_event (s, x_bar, q2_max) result (q2)
    real(default), intent(in) :: s
    real(default), intent(in) :: x_bar
    real(default), intent(in) :: q2_max
    real(default) :: q2

    q2 = min (x_bar * s, q2_max)

  end function q2_max_event

```

### 32.4.3 Kinematics functions

Given values for energies,  $Q_{1,2}^2$ , azimuthal angle, compute the matching polar angle of the radiating particle. The subroutine returns  $\sin \theta$  and  $\cos \theta$ .

```

(Recoil kinematics: procedures)+≡
  subroutine polar_angles (s, xb, rho, ee, q2, sin_th, cos_th, ok)
    real(default), intent(in) :: s
    real(default), intent(in) :: xb
    real(default), intent(in) :: rho
    real(default), dimension(2), intent(in) :: ee
    real(default), dimension(2), intent(in) :: q2
    real(default), dimension(2), intent(out) :: sin_th
    real(default), dimension(2), intent(out) :: cos_th
    logical, intent(out) :: ok

    real(default), dimension(2) :: sin2_th_2

    sin2_th_2 = q2 / (ee * rho * xb * s)

    if (all (sin2_th_2 <= 1)) then
      sin_th = 2 * sqrt (sin2_th_2 * (1 - sin2_th_2))
      cos_th = 1 - 2 * sin2_th_2
      ok = .true.
    else
      sin_th = 0
      cos_th = 1
      ok = .false.
    end if

  end subroutine polar_angles

```

Compute the acollinearity parameter  $\lambda$  from azimuthal and polar angles. The result is a number between 0 and 1.

```

(Recoil kinematics: procedures)+≡
  function lambda_factor (sin_th, cos_th, cphi) result (lambda)

```

```

real(default), dimension(2), intent(in) :: sin_th
real(default), dimension(2), intent(in) :: cos_th
real(default), intent(in) :: cphi
real(default) :: lambda

lambda = (1 - cos_th(1) * cos_th(2) - cphi * sin_th(1) * sin_th(2)) / 2

end function lambda_factor

```

Compute the factor that rescales photon energies, such that the radiation angles match the kinematics parameters.

For small values of  $\bar{x}/\cosh\eta$ , we have to use the Taylor expansion if we do not want to lose precision. The optional argument allows for a unit test that compares exact and approximate.

```

<Recoil kinematics: procedures>+≡
function scale_factor (che, lambda, xb0, approximate) result (rho)

  real(default), dimension(2), intent(out) :: xb

  xb = rho * ee * xb0
  x = 1 - xb

end subroutine scaled_x

```

#### 32.4.4 Iterative solution of kinematics constraints

Find a solution of the kinematics constraints. We know the parameters appropriate for collinear kinematics  $\sqrt{s}$ ,  $x_{1,2}^c$ . We have picked values for the momentum transfer  $Q_{1,2}$  and the azimuthal angles  $\phi_{1,2}$ . The solution consists of modified energy fractions  $x_{1,2}$  and polar angles  $\theta_{1,2}$ .

If the computation fails, which can happen for large momentum transfer, the flag ok will indicate this.

```

```

### 32.4.5 Generate recoil event

Combine the above kinematics calculations. First generate azimuthal angles and momentum transfer, solve kinematics and compute momenta for the radiated photons and the on-shell projected, recoiling partons.

The `mo` masses are used for the on-shell projection of the partons after radiation. They may be equal to `m`, or set to zero.

If `ok` is false, the data point has failed and we should repeat the procedure for a new set of RNG parameters `r`.

```

## 32.5 Transverse momentum for the ISR and EPA approximations

The ISR and EPA handler takes an event with a single radiated collinear particle (photon for ISR, beam particle for EPA) for each beam, respectively, and inserts transverse momentum for both. The four-particle kinematics allows us to generate  $Q^2$  and azimuthal angles independently, without violating energy-momentum conservation. The  $Q^2$  distribution is logarithmic, as required by the effective particle approximation, and reflected in the inclusive ISR/EPA structure functions. We also conserve the invariant mass of the partonic system after radiation. The total transverse-momentum kick is applied in form of a Lorentz transformation to the elementary process, both in- and out-particles. In fact, the incoming partons (beam particle for ISR, photon for EPA) which would be virtual space-like in the exact kinematics configuration, are replaced by on-shell incoming partons, such that energy, momentum, and invariant mass  $\sqrt{\hat{s}}$  are conserved.

Regarding kinematics, we treat all particles as massless. The beam-particle mass only appears as the parameter `isr_mass` or `epa_mass`, respectively, and cuts off the logarithmic distribution. The upper cutoff is `isr_q_max` (`epa_q_max`), which defaults to the available energy  $\sqrt{s}$ .

The only differences between ISR and EPA, in this context, are the particle types, and an extra  $\bar{x}$  factor in the lower cutoff for EPA, see below.

### 32.5.1 Event transform type

Convention: **beam** are the incoming partons before ISR – not necessarily the actual beams, need not be in c.m. frame. **radiated** are the radiated particles (photon for ISR), and **parton** are the remainders which initiate the elementary process. These particles are copied verbatim from the event record, and must be collinear.

The kinematical parameters are **sqrts** = invariant mass of the **beam** particles, **q\_max** and **m** determining the  $Q^2$  distribution, and **xc/xc<sub>b</sub>** as the energy fraction (complement) of the partons, relative to the beams.

Transformations: **lti** is the Lorentz transformation that would boost **pi** (c.m. frame) back to the original **beam** momenta (lab frame). **lto** is the recoil transformation, transforming the partons after ISR from the collinear frame to the recoiling frame. **lt** is the combination of both, which is to be applied to all particles after the hard interaction.

Momenta: **pi** are the beams transformed to their common c.m. frame. **ki** and **qi** are the photon/parton momenta in the **pi** c.m. frame. **km** and **qm** are the photon/parton momenta with the  $Q$  distribution applied, and finally **qo** are the partons **qm** projected on-shell.

### 32.5.5 Initialization

Manually import a random-number generator object. This should be done only for testing purposes. The standard procedure is to **connect** a process to an event transform; this will create an appropriate **rng** from the RNG factory in the process object.

```

<ISR/EPA handler: evt_isr: TBP>+≡
  procedure :: import_rng => evt_isr_epa_import_rng

<ISR/EPA handler: procedures>+≡
  subroutine evt_isr_epa_import_rng (evt, rng)
    class(evt_isr_epa_t), intent(inout) :: evt
    class(rng_t), allocatable, intent(inout) :: rng
    call move_alloc (from = rng, to = evt%rng)
  end subroutine evt_isr_epa_import_rng

```

Set constant kinematics limits and initialize for ISR. Note that **sqrts** is used only as the fallback value for **q\_max**. The actual **sqrts** value for the transform object is inferred from the incoming particles, event by event.

```

<ISR/EPA handler: evt_isr: TBP>+≡
  procedure :: set_data_isr => evt_isr_epa_set_data_isr

<ISR/EPA handler: procedures>+≡
  subroutine evt_isr_epa_set_data_isr (evt, sqrts, q_max, m, keep_mass)
    class(evt_isr_epa_t), intent(inout) :: evt
    real(default), intent(in) :: sqrts
    real(default), intent(in) :: q_max
    real(default), intent(in) :: m
    logical, intent(in) :: keep_mass
    if (sqrts <= 0) then
      call msg_fatal ("ISR handler: sqrts value must be positive")
    end if
    if (q_max <= 0 .or. q_max > sqrts) then
      evt%isr_q_max = sqrts
    else
      evt%isr_q_max = q_max
    end if
    if (m > 0) then
      evt%isr_mass = m
    else
      call msg_fatal ("ISR handler: ISR_mass value must be positive")
    end if
  end subroutine evt_isr_epa_set_data_isr

```

```

end if
evt%isr_active = .true.
evt%isr_keep_mass = keep_mass
end subroutine evt_isr_epa_set_data_isr

```

Set constant kinematics limits and initialize for EPA. Note that `sqrts` is used only as the fallback value for `q_max`. The actual `sqrts` value for the transform object is inferred from the incoming particles, event by event.

```

<ISR/EPA handler: evt isr: TBP>+≡
  procedure :: set_data_epa => evt_isr_epa_set_data_epa

<ISR/EPA handler: procedures>+≡
  subroutine evt_isr_epa_set_data_epa (evt, sqrts, q_max, m)
    class(evt_isr_epa_t), intent(inout) :: evt
    real(default), intent(in) :: sqrts
    real(default), intent(in) :: q_max
    real(default), intent(in) :: m
    if (sqrts <= 0) then
      call msg_fatal ("EPA handler: sqrts value must be positive")
    end if
    if (q_max <= 0 .or. q_max > sqrts) then
      evt%epa_q_max = sqrts
    else
      evt%epa_q_max = q_max
    end if
    if (m > 0) then
      evt%epa_mass = m
    else
      call msg_fatal ("EPA handler: EPA_mass value must be positive")
    end if
    evt%epa_active = .true.
  end subroutine evt_isr_epa_set_data_epa

```

### 32.5.6 Fetch event data

Identify the radiated particles and the recoil momenta in the particle set. Without much sophistication, start from the end and find particles with the “remnant” status. Their parents should point to the recoiling parton. If successful, set the particle indices in the `evt` object, for further processing.

```

<ISR/EPA handler: evt isr: TBP>+≡
  procedure, private :: identify_radiated

<ISR/EPA handler: procedures>+≡
  subroutine identify_radiated (evt)

end subroutine infer_x

```

### 32.5.7 Two-parton recoil

For transforming partons into recoil momenta, we make use of the routines in the `recoil_kinematics` module. In addition to the collinear momenta, we use the  $x$  energy fractions, and four numbers from the RNG.

There is one subtle difference w.r.t. ISR case: the EPA mass parameter is multiplied by the energy fraction  $x$ , separately for each beam. This is the effective lower  $Q$  cutoff.

For certain kinematics, close to the  $Q_{\max}$  endpoint, this may fail, and `ok` is set to false. In that case, we should generate new recoil momenta for the same event. This is handled by the generic unweighting procedure.

```

<ISR/EPA handler: evt isr: TBP>+≡
  procedure, private :: generate_recoil => evt_generate_recoil

<ISR/EPA handler: procedures>+≡
  subroutine evt_generate_recoil (evt, ok)
    class(evt_isr_epa_t), intent(inout) :: evt
    logical, intent(out) :: ok
    real(default), dimension(4) :: r
    real(default), dimension(2) :: m, mo
    integer :: i
    call evt%rng%generate (r)
    m = 0
    mo = 0
    do i = 1, 2
      select case (evt%rad_mode(i))
        case (BEAM_RAD_ISR)
          m(i) = evt%m(i)
          if (evt%isr_keep_mass) mo(i) = m(i)
        case (BEAM_RAD_EPA)
          m(i) = evt%xc(i) * evt%m(i)
      end select
    end do
    call generate_recoil (evt%sqrts, evt%q_max, m, mo, evt%xc, evt%xcb, r, &

```

```

        evt%km, evt%qm, evt%qo, ok)
end subroutine evt_generate_recoil

```

Replace the collinear radiated (incoming) parton momenta by the momenta that we have generated, respectively. Recall that the recoil has been applied in the c.m. system of the partons before ISR, so we apply the stored Lorentz transformation to boost them to the lab frame.

```

<ISR/EPA handler: evt_isr: TBP>+≡
  procedure, private :: replace_radiated
  procedure, private :: replace_partons

<ISR/EPA handler: procedures>+≡
  subroutine replace_radiated (evt)
    class(evt_isr_epa_t), intent(inout) :: evt
    integer :: i
    do i = 1, 2
      associate (prt => evt%particle_set%prt(evt%i_radiated(i)))
        call prt%set_momentum (evt%lti * evt%km(i))
      end associate
    end do
  end subroutine replace_radiated

  subroutine replace_partons (evt)
    class(evt_isr_epa_t), intent(inout) :: evt
    integer :: i
    do i = 1, 2
      associate (prt => evt%particle_set%prt(evt%i_parton(i)))
        call prt%set_momentum (evt%lti * evt%qo(i))
      end associate
    end do
  end subroutine replace_partons

```

### 32.5.8 Transform the event

Knowing the new incoming partons for the elementary process, we can make use of another procedure in `recoil_kinematics` to determine the Lorentz transformation that transforms the collinear frame into the frame with transverse momentum. We apply this transformation, recursively, to all particles that originate from those incoming partons in the original particle set.

We have to allow for the pre-ISR partons being not in their common c.m. frame. Taking into account non-commutativity, we actually have to first transform the outgoing particles to that c.m. frame, then apply the recoil transformation, then boost back to the lab frame.

The `mask` keep track of particles that we transform, just in case the parent-child tree is multiply connected.

```

<ISR/EPA handler: evt_isr: TBP>+≡
  procedure :: transform_outgoing => evt_transform_outgoing

<ISR/EPA handler: procedures>+≡
  subroutine evt_transform_outgoing (evt)
    class(evt_isr_epa_t), intent(inout) :: evt

```

```

logical, dimension(:), allocatable :: mask
call recoil_transformation (evt%sqrts, evt%xc, evt%qo, evt%lto)
evt%lt = evt%lti * evt%lto * inverse (evt%lti)
allocate (mask (evt%particle_set%get_n_tot ()), source=.false.)
call transform_children (evt%i_parton(1))
contains
recursive subroutine transform_children (i)
integer, intent(in) :: i
integer :: j, n_child, c
integer, dimension(:), allocatable :: child
child = evt%particle_set%prt(i)%get_children ()
do j = 1, size (child)
c = child(j)
if (.not. mask(c)) then
associate (prt => evt%particle_set%prt(c))
call prt%set_momentum (evt%lt * prt%get_momentum ())
mask(c) = .true.
call transform_children (c)
end associate
end if
end do
end subroutine transform_children
end subroutine evt_transform_outgoing

```

### 32.5.9 Implemented methods

Here we take the particle set from the previous event transform and copy it, then generate the transverse momentum for the radiated particles and for the incoming partons. If this fails (rarely, for large  $p_T$ ), return zero for the probability, to trigger another try.

NOTE: The boost for the initial partonic system, if not in the c.m. frame, has not been implemented yet.

```

<ISR/EPA handler: evt_isr: TBP>+≡
procedure :: generate_weighted => &
    evt_isr_epa_generate_weighted

<ISR/EPA handler: procedures>+≡
subroutine evt_isr_epa_generate_weighted (evt, probability)

    use process_stacks
    use event_transforms

    ⟨Standard module head⟩

    ⟨Decays: public⟩

    ⟨Decays: types⟩

    ⟨Decays: interfaces⟩

    contains

    ⟨Decays: procedures⟩

```

```
end module decays
```

### 32.6.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```
<Decays: types>≡
  type, abstract :: any_config_t
  private
  contains
  <Decays: any config: TBP>
end type any_config_t
```

Finalizer, depends on the implementation.

```
<Decays: any config: TBP>≡
  procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
  interface
    subroutine any_config_final (object)
      import
      class(any_config_t), intent(inout) :: object
    end subroutine any_config_final
  end interface
```

The output is also deferred:

```
<Decays: any config: TBP>+≡
  procedure (any_config_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_config_write (object, unit, indent, verbose)
      import
      class(any_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
    end subroutine any_config_write
  end interface
```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```
<Decays: types>+≡
  type :: particle_config_t
  private
  class(any_config_t), allocatable :: c
end type particle_config_t
```

### 32.6.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above.

```
<Decays: types>+≡
  type, abstract :: any_t
  private
  contains
    <Decays: any: TBP>
  end type any_t
```

Finalizer, depends on the implementation.

```
<Decays: any: TBP>≡
  procedure (any_final), deferred :: final

<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
        class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface
```

The output is also deferred:

```
<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
      import
        class(any_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
    end subroutine any_write
  end interface
```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```
<Decays: types>+≡
  type :: particle_out_t
  private
    class(any_t), allocatable :: c
  end type particle_out_t
```

### 32.6.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```
<Decays: types>+≡
```

```

type :: decay_term_config_t
  private
    type(particle_config_t), dimension(:), allocatable :: prt
  contains
    <Decays: decay term config: TBP>
  end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>≡
  procedure :: final => decay_term_config_final

<Decays: procedures>≡

### 32.6.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```

<Decays: public>≡
    public :: decay_root_config_t

<Decays: types>+≡
    type :: decay_root_config_t
        private
        type(string_t) :: process_id
        type(process_t), pointer :: process => null ()
        class(model_data_t), pointer :: model => null ()
        type(decay_term_config_t), dimension(:), allocatable :: term_config
    contains
        <Decays: decay root config: TBP>
    end type decay_root_config_t

```

The finalizer is recursive since there may be cascade decays.

```

<Decays: decay root config: TBP>≡
    procedure :: final => decay_root_config_final

<Decays: procedures>+≡
    recursive subroutine decay_root_config_final (object)
        class(decay_root_config_t), intent(inout) :: object
        integer :: i
        if (allocated (object%term_config)) then
            do i = 1, size (object%term_config)
                call object%term_config(i)%final ()
            end do
        end if
    end subroutine

```

```
end subroutine decay_root_config_final
```

The output routine is also recursive, and it contains an adjustable indentation.

```
<Decays: decay root config: TBP>+=
  procedure :: write => decay_root_config_write
  procedure :: write_header => decay_root_config_write_header
  procedure :: write_terms => decay_root_config_write_terms

    end if
  end subroutine decay_root_config_init

```

Declare a decay term, given an array of flavors.

```

<Decays: decay root config: TBP>+≡
  procedure :: init_term => decay_root_config_init_term

<Decays: procedures>+≡
  recursive subroutine decay_root_config_init_term &
    (decay, i, flv, stable, model, process_stack, var_list)
    class(decay_root_config_t), intent(inout) :: decay
    integer, intent(in) :: i
    type(flavor_t), dimension(:,:), intent(in) :: flv
    logical, dimension(:), intent(in) :: stable
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(var_list_t), intent(in), optional, target :: var_list
    call decay%term_config(i)%init (flv, stable, model, process_stack, var_list)
  end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the **process\_instance** argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

For the unstable particles, we have to check whether their masses match between the production and the decay. Fortunately, both versions are available for comparison.

The optional `var_list` argument may override integral/error values for decay processes.

        end do
    end subroutine decay_root_config_compute

```

### 32.6.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```

<Decays: types>+≡
    type, abstract :: decay_gen_t
    private
        type(decay_term_t), dimension(:), allocatable :: term
        type(process_instance_t), pointer :: process_instance => null ()
        integer :: selected_mci = 0
        integer :: selected_term = 0
    contains
        <Decays: decay gen: TBP>
    end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

<Decays: public>+≡
    public :: decay_root_t

<Decays: types>+≡
    type, extends (decay_gen_t) :: decay_root_t
    private
        type(decay_root_config_t), pointer :: config => null ()
    contains
        <Decays: decay root: TBP>

```

```
end type decay_root_t
```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```
<Decays: decay gen: TBP>≡
  procedure :: base_final => decay_gen_final

<Decays: procedures>+≡
  recursive subroutine decay_gen_final (object)
    class(decay_gen_t), intent(inout) :: object
    integer :: i
    if (allocated (object%term)) then
      do i = 1, size (object%term)
        call object%term(i)%final ()
      end do
    end if
  end subroutine decay_gen_final
```

No extra finalization for the decay root.

```
<Decays: decay root: TBP>≡
  procedure :: final => decay_root_final

<Decays: procedures>+≡
  subroutine decay_root_final (object)
    class(decay_root_t), intent(inout) :: object
    call object%base_final ()
  end subroutine decay_root_final
```

Output.

```
<Decays: decay root: TBP>+≡
  procedure :: write => decay_root_write

<Decays: procedures>+≡
  subroutine decay_root_write (object, unit)
    class(decay_root_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    if (associated (object%config)) then
      call object%config%write (unit, verbose = .false.)
    else
      write (u, "(1x,A)") "Final-state decay tree: [not configured]"
    end if
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI      = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI      = [undefined]"
    end if
    if (object%selected_term > 0) then
      write (u, "(3x,A,I0)") "Selected term    = ", object%selected_term
      call object%term(object%selected_term)%write (u, 1)
    else
      write (u, "(3x,A)") "Selected term     = [undefined]"
    end if
  end subroutine decay_root_write
```

```

        end if
    end subroutine decay_root_write

```

Write the process instances, recursively.

```

<Decays: decay gen: TBP>+≡
    procedure :: write_process_instances => decay_gen_write_process_instances

<Decays: procedures>+≡
    recursive subroutine decay_gen_write_process_instances (decay, unit, verbose)
        class(decay_gen_t), intent(in) :: decay

        logical, intent(in), optional :: verbose
        logical :: verb
        verb = .true.; if (present (verbose)) verb = verbose
        if (associated (decay%process_instance)) then
            if (verb) then
                call decay%process_instance%write (unit)
            else
                call decay%process_instance%write_header (unit)
            end if
        end if
        if (decay%selected_term > 0) then
            call decay%term(decay%selected_term)%write_process_instances (unit, verb)
        end if
    end subroutine decay_gen_write_process_instances

```

Generic initializer. All can be done recursively.

```

<Decays: decay gen: TBP>+≡
    procedure :: base_init => decay_gen_init

<Decays: procedures>+≡
    recursive subroutine decay_gen_init (decay, term_config)
        class(decay_gen_t), intent(out) :: decay
        type(decay_term_config_t), dimension(:), intent(in), target :: term_config
        integer :: i
        allocate (decay%term (size (term_config)))
        do i = 1, size (decay%term)
            call decay%term(i)%init (term_config(i))
        end do
    end subroutine decay_gen_init

```

Specific initializer. We assign the configuration object, which should correspond to a completely initialized decay configuration tree. We also connect to an existing process instance. Then, we recursively link the child interactions to the parent process.

```

<Decays: decay root: TBP>+≡
    procedure :: init => decay_root_init

<Decays: procedures>+≡
    subroutine decay_root_init (decay_root, config, process_instance)
        class(decay_root_t), intent(out) :: decay_root
        type(decay_root_config_t), intent(in), target :: config
        type(process_instance_t), intent(in), target :: process_instance

```

```

    call decay_root%base_init (config%term_config)
    decay_root%config => config
    decay_root%process_instance => process_instance
    call decay_root%make_term_rng (config%process)
    call decay_root%link_term_interactions ()
end subroutine decay_root_init

```

Explicitly set/get mci and term indices. (Used in unit test.)

```

<Decays: decay gen: TBP>+≡
  procedure :: set_mci => decay_gen_set_mci
  procedure :: set_term => decay_gen_set_term
  procedure :: get_mci => decay_gen_get_mci
  procedure :: get_term => decay_gen_get_term

<Decays: procedures>+≡
  subroutine decay_gen_set_mci (decay, i)
    class(decay_gen_t), intent(inout) :: decay

            end do
        end associate
    end subroutine decay_gen_link_term_interactions

```

Select a decay chain: decay modes and process components.

```

<Decays: decay root: TBP>+≡
    procedure :: select_chain => decay_root_select_chain

<Decays: procedures>+≡
    subroutine decay_root_select_chain (decay_root)
        class(decay_root_t), intent(inout) :: decay_root
        if (decay_root%selected_term > 0) then
            call decay_root%term(decay_root%selected_term)%select_chain ()
        else
            call msg_bug ("Decays: no term selected for parent process")
        end if
    end subroutine decay_root_select_chain

```

Generate a decay tree, i.e., for the selected term in the parent process, recursively generate a decay event for all unstable particles.

Factor out the trace of the connected state of the parent process. This trace should not be taken into account for unweighting the decay chain, since it was already used for unweighting the parent event, or it determines the overall event weight.

```

<Decays: decay root: TBP>+≡
    procedure :: generate => decay_root_generate

<Decays: procedures>+≡
    subroutine decay_root_generate (decay_root)
        class(decay_root_t), intent(inout) :: decay_root
        type(connected_state_t), pointer :: connected_state
        if (decay_root%selected_term > 0) then
            connected_state => decay_root%process_instance%get_connected_state_ptr &
                (decay_root%selected_term)
            call connected_state%normalize_matrix_by_trace ()
        end if
    end subroutine decay_root_generate

```

```

        call decay_root%term(decay_root%selected_term)%generate ()
    else
        call msg_bug ("Decays: no term selected for parent process")
    end if
end subroutine decay_root_generate

```

### 32.6.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

The flavor component should be identical to the flavor component of the parent particle (`unstable` object).

```

<Decays: types>+≡
    type, extends (decay_root_config_t) :: decay_config_t
    private
        type(flavor_t) :: flv
        real(default) :: weight = 0
        real(default) :: integral = 0
        real(default) :: abs_error = 0
        real(default) :: rel_error = 0
        type(selector_t) :: mci_selector
    contains
        <Decays: decay config: TBP>
    end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
    procedure :: write => decay_config_write

<Decays: procedures>+≡
    recursive subroutine decay_config_write (object, unit, indent, verbose)
        class(decay_config_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        logical, intent(in), optional :: verbose
        integer :: u, ind
        u = given_output_unit (unit)
        ind = 0; if (present (indent)) ind = indent
        call write_indent (u, ind)
        write (u, "(1x,A)") "Decay:"
        call object%write_header (unit, indent)
        call write_indent (u, ind)
        write (u, 2) "branching ratio =", object%weight * 100
        call write_indent (u, ind)
        write (u, 1) "partial width   =", object%integral
        call write_indent (u, ind)
        write (u, 1) "error (abs)      =", object%abs_error
        call write_indent (u, ind)
        write (u, 1) "error (rel)      =", object%rel_error
    end subroutine decay_config_write

```

```

1  format (3x,A,ES19.12)
2  format (3x,A,F11.6,1x,'%')
   call object%write_terms (unit, indent, verbose)
end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should be used instead.

If there is an optional `var_list`, check if the stored values for the decay partial width and error have been overridden there.

