Write the BLHA file. Internal mode is intended for md5summing only.

Special cases of external photons in `OpenLoops`:

For electroweak corrections the particle ID (PID) of photons is a crucial input for the computation of matrix elements by `OpenLoops`. According to "arXiv:1907.13071", section 3.2, external photons are classified by the following types:

- PID = -2002: off-shell photons, that undergo  $\gamma \rightarrow f\bar{f}$  splittings at NLO EW, or initial state photons from QED PDFs
- PID = 2002: on-shell photons, that do not undergo  $\gamma \rightarrow f\bar{f}$  splittings at NLO EW, or initial state photons for example at photon colliders
- PID = 22: unresolved photons, representing radiated photons at NLO EW, absent at LO

For the first two types scattering amplitudes for processes with external photons at NLO EW get renormalisation factors containing photon-coupling and wave function counterterms. Logarithmic mass singularities arising due to the renormalisation of off-shell external photon wave functions are cancelled by collinear singularities of photon PDF counterterms or analogous terms in virtual contributions originating from  $\gamma \rightarrow f\bar{f}$  splittings of final state photons.

The finite remainders of the renormalisation factors are thus dictated by the specific photon PID stated above. As consequence, we have to adjust the input PIDs written into the BLHA file which will be read by `OpenLoops`.

Concretely, for the case of electroweak corrections initial state photons associated with photon PDFs and final state photons (if existent at LO) are labeled as off-shell photons with PID "-2002". On-shell photons with PID "2002" are

neglected for now since to include them for processes at NLO EW is non-trivial from the phenomenological point of view. Processes at NLO EW typically are studied at high energy scales for which photon-induced sub-processes in most cases can not be neglected. However, on-shell, e. g. tagged, photons are defined at low energy scales and thus the process has to be described with external photon fields and couplings at two different scales.

Another issue which has to be addressed if various photon PIDs are taken into account is that real and virtual amplitudes have to be computed at the same order in  $\alpha$  at a specific scale for the subtraction scheme to be consistent. The complication comes by the fact that the EW coupling  $\alpha$  of each external photon in the amplitudes will automatically be rescaled by **OpenLoops** corresponding to the specific photon type. Following eq. (3.30) of "arXiv: 1907.13071", by default the coupling of an on-shell photon will be changed to  $\alpha(0)$  and that of an off-shell photon to  $\alpha_{G_\mu}$  if not chosen already at a high scale, e. g.  $\alpha(M_Z)$ . In order to not spoil the IR cancellation **OpenLoops** supplies to register unresolved photons with PID "22" describing a radiated photon at NLO EW for which the photon-coupling  $\alpha$  is left unchanged at the value which is computed with the electroweak input scheme chosen by the user. This is adopted here by labeling each emitted photon as unresolved with PID "22" if no photons are present at LO.

For EW corrections the freedom to choose an electroweak input scheme is restricted, however, since the number of external photons present at LO is not conserved for the corresponding real flavor structures due to possible  $\gamma \rightarrow f\bar{f}$  splittings. This forbids to choose  $\alpha = \alpha(0)$  since otherwise the order in  $\alpha(0)$  is not conserved in the real amplitudes corresponding to the factorizing Born process. Consequently, for FKS the NLO components are not of the same order in  $\alpha(0)$ . The option `$blha_ew_scheme = "alpha_0"` is thus refused for the case if EW corrections are activated and photons are present at LO.

## Chapter 25

# GoSam Interface

The code in this chapter makes amplitudes accessible to **WHIZARD** that are generated and computed by the GoSam package.

These are the modules:

**loop\_archive** Provide some useful extra functionality.

**prc\_gosam** The actual interface, following the **WHIZARD** conventions for matrix-element generator methods.

No internal dependencies

Figure 25.1: Module dependencies in `src/gosam`.

## 25.1 Gosam Interface

```

The BLHA-interface conventions require the quantity  $S_{ij} = \langle M_{i,+} | T_i T_j | M_{i,-} \rangle$  to be produced, where  $i$  is the position of the splitting gluon. However,  $\tilde{M} = \langle M_{i,-} | M_{i,+} \rangle$  is needed. This can be obtained using color conservation,  $\sum_j T_j |M\rangle = 0$ , so that

$$\sum_{j \neq i} S_{ij} = -\langle M_{i,+} | T_i^2 | M_{i,-} \rangle = -C_A \langle M_{i,+} | M_{i,-} \rangle = -C_A \tilde{M}^*$$

According to BLHA conventions, the real part of  $S_{ij}$  is located at positions  $2i + 2nj$  in the output array, where  $n$  denotes the number of external particles and the enumeration of particles starts at zero. The subsequent position, i.e.  $2i + 2nj + 1$  is designated to the imaginary part of  $S_{ij}$ . Note that, since the first array position is 1, the implemented position association deviates from the above one in the addition of 1.

## Chapter 27

# FKS Subtraction Scheme

The code in this chapter implements the FKS subtraction scheme for use with WHIZARD.

These are the modules:

**fks\_regions** Given a process definition, identify singular regions in the associated phase space.

**virtual** Handle the virtual correction matrix element.

**real\_subtraction** Handle the real-subtraction matrix element.

**nlo\_data** Manage the subtraction objects.

This chapter deals with next-to-leading order contributions to cross sections. Basically, there are three major issues to be addressed: The creation of the  $N + 1$ -particle flavor structure, the construction of the  $N + 1$ -particle phase space and the actual calculation of the real- and virtual-subtracted matrix elements. The first is dealt with using the `auto_components` class, and it will be shown that the second and third issue are connected in FKS subtraction.

### 27.1 Brief outline of FKS subtraction

*In the current state, this discussion is only concerned with lepton collisions. For hadron collisions, renormalization of parton distributions has to be taken into account. Further, for QCD corrections, initial-state radiation is necessarily present.*

The aim is to calculate the next-to-leading order cross section according to

$$d\sigma_{\text{NLO}} = \mathcal{B} + \mathcal{V} + \mathcal{R}d\Phi_{\text{rad}}.$$

Analytically, the divergences, in terms of poles in the complex quantity  $\varepsilon = 2 - d/2$ , cancel. However, this is in general only valid in an arbitrary, complex number of dimensions. This is, roughly, the content of the KLN-theorem. WHIZARD, as any other numerical program, is confined to four dimensions. We will assume that the KLN-theorem is valid and that there exist subtraction terms  $\mathcal{C}$  such that

$$d\sigma_{\text{NLO}} = \mathcal{B} + \underbrace{\mathcal{V} + \mathcal{C}}_{\text{finite}} + \underbrace{\mathcal{R} - \mathcal{C}}_{\text{finite}},$$

Figure 27.1: Module dependencies in `src/fks`.

i.e. the subtraction terms correspond to the divergent limits of the real and virtual matrix element.

Because  $\mathcal{C}$  subtracts the divergences of  $\mathcal{R}$  as well as those of  $\mathcal{V}$ , it suffices to consider one of them, so we focus on  $\mathcal{R}$ . For this purpose,  $\mathcal{R}$  is rewritten as

$$\mathcal{R} = \frac{1}{\xi^2} \frac{1}{1-y} (\xi^2(1-y)\mathcal{R}) = \frac{1}{\xi^2} \frac{1}{1-y} \tilde{\mathcal{R}},$$

with  $\xi = (2k_{\text{rad}}^0)/\sqrt{s}$  and  $y = \cos\theta$ , where  $k_{\text{rad}}^0$  denotes the energy of the radiated parton and  $\theta$  is the angle between emitter and radiated parton.  $\tilde{\mathcal{R}}$  is finite, therefore the whole singularity structure is contained in the prefactor  $\xi^{-2}(1-y)^{-1}$ . Combined with the  $d$ -dimensional phase space element,

$$\frac{d^{d-1}k}{2k^0(2\pi)^{d-1}} = \frac{s^{1-\varepsilon}}{(4\pi)^{d-1}} \xi^{1-2\varepsilon} (1-y^2)^{-\varepsilon} d\xi dy d\Omega^{d-2},$$

this yields

$$d\Phi_{\text{rad}} \mathcal{R} = dy(1-y)^{-1-\varepsilon} d\xi \xi^{-1-2\varepsilon} \tilde{\mathcal{R}}.$$

This can further be rewritten in terms of plus-distributions,

$$\begin{aligned} \xi^{-1-2\varepsilon} &= -\frac{1}{2\varepsilon} \delta(\xi) + \left(\frac{1}{\xi}\right)_+ - 2\varepsilon \left(\frac{\log \xi}{\xi}\right)_+ + \mathcal{O}(\varepsilon^2), \\ (1-y)^{-1-\varepsilon} &= -\frac{2^{-\varepsilon}}{\varepsilon} \delta(1-y) + \left(\frac{1}{1-y}\right)_+ - \varepsilon \left(\frac{1}{1-y}\right)_+ \log(1-y) + \mathcal{O}(\varepsilon^2), \end{aligned}$$

(imagine that all this is written inside of integrals, which are spared for ease of

notation) such that

$$d\Phi_{\text{rad}}\mathcal{R} = -\frac{1}{2\varepsilon}dy(1-y)^{-1-\varepsilon}\tilde{R}(0,y) - d\xi \left[ \frac{2^{-\varepsilon}}{\varepsilon} \left( \frac{1}{\xi} \right)_+ - 2 \left( \frac{\log \xi}{\xi} \right)_+ \right] \tilde{R}(\xi,1) \\ + dyd\xi \left( \frac{1}{\xi} \right)_+ \left( \frac{1}{1-y} \right)_+ \tilde{R}(\xi,y) + \mathcal{O}(\varepsilon).$$

The summand in the second line is of order  $\mathcal{O}(1)$  and is the only one to reproduce  $\mathcal{R}(\xi,y)$ . It thus constitutes the sum of the real matrix element and the corresponding counterterms. The first summand consequently consists of the subtraction terms to the virtual matrix elements. Above formula thus allows to calculate all quantities to render the matrix elements finite.

alr	flst_alr	emitter	ftuple_list
1	[-11,11,2,-2,21,21]	3	(3,5), (3,6), (4,5), (4,6), (5,6)

4	[-11,11,2,-2,2,-2]	5	(3,4), (3,6), (4,5), (5,6)

Table 27.1: List of singular regions. The particles are represented by their PDG codes. The third column contains the emitter for the specific singular region. For the process involving an additional gluon, the gluon can either be emitted from one of the quarks or from the first gluon. Each emitter yields the same list of fundamental tuples, five in total. The last singular region corresponds to the process where the gluon splits up into two quarks. As the matrix element for this process has no information on which quarks originate from a gluon splitting, there are ftuples for all the quark pairs and not just those involving the emitter.

## 27.2 Identifying singular regions

In the FKS subtraction scheme, the phase space is decomposed into disjoint singular regions, such that

$$\sum_i \mathcal{S}_i + \sum_{ij} \mathcal{S}_{ij} = 1. \quad (27.1)$$

The quantities  $\mathcal{S}_i$  and  $\mathcal{S}_{ij}$  are functions of phase space corresponding to a pair of particles indices which can make up a divergent phase space region. We call such an index pair a fundamental tuple. For example, the process  $e^+ e^- \rightarrow u \bar{u} g$  has two singular regions, (3, 5) and (4, 5), indicating that the gluon can be soft or collinear with respect to either the quark or the anti-quark. Therefore, the functions  $\mathcal{S}_{ij}$  have to be chosen in such a way that their contribution makes up most of (27.1) in phase-space configurations where (final-state) particle  $j$  is collinear to particle  $i$  or/and particle  $j$  is soft. The functions  $\mathcal{S}_i$  is the corresponding quantity for initial-state divergences.

As a singular region we understand the collection of real flavor structures associated with an emitter and a list of all possible fundamental tuples. As an example, consider the process  $e^+ e^- \rightarrow u \bar{u} g$ . At next-to-leading order, processes with an additionally radiated particle have to be considered. In this case, these are  $e^+ e^- \rightarrow u \bar{u}, g g$ , and  $e^+ e^- \rightarrow u \bar{u} u \bar{u}$  (or the same process with any other quark). Table 27.1 sums up all possible singular regions for this problem.

Thus, during the preparation of a NLO-calculation, the possible singular regions have to be identified. `fkf_regions.f90` deals with this issue.

Determines the splitting type for FSR. There are three different types of splittings relevant here:  $g \rightarrow gg$  tagged V\_TO\_VV,  $g \rightarrow qq$  tagged V\_TO\_FF and  $q \rightarrow qq$  tagged F\_TO\_FV. For FSR, there is no need to differentiate between  $q \rightarrow qq$  and  $q \rightarrow gq$  splittings.

    end associate
end subroutine ftuple_determine_splitting_type_fsr

```

Determines the splitting type for ISR. There are four different types of splittings relevant here:  $g \rightarrow gg$  tagged V\_TO\_VV,  $g \rightarrow qq$  tagged V\_TO\_FF,  $q \rightarrow qq$  tagged F\_TO\_FV and  $q \rightarrow gq$  tagged F\_TO\_VF. The latter two need to be considered separately for ISR as they differ with respect to which particle enters the hard process. A splitting F\_TO\_FV may lead to soft divergences while F\_TO\_VF does not.

We also want to emphasize that the splitting type naming convention for ISR names the splittings considering backwards evolution. So in the splitting V\_TO\_FF, it is the *gluon* that enters the hard process!

Special treatment here is required if emitter 0 is assigned. This is the case only when a gluon was radiated from any of the IS particles. In this case, both splittings are soft divergent so we can equivalently choose 1 or 2 as the emitter here even if both have different flavors.

Returns `true` if the two particles at position `i` and `j` in the flavor array can originate from the same splitting. For this purpose, the function first checks whether the splitting is allowed at all. If this is the case, the emitter is removed from the flavor array. If the resulting array is equivalent to the Born flavor structure `flv_born`, the pair is accepted as a valid splitting.