```

<Decays: decay config: TBP>+≡
  procedure :: connect => decay_config_connect

<Decays: procedures>+≡
  recursive subroutine decay_config_connect &
    (decay, process, model, process_stack, process_instance, var_list)
    class(decay_config_t), intent(out) :: decay
    type(process_t), intent(in), target :: process
    class(model_data_t), intent(in), target :: model

    type(process_instance_t), intent(in), optional, target :: process_instance
    type(var_list_t), intent(in), optional, target :: var_list
    real(default), dimension(:), allocatable :: integral_mci
    type(string_t) :: process_id
    integer :: i, n_mci
    call decay%decay_root_config_t%connect &
      (process, model, process_stack, var_list=var_list)
    process_id = process%get_id ()
    if (process%cm_frame ()) then
      call msg_fatal ("Decay process " // char (process_id) &
        // ": unusable because rest frame is fixed.")
    end if
    decay%integral = process%get_integral ()
    decay%abs_error = process%get_error ()
    if (present (var_list)) then
      call update (decay%integral, "integral(" // process_id // ")")
      call update (decay%abs_error, "error(" // process_id // ")")
    end if
    n_mci = process%get_n_mci ()
    allocate (integral_mci (n_mci))
    do i = 1, n_mci
      integral_mci(i) = process%get_integral_mci (i)
    end do
    call decay%mci_selector%init (integral_mci)
contains
    subroutine update (var, var_name)
      real(default), intent(inout) :: var
      type(string_t), intent(in) :: var_name
      if (var_list%contains (var_name)) then
        var = var_list%get_rval (var_name)

```

```

        end if
    end subroutine update
end subroutine decay_config_connect

```

Set the flavor entry, which repeats the flavor of the parent unstable particle.

```

⟨Decays: decay config: TBP⟩+≡
    procedure :: set_flv => decay_config_set_flv

⟨Decays: procedures⟩+≡
    subroutine decay_config_set_flv (decay, flv)
        class(decay_config_t), intent(inout) :: decay
        type(flavor_t), intent(in) :: flv
        decay%flv = flv
    end subroutine decay_config_set_flv

```

Compute embedded branchings and the relative error. This method does not apply to the decay root.

```

⟨Decays: decay config: TBP⟩+≡
    procedure :: compute => decay_config_compute

⟨Decays: procedures⟩+≡
    recursive subroutine decay_config_compute (decay)
        class(decay_config_t), intent(inout) :: decay
        call decay%decay_root_config_t%compute ()
        if (.not. vanishes (decay%integral)) then
            decay%rel_error = decay%abs_error / decay%integral
        else
            decay%rel_error = 0
        end if
    end subroutine decay_config_compute

```

### 32.6.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

⟨Decays: types⟩+≡
    type, extends (decay_gen_t) :: decay_t
    private
        type(decay_config_t), pointer :: config => null ()
        class(rng_t), allocatable :: rng
    contains
        ⟨Decays: decay: TBP⟩
    end type decay_t

```

The finalizer is recursive.

```

⟨Decays: decay: TBP⟩≡
    procedure :: final => decay_final

```

```

<Decays: procedures>+≡
recursive subroutine decay_final (object)
  class(decay_t), intent(inout) :: object
  integer :: i
  call object%base_final ()
  do i = 1, object%config%process%get_n_mci ()
    call object%process_instance%final_simulation (i)
  end do
  call object%process_instance%final ()
  deallocate (object%process_instance)
end subroutine decay_final

```

Output.

```

<Decays: decay: TBP>+≡
  procedure :: write => decay_write

<Decays: procedures>+≡
recursive subroutine decay_write (object, unit, indent, recursive)
  class(decay_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent, recursive
  integer :: u, ind
  u = given_output_unit (unit)
  ind = 0; if (present (indent)) ind = indent
  call object%config%write (unit, indent, verbose = .false.)
  if (allocated (object%rng)) then
    call object%rng%write (u, ind + 1)
  end if
  call write_indent (u, ind)
  if (object%selected_mci > 0) then
    write (u, "(3x,A,I0)") "Selected MCI      = ", object%selected_mci
  else
    write (u, "(3x,A)") "Selected MCI      = [undefined]"
  end if
  call write_indent (u, ind)
  if (object%selected_term > 0) then
    write (u, "(3x,A,I0)") "Selected term    = ", object%selected_term
    call object%term(object%selected_term)%write (u, ind + 1)
  else
    write (u, "(3x,A)") "Selected term    = [undefined]"
  end if
end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
  procedure :: init => decay_init

<Decays: procedures>+≡
recursive subroutine decay_init (decay, config)
  class(decay_t), intent(out) :: decay
  type(decay_config_t), intent(in), target :: config
  integer :: i

```

```

call decay%base_init (config%term_config)
decay%config => config
allocate (decay%process_instance)
call decay%process_instance%init (decay%config%process)
call decay%process_instance%setup_event_data (decay%config%model)
do i = 1, decay%config%process%get_n_mci ()
    call decay%process_instance%init_simulation (i)
end do
call decay%config%process%make_rng (decay%rng)
call decay%make_term_rng (decay%config%process)
end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
    procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
    recursive subroutine decay_link_interactions (decay, i_prt, trace)
        class(decay_t), intent(inout) :: decay
        integer, intent(in) :: i_prt
        type(interaction_t), intent(in), target :: trace
        type(interaction_t), pointer :: beam_int
        integer :: n_in, n_vir
        beam_int => decay%process_instance%get_beam_int_ptr ()
        n_in = trace%get_n_in ()
        n_vir = trace%get_n_vir ()
        call beam_int%set_source_link (1, trace, &
            n_in + n_vir + i_prt)
        call decay%link_term_interactions ()
    end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
    procedure :: select_chain => decay_select_chain

<Decays: procedures>+≡
    recursive subroutine decay_select_chain (decay)
        class(decay_t), intent(inout) :: decay
        real(default) :: x
        integer :: i
        call decay%rng%generate (x)
        decay%selected_mci = decay%config%mci_selector%select (x)
        call decay%process_instance%choose_mci (decay%selected_mci)
        decay%selected_term = decay%process_instance%select_i_term ()
        do i = 1, size (decay%term)
            call decay%term(i)%select_chain ()
        end do
    end subroutine decay_select_chain

```

```
end subroutine decay_select_chain
```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```
<Decays: decay: TBP>+≡
  procedure :: generate => decay_generate

<Decays: procedures>+≡
  recursive subroutine decay_generate (decay)
    class(decay_t), intent(inout) :: decay
    type(isolated_state_t), pointer :: isolated_state
    integer :: i
    call decay%process_instance%receive_beam_momenta ()
    call decay%process_instance%generate_unweighted_event (decay%selected_mci)
    if (signal_is_pending ()) return
    call decay%process_instance%evaluate_event_data ()
    isolated_state => &
      decay%process_instance%get_isolated_state_ptr (decay%selected_term)
    call isolated_state%normalize_matrix_by_trace ()
    do i = 1, size (decay%term)
      call decay%term(i)%generate ()
      if (signal_is_pending ()) return
    end do
  end subroutine decay_generate
```

### 32.6.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```
<Decays: types>+≡
  type, extends (any_config_t) :: stable_config_t
  private
  type(flavor_t), dimension(:), allocatable :: flv
  contains
  <Decays: stable config: TBP>
  end type stable_config_t
```

The finalizer is empty:

```
<Decays: stable config: TBP>≡
  procedure :: final => stable_config_final

<Decays: procedures>+≡
  subroutine stable_config_final (object)
    class(stable_config_t), intent(inout) :: object
  end subroutine stable_config_final
```

Output.

```

<Decays: stable config: TBP>+≡
  procedure :: write => stable_config_write

<Decays: procedures>+≡

        type(stable_config_t), intent(in), target :: config
        stable%config => config
    end subroutine stable_init

```

### 32.6.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: public>+≡
    public :: unstable_config_t

<Decays: types>+≡
    type, extends (any_config_t) :: unstable_config_t
    private
        type(flavor_t) :: flv
        real(default) :: integral = 0
        real(default) :: abs_error = 0
        real(default) :: rel_error = 0
        type(selector_t) :: selector
        type(decay_config_t), dimension(:), allocatable :: decay_config
    contains

```

```

    <Decays: unstable config: TBP>
end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
  procedure :: final => unstable_config_final

<Decays: procedures>+≡
  recursive subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%final ()
      end do
    end if
  end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
  procedure :: write => unstable_config_write

<Decays: procedures>+≡
  recursive subroutine unstable_config_write (object, unit, indent, verbose)
    class(unstable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    logical :: verb
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
      char (object%flv%get_name ())
    call write_indent (u, ind)
    write (u, 1) "total width =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs) =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel) =", object%rel_error
1  format (5x,A,ES19.12)
    if (verb .and. allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%write (u, ind + 1)
      end do
    end if
  end subroutine unstable_config_write

```

Initializer. For the unstable particle, the flavor is unique.

```

<Decays: unstable config: TBP>+≡
  procedure :: init => unstable_config_init

```

```

<Decays: procedures>+≡
  subroutine unstable_config_init (unstable, flv, set_decays, model)
    class(unstable_config_t), intent(out) :: unstable
    type(flavor_t), intent(in) :: flv
    logical, intent(in), optional :: set_decays
    class(model_data_t), intent(in), optional, target :: model
    type(string_t), dimension(:), allocatable :: decay
    unstable%flv = flv
    if (present (set_decays)) then
      call unstable%flv%get_decays (decay)
      call unstable%init_decays (decay, model)
    end if
  end subroutine unstable_config_init

```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```

<Decays: unstable config: TBP>+≡
  procedure :: init_decays => unstable_config_init_decays

<Decays: procedures>+≡
  recursive subroutine unstable_config_init_decays &
    (unstable, decay_id, model, process_stack, var_list)
    class(unstable_config_t), intent(inout) :: unstable
    type(string_t), dimension(:), intent(in) :: decay_id
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(var_list_t), intent(in), optional :: var_list
    integer :: i
    allocate (unstable%decay_config (size (decay_id)))
    do i = 1, size (decay_id)
      associate (decay => unstable%decay_config(i))
        if (present (process_stack)) then
          call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
            model, process_stack, var_list=var_list)
        else
          call decay%init (model, decay_id(i))
        end if
        call decay%set_flv (unstable%flv)
      end associate
    end do
  end subroutine unstable_config_init_decays

```

Explicitly connect a specific decay with a process. This is used only in unit tests.

```

<Decays: unstable config: TBP>+≡
  procedure :: connect_decay => unstable_config_connect_decay

<Decays: procedures>+≡
  subroutine unstable_config_connect_decay (unstable, i, process, model)
    class(unstable_config_t), intent(inout) :: unstable
    integer, intent(in) :: i

```

```

    type(process_t), intent(in), target :: process
    class(model_data_t), intent(in), target :: model
    associate (decay => unstable%decay_config(i))
        call decay%connect (process, model)
    end associate
end subroutine unstable_config_connect_decay

```

Compute the total width and branching ratios, initializing the decay selector.

```

<Decays: unstable config: TBP>+≡
    procedure :: compute => unstable_config_compute

<Decays: procedures>+≡
    recursive subroutine unstable_config_compute (unstable)
        class(unstable_config_t), intent(inout) :: unstable
        integer :: i
        do i = 1, size (unstable%decay_config)
            call unstable%decay_config(i)%compute ()
        end do
        unstable%integral = sum (unstable%decay_config%integral)
        if (unstable%integral <= 0) then
            call unstable%write ()
            call msg_fatal ("Decay configuration: computed total width is zero")
        end if
        unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
        unstable%rel_error = unstable%abs_error / unstable%integral
        call unstable%selector%init (unstable%decay_config%integral)
        do i = 1, size (unstable%decay_config)
            unstable%decay_config(i)%weight &
                = unstable%selector%get_weight (i)
        end do
    end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: public>+≡
    public :: unstable_t

<Decays: unstable: TBP>+≡
  procedure :: generate => unstable_generate

<Decays: procedures>+≡
  recursive subroutine unstable_generate (unstable)
    class(unstable_t), intent(inout) :: unstable
    call unstable%decay(unstable%selected_decay)%generate ()
  end subroutine unstable_generate

```

### 32.6.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+≡
  type, extends (connected_state_t) :: decay_chain_entry_t
  private
    integer :: index = 0
    type(decay_config_t), pointer :: config => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
    type(decay_chain_entry_t), pointer :: previous => null ()
  end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: public>+≡

```

```

    public :: decay_chain_t
  <Decays: types>+≡
    type :: decay_chain_t
      private
        type(process_instance_t), pointer :: process_instance => null ()
        integer :: selected_term = 0
        type(evaluator_t) :: correlated_trace
        type(decay_chain_entry_t), pointer :: last => null ()
      contains
        <Decays: decay_chain: TBP>
      end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

  <Decays: decay_chain: TBP>≡
    procedure :: final => decay_chain_final

  <Decays: procedures>+≡
    subroutine decay_chain_final (object)
      class(decay_chain_t), intent(inout) :: object
      type(decay_chain_entry_t), pointer :: entry
      do while (associated (object%last))
        entry => object%last
        object%last => entry%previous
        call entry%final ()
        deallocate (entry)
      end do
      call object%correlated_trace%final ()
    end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

  <Decays: decay_chain: TBP>+≡
    procedure :: write => decay_chain_write

  <Decays: procedures>+≡
    subroutine decay_chain_write (object, unit)
      class(decay_chain_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u
      u = given_output_unit (unit)
      call write_separator (u, 2)
      write (u, "(1x,A)") "Decay chain:"
      call write_entries (object%last)
      call write_separator (u, 2)
      write (u, "(1x,A)") "Evaluator (correlated trace of the decay chain):"
      call write_separator (u)
      call object%correlated_trace%write (u)
      call write_separator (u, 2)
    contains
      recursive subroutine write_entries (entry)
        type(decay_chain_entry_t), intent(in), pointer :: entry
        if (associated (entry)) then
          call write_entries (entry%previous)
          call write_separator (u, 2)
        end if
      end subroutine write_entries

```

```

        write (u, "(1x,A,I0)") "Decay #", entry%index
        call entry%config%write_header (u)
        write (u, "(3x,A,I0)") "Selected MCI      = ", entry%selected_mci
        write (u, "(3x,A,I0)") "Selected term   = ", entry%selected_term
        call entry%config%term_config(entry%selected_term)%write (u, indent=1)
        call entry%write (u)
    end if
end subroutine write_entries
end subroutine decay_chain_write

```

Build a decay chain, recursively following the selected decays and terms in a decay tree. Before start, we finalize the chain, deleting any previous contents.

```

<Decays: decay chain: TBP>+≡
    procedure :: build => decay_chain_build

<Decays: procedures>+≡
    subroutine decay_chain_build (chain, decay_root)
        class(decay_chain_t), intent(inout), target :: chain
        type(decay_root_t), intent(in) :: decay_root
        type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
        type(interaction_t), pointer :: int_last_decay
        call chain%final ()
        if (decay_root%selected_term > 0) then
            chain%process_instance => decay_root%process_instance
            chain%selected_term = decay_root%selected_term
            call chain%build_term_entries (decay_root%term(decay_root%selected_term))
        end if
        int_last_decay => chain%last%get_matrix_int_ptr ()
        allocate (qn_mask (int_last_decay%get_n_tot ()))
        call qn_mask%init (mask_f = .true., mask_c = .true., mask_h = .true.)
        call chain%correlated_trace%init_qn_sum (int_last_decay, qn_mask)
    end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable particles.

```

<Decays: decay chain: TBP>+≡
    procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: procedures>+≡
    recursive subroutine decay_chain_build_term_entries (chain, term)
        class(decay_chain_t), intent(inout) :: chain
        type(decay_term_t), intent(in) :: term
        integer :: i
        do i = 1, size (term%particle_out)
            select type (unstable => term%particle_out(i)%c)
            type is (unstable_t)
                if (unstable%selected_decay > 0) then
                    call chain%build_decay_entries &
                        (unstable%decay(unstable%selected_decay))
                end if
            end select
        end do
    end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_decay_entries => decay_chain_build_decay_entries

<Decays: procedures>+≡

    end if
    chain%last => entry
    call chain%build_term_entries (decay%term(decay%selected_term))
end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

```

<Decays: decay chain: TBP>+≡
    procedure :: evaluate => decay_chain_evaluate

<Decays: procedures>+≡
    subroutine decay_chain_evaluate (chain)
        class(decay_chain_t), intent(inout) :: chain
        call evaluate (chain%last)
        call chain%correlated_trace%receive_momenta ()
        call chain%correlated_trace%evaluate ()
    contains
        recursive subroutine evaluate (entry)
            type(decay_chain_entry_t), intent(inout), pointer :: entry
            if (associated (entry)) then
                call evaluate (entry%previous)

                call entry%evaluate_event_data ()
            end if
        end subroutine evaluate
    end subroutine decay_chain_evaluate

```

Return the probability of a decay chain. This is given as the trace of the density matrix with intermediate helicity correlations, normalized by the product of the uncorrelated density matrix traces. This works only if an event has been evaluated and the `correlated_trace` evaluator is filled. By definition, this evaluator has only one matrix element, and this must be real.

```

<Decays: decay chain: TBP>+≡
    procedure :: get_probability => decay_chain_get_probability

<Decays: procedures>+≡
    function decay_chain_get_probability (chain) result (x)

        real(default) :: x
        x = real (chain%correlated_trace%get_matrix_element (1))
    end function decay_chain_get_probability

```

### 32.6.12 Decay as Event Transform

The `evt_decay` object combines decay configuration, decay tree, and chain in a single object, as an implementation of the `evt` (event transform) abstract type.

The `var_list` may be a pointer to the user variable list, which could contain overridden parameters for the decay processes.

```

<Decays: public>+≡
    public :: evt_decay_t

<Decays: types>+≡
    type, extends (evt_t) :: evt_decay_t
    private
        type(decay_root_config_t) :: decay_root_config
        type(decay_root_t) :: decay_root
        type(decay_chain_t) :: decay_chain
        type(var_list_t), pointer :: var_list => null ()
    contains
        <Decays: evt decay: TBP>
    end type evt_decay_t

<Decays: evt decay: TBP>≡
    procedure :: write_name => evt_decay_write_name

<Decays: procedures>+≡
    subroutine evt_decay_write_name (evt, unit)
        class(evt_decay_t), intent(in) :: evt
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Event transform: partonic decays"
    end subroutine evt_decay_write_name

```

Output. We display the currently selected decay tree, which includes configuration data, and the decay chain, i.e., the evaluators.

```

<Decays: evt decay: TBP>+≡
    procedure :: write => evt_decay_write

end subroutine evt_shower_first_event

```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations is under construction. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid. This procedure directly takes the (MLM) matching into account.

## 32.9 Fixed Order NLO Events

This section deals with the generation of weighted event samples which take into account next-to-leading order corrections. An approach generating unweighted events is not possible here, because negative weights might occur due to subtraction. Note that the events produced this way are not physical in the sense that they will not keep NLO-accuracy when interfaced to a parton shower. They are rather useful for theoretical consistency checks and a fast estimate of NLO effects.

We generate NLO events in the following way: First, the integration is car-

ried out using the complete divergence-subtracted NLO matrix element. In the subsequent simulation,  $N$ -particle kinematics are generated using  $\mathcal{B} + \mathcal{V} + \mathcal{C}$  as weight. After that, the program loops over all singular regions and for each of them generates an event with  $N + 1$ -particle kinematics. The weight for those events corresponds to the real matrix element  $\mathcal{R}^\alpha$  evaluated at the  $\alpha$ -region's emitter's phase space point, multiplied with  $S_\alpha$ . This procedure is implemented using the `evt_nlo` transform.

This event transformation is for the generation of fixed-order NLO events. It takes an event with Born kinematics and creates  $N_\alpha + 1$  modified weighted events. The first one has Born kinematics and its weight is the sum of Born, Real and subtraction matrix elements. The other  $N_\alpha$  events have a weight which is equal to the real matrix element, evaluated with the phase space corresponding to the emitter of the  $\alpha$ -region. All NLO event objects share the same event transformation. For this reason, we save the particle set of the current  $\alpha$ -region in the array `particle_set_radiated`. Otherwise it would be unretrievable if the usual particle set of the event object was used. @

```

The event transform has a variable which counts the number of times it has already been called for one generation point. If `i_evaluation` is zero, this means that `evt_nlo_generate` is called for the first time, so that the generation of an  $N$ -particle event is required. In all other cases, emission events are generated. Note that for the first event, the computed weights are added to `probability`, which at this point is equal to  $\mathcal{B} + \mathcal{V}$ , whereas for all other runs `probability` is replaced. To keep  $\langle \sum w_i \rangle = N \times \sigma$  as it is for weighted LO events, we have to multiply by  $N_{\text{phs}} + 1$  since the cross section is distributed over the real and Born subevents.

### 32.10.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The **safety\_factor** reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The **sigma** and **n** values, if nontrivial, allow for reweighting the events according to the requested **norm\_mode**.

Various **parse\_node\_t** objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the **event\_expr\_t** objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

```

### 32.10.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event_base` module. The core manages the main (dressed) particle set pointer and the current values for weights and sqme. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers

should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

The `sqme` and `weight` values mirror corresponding values in the `expr` subobject. The idea is that when generating or reading events, the event record is filled first, then the `expr` object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the `expr` subobject. In particular, evaluating the event-selection expression sets the `passed` flag. Furthermore, the `expr` subobject collects data that can be used in the analysis and should be written to file, including copies of `sqme` and `weight`.

    call write_separator (u, 2)
end if
end subroutine event_write

```

### 32.10.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```

<Events: event: TBP>+≡
  procedure :: basic_init => event_init

<Events: procedures>+≡
  subroutine event_init (event, var_list, n_alt)
    class(event_t), intent(out) :: event
    type(var_list_t), intent(in), optional :: var_list
    integer, intent(in), optional :: n_alt
    type(string_t) :: norm_string, mode_string
    logical :: polarized_events
    if (present (n_alt)) then
      call event%base_init (n_alt)
      call event%expr%init (n_alt)
    else
      call event%base_init (0)
    end if
    if (present (var_list)) then
      event%config%unweighted = var_list%get_lval (&
        var_str ("?unweighted"))
      norm_string = var_list%get_sval (&
        var_str ("$_sample_normalization"))
      event%config%norm_mode = &
        event_normalization_mode (norm_string, event%config%unweighted)
      polarized_events = &
        var_list%get_lval (var_str ("?polarized_events"))
      if (polarized_events) then
        mode_string = &
          var_list%get_sval (var_str ("$_polarization_mode"))
        select case (char (mode_string))
          case ("ignore")
            event%config%factorization_mode = FM_IGNORE_HELICITY
          case ("helicity")
            event%config%factorization_mode = FM_SELECT_HELICITY
          case ("factorized")
            event%config%factorization_mode = FM_FACTOR_HELICITY
          case ("correlated")
            event%config%factorization_mode = FM_CORRELATED_HELICITY
          case default
            call msg_fatal ("Polarization mode " &
              // char (mode_string) // " is undefined")
        end select
      else
        event%config%factorization_mode = FM_IGNORE_HELICITY
      end if
      event%config%colorize_subevt = &

```

```

        var_list%get_lval (var_str ("?colorize_subevt"))
    if (event%config%unweighted) then
        event%config%safety_factor = var_list%get_rval (&
            var_str ("safety_factor"))
    end if
else
    event%config%norm_mode = NORM_SIGMA
end if
allocate (evt_trivial_t :: event%transform_first)
event%transform_last => event%transform_first
end subroutine event_init

```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

```

<Events: event: TBP>+≡
    procedure :: set_sigma => event_set_sigma
    procedure :: set_n => event_set_n

<Events: procedures>+≡
    elemental subroutine event_set_sigma (event, sigma)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: sigma
        event%config%sigma = sigma
    end subroutine event_set_sigma

    elemental subroutine event_set_n (event, n)
        class(event_t), intent(inout) :: event
        integer, intent(in) :: n
        event%config%n = n
    end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
    procedure :: import_transform => event_import_transform

<Events: procedures>+≡
    subroutine event_import_transform (event, evt)
        class(event_t), intent(inout) :: event
        class(evt_t), intent(inout), pointer :: evt
        event%transform_last%next => evt
        evt%previous => event%transform_last
        event%transform_last => evt
        evt => null ()
    end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

<Events: procedures>+≡
  subroutine event_connect (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(string_t) :: id
    integer :: num_id
    class(evt_t), pointer :: evt
    event%process => process_instance%process
    event%instance => process_instance
    id = event%process%get_id ()
    if (id /= "") call event%expr%set_process_id (id)
    num_id = event%process%get_num_id ()
    if (num_id /= 0) call event%expr%set_process_num_id (num_id)
    call event%expr%setup_vars (event%process%get_sqrts ())
    call event%expr%link_var_list (event%process%get_var_list_ptr ())
    call event%process%make_rng (event%rng)
    evt => event%transform_first
    do while (associated (evt))
      call evt%connect (process_instance, model, process_stack)
      evt => evt%next
    end do
  end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
  procedure :: set_selection => event_set_selection
  procedure :: set_reweight => event_set_reweight
  procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡
  subroutine event_set_selection (event, ef_selection)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_selection
    allocate (event%config%ef_selection, source = ef_selection)
  end subroutine event_set_selection

  subroutine event_set_reweight (event, ef_reweight)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_reweight
    allocate (event%config%ef_reweight, source = ef_reweight)

```

```

end subroutine event_set_reweight

subroutine event_set_analysis (event, ef_analysis)
  class(event_t), intent(inout) :: event
  class(expr_factory_t), intent(in) :: ef_analysis
  allocate (event%config%ef_analysis, source = ef_analysis)
end subroutine event_set_analysis

```

Create evaluation trees from the parse trees. The `target` attribute is required because the expressions contain pointers to event subobjects.