We first check whether the splitting is possible. The array `flv_orig` contains all particles which share a vertex with the particles at position `i` and `j`. If any of these particles belongs to the initial state, a PDG-ID flip is necessary to correctly recognize the vertex. If its size is equal to zero, no splitting is possible and the subroutine is exited. Otherwise, we loop over all possible underlying Born flavor structures and check if any of them equals the actual underlying Born flavor structure. For a quark emitting a gluon, `flv_orig` contains the PDG code of the anti-quark. To be on the safe side, a second array is created, which contains both the positively and negatively signed PDG codes. Then, the original tuple  $(i, j)$  is removed from the real flavor structure and the particles in `flv_orig2` are inserted. If the resulting Born configuration is equal to the underlying Born configuration, up to a permutation of final-state particles, the tuple  $(i, j)$  is accepted as valid.

A singular region is a partition of phase space which is associated with an individual emitter and, if relevant, resonance. It is associated with an  $\alpha_r$ - and resonance-index, with a real flavor structure and its underlying Born flavor structure. To compute the FKS weights, it is relevant to know all the other particle indices which can result in a divergent phase space configuration, which are collected in the `ftuples`-array.

Some singular regions might behave physically identical. E.g. a real flavor structure associated with three-jet production is  $[11, -11, 2, -2, 21, 21]$ . Here, there are two possible `ftuples` which contribute to the same  $u \rightarrow ug$  splitting, namely (3,5) and (3,6). The resulting singular regions will be identical. To avoid this, one singular region is associated with the multiplicity factor `mult`. When computing the subtraction terms for each singular region, the result is then simply multiplied by this factor.

The `double_fsr`-flag indicates whether the singular region should also be supplied by a symmetry factor, explained below.

In case of a  $g \rightarrow gg$  splitting, the factor

$$\frac{2E_{\text{em}}}{E_{\text{em}} + E_{\text{rad}}}$$

is multiplied to the real matrix element. This way, the symmetry of the splitting is used and only one singular region has to be taken into account. However, the factor ensures that there is only a soft singularity if the radiated parton becomes soft.

This subroutine splits up the ftuple-list of the singular regions into interference-free lists, i.e. lists which only contain the same emitter. This is relevant for factorized NLO calculations. In the current implementation, it is hand-tailored for the threshold computation, but should be generalized further in the future.

This subroutine starts with a specification of  $N$ - and  $N + 1$ -particle configurations, `flst_born` and `flst_real`, saved in `reg_data`. From these, it creates a list of fundamental tuples, a list of emitters and a list containing the  $N + 1$ -particle configuration, rearranged in such a way that the emitter-radiation pair is last (`flst_alr`). For the  $e^+ e^- \rightarrow u \bar{u} g$ - example, the generated objects are shown in table 27.2. Note that at this point, `flst_alr` is arranged in such a way that the emitter can only be equal to  $n_{legs} - 1$  for final-state radiation or 0, 1, or 2 for initial-state radiation. Further, it occurs that regions can be equivalent. For example in table 27.2 the regions corresponding to `alr = 1` and `alr = 3` as well as `alr = 2` and `alr = 4` describe the same physics and are therefore equivalent.

```

In the soft limit, our treatment of the divergencies requires a modification of the mapping functions. Recall that there, the ratios of the  $d$ -functions must approach either 1 or 0. This means

$$\frac{d_{lm}}{d_{0m}} = \frac{(2k_l \cdot k_m) [E_l E_m / (E_l + E_m)^2]}{E_m^2 (1 - y^2)} \Big|_{k_m = E_m \hat{k}} \frac{E_l E_m^2}{(E_l + E_m)^2} \frac{2k_l \cdot \hat{k}}{E_m^2 (1 - y^2)} \Big|_{E_m \rightarrow 0} \frac{2k_l \cdot \hat{k}}{E_l} (1 - y^2),$$

where we have written the gluon momentum in terms of the soft momentum  $\hat{k}$ . In the same limit

$$\frac{d_{lm}}{d_{nm}} = \frac{k_l \cdot \hat{k}}{k_n \cdot \hat{k}} \frac{E_n}{E_l}.$$

From these equations we can deduce the soft limit of  $d$ :

$$\begin{aligned} d_0^{\text{soft}} &= 1 - y^2, \\ d_1^{\text{soft}} &= 2(1 - y), \\ d_2^{\text{soft}} &= 2(1 + y), \\ d_i^{\text{soft}} &= \frac{2k_i \cdot \hat{k}}{E_i}. \end{aligned}$$

Computes the sum of all soft dijs required to normalize the soft S functions `s_alpha_soft` similar to `fks_mapping_default_compute_sumdij`. In the soft limit however, we need to skip all ftuples  $(i, j)$  in which  $j$  does not correspond to the emitted particle because those  $d_{ij}$ s are finite and thus their contribution to the soft S function vanishes in the limit of soft radiation. Technically, they would not vanish if computed here because the fixed `p_soft` at this point would not fit their actual emitter.

The  $d_{ij,k}$ -functions for the resonance mapping are basically the same as in the default case, but the kinematical values here must be evaluated in the resonance frame of reference. The energy of parton  $i$  in a given resonance frame with momentum  $p_{res}$  is

$$E_i = \frac{p_i^0 \cdot p_{res}}{m_{res}}.$$

However, since the expressions only depend on ratios of four-momenta, we leave out the denominator because it will cancel out anyway.

```

The virtual subtraction terms contain Casimir operators and derived constants, listed below:

$$C(q) = C(\bar{q}) = C_F, \quad (27.2)$$

$$C(g) = C_A, \quad (27.3)$$

$$\gamma(q) = \gamma(\bar{q}) = \frac{3}{2}C_F, \quad (27.4)$$

$$\gamma(g) = \frac{11}{6}C_A - \frac{2}{3}T_F N_f, \quad (27.5)$$

$$\gamma'(q) = \gamma'(\bar{q}) = \left( \frac{13}{2} - \frac{2\pi^2}{3} \right) C_F, \quad (27.6)$$

$$\gamma'(g) = \left( \frac{67}{9} - \frac{2\pi^2}{3} \right) C_A - \frac{23}{9}T_F N_f. \quad (27.7)$$

For uncolored particles, `virtual_init_constants` sets  $C$ ,  $\gamma$  and  $\gamma'$  to zero.

The virtual-subtracted matrix element is given by the equation

$$\mathcal{V} = \frac{\alpha_s}{2\pi} \left( \mathcal{Q}\mathcal{B} + \sum \mathcal{I}_{ij} \mathcal{B}_{ij} + \mathcal{V}_{fin} \right), \quad (27.8)$$

The expressions for  $\mathcal{Q}$  can be found in equations 27.9 and 27.11. The expressions for  $\mathcal{I}_{ij}$  can be found in equations (27.13), (27.14), (27.29), depending on whether the particles involved in the radiation process are massive or massless.

If two or more flavor structures would produce the same amplitude we only compute one and use the `eqv_index` to copy the result to the others (if `reuse_amplitudes_fks` is true).

The collinear limit of  $\tilde{\mathcal{R}}$  can be integrated over the radiation degrees of freedom, giving the collinear contribution to the virtual component. Its general structure is  $\mathcal{Q} \cdot \mathcal{B}$ . The initial-state contribution to  $\mathcal{Q}$  is simply given by

$$\mathcal{Q} = -\log \frac{\mu_F^2}{Q^2} (\gamma(\mathcal{I}_1) + 2C(\mathcal{I}_1) \log(\xi_{\text{cut}}) + \gamma(\mathcal{I}_2) + 2C(\mathcal{I}_2) \log(\xi_{\text{cut}})), \quad (27.9)$$

where  $Q^2$  is the Ellis-Sexton scale and  $\gamma$  is as in eqns. 27.4 and 27.5. `virtual_evaluate_initial_state` computes this quantity. The loop over the initial-state particles is only executed if we are dealing with a scattering process, because for decays there are no virtual initial-initial interactions.

```

<virtual: virtual: TBP>+=
    procedure :: evaluate_initial_state => virtual_evaluate_initial_state
<virtual: procedures>+=
    subroutine virtual_evaluate_initial_state (virt, i_flg, QB)
        class(virtual_t), intent(inout) :: virt

                    * log (virt%settings%fks_template%xi_cut)) &
                    * log(virt%fac_scale**2 / virt%es_scale2) * virt%sqme_born (i_flg)
            end do
        end if
    end subroutine virtual_evaluate_initial_state

```

Same as above, but for final-state particles. The collinear limit for final-state particles follows from the integral

$$I_{+, \alpha_r} = \int d\Phi_{n+1} \frac{\xi_+^{-1-2\epsilon}}{\xi^{-1-2\epsilon}} \mathcal{R}_{\alpha_r}.$$

We can distinguish three situations:

1.  $\alpha_r$  contains a massive emitter. In this case, no collinear subtraction term is required and the integral above is irrelevant.
2.  $\alpha_r$  contains a massless emitter, but resonances are not taken into account in the subtraction. Here,  $\xi_{max} = \frac{2E_{em}}{\sqrt{s}}$  is the upper bound on  $\xi$ .
3.  $\alpha_r$  contains a massless emitter and resonance-aware subtraction is used. Here,  $\xi_{max} = \frac{2E_{em}}{\sqrt{k_{res}^2}}$ .

Before version 2.4, only situations 1 and 2 were covered. The difference between situation 2 and 3 comes from the expansion of the plus-distribution in the integral above,

$$\xi_+^{-1-2\epsilon} = \xi^{-1-2\epsilon} + \frac{1}{2\epsilon} \delta(\xi) = \xi_{max}^{-1-2\epsilon} \left[ (1-z)^{-1-2\epsilon} + \frac{\xi_{max}^{2\epsilon}}{2\epsilon} \delta(1-z) \right].$$

The expression from the standard FKS literature is given by  $\mathcal{Q}$  is given by

$$\begin{aligned} \mathcal{Q} = \sum_{k=n_{in}}^{n_L^{(B)}} & \left[ \gamma'(\mathcal{I}_k) - \log \frac{s\delta_o}{2Q^2} \left( \gamma(\mathcal{I}_k) - 2C(\mathcal{I}_k) \log \frac{2E_k}{\xi_{cut}\sqrt{s}} \right) \right. \\ & \left. + 2C(\mathcal{I}_k) \left( \log^2 \frac{2E_k}{\sqrt{s}} - \log^2 \xi_{cut} \right) - 2\gamma(\mathcal{I}_k) \log \frac{2E_k}{\sqrt{s}} \right]. \end{aligned} \quad (27.10)$$

$n_L^{(B)}$  is the number of legs at Born level. Here,  $\xi_{max}$  is implicitly present in the ratios in the logarithms. Using the resonance-aware  $\xi_{max}$  yields

$$\begin{aligned} \mathcal{Q} = \sum_{k=n_{in}}^{n_L^{(B)}} & \left[ \gamma'(\mathcal{I}_k) + 2 \left( \log \frac{\sqrt{s}}{2E_{em}} + \log \xi_{max} \right) \left( \log \frac{\sqrt{s}}{2E_{em}} + \log \xi_{max} + \log \frac{Q^2}{s} \right) C(\mathcal{I}_k) \right. \\ & \left. + 2 \log \xi_{max} \left( \log \xi_{max} - \log \frac{Q^2}{k_{res}^2} \right) C(\mathcal{I}_k) + \left( \log \frac{Q^2}{k_{res}^2} - 2 \log \xi_{max} \right) \gamma(\mathcal{I}_k) \right]. \end{aligned} \quad (27.11)$$

Equation 27.11 leads to 27.10 with the substitutions  $\xi_{max} \rightarrow \frac{2E_{em}}{\sqrt{s}}$  and  $k_{res}^2 \rightarrow s$ . `virtual_compute_collinear_contribution` only implements the second one.

The following code implements the  $\mathcal{I}_{ij}$ -function. The complete formulas can be found in arXiv:0908.4272 (A.1-A.17) and are also discussed in arXiv:1002.2581 in Appendix A. The implementation may differ in the detail from the formulas presented in the above paper. The parameter  $\xi_{\text{cut}}$  is unphysically and cancels with appropriate factors in the real subtraction. We keep the additional parameter for debug usage. The implemented formulas are then defined as follows:

massless-massless case  $p^2 = 0, k^2 = 0$ ,

$$\begin{aligned} \mathcal{I}_{ij} = & \frac{1}{2} \log^2 \frac{\xi_{\text{cut}}^2 s}{Q^2} + \log \frac{\xi_{\text{cut}}^2 s}{Q^2} \log \frac{k_i k_j}{2E_i E_j} - \text{Li}_2 \left( \frac{k_i k_j}{2E_i E_j} \right) \\ & + \frac{1}{2} \log^2 \frac{k_i k_j}{2E_i E_j} - \log \left( 1 - \frac{k_i k_j}{2E_i E_j} \right) \log \frac{k_i k_j}{2E_i E_j}. \end{aligned} \quad (27.13)$$

massive-massive case  $p^2 \neq 0, k^2 \neq 0$ ,

$$\mathcal{I}_{ij} = \frac{1}{2} I_0(k_i, k_j) \log \frac{\xi_{\text{cut}}^2 s}{Q^2} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (27.14)$$

with

$$I_0(k_i, k_j) = \frac{1}{\beta} \log \frac{1 + \beta}{1 - \beta}, \quad \beta = \sqrt{1 - \frac{k_i^2 k_j^2}{(k_i \cdot k_j)^2}} \quad (27.15)$$

and a rather involved expression for  $I_\epsilon$ :

$$I_\epsilon(k_i, k_j) = (K(z_j) - K(z_i)) \frac{1 - \vec{\beta}_i \cdot \vec{\beta}_j}{\sqrt{a(1-b)}}, \quad (27.16)$$

$$\vec{\beta}_i = \frac{\vec{k}_i}{k_i^0}, \quad (27.17)$$

$$a = \beta_i^2 + \beta_j^2 - 2\vec{\beta}_i \cdot \vec{\beta}_j, \quad (27.18)$$

$$x_i = \frac{\beta_i^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a}, \quad (27.19)$$

$$x_j = \frac{\beta_j^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a} = 1 - x_i, \quad (27.20)$$

$$b = \frac{\beta_i^2 \beta_j^2 - (\vec{\beta}_i \cdot \vec{\beta}_j)^2}{a}, \quad (27.21)$$