```

<Events: event: TBP>+≡
  procedure :: setup_expressions => event_setup_expressions

<Events: procedures>+≡
  subroutine event_setup_expressions (event)
    class(event_t), intent(inout), target :: event
    call event%expr%setup_selection (event%config%ef_selection)
    call event%expr%setup_analysis (event%config%ef_analysis)
    call event%expr%setup_reweight (event%config%ef_reweight)
    call event%expr%colorize (event%config%colorize_subevt)
  end subroutine event_setup_expressions

```

### 32.10.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

<Events: event: TBP>+≡
  procedure :: evaluate_transforms => event_evaluate_transforms

<Events: procedures>+≡
  subroutine event_evaluate_transforms (event, r)

        class(event_t), intent(inout) :: event
        call event%expr%reset_event_index ()
    end subroutine event_reset_index

```

### 32.10.6 Squared Matrix Element and Weight

Transfer the result of the process instance calculation to the event record header.

```
<Events: event: TBP>+≡
  procedure :: import_instance_results => event_import_instance_results

<Events: procedures>+≡
  subroutine event_import_instance_results (event)
    class(event_t), intent(inout) :: event
    if (associated (event%instance)) then
      if (event%instance%has_evaluated_trace ()) then
        call event%set ( &
          sqme_prc = event%instance%get_sqme (), &
          weight_prc = event%instance%get_weight (), &
          excess_prc = event%instance%get_excess (), &
          n_dropped = event%instance%get_n_dropped () &
        )
      end if
    end if
  end subroutine event_import_instance_results
```

Duplicate the instance result / the reference result in the event record.

```
<Events: event: TBP>+≡
  procedure :: accept_sqme_ref => event_accept_sqme_ref
  procedure :: accept_sqme_prc => event_accept_sqme_prc
  procedure :: accept_weight_ref => event_accept_weight_ref
  procedure :: accept_weight_prc => event_accept_weight_prc

<Events: procedures>+≡
  subroutine event_accept_sqme_ref (event)
    class(event_t), intent(inout) :: event
    if (event%sqme_ref_is_known ()) then
      call event%set (sqme_prc = event%get_sqme_ref ())
    end if
  end subroutine event_accept_sqme_ref

  subroutine event_accept_sqme_prc (event)
    class(event_t), intent(inout) :: event
    if (event%sqme_prc_is_known ()) then
      call event%set (sqme_ref = event%get_sqme_prc ())
    end if
  end subroutine event_accept_sqme_prc

  subroutine event_accept_weight_ref (event)
    class(event_t), intent(inout) :: event
    if (event%weight_ref_is_known ()) then
      call event%set (weight_prc = event%get_weight_ref ())
    end if
  end subroutine event_accept_weight_ref

  subroutine event_accept_weight_prc (event)
    class(event_t), intent(inout) :: event
    if (event%weight_prc_is_known ()) then
      call event%set (weight_ref = event%get_weight_prc ())
    end if
```

```
end subroutine event_accept_weight_prc
```

Update the weight normalization, just after generation. Unweighted and weighted events are generated with a different default normalization. The intended normalization is stored in the configuration record.

```
<Events: event: TBP>+≡
  procedure :: update_normalization => event_update_normalization

<Events: procedures>+≡
  subroutine event_update_normalization (event, mode_ref)
    class(event_t), intent(inout) :: event
    integer, intent(in), optional :: mode_ref
    integer :: mode_old
    real(default) :: weight, excess
    if (present (mode_ref)) then
      mode_old = mode_ref
    else if (event%config%unweighted) then

    end if
  end subroutine event_check
```

### 32.10.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we **accept** the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
  procedure :: generate => event_generate

<Events: procedures>+≡
  subroutine event_generate (event, i_mci, r, i_nlo)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci
    real(default), dimension(:), intent(in), optional :: r
    integer, intent(in), optional :: i_nlo
    logical :: generate_new
    generate_new = .true.
    if (present (i_nlo)) generate_new = (i_nlo == 1)
    if (generate_new) call event%reset_contents ()
    event%selected_i_mci = i_mci
    if (event%config%unweighted) then
      call event%instance%generate_unweighted_event (i_mci)
      if (signal_is_pending ()) return
      call event%instance%evaluate_event_data ()
      call event%instance%normalize_weight ()
    else
      if (generate_new) &
        call event%instance%generate_weighted_event (i_mci)
      if (signal_is_pending ()) return
      call event%instance%evaluate_event_data ()
    end if
    event%selected_channel = event%instance%get_channel ()
    call event%import_instance_results ()
    call event%accept_sqme_prc ()
    call event%update_normalization ()
    call event%accept_weight_prc ()
    call event%evaluate_transforms (r)
    if (signal_is_pending ()) return
    call event%check ()
  end subroutine event_generate

```

Get a copy of the particle set belonging to the hard process.

```

<Events: event: TBP>+≡
  procedure :: get_hard_particle_set => event_get_hard_particle_set

```

```

<Events: procedures>+≡
  subroutine event_get_hard_particle_set (event, pset)
    class(event_t), intent(in) :: event
    type(particle_set_t), intent(out) :: pset
    class(evt_t), pointer :: evt
    evt => event%transform_first
    pset = evt%particle_set
  end subroutine event_get_hard_particle_set

```

### 32.10.8 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
  procedure :: select => event_select

<Events: procedures>+≡
  subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
    if (associated (event%instance)) then
      event%selected_i_mci = i_mci
      event%selected_i_term = i_term
      event%selected_channel = channel
    else
      event%selected_i_mci = 0
      event%selected_i_term = 0
      event%selected_channel = 0
    end if
  end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. The event reader may either read in the transformed event separately, or apply all event transforms to the hard particle set to (re)generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
  procedure :: set_hard_particle_set => event_set_hard_particle_set

<Events: procedures>+≡
  subroutine event_set_hard_particle_set (event, particle_set)
    class(event_t), intent(inout) :: event
    type(particle_set_t), intent(in) :: particle_set
    class(evt_t), pointer :: evt
    evt => event%transform_first
    call evt%set_particle_set (particle_set, &
      event%selected_i_mci, event%selected_i_term)
    call event%link_particle_set (evt%particle_set)
    evt => evt%next
    do while (associated (evt))
      call evt%reset ()
    end do
  end subroutine event_set_hard_particle_set

```

```

        evt => evt%next
    end do
end subroutine event_set_hard_particle_set

```

Set the  $\alpha_s$  value that should be used in a recalculation. This should be called only if we explicitly want to override the QCD setting of the process core.

```

<Events: event: TBP>+≡
    procedure :: set_alpha_qcd_forced => event_set_alpha_qcd_forced
<Events: procedures>+≡
    subroutine event_set_alpha_qcd_forced (event, alpha_qcd)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: alpha_qcd
        if (allocated (event%alpha_qcd_forced)) then
            event%alpha_qcd_forced = alpha_qcd
        else
            allocate (event%alpha_qcd_forced, source = alpha_qcd)
        end if
    end subroutine event_set_alpha_qcd_forced

```

Analogously, for the common scale. This forces also renormalization and factorization scale.

```

<Events: event: TBP>+≡
    procedure :: set_scale_forced => event_set_scale_forced
<Events: procedures>+≡
    subroutine event_set_scale_forced (event, scale)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: scale
        if (allocated (event%scale_forced)) then
            event%scale_forced = scale
        else
            allocate (event%scale_forced, source = scale)
        end if
    end subroutine event_set_scale_forced

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which

should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

If `recover_phs` is set (and false), do not attempt any phase-space calculation, including MCI evaluation. Useful if we need only matrix elements.

```

<Events: event: TBP>+≡

## 32.11 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the `events` module which provides the concrete implementation of `event_base`. The other I/O formats access only the methods that are defined in `event_base`.

```

<eio_raw.f90>≡
  <File header>

module eio_raw

```

```

    <Use kinds>
    <Use strings>
    use io_units
    use diagnostics
    use model_data
    use particles
    use event_base
    use eio_data
    use eio_base
    use events

    <Standard module head>

    <EIO raw: public>

    <EIO raw: parameters>

    <EIO raw: types>

    contains

    <EIO raw: procedures>

    end module eio_raw

```

### 32.11.1 File Format Version

This is the current default file version.

```

<EIO raw: parameters>≡
    integer, parameter :: CURRENT_FILE_VERSION = 2

```

The user may change this number; this should force some compatibility mode for reading and writing. In any case, the file version stored in a event file that we read has to match the expected file version.

History of version numbers:

1. Format for WHIZARD 2.2.0 to 2.2.3. No version number stored in the raw file.
2. Format from 2.2.4 on. File contains version number. The file contains the transformed particle set (if applicable) after the hard-process particle set.

### 32.11.2 Type

Note the file version number. The default may be reset during initialization, which should enforce some compatibility mode.

```

<EIO raw: public>≡
    public :: eio_raw_t

```

```

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

The `passed` flag is not written. This allow us to apply different selection criteria upon rereading.

```

Initialize the ISR/EPA handler, depending on active settings.

The activation is independent for both handlers, since only one may be needed at a time. However, if both handlers are active, the current implementation requires the handler modes of ISR and EPA to coincide.

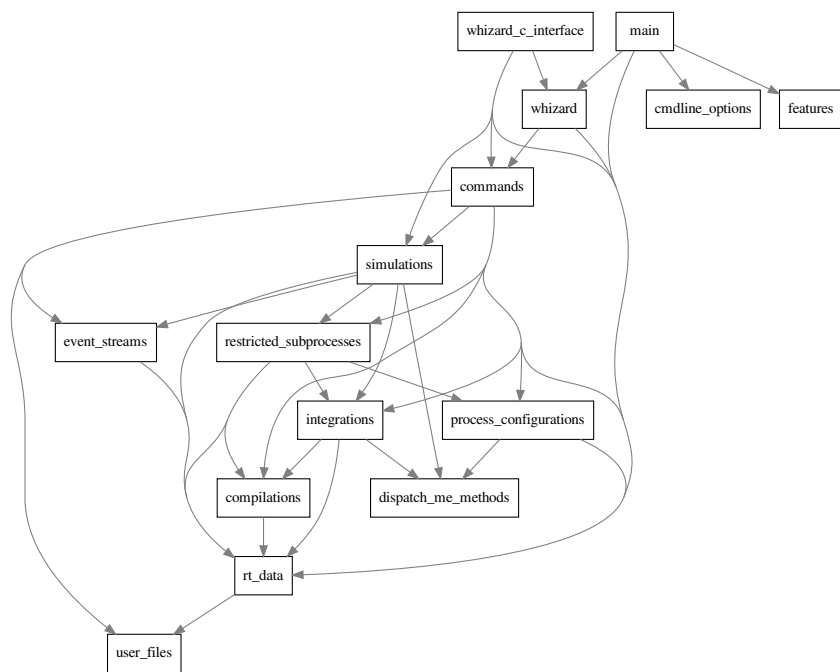

Figure 32.2: Module dependencies in `src/whizard-core`.

## Chapter 33

# Integration and Simulation

### 33.1 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```
<user_files.f90>≡  
  <File header>  
  
  module user_files  
  
    <Use strings>  
    use io_units  
    use diagnostics  
    use ifiles  
    use analysis  
  
    <Standard module head>  
  
    <User files: public>  
  
    <User files: types>  
  
    <User files: interfaces>  
  
    contains  
  
    <User files: procedures>  
  
  end module user_files
```

#### 33.1.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡
```

```

type :: file_t
  private
  type(string_t) :: name
  integer :: unit = -1
  logical :: reading = .false.
  logical :: writing = .false.
  type(file_t), pointer :: prev => null ()
  type(file_t), pointer :: next => null ()
end type file_t

```

The initializer opens the file.

```

<User files: procedures>≡
subroutine file_init (file, name, action, status, position)
  type(file_t), intent(out) :: file
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position
  file%unit = free_unit ()
  file%name = name
  open (unit = file%unit, file = char (file%name), &
        action = action, status = status, position = position)
  select case (action)
  case ("read")
    file%reading = .true.
  case ("write")
    file%writing = .true.
  case ("readwrite")
    file%reading = .true.
    file%writing = .true.
  end select
end subroutine file_init

```

The finalizer closes it.

```

<User files: procedures>+≡
subroutine file_final (file)
  type(file_t), intent(inout) :: file
  close (unit = file%unit)
  file%unit = -1
end subroutine file_final

```

Check if a file is open with correct status.

```

<User files: procedures>+≡
function file_is_open (file, action) result (flag)
  logical :: flag
  type(file_t), intent(in) :: file
  character(*), intent(in) :: action
  select case (action)
  case ("read")
    flag = file%reading
  case ("write")
    flag = file%writing
  case ("readwrite")
    flag = file%reading .and. file%writing
  end select
end function file_is_open

```

```

        case default
            call msg_bug ("Checking file '" // char (file%name) &
                // "' : illegal action specifier")
        end select
    end function file_is_open

```

Return the unit number of a file for direct access. It should be checked first whether the file is open.

```

<User files: procedures>+≡
    function file_get_unit (file) result (unit)
        integer :: unit
        type(file_t), intent(in) :: file
        unit = file%unit
    end function file_get_unit

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the `advancing` option.

```

<User files: procedures>+≡
    subroutine file_write_string (file, string, advancing)
        type(file_t), intent(in) :: file
        type(string_t), intent(in), optional :: string
        logical, intent(in), optional :: advancing
        if (file%writing) then
            if (present (string)) then
                if (present (advancing)) then
                    if (advancing) then
                        write (file%unit, "(A)") char (string)
                    else
                        write (file%unit, "(A)", advance="no") char (string)
                    end if
                else
                    write (file%unit, "(A)") char (string)
                end if
            else
                write (file%unit, *)
            end if
        else
            call msg_error ("Writing to file: File '" // char (file%name) &
                // "' is not open for writing.")
        end if
    end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
    subroutine file_write_ifile (file, ifile)
        type(file_t), intent(in) :: file
        type(ifile_t), intent(in) :: ifile
        type(line_p) :: line
        call line_init (line, ifile)
        do while (line_is_associated (line))
            call file_write_string (file, line_get_string_advance (line))
        end do
    end subroutine

```

```
end subroutine file_write_ifile
```

Write an analysis object (or all objects) to an open file.

*<User files: procedures>+≡*

```
subroutine file_write_analysis (file, tag)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: tag
  if (file%writing) then
    if (present (tag)) then
      call analysis_write (tag, unit = file%unit)
    else
      call analysis_write (unit = file%unit)
    end if
  else
    call msg_error ("Writing analysis to file: File ' " // char (file%name) &
      // "' is not open for writing.")
  end if
end subroutine file_write_analysis
```

### 33.1.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

*<User files: public>≡*

```
public :: file_list_t
```

*<User files: types>+≡*

```
type :: file_list_t
  type(file_t), pointer :: first => null ()
  type(file_t), pointer :: last => null ()
end type file_list_t
```

There is no initialization routine, but a finalizer which deletes all:

*<User files: public>+≡*

```
public :: file_list_final
```

*<User files: procedures>+≡*

```
subroutine file_list_final (file_list)
  type(file_list_t), intent(inout) :: file_list
  type(file_t), pointer :: current
  do while (associated (file_list%first))
    current => file_list%first
    file_list%first => current%next
    call file_final (current)
    deallocate (current)
  end do
  file_list%last => null ()
end subroutine file_list_final
```

Find an entry in the list. Return null pointer on failure.

```
<User files: procedures>+≡
function file_list_get_file_ptr (file_list, name) result (current)
  type(file_t), pointer :: current
  type(file_list_t), intent(in) :: file_list
  type(string_t), intent(in) :: name
  current => file_list%first
  do while (associated (current))
    if (current%name == name) return
    current => current%next
  end do
end function file_list_get_file_ptr
```

Check if a file is open, public version:

```
<User files: public>+≡
public :: file_list_is_open

<User files: procedures>+≡
function file_list_is_open (file_list, name, action) result (flag)
  logical :: flag
  type(file_list_t), intent(in) :: file_list
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action
  type(file_t), pointer :: current
  current => file_list_get_file_ptr (file_list, name)
  if (associated (current)) then
    flag = file_is_open (current, action)
  else
    flag = .false.
  end if
end function file_list_is_open
```

Return the unit number for a file. It should be checked first whether the file is open.

```
<User files: public>+≡
public :: file_list_get_unit

<User files: procedures>+≡
function file_list_get_unit (file_list, name) result (unit)
  integer :: unit
  type(file_list_t), intent(in) :: file_list
  type(string_t), intent(in) :: name
  type(file_t), pointer :: current
  current => file_list_get_file_ptr (file_list, name)
  if (associated (current)) then
    unit = file_get_unit (current)
  else
    unit = -1
  end if
end function file_list_get_unit
```

Append a new file entry, i.e., open this file. Error if it is already open.

```
<User files: public>+≡
public :: file_list_open
```

```

<User files: procedures>+=
subroutine file_list_open (file_list, name, action, status, position)
  type(file_list_t), intent(inout) :: file_list
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position
  type(file_t), pointer :: current
  if (.not. associated (file_list_get_file_ptr (file_list, name))) then
    allocate (current)

```

### 33.2.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn, is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

### 33.2.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()
    type(parse_node_t), pointer :: fac_scale_expr => null ()
    type(parse_node_t), pointer :: ren_scale_expr => null ()
    type(parse_node_t), pointer :: weight_expr => null ()
    type(parse_node_t), pointer :: selection_lexpr => null ()
    type(parse_node_t), pointer :: reweight_expr => null ()
    type(parse_node_t), pointer :: analysis_lexpr => null ()
    type(parse_node_p), dimension(:), allocatable :: alt_setup
  contains
    <RT data: rt parse nodes: TBP>
  end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

```

```

<RT data: procedures>≡
subroutine rt_parse_nodes_clear (rt_pn, name)
  class(rt_parse_nodes_t), intent(inout) :: rt_pn
  type(string_t), intent(in) :: name
  select case (char (name))
  case ("cuts")
    rt_pn%cuts_lexpr => null ()
  case ("scale")
    rt_pn%scale_expr => null ()
  case ("factorization_scale")
    rt_pn%fac_scale_expr => null ()
  case ("renormalization_scale")
    rt_pn%ren_scale_expr => null ()
  case ("weight")
    rt_pn%weight_expr => null ()
  case ("selection")
    rt_pn%selection_lexpr => null ()
  case ("reweight")
    rt_pn%reweight_expr => null ()
  case ("analysis")
    rt_pn%analysis_lexpr => null ()
  end select
end subroutine rt_parse_nodes_clear

```

Output for the parse nodes.

```

<RT data: rt parse nodes: TBP>+≡
  procedure :: write => rt_parse_nodes_write

<RT data: procedures>+≡
subroutine rt_parse_nodes_write (object, unit)

```

### 33.2.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

```

<RT data: rt data: TBP>+≡
    procedure :: global_init => rt_data_global_init

```

```

<RT data: procedures>+≡
subroutine rt_data_global_init (global, paths, logfile)
  class(rt_data_t), intent(out), target :: global
  type(paths_t), intent(in), optional :: paths
  type(string_t), intent(in), optional :: logfile
  integer :: seed
  call global%os_data%init (paths)
  if (present (logfile)) then
    global%logfile = logfile
  else
    global%logfile = ""
  end if
  allocate (global%out_files)
  call system_clock (seed)
  call global%var_list%init_defaults (seed, paths)
  call global%init_pointer_variables ()
  call global%process_stack%init_var_list (global%var_list)
end subroutine rt_data_global_init

```

### 33.2.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init

<RT data: procedures>+≡
subroutine rt_data_local_init (local, global, env)
  class(rt_data_t), intent(inout), target :: local
  type(rt_data_t), intent(in), target :: global
  integer, intent(in), optional :: env
  local%context => global
  call local%process_stack%link (global%process_stack)
  call local%process_stack%init_var_list (local%var_list)
  call local%process_stack%link_var_list (global%var_list)
  call local%var_list%append_string (var_str ("model_name"), &
    var_str (""), intrinsic=.true.)
  call local%init_pointer_variables ()
  local%fallback_model => global%fallback_model
  local%os_data = global%os_data
  local%logfile = global%logfile
  call local%model_list%link (global%model_list)
  local%model => global%model
  if (associated (local%model)) then
    call local%model%link_var_list (local%var_list)
  end if
  if (allocated (global%event_callback)) then
    allocate (local%event_callback, source = global%event_callback)
  end if

```

```
end subroutine rt_data_local_init
```

These variables point to objects which get local copies:

```
<RT data: rt data: TBP>+≡
  procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: procedures>+≡
  subroutine rt_data_init_pointer_variables (local)
    class(rt_data_t), intent(inout), target :: local
    logical, target, save :: known = .true.
    call local%var_list%append_string_ptr (var_str ("%fc"), &
      local%os_data%fc, known, intrinsic=.true., &
      description=var_str('This string variable gives the ' // &
        '\ttt{Fortran} compiler used within \whizard. It can ' // &
        'only be accessed, not set by the user. (cf. also ' // &
        '\ttt{\$fcflags}'))
    call local%var_list%append_string_ptr (var_str ("%fcflags"), &
      local%os_data%fcflags, known, intrinsic=.true., &
      description=var_str('This string variable gives the ' // &
        'compiler flags for the \ttt{Fortran} compiler used ' // &
        'within \whizard. It can only be accessed, not set by ' // &
        'the user. (cf. also \ttt{\$fc}'))
  end subroutine rt_data_init_pointer_variables
```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```
<RT data: rt data: TBP>+≡
  procedure :: activate => rt_data_activate

<RT data: procedures>+≡
  subroutine rt_data_activate (local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), pointer :: global
    global => local%context
    if (associated (global)) then
      local%lexer => global%lexer
      call global%copy_globals (local)
      local%os_data = global%os_data
      local%logfile = global%logfile
      if (associated (global%prclib)) then
        local%prclib => &
          local%prclib_stack%get_library_ptr (global%prclib%get_name ())
      end if
    end if
```

```

call local%import_values ()
call local%process_stack%link (global%process_stack)
local%it_list = global%it_list
local%beam_structure = global%beam_structure
local%pn = global%pn
if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
if (allocated (global%sample_fmt)) then
  allocate (local%sample_fmt (size (global%sample_fmt)), &
    source = global%sample_fmt)
end if
local%out_files => global%out_files
local%model => global%model
local%model_is_copy = .false.
else if (.not. associated (local%model)) then
  local%model => local%preload_model
  local%model_is_copy = .false.
end if
if (associated (local%model)) then
  call local%model%link_var_list (local%var_list)
  call local%var_list%set_string (var_str ("model_name"), &
    local%model%get_name (), is_known = .true.)
else
  call local%var_list%set_string (var_str ("model_name"), &
    var_str (""), is_known = .false.)
end if
end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
  procedure :: deactivate => rt_data_deactivate

<RT data: procedures>+≡
  subroutine rt_data_deactivate (local, global, keep_local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), optional, target :: global
    logical, intent(in), optional :: keep_local
    type(string_t) :: local_model, local_scheme
    logical :: same_model, delete
    delete = .true.; if (present (keep_local)) delete = .not. keep_local
    if (present (global)) then
      if (associated (global%model) .and. associated (local%model)) then
        local_model = local%model%get_name ()
        if (global%model%has_schemes ()) then
          local_scheme = local%model%get_scheme ()
          same_model = &
            global%model%matches (local_model, local_scheme)

```

```

        else
            same_model = global%model%matches (local_model)
        end if
    else
        same_model = .false.
    end if
    if (delete) then
        call local%process_stack%clear ()
        call local%unselect_model ()
        call local%unset_values ()
    else if (associated (local%model)) then
        call local%ensure_model_copy ()
    end if
    if (.not. same_model .and. associated (global%model)) then
        if (global%model%has_schemes ()) then
            call msg_message ("Restoring model '" // &
                char (global%model%get_name ()) // "', scheme '" // &
                char (global%model%get_scheme ()) // "'")
        else
            call msg_message ("Restoring model '" // &
                char (global%model%get_name ()) // "'")
        end if
    end if
    if (associated (global%model)) then
        call global%model%link_var_list (global%var_list)
    end if
    call global%restore_globals (local)
else
    call local%unselect_model ()
end if
end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
    procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
    subroutine rt_data_copy_globals (global, local)
        class(rt_data_t), intent(in) :: global
        class(rt_data_t), intent(inout) :: local
        local%prclib_stack = global%prclib_stack
    end subroutine rt_data_copy_globals

```

This restores global objects for which local modifications should be kept. May also modify (remove) the local objects.

```

<RT data: rt data: TBP>+≡
    procedure :: restore_globals => rt_data_restore_globals

<RT data: procedures>+≡
    subroutine rt_data_restore_globals (global, local)
        class(rt_data_t), intent(inout) :: global
        class(rt_data_t), intent(inout) :: local
        global%prclib_stack = local%prclib_stack

```

```

        call local%handle_exports (global)
    end subroutine rt_data_restore_globals

```

### 33.2.8 Exported objects

Exported objects are transferred to the global state when a local environment is closed. (For the top-level global data set, there is no effect.)

The current implementation handles only the **results** object, which resolves to the local process stack. The stack elements are appended to the global stack without modification, the local stack becomes empty.

Write names of objects to be exported:

```

<RT data: rt data: TBP>+≡
    procedure :: write_exports => rt_data_write_exports

<RT data: procedures>+≡
    subroutine rt_data_write_exports (rt_data, unit)
        class(rt_data_t), intent(in) :: rt_data
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        do i = 1, rt_data%get_n_export ()
            write (u, "(A)") char (rt_data%export(i))
        end do
    end subroutine rt_data_write_exports

```

The number of entries in the export list.

```

<RT data: rt data: TBP>+≡
    procedure :: get_n_export => rt_data_get_n_export

<RT data: procedures>+≡
    function rt_data_get_n_export (rt_data) result (n)
        class(rt_data_t), intent(in) :: rt_data
        integer :: n
        if (allocated (rt_data%export)) then
            n = size (rt_data%export)
        else
            n = 0
        end if
    end function rt_data_get_n_export

```

Return a specific export Append new names to the export list. If a duplicate occurs, do not transfer it.

```

<RT data: rt data: TBP>+≡
    procedure :: append_exports => rt_data_append_exports

<RT data: procedures>+≡
    subroutine rt_data_append_exports (rt_data, export)
        class(rt_data_t), intent(inout) :: rt_data
        type(string_t), dimension(:), intent(in) :: export
        logical, dimension(:), allocatable :: mask
        type(string_t), dimension(:), allocatable :: tmp
        integer :: i, j, n

```

```

if (.not. allocated (rt_data%export)) allocate (rt_data%export (0))
n = size (rt_data%export)
allocate (mask (size (export)), source=.false.)
do i = 1, size (export)
    mask(i) = all (export(i) /= rt_data%export) &
        .and. all (export(i) /= export(:i-1))
end do
if (count (mask) > 0) then
    allocate (tmp (n + count (mask)))
    tmp(1:n) = rt_data%export(:)
    j = n
    do i = 1, size (export)
        if (mask(i)) then
            j = j + 1
            tmp(j) = export(i)
        end if
    end do
    call move_alloc (from=tmp, to=rt_data%export)
end if
end subroutine rt_data_append_exports

```

Transfer export-objects from the local rt data to the global rt data, as far as supported.