$$c = \sqrt{\frac{b}{4a}}, \quad (27.22)$$

$$z_+ = \frac{1 + \sqrt{1-b}}{\sqrt{b}}, \quad (27.23)$$

$$z_- = \frac{1 - \sqrt{1-b}}{\sqrt{b}}, \quad (27.24)$$

$$z_i = \frac{\sqrt{x_i^2 + 4c^2} - x_i}{2c}, \quad (27.25)$$

$$z_j = \frac{\sqrt{x_j^2 + 4c^2} + x_j}{2c}, \quad (27.26)$$

$$K(z) = -\frac{1}{2} \log^2 \frac{(z - z_-)(z_+ - z)}{(z_+ + z)(z_- + z)} - 2Li_2 \left( \frac{2z_-(z_+ - z)}{(z_+ - z_-)(z_- + z)} \right) \quad (27.27)$$

$$- 2Li_2 \left( -\frac{2z_+(z_- + z)}{(z_+ - z_-)(z_+ - z)} \right) \quad (27.28)$$

massless-massive case  $p^2 = 0, k^2 \neq 0$ ,

$$\mathcal{I}_{ij} = \frac{1}{2} \left[ \frac{1}{2} \log^2 \frac{\xi_{\text{cut}}^2 s}{Q^2} - \frac{\pi^2}{6} \right] + \frac{1}{2} I_0(k_i, k_j) \log \frac{\xi_{\text{cut}}^2 s}{Q^2} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (27.29)$$

with

$$I_0(p, k) = \log \frac{(\hat{p} \cdot \hat{k})^2}{\hat{k}^2}, \quad (27.30)$$

$$I_\epsilon(p, k) = -2 \left[ \frac{1}{4} \log^2 \frac{1-\beta}{1+\beta} + \log \frac{\hat{p} \cdot \hat{k}}{1+\beta} \log \frac{\hat{p} \cdot \hat{k}}{1-\beta} + \text{Li}_2 \left( 1 - \frac{\hat{p} \cdot \hat{k}}{1+\beta} \right) + \text{Li}_2 \left( 1 - \frac{\hat{p} \cdot \hat{k}}{1-\beta} \right) \right], \quad (27.31)$$

using

$$\hat{p} = \frac{p}{p^0}, \quad \hat{k} = \frac{k}{k^0}, \quad \beta = \frac{|\vec{k}|}{k^0}, \quad (27.32)$$

$$\text{Li}_2(1-x) + \text{Li}_2(1-x^{-1}) = -\frac{1}{2} \log^2 x. \quad (27.33)$$

In the soft limit, the real matrix element behaves as

$$\mathcal{R}_{\text{soft}} = 4\pi\alpha_s \left[ \sum_{i \neq j} \mathcal{B}_{ij} \frac{k_i \cdot k_j}{(k_i \cdot k)(k_j \cdot k)} - \mathcal{B} \sum_i \frac{k_i^2}{(k_i \cdot k)^2} C_i \right],$$

where  $k$  denotes the momentum of the emitted parton. The quantity  $\mathcal{B}_{ij}$  is called the color-correlated Born matrix element defined as

$$\mathcal{B}_{ij} = \frac{1}{2s} \sum_{\substack{\text{colors} \\ \text{spins}}} \mathcal{M}_{\{c_k\}} \left( \mathcal{M}_{\{c_k\}}^\dagger \right)_{\substack{c_i \rightarrow c'_i \\ c_j \rightarrow c'_j}} T_{c_i, c'_i}^a T_{c_j, c'_j}^a.$$

The treatment of the momentum  $k$  follows the discussion about the soft limit of the partition functions (see [1002.2581], p. 29 and C. Weiss' PhD Thesis, p. 24). The parton momentum is pulled out,  $k = E\hat{k}$ . In fact, we will substitute  $\hat{k}$  for  $k$  throughout the code, because the energy will factor out of the equation when the soft  $\mathcal{S}$ -function is multiplied. The momentum  $\mathbf{p}_{\text{soft}}$  represents the soft limit of the radiated particle divided by its energy. It is a unit vector, because  $k^2 = (k^0)^2 - (\vec{k})^2 = 0$ .

The soft momentum is constructed by first creating a unit vector parallel to the emitter's Born momentum. This unit vector is then rotated about the corresponding angles  $y$  and  $\phi$  to match the direction of the real radiation in the soft limit.

```

<real subtraction: soft sub: TBP>+≡

        end associate
    end subroutine soft_subtraction_create_softvec_isr

```

The soft vector for the real mismatch is basically the same as for usual FSR, except for the scaling with the total gluon energy. Moreover, the resulting vector is rotated into the frame where the 3-axis points along the direction of the emitter. This is necessary because in the collinear limit, the approximation

$$k_i = \frac{k_i^0}{\bar{k}_j^0} \bar{k}_j = \frac{\xi \sqrt{s}}{2\bar{k}_j^0} \bar{k}_j$$

is used. The collinear limit is not included in the soft mismatch yet, but we keep the rotation for future usage here already (the performance loss is negligible).

```

<real subtraction: soft sub: TBP>+≡
    procedure :: create_softvec_mismatch => &
        soft_subtraction_create_softvec_mismatch

```

*(real subtraction: procedures)+≡*

```

subroutine soft_subtraction_create_softvec_mismatch (sub_soft, E, y, phi, p_em)

  sub_soft%p_soft = rot_em_off_3_axis * sub_soft%p_soft
end subroutine soft_subtraction_create_softvec_mismatch

```

Computation of the soft limit of  $R_\alpha$ . Note that what we are actually integrating (in the case of final-state radiation) is the quantity  $f(0, y)/\xi$ , where

$$f(\xi, y) = \frac{J(\xi, y, \phi)}{\xi} \xi^2 R_\alpha.$$

$J/\xi$  is computed by the phase space generator. The additional factor of  $\xi^{-1}$  is supplied in the `evaluate_region_fsr`-routine. Thus, we are left with a factor of  $\xi^2$ . A look on the expression for the soft limit of  $R_\alpha$  below reveals that we are factoring out the gluon energy  $E_i$  in the denominator. Therefore, we have a factor  $\xi^2/E_i^2 = 4/q^2$ .

Note that the same routine is used also for the computation of the soft mismatch. There, the gluon energy is not factored out from the soft vector, so that we are left with the  $\xi^2$ -factor, which will eventually be cancelled out again. So, we just multiply with 1. Both cases are distinguished by the flag `xi2_expanded`.

Note that for the soft subtraction term, also the S functions are computed in the soft limit. The input momenta are thus the real momenta in the soft limit, i.e. the Born momenta given by `p_born`.

```

This subroutine computes the collinear limit of  $g^\alpha(\xi, y)$  introduced in eq. 27.34. Care is given to also enable the usage for the soft-collinear limit. This, we write all formulas in terms of soft-finite quantities.

We have to compute

$$\frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1-y)\xi^2 \mathcal{R}^\alpha(\Phi_{n+1})] |_{y=1}.$$

The Jacobian  $J$  is proportional to  $\xi$ , due to the  $d^3k_{n+1}/k_{n+1}^0$  factor in the integration measure. It cancels the factor of  $\xi$  in the denominator. The remaining part of the Jacobian is multiplied in `evaluate_region_fsr` and is not relevant here. Inserting the splitting functions exemplarily for  $q \rightarrow qg$  yields

$$g^\alpha = \frac{8\pi\alpha_s}{k_{\text{em}}^2} C_F (1-y) \xi^2 \frac{1+(1-z)^2}{z} \mathcal{B},$$

where we have chosen  $z = E_{\text{rad}}/\bar{E}_{\text{em}}$  and  $\bar{E}_{\text{em}}$  denotes the emitter energy in the Born frame. The collinear final state imposes  $\bar{k}_n = k_n + k_{n+1}$  for the connection between  $\Phi_n$ - and  $\Phi_{n+1}$ -phasepace and we get  $1-z = E_{\text{em}}/\bar{E}_{\text{em}}$ . The denominator can be rewritten by the constraint  $\bar{k}_n^2 = (k_n + k_{n+1})^2 = 0$  to

$$k_{\text{em}}^2 = 2E_{\text{rad}}E_{\text{em}}(1-y)$$

which cancels the  $(1-y)$  factor in the numerator, thus showing that the whole expression is indeed collinear-finite. We can further transform

$$E_{\text{rad}}E_{\text{em}} = z(1-z)\bar{E}_{\text{em}}^2$$

so that in total we have

$$g^\alpha = \frac{4\pi\alpha_s}{1-z} \frac{1}{\bar{k}_{\text{em}}^2} C_F \left( \frac{\xi}{z} \right)^2 (1 + (1-z)^2) \mathcal{B}$$

Follow up calculations give us

$$g^{\alpha, g \rightarrow gg} = \frac{4\pi\alpha_s}{1-z} \frac{1}{\bar{k}_{\text{em}}^2} C_A \frac{\xi}{z} \left\{ 2 \left( \frac{z}{1-z} \xi + \frac{1-z}{\xi} \right) \mathcal{B} + 4\xi z(1-z) \hat{k}_\perp^\mu \hat{k}_\perp^\nu \mathcal{B}_{\mu\nu} \right\},$$

$$g^{\alpha, g \rightarrow qq} = \frac{4\pi\alpha_s}{1-z} \frac{1}{\bar{k}_{\text{em}}^2} T_R \frac{\xi}{z} \left\{ \xi \mathcal{B} - 4\xi z(1-z) \hat{k}_\perp^\mu \hat{k}_\perp^\nu \mathcal{B}_{\mu\nu} \right\}.$$

The ratio  $z/\xi$  is finite in the soft limit

$$\frac{z}{\xi} = \frac{q^0}{2E_{\text{em}}}$$

so that  $\xi$  does not appear explicitly in the computation.

The argumentation above is valid for  $q \rightarrow qg$ -splittings, but the general factorization is valid for general splittings, also for those involving spin correlations and QED splittings. Note that care has to be given to the definition of  $z$ . Further, we have factored out a factor of  $z$  to include in the ratio  $z/\xi$ , which has to be taken into account in the implementation of the splitting functions.

integer :: nlegs, flv_em, flv_rad
nlegs = size (flst)
flv_rad = flst(nlegs); flv_em = flst(emitter)
q0 = p_res**1
p0 = p_res * p_born(emitter) / q0
!!! Here, z corresponds to 1-z in the formulas of arXiv:1002.2581;
!!! the integrand is symmetric under this variable change
z_o_xi = q0 / (two * p0)
z = xi * z_o_xi; onemz = one - z
if (is_gluon (flv_em) .and. is_gluon (flv_rad)) then
  sqme = coll_sub%CA * ( two * ( z / onemz * xi + onemz / z_o_xi ) * sqme_born &
    + four * xi * z * onemz * mom_times_sqme_spin_c )
else if (is_fermion (flv_em) .and. is_fermion (flv_rad)) then
```

```

    sqme = coll_sub%TR * xi * (sqme_born - four * z * onemz * mom_times_sqme_spin_c)
  else if (is_fermion (flv_em) .and. is_massless_vector (flv_rad)) then
    sqme = sqme_born * coll_sub%CF * (one + onemz**2) / z_o_xi
  else
    sqme = zero
  end if
  sqme = sqme / (p0**2 * onemz * z_o_xi)
  sqme = sqme * four * pi * alpha_coupling
  if (double_fsr) sqme = sqme * onemz * two
end function coll_subtraction_compute_fsr

```

Like in the context of `coll_subtraction_compute_fsr` we compute the quantity

$$\lim_{y \rightarrow \pm 1} \left\{ \frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1 - y^2) \xi^2 \mathcal{R}^\alpha(\Phi_{n+1})] \right\},$$

where the  $(1 - y^2)$  accounts for both  $y = \pm 1$ . Again, the Jacobian is proportional to  $\xi$ , so we drop the  $J/\xi$  factor. Note that it is important to take into account this missing factor of  $\xi$  in the computation of the Jacobian during phase-space generation both for fixed-beam and structure ISR. We consider only a  $q \rightarrow qg$  splitting arguing that other splittings are identical in terms of the factors which cancel. It is given by

$$g^\alpha = \frac{8\pi\alpha_s}{-k_{\text{em}}^2} C_F (1 - y^2) \xi^2 \frac{1 + z^2}{1 - z} \mathcal{B},$$

where  $g^\alpha$  is defined akin to the one for FSR in eq. 27.34. Note the negative sign of  $k_{\text{em}}^2$  to compensate the negative virtuality of the initial-state emitter. For ISR,  $z$  is defined with respect to the emitter energy entering the hard interaction, i.e.

$$z = \frac{E_{\text{beam}} - E_{\text{rad}}}{E_{\text{beam}}} = 1 - \frac{E_{\text{rad}}}{E_{\text{beam}}}.$$

Because  $E_{\text{rad}} = E_{\text{beam}} \cdot \xi$ , it is  $z = 1 - \xi$ , thus one factor of  $\xi$  is cancelled by  $(1 - z)$  in the denominator of  $g^\alpha$ . The factor  $k_{\text{em}}^2$  in the denominator is rewritten as

$$k_{\text{em}}^2 = (p_{\text{beam}} - p_{\text{rad}})^2 = -2p_{\text{beam}} \cdot p_{\text{rad}} = -2E_{\text{beam}} E_{\text{rad}} (1 \pm y) = -2E_{\text{beam}}^2 (1 - z)(1 \pm y),$$

where we used

$$E_{\text{beam}} E_{\text{rad}} = E_{\text{beam}}^2 (1 - z).$$

This leads to the cancellation of the corresponding  $(1 \pm y)$  factor in  $(1 - y^2)$ , with the other factor becoming a simple factor of 2, and the remaining factor of  $\xi$  in the numerator. We thus end up with

$$g^\alpha = \frac{8\pi\alpha_s}{E_{\text{beam}}^2} C_F (1 + z^2) \mathcal{B},$$

which is soft-finite.

Note that here in `compute_isr`, `sqme_born` is supposed to be the squared Born matrix element convoluted with the real PDF.

#### 27.5.4 The real contribution to the cross section

In each singular region  $\alpha$ , the real contribution to  $\sigma$  is given by the second summand of eqn. ??,

$$\sigma_{\text{real}}^\alpha = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 dy \int_0^{\xi_{\text{max}}} d\xi \left( \frac{1}{\xi} \right)_+ \left( \frac{1}{1-y} \right)_+ \underbrace{\frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1-y)\xi^2 \mathcal{R}^\alpha(\Phi_{n+1})]}_{g^\alpha(\xi, y)} \quad (27.34)$$

Writing out the plus-distribution and introducing  $\tilde{\xi} = \xi/\xi_{\text{max}}$  to set the upper integration limit to 1, this turns out to be equal to

$$\begin{aligned} \sigma_{\text{real}}^\alpha = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 \frac{dy}{1-y} \left\{ \int_0^1 d\tilde{\xi} \left[ \frac{g^\alpha(\tilde{\xi}\xi_{\text{max}}, y)}{\tilde{\xi}} - \underbrace{\frac{g^\alpha(0, y)}{\tilde{\xi}}}_{\text{soft}} - \underbrace{\frac{g^\alpha(\tilde{\xi}\xi_{\text{max}}, 1)}{\tilde{\xi}}}_{\text{coll.}} + \underbrace{\frac{g^\alpha(0, 1)}{\tilde{\xi}}}_{\text{coll.+soft}} \right] \right. \\ \left. + [\log \xi_{\text{max}}(y)g^\alpha(0, y) - \log \xi_{\text{max}}(1)g^\alpha(0, 1)] \right\}. \end{aligned} \quad (27.35)$$

This formula is implemented in `compute_sqme_real_fin`

If two or more singular regions would produce the same amplitude we only compute one and use the `eqv_index` to copy the result to the others (if `reuse_amplitudes_fks` is true).

```

```
end function real_subtraction_sum_up_s_alpha
```

Sums up  $\sum_{i_1, i_2} S_{i_1 i_2}$  for the given alr. The soft S functions take the real momenta in the soft limit, i.e. the Born momenta. For each summand of `sum_s_alpha_soft` we take `p_soft` constructed from the emitter of the given alpha region also for ftuples in which the first integer `i1` does not coincide with the emitter. This is necessary because only if we keep `p_soft` fixed, all soft S functions are computed with the same denominator and thus add up to 1.

This subroutine computes the finite part of the real matrix element in an individual singular region. First, the radiation variables are fetched and  $\mathcal{R}$  is multiplied by the appropriate  $S_\alpha$ -factors, region multiplicities and double-FSR factors. Then, it computes the soft, collinear, soft-collinear and remnant matrix elements and supplies the corresponding factor  $1/\xi/(1-y)$  as well as the corresponding Jacobians.

```

Compares the real matrix element to the subtraction terms in the soft, the collinear or the soft-collinear limits. Used for debug purposes if ?test\_anti\_coll\_limit, ?test\_coll\_limit and/or ?test\_soft\_limit are set in the Sindarin. sqme\_soft and sqme\_cs need to be provided if called for FSR and sqme\_coll\_plus, sqme\_coll\_minus, sqme\_cs\_plus as well as sqme\_cs\_minus need to be provided if called for ISR.

For final state radiation, the subtraction remnant cross section is

$$\sigma_{\text{remn}} = (\sigma_{\text{soft}} - \sigma_{\text{soft-coll}}) \log(\xi_{\text{max}}) \cdot \frac{\tilde{\xi}}{\xi_{\text{cut}}}. \quad (27.36)$$

There is only one factor of  $\log(\xi_{\text{max}})$  for both limits as  $\xi_{\text{max}}$  does not depend on  $y$  in the case of FSR. We use the already computed `sqme_soft` and `sqme_cs` with a factor of  $\tilde{\xi}$  which we have to compensate. We also need a factor  $1/\xi_{\text{cut}}$  here to assure that the cross section is independent of this free cutoff parameter. However, it still remains to be motivated analytically.

Computes the soft remnant for ISR. The formulas can be found in arXiv:1002.2581, eq. 4.21. and arXiv:0709.2092, sec. 5.1.2. This results in

$$\sigma_{\text{remn}}^{\text{ISR}} = \log(\xi_{\text{max}}(y))\sigma_{\text{soft}} - \frac{1}{2}\log(\xi_{\text{max}}(1))\sigma_{\oplus}^{\text{soft-coll}} - \frac{1}{2}\log(\xi_{\text{max}}(-1))\sigma_{\ominus}^{\text{soft-coll}} \quad (27.37)$$

where for ISR,  $\xi_{\text{max}}$  does explicitly depend on  $y$  due to the rescaling of the  $x$  values from the Born to the real partonic system according to

$$x_{\oplus} = \frac{\bar{x}_{\oplus}}{\sqrt{1-\xi}} \sqrt{\frac{2-\xi(1-y)}{2-\xi(1+y)}}, \quad x_{\ominus} = \frac{\bar{x}_{\ominus}}{\sqrt{1-\xi}} \sqrt{\frac{2-\xi(1+y)}{2-\xi(1-y)}} \quad (27.38)$$

As  $\xi_{\text{max}}$  is determined by the fact that the real  $x_{\oplus}, x_{\ominus}$  have to stay in a physically meaningful regime, i.e.  $x_{\oplus}, x_{\ominus} < 1$ , this leads to

$$\xi_{\text{max}} = 1 - \max \left\{ \frac{2(1+y)\bar{x}_{\oplus}^2}{\sqrt{(1+\bar{x}_{\oplus}^2)^2(1-y)^2 + 16y\bar{x}_{\oplus}^2} + (1-y)(1-\bar{x}_{\oplus}^2)}, \quad (27.39)$$

$$\frac{2(1-y)\bar{x}_{\oplus}^2}{\sqrt{(1+\bar{x}_{\oplus}^2)^2(1+y)^2 - 16y\bar{x}_{\oplus}^2} + (1+y)(1-\bar{x}_{\oplus}^2)} \right\} \quad (27.40)$$

and thus

$$\xi_{\text{max}}(y=1) = 1 - \bar{x}_{\oplus} \quad (27.41)$$

$$\xi_{\text{max}}(y=-1) = 1 - \bar{x}_{\ominus} \quad (27.42)$$

So we need to use the unrescaled  $\bar{x}_{\oplus}, \bar{x}_{\ominus}$  here. Factors of  $\frac{1}{2}$  and  $\frac{1}{\xi}$  are already included in the matrix elements from `apply_kinematic_factors_subtraction_isr`. We keep the former and remove the latter by multiplying with  $\tilde{\xi}$ . The factor  $1/\xi_{\text{cut}}$  is probably needed to assure that the cross section is independent of this

free cutoff parameter in analogy to the FSR case. However, it still remains to be motivated analytically and to be validated.

This subroutine evaluates the soft and collinear subtraction terms for ISR. References:

- arXiv:0709.2092, sec. 2.4.2
- arXiv:0908.4272, sec. 4.2

For the collinear terms, the procedure is as follows:

If the emitter is 0, then a gluon was radiated from one of the incoming partons. Gluon emissions require two counter terms: One for emission in the direction of the first incoming parton  $\oplus$  and a second for emission in the direction of the second incoming parton  $\ominus$  because in both cases, there are divergent diagrams contributing to the matrix element. So in this case both, `sqme_coll_plus` and `sqme_coll_minus`, are non-zero.

If the emitter is 1 or 2, then a quark was emitted instead of a gluon. This only leads to a divergence collinear to the emitter because for anti-collinear quark emission, there are simply no divergent diagrams in the same region as two collinear quarks that cannot originate in the same splitting are non-divergent. This means that in case the emitter is 1, we need non-zero `sqme_coll_plus` and in case the emitter is 2, we need non-zero `sqme_coll_minus`.

At this point, we want to remind ourselves that in case of initial state divergences,  $y$  is just the polar angle, so the `sqme_coll_minus` terms are there to counter emissions in the direction of the second incoming parton  $\ominus$  and **not** to counter in general anti-collinear divergences.

This is basically the global part of the real Jacobian corresponding to

$$\frac{q^2}{8(2\pi)^3}.$$

We interpret it as the additional phase space factor of the real component, to be more consistent with the evaluation of the Born phase space.

We specifically use the Born center-of-mass energy here. The real center-of-mass energy is only different from the Born center-of-mass energy in case of ISR. The missing factor  $\frac{1}{1-\xi}$  for this conversion is supplied in `apply_kinematic_factors_radiation` and `phs_fks_generator_generate_isr`.

Computes the soft subtraction term. If there is an initial state emission having a soft divergence, then a gluon has to have been emitted. A gluon can always be emitted from both IS partons and thus, we can take the `sf_factor` for emitter 0 in this case. Be aware that this approach will not work for *pe* collisions.

## 27.7 Contribution of divergencies due to PDF Evolution

References:

- arXiv:hep-ph/9512328, (2.1)-(2.5), (4.29)-(4.53)
- arXiv:0709.2092, (2.102)-(2.106)

The parton distribution densities have to be evaluated at NLO, too. The NLO PDF evolution is given by

$$f(\bar{x}) = \int_0^1 \int_0^1 dx dz f(x) \Gamma(z) \delta(\bar{x} - xz), \quad (27.43)$$

where  $\Gamma$  are the DGLAP evolution kernels for an  $a \rightarrow d$  splitting,

$$\Gamma_a^{(d)} = \delta_{ad} \delta(1-x) - \frac{\alpha_s}{2\pi} \left( \frac{1}{\epsilon} P_{ad}(x, 0) - K_{ad}(x) \right) + \mathcal{O}(\alpha_s^2). \quad (27.44)$$

$K_{ad}$  is a renormalization scheme matching factor, which is exactly zero in  $\overline{\text{MS}}$ . Let the leading-order hadronic cross section be given by

$$d\sigma^{(0)}(s) = \int dx_{\oplus} dx_{\ominus} f_{\oplus}(x_{\oplus}) f_{\ominus}(x_{\ominus}) d\tilde{\sigma}^{(0)}(x_{\oplus} x_{\ominus} s), \quad (27.45)$$

then the NLO hadronic cross section is

$$d\sigma^{(1)}(s) = \int dx_{\oplus} dx_{\ominus} dz_{\oplus} dz_{\ominus} f_{\oplus}(x_{\oplus}) f_{\ominus}(x_{\ominus}) \underbrace{\Gamma_{\oplus}(z_{\oplus}) \Gamma_{\ominus}(z_{\ominus}) d\tilde{\sigma}^{(1)}(z_{\oplus} z_{\ominus} s)}_{d\hat{\sigma}^{(1)}}. \quad (27.46)$$

$d\hat{\sigma}$  is called the subtracted partonic cross section. Expanding in  $\alpha_s$  we find

$$d\hat{\sigma}_{ab}^{(0)}(k_1, k_2) = d\tilde{\sigma}_{ab}^{(0)}(k_1, k_2), \quad (27.47)$$

$$d\hat{\sigma}_{ab}^{(1)}(k_1, k_2) = d\tilde{\sigma}_{ab}^{(1)}(k_1, k_2) \quad (27.48)$$

$$+ \frac{\alpha_s}{2\pi} \sum_d \int dx \left( \frac{1}{\epsilon} P_{da}(x, 0) - K_{da}(x) \right) d\tilde{\sigma}_{db}^{(0)}(xk_1, k_2) \quad (27.49)$$

$$+ \frac{\alpha_s}{2\pi} \sum_d \int \left( \frac{1}{\epsilon} P_{db}(x, 0) - K_{db}(x) \right) d\tilde{\sigma}_{ad}^{(0)}(k_1, xk_2). \quad (27.50)$$

$$= d\tilde{\sigma}_{ab}^{(1)} + d\tilde{\sigma}_{ab}^{(cnt,+)} + d\tilde{\sigma}_{ab}^{(cnt,-)} \quad (27.51)$$

Let us now turn to the soft-subtracted real part of the cross section. For ease of notation, it is constrained to one singular region,

$$d\sigma_{\alpha}^{(in)} = \left[ \left( \frac{1}{\xi} \right)_c - 2\epsilon \left( \frac{\log \xi}{\xi} \right)_c \right] (1-y^2) \xi^2 \mathcal{R}_{\alpha} \mathcal{S}_{\alpha} \\ \times \frac{1}{2(2\pi)^{3-2\epsilon}} \left( \frac{\sqrt{s}}{2} \right)^{2-2\epsilon} (1-y^2)^{-1-\epsilon} d\phi d\xi dy d\Omega^{2-2\epsilon},$$

where we regularize collinear divergencies using the identity

$$(1 - y^2)^{-1-\epsilon} = -\frac{2^{-\epsilon}}{2\epsilon} (\delta(1 - y) + \delta(1 + y)) + \underbrace{\frac{1}{2} \left[ \left( \frac{1}{1 - y} \right)_c + \left( \frac{1}{1 + y} \right)_c \right]}_{\mathcal{P}(y)}.$$

This enables us to split the cross section into a finite and a singular part. The latter can further be separated into a contribution of the incoming and of the outgoing particles,

$$d\sigma_\alpha^{(in)} = d\sigma_\alpha^{(in,+)} + d\sigma_\alpha^{(in,-)} + d\sigma_\alpha^{(in,f)}.$$

They are given by

$$d\sigma_\alpha^{(in,f)} = \mathcal{P}(y) \left[ \left( \frac{1}{\xi} \right)_c - 2\epsilon \left( \frac{\log \xi}{\xi} \right)_c \right] \frac{1}{2(2\pi)^{3-2\epsilon}} \left( \frac{\sqrt{s}}{2} \right)^{2-2\epsilon} \times (1 - y^2) \xi^2 \mathcal{R}_\alpha \mathcal{S}_\alpha d\phi d\xi dy d\Omega^{2-2\epsilon} \quad (27.52)$$

and

$$d\sigma_\alpha^{(in,\pm)} = -\frac{2^{-\epsilon}}{2\epsilon} \delta(1 \mp y) \left[ \left( \frac{1}{\xi} \right)_c - 2\epsilon \left( \frac{\log \xi}{\xi} \right)_c \right] \times \frac{1}{2(2\pi)^{3-2\epsilon}} \left( \frac{\sqrt{s}}{2} \right)^{2-2\epsilon} (1 - y^2) \xi^2 \mathcal{R}_\alpha \mathcal{S}_\alpha d\phi d\xi dy d\Omega^{2-2\epsilon}. \quad (27.53)$$