*<RT data: rt data: TBP>+≡*

```

procedure :: handle_exports => rt_data_handle_exports

```

*<RT data: procedures>+≡*

```

subroutine rt_data_handle_exports (local, global)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), target :: global
    type(string_t) :: export
    integer :: i
    if (local%get_n_export () > 0) then
        do i = 1, local%get_n_export ()
            export = local%export(i)
            select case (char (export))
            case ("results")
                call msg_message ("Exporting integration results &
                    &to outer environment")
                call local%transfer_process_stack (global)
            case default
                call msg_bug ("handle exports: '" &
                    // char (export) // "' unsupported")
            end select
        end do
    end if
end subroutine rt_data_handle_exports

```

Export the process stack. One-by-one, take the last process from the local stack and push it on the global stack. Also handle the corresponding result variables: append if the process did not exist yet in the global stack, otherwise update.

TODO: result variables don't work that way yet, require initialization in the global variable list.

```

<RT data: rt data: TBP>+≡
  procedure :: transfer_process_stack => rt_data_transfer_process_stack

<RT data: procedures>+≡
  subroutine rt_data_transfer_process_stack (local, global)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), target :: global
    type(process_entry_t), pointer :: process
    type(string_t) :: process_id
    do
      call local%process_stack%pop_last (process)
      if (.not. associated (process)) exit
      process_id = process%get_id ()
      call global%process_stack%push (process)
      call global%process_stack%fill_result_vars (process_id)
      call global%process_stack%update_result_vars &
        (process_id, global%var_list)
    end do
  end subroutine rt_data_transfer_process_stack

```

### 33.2.9 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
  procedure :: final => rt_data_global_final

<RT data: procedures>+≡
  subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
    call global%model_list%final ()
    call global%var_list%final (follow_link=.false.)
    if (associated (global%out_files)) then
      call file_list_final (global%out_files)
      deallocate (global%out_files)
    end if
  end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: local_final => rt_data_local_final

<RT data: procedures>+≡
  subroutine rt_data_local_final (local)
    class(rt_data_t), intent(inout) :: local
    call local%process_stack%clear ()
    call local%model_list%final ()

```

```

    call local%var_list%final (follow_link=.false.)
end subroutine rt_data_local_final

```

### 33.2.10 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
  procedure :: read_model => rt_data_read_model

<RT data: procedures>+≡
  subroutine rt_data_read_model (global, name, model, scheme)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(string_t), intent(in), optional :: scheme
    type(model_t), pointer, intent(out) :: model
    type(string_t) :: filename
    filename = name // ".mdl"
    call global%model_list%read_model &
      (name, filename, global%os_data, model, scheme)
  end subroutine rt_data_read_model

```

Read a UFO model. Create it on the fly if necessary.

```

<RT data: rt data: TBP>+≡
  procedure :: read_ufo_model => rt_data_read_ufo_model

<RT data: procedures>+≡
  subroutine rt_data_read_ufo_model (global, name, model, ufo_path)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(model_t), pointer, intent(out) :: model
    type(string_t), intent(in), optional :: ufo_path
    type(string_t) :: filename
    filename = name // ".ufo.mdl"
    call global%model_list%read_model &
      (name, filename, global%os_data, model, ufo=.true., ufo_path=ufo_path)
  end subroutine rt_data_read_ufo_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
  procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: procedures>+≡
  subroutine rt_data_init_fallback_model (global, name, filename)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name, filename
    call global%model_list%read_model &
      (name, filename, global%os_data, global%fallback_model)
  end subroutine rt_data_init_fallback_model

```

```
end subroutine rt_data_init_fallback_model
```

Activate a model: assign the current-model pointer and set the model name in the variable list. If necessary, read the model from file. Link the global variable list to the model variable list.

```
<RT data: rt data: TBP>+≡
  procedure :: select_model => rt_data_select_model

<RT data: procedures>+≡
  subroutine rt_data_select_model (global, name, scheme, ufo, ufo_path)
    class(rt_data_t), intent(inout), target :: global
    type(string_t), intent(in) :: name
    type(string_t), intent(in), optional :: scheme
    logical, intent(in), optional :: ufo
    type(string_t), intent(in), optional :: ufo_path
    logical :: same_model, ufo_model
    ufo_model = .false.; if (present(ufo)) ufo_model = ufo
    if (associated(global%model)) then
      same_model = global%model%matches(name, scheme, ufo)
    else
      same_model = .false.
    end if
    if (.not. same_model) then
      global%model => global%model_list%get_model_ptr(name, scheme, ufo)
      if (.not. associated(global%model)) then
        if (ufo_model) then
          call global%read_ufo_model(name, global%model, ufo_path)
        else
          call global%read_model(name, global%model)
        end if
        global%model_is_copy = .false.
      else if (associated(global%context)) then
        global%model_is_copy = &
          global%model_list%model_exists(name, scheme, ufo, &
            follow_link=.false.)
      else
        global%model_is_copy = .false.
      end if
    end if
    if (associated(global%model)) then
      call global%model%link_var_list(global%var_list)
      call global%var_list%set_string(var_str("$model_name"), &
        name, is_known = .true.)
      if (global%model%is_ufo_model()) then
        call msg_message("Switching to model '" // char(name) // "' " &
          // "(generated from UFO source)")
      else if (global%model%has_schemes()) then
        call msg_message("Switching to model '" // char(name) // "', " &
          // "scheme '" // char(global%model%get_scheme()) // "'")
      else
        call msg_message("Switching to model '" // char(name) // "'")
      end if
    else
      call global%var_list%set_string(var_str("$model_name"), &
```

```

        var_str (""), is_known = .false.)
    end if
end subroutine rt_data_select_model

```

Remove the model link. Do not unset the model name variable, because this may unset the variable in a parent `rt_data` object (via linked var lists).

```

<RT data: rt data: TBP>+≡
    procedure :: unselect_model => rt_data_unselect_model

<RT data: procedures>+≡
    subroutine rt_data_unselect_model (global)
        class(rt_data_t), intent(inout), target :: global
        if (associated (global%model)) then
            global%model => null ()
            global%model_is_copy = .false.
        end if
    end subroutine rt_data_unselect_model

```

Create a copy of the currently selected model and append it to the local model list. The model pointer is redirected to the copy. (Not applicable for the global model list, those models will be modified in-place.)

```

<RT data: rt data: TBP>+≡
    procedure :: ensure_model_copy => rt_data_ensure_model_copy

<RT data: procedures>+≡
    subroutine rt_data_ensure_model_copy (global)
        class(rt_data_t), intent(inout), target :: global
        if (associated (global%context)) then
            if (.not. global%model_is_copy) then
                call global%model_list%append_copy (global%model, global%model)
                global%model_is_copy = .true.
                call global%model%link_var_list (global%var_list)
            end if
        end if
    end subroutine rt_data_ensure_model_copy

```

Modify a model variable. The update mechanism will ensure that the model parameter set remains consistent. This has to take place in a local copy of the current model. If there is none yet, create one.

```

<RT data: rt data: TBP>+≡
    procedure :: model_set_real => rt_data_model_set_real

<RT data: procedures>+≡
    subroutine rt_data_model_set_real (global, name, rval, verbose, pacified)
        class(rt_data_t), intent(inout), target :: global
        type(string_t), intent(in) :: name
        real(default), intent(in) :: rval
        logical, intent(in), optional :: verbose, pacified
        call global%ensure_model_copy ()
        call global%model%set_real (name, rval, verbose, pacified)
    end subroutine rt_data_model_set_real

```

Modify particle properties. This has to take place in a local copy of the current model. If there is none yet, create one.

```

<RT data: rt data: TBP>+≡
  procedure :: modify_particle => rt_data_modify_particle

### 33.2.11 Managing Variables

Return a pointer to the currently active variable list. If there is no model, this is the global variable list. If there is one, it is the model variable list, which should be linked to the former.

```

<RT data: rt data: TBP>+≡
  procedure :: get_var_list_ptr => rt_data_get_var_list_ptr

<RT data: procedures>+≡
  function rt_data_get_var_list_ptr (global) result (var_list)
    class(rt_data_t), intent(in), target :: global
    type(var_list_t), pointer :: var_list
    if (associated (global%model)) then
      var_list => global%model%get_var_list_ptr ()
    else
      var_list => global%var_list
    end if
  end function rt_data_get_var_list_ptr

```

Initialize a local variable: append it to the current variable list. No initial value, yet.

```

<RT data: rt data: TBP>+≡

  if (allocated (global%event_callback)) then
    allocate (callback, source = global%event_callback)
  end if
end function rt_data_get_event_callback

```

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```

### 33.3 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

We would like to put this in the `me_methods` folder but it also depends on `gosam` and `openloops`, so it is unclear where to put it.

```
<dispatch_me_methods.f90>≡  
  <File header>  
  
  module dispatch_me_methods  
  
    <Use strings>  
    <Use debug>  
    use physics_defs, only: BORN  
    use diagnostics  
    use sm_qcd  
    use variables, only: var_list_t  
    use models  
    use model_data  
  
    use prc_core_def  
    use prc_core  
    use prc_test_core  
    use prc_template_me  
    use prc_test  
    use prc_omega  
    use prc_external  
    use prc_gosam  
    use prc_openloops  
    use prc_recola  
    use prc_threshold  
  
    <Standard module head>  
  
    <Dispatch me methods: public>  
  
    contains  
  
    <Dispatch me methods: procedures>  
  
  end module dispatch_me_methods
```

#### 33.3.1 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable.

```
<Dispatch me methods: public>≡  
  public :: dispatch_core_def  
  
<Dispatch me methods: procedures>≡  
  subroutine dispatch_core_def (core_def, prt_in, prt_out, &

### 33.3.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```

(Dispatch me methods: public)+≡
    public :: dispatch_core

(Dispatch me methods: procedures)+≡
    subroutine dispatch_core (core, core_def, model, &
        helicity_selection, qcd, use_color_factors, has_beam_pol)
        class(prc_core_t), allocatable, intent(inout) :: core
        class(prc_core_def_t), intent(in) :: core_def
        class(model_data_t), intent(in), target, optional :: model
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        type(qcd_t), intent(in), optional :: qcd
        logical, intent(in), optional :: use_color_factors
        logical, intent(in), optional :: has_beam_pol
        select type (core_def)
            type is (prc_test_def_t)
                allocate (test_t :: core)
            type is (template_me_def_t)
                allocate (prc_template_me_t :: core)
                select type (core)
                    type is (prc_template_me_t)
                        call core%set_parameters (model)
                end select
            class is (omega_def_t)
                if (.not. allocated (core)) allocate (prc_omega_t :: core)
                select type (core)
                    type is (prc_omega_t)
                        call core%set_parameters (model, &
                            helicity_selection, qcd, use_color_factors)
                end select
            type is (gosam_def_t)
                if (.not. allocated (core)) allocate (prc_gosam_t :: core)

        end select
class default
    call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

### 33.3.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

```

<Dispatch me methods: public>+≡
    public :: dispatch_core_update
    public :: dispatch_core_restore

<Dispatch me methods: procedures>+≡
    subroutine dispatch_core_update &
        (core, model, helicity_selection, qcd, saved_core)

        class(prc_core_t), allocatable, intent(inout) :: core
        class(model_data_t), intent(in), optional, target :: model
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        type(qcd_t), intent(in), optional :: qcd
        class(prc_core_t), allocatable, intent(inout), optional :: saved_core

        if (present (saved_core)) then
            allocate (saved_core, source = core)
        end if
        select type (core)
            type is (test_t)
            type is (prc_omega_t)
                call core%set_parameters (model, helicity_selection, qcd)
                call core%activate_parameters ()
            class is (prc_external_t)
                call msg_message ("Updating user defined cores is not implemented yet.")
            class default
                call msg_bug ("Process core update: unexpected process definition type")
        end select
    end subroutine dispatch_core_update

    subroutine dispatch_core_restore (core, saved_core)

```

```

class(prc_core_t), allocatable, intent(inout) :: core
class(prc_core_t), allocatable, intent(inout) :: saved_core

call move_alloc (from = saved_core, to = core)
select type (core)

## 33.4 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

```
<process_configurations.f90>≡
  <File header>

  module process_configurations

    <Use strings>
    <Use debug>
    use diagnostics
    use io_units
    use physics_defs, only: BORN, NLO_VIRTUAL, NLO_REAL, NLO_DGLAP, &
      NLO_SUBTRACTION, NLO_MISMATCH
    use models
    use prc_core_def
    use particle_specifiers
    use process_libraries
    use rt_data
    use variables, only: var_list_t

    use dispatch_me_methods, only: dispatch_core_def
    use prc_external, only: prc_external_def_t

    <Standard module head>

    <Process configurations: public>

    <Process configurations: types>

    contains

    <Process configurations: procedures>

  end module process_configurations
```

### 33.4.1 Data Type

```
<Process configurations: public>≡

            requires_resonances = requires_resonances)
    end if
end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

```

        type(test_results_t), intent(inout) :: results
    <Process configurations: execute tests>
    end subroutine process_configurations_test

```

## Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

This is re-exported by the UT module.

```

<Process configurations: public test auxiliary>≡
    public :: prepare_test_library

<Process configurations: test auxiliary>≡
    subroutine prepare_test_library (global, libname, mode, procname)

## 33.5 Compilation

This module manages compilation and loading of process libraries. It is needed as a separate module because integration depends on it.

```
<compilations.f90>≡  
  <File header>  
  
  module compilations  
  
    <Use strings>  
    use io_units  
    use system_defs, only: TAB  
    use diagnostics  
    use os_interface  
    use variables, only: var_list_t  
    use model_data  
    use process_libraries  
    use prclib_stacks  
    use rt_data  
  
    <Standard module head>  
  
    <Compilations: public>  
  
    <Compilations: types>  
  
    <Compilations: parameters>  
  
    contains  
  
    <Compilations: procedures>  
  
  end module compilations
```

### 33.5.1 The data type

The compilation item handles the compilation and loading of a single process library.

```
<Compilations: public>≡  
  public :: compilation_item_t  
  
<Compilations: types>≡  
  type :: compilation_item_t  
    private  
    type(string_t) :: libname  
    type(string_t) :: static_external_tag  
    type(process_library_t), pointer :: lib => null ()  
    logical :: recompile_library = .false.  
    logical :: verbose = .false.  
    logical :: use_workspace = .false.  
    type(string_t) :: workspace  
    contains  
    <Compilations: compilation item: TBP>  
  end type compilation_item_t
```

Initialize.

Set flags and global properties of the library. Establish the workspace name, if defined.

*<Compilations: compilation item: TBP>*≡

```
procedure :: init => compilation_item_init
```

*<Compilations: procedures>*≡

```
subroutine compilation_item_init (comp, libname, stack, var_list)
  class(compilation_item_t), intent(out) :: comp
  type(string_t), intent(in) :: libname
  type(prclib_stack_t), intent(inout) :: stack
  type(var_list_t), intent(in) :: var_list
  comp%libname = libname
  comp%lib => stack%get_library_ptr (comp%libname)
  if (.not. associated (comp%lib)) then
    call msg_fatal ("Process library '" // char (comp%libname) &
      // "' has not been declared.")
  end if
  comp%recompile_library = &
    var_list%get_lval (var_str ("?recompile_library"))
  comp%verbose = &
    var_list%get_lval (var_str ("?me_verbose"))
  comp%use_workspace = &
    var_list%is_known (var_str ("$compile_workspace"))
  if (comp%use_workspace) then
    comp%workspace = &
      var_list%get_sval (var_str ("$compile_workspace"))
    if (comp%workspace == "") comp%use_workspace = .false.
  else
    comp%workspace = ""
  end if
end subroutine compilation_item_init
```

Compile the current library. The force flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

*<Compilations: compilation item: TBP>*+≡

```
procedure :: compile => compilation_item_compile
```

*<Compilations: procedures>*+≡

```
subroutine compilation_item_compile (comp, model, os_data, force, recompile)
  class(compilation_item_t), intent(inout) :: comp
  class(model_data_t), intent(in), target :: model
  type(os_data_t), intent(in) :: os_data
  logical, intent(in) :: force, recompile
  if (associated (comp%lib)) then
    if (comp%use_workspace) call setup_workspace (comp%workspace, os_data)
    call msg_message ("Process library '" &
      // char (comp%libname) // "': compiling ...")
    call comp%lib%configure (os_data)
    if (signal_is_pending ()) return
    call comp%lib%compute_md5sum (model)
```

```

    call comp%lib%write_makefile &
      (os_data, force, verbose=comp%verbose, workspace=comp%workspace)
    if (signal_is_pending ()) return
    if (force) then
      call comp%lib%clean &
        (os_data, distclean = .false., workspace=comp%workspace)
      if (signal_is_pending ()) return
    end if
    call comp%lib%write_driver (force, workspace=comp%workspace)
    if (signal_is_pending ()) return
    if (recompile) then
      call comp%lib%load &
        (os_data, keep_old_source = .true., workspace=comp%workspace)
      if (signal_is_pending ()) return
    end if
    call comp%lib%update_status (os_data, workspace=comp%workspace)
  end if
end subroutine compilation_item_compile

```

The workspace directory is created if it does not exist. (Applies only if the use has set the workspace directory.)

*<Compilations: parameters>+≡*

```

character(*), parameter :: ALLOWED_IN_DIRNAME = &
  "abcdefghijklmnopqrstuvwxyz&
  &ABCDEFGHIJKLMNOPQRSTUVWXYZ&
  &1234567890&
  &.,_-= "

```

*<Compilations: procedures>+≡*

```

subroutine setup_workspace (workspace, os_data)
  type(string_t), intent(in) :: workspace
  type(os_data_t), intent(in) :: os_data
  if (verify (workspace, ALLOWED_IN_DIRNAME) == 0) then
    call msg_message ("Compile: preparing workspace directory '" &
      // char (workspace) // "'")
    call os_system_call ("mkdir -p '" // workspace // "'")
  else
    call msg_fatal ("compile: workspace name '" &
      // char (workspace) // "' contains illegal characters")
  end if
end subroutine setup_workspace

```

Load the current library, just after compiling it.

*<Compilations: compilation item: TBP>+≡*

```

procedure :: load => compilation_item_load

```

*<Compilations: procedures>+≡*

```

subroutine compilation_item_load (comp, os_data)
  class(compilation_item_t), intent(inout) :: comp
  type(os_data_t), intent(in) :: os_data
  if (associated (comp%lib)) then
    call comp%lib%load (os_data, workspace=comp%workspace)
  end if
end subroutine compilation_item_load

```

Message as a separate call:

```

<Compilations: compilation item: TBP>+≡
    procedure :: success => compilation_item_success

<Compilations: procedures>+≡
    subroutine compilation_item_success (comp)
        class(compilation_item_t), intent(in) :: comp
        if (associated (comp%lib)) then
            call msg_message ("Process library '" // char (comp%libname) &
                // "': ... success.")
        else
            call msg_fatal ("Process library '" // char (comp%libname) &
                // "': ... failure.")
        end if
    end subroutine compilation_item_success

```

### 33.5.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
    public :: compile_library

<Compilations: procedures>+≡
    subroutine compile_library (libname, global)
        type(string_t), intent(in) :: libname
        type(rt_data_t), intent(inout), target :: global
        type(compilation_item_t) :: comp
        logical :: force, recompile
        force = &
            global%var_list%get_lval (var_str ("?rebuild_library"))
        recompile = &
            global%var_list%get_lval (var_str ("?recompile_library"))
        if (associated (global%model)) then
            call comp%init (libname, global%prclib_stack, global%var_list)
            call comp%compile (global%model, global%os_data, force, recompile)
            if (signal_is_pending ()) return
            call comp%load (global%os_data)
            if (signal_is_pending ()) return
        else
            call msg_fatal ("Process library compilation: " &
                // " model is undefined.")
        end if
        call comp%success ()
    end subroutine compile_library

```

### 33.5.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```
<Compilations: public>+≡
    public :: compilation_t
<Compilations: types>+≡
    type :: compilation_t
        private
            type(string_t) :: exe_name
            type(string_t), dimension(:), allocatable :: lib_name
        contains
            <Compilations: compilation: TBP>
        end type compilation_t
```

Output.

```
<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write
<Compilations: procedures>+≡
    subroutine compilation_write (object, unit)
        class(compilation_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Compilation object:"
        write (u, "(3x,3A)") "executable      = '", &
            char (object%exe_name), "'"
        write (u, "(3x,A)", advance="no") "process libraries ="
        do i = 1, size (object%lib_name)
            write (u, "(1x,3A)", advance="no") " '", char (object%lib_name(i)), "'"
        end do
        write (u, *)
    end subroutine compilation_write
```

Initialize: we know the names of the executable and of the libraries. Optionally, we may provide a workspace directory.

```
<Compilations: compilation: TBP>+≡
    procedure :: init => compilation_init
<Compilations: procedures>+≡
    subroutine compilation_init (compilation, exe_name, lib_name)
        class(compilation_t), intent(out) :: compilation
        type(string_t), intent(in) :: exe_name
        type(string_t), dimension(:), intent(in) :: lib_name
        compilation%exe_name = exe_name
        allocate (compilation%lib_name (size (lib_name)))
        compilation%lib_name = lib_name
    end subroutine compilation_init
```

Write the dispatcher subroutine for the compiled libraries. Also write a subroutine which returns the names of the compiled libraries.

```
<Compilations: compilation: TBP>+≡
```

```

procedure :: write_dispatcher => compilation_write_dispatcher
{Compilations: procedures}+=
subroutine compilation_write_dispatcher (compilation)
  class(compilation_t), intent(in) :: compilation
  type(string_t) :: file
  integer :: u, i

  end subroutine compilation_make_clean_exe

```

### 33.5.4 API for executable compilation

This is a shorthand for compiling and loading an executable, including the enclosed libraries. The `compilation` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
  public :: compile_executable

```

```

<Compilations: procedures>+≡
subroutine compile_executable (exename, libname, global)
  type(string_t), intent(in) :: exename
  type(string_t), dimension(:), intent(in) :: libname
  type(rt_data_t), intent(inout), target :: global
  type(compilation_t) :: compilation
  type(compilation_item_t) :: item
  type(string_t) :: ext_libtag
  logical :: force, recompile, verbose
  integer :: i
  ext_libtag = ""
  force = &
    global%var_list%get_lval (var_str ("?rebuild_library"))
  recompile = &
    global%var_list%get_lval (var_str ("?recompile_library"))
  verbose = &
    global%var_list%get_lval (var_str ("?me_verbose"))
  call compilation%init (exename, [libname])
  if (signal_is_pending ()) return
  call compilation%write_dispatcher ()
  if (signal_is_pending ()) return

  if (signal_is_pending ()) return
  call compilation%make_compile (global%os_data)
  if (signal_is_pending ()) return
  call compilation%make_link (global%os_data)
end subroutine compile_executable

```

### 33.5.5 Unit Tests

Test module, followed by the stand-alone unit-test procedures.

```

<compilations_ut.f90>≡
  <File header>

  module compilations_ut
    use unit_tests
    use compilations_util

  <Standard module head>

  <Compilations: public test>

  contains

```

```

    <Compilations: test driver>

    end module compilations_ut

    <compilations_uti.f90>≡
    <File header>

    module compilations_uti

    <Use strings>
        use io_units
        use models
        use rt_data
        use process_configurations_ut, only: prepare_test_library

        use compilations

    <Standard module head>

    <Compilations: test declarations>

    contains

    <Compilations: tests>

    end module compilations_uti

```

API: driver for the unit tests below.

```

    <Compilations: public test>≡
        public :: compilations_test

    <Compilations: test driver>≡
        subroutine compilations_test (u, results)
            integer, intent(in) :: u
            type(test_results_t), intent(inout) :: results
            <Compilations: execute tests>
        end subroutine compilations_test

```

## Intrinsic Matrix Element

Compile an intrinsic test matrix element (`prc_test` type).

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```

    <Compilations: execute tests>≡
        call test (compilations_1, "compilations_1", &
            "intrinsic test processes", &
            u, results)

    <Compilations: test declarations>≡
        public :: compilations_1

```

```

<Compilations: tests>≡
subroutine compilations_1 (u)
  integer, intent(in) :: u
  type(string_t) :: libname, procname
  type(rt_data_t), target :: global

  write (u, "(A)")  "* Test output: compilations_1"
  write (u, "(A)")  "* Purpose: configure and compile test process"
  write (u, "(A)")

  call syntax_model_file_init ()

  call global%global_init ()

  libname = "compilation_1"
  procname = "prc_comp_1"
  call prepare_test_library (global, libname, 1, [procname])

  call compile_library (libname, global)

  call global%write_libraries (u)

  call global%final ()
  call syntax_model_file_final ()

  write (u, "(A)")
  write (u, "(A)")  "* Test output end: compilations_1"

end subroutine compilations_1

```

## External Matrix Element

Compile an external test matrix element (omega type)

```

<Compilations: execute tests>+≡
  call test (compilations_2, "compilations_2", &
    "external process (omega)", &
    u, results)

<Compilations: test declarations>+≡
  public :: compilations_2

<Compilations: tests>+≡
subroutine compilations_2 (u)
  integer, intent(in) :: u
  type(string_t) :: libname, procname
  type(rt_data_t), target :: global

  write (u, "(A)")  "* Test output: compilations_2"
  write (u, "(A)")  "* Purpose: configure and compile test process"
  write (u, "(A)")

  call syntax_model_file_init ()

  call global%global_init ()

```

```

call global%set_log (var_str ("?omega_omp"), &
    .false., is_known = .true.)

libname = "compilation_2"
procname = "prc_comp_2"
call prepare_test_library (global, libname, 2, [procname,procname])

call compile_library (libname, global)

call global%write_libraries (u, libpath = .false.)

call global%final ()
call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: compilations_2"

write (u, "(A)")  "* Test output end: compilations_static_1"

end subroutine compilations_static_1

```

## External Matrix Element

Compile an external test matrix element (*omega* type) and incorporate this in a new static WHIZARD executable. In this version, we use the wrapper `compile_executable` procedure.