Equation 27.52 is the contribution to the real cross section which is computed in `evaluate_region_isr`. It is regularized both in the soft and collinear limit via the plus distributions. Equation 27.53 is a different contribution. It is only present exactly in the collinear limit, due to the delta function. The divergences present in this term do not completely cancel out divergences in the virtual matrix element, because the beam axis is distinguished. Thus, the conditions in which the KLN theorem applies are not met. To see this, we carry out the collinear limit, obtaining

$$\lim_{y \rightarrow 1} (1 - y^2) \xi^2 \mathcal{R}_\alpha = 8\pi\alpha_s \mu^{2\epsilon} \left( \frac{2}{\sqrt{s}} \right)^2 \xi P^<(1 - \xi, \epsilon) \mathcal{R}_\alpha,$$

with the Altarelli-Parisi splitting kernel for  $z < 1$ ,  $P^<(z, \epsilon)$ . Moreover,  $\lim_{\vec{k} \parallel \vec{k}_1} d\phi = d\phi_3$  violates spatial averaging. The integration over the spherical angle  $d\Omega$  can be carried out easily, yielding a factor of  $2\pi^{1-\epsilon}/\Gamma(1 - \epsilon)$ . This allows us to redefine  $\epsilon$ ,

$$\frac{1}{\epsilon} - \gamma_E + \log(4\pi) \rightarrow \frac{1}{\epsilon}. \quad (27.54)$$

Coming back to  $d\tilde{\sigma}_{ab}^{(cnt,+)}$  in order to make a connection to  $d\sigma_\alpha^{(in,+)}$ , we relate  $P_{ab}(z, 0)$  to  $P_{ab}^<(z, 0)$  via the equation

$$P_{ab}(z, 0) = (1 - z) P_{ab}^<(z, 0) \left( \frac{1}{1 - z} \right)_+ + \gamma(a) \delta_{ab} \delta(1 - z),$$

which yields

$$d\tilde{\sigma}_\alpha^{(cnt,+)} = \frac{\alpha_s}{2\pi} \sum_d \left\{ -K_{da}(1 - \xi) + \frac{1}{\epsilon} \left[ \left( \frac{1}{\xi} \right)_+ \xi P_{da}^<(1 - \xi, 0) + \delta_{da} \delta(\xi) \gamma(d) \right] \right\} \mathcal{R}_\alpha \mathcal{S}_\alpha d\phi d\xi dy. \quad (27.55)$$

This term has the same pole structure as eqn. 27.53. This makes clear that the quantity

$$d\hat{\sigma}^{(in,+)} = d\tilde{\sigma}^{(in,+)} + d\tilde{\sigma}^{(cnt,+)} \quad (27.56)$$

has no collinear poles. Therefore, our task is to add up eqns. 27.53 and 27.55 in order to compute the finite remainder. This is the integrand which is evaluated in the `dglap_remnant` component.

So, we have to perform an expansion of  $d\hat{\sigma}^{(in,+)}$  in  $\epsilon$ . Hereby, we must not neglect the implicit  $\epsilon$ -dependence of  $P^<$ , which leads to additional terms involving the first derivative,

$$P_{ab}^<(z, \epsilon) = P_{ab}^<(z, 0) + \epsilon \frac{\partial P_{ab}^<(z, \epsilon)}{\partial \epsilon} \Big|_{\epsilon=0} + \mathcal{O}(\alpha_s^2).$$

This finally gives us the equation for the collinear remnant. Note that there is still one soft  $1/\epsilon$ -pole, which cancels out with the corresponding expression in the soft-virtual terms.

$$\begin{aligned} d\hat{\sigma}^{(in,+)} &= \frac{\alpha_s}{2\pi} \frac{1}{\epsilon} \gamma(a) \mathcal{R}_\alpha \mathcal{S}_\alpha \\ &+ \frac{\alpha_s}{2\pi} \sum_d \left\{ (1-z) P_{da}^<(z, 0) \left[ \left( \frac{1}{1-z} \right)_c \log \frac{s\delta_I}{2\mu^2} + 2 \left( \frac{\log(1-z)}{1-z} \right)_c \right] \right. \\ &\quad \left. - (1-z) \frac{\partial P_{da}^<(z, \epsilon)}{\partial \epsilon} \left( \frac{1}{1-z} \right)_c - K_{da}(z) \right\} \mathcal{R}_\alpha \mathcal{S}_\alpha d\phi d\xi dy \end{aligned} \quad (27.57)$$

```

Evaluates formula 27.57. Note that, as also in the case for the real subtraction, we have to take into account an additional term, occurring because the integral the plus distribution is evaluated over is not constrained on the interval  $[0, 1]$ .

Explicitly, this means (see JHEP 06(2010)043, (4.11)-(4.12))

$$\int_{\bar{x}_{\oplus}}^1 dz \left( \frac{1}{1-z} \right)_{\xi_{\text{cut}}} = \log \frac{1-\bar{x}_{\oplus}}{\xi_{\text{cut}}} f(1) + \int_{\bar{x}_{\oplus}}^1 \frac{f(z) - f(1)}{1-z}, \quad (27.58)$$

$$\int_{\bar{x}_{\oplus}}^1 dz \left( \frac{\log(1-z)}{1-z} \right)_{\xi_{\text{cut}}} f(z) = \frac{1}{2} (\log^2(1-\bar{x}_{\oplus}) - \log^2(\xi_{\text{cut}})) f(1) + \int_{\bar{x}_{\oplus}}^1 \frac{\log(1-z)[f(z) - f(1)]}{1-z}, \quad (27.59)$$

and the same of course for  $\bar{x}_{\ominus}$ . These two terms are stored in the `plus_dist_remnant` variable below.

The option `separate_uborns` allows to compute the contribution of the DGLAP remnant separately for each underlying Born flavor structure. We need this option during event generation to generate counter events with a specific Born flavor structure.

## Chapter 28

# Model Handling and Features

These modules deal with process definitions and physics models.

These modules use the `model_data` methods to automatically generate process definitions.

**auto\_components** Generic process-definition generator. We can specify a basic process or initial particle(s) and some rules to extend this process, given a model definition with particle names and vertex structures.

**radiation\_generator** Applies the generic generator to the specific problem of generating NLO corrections in a restricted setup.

Model construction:

**eval\_trees** Implementation of the generic `expr_t` type for the concrete evaluation of expressions that access user variables.

This module is actually part of the Sindarin language implementation, and should be moved elsewhere. Currently, the `models` module relies on it.

**models** Extends the `model_data.t` structure by user-variable objects for easy access, and provides the means to read a model definition from file.

**slha\_interface** Read/write a SUSY model in the standardized SLHA format. The format defines fields and parameters, but no vertices.

Figure 28.1: Module dependencies in `src/model_features`.

## 28.1 Automatic generation of process components

This module provides the functionality for automatically generating radiation corrections or decays, provided as lists of PDG codes.

```
<auto_components.f90>≡  
  <File header>  
  
  module auto_components

    <Auto components: interfaces>  
  
    contains  
  
    <Auto components: procedures>  
  
  end module auto_components
```

### 28.1.1 Constraints: Abstract types

An abstract type that denotes a constraint on the automatically generated states. The concrete objects are applied as visitor objects at certain hooks during the splitting algorithm.

```
<Auto components: types>≡  
  type, abstract :: split_constraint_t  
  contains  
    <Auto components: split constraint: TBP>  
  end type split_constraint_t
```

By default, all checks return true.

```
<Auto components: split constraint: TBP>≡  
  procedure :: check_before_split => split_constraint_check_before_split  
  procedure :: check_before_insert => split_constraint_check_before_insert  
  procedure :: check_before_record => split_constraint_check_before_record
```

```

<Auto components: procedures>≡
  subroutine split_constraint_check_before_split (c, table, pl, k, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: k
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_split

  subroutine split_constraint_check_before_insert (c, table, pa, pl, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_array_t), intent(in) :: pa
    type(pdg_list_t), intent(inout) :: pl
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_insert

  subroutine split_constraint_check_before_record (c, table, pl, n_loop, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_record

```

A transparent wrapper, so we can collect constraints of different type.

```

<Auto components: types>+≡
  type :: split_constraint_wrap_t
    class(split_constraint_t), allocatable :: c
  end type split_constraint_wrap_t

```

A collection of constraints.

```

<Auto components: public>≡
  public :: split_constraints_t

<Auto components: types>+≡
  type :: split_constraints_t
    class(split_constraint_wrap_t), dimension(:), allocatable :: cc
    contains
    <Auto components: split constraints: TBP>
  end type split_constraints_t

```

Initialize the constraints set with a specific number of elements.

```

<Auto components: split constraints: TBP>≡
  procedure :: init => split_constraints_init

<Auto components: procedures>+≡
  subroutine split_constraints_init (constraints, n)
    class(split_constraints_t), intent(out) :: constraints
    integer, intent(in) :: n

```

```

        allocate (constraints%cc (n))
    end subroutine split_constraints_init

```

Set a constraint.

```

<Auto components: split constraints: TBP>+≡
    procedure :: set => split_constraints_set

```

```

<Auto components: procedures>+≡
    subroutine split_constraints_set (constraints, i, c)
        class(split_constraints_t), intent(inout) :: constraints
        integer, intent(in) :: i
        class(split_constraint_t), intent(in) :: c
        allocate (constraints%cc(i)%c, source = c)
    end subroutine split_constraints_set

```

Apply checks.

`check_before_split` is applied to the particle list that we want to split.

`check_before_insert` is applied to the particle list `pl` that is to replace the particle `pa` that is split. This check may transform the particle list.

`check_before_record` is applied to the complete new particle list that results from splitting before it is recorded.

```

<Auto components: split constraints: TBP>+≡
    procedure :: check_before_split => split_constraints_check_before_split
    procedure :: check_before_insert => split_constraints_check_before_insert
    procedure :: check_before_record => split_constraints_check_before_record

```

```

<Auto components: procedures>+≡
    subroutine split_constraints_check_before_split &
        (constraints, table, pl, k, passed)
        class(split_constraints_t), intent(in) :: constraints
        class(ps_table_t), intent(in) :: table
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: k
        logical, intent(out) :: passed
        integer :: i
        passed = .true.
        do i = 1, size (constraints%cc)
            call constraints%cc(i)%c%check_before_split (table, pl, k, passed)
            if (.not. passed) return
        end do
    end subroutine split_constraints_check_before_split

    subroutine split_constraints_check_before_insert &
        (constraints, table, pa, pl, passed)
        class(split_constraints_t), intent(in) :: constraints
        class(ps_table_t), intent(in) :: table
        type(pdg_array_t), intent(in) :: pa
        type(pdg_list_t), intent(inout) :: pl
        logical, intent(out) :: passed
        integer :: i
        passed = .true.
        do i = 1, size (constraints%cc)
            call constraints%cc(i)%c%check_before_insert (table, pa, pl, passed)

```

```

        if (.not. passed) return
    end do
end subroutine split_constraints_check_before_insert

subroutine split_constraints_check_before_record &
    (constraints, table, pl, n_loop, passed)
    class(split_constraints_t), intent(in) :: constraints
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    integer :: i
    passed = .true.
    do i = 1, size (constraints%cc)
        call constraints%cc(i)%check_before_record (table, pl, n_loop, passed)
        if (.not. passed) return
    end do
end subroutine split_constraints_check_before_record

```

## 28.1.2 Specific constraints

### Number of particles

Specific constraint: The number of particles plus the number of loops, if any, must remain less than the given limit. Note that the number of loops is defined only when we are recording the entry.

```

<Auto components: types>+≡
    type, extends (split_constraint_t) :: constraint_n_tot
    private
    integer :: n_max = 0
    contains
    procedure :: check_before_split => constraint_n_tot_check_before_split

## Particles required in final state

Specific constraint: The entries in the recorded state must be a superset of the entries in the given list (for instance, the lowest-order state).

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_require
  private
  type(pdg_list_t) :: pl
  contains
  procedure :: check_before_record => constraint_require_check_before_record
end type constraint_require

```

We check the current state by matching all particle entries against the stored particle list, and crossing out the particles in the latter list when a match is found. The constraint passed if all entries have been crossed out.

For an `if_table` in particular, we check the final state only.

```

<Auto components: public>+≡
  public :: constrain_require

<Auto components: procedures>+≡
  function constrain_require (pl) result (c)

### 28.1.3 Tables of states

Automatically generate a list of possible process components for a given initial set (a single massive particle or a preset list of states).

The set of process components are generated by recursive splitting, applying constraints on the fly that control and limit the process. The generated states are accumulated in a table that we can read out after completion.

```

<Auto components: types>+≡
type, extends (pdg_list_t) :: ps_entry_t
  integer :: n_loop = 0
  integer :: n_rad = 0
  type(ps_entry_t), pointer :: previous => null ()
  type(ps_entry_t), pointer :: next => null ()
end type ps_entry_t

```

```

<Auto components: parameters>≡
integer, parameter :: PROC_UNDEFINED = 0
integer, parameter :: PROC_DECAY = 1
integer, parameter :: PROC_SCATTER = 2

```

This is the wrapper type for the decay tree for the list of final states and the final array. First, an abstract base type:

```

<Auto components: public>+≡
public :: ps_table_t

<Auto components: types>+≡
type, abstract :: ps_table_t
  private
  class(model_data_t), pointer :: model => null ()
  logical :: loops = .false.
  type(ps_entry_t), pointer :: first => null ()
  type(ps_entry_t), pointer :: last => null ()
  integer :: proc_type
contains
  <Auto components: ps table: TBP>
end type ps_table_t

```

The extensions: one for decay, one for generic final states. The decay-state table stores the initial particle. The final-state table is indifferent, and the initial/final state table treats the first two particles in its list as incoming antiparticles.

```

<Auto components: public>+≡
  public :: ds_table_t
  public :: fs_table_t
  public :: if_table_t

<Auto components: types>+≡
  type, extends (ps_table_t) :: ds_table_t
    private
      integer :: pdg_in = 0
    contains
      <Auto components: ds table: TBP>
    end type ds_table_t

  type, extends (ps_table_t) :: fs_table_t
    contains
      <Auto components: fs table: TBP>
    end type fs_table_t

  type, extends (fs_table_t) :: if_table_t
    contains
      <Auto components: if table: TBP>
    end type if_table_t

```

Finalizer: we must deallocate the embedded list.

```

<Auto components: ps table: TBP>≡
  procedure :: final => ps_table_final

<Auto components: procedures>+≡
  subroutine ps_table_final (object)
    class(ps_table_t), intent(inout) :: object

        do_not_check_regular = do_not_check_regular)
    current => current%next
end do
end subroutine fs_table_radiate

```

### 28.1.5 Splitting algorithm

Recursive splitting. First of all, we record the current `pdg_list` in the table, subject to `constraints`, if requested. We also record copies of the list marked as loop corrections.

When we record a particle list, we sort it first.

If there is room for splitting, We take a PDG array list and the index of an element, and split this element in all possible ways. The split entry is inserted into the list, which we split further.

The recursion terminates whenever the split array would have a length greater than  $n_{\max}$ .

*(Auto components: ps table: TBP)+≡*

```

procedure :: split => ps_table_split

```

*(Auto components: procedures)+≡*

```

recursive subroutine ps_table_split (table, pl, n_rad, constraints, &
    record, do_not_check_regular)
    class(ps_table_t), intent(inout) :: table
    class(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_rad
    type(split_constraints_t), intent(in) :: constraints
    logical, intent(in), optional :: record, do_not_check_regular
    integer :: n_loop, i
    logical :: passed, save_pdg_index
    type(vertex_iterator_t) :: vit
    integer, dimension(:), allocatable :: pdg1
    integer, dimension(:), allocatable :: pdg2
    if (present (record)) then
        if (record) then
            n_loop = 0
            INCR_LOOPS: do
                call table%record_sorted (pl, n_loop, n_rad, constraints, &
                    do_not_check_regular, passed)
                if (.not. passed) exit INCR_LOOPS
                if (.not. table%loops) exit INCR_LOOPS
                n_loop = n_loop + 1
            end do INCR_LOOPS
        end if
    end if
    select type (table)
    type is (if_table_t)
        save_pdg_index = .true.

```

```

class default
  save_pdg_index = .false.
end select
do i = 1, pl%get_size ()
  call constraints%check_before_split (table, pl, i, passed)
  if (passed) then
    pdg1 = pl%get (i)
    call vit%init (table%model, pdg1, save_pdg_index)
    SCAN_VERTICES: do
      call vit%get_next_match (pdg2)
      if (allocated (pdg2)) then
        call table%insert (pl, n_rad, i, pdg2, constraints, &
          do_not_check_regular = do_not_check_regular)
      else
        exit SCAN_VERTICES
      end if
    end do SCAN_VERTICES
  end if
end do
end subroutine ps_table_split

```

The worker part: insert the list of particles found by vertex matching in place of entry *i* in the PDG list. Then split/record further.

The *n\_in* parameter tells the replacement routine to insert the new particles after entry *n\_in*. Otherwise, they follow index *i*.

*(Auto components: ps table: TBP)+≡*

```

procedure :: insert => ps_table_insert

```

*(Auto components: procedures)+≡*

```

recursive subroutine ps_table_insert &
  (table, pl, n_rad, i, pdg, constraints, n_in, do_not_check_regular)
class(ps_table_t), intent(inout) :: table
class(pdg_list_t), intent(in) :: pl

if (passed) then
  if (.not. is_colored_isr ()) return
  call table%split (pl%replace (i, pl_insert, n_in), n_rad + s - 1, &
    constraints, record = .true., do_not_check_regular = .true.)
end if
contains
  logical function is_colored_isr () result (ok)

```

```

type(pdg_list_t) :: pl_replaced
ok = .true.
if (present (n_in)) then
  if (i <= n_in) then
    ok = pl_insert%contains_colored_particles ()
    if (.not. ok) then
      pl_replaced = pl%replace (i, pl_insert, n_in)
      associate (size_replaced => pl_replaced%get_pdg_sizes (), &
        size => pl%get_pdg_sizes ())
        ok = all (size_replaced(:n_in) == size(:n_in))
      end associate
    end if
  end if
end if
end function is_colored_isr
end subroutine ps_table_insert

```

Special case: If we are splitting an initial particle, there is slightly more to do. We loop over the particles from the vertex match and replace the initial particle by each of them in turn. The remaining particles must be appended after the second initial particle, so they will end up in the out state. This is done by providing the `n_in` argument to the base method as an optional argument.

Note that we must call the base-method procedure explicitly, so the `table` argument keeps its dynamic type as `if_table` inside this procedure.

```

<Auto components: if table: TBP>+≡
  procedure :: insert => if_table_insert

<Auto components: procedures>+≡
  recursive subroutine if_table_insert &

### 28.1.6 Tools

Compute the mass sum for a PDG list object, counting the entries with indices between (including) `n1` and `n2`. Rely on the requirement that if an entry is a PDG array, this array must be degenerate in mass.

```

<Auto components: procedures>+≡
function mass_sum (pl, n1, n2, model) result (m)
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n1, n2
    class(model_data_t), intent(in), target :: model
    integer, dimension(:), allocatable :: pdg
    real(default) :: m
    type(field_data_t), pointer :: prt
    integer :: i
    m = 0
    do i = n1, n2
        pdg = pl%get (i)
        prt => model%get_field_ptr (pdg(1))
        m = m + prt%get_mass ()
    end do
end function mass_sum

```

Invert a PDG array, replacing particles by antiparticles. This depends on the model.

```

<Auto components: procedures>+≡
function invert_pdg_array (pa, model) result (pa_inv)
    type(pdg_array_t), intent(in) :: pa
    class(model_data_t), intent(in), target :: model
    type(pdg_array_t) :: pa_inv
    type(field_data_t), pointer :: prt
    integer :: i, pdg
    pa_inv = pa
    do i = 1, pa_inv%get_length ()
        pdg = pa_inv%get (i)
        prt => model%get_field_ptr (pdg)
        if (prt%has_antiparticle ()) call pa_inv%set (i, -pdg)
    end do
end function invert_pdg_array

```

```

We need to reset the `reshuffle_list` in order to deal with subsequent usages of the `radiation_generator`. Below is obviously the lazy and dirty solution. Otherwise, we would have to equip this auxiliary type with additional information about `last` and `previous` pointers. Considering that at most  $n_{\text{legs}}$  integers are saved in the lists, and that the subroutine is only called during the initialization phase (more precisely: at the moment only in the `radiation_generator` unit tests), I think this quick fix is justified.

## 28.3 Sindarin Expression Implementation

This module defines expressions of all kinds, represented in a tree structure, for repeated evaluation. This provides an implementation of the `expr_base` abstract type.

We have two flavors of expressions: one with particles and one without particles. The latter version is used for defining cut/selection criteria and for online analysis.

```
<eval_trees.f90>≡  
  <File header>  
  
  module eval_trees

```

### 28.3.1 Tree nodes

The evaluation tree consists of branch nodes (unary and binary) and of leaf nodes, originating from a common root. The node object should be polymorphic. For the time being, polymorphism is emulated here. This means that we have to maintain all possibilities that the node may hold, including associated procedures as pointers.

The following parameter values characterize the node. Unary and binary operators have sub-nodes. The other are leaf nodes. Possible leafs are literal constants or named-parameter references.

*<Eval trees: types>*≡

```
integer, parameter :: EN_UNKNOWN = 0, EN_UNARY = 1, EN_BINARY = 2
integer, parameter :: EN_CONSTANT = 3, EN_VARIABLE = 4
integer, parameter :: EN_CONDITIONAL = 5, EN_BLOCK = 6
integer, parameter :: EN_RECORD_CMD = 7
integer, parameter :: EN_OBS1_INT = 11, EN_OBS2_INT = 12
integer, parameter :: EN_OBS1_REAL = 21, EN_OBS2_REAL = 22
integer, parameter :: EN_PRT_FUN_UNARY = 101, EN_PRT_FUN_BINARY = 102
integer, parameter :: EN_EVAL_FUN_UNARY = 111, EN_EVAL_FUN_BINARY = 112
integer, parameter :: EN_LOG_FUN_UNARY = 121, EN_LOG_FUN_BINARY = 122
integer, parameter :: EN_INT_FUN_UNARY = 131, EN_INT_FUN_BINARY = 132
integer, parameter :: EN_REAL_FUN_UNARY = 141, EN_REAL_FUN_BINARY = 142
integer, parameter :: EN_FORMAT_STR = 161
```

This is exported only for use within unit tests.

    case (V_STR); allocate (node%sval)
  end select
  allocate (node%value_is_known)
  node%value_is_known = .false.
end subroutine eval_node_allocate_value
```

Initialize a block node which contains, in addition to the expression to be evaluated, a variable definition. The result type is not yet assigned, because we can compile the enclosed expression only after the var list is set up.

Note that the node always allocates a new variable list and appends it to the current one. Thus, if the variable redefines an existing one, it only shadows it but does not reset it. Any side-effects are therefore absent and need not be undone outside the block.

If the flag **new** is set, a variable is (re)declared. This must not be done for intrinsic variables. Vice versa, if the variable is not existent, the **new** flag is

required.

*(Eval trees: procedures)*+≡

```

subroutine eval_node_init_block (node, name, type, var_def, var_list)
  type(eval_node_t), intent(out), target :: node
  type(string_t), intent(in) :: name

  end if
  call eval_node_allocate_value (node)
  node%arg0 => arg
end subroutine eval_node_set_expr

```

Initialize a conditional. There are three branches: the condition (evaluates to logical) and the two alternatives (evaluate both to the same arbitrary type).

```

<Eval trees: procedures>+≡
subroutine eval_node_init_conditional (node, result_type, cond, arg1, arg2)
  type(eval_node_t), intent(out) :: node
  integer, intent(in) :: result_type
  type(eval_node_t), intent(in), target :: cond, arg1, arg2
  node%type = EN_CONDITIONAL
  node%tag = "cond"
  node%result_type = result_type
  call eval_node_allocate_value (node)
  node%arg0 => cond
  node%arg1 => arg1
  node%arg2 => arg2
end subroutine eval_node_init_conditional

```

Initialize a recording command (which evaluates to a logical constant). The first branch is the ID of the analysis object to be filled, the optional branches 1 to 4 are the values to be recorded.

If the event-weight pointer is null, we record values with unit weight. Otherwise, we use the value pointed to as event weight.

There can be up to four arguments which represent  $x$ ,  $y$ ,  $\Delta y$ ,  $\Delta x$ . Therefore, this is the only node type that may fill four sub-nodes.

```

<Eval trees: procedures>+≡
subroutine eval_node_init_record_cmd &
  (node, event_weight, id, arg1, arg2, arg3, arg4)
  type(eval_node_t), intent(out) :: node
  real(default), pointer :: event_weight
  type(eval_node_t), intent(in), target :: id
  type(eval_node_t), intent(in), optional, target :: arg1, arg2, arg3, arg4
  call eval_node_init_log (node, .true.)
  node%type = EN_RECORD_CMD
  node%rval => event_weight
  node%tag = "record_cmd"
  node%arg0 => id
  if (present (arg1)) then
    node%arg1 => arg1
    if (present (arg2)) then

```

```

        node%arg2 => arg2
        if (present (arg3)) then
            node%arg3 => arg3
            if (present (arg4)) then
                node%arg4 => arg4
            end if
        end if
    end if
end if
end if
end subroutine eval_node_init_record_cmd

```

Initialize a node for operations on subevents. The particle lists (one or two) are inserted as `arg1` and `arg2`. We allocated particle pointers as temporaries for iterating over particle lists. The procedure pointer which holds the function to evaluate for the subevents (e.g., combine, select) is also initialized.

*(Eval trees: procedures)+≡*

```

subroutine eval_node_init_prt_fun_unary (node, arg1, name, proc)
    type(eval_node_t), intent(out) :: node
    type(eval_node_t), intent(in), target :: arg1
    type(string_t), intent(in) :: name

  node%arg0 => fmt
  node%arg1 => arg
  allocate (node%ival)
  node%ival = n_args
end subroutine eval_node_init_format_string

```

If particle functions depend upon a condition (or an expression is evaluated), the observables that can be evaluated for the given particles have to be thrown on the local variable stack. This is done here. Each observable is initialized with the particle pointers which have been allocated for the node.

The integer variable that is referred to by the `Index` pseudo-observable is always known when it is referred to.

*(Eval trees: procedures)*+≡

```

subroutine eval_node_set_observables (node, var_list)

### 28.3.2 Operation types

For the operations associated to evaluation tree nodes, we define abstract interfaces for all cases.

Particles/subevents are transferred by-reference, to avoid unnecessary copying. Therefore, subroutines instead of functions.