```

<Compilations: static tests>+≡
  call test (compilations_static_2, "compilations_static_2", &
    "static executable: shortcut", &
    u, results)

<Compilations: test declarations>+≡
  public :: compilations_static_2

<Compilations: tests>+≡
  subroutine compilations_static_2 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    logical :: exist
    integer :: u_file

    write (u, "(A)")  "* Test output: compilations_static_2"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library and compile"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()
    call global%set_log (var_str ("?omega_openmp"), &
      .false., is_known = .true.)

    libname = "compilations_static_2_lib"
    procname = "prc_comp_stat_2"
    exename = "compilations_static_2"

    call prepare_test_library (global, libname, 2, [procname,procname])

    call compile_executable (exename, [libname], global)

    write (u, "(A)")  "* Check executable (should be present)"

```

```

write (u, "(A)")

### 33.6.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

<Integrations: public>≡
    public :: integration_t

<Integrations: types>≡
    type :: integration_t
        private
            type(string_t) :: process_id
            type(string_t) :: run_id
            type(process_t), pointer :: process => null ()
            logical :: rebuild_phs = .false.
            logical :: ignore_phs_mismatch = .false.
            logical :: phs_only = .false.
            logical :: process_has_me = .true.
            integer :: n_calls_test = 0
            logical :: vis_history = .true.
            type(string_t) :: history_filename
            type(string_t) :: log_filename
            type(helicity_selection_t) :: helicity_selection
            logical :: use_color_factors = .false.
            logical :: has_beam_pol = .false.
            logical :: combined_integration = .false.
            type(iteration_multipliers_t) :: iteration_multipliers
            type(nlo_settings_t) :: nlo_settings
        contains
            <Integrations: integration: TBP>
    end type integration_t

```

### 33.6.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied.

```

<Integrations: integration: TBP>≡
    procedure :: create_process => integration_create_process

```

```

<Integrations: procedures>≡
subroutine integration_create_process (intg, process_id, global)
  class(integration_t), intent(out) :: intg

    call global%process_stack%push (process_entry)
  else
    allocate (process_t :: intg%process)
  end if
end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the local stack directly. The intent(inout) attribute for the local data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

```

### 33.6.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

<Integrations: integration: TBP>+=
    procedure :: evaluate => integration_evaluate

<Integrations: procedures>+=
    subroutine integration_evaluate &
        (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
    integer :: n_calls, n_it
    logical :: adapt_grids, adapt_weights, final
    n_it = it_list%get_n_it (pass)
    n_calls = it_list%get_n_calls (pass)
    adapt_grids = it_list%adapt_grids (pass)
    adapt_weights = it_list%adapt_weights (pass)
    final = pass == it_list%get_n_pass ()
    call process_instance%integrate ( &
        i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
        final, pacify)
    end subroutine integration_evaluate

```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct

passes, one for adaptation and one for integration.

```

<Integrations: integration: TBP>+≡
  procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: procedures>+≡
  subroutine integration_make_iterations_list (intg, it_list)
    class(integration_t), intent(in) :: intg
    type(iterations_list_t), intent(out) :: it_list
    integer :: pass, n_pass
    integer, dimension(:), allocatable :: n_it, n_calls
    logical, dimension(:), allocatable :: adapt_grids, adapt_weights
    n_pass = intg%process%get_n_pass_default ()
    allocate (n_it (n_pass), n_calls (n_pass))
    allocate (adapt_grids (n_pass), adapt_weights (n_pass))
    do pass = 1, n_pass
      n_it(pass)      = intg%process%get_n_it_default (pass)
      n_calls(pass)   = intg%process%get_n_calls_default (pass)
      adapt_grids(pass) = intg%process%adapt_grids_default (pass)
      adapt_weights(pass) = intg%process%adapt_weights_default (pass)
    end do
    call it_list%init (n_it, n_calls, &
      adapt_grids = adapt_grids, adapt_weights = adapt_weights)
  end subroutine integration_make_iterations_list

```

In NLO calculations, the individual components might scale very differently with the number of calls. This especially applies to the real-subtracted component, which usually fluctuates more than the Born and virtual component, making it a bottleneck of the calculation. Thus, the calculation is throttled twice, first by the number of calls for the real component, second by the number of surplus calls of computation-intense virtual matrix elements. Therefore, we want to set a different number of calls for each component, which is done by the subroutine `integration_apply_call_multipliers`.

```

<Integrations: integration: TBP>+≡
  procedure :: init_iteration_multipliers => integration_init_iteration_multipliers

<Integrations: procedures>+≡
  subroutine integration_init_iteration_multipliers (intg, local)

Return the process pointer (needed by simulate):

```

<Integrations: integration: TBP>+≡
  procedure :: get_process_ptr => integration_get_process_ptr

<Integrations: procedures>+≡
  function integration_get_process_ptr (intg) result (ptr)
    class(integration_t), intent(in) :: intg
    type(process_t), pointer :: ptr
    ptr => intg%process
  end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the `global` environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the `process` object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

### Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the  $2 \rightarrow 2$  process  $ss \rightarrow ss$  with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (33.1)$$

$c$  is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (33.2)$$

$f$  is the flux of the incoming particles with mass  $m = 125 \text{ GeV}$  and energy  $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (33.3)$$

$\Phi_2$  is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (33.4)$$

The squared matrix element  $|M|^2$  is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (33.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```

## Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function  $f(x) = x$  for both beams. Together with the  $1/x_1 x_2$  factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the  $m_s$  mass which we set to zero here.

```

<Integrations: execute tests>+≡

### Integration with sign change

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`. The weight that is applied changes the sign in half of phase space. The weight is  $-3$  and  $1$ , respectively, so the total result is equal to the original, but negative sign.

The efficiency should (approximately) become the average of  $1$  and  $1/3$ , that is  $2/3$ .

```

## 33.7 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
(event_streams.f90)≡  
  <File header>  
  
  module event_streams  
  
    <Use strings>  
    use io_units  
    use diagnostics  
    use events  
    use eio_data  
    use eio_base  
    use rt_data  
  
    use dispatch_transforms, only: dispatch_eio  
  
    <Standard module head>  
  
    <Event streams: public>  
  
    <Event streams: types>  
  
    contains  
  
    <Event streams: procedures>  
  
  end module event_streams
```

### 33.7.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡  
  type :: event_stream_entry_t  
    class(eio_t), allocatable :: eio  
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```
<Event streams: public>≡  
  public :: event_stream_array_t  
  
<Event streams: types>+≡  
  type :: event_stream_array_t  
    type(event_stream_entry_t), dimension(:), allocatable :: entry  
    integer :: i_in = 0  
    contains  
    <Event streams: event stream array: TBP>  
  end type event_stream_array_t
```

Output.

```

(Event streams: event stream array: TBP)≡
  procedure :: write => event_stream_array_write

(Event streams: procedures)≡
  subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object

    end do
  end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

## 33.8 Restricted Subprocesses

This module provides an automatic means to construct restricted subprocesses of a current process object. A restricted subprocess has the same initial and final state as the current process, but a restricted set of Feynman graphs.

The actual application extracts the set of resonance histories that apply to the process and uses this to construct subprocesses that are restricted to one of those histories, respectively. The resonance histories are derived from the phase-space setup. This implies that the method is tied to the OMega matrix element generator and to the wood phase space method.

The processes are collected in a new process library that is generated on-the-fly.

The `resonant_subprocess_t` object is intended as a component of the event record, which manages all operations regarding resonance handling.

The run-time calculations are delegated to an event transform (`evt_resonance_t`), as a part of the event transform chain. The transform selects one (or none) of the resonance histories, given the momentum configuration, computes matrix elements and inserts resonances into the particle set.

end module restricted_subprocesses

```

### 33.8.1 Process configuration

We extend the `process_configuration_t` by another method for initialization that takes into account a resonance history.

```

<Restricted subprocesses: public>≡
    public :: restricted_process_configuration_t

<Restricted subprocesses: types>≡
    type, extends (process_configuration_t) :: restricted_process_configuration_t
    private
    contains
    <Restricted subprocesses: restricted process configuration: TBP>
end type restricted_process_configuration_t

```

Resonance history as an argument. We use it to override the `restrictions` setting in a local variable list. Since we can construct the restricted process only by using OMega, we enforce it as the ME method. Other settings are taken from the variable list. The model will most likely be set, but we insert a safeguard just in case.

Also, the resonant subprocess should not itself spawn resonant subprocesses, so we unset `?resonance_history`.

We have to create a local copy of the model here, via pointer allocation. The reason is that the model as stored (via pointer) in the base type will be finalized and deallocated.

The current implementation will generate a LO process, the optional `nlo_process` is unset. (It is not obvious whether the construction makes sense beyond LO.)

```

<Restricted subprocesses: restricted process configuration: TBP>≡
    procedure :: init_resonant_process

<Restricted subprocesses: procedures>≡
    subroutine init_resonant_process &
        (prc_config, prc_name, prt_in, prt_out, res_history, model, var_list)

end subroutine init_resonant_process

```

### 33.8.2 Resonant-subprocess set manager

This data type enables generation of a library of resonant subprocesses for a given master process, and it allows for convenient access. The matrix elements from the subprocesses can be used as channel weights to activate a selector, which then returns a preferred channel via some random number generator.

```

<Restricted subprocesses: public>+≡
    public :: resonant_subprocess_set_t

<Restricted subprocesses: types>+≡
    type :: resonant_subprocess_set_t
    private

### 33.8.3 Resonance history set

Initialize subprocess set with an array of pre-created resonance history sets.

Safeguard: if there are no resonances in the input, initialize the local set as

empty, but complete.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: init => resonant_subprocess_set_init
  procedure :: fill_resonances => resonant_subprocess_set_fill_resonances

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_init (prc_set, n_component)
    class(resonant_subprocess_set_t), intent(out) :: prc_set
    integer, intent(in) :: n_component
    allocate (prc_set%res_history_set (n_component))
    allocate (prc_set%n_history (n_component), source = 0)
  end subroutine resonant_subprocess_set_init

  subroutine resonant_subprocess_set_fill_resonances (prc_set, &
    res_history_set, i_component)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    type(resonance_history_set_t), intent(in) :: res_history_set
    integer, intent(in) :: i_component
    prc_set%n_history(i_component) = res_history_set%get_n_history ()
    if (prc_set%n_history(i_component) > 0) then
      prc_set%res_history_set(i_component) = res_history_set
    else
      call prc_set%res_history_set(i_component)%init (initial_size = 0)
      call prc_set%res_history_set(i_component)%freeze ()
    end if
  end subroutine resonant_subprocess_set_fill_resonances

```

Return the resonance history set.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: get_resonance_history_set &
    => resonant_subprocess_set_get_resonance_history_set

<Restricted subprocesses: procedures>+≡
  function resonant_subprocess_set_get_resonance_history_set (prc_set) &
    result (res_history_set)
    class(resonant_subprocess_set_t), intent(in) :: prc_set
    type(resonance_history_set_t), dimension(:), allocatable :: res_history_set
    res_history_set = prc_set%res_history_set
  end function resonant_subprocess_set_get_resonance_history_set

```

### 33.8.4 Library for the resonance history set

The recommended library name: append `_R` to the process name.

```

<Restricted subprocesses: public>+≡
  public :: get_libname_res

<Restricted subprocesses: procedures>+≡
  elemental function get_libname_res (proc_id) result (libname)
    type(string_t), intent(in) :: proc_id
    type(string_t) :: libname
    libname = proc_id // "_R"
  end function get_libname_res

```

Here we scan the global process library whether any processes require resonant subprocesses to be constructed. If yes, create process objects with phase space and construct the process libraries as usual. Then append the library names to the array.

The temporary integration objects should carry the `phs_only` flag. We set this in the local environment.

Once a process object with resonance histories (derived from phase space) has been created, we extract the resonance histories and use them, together with the process definition, to create the new library.

Finally, compile the library.

```

<Restricted subprocesses: public>+=
  public :: spawn_resonant_subprocess_libraries

<Restricted subprocesses: procedures>+=
  subroutine spawn_resonant_subprocess_libraries &
    (libname, local, global, libname_res)

```

### 33.8.5 Process objects and instances

Prepare process objects for all entries in the resonant-subprocesses library. The process objects are appended to the global process stack. A local environment can be used where we place temporary variable settings that affect process-object generation. We initialize the processes, such that we can evaluate matrix elements, but we do not need to integrate them.

The internal procedure `prepare_process` is an abridged version of the procedure with this name in the `simulations` module.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: prepare_process_objects &
    => resonant_subprocess_set_prepare_process_objects

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_prepare_process_objects &
    (prc_set, local, global)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set

    end do

```

```
end subroutine resonant_subprocess_set_prepare_process_instances
```

### 33.8.6 Event transform connection

The idea is that the resonance-insertion event transform has been allocated somewhere (namely, in the standard event-transform chain), but we maintain a link such that we can inject matrix-element results event by event. The event transform holds a selector, to choose one of the resonance histories (or none), and it manages resonance insertion for the particle set.

The data that the event transform requires can be provided here. The resonance history set has already been assigned with the `dispatch` initializer. Here, we supply the set of subprocess instances that we have generated (see above). The master-process instance is set when we `connect` the transform by the standard method.

```
<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: connect_transform => &
    resonant_subprocess_set_connect_transform

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_connect_transform (prc_set, evt)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    class(evt_t), intent(in), target :: evt
    select type (evt)
    type is (evt_resonance_t)
      prc_set%evt => evt
      call prc_set%evt%set_subprocess_instances (prc_set%instance)
    class default
      call msg_bug ("Resonant subprocess set: event transform has wrong type")
    end select
  end subroutine resonant_subprocess_set_connect_transform
```

Set the on-shell limit value in the connected transform.

```
<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: set_on_shell_limit => resonant_subprocess_set_on_shell_limit

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_on_shell_limit (prc_set, on_shell_limit)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    real(default), intent(in) :: on_shell_limit
    call prc_set%evt%set_on_shell_limit (on_shell_limit)
  end subroutine resonant_subprocess_set_on_shell_limit
```

Set the Gaussian turnoff parameter in the connected transform.

```
<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: set_on_shell_turnoff => resonant_subprocess_set_on_shell_turnoff

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_on_shell_turnoff &
    (prc_set, on_shell_turnoff)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    real(default), intent(in) :: on_shell_turnoff
    call prc_set%evt%set_on_shell_turnoff (on_shell_turnoff)
```

```
end subroutine resonant_subprocess_set_on_shell_turnoff
```

Reweight (suppress) the background contribution probability, for the kinematics where a resonance history is active.

```
<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: set_background_factor &
    => resonant_subprocess_set_background_factor

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_background_factor &
    (prc_set, background_factor)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    real(default), intent(in) :: background_factor
    call prc_set%evt%set_background_factor (background_factor)
  end subroutine resonant_subprocess_set_background_factor
```

### 33.8.7 Wrappers for runtime calculations

All runtime calculations are delegated to the event transform. The following procedures are essentially redundant wrappers. We retain them for a unit test below.

Debugging aid:

```
<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: dump_instances => resonant_subprocess_set_dump_instances

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_dump_instances (prc_set, unit, testflag)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: i, n, u
    u = given_output_unit (unit)
    write (u, "(A)")  "*** Process instances of resonant subprocesses"
    write (u, *)
    n = size (prc_set%subprocess)
    do i = 1, n
      associate (instance => prc_set%instance(i)%p)
        call instance%write (u, testflag)
        write (u, *)
        write (u, *)
      end associate
    end do
  end subroutine resonant_subprocess_set_dump_instances
```

Inject the current kinematics configuration, reading from the previous event transform or from the process instance.

```
<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: fill_momenta => resonant_subprocess_set_fill_momenta
```

```

<Restricted subprocesses: procedures>+≡
subroutine resonant_subprocess_set_fill_momenta (prc_set)
  class(resonant_subprocess_set_t), intent(inout) :: prc_set
  integer :: i, n
  call prc_set%evt%fill_momenta ()
end subroutine resonant_subprocess_set_fill_momenta

```

Determine the indices of the resonance histories that can be considered on-shell for the current kinematics.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: determine_on_shell_histories &
    => resonant_subprocess_set_determine_on_shell_histories

<Restricted subprocesses: procedures>+≡
subroutine resonant_subprocess_set_determine_on_shell_histories &
  (prc_set, i_component, index_array)
  class(resonant_subprocess_set_t), intent(in) :: prc_set
  integer, intent(in) :: i_component
  integer, dimension(:), allocatable, intent(out) :: index_array
  call prc_set%evt%determine_on_shell_histories (index_array)
end subroutine resonant_subprocess_set_determine_on_shell_histories

```

Evaluate selected subprocesses. (In actual operation, the ones that have been tagged as on-shell.)

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: evaluate_subprocess &
    => resonant_subprocess_set_evaluate_subprocess

<Restricted subprocesses: procedures>+≡
subroutine resonant_subprocess_set_evaluate_subprocess (prc_set, index_array)
  class(resonant_subprocess_set_t), intent(inout) :: prc_set
  integer, dimension(:), intent(in) :: index_array
  call prc_set%evt%evaluate_subprocess (index_array)
end subroutine resonant_subprocess_set_evaluate_subprocess

```

Extract the matrix elements of the master process / the resonant subprocesses. After the previous routine has been executed, they should be available and stored in the corresponding process instances.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: get_master_sqme &
    => resonant_subprocess_set_get_master_sqme
  procedure :: get_subprocess_sqme &
    => resonant_subprocess_set_get_subprocess_sqme

<Restricted subprocesses: procedures>+≡
function resonant_subprocess_set_get_master_sqme (prc_set) result (sqme)
  class(resonant_subprocess_set_t), intent(in) :: prc_set
  real(default) :: sqme
  sqme = prc_set%evt%get_master_sqme ()
end function resonant_subprocess_set_get_master_sqme

subroutine resonant_subprocess_set_get_subprocess_sqme (prc_set, sqme)
  class(resonant_subprocess_set_t), intent(in) :: prc_set

```

```

    real(default), dimension(:), intent(inout) :: sqme
    integer :: i
    call prc_set%evt%get_subprocess_sqme (sqme)
end subroutine resonant_subprocess_set_get_subprocess_sqme

```

We use the calculations of resonant matrix elements to determine probabilities for all resonance configurations.

```

⟨Restricted subprocesses: resonant subprocess set: TBP⟩+≡
    procedure :: compute_probabilities &
        => resonant_subprocess_set_compute_probabilities

⟨Restricted subprocesses: procedures⟩+≡
    subroutine resonant_subprocess_set_compute_probabilities (prc_set, prob_array)
        class(resonant_subprocess_set_t), intent(inout) :: prc_set
        real(default), dimension(:), allocatable, intent(out) :: prob_array
        integer, dimension(:), allocatable :: index_array
        real(default) :: sqme, sqme_sum, sqme_bg
        real(default), dimension(:), allocatable :: sqme_res
        integer :: n
        n = size (prc_set%subprocess)
        allocate (prob_array (0:n), source = 0._default)
        call prc_set%evt%compute_probabilities ()
        call prc_set%evt%get_selector_weights (prob_array)
    end subroutine resonant_subprocess_set_compute_probabilities

```

```

Count an event. The weight and event source are optional; by default we assume that the event has been generated and has positive weight.

The optional integer `n_dropped` counts weighted events with weight zero that were encountered while generating the current event, but dropped (because of their zero weight). Accumulating this number allows for renormalizing event weight sums in histograms, after the generation step has been completed.

### 33.9.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

```

<Simulations: types>+=
    type :: core_safe_t
        class(prc_core_t), allocatable :: core
    end type core_safe_t

```

### 33.9.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. `use_process` implies that the process should already exist as an object in the process stack. If integration is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

```

<Simulations: procedures>+=
    subroutine prepare_process &
        (process, process_id, use_process, integrate, local, global)
        type(process_t), pointer, intent(out) :: process

### 33.9.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

For the purpose of NLO events, `entry_t` contains a pointer list to other simulation-entries. This is due to the fact that we have to associate an event for each component of the fixed order simulation, i.e. one  $N$ -particle event and  $N_\alpha$   $N+1$ -particle events. However, all entries share the same event transforms.

```

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the **process\_instance** pointer. Assign data by looking at the process object and at the environment.

If **n\_alt** is set, we prepare for additional alternate sqme and weight entries.

The **compile** flag is only false if we don't need the Whizard process at all, just its definition. In that case, we skip process initialization.

Otherwise, and if the process object is not found initially: if **integrate** is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If **generate** is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

If **resonance\_history** is set, we create a separate process library which contains all possible restricted subprocesses with distinct resonance histories. These processes will not be integrated, but their matrix element codes are used for determining probabilities of resonance histories. Note that this can work only if the process method is OMega, and the phase-space method is 'wood'.

When done, we assign the **instance** and **process** pointers of the base type by the **connect** method, so we can reference them later.

TODO: In case of NLO event generation, copying the configuration from the

master process is rather intransparent. For instance, we override the process var list by the global var list.

Update and restore the process core that this entry accesses, when parameters change. If explicit arguments `model`, `qcd`, or `helicity_selection` are provided, use those. Otherwise use the parameters stored in the process object.

These two procedures come with a caching mechanism which guarantees that the current core object is saved when calling `update_process`, and restored by calling `restore_process`. If the flag `saved` is unset, saving is skipped, and the `restore` procedure should not be called.

### 33.9.6 Handling resonant subprocesses

Resonant subprocesses are required if we want to determine resonance histories when generating events. The feature is optional, to be switched on by the user.

This procedure initializes a new, separate process library that contains copies of the current process, restricted to the relevant resonance histories. (If this library exists already, it is just kept.) The histories can be extracted from the process object.

The code has to match the assignments in `create_resonant_subprocess_library`. The library may already exist – in that case, here it will be recovered without recompilation.

*<Simulations: entry: TBP>+≡*

    type(rt_data_t), intent(inout), target :: global
    call entry%resonant_subprocess_set%compile_library (global)
  end subroutine entry_compile_resonant_subprocesses

```

Prepare process objects for the resonant-subprocesses library. The process objects are appended to the global process stack. We initialize the processes, such that we can evaluate matrix elements, but we do not need to integrate them.

```

<Simulations: entry: TBP>+≡
  procedure :: prepare_resonant_subprocesses &
    => entry_prepare_resonant_subprocesses

<Simulations: procedures>+≡
  subroutine entry_prepare_resonant_subprocesses (entry, local, global)
    class(entry_t), intent(inout) :: entry
    type(rt_data_t), intent(inout), target :: local

```

```

        type(rt_data_t), intent(inout), optional, target :: global
        call entry%resonant_subprocess_set%prepare_process_objects (local, global)
    end subroutine entry_prepare_resonant_subprocesses

```

Prepare process instances. They are linked to their corresponding process objects. Both, process and instance objects, are allocated as anonymous targets inside the `resonant_subprocess_set` component.

NOTE: those anonymous object are likely forgotten during finalization of the parent `event_t` (extended as `entry_t`) object. This should be checked! The memory leak is probably harmless as long as the event object is created once per run, not once per event.

```

<Simulations: entry: TBP>+≡
    procedure :: prepare_resonant_subprocess_instances &
        => entry_prepare_resonant_subprocess_instances

<Simulations: procedures>+≡
    subroutine entry_prepare_resonant_subprocess_instances (entry, global)

### 33.9.7 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
  type, extends (entry_t) :: alt_entry_t
  contains
    <Simulations: alt entry: TBP>
  end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage

of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

<Simulations: alt entry: TBP>≡
  procedure :: init_alt => alt_entry_init

<Simulations: procedures>+≡

```

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take

`n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the luminosity setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the luminosity, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

```

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

NB: When reading from file, event transforms can't be applied because the process instance will not be complete. This should be fixed.

```

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

Here we handle the event index that is kept in the simulation record. The event index is valid for the current sample. When generating or reading events, we initialize the index with the offset that the user provides (if any) and increment it for each event that is generated or read from file. The event index is stored in the event-entry that is current for the event. If an event on file comes with its own index, that index overwrites the predefined one and also resets the index within the simulation record.

The event index is not connected to the `counter` object. The counter is supposed to collect statistical information. The event index is a user-level object that is visible in event records and analysis expressions.

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the

changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

    else
        call msg_fatal ("Simulation: write event: no process selected")
    end if
end subroutine simulation_write_event_eio

```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```

<Simulations: simulation: TBP>+=
    generic :: read_event => read_event_eio
    procedure :: read_event_eio => simulation_read_event_eio

<Simulations: procedures>+=

    integer, intent(in) :: i
    character(32) :: md5sum
    md5sum = simulation%md5sum_alt(i)
  end function simulation_get_md5sum_alt

```

Return data that may be useful for writing event files.

Usually we can refer to a previously integrated process, for which we can fetch a process pointer. Occasionally, we don't have this because we're just rescanning an externally generated file without calculation. For that situation, we generate our local beam data object using the current environment, or, in simple cases, just fetch the necessary data from the process definition and environment.