*(Eval trees: interfaces)*≡

```
abstract interface
  logical function unary_log (arg)
    import eval_node_t
    type(eval_node_t), intent(in) :: arg
  end function unary_log
end interface
abstract interface
  integer function unary_int (arg)
    import eval_node_t
    type(eval_node_t), intent(in) :: arg
  end function unary_int
end interface
abstract interface
  real(default) function unary_real (arg)
    import default
    import eval_node_t
    type(eval_node_t), intent(in) :: arg
  end function unary_real
end interface
abstract interface
  complex(default) function unary_cmplx (arg)
    import default
    import eval_node_t
    type(eval_node_t), intent(in) :: arg
  end function unary_cmplx
end interface
abstract interface
  subroutine unary_pdg (pdg_array, arg)
    import pdg_array_t
    import eval_node_t
    type(pdg_array_t), intent(out) :: pdg_array

### 28.3.3 Specific operators

Our expression syntax contains all Fortran functions that make sense. These functions have to be provided in a form that they can be used in procedures pointers, and have the abstract interfaces above. For some intrinsic functions, we could use specific versions provided by Fortran directly. However, this has two drawbacks: (i) We should work with the values instead of the eval-nodes as argument, which complicates the interface; (ii) more importantly, the **default** real type need not be equivalent to double precision. This would, at least, introduce system dependencies. Finally, for operators there are no specific versions.

Therefore, we write wrappers for all possible functions, at the expense of some overhead.

#### Binary numerical functions

*(Eval trees: procedures)* + ≡

```

integer function add_ii (en1, en2) result (y)
  type(eval_node_t), intent(in) :: en1, en2
  y = en1%ival + en2%ival
end function add_ii

real(default) function add_ir (en1, en2) result (y)
  type(eval_node_t), intent(in) :: en1, en2
  y = en1%ival + en2%rval
end function add_ir

complex(default) function add_ic (en1, en2) result (y)
  type(eval_node_t), intent(in) :: en1, en2

```

```

    y = en1%ival + en2%cval

## Binary particle-list functions

This joins two subevents, stored in the evaluation nodes **en1** and **en2**. If **en0** is also present, it amounts to a logical test returning true or false for every pair of particles. A particle of the second list gets a mask entry only if it passes the test for all particles of the first list.

*(Eval trees: procedures)+≡*

```

subroutine join_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:), allocatable :: mask2
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    allocate (mask2 (n2))
    mask2 = .true.
    if (present (en0)) then
        do i = 1, n1
            en0%index = i
            en0%prt1 = subevt_get_prt (en1%pval, i)
            do j = 1, n2
                en0%prt2 = subevt_get_prt (en2%pval, j)
                call eval_node_evaluate (en0)
                mask2(j) = mask2(j) .and. en0%lval
            end do
        end do
    end if
    call subevt_join (subevt, en1%pval, en2%pval, mask2)
end subroutine join_pp

```

Combine two subevents, i.e., make a list of composite particles built from all possible particle pairs from the two lists. If **en0** is present, create a mask which is true only for those pairs that pass the test.

*(Eval trees: procedures)+≡*

```

subroutine combine_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:,:), allocatable :: mask12
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    if (present (en0)) then
        allocate (mask12 (n1, n2))
        do i = 1, n1

## Binary string functions

Currently, the only string operation is concatenation.

*(Eval trees: procedures)+≡*

```

subroutine concat_ss (string, en1, en2)
    type(string_t), intent(out) :: string
    type(eval_node_t), intent(in) :: en1, en2
    string = en1%sval // en2%sval
end subroutine concat_ss

```

## 28.3.4 Compiling the parse tree

The evaluation tree is built recursively by following a parse tree. Evaluate an expression. The requested type is given as an optional argument; default is numeric (integer or real).

*(Eval trees: procedures)+≡*

```

recursive subroutine eval_node_compile_genexpr &
    (en, pn, var_list, result_type)
    type(eval_node_t), pointer :: en
    type(parse_node_t), intent(in) :: pn
    type(var_list_t), intent(in), target :: var_list
    integer, intent(in), optional :: result_type
    if (debug_active (D_MODEL_F)) then
        print *, "read genexpr"; call parse_node_write (pn)
    end if
    if (present (result_type)) then

```

```

    print *, "done genexpr"
end if
end subroutine eval_node_compile_genexpr

```

## Numeric expressions

This procedure compiles a numerical expression. This is a single term or a sum or difference of terms. We have to account for all combinations of integer and real arguments. If both are constant, we immediately do the calculation and allocate a constant node.

*(Eval trees: procedures)+≡*

```

```

Real, complex and integer values are numeric literals with an optional unit attached. In case of an integer, the unit actually makes it a real value in disguise. The signed version of real values is not possible in generic expressions; it is a special case for numeric constants in model files (see below). We do not introduce signed versions of complex values.

```

Compile a variable, with or without a specified type. Take the list of variables, look for the name and make a node with a pointer to the value. If no type is provided, the variable is numeric, and the stored value determines whether it is real or integer.

We explicitly demand that the variable is defined, so we do not accidentally point to variables that are declared only later in the script but have come into existence in a previous compilation pass.

Variables may actually be anonymous, these are expressions in disguise. In that case, the expression replaces the variable name in the parse tree, and we allocate an ordinary expression node in the eval tree.

Variables of type V.PDG (pdg-code array) are not treated here. They are handled by `eval_node_compile_cvariable`.

end subroutine check_var_type

```

Retrieve the result of an integration. If the requested process has been integrated, the results are available as special variables. (The variables cannot be accessed in the usual way since they contain brackets in their names.)

Since this compilation step may occur before the processes have been loaded, we have to initialize the required variables before they are used.

## Variable definition

A block expression contains a variable definition (first argument) and an expression where the definition can be used (second argument). The `result_type` decides which type of expression is expected for the second argument. For numeric variables, if there is a mismatch between real and integer type, insert an extra node for type conversion.

## Conditionals

A conditional has the structure `if lexpr then expr else expr`. So we first evaluate the logical expression, then depending on the result the first or second expression. Note that the second expression is mandatory.

The `result_type`, if present, defines the requested type of the `then` and `else` clauses. Default is numeric (int/real). If there is a mismatch between real and integer result types, insert conversion nodes.

*(Eval trees: procedures)+≡*

```

## Comparisons

Up to the loop, this is easy. There is always at least one comparison. This is evaluated, and the result is the logical node *en*. If it is constant, we keep its

second sub-node as **en2**. (Thus, at the very end **en2** has to be deleted if **en** is (still) constant.)

If there is another comparison, we first check if the first comparison was constant. In that case, there are two possibilities: (i) it was true. Then, its right-hand side is compared with the new right-hand side, and the result replaces the previous one which is deleted. (ii) it was false. In this case, the result of the whole comparison is false, and we can exit the loop without evaluating anything else.

Now assume that the first comparison results in a valid branch, its second sub-node kept as **en2**. We first need a copy of this, which becomes the new left-hand side. If **en2** is constant, we make an identical constant node **en1**. Otherwise, we make **en1** an appropriate pointer node. Next, the first branch is saved as **en0** and we evaluate the comparison between **en1** and the a right-hand side. If this turns out to be constant, there are again two possibilities: (i) true, then we revert to the previous result. (ii) false, then the wh

end subroutine eval_node_compile_compared_expr

```

This takes two extra arguments: **en1**, the left-hand-side of the comparison, is already allocated and evaluated. **en2** (the right-hand side) and **en** (the result) are allocated by the routine. **pn** is the parse node which contains the operator and the right-hand side as subnodes.

If the result of the comparison is constant, **en1** is deleted but **en2** is kept, because it may be used in a subsequent comparison. **en** then becomes a constant. If the result is variable, **en** becomes a branch node which refers to **en1** and **en2**.

        print *, "done pterm"
    end if
end subroutine eval_node_compile_pterm

```

A particle-list value is a PDG-code array, a particle identifier, a variable, a (grouped) pexpr, a block pexpr, a conditional, or a particle-list function.

The `cexpr` node is responsible for transforming a constant PDG-code array into a subevent. It takes the code array as its first argument, the event subevent as its second argument, and the requested particle type (incoming/outgoing) as its zero-th argument. The result is the list of particles in the event that match the code array.

## Particle functions

This combines the treatment of 'join', 'combine', 'collect', 'cluster', 'select', and 'extract', as well as the functions for  $b$ ,  $c$  and light jet selection and photon recombination which all have the same syntax. The one or two argument nodes are allocated. If there is a condition, the condition node is also allocated as a logical expression, for which the variable list is augmented by the appropriate (unary/binary) observables.

### 28.3.5 Auxiliary functions for the compiler

Issue an error that the current node could not be compiled because of type mismatch:

```

<Eval trees: procedures>+≡
subroutine eval_type_error (pn, string, t)
  type(parse_node_t), intent(in) :: pn
  character(*), intent(in) :: string
  integer, intent(in) :: t
  type(string_t) :: type

```

```

select case (t)
case (V_NONE); type = "(none)"
case (V_LOG); type = "'logical'"
case (V_INT); type = "'integer'"
case (V_REAL); type = "'real'"
case (V_CMPLX); type = "'complex'"
case default; type = "(unknown)"
end select
call parse_node_write (pn)
call msg_fatal (" The " // string // &
               " operation is not defined for the given argument type " // &
               char (type))
end subroutine eval_type_error

```

If two numerics are combined, the result is integer if both arguments are integer, if one is integer and the other real or both are real, than its argument is real, otherwise complex.

*(Eval trees: procedures)*+≡

```

function numeric_result_type (t1, t2) result (t)
integer, intent(in) :: t1, t2
integer :: t
if (t1 == V_INT .and. t2 == V_INT) then
t = V_INT
else if (t1 == V_INT .and. t2 == V_REAL) then
t = V_REAL
else if (t1 == V_REAL .and. t2 == V_INT) then
t = V_REAL
else if (t1 == V_REAL .and. t2 == V_REAL) then
t = V_REAL
else
t = V_CMPLX
end if
end function numeric_result_type

```

### 28.3.6 Evaluation

Evaluation is done recursively. For leaf nodes nothing is to be done.

Evaluating particle-list functions: First, we evaluate the particle lists. If a condition is present, we assign the particle pointers of the condition node to the allocated particle entries in the parent node, keeping in mind that the observables in the variable stack used for the evaluation of the condition also contain pointers to these entries. Then, the assigned procedure is evaluated, which sets the subevent in the parent node. If required, the procedure evaluates the condition node once for each (pair of) particles to determine the result.

*(Eval trees: procedures)*+≡

```

### Test method

This is called from a unit test: initialize a particular observable.

*<Eval trees: eval node: TBP>+≡*

```

procedure :: test_obs => eval_node_test_obs

```

*<Eval trees: procedures>+≡*

```

subroutine eval_node_test_obs (node, var_list, var_name)
    class(eval_node_t), intent(inout) :: node
    type(var_list_t), intent(in) :: var_list
    type(string_t), intent(in) :: var_name
    procedure(obs_unary_int), pointer :: obs1_iptr
    type(prt_t), pointer :: p1
    call var_list%get_obs1_iptr (var_name, obs1_iptr, p1)
    call eval_node_init_obs1_int_ptr (node, var_name, obs1_iptr, p1)
end subroutine eval_node_test_obs

```

### 28.3.7 Evaluation syntax

We have two different flavors of the syntax: with and without particles.

*<Eval trees: public>+≡*

```

    public :: syntax_expr
    public :: syntax_pexpr
  <Eval trees: variables>≡
    type(syntax_t), target, save :: syntax_expr
    type(syntax_t), target, save :: syntax_pexpr

```

These are for testing only and may be removed:

```

  <Eval trees: public>+≡
    public :: syntax_expr_init
    public :: syntax_pexpr_init
  <Eval trees: procedures>+≡
    subroutine syntax_expr_init ()
      type(ifile_t) :: ifile
      call define_expr_syntax (ifile, particles=.false., analysis=.false.)
      call syntax_init (syntax_expr, ifile)
      call ifile_final (ifile)
    end subroutine syntax_expr_init

    subroutine syntax_pexpr_init ()
      type(ifile_t) :: ifile
      call define_expr_syntax (ifile, particles=.true., analysis=.false.)
      call syntax_init (syntax_pexpr, ifile)
      call ifile_final (ifile)
    end subroutine syntax_pexpr_init

  <Eval trees: public>+≡
    public :: syntax_expr_final
    public :: syntax_pexpr_final
  <Eval trees: procedures>+≡
    subroutine syntax_expr_final ()
      call syntax_final (syntax_expr)
    end subroutine syntax_expr_final

    subroutine syntax_pexpr_final ()
      call syntax_final (syntax_pexpr)
    end subroutine syntax_pexpr_final

  <Eval trees: public>+≡
    public :: syntax_pexpr_write
  <Eval trees: procedures>+≡
    subroutine syntax_pexpr_write (unit)
      integer, intent(in), optional :: unit
      call syntax_write (syntax_pexpr, unit)
    end subroutine syntax_pexpr_write

  <Eval trees: public>+≡
    public :: define_expr_syntax

```

Numeric expressions.

```

  <Eval trees: procedures>+≡
    subroutine define_expr_syntax (ifile, particles, analysis)

```

```

### 28.3.9 The evaluation tree

The evaluation tree contains the initial variable list and the root node.

```

<Eval trees: public>+≡
  public :: eval_tree_t

<Eval trees: types>+≡
  type, extends (expr_t) :: eval_tree_t
  private
    type(parse_node_t), pointer :: pn => null ()
    type(var_list_t) :: var_list
    type(eval_node_t), pointer :: root => null ()
  contains
    <Eval trees: eval tree: TBP>
  end type eval_tree_t

```

Init from stream, using a temporary parse tree.

```

<Eval trees: eval tree: TBP>≡
  procedure :: init_stream => eval_tree_init_stream

<Eval trees: procedures>+≡
  subroutine eval_tree_init_stream &
    (eval_tree, stream, var_list, subvt, result_type)
    class(eval_tree_t), intent(out), target :: eval_tree
    type(stream_t), intent(inout), target :: stream
    type(var_list_t), intent(in), target :: var_list
    type(subvt_t), intent(in), target, optional :: subvt
    integer, intent(in), optional :: result_type
    type(parse_tree_t) :: parse_tree
    type(parse_node_t), pointer :: nd_root
    integer :: type
    type = V_REAL; if (present (result_type)) type = result_type
    select case (type)
    case (V_INT, V_REAL, V_CMPLX)
      call parse_tree_init_expr (parse_tree, stream, present (subvt))
    case (V_LOG)
      call parse_tree_init_lexpr (parse_tree, stream, present (subvt))
    case (V_SEV)
      call parse_tree_init_pexpr (parse_tree, stream)

```

```

case (V_PDG)
  call parse_tree_init_cexpr (parse_tree, stream)
case (V_STR)
  call parse_tree_init_sexpr (parse_tree, stream, present (subevt))
end select
nd_root => parse_tree%get_root_ptr ()
if (associated (nd_root)) then
  select case (type)
  case (V_INT, V_REAL, V_CMPLX)
    call eval_tree_init_expr (eval_tree, nd_root, var_list, subevt)
  case (V_LOG)
    call eval_tree_init_lexpr (eval_tree, nd_root, var_list, subevt)
  case (V_SEV)
    call eval_tree_init_pexpr (eval_tree, nd_root, var_list, subevt)
  case (V_PDG)
    call eval_tree_init_cexpr (eval_tree, nd_root, var_list, subevt)
  case (V_STR)
    call eval_tree_init_sexpr (eval_tree, nd_root, var_list, subevt)
  end select
end if
call parse_tree_final (parse_tree)
end subroutine eval_tree_init_stream

```

API (to be superseded by the methods below): Init from a given parse-tree node. If we evaluate an expression that contains particle-list references, the original subevent has to be supplied. The initial variable list is optional.