```

<Simulations: simulation: TBP>+≡

```

```

## Chapter 34

# More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in init/final hooks that we can set at runtime.)

### 34.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
(expr_tests_ut.f90)≡  
  <File header>  
  module expr_tests_ut  
  
    use unit_tests  
    use expr_tests_uti  
  
    <Standard module head>  
  
    <Expr tests: public test>  
  
    contains  
  
    <Expr tests: test driver>  
  
  end module expr_tests_ut  
(expr_tests_uti.f90)≡  
  <File header>  
  
  module expr_tests_uti  
  
    <Use kinds>  
    <Use strings>  
    use format_defs, only: FMT_12  
    use format_utils, only: write_separator
```

```

    use os_interface
    use sm_qcd
    use lorentz
    use ifiles
    use lexers
    use parser
    use model_data
    use interactions, only: reset_interaction_counter
    use process_libraries
    use subevents
    use subvt_expr

## Chapter 35

# Top Level

The top level consists of

**commands** Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

**whizard** This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

**main** The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

**whizard\_c\_interface** Alternative top-level procedures, for use in the context of a C-compatible caller program.

## 35.1 Commands

This module defines the command language of the main input file.

```
<commands.f90>≡

### 35.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```

<Commands: types>≡
    type, abstract :: command_t
        type(parse_node_t), pointer :: pn => null ()
        class(command_t), pointer :: next => null ()
        type(parse_node_t), pointer :: pn_opt => null ()
        type(command_list_t), pointer :: options => null ()
        type(rt_data_t), pointer :: local => null ()
    contains
        <Commands: command: TBP>
    end type command_t

```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```

<Commands: command: TBP>≡
    procedure :: final => command_final

<Commands: procedures>≡
    recursive subroutine command_final (cmd)
        class(command_t), intent(inout) :: cmd
        if (associated (cmd%options)) then
            call cmd%options%final ()
            deallocate (cmd%options)
            call cmd%local%local_final ()
        end if
    end subroutine command_final

```

```

        deallocate (cmd%local)
    else
        cmd%local => null ()
    end if
end subroutine command_final

```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

*(Commands: procedures)*+≡

```

end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

<Commands: command: TBP>+≡
  procedure (command_write), deferred :: write

<Commands: interfaces>≡
  abstract interface
    subroutine command_write (cmd, unit, indent)
      import
      class(command_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
    end subroutine command_write
  end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

<Commands: command: TBP>+≡
  procedure (command_compile), deferred :: compile

<Commands: interfaces>+≡
  abstract interface
    subroutine command_compile (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_compile
  end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

<Commands: command: TBP>+≡
  procedure (command_execute), deferred :: execute

<Commands: interfaces>+≡
  abstract interface
    subroutine command_execute (cmd, global)
      import
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
    end subroutine command_execute

```

```
end interface
```

### 35.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```
<Commands: command: TBP>+≡
  procedure :: write_options => command_write_options

<Commands: procedures>+≡
  recursive subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options
```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```
<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
  recursive subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call cmd%options%compile (cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
      call cmd%local%deactivate ()
    else
      cmd%local => global
    end if
  end subroutine command_compile_options
```

Execute options. First prepare the local environment, then execute the command list.

```
<Commands: command: TBP>+≡
  procedure :: execute_options => cmd_execute_options
```

```

⟨Commands: procedures⟩+≡
recursive subroutine cmd_execute_options (cmd, global)
  class(command_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  if (associated (cmd%options)) then
    call cmd%local%activate ()
    call cmd%options%execute (cmd%local)
  end if
end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

⟨Commands: command: TBP⟩+≡
  procedure :: reset_options => cmd_reset_options

⟨Commands: procedures⟩+≡
subroutine cmd_reset_options (cmd, global)
  class(command_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  if (associated (cmd%options)) then
    call cmd%local%deactivate (global)
  end if
end subroutine cmd_reset_options

```

### 35.1.3 Specific command types

#### Model configuration

The command declares a model, looks for the specified file and loads it.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_model_t
  private
  type(string_t) :: name
  type(string_t) :: scheme
  logical :: ufo_model = .false.
  logical :: ufo_path_set = .false.
  type(string_t) :: ufo_path
contains
  ⟨Commands: cmd model: TBP⟩
end type cmd_model_t

```

#### Output

```

⟨Commands: cmd model: TBP⟩≡
  procedure :: write => cmd_model_write

⟨Commands: procedures⟩+≡
subroutine cmd_model_write (cmd, unit, indent)
  class(cmd_model_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return

```

```

call write_indent (u, indent)
write (u, "(1x,A,1x,'"',A,'\"')", advance="no") "model =", char (cmd%name)
if (cmd%ufo_model) then
  if (cmd%ufo_path_set) then
    write (u, "(1x,A,A,A)") "(ufo (", char (cmd%ufo_path), ")")
  else
    write (u, "(1x,A)") "(ufo)"
  end if
else if (cmd%scheme /= "") then
  write (u, "(1x,'(,A,')')") char (cmd%scheme)
else
  write (u, *)
end if
end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed. If the model has a scheme argument, take this into account.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

*(Commands: cmd model: TBP)+≡*

      call lib%update_status (global%os_data)
    end if
  end subroutine cmd_library_execute

```

## Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_process_t
  private
  type(string_t) :: id
  integer :: n_in = 0
  type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
  type(parse_node_t), pointer :: pn_out => null ()
  contains
  ⟨Commands: cmd process: TBP⟩
end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

⟨Commands: cmd process: TBP⟩≡
  procedure :: write => cmd_process_write

⟨Commands: procedures⟩+≡
  subroutine cmd_process_write (cmd, unit, indent)
    class(cmd_process_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)") "process: ", char (cmd%id), " (", &
      size (cmd%pn_pdg_in), " -> X)"
    call cmd%write_options (u, indent)
  end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

⟨Commands: cmd process: TBP⟩+≡
  procedure :: compile => cmd_process_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_process_compile (cmd, global)
    class(cmd_process_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_id, pn_in, pn_codes
    integer :: i
    pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_in => parse_node_get_next_ptr (pn_id, 2)
    cmd%pn_out => parse_node_get_next_ptr (pn_in, 2)
    cmd%pn_opt => parse_node_get_next_ptr (cmd%pn_out)
    call cmd%compile_options (global)
    cmd%id = parse_node_get_string (pn_id)

```

```

cmd%n_in = parse_node_get_n_sub (pn_in)
pn_codes => parse_node_get_sub_ptr (pn_in)
allocate (cmd%pn_pdg_in (cmd%n_in))
do i = 1, cmd%n_in
    cmd%pn_pdg_in(i)%ptr => pn_codes
    pn_codes => parse_node_get_next_ptr (pn_codes)
end do
end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

There are two possibilities that a process contains more than component: by an explicit component statement by the user for inclusive processes, or by having one process at NLO level. The first option is determined in the routine `scan_components`, and determines `n_components`.

```

Command execution. Generate code, write driver, compile and link. Do this for all libraries in the list.

If no library names have been given and stored while compiling this command, we collect all libraries from the current stack and compile those.

As a bonus, a compiled library may be able to spawn new process libraries. For instance, a processes may ask for a set of resonant subprocesses which go into their own library, but this can be determined only after the process is available as a compiled object. Therefore, the compilation loop is implemented as a recursive internal subroutine.

We can compile static libraries (which actually just loads them). However, we can't incorporate in a generated executable.

```

## Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

## SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_slha_t
private
type(string_t) :: file
logical :: write_mode = .false.
contains
⟨Commands: cmd slha: TBP⟩
end type cmd_slha_t

```

Output.

```

⟨Commands: cmd slha: TBP⟩≡

```

```

    procedure :: write => cmd_slha_write
<Commands: procedures>+≡
    subroutine cmd_slha_write (cmd, unit, indent)
        class(cmd_slha_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A)") "slha: file name = ", char (cmd%file)
        write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
    end subroutine cmd_slha_write

```

Compile. Read the filename and store it.

```

<Commands: cmd slha: TBP>+≡
    procedure :: compile => cmd_slha_compile
<Commands: procedures>+≡
    subroutine cmd_slha_compile (cmd, global)
        class(cmd_slha_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_key, pn_arg, pn_file
        pn_key => parse_node_get_sub_ptr (cmd%pn)
        pn_arg => parse_node_get_next_ptr (pn_key)
        pn_file => parse_node_get_sub_ptr (pn_arg)
        call cmd%compile_options (global)
        cmd%pn_opt => parse_node_get_next_ptr (pn_arg)
        select case (char (parse_node_get_key (pn_key)))
            case ("read_slha")
                cmd%write_mode = .false.
            case ("write_slha")
                cmd%write_mode = .true.
            case default
                call parse_node_mismatch ("read_slha|write_slha", cmd%pn)
        end select
        cmd%file = parse_node_get_string (pn_file)
    end subroutine cmd_slha_compile

```

Execute. Read or write the specified SLHA file. Behind the scenes, this will first read the WHIZARD model file, then read the SLHA file and assign the SLHA parameters as far as determined by `dispatch_slha`. Finally, the global variables are synchronized with the model. This is similar to executing `cmd_model`.

```

<Commands: cmd slha: TBP>+≡
    procedure :: execute => cmd_slha_execute

### Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_expect_t
    private
        type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
        ⟨Commands: cmd expect: TBP⟩
    end type cmd_expect_t

```

Simply tell the status.

```

⟨Commands: cmd expect: TBP⟩≡
    procedure :: write => cmd_expect_write

⟨Commands: procedures⟩+≡
    subroutine cmd_expect_write (cmd, unit, indent)
        class(cmd_expect_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        if (associated (cmd%pn_lexpr)) then
            write (u, "(1x,A)") "expect: [expression associated]"
        else
            write (u, "(1x,A)") "expect: [undefined]"
        end if
    end subroutine cmd_expect_write

```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

```

⟨Commands: cmd expect: TBP⟩+≡
    procedure :: compile => cmd_expect_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_expect_compile (cmd, global)
        class(cmd_expect_t), intent(inout) :: cmd

## Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

⟨Commands: types⟩+≡
  type :: sentry_expr_t
    type(parse_node_p), dimension(:), allocatable :: expr
    contains
    ⟨Commands: sentry_expr: TBP⟩
  end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

⟨Commands: sentry_expr: TBP⟩≡
  procedure :: compile => sentry_expr_compile

⟨Commands: procedures⟩+≡
  subroutine sentry_expr_compile (sentry, pn)
    class(sentry_expr_t), intent(out) :: sentry
    type(parse_node_t), intent(in), target :: pn
    type(parse_node_t), pointer :: pn_expr, pn_extra
    integer :: n_expr, i
    n_expr = parse_node_get_n_sub (pn)
    allocate (sentry%expr (n_expr))
    if (n_expr > 0) then
      i = 0
      pn_expr => parse_node_get_sub_ptr (pn)
      pn_extra => parse_node_get_next_ptr (pn_expr)
      do i = 1, n_expr
        sentry%expr(i)%ptr => pn_expr
        if (associated (pn_extra)) then
          pn_expr => parse_node_get_sub_ptr (pn_extra, 2)
          pn_extra => parse_node_get_next_ptr (pn_extra)
        end if
      end do
    end if
  end subroutine sentry_expr_compile

```

```

    end if
end subroutine sentry_expr_compile

```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

*(Commands: sentry\_expr: TBP)+≡*

```

## Beam polarization density

The beam polarization command defines spin density matrix for one or two beams (scattering or decay).

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_beams_pol_density_t
    private
    integer :: n_in = 0
    type(smatrix_expr_t), dimension(:), allocatable :: smatrix
  contains
    <Commands: cmd beams pol density: TBP>
  end type cmd_beams_pol_density_t
```

Output.

```
<Commands: cmd beams pol density: TBP>≡
  procedure :: write => cmd_beams_pol_density_write

<Commands: procedures>+≡
  subroutine cmd_beams_pol_density_write (cmd, unit, indent)
    class(cmd_beams_pol_density_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    select case (cmd%n_in)
    case (1)
      write (u, "(1x,A)") "beams polarization setup: 1 [decay]"
    case (2)
      write (u, "(1x,A)") "beams polarization setup: 2 [scattering]"
    case default
      write (u, "(1x,A)") "beams polarization setup: [undefined]"
    end select
  end subroutine cmd_beams_pol_density_write
```

Compile. Find and assign the parse nodes.

Note: local environments are not yet supported.

```
<Commands: cmd beams pol density: TBP>+≡
  procedure :: compile => cmd_beams_pol_density_compile

<Commands: procedures>+≡
  subroutine cmd_beams_pol_density_compile (cmd, global)
    class(cmd_beams_pol_density_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_pol_spec, pn_smatrix
    integer :: i
    pn_pol_spec => parse_node_get_sub_ptr (cmd%pn, 3)

            else
                call msg_fatal ("beams polarization fraction: undefined value")
            end if
            call expr%final ()
        end do
        call global%beam_structure%set_pol_f (pol_f)
    end subroutine cmd_beams_pol_fraction_execute

```

## Beam momentum

This is completely analogous to the previous command, hence we can use inheritance.

```
<Commands: types>+≡
  type, extends (cmd_beams_pol_fraction_t) :: cmd_beams_momentum_t
  contains
    <Commands: cmd beams momentum: TBP>
  end type cmd_beams_momentum_t
```

Output.

```
<Commands: cmd beams momentum: TBP>≡
  procedure :: write => cmd_beams_momentum_write

<Commands: procedures>+≡
  subroutine cmd_beams_momentum_write (cmd, unit, indent)
    class(cmd_beams_momentum_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    select case (cmd%n_in)
    case (1)
      write (u, "(1x,A)") "beams momentum: 1 [decay]"
    case (2)
      write (u, "(1x,A)") "beams momentum: 2 [scattering]"
    case default
      write (u, "(1x,A)") "beams momentum: [undefined]"
    end select
  end subroutine cmd_beams_momentum_write
```

Compile: inherited.

Command execution: Not inherited, but just the error string and the final command are changed.

```
<Commands: cmd beams momentum: TBP>+≡
  procedure :: execute => cmd_beams_momentum_execute

<Commands: procedures>+≡
  subroutine cmd_beams_momentum_execute (cmd, global)
    class(cmd_beams_momentum_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    real(default), dimension(:), allocatable :: p
    type(eval_tree_t) :: expr
    integer :: i
    var_list => global%get_var_list_ptr ()
    allocate (p (cmd%n_in))
    do i = 1, cmd%n_in
      call expr%init_expr (cmd%expr(i)%ptr, var_list)
      call expr%evaluate ()
      if (expr%is_known ()) then
```

```

        p(i) = expr%get_real ()
    else
        call msg_fatal ("beams momentum: undefined value")
    end if
    call expr%final ()
end do
call global%beam_structure%set_momentum (p)
end subroutine cmd_beams_momentum_execute

```

## Beam angles

Again, this is analogous. There are two angles, polar angle  $\theta$  and azimuthal angle  $\phi$ , which can be set independently for both beams.

```

⟨Commands: types⟩+≡
    type, extends (cmd_beams_pol_fraction_t) :: cmd_beams_theta_t
    contains
    ⟨Commands: cmd beams theta: TBP⟩
end type cmd_beams_theta_t

    type, extends (cmd_beams_pol_fraction_t) :: cmd_beams_phi_t
    contains
    ⟨Commands: cmd beams phi: TBP⟩
end type cmd_beams_phi_t

```

Output.

```

⟨Commands: cmd beams theta: TBP⟩≡
    procedure :: write => cmd_beams_theta_write

⟨Commands: cmd beams phi: TBP⟩≡
    procedure :: write => cmd_beams_phi_write

⟨Commands: procedures⟩+≡

        else
            call msg_fatal ("beams phi: undefined value")
        end if
        call expr%final ()
    end do
    call global%beam_structure%set_phi (phi)
end subroutine cmd_beams_phi_execute

```

## Cuts

Define a cut expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the cut expression is used.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_cuts_t
    private
        type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
        ⟨Commands: cmd cuts: TBP⟩
    end type cmd_cuts_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```

⟨Commands: cmd cuts: TBP⟩≡
    procedure :: write => cmd_cuts_write

⟨Commands: procedures⟩+≡
    subroutine cmd_cuts_write (cmd, unit, indent)
        class(cmd_cuts_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)") "cuts: [defined]"
    end subroutine cmd_cuts_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd cuts: TBP⟩+≡
    procedure :: compile => cmd_cuts_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_cuts_compile (cmd, global)
        class(cmd_cuts_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
    end subroutine cmd_cuts_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd cuts: TBP⟩+≡
  procedure :: execute => cmd_cuts_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_cuts_execute (cmd, global)
    class(cmd_cuts_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%cuts_lexpr => cmd%pn_lexpr
  end subroutine cmd_cuts_execute

```

## General, Factorization and Renormalization Scales

Define a scale expression for either the renormalization or the factorization scale. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd scale: TBP⟩
  end type cmd_scale_t

```

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_fac_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd fac scale: TBP⟩
  end type cmd_fac_scale_t

```

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_ren_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    ⟨Commands: cmd ren scale: TBP⟩
  end type cmd_ren_scale_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

⟨Commands: cmd scale: TBP⟩≡
  procedure :: write => cmd_scale_write

⟨Commands: procedures⟩+≡
  subroutine cmd_scale_write (cmd, unit, indent)
    class(cmd_scale_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent

```

```

integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)") "scale: [defined]"
end subroutine cmd_scale_write

```

    global%pn%ren_scale_expr => cmd%pn_expr
  end subroutine cmd_ren_scale_execute

```

## Weight

Define a weight expression. The weight is applied to a process to be integrated, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

<Commands: types>+=
  type, extends (command_t) :: cmd_weight_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()

```

```

contains
  <Commands: cmd weight: TBP>
end type cmd_weight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd weight: TBP>≡
  procedure :: write => cmd_weight_write

<Commands: procedures>+≡
  subroutine cmd_weight_write (cmd, unit, indent)
    class(cmd_weight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "weight expression: [defined]"
  end subroutine cmd_weight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd weight: TBP>+≡
  procedure :: compile => cmd_weight_compile

<Commands: procedures>+≡
  subroutine cmd_weight_compile (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_weight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd weight: TBP>+≡
  procedure :: execute => cmd_weight_execute

<Commands: procedures>+≡
  subroutine cmd_weight_execute (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%weight_expr => cmd%pn_expr
  end subroutine cmd_weight_execute

```

## Selection

Define a selection expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_selection_t
  private

```

```

        type(parse_node_t), pointer :: pn_expr => null ()
contains
  <Commands: cmd selection: TBP>≡
end type cmd_selection_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd selection: TBP>≡
  procedure :: write => cmd_selection_write

<Commands: procedures>+≡
  subroutine cmd_selection_write (cmd, unit, indent)
    class(cmd_selection_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "selection expression: [defined]"
  end subroutine cmd_selection_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd selection: TBP>+≡
  procedure :: compile => cmd_selection_compile

<Commands: procedures>+≡
  subroutine cmd_selection_compile (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_selection_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd selection: TBP>+≡
  procedure :: execute => cmd_selection_execute

<Commands: procedures>+≡
  subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

## Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_reweight_t

```

```

    private
    type(parse_node_t), pointer :: pn_expr => null ()
contains
  <Commands: cmd reweight: TBP>
end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd reweight: TBP>≡
  procedure :: write => cmd_reweight_write
<Commands: procedures>+≡
  subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: compile => cmd_reweight_compile
<Commands: procedures>+≡
  subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: execute => cmd_reweight_execute
<Commands: procedures>+≡
  subroutine cmd_reweight_execute (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%reweight_expr => cmd%pn_expr
  end subroutine cmd_reweight_execute

```

## Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

<Commands: types>+≡

```

```

type, extends (command_t) :: cmd_alt_setup_t
  private
  type(parse_node_p), dimension(:), allocatable :: setup
contains
  <Commands: cmd alt setup: TBP>
end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

<Commands: cmd alt setup: TBP>≡
  procedure :: write => cmd_alt_setup_write

<Commands: procedures>+≡
  subroutine cmd_alt_setup_write (cmd, unit, indent)
    class(cmd_alt_setup_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
  end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

<Commands: cmd alt setup: TBP>+≡
  procedure :: compile => cmd_alt_setup_compile

<Commands: procedures>+≡
  subroutine cmd_alt_setup_compile (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_list, pn_setup
    integer :: i
    pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
    if (associated (pn_list)) then
      allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
      i = 1
      pn_setup => parse_node_get_sub_ptr (pn_list)
      do while (associated (pn_setup))
        cmd%setup(i)%ptr => pn_setup
        i = i + 1
        pn_setup => parse_node_get_next_ptr (pn_setup)
      end do
    else
      allocate (cmd%setup (0))
    end if
  end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

<Commands: cmd alt setup: TBP>+≡
  procedure :: execute => cmd_alt_setup_execute

<Commands: procedures>+≡
  subroutine cmd_alt_setup_execute (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global

```

```

        if (allocated (global%pn%alt_setup)) deallocate (global%pn%alt_setup)
        allocate (global%pn%alt_setup (size (cmd%setup)))
        global%pn%alt_setup = cmd%setup
    end subroutine cmd_alt_setup_execute

```

## Integration

Integrate several processes, consecutively with identical parameters.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_integrate_t
    private
        integer :: n_proc = 0
        type(string_t), dimension(:), allocatable :: process_id
    contains
        ⟨Commands: cmd integrate: TBP⟩
    end type cmd_integrate_t

```

Output: we know the process IDs.

```

⟨Commands: cmd integrate: TBP⟩≡
    procedure :: write => cmd_integrate_write

⟨Commands: procedures⟩+≡
    subroutine cmd_integrate_write (cmd, unit, indent)
        class(cmd_integrate_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u, i
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)", advance="no") "integrate ("
        do i = 1, cmd%n_proc
            if (i > 1) write (u, "(A,1x)", advance="no") ", "
            write (u, "(A)", advance="no") char (cmd%process_id(i))
        end do
        write (u, "(A)") ")"
    end subroutine cmd_integrate_write

```

Compile.

```

⟨Commands: cmd integrate: TBP⟩+≡
    procedure :: compile => cmd_integrate_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_integrate_compile (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_proclist, pn_proc
        integer :: i
        pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
        cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
        call cmd%compile_options (global)
        cmd%n_proc = parse_node_get_n_sub (pn_proclist)
        allocate (cmd%process_id (cmd%n_proc))
        pn_proc => parse_node_get_sub_ptr (pn_proclist)

```

```

do i = 1, cmd%n_proc
  cmd%process_id(i) = parse_node_get_string (pn_proc)
  call global%process_stack%init_result_vars (cmd%process_id(i))
  pn_proc => parse_node_get_next_ptr (pn_proc)
end do
end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

⟨Commands: cmd integrate: TBP⟩+≡
  procedure :: execute => cmd_integrate_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_integrate_execute (cmd, global)
    class(cmd_integrate_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    integer :: i
    if (debug_on) call msg_debug (D_CORE, "cmd_integrate_execute")
    do i = 1, cmd%n_proc
      if (debug_on) call msg_debug (D_CORE, "cmd%process_id(i) ", cmd%process_id(i))
      call integrate_process (cmd%process_id(i), cmd%local, global)
      call global%process_stack%fill_result_vars (cmd%process_id(i))
      call global%process_stack%update_result_vars &
        (cmd%process_id(i), global%var_list)
      if (signal_is_pending ()) return
    end do
  end subroutine cmd_integrate_execute

```

## Observables

Declare an observable. After the declaration, it can be used to record data, and at the end one can retrieve average and error.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_observable_t
  private
  type(string_t) :: id
  contains
  ⟨Commands: cmd observable: TBP⟩
end type cmd_observable_t

```

Output. We know the ID.

```

⟨Commands: cmd observable: TBP⟩≡
  procedure :: write => cmd_observable_write

```

```

<Commands: procedures>+≡
subroutine cmd_observable_write (cmd, unit, indent)
  class(cmd_observable_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,A)") "observable: ", char (cmd%id)
end subroutine cmd_observable_write

```

Compile. Just record the observable ID.

```

<Commands: cmd observable: TBP>+≡
  procedure :: compile => cmd_observable_compile

<Commands: procedures>+≡
subroutine cmd_observable_compile (cmd, global)
  class(cmd_observable_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_tag
  pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
  if (associated (pn_tag)) then
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
  end if
  call cmd%compile_options (global)
  select case (char (parse_node_get_rule_key (pn_tag)))
  case ("analysis_id")
    cmd%id = parse_node_get_string (pn_tag)
  case default
    call msg_bug ("observable: name expression not implemented (yet)")
  end select
end subroutine cmd_observable_compile

```

Command execution. This declares the observable and allocates it in the analysis store.

```

<Commands: cmd observable: TBP>+≡
  procedure :: execute => cmd_observable_execute

<Commands: procedures>+≡
subroutine cmd_observable_execute (cmd, global)
  class(cmd_observable_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global

```

## Plots

Declare a plot. No mandatory arguments, just options.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_plot_t
    private
    type(string_t) :: id
    contains
    <Commands: cmd plot: TBP>
end type cmd_plot_t

```

Output. Just print the ID.

```

<Commands: cmd plot: TBP>≡
    procedure :: write => cmd_plot_write

<Commands: procedures>+≡
    subroutine cmd_plot_write (cmd, unit, indent)
        class(cmd_plot_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A)") "plot: ", char (cmd%id)
    end subroutine cmd_plot_write

```

Compile. Record the plot ID and initialize lower, upper bound and bin width.

```

⟨Commands: cmd plot: TBP⟩+≡
  procedure :: compile => cmd_plot_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_plot_compile (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_tag
    pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%init (pn_tag, global)
  end subroutine cmd_plot_compile

```

This init routine is separated because it is reused below for graph initialization.

```

⟨Commands: cmd plot: TBP⟩+≡
  procedure :: init => cmd_plot_init

⟨Commands: procedures⟩+≡
  subroutine cmd_plot_init (plot, pn_tag, global)
    class(cmd_plot_t), intent(inout) :: plot
    type(parse_node_t), intent(in), pointer :: pn_tag
    type(rt_data_t), intent(inout), target :: global
    call plot%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      plot%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("plot: name expression not implemented (yet)")
    end select
  end subroutine cmd_plot_init

```

Command execution. This declares the plot and allocates it in the analysis store.

```

⟨Commands: cmd plot: TBP⟩+≡
  procedure :: execute => cmd_plot_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_plot_execute (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call drawing_options_init_plot (drawing_options)
    call set_drawing_options (drawing_options, var_list)

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

## Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_graph_t
    private
    type(string_t) :: id
    integer :: n_elements = 0
    type(cmd_plot_t), dimension(:), allocatable :: el
    type(string_t), dimension(:), allocatable :: element_id
  contains
    <Commands: cmd graph: TBP>
  end type cmd_graph_t
```

Output. Just print the ID.

```
<Commands: cmd graph: TBP>≡
  procedure :: write => cmd_graph_write

<Commands: procedures>+≡
  subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)") "graph: ", char (cmd%id), &
      " (", cmd%n_elements, " entries)"
  end subroutine cmd_graph_write
```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```
<Commands: cmd graph: TBP>+≡
  procedure :: compile => cmd_graph_compile

<Commands: procedures>+≡
  subroutine cmd_graph_compile (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
    integer :: i

    pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      cmd%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("graph: name expression not implemented (yet)")
```

```

end select
pn_def => parse_node_get_next_ptr (pn_term, 2)
cmd%n_elements = parse_node_get_n_sub (pn_def)
allocate (cmd%element_id (cmd%n_elements))
allocate (cmd%el (cmd%n_elements))
pn_term => parse_node_get_sub_ptr (pn_def)
pn_tag => parse_node_get_sub_ptr (pn_term)
cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
call cmd%el(1)%init (pn_tag, global)
cmd%element_id(1) = parse_node_get_string (pn_tag)
pn_app => parse_node_get_next_ptr (pn_term)
do i = 2, cmd%n_elements
  pn_term => parse_node_get_sub_ptr (pn_app, 2)
  pn_tag => parse_node_get_sub_ptr (pn_term)
  cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
  call cmd%el(i)%init (pn_tag, global)
  cmd%element_id(i) = parse_node_get_string (pn_tag)
  pn_app => parse_node_get_next_ptr (pn_app)
end do

end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: execute => cmd_graph_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_execute (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options
    integer :: i, type

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

    do i = 1, cmd%n_elements
      if (associated (cmd%el(i)%options)) then
        call cmd%el(i)%options%execute (cmd%el(i)%local)
      end if
      type = analysis_store_get_object_type (cmd%element_id(i))
      select case (type)
        case (AN_HISTOGRAM)

```

```

        call drawing_options_init_histogram (drawing_options)
    case (AN_PLOT)
        call drawing_options_init_plot (drawing_options)
    end select
    call set_drawing_options (drawing_options, var_list)
    if (associated (cmd%el(i)%options)) then
        call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
    end if
    call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
end do
end subroutine cmd_graph_execute

```

## Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
    type :: analysis_id_t
        type(string_t) :: tag
        type(parse_node_t), pointer :: pn_sexpr => null ()
    end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_analysis_t
        private
        type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
        ⟨Commands: cmd analysis: TBP⟩
    end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

⟨Commands: cmd analysis: TBP⟩≡
    procedure :: write => cmd_analysis_write

⟨Commands: procedures⟩+≡
    subroutine cmd_analysis_write (cmd, unit, indent)
        class(cmd_analysis_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)") "analysis: [defined]"
    end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd analysis: TBP⟩+≡
    procedure :: compile => cmd_analysis_compile

```

```

<Commands: procedures>+≡
  subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd analysis: TBP>+≡
  procedure :: execute => cmd_analysis_execute

<Commands: procedures>+≡
  subroutine cmd_analysis_execute (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%analysis_lexpr => cmd%pn_lexpr
  end subroutine cmd_analysis_execute

```

## Write histograms and plots

The data type encapsulating the command:

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_write_analysis_t
  private
    type(analysis_id_t), dimension(:), allocatable :: id
    type(string_t), dimension(:), allocatable :: tag
  contains
    <Commands: cmd write analysis: TBP>
  end type cmd_write_analysis_t

```

Output. Just the keyword.

```

<Commands: cmd write analysis: TBP>≡
  procedure :: write => cmd_write_analysis_write

<Commands: procedures>+≡
  subroutine cmd_write_analysis_write (cmd, unit, indent)
    class(cmd_write_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "write_analysis"
  end subroutine cmd_write_analysis_write

```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: compile => cmd_write_analysis_compile

```

```

<Commands: procedures>+≡
subroutine cmd_write_analysis_compile (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
  integer :: n, i
  pn_clause => parse_node_get_sub_ptr (cmd%pn)
  pn_args => parse_node_get_sub_ptr (pn_clause, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
  call cmd%compile_options (global)
  if (associated (pn_args)) then
    n = parse_node_get_n_sub (pn_args)
    allocate (cmd%id (n))
    do i = 1, n
      pn_id => parse_node_get_sub_ptr (pn_args, i)
      if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
        cmd%id(i)%tag = parse_node_get_string (pn_id)
      else
        cmd%id(i)%pn_sexpr => pn_id
      end if
    end do
  else
    allocate (cmd%id (0))
  end if
end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

<Commands: parameters>+≡
character(*), parameter, public :: &
  DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
  FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(6), parameter, public :: &
  FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "pg", "lo", "la" ]
character(len=3), dimension(18), parameter, public :: &
  FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
    "f95", "log", "ltp", "mpx", "olc", "olp", "pdf", "phs", "sin", &
    "tex", "vg2", "vgx" ]

```

As this contains a lot of similar code to `cmd.compile_analysis_execute` we outsource the main code to a subroutine.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: execute => cmd_write_analysis_execute

<Commands: procedures>+≡
subroutine cmd_write_analysis_execute (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  var_list => cmd%local%get_var_list_ptr ()
  call write_analysis_wrap (var_list, global%out_files, &
    cmd%id, tag = cmd%tag)
end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

*(Commands: procedures)+≡*

```

subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
  type(var_list_t), intent(inout), target :: var_list
  type(file_list_t), intent(inout), target :: out_files

### 35.1.4 User-controlled output to data files

#### Open file (output)

Open a file for output.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_open_out_t
  private
  type(parse_node_t), pointer :: file_expr => null ()
  contains
  <Commands: cmd open out: TBP>
end type cmd_open_out_t

```

Finalizer for the embedded eval tree.

```

<Commands: procedures>+≡
  subroutine cmd_open_out_final (object)
    class(cmd_open_out_t), intent(inout) :: object
  end subroutine cmd_open_out_final

```

Output (trivial here).

```

<Commands: cmd open out: TBP>≡
  procedure :: write => cmd_open_out_write

<Commands: procedures>+≡
  subroutine cmd_open_out_write (cmd, unit, indent)
    class(cmd_open_out_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)", advance="no") "open_out: <filename>"
  end subroutine cmd_open_out_write

```

Compile: create an eval tree for the filename expression.

```

<Commands: cmd open out: TBP>+≡
  procedure :: compile => cmd_open_out_compile

```

```

⟨Commands: procedures⟩+≡
  subroutine cmd_open_out_compile (cmd, global)
    class(cmd_open_out_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%file_expr => parse_node_get_sub_ptr (cmd%pn, 2)

    type(eval_tree_t) :: file_expr
    type(string_t) :: file
    var_list => cmd%local%var_list
    call file_expr%init_sexpr (cmd%file_expr, var_list)
    call file_expr%evaluate ()
    if (file_expr%is_known ()) then
      file = file_expr%get_string ()
      call file_list_close (global%out_files, file)
    else
      call msg_fatal ("close_out: file name argument evaluates to unknown")
    end if
    call file_expr%final ()
  end subroutine cmd_close_out_execute

```

### 35.1.5 Print custom-formatted values

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_printf_t
  private
    type(parse_node_t), pointer :: sexpr => null ()
    type(parse_node_t), pointer :: sprintf_fun => null ()
    type(parse_node_t), pointer :: sprintf_clause => null ()
    type(parse_node_t), pointer :: sprintf => null ()
  contains
    ⟨Commands: cmd printf: TBP⟩
  end type cmd_printf_t

```

Finalize.

```

⟨Commands: cmd printf: TBP⟩≡
  procedure :: final => cmd_printf_final

⟨Commands: procedures⟩+≡
  subroutine cmd_printf_final (cmd)
    class(cmd_printf_t), intent(inout) :: cmd
    call parse_node_final (cmd%sexpr, recursive = .false.)
    deallocate (cmd%sexpr)
    call parse_node_final (cmd%sprintf_fun, recursive = .false.)
    deallocate (cmd%sprintf_fun)
    call parse_node_final (cmd%sprintf_clause, recursive = .false.)
    deallocate (cmd%sprintf_clause)
    call parse_node_final (cmd%sprintf, recursive = .false.)
    deallocate (cmd%sprintf)
  end subroutine cmd_printf_final

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```

⟨Commands: cmd printf: TBP⟩+≡

```

```

procedure :: write => cmd_printf_write
<Commands: procedures>+≡
subroutine cmd_printf_write (cmd, unit, indent)
  class(cmd_printf_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A)") "printf:"
end subroutine cmd_printf_write

```

Compile. We create a fake parse node (subtree) with a `sprintf` command with identical arguments which can then be handled by the corresponding evaluation procedure.

```

<Commands: cmd printf: TBP>+≡
procedure :: compile => cmd_printf_compile
<Commands: procedures>+≡
subroutine cmd_printf_compile (cmd, global)
  class(cmd_printf_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global

  allocate (cmd%sprintf)
  call parse_node_create_key (cmd%sprintf, &
    syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf")))
  call parse_node_append_sub (cmd%sprintf_clause, cmd%sprintf)
  call parse_node_append_sub (cmd%sprintf_clause, pn_format)
  call parse_node_freeze_branch (cmd%sprintf_clause)
  call parse_node_append_sub (cmd%sprintf_fun, cmd%sprintf_clause)
  if (associated (pn_args)) then
    call parse_node_append_sub (cmd%sprintf_fun, pn_args)
  end if
  call parse_node_freeze_branch (cmd%sprintf_fun)
  call parse_node_append_sub (cmd%sexpr, cmd%sprintf_fun)
  call parse_node_freeze_branch (cmd%sexpr)
end subroutine cmd_printf_compile

```

Execute. Evaluate the string (pretending this is a `sprintf` expression) and print it.

```

⟨Commands: cmd printf: TBP⟩+≡
  procedure :: execute => cmd_printf_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_printf_execute (cmd, global)
    class(cmd_printf_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(string_t) :: string, file
    type(eval_tree_t) :: sprintf_expr
    logical :: advance
    var_list => cmd%local%get_var_list_ptr ()
    advance = var_list%get_lval (&
      var_str ("?out_advance"))
    file = var_list%get_sval (&
      var_str ("out_file"))
    call sprintf_expr%init_sexpr (cmd%sexpr, var_list)
    call sprintf_expr%evaluate ()
    if (sprintf_expr%is_known ()) then
      string = sprintf_expr%get_string ()
      if (len (file) == 0) then
        call msg_result (char (string))
      else
        call file_list_write (global%out_files, file, string, advance)
      end if
    end if
  end subroutine cmd_printf_execute

```

## Record data

The expression syntax already contains a `record` keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_record_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  ⟨Commands: cmd record: TBP⟩
  end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

⟨Commands: cmd record: TBP⟩≡
  procedure :: write => cmd_record_write

⟨Commands: procedures⟩+≡
  subroutine cmd_record_write (cmd, unit, indent)
    class(cmd_record_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u

```

```

    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "record"
end subroutine cmd_record_write

```

Compile. This is a hack which transforms the `record` command into a `record` expression, which we handle in the `expressions` module.

```

⟨Commands: cmd record: TBP⟩+≡
  procedure :: compile => cmd_record_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_record_compile (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
    call parse_node_create_branch (pn_lexpr, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))
    call parse_node_create_branch (pn_lsinglet, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lsinglet")))
    call parse_node_append_sub (pn_lexpr, pn_lsinglet)
    call parse_node_create_branch (pn_lterm, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lterm")))
    call parse_node_append_sub (pn_lsinglet, pn_lterm)
    pn_record => parse_node_get_sub_ptr (cmd%pn)
    call parse_node_append_sub (pn_lterm, pn_record)
    cmd%pn_lexpr => pn_lexpr
  end subroutine cmd_record_compile

```

Command execution. Again, transfer this to the embedded expression and just forget the logical result.

```

⟨Commands: cmd record: TBP⟩+≡
  procedure :: execute => cmd_record_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_record_execute (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    logical :: lval
    var_list => global%get_var_list_ptr ()
    lval = eval_log (cmd%pn_lexpr, var_list)
  end subroutine cmd_record_execute

```

## Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_unstable_t
  private
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id

```

```

        type(parse_node_t), pointer :: pn_prt_in => null ()
contains
  <Commands: cmd unstable: TBP>≡
end type cmd_unstable_t

```

Output: we know the process IDs.

```

<Commands: cmd unstable: TBP>≡
  procedure :: write => cmd_unstable_write

<Commands: procedures>+≡
  subroutine cmd_unstable_write (cmd, unit, indent)
    class(cmd_unstable_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u, i
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,1x,I0,1x,A)", advance="no") &
      "unstable:", 1, "("
    do i = 1, cmd%n_proc
      if (i > 1) write (u, "(A,1x)", advance="no") " ,"
      write (u, "(A)", advance="no") char (cmd%process_id(i))
    end do
    write (u, "(A)" )
  end subroutine cmd_unstable_write

```

Compile. Initiate an eval tree for the decaying particle and determine the decay channel process IDs.

```

<Commands: cmd unstable: TBP>+≡
  procedure :: compile => cmd_unstable_compile

<Commands: procedures>+≡
  subroutine cmd_unstable_compile (cmd, global)

```

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

```

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

## Range expressions

We need a special type for storing and evaluating range expressions.

```

⟨Commands: parameters⟩+≡
    integer, parameter :: STEP_NONE = 0
    integer, parameter :: STEP_ADD = 1
    integer, parameter :: STEP_SUB = 2
    integer, parameter :: STEP_MUL = 3
    integer, parameter :: STEP_DIV = 4
    integer, parameter :: STEP_COMP_ADD = 11
    integer, parameter :: STEP_COMP_MUL = 13

```

There is an abstract base type and two implementations: scan over integers and scan over reals.

```

⟨Commands: types⟩+≡
    type, abstract :: range_t
        type(parse_node_t), pointer :: pn_expr => null ()
        type(parse_node_t), pointer :: pn_term => null ()
        type(parse_node_t), pointer :: pn_factor => null ()
        type(parse_node_t), pointer :: pn_value => null ()
        type(parse_node_t), pointer :: pn_literal => null ()
        type(parse_node_t), pointer :: pn_beg => null ()
        type(parse_node_t), pointer :: pn_end => null ()
        type(parse_node_t), pointer :: pn_step => null ()
        type(eval_tree_t) :: expr_beg
        type(eval_tree_t) :: expr_end
        type(eval_tree_t) :: expr_step

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

<Commands: cmd scan: TBP>≡

```

```

    procedure :: final => cmd_scan_final
  <Commands: procedures>+≡
    recursive subroutine cmd_scan_final (cmd)
      class(cmd_scan_t), intent(inout) :: cmd

        cmd%n_values
    end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

```

## Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of **else if** constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

```

## Export values

This command exports the current values of variables or other objects to the surrounding scope. By default, a scope enclosed by braces keeps all objects local to it. The `export` command exports the values that are generated within the scope to the corresponding object in the outer scope.

The allowed set of exportable objects is, in principle, the same as the set of objects that the **show** command supports. This includes some convenience abbreviations.

TODO: The initial implementation inherits syntax from **show**, but supports only the **results** pseudo-object. The results (i.e., the process stack) is appended to the outer process stack instead of being discarded. The behavior of the **export** command for other object kinds is to be defined on a case-by-case basis. It may involve replacing the outer value or, instead, doing some sort of appending or reduction.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_export_t
    private
      type(string_t), dimension(:), allocatable :: name
    contains
      ⟨Commands: cmd export: TBP⟩
    end type cmd_export_t

```

Output: list the object names, not values.

```

⟨Commands: cmd export: TBP⟩≡
  procedure :: write => cmd_export_write

⟨Commands: procedures⟩+≡

Execute. Scan the list of objects to export.

```

⟨Commands: cmd export: TBP⟩+≡
    procedure :: execute => cmd_export_execute

⟨Commands: procedures⟩+≡
    subroutine cmd_export_execute (cmd, global)
        class(cmd_export_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        call global%append_exports (cmd%name)
    end subroutine cmd_export_execute

```

## Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_quit_t
        private
        logical :: has_code = .false.
        type(parse_node_t), pointer :: pn_code_expr => null ()
    contains
        ⟨Commands: cmd quit: TBP⟩
    end type cmd_quit_t

```

Output.

```

⟨Commands: cmd quit: TBP⟩≡
    procedure :: write => cmd_quit_write

⟨Commands: procedures⟩+≡
    subroutine cmd_quit_write (cmd, unit, indent)
        class(cmd_quit_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
    end subroutine cmd_quit_write

```

```

        write (u, "(1x,A,L1)") "quit: has_code = ", cmd%has_code
    end subroutine cmd_quit_write

```

Compile: allocate a quit object which serves as a placeholder.

```

⟨Commands: cmd quit: TBP⟩+≡
    procedure :: compile => cmd_quit_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_quit_compile (cmd, global)
        class(cmd_quit_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_arg
        pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
        if (associated (pn_arg)) then
            cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
            cmd%has_code = .true.
        end if
    end subroutine cmd_quit_compile

```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```

⟨Commands: cmd quit: TBP⟩+≡
    procedure :: execute => cmd_quit_execute

⟨Commands: procedures⟩+≡
    subroutine cmd_quit_execute (cmd, global)
        class(cmd_quit_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(var_list_t), pointer :: var_list
        logical :: is_known
        var_list => global%get_var_list_ptr ()
        if (cmd%has_code) then
            global%quit_code = eval_int (cmd%pn_code_expr, var_list, &
                is_known=is_known)
            if (.not. is_known) then
                call msg_error ("Undefined return code of quit/exit command")
            end if
        end if
        global%quit = .true.
    end subroutine cmd_quit_execute

```

### 35.1.6 The command list

The command list holds a list of commands and relevant global data.

```

⟨Commands: public⟩+≡
    public :: command_list_t

```

```

⟨Commands: types⟩+≡
  type :: command_list_t
    ! not private anymore as required by the whizard-c-interface
    class(command_t), pointer :: first => null ()
    class(command_t), pointer :: last => null ()
  contains
    ⟨Commands: command list: TBP⟩
  end type command_list_t

```

Output.

```

⟨Commands: command list: TBP⟩≡
  procedure :: write => command_list_write

⟨Commands: procedures⟩+≡
  recursive subroutine command_list_write (cmd_list, unit, indent)
    class(command_list_t), intent(in) :: cmd_list
    integer, intent(in), optional :: unit, indent
    class(command_t), pointer :: cmd
    cmd => cmd_list%first
    do while (associated (cmd))
      call cmd%write (unit, indent)
      cmd => cmd%next
    end do
  end subroutine command_list_write

```

Append a new command to the list and free the original pointer.

```

⟨Commands: command list: TBP⟩+≡
  procedure :: append => command_list_append

⟨Commands: procedures⟩+≡
  subroutine command_list_append (cmd_list, command)
    class(command_list_t), intent(inout) :: cmd_list
    class(command_t), intent(inout), pointer :: command
    if (associated (cmd_list%last)) then
      cmd_list%last%next => command
    else
      cmd_list%first => command
    end if
    cmd_list%last => command
    command => null ()
  end subroutine command_list_append

```

Finalize.

```

⟨Commands: command list: TBP⟩+≡
  procedure :: final => command_list_final

⟨Commands: procedures⟩+≡
  recursive subroutine command_list_final (cmd_list)
    class(command_list_t), intent(inout) :: cmd_list
    class(command_t), pointer :: command
    do while (associated (cmd_list%first))
      command => cmd_list%first
      cmd_list%first => cmd_list%first%next
      call command%final ()
    end do
  end subroutine command_list_final

```

```

        deallocate (command)
    end do
    cmd_list%last => null ()
end subroutine command_list_final

```

### 35.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```

<Commands: command list: TBP>+≡
    procedure :: compile => command_list_compile

<Commands: procedures>+≡
    recursive subroutine command_list_compile (cmd_list, pn, global)
        class(command_list_t), intent(inout), target :: cmd_list
        type(parse_node_t), intent(in), target :: pn
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_cmd
        class(command_t), pointer :: command
        integer :: i
        pn_cmd => parse_node_get_sub_ptr (pn)
        do i = 1, parse_node_get_n_sub (pn)
            call dispatch_command (command, pn_cmd)
            call command%compile (global)
            call cmd_list%append (command)
            call terminate_now_if_signal ()
            pn_cmd => parse_node_get_next_ptr (pn_cmd)
        end do
    end subroutine command_list_compile

```

### 35.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```

<Commands: command list: TBP>+≡
    procedure :: execute => command_list_execute

<Commands: procedures>+≡
    recursive subroutine command_list_execute (cmd_list, global)
        class(command_list_t), intent(in) :: cmd_list
        type(rt_data_t), intent(inout), target :: global
        class(command_t), pointer :: command
        command => cmd_list%first
        COMMAND_COND: do while (associated (command))
            call command%execute_options (global)
            call command%execute (global)
            call command%reset_options (global)
            call terminate_now_if_signal ()
            if (global%quit) exit COMMAND_COND
        end do
    end subroutine command_list_execute

```

```

        command => command%next
    end do COMMAND_COND
end subroutine command_list_execute

```

### 35.1.9 Command list syntax

```

<Commands: public>+≡

```

API: driver for the unit tests below.

```
<Commands: public test>≡
  public :: commands_test

<Commands: test driver>≡
  subroutine commands_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Commands: execute tests>
  end subroutine commands_test
```

### Prepare Sindarin code

This routine parses an internal file, prints the parse tree, and returns a parse node to the root. We use the routine in the tests below.

```
<Commands: public test auxiliary>≡
  public :: parse_ifile

<Commands: test auxiliary>≡
  subroutine parse_ifile (ifile, pn_root, u)
    use ifiles
    use lexers
    use parser
    use commands
    type(ifile_t), intent(in) :: ifile
    type(parse_node_t), pointer, intent(out) :: pn_root
    integer, intent(in), optional :: u
    type(stream_t), target :: stream
    type(lexer_t), target :: lexer
    type(parse_tree_t) :: parse_tree

    call lexer_init_cmd_list (lexer)
    call stream_init (stream, ifile)
    call lexer_assign_stream (lexer, stream)

    call parse_tree_init (parse_tree, syntax_cmd_list, lexer)
    if (present (u)) call parse_tree_write (parse_tree, u)
    pn_root => parse_tree%get_root_ptr ()

    call stream_final (stream)
    call lexer_final (lexer)
  end subroutine parse_ifile
```

### Empty command list

Compile and execute an empty command list. Should do nothing but test the integrity of the workflow.

```
<Commands: execute tests>≡
  call test (commands_1, "commands_1", &
    "empty command list", &
    u, results)
```

```

end subroutine commands_34

```

For this test, we invent a callback object which simply writes the analysis file, using the standard call for this. Here we rely on the fact that the analysis data are stored as a global entity, otherwise we would have to access them via the event object.

```

<Commands: test auxiliary types>≡
type, extends (event_callback_t) :: event_callback_34_t

```

```

    private
    integer :: u = 0
contains
    procedure :: write => event_callback_34_write
    procedure :: proc => event_callback_34
end type event_callback_34_t

```

The output routine is unused. The actual callback should write the analysis data to the output unit that we have injected into the callback object.

*(Commands: test auxiliary)+≡*

```

subroutine event_callback_34_write (event_callback, unit)
    class(event_callback_34_t), intent(in) :: event_callback
    integer, intent(in), optional :: unit
end subroutine event_callback_34_write

subroutine event_callback_34 (event_callback, i, event)
    class(event_callback_34_t), intent(in) :: event_callback
    integer(i64), intent(in) :: i
    class(generic_event_t), intent(in) :: event
    call analysis_write (event_callback%u)
end subroutine event_callback_34

```

## 35.2 Toplevel module WHIZARD

```
<whizard.f90>≡  
  <File header>  
  
  module whizard  
  
    use io_units  
    <Use strings>  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF, BACKSLASH  
    use diagnostics

  end module whizard
```

### 35.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```
<WHIZARD: public>≡  
  public :: whizard_options_t  
  
<WHIZARD: types>≡  
  type :: whizard_options_t  
    type(string_t) :: job_id  
    type(string_t), dimension(:), allocatable :: pack_args  
    type(string_t), dimension(:), allocatable :: unpack_args  
    type(string_t) :: preload_model  
    type(string_t) :: default_lib
```

```

    type(string_t) :: preload_libraries
    logical :: rebuild_library = .false.
    logical :: recompile_library = .false.
    logical :: rebuild_phs = .false.
    logical :: rebuild_grids = .false.
    logical :: rebuild_events = .false.
end type whizard_options_t

```

### 35.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

<WHIZARD: types>+=
    type, extends (parse_tree_t) :: pt_entry_t
        type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the `last` pointer.

```

<WHIZARD: types>+=
    type :: pt_stack_t
        type(pt_entry_t), pointer :: last => null ()
        contains
        <WHIZARD: pt_stack: TBP>
    end type pt_stack_t

```

The finalizer is called at the very end.

```

<WHIZARD: pt_stack: TBP>=
    procedure :: final => pt_stack_final

<WHIZARD: procedures>=
    subroutine pt_stack_final (pt_stack)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(pt_entry_t), pointer :: current
        do while (associated (pt_stack%last))
            current => pt_stack%last
            pt_stack%last => current%previous
            call parse_tree_final (current%parse_tree_t)
            deallocate (current)
        end do
    end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt_stack: TBP>+=
    procedure :: push => pt_stack_push

<WHIZARD: procedures>+=
    subroutine pt_stack_push (pt_stack, parse_tree)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(parse_tree_t), intent(out), pointer :: parse_tree

```

```

    type(pt_entry_t), pointer :: current
    allocate (current)
    parse_tree => current%parse_tree_t
    current%previous => pt_stack%last
    pt_stack%last => current
end subroutine pt_stack_push

```

### 35.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a WHIZARD instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+≡
    public :: whizard_t

<WHIZARD: types>+≡
    type :: whizard_t
        type(whizard_options_t) :: options
        type(rt_data_t) :: global
        type(pt_stack_t) :: pt_stack
    contains
        <WHIZARD: whizard: TBP>
end type whizard_t

```

### 35.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>≡
    procedure :: init => whizard_init

<WHIZARD: procedures>+≡
    subroutine whizard_init (whizard, options, paths, logfile)
        class(whizard_t), intent(out), target :: whizard
        type(whizard_options_t), intent(in) :: options
        type(paths_t), intent(in), optional :: paths
        type(string_t), intent(in), optional :: logfile
        call init_syntax_tables ()
        whizard%options = options
        call whizard%global%global_init (paths, logfile)
        call whizard%init_job_id ()
        call whizard%init_rebuild_flags ()
        call whizard%unpack_files ()
        call whizard%preload_model ()
    end subroutine whizard_init

```

```

    call whizard%preload_library ()
    call whizard%global%init_fallback_model &
        (var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))
end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+=
    procedure :: final => whizard_final

<WHIZARD: procedures>+=
    subroutine whizard_final (whizard)
        class(whizard_t), intent(inout), target :: whizard
        call whizard%global%final ()
        call whizard%pt_stack%final ()
        call whizard%pack_files ()
        call final_syntax_tables ()
    end subroutine whizard_final

```

Set the job ID, if nonempty. If the ID string is empty, the value remains undefined.

```

<WHIZARD: whizard: TBP>+=
    procedure :: init_job_id => whizard_init_job_id

<WHIZARD: procedures>+=
    subroutine whizard_init_job_id (whizard)
        class(whizard_t), intent(inout), target :: whizard
        associate (var_list => whizard%global%var_list, options => whizard%options)
            if (options%job_id /= "") then
                call var_list%set_string (var_str ("$_job_id"), &
                    options%job_id, is_known=.true.)
            end if
        end associate
    end subroutine whizard_init_job_id

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+=
    procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: procedures>+=
    subroutine whizard_init_rebuild_flags (whizard)
        class(whizard_t), intent(inout), target :: whizard
        associate (var_list => whizard%global%var_list, options => whizard%options)
            call var_list%append_log (var_str ("?rebuild_library"), &
                options%rebuild_library, intrinsic=.true.)
            call var_list%append_log (var_str ("?recompile_library"), &
                options%recompile_library, intrinsic=.true.)
            call var_list%append_log (var_str ("?rebuild_phase_space"), &
                options%rebuild_phs, intrinsic=.true.)
            call var_list%append_log (var_str ("?rebuild_grids"), &
                options%rebuild_grids, intrinsic=.true.)
            call var_list%append_log (var_str ("?powheg_rebuild_grids"), &

```

```

        options%rebuild_grids, intrinsic=.true.)
    call var_list%append_log (var_str ("?rebuild_events"), &
        options%rebuild_events, intrinsic=.true.)
end associate
end subroutine whizard_init_rebuild_flags

```

Pack/unpack files in the working directory, if requested.

```

        call msg_message ("Preloaded library: " // char (library_name))
    end if
end do SCAN_LIBS
end subroutine whizard_preload_library

```

### 35.2.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

```

<WHIZARD: public>+≡
    public :: init_syntax_tables
    public :: final_syntax_tables

<WHIZARD: procedures>+≡
    subroutine init_syntax_tables ()
        call syntax_model_file_init ()
        call syntax_phs_forest_init ()
        call syntax_pexpr_init ()
        call syntax_slha_init ()
        call syntax_cmd_list_init ()
    end subroutine init_syntax_tables

    subroutine final_syntax_tables ()
        call syntax_model_file_final ()
        call syntax_phs_forest_final ()
        call syntax_pexpr_final ()
        call syntax_slha_final ()
        call syntax_cmd_list_final ()
    end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
    public :: write_syntax_tables

<WHIZARD: procedures>+≡
    subroutine write_syntax_tables ()
        integer :: unit
        character(*), parameter :: file_model = "whizard.model_file.syntax"
        character(*), parameter :: file_phs = "whizard.phase_space_file.syntax"
        character(*), parameter :: file_pexpr = "whizard.prt_expressions.syntax"
        character(*), parameter :: file_slha = "whizard.slha.syntax"
        character(*), parameter :: file_sindarin = "whizard.sindarin.syntax"
        unit = free_unit ()
    end subroutine write_syntax_tables

```

```

print *, "Writing file '" // file_model // "'"
open (unit=unit, file=file_model, status="replace", action="write")
write (unit, "(A)")  VERSION_STRING
write (unit, "(A)")  "Syntax definition file: " // file_model
call syntax_model_file_write (unit)
close (unit)
print *, "Writing file '" // file_phs // "'"

call syntax_pexpr_write (unit)
close (unit)
print *, "Writing file '" // file_slha // "'"
open (unit=unit, file=file_slha, status="replace", action="write")
write (unit, "(A)")  VERSION_STRING
write (unit, "(A)")  "Syntax definition file: " // file_slha
call syntax_slha_write (unit)
close (unit)
print *, "Writing file '" // file_sindarin // "'"
open (unit=unit, file=file_sindarin, status="replace", action="write")
write (unit, "(A)")  VERSION_STRING
write (unit, "(A)")  "Syntax definition file: " // file_sindarin
call syntax_cmd_list_write (unit)
close (unit)
end subroutine write_syntax_tables

```

### 35.2.6 Execute command lists

Process commands given on the command line, stored as an ifile. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: process_ifile => whizard_process_ifile

<WHIZARD: procedures>+≡
    subroutine whizard_process_ifile (whizard, ifile, quit, quit_code)
        class(whizard_t), intent(inout), target :: whizard
        type(ifile_t), intent(in) :: ifile
        logical, intent(out) :: quit
        integer, intent(out) :: quit_code
        type(lexer_t), target :: lexer
        type(stream_t), target :: stream
        call msg_message ("Reading commands given on the command line")
        call lexer_init_cmd_list (lexer)
        call stream_init (stream, ifile)
        call whizard%process_stream (stream, lexer, quit, quit_code)
        call stream_final (stream)
        call lexer_final (lexer)
    end subroutine whizard_process_ifile

```

```
end subroutine whizard_process_ifile
```

Process standard input as a command list. The whole input is read, compiled and executed as a whole.

```
<WHIZARD: whizard: TBP>+=
  procedure :: process_stdin => whizard_process_stdin
<WHIZARD: procedures>+=
  subroutine whizard_process_stdin (whizard, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    call msg_message ("Reading commands from standard input")
    call lexer_init_cmd_list (lexer)
    call stream_init (stream, 5)
    call whizard%process_stream (stream, lexer, quit, quit_code)
    call stream_final (stream)
    call lexer_final (lexer)
  end subroutine whizard_process_stdin
```

Process a file as a command list.

```
<WHIZARD: whizard: TBP>+=
  procedure :: process_file => whizard_process_file
<WHIZARD: procedures>+=
  subroutine whizard_process_file (whizard, file, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t), intent(in) :: file
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    logical :: exist
    call msg_message ("Reading commands from file '" // char (file) // "'")
    inquire (file=char(file), exist=exist)
    if (exist) then
      call lexer_init_cmd_list (lexer)
      call stream_init (stream, char (file))
      call whizard%process_stream (stream, lexer, quit, quit_code)
      call stream_final (stream)
      call lexer_final (lexer)
    else
      call msg_error ("File '" // char (file) // "' not found")
    end if
  end subroutine whizard_process_file
```

```
<WHIZARD: whizard: TBP>+=
  procedure :: process_stream => whizard_process_stream
<WHIZARD: procedures>+=

    mask_fatal_errors = mask_tmp
    call stream_final (stream)
    if (quit) exit COMMAND_LOOP
end do COMMAND_LOOP
print *
call lexer_final (lexer)
end subroutine whizard_shell

```

## 35.3 Tools for the command line

We do not intent to be very smart here, but this module provides a few small tools that simplify dealing with the command line.

The `unquote_value` subroutine handles an option value that begins with a single/double quote character. It swallows extra option strings until it finds a value that ends with another quote character. The returned string consists of all argument strings between quotes, concatenated by blanks (with a leading blank). Note that more complex patterns, such as quoted or embedded quotes, or multiple blanks, are not accounted for.

```

## 35.4 Query Feature Support

This module accesses the various optional features (modules) that WHIZARD can support and reports on their availability.

```
<features.f90>≡
  module features

    use string_utils, only: lower_case
    use system_dependencies, only: WHIZARD_VERSION
    <Features: dependencies>

    <Standard module head>

    <Features: public>

    contains

    <Features: procedures>

  end module features
```

### 35.4.1 Output

```
<Features: public>≡
  public :: print_features

<Features: procedures>≡
  subroutine print_features ()
    print "(A)", "WHIZARD " // WHIZARD_VERSION
    print "(A)", "Build configuration:"
    <Features: config>
    print "(A)", "Optional features available in this build:"
    <Features: print>
  end subroutine print_features
```

### 35.4.2 Query function

```
<Features: procedures>+≡
  subroutine check (feature, recognized, result, help)
    character(*), intent(in) :: feature
    logical, intent(out) :: recognized
    character(*), intent(out) :: result, help
    recognized = .true.
    result = "no"
    select case (lower_case (trim (feature)))
    <Features: cases>
    case default
      recognized = .false.
    end select
  end subroutine check
```

Print this result:

```
<Features: procedures>+≡
  subroutine print_check (feature)
    character(*), intent(in) :: feature
    character(16) :: f
    logical :: recognized
    character(10) :: result
    character(48) :: help
    call check (feature, recognized, result, help)
    if (.not. recognized) then
      result = "unknown"

## 35.5 Driver program

The main program handles command options, initializes the environment, and runs WHIZARD in a particular mode (interactive, file, standard input).

This is also used in the C interface:

*<Main: cmdline arg len declaration>*≡

```
integer, parameter :: CMDLINE_ARG_LEN = 1000
```

The actual main program:

*<main.f90>*≡

*<File header>*

```
program main
```

*<Use strings>*

```
use system_dependencies
use diagnostics
use ifiles
use os_interface
use rt_data, only: show_description_of_string, show_tex_descriptions
use whizard
```

```
use cmdline_options
use features
```

*<Use mpi f08>*

```
implicit none
```

*<Main: cmdline arg len declaration>*

```
!!! (WK 02/2016) Interface for the separate external routine below

```

### 35.6.1 Self-tests

For those self-tests, we need some auxiliary routines that provide an environment. The environment depends on things that are not available at the level of the module that we want to test.

#### Testbed for event I/O

This subroutine prepares a test process with a single event. All objects are allocated via anonymous pointers, because we want to recover the pointers and delete the objects in a separate procedure.

*(Main: tests)*≡

```
subroutine prepare_eio_test (event, unweighted, n_alt, sample_norm)
  use variables, only: var_list_t
  use model_data
  use process, only: process_t
  use instances, only: process_instance_t
  use processes_ut, only: prepare_test_process
  use event_base
  use events

  class(generic_event_t), intent(inout), pointer :: event
  logical, intent(in), optional :: unweighted
  integer, intent(in), optional :: n_alt
  type(string_t), intent(in), optional :: sample_norm
  type(model_data_t), pointer :: model
  type(var_list_t) :: var_list
  type(string_t) :: sample_normalization
  type(process_t), pointer :: proc
  type(process_instance_t), pointer :: process_instance

  allocate (model)
  call model%init_test ()

  allocate (proc)
  allocate (process_instance)

  call prepare_test_process (proc, process_instance, model, &
    run_id = var_str ("run_test"))
  call process_instance%setup_event_data ()

  call model%final ()
  deallocate (model)

  allocate (event_t :: event)
  select type (event)
  type is (event_t)
    if (present (unweighted)) then
      call var_list%append_log (&
        var_str ("?unweighted"), unweighted, &
        intrinsic = .true.)
    else
      call var_list%append_log (&
        var_str ("?unweighted"), .true., &
```

```

        intrinsic = .true.)
    end if
    if (present (sample_norm)) then
        sample_normalization = sample_norm
    else
        sample_normalization = var_str ("auto")
    end if
    call var_list%append_string (&
        var_str ("sample_normalization"), &
        sample_normalization, intrinsic = .true.)
    call event%basic_init (var_list, n_alt)
    call event%connect (process_instance, proc%get_model_ptr ())
    call var_list%final ()
end select

end subroutine prepare_eio_test

```

Recover those pointers, finalize the objects and deallocate.

```

(Main: tests)+≡
subroutine cleanup_eio_test (event)
    use model_data
    use process, only: process_t
    use instances, only: process_instance_t
    use processes_ut, only: cleanup_test_process
    use event_base
    use events

    class(generic_event_t), intent(inout), pointer :: event
    type(process_t), pointer :: proc
    type(process_instance_t), pointer :: process_instance

    select type (event)
    type is (event_t)
        proc => event%get_process_ptr ()
        process_instance => event%get_process_instance_ptr ()
        call cleanup_test_process (proc, process_instance)
        deallocate (process_instance)
        deallocate (proc)
        call event%final ()
    end select
    deallocate (event)

end subroutine cleanup_eio_test

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

(Main: use tests)≡
    use eio_base_ut, only: eio_prepare_test
    use eio_base_ut, only: eio_cleanup_test

(Main: prepare testbed)≡
    eio_prepare_test => prepare_eio_test
    eio_cleanup_test => cleanup_eio_test

```

## Any Model

This procedure reads any model from file and, optionally, assigns a var-list pointer. If the model pointer is still null, we allocate the model object first, with concrete type `model_t`. This is a service for modules which do just have access to the `model_data_t` base type.

```
<Main: tests>+≡
  subroutine prepare_whizard_model (model, name, vars)
    <Use strings>
    use os_interface
    use model_data
    use var_base
    use models
    class(model_data_t), intent(inout), pointer :: model
    type(string_t), intent(in) :: name
    class(vars_t), pointer, intent(out), optional :: vars
    type(os_data_t) :: os_data
    call syntax_model_file_init ()
    call os_data%init ()
    if (.not. associated (model)) allocate (model_t :: model)
    select type (model)
    type is (model_t)
      call model%read (name // ".mdl", os_data)
      if (present (vars)) then
        vars => model%get_var_list_ptr ()
      end if
    end select
  end subroutine prepare_whizard_model
```

Cleanup after use. Includes deletion of the model-file syntax.

```
<Main: tests>+≡
  subroutine cleanup_whizard_model (model)
    use model_data
    use models
    class(model_data_t), intent(inout), target :: model
    call model%final ()
    call syntax_model_file_final ()
  end subroutine cleanup_whizard_model
```

Assign those procedures to appropriate pointers (module variables) in the `model_testbed` module, so they can be called as if they were module procedures.

```
<Main: prepare testbed>+≡
  prepare_model => prepare_whizard_model
  cleanup_model => cleanup_whizard_model
```

## Fallback model: hadrons

Some event format tests require the hadronic SM implementation, which has to be read from file. We provide the functionality here, so the tests do not depend on model I/O.

```
<Main: tests>+≡
  subroutine prepare_fallback_model (model)
```

```

    use model_data
    class(model_data_t), intent(inout), pointer :: model
    call prepare_whizard_model (model, var_str ("SM_hadrons"))
end subroutine prepare_fallback_model

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

<Main: use tests>+≡
    use eio_base_ut, only: eio_prepare_fallback_model
    use eio_base_ut, only: eio_cleanup_fallback_model

<Main: prepare testbed>+≡
    eio_prepare_fallback_model => prepare_fallback_model
    eio_cleanup_fallback_model => cleanup_model

```

### Access to the test random-number generator

This generator is not normally available for the dispatcher. We assign an additional dispatch routine to the hook in the `dispatch` module which will be checked before the default rule.

```

<Main: use tests>+≡
    use dispatch_rng, only: dispatch_rng_factory_fallback
    use dispatch_rng_ut, only: dispatch_rng_factory_test

<Main: prepare testbed>+≡
    dispatch_rng_factory_fallback => dispatch_rng_factory_test

```

### Access to the test structure functions

These are not normally available for the dispatcher. We assign an additional dispatch routine to the hook in the `dispatch` module which will be checked before the default rule.

```

<Main: use tests>+≡
    use dispatch_beams, only: dispatch_sf_data_extra
    use dispatch_ut, only: dispatch_sf_data_test

<Main: prepare testbed>+≡
    dispatch_sf_data_extra => dispatch_sf_data_test

```

### Procedure for Checking

This is for developers only, but needs a well-defined interface.

```

<Main: tests>+≡
    subroutine whizard_check (check, results)
        type(string_t), intent(in) :: check
        type(test_results_t), intent(inout) :: results
        type(os_data_t) :: os_data
        integer :: u
        call os_data%init ()
        u = free_unit ()
        open (u, file="whizard_check." // char (check) // ".log", &
            action="write", status="replace")

## 35.6.2 Unit test references

### Formats

```

<Main: use tests>+≡
    use formats_ut, only: format_test
<Main: test cases>≡
    case ("formats")
        call format_test (u, results)
<Main: all tests>≡
    call format_test (u, results)

```

### MD5

```

<Main: use tests>+≡
    use md5_ut, only: md5_test
<Main: test cases>+≡
    case ("md5")
        call md5_test (u, results)
<Main: all tests>+≡
    call md5_test (u, results)

```

### OS Interface

```

<Main: use tests>+≡
    use os_interface_ut, only: os_interface_test
<Main: test cases>+≡
    case ("os_interface")
        call os_interface_test (u, results)
<Main: all tests>+≡
    call os_interface_test (u, results)

```

### Sorting

```

<Main: use tests>+≡
    use sorting_ut, only: sorting_test

```

```

⟨Main: test cases⟩+≡
    case ("sorting")
        call sorting_test (u, results)
⟨Main: all tests⟩+≡
    call sorting_test (u, results)

```

## Grids

```

⟨Main: use tests⟩+≡
    use grids_ut, only: grids_test
⟨Main: test cases⟩+≡
    case ("grids")
        call grids_test (u, results)
⟨Main: all tests⟩+≡
    call grids_test (u, results)

```

## Solver

```

⟨Main: use tests⟩+≡
    use solver_ut, only: solver_test
⟨Main: test cases⟩+≡
    case ("solver")
        call solver_test (u, results)
⟨Main: all tests⟩+≡
    call solver_test (u, results)

```

## CPU Time

```

⟨Main: use tests⟩+≡
    use cputime_ut, only: cputime_test
⟨Main: test cases⟩+≡
    case ("cputime")
        call cputime_test (u, results)
⟨Main: all tests⟩+≡
    call cputime_test (u, results)

```

## SM QCD

```

⟨Main: use tests⟩+≡
    use sm_qcd_ut, only: sm_qcd_test
⟨Main: test cases⟩+≡
    case ("sm_qcd")
        call sm_qcd_test (u, results)
⟨Main: all tests⟩+≡
    call sm_qcd_test (u, results)

```

## SM physics

```

⟨Main: use tests⟩+≡
    use sm_physics_ut, only: sm_physics_test

```

```

<Main: test cases>+≡
  case ("sm_physics")
    call sm_physics_test (u, results)
<Main: all tests>+≡
  call sm_physics_test (u, results)

```

## Lexers

```

<Main: use tests>+≡
  use lexers_ut, only: lexer_test
<Main: test cases>+≡
  case ("lexers")
    call lexer_test (u, results)
<Main: all tests>+≡
  call lexer_test (u, results)

```

## Parser

```

<Main: use tests>+≡
  use parser_ut, only: parse_test
<Main: test cases>+≡
  case ("parser")
    call parse_test (u, results)
<Main: all tests>+≡
  call parse_test (u, results)

```

## XML

```

<Main: use tests>+≡
  use xml_ut, only: xml_test
<Main: test cases>+≡
  case ("xml")
    call xml_test (u, results)
<Main: all tests>+≡
  call xml_test (u, results)

```

## Colors

```

<Main: use tests>+≡
  use colors_ut, only: color_test
<Main: test cases>+≡
  case ("colors")
    call color_test (u, results)
<Main: all tests>+≡
  call color_test (u, results)

```

## State matrices

```

<Main: use tests>+≡
  use state_matrices_ut, only: state_matrix_test

```

```

<Main: test cases>+≡
    case ("state_matrices")
        call state_matrix_test (u, results)
<Main: all tests>+≡
    call state_matrix_test (u, results)

```

## Analysis

```

<Main: use tests>+≡
    use analysis_ut, only: analysis_test
<Main: test cases>+≡
    case ("analysis")
        call analysis_test (u, results)
<Main: all tests>+≡
    call analysis_test (u, results)

```

## Particles

```

<Main: use tests>+≡
    use particles_ut, only: particles_test
<Main: test cases>+≡
    case ("particles")
        call particles_test (u, results)
<Main: all tests>+≡
    call particles_test (u, results)

```

## Models

```

<Main: use tests>+≡
    use models_ut, only: models_test
<Main: test cases>+≡
    case ("models")
        call models_test (u, results)
<Main: all tests>+≡
    call models_test (u, results)

```

## Auto Components

```

<Main: use tests>+≡
    use auto_components_ut, only: auto_components_test
<Main: test cases>+≡
    case ("auto_components")
        call auto_components_test (u, results)
<Main: all tests>+≡
    call auto_components_test (u, results)

```

## Radiation Generator

```

<Main: use tests>+≡
    use radiation_generator_ut, only: radiation_generator_test

```

```

<Main: test cases>+≡
    case ("radiation_generator")
        call radiation_generator_test (u, results)
<Main: all tests>+≡
    call radiation_generator_test (u, results)

```

### 35.6.3 BLHA

```

<Main: use tests>+≡
    use blha_ut, only: blha_test
<Main: test cases>+≡
    case ("blha")
        call blha_test (u, results)
<Main: all tests>+≡
    call blha_test (u, results)

```

### Evaluators

```

<Main: use tests>+≡
    use evaluators_ut, only: evaluator_test
<Main: test cases>+≡
    case ("evaluators")
        call evaluator_test (u, results)
<Main: all tests>+≡
    call evaluator_test (u, results)

```

### Expressions

```

<Main: use tests>+≡
    use eval_trees_ut, only: expressions_test
<Main: test cases>+≡
    case ("expressions")
        call expressions_test (u, results)
<Main: all tests>+≡
    call expressions_test (u, results)

```

### Resonances

```

<Main: use tests>+≡
    use resonances_ut, only: resonances_test
<Main: test cases>+≡
    case ("resonances")
        call resonances_test (u, results)
<Main: all tests>+≡
    call resonances_test (u, results)

```

## PHS Trees

```
<Main: use tests>+≡
  use phs_trees_ut, only: phs_trees_test
<Main: test cases>+≡
  case ("phs_trees")
    call phs_trees_test (u, results)
<Main: all tests>+≡
  call phs_trees_test (u, results)
```

## PHS Forests

```
<Main: use tests>+≡
  use phs_forests_ut, only: phs_forests_test
<Main: test cases>+≡
  case ("phs_forests")
    call phs_forests_test (u, results)
<Main: all tests>+≡
  call phs_forests_test (u, results)
```

## Beams

```
<Main: use tests>+≡
  use beams_ut, only: beams_test
<Main: test cases>+≡
  case ("beams")
    call beams_test (u, results)
<Main: all tests>+≡
  call beams_test (u, results)
```

## $su(N)$ Algebra

```
<Main: use tests>+≡
  use su_algebra_ut, only: su_algebra_test
<Main: test cases>+≡
  case ("su_algebra")
    call su_algebra_test (u, results)
<Main: all tests>+≡
  call su_algebra_test (u, results)
```

## Bloch Vectors

```
<Main: use tests>+≡
  use bloch_vectors_ut, only: bloch_vectors_test
<Main: test cases>+≡
  case ("bloch_vectors")
    call bloch_vectors_test (u, results)
<Main: all tests>+≡
  call bloch_vectors_test (u, results)
```

## Polarizations

```
<Main: use tests>+≡
    use polarizations_ut, only: polarizations_test

<Main: test cases>+≡
    case ("polarizations")
        call polarizations_test (u, results)

<Main: all tests>+≡
    call polarizations_test (u, results)
```

## SF Aux

```
<Main: use tests>+≡
    use sf_aux_ut, only: sf_aux_test

<Main: test cases>+≡
    case ("sf_aux")
        call sf_aux_test (u, results)

<Main: all tests>+≡
    call sf_aux_test (u, results)
```

## SF Mappings

```
<Main: use tests>+≡
    use sf_mappings_ut, only: sf_mappings_test

<Main: test cases>+≡
    case ("sf_mappings")
        call sf_mappings_test (u, results)

<Main: all tests>+≡
    call sf_mappings_test (u, results)
```

## SF Base

```
<Main: use tests>+≡
    use sf_base_ut, only: sf_base_test

<Main: test cases>+≡
    case ("sf_base")
        call sf_base_test (u, results)

<Main: all tests>+≡
    call sf_base_test (u, results)
```

## SF PDF Builtin

```
<Main: use tests>+≡
    use sf_pdf_builtin_ut, only: sf_pdf_builtin_test

<Main: test cases>+≡
    case ("sf_pdf_builtin")
        call sf_pdf_builtin_test (u, results)

<Main: all tests>+≡
    call sf_pdf_builtin_test (u, results)
```

## SF LHAPDF

```
<Main: use tests>+≡  
    use sf_lhapdf_ut, only: sf_lhapdf_test  
  
<Main: test cases>+≡  
    case ("sf_lhapdf")  
        call sf_lhapdf_test (u, results)  
  
<Main: all tests>+≡  
    call sf_lhapdf_test (u, results)
```

## SF ISR

```
<Main: use tests>+≡  
    use sf_isr_ut, only: sf_isr_test  
  
<Main: test cases>+≡  
    case ("sf_isr")  
        call sf_isr_test (u, results)  
  
<Main: all tests>+≡  
    call sf_isr_test (u, results)
```

## SF EPA

```
<Main: use tests>+≡  
    use sf_epa_ut, only: sf_epa_test  
  
<Main: test cases>+≡  
    case ("sf_epa")  
        call sf_epa_test (u, results)  
  
<Main: all tests>+≡  
    call sf_epa_test (u, results)
```

## SF EWA

```
<Main: use tests>+≡  
    use sf_ewa_ut, only: sf_ewa_test  
  
<Main: test cases>+≡  
    case ("sf_ewa")  
        call sf_ewa_test (u, results)  
  
<Main: all tests>+≡  
    call sf_ewa_test (u, results)
```

## SF CIRCE1

```
<Main: use tests>+≡  
    use sf_circe1_ut, only: sf_circe1_test  
  
<Main: test cases>+≡  
    case ("sf_circe1")  
        call sf_circe1_test (u, results)