*<Eval trees: eval tree: TBP>+≡*

```

    if (present (ival)) ival = 0
    if (present (rval)) rval = 0
    if (present (cval)) cval = 0
    if (present (is_known)) is_known = .false.
end if
if (present (result_type)) &
    result_type = eval_tree_get_result_type (eval_tree)
call eval_tree_final (eval_tree)
end subroutine eval_numeric

```

Error message with debugging info:

```

<Eval trees: procedures>+≡
subroutine eval_tree_unknown (eval_tree, parse_node)
    type(eval_tree_t), intent(in) :: eval_tree
    type(parse_node_t), intent(in) :: parse_node
    call parse_node_write_rec (parse_node)
    call eval_tree_write (eval_tree)
    call msg_error ("Evaluation yields an undefined result, inserting default")
end subroutine eval_tree_unknown

```

### 28.3.11 Factory Type

Since `eval_tree_t` is an implementation of `expr_t`, we also need a matching factory type and build method.

```

<Eval trees: public>+≡
public :: eval_tree_factory_t

<Eval trees: types>+≡
type, extends (expr_factory_t) :: eval_tree_factory_t
private
    type(parse_node_t), pointer :: pn => null ()
contains
<Eval trees: eval tree factory: TBP>
end type eval_tree_factory_t

```

Output: delegate to the output of the embedded parse node.

```
<Eval trees: eval tree factory: TBP>≡
  procedure :: write => eval_tree_factory_write

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_write (expr_factory, unit)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    integer, intent(in), optional :: unit
    if (associated (expr_factory%pn)) then
      call parse_node_write_rec (expr_factory%pn, unit)
    end if
  end subroutine eval_tree_factory_write
```

Initializer: take a parse node and hide it thus from the environment.

```
<Eval trees: eval tree factory: TBP>+≡
  procedure :: init => eval_tree_factory_init

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_init (expr_factory, pn)
    class(eval_tree_factory_t), intent(out) :: expr_factory
    type(parse_node_t), intent(in), pointer :: pn
    expr_factory%pn => pn
  end subroutine eval_tree_factory_init
```

Factory method: allocate expression with correct eval tree type. If the stored parse node is not associate, don't allocate.

```
<Eval trees: eval tree factory: TBP>+≡
  procedure :: build => eval_tree_factory_build

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_build (expr_factory, expr)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    class(expr_t), intent(out), allocatable :: expr
    if (associated (expr_factory%pn)) then
      allocate (eval_tree_t :: expr)
      select type (expr)
        type is (eval_tree_t)
          expr%pn => expr_factory%pn
        end select
      end if
    end subroutine eval_tree_factory_build
```

### 28.3.12 Unit tests

## 28.4 Physics Models

A model object represents a physics model. It contains a table of particle data, a list of parameters, and a vertex table. The list of parameters is a variable list which includes the real parameters (which are pointers to the particle data table) and PDG array variables for the particles themselves. The vertex list is used for phase-space generation, not for calculating the matrix element.

The actual numeric model data are in the base type `model_data_t`, as part of the `qft` section. We implement the `model_t` as an extension of this, for convenient direct access to the base-type methods via inheritance. (Alternatively, we could delegate these calls explicitly.) The extension contains administrative additions, such as the methods for recalculating derived data and keeping the parameter set consistent. It thus acts as a proxy of the actual model-data object towards the WHIZARD package. There are further proxy objects, such as the `parameter_t` array which provides the interface to the actual numeric parameters.

Model definitions are read from model files. Therefore, this module contains a parser for model files. The parameter definitions (derived parameters) are Sindarin expressions.

The models, as read from file, are stored in a model library which is a simple list of model definitions. For setting up a process object we should make a copy (an instance) of a model, which gets the current parameter values from the global variable list.

### 28.4.1 Module

```

    <Models: parameters>

    <Models: types>

    <Models: interfaces>

    <Models: variables>

contains

    <Models: procedures>

end module models

```

## 28.4.2 Physics Parameters

A parameter has a name, a value. Derived parameters also have a definition in terms of other parameters, which is stored as an `eval_tree`. External parameters are set by an external program.

This parameter object should be considered as a proxy object. The parameter name and value are stored in a corresponding `modelpar_data_t` object which is located in a `model_data_t` object. The latter is a component of the `model_t` handler. Methods of `parameter_t` can be delegated to the `par_data_t` component.

The `block_name` and `block_index` values, if nonempty, indicate the possibility of reading this parameter from a SLHA-type input file. (Within the `parameter_t` object, this info is just used for I/O, the actual block register is located in the parent `model_t` object.)

The `pn` component is a pointer to the parameter definition inside the model parse tree. It allows us to recreate the `eval_tree` when making copies (instances) of the parameter object.

```

<Models: parameters>≡
    integer, parameter :: PAR_NONE = 0, PAR_UNUSED = -1
    integer, parameter :: PAR_INDEPENDENT = 1, PAR_DERIVED = 2
    integer, parameter :: PAR_EXTERNAL = 3

<Models: types>≡
    type :: parameter_t
    private
    integer :: type = PAR_NONE
    class(modelpar_data_t), pointer :: data => null ()
    type(string_t) :: block_name
    integer, dimension(:), allocatable :: block_index
    type(parse_node_t), pointer :: pn => null ()
    class(expr_t), allocatable :: expr
contains

```

```

    <Models: parameter: TBP>
end type parameter_t

```

Initialization depends on parameter type. Independent parameters are initialized by a constant value or a constant numerical expression (which may contain a unit). Derived parameters are initialized by an arbitrary numerical expression, which makes use of the current variable list. The expression is evaluated by the function `parameter_reset`.

This implementation supports only real parameters and real values.

```

<Models: parameter: TBP>≡
  procedure :: init_independent_value => parameter_init_independent_value
  procedure :: init_independent => parameter_init_independent
  procedure :: init_derived => parameter_init_derived
  procedure :: init_external => parameter_init_external

    type(parse_node_t), intent(in), target :: pn
    par%type = PAR_INDEPENDENT
    par%pn => pn
    allocate (eval_tree_t :: par%expr)
    select type (expr => par%expr)
    type is (eval_tree_t)
      call expr%init_numeric_value (pn)
    end select
    par%data => par_data
    call par%data%init (name, par%expr%get_real ())
  end subroutine parameter_init_independent

  subroutine parameter_init_derived (par, par_data, name, pn, var_list)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    type(parse_node_t), intent(in), target :: pn
    type(var_list_t), intent(in), target :: var_list
    par%type = PAR_DERIVED
    par%pn => pn
    allocate (eval_tree_t :: par%expr)
    select type (expr => par%expr)
    type is (eval_tree_t)

```

```

        call expr%init_expr (pn, var_list=var_list)
    end select
    par%data => par_data
!    call par%expr%evaluate ()
    call par%data%init (name, 0._default)
end subroutine parameter_init_derived

subroutine parameter_init_external (par, par_data, name)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    par%type = PAR_EXTERNAL
    par%data => par_data
    call par%data%init (name, 0._default)
end subroutine parameter_init_external

subroutine parameter_init_unused (par, par_data, name)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data
    type(string_t), intent(in) :: name
    par%type = PAR_UNUSED
    par%data => par_data
    call par%data%init (name, 0._default)
end subroutine parameter_init_unused

```

The finalizer is needed for the evaluation tree in the definition.

```

<Models: parameter: TBP>+≡
    procedure :: final => parameter_final

<Models: procedures>+≡
    subroutine parameter_final (par)
        class(parameter_t), intent(inout) :: par
        if (allocated (par%expr)) then
            call par%expr%final ()
        end if
    end subroutine parameter_final

```

All derived parameters should be recalculated if some independent parameters have changed:

```

<Models: parameter: TBP>+≡
    procedure :: reset_derived => parameter_reset_derived

<Models: procedures>+≡
    subroutine parameter_reset_derived (par)
        class(parameter_t), intent(inout) :: par
        select case (par%type)
        case (PAR_DERIVED)
            call par%expr%evaluate ()
            par%data = par%expr%get_real ()
        end select
    end subroutine parameter_reset_derived

```

Output. [We should have a formula format for the eval tree, suitable for input and output!]

*<Models: parameter: TBP>+≡*

procedure :: write => parameter\_write

```

### 28.4.3 SLHA block register

For the optional SLHA interface, the model record contains a register of SLHA-type block names together with index values, which point to a particular parameter. These are private types:

```

⟨Models: types⟩ +=
    type :: slha_entry_t
        integer, dimension(:), allocatable :: block_index
        integer :: i_par = 0
    end type slha_entry_t

⟨Models: types⟩ +=
    type :: slha_block_t
        type(string_t) :: name
        integer :: n_entry = 0
        type(slha_entry_t), dimension(:), allocatable :: entry
    end type slha_block_t

```

### 28.4.4 Model Object

A model object holds all information about parameters, particles, and vertices. For models that require an external program for parameter calculation, there is the pointer to a function that does this calculation, given the set of independent and derived parameters.

As explained above, the type inherits from `model_data_t`, which is the actual storage for the model data.

When reading a model, we create a parse tree. Parameter definitions are available via parse nodes. Since we may need those later when making model instances, we keep the whole parse tree in the model definition (but not in the instances).

```

⟨Models: public⟩ =
    public :: model_t

⟨Models: types⟩ +=
    type, extends (model_data_t) :: model_t
        private
        character(32) :: md5sum = ""
        logical :: ufo_model = .false.
        type(string_t) :: ufo_path
        type(string_t), dimension(:), allocatable :: schemes
        type(string_t), allocatable :: selected_scheme
        type(parameter_t), dimension(:), allocatable :: par

```

```

integer :: n_slha_block = 0
type(slha_block_t), dimension(:), allocatable :: slha_block
integer :: max_par_name_length = 0
integer :: max_field_name_length = 0
type(var_list_t) :: var_list
type(string_t) :: dlname
procedure(model_init_external_parameters), nopass, pointer :: &
    init_external_parameters => null ()
type(dlaccess_t) :: dlaccess
type(parse_tree_t) :: parse_tree
contains
  <Models: model: TBP>
end type model_t

```

This is the interface for a procedure that initializes the calculation of external parameters, given the array of all parameters.

```

<Models: interfaces>≡
  abstract interface
    subroutine model_init_external_parameters (par) bind (C)
      import
      real(c_default_float), dimension(*), intent(inout) :: par
    end subroutine model_init_external_parameters
  end interface

```

Initialization: Specify the number of parameters, particles, vertices and allocate memory. If an associated DL library is specified, load this library.

The model may already carry scheme information, so we have to save and restore the scheme number when actually initializing the `model_data_t` base.

```

<Models: model: TBP>≡

#### 28.4.6 UFO models

A single flag identifies a model as a UFO model. There is no other distinction, but the flag allows us to handle built-in and UFO models with the same name in parallel.

```

<Models: model: TBP>+≡
  procedure :: is_ufo_model => model_is_ufo_model

```

```

<Models: procedures>+≡
function model_is_ufo_model (model) result (flag)
  class(model_t), intent(in) :: model
  logical :: flag
  flag = model%ufo_model
end function model_is_ufo_model

```

Return the UFO path used for fetching the UFO source.

```

<Models: model: TBP>+≡
  procedure :: get_ufo_path => model_get_ufo_path

<Models: procedures>+≡
function model_get_ufo_path (model) result (path)
  class(model_t), intent(in) :: model
  type(string_t) :: path
  if (model%ufo_model) then
    path = model%ufo_path
  else
    path = ""
  end if
end function model_get_ufo_path

```

Call Omega and generate a model file from an UFO source file. We start with a file name; the model name is expected to be the base name, stripping extensions.

The path search either takes `ufo_path_requested`, or searches first in the working directory, then in a hard-coded UFO model directory.

```

<Models: procedures>+≡
subroutine model_generate_ufo (filename, os_data, ufo_path, &
  ufo_path_requested)

    call split (string, model_name, ".")
end subroutine get_model_name
end subroutine model_generate_ufo

```

## 28.4.7 Scheme handling

A model can specify a set of allowed schemes that steer the setup of model variables. The model file can contain scheme-specific declarations that are selected by a `select scheme` clause. Scheme support is optional.

If enabled, the model object contains a list of allowed schemes, and the model reader takes the active scheme as an argument. After the model has been read, the scheme is fixed and can no longer be modified.

The model supports schemes if the scheme array is allocated.

*(Models: model: TBP)+≡*

```
procedure :: has_schemes => model_has_schemes
```

*(Models: procedures)+≡*

```

function model_has_schemes (model) result (flag)
  logical :: flag
  class(model_t), intent(in) :: model
  flag = allocated (model%schemes)
end function model_has_schemes

```

Enable schemes: fix the list of allowed schemes.

```

<Models: model: TBP>+≡
  procedure :: enable_schemes => model_enable_schemes

<Models: procedures>+≡
  subroutine model_enable_schemes (model, scheme)
    class(model_t), intent(inout) :: model
    type(string_t), dimension(:), intent(in) :: scheme
    allocate (model%schemes (size (scheme)), source = scheme)
  end subroutine model_enable_schemes

```

Find the scheme. Check if the scheme is allowed. The numeric index of the selected scheme is stored in the `model_data_t` base object.

If no argument is given, select the first scheme. The numeric scheme ID will then be 1, while a model without schemes retains 0.

```

<Models: model: TBP>+≡
  procedure :: set_scheme => model_set_scheme

<Models: procedures>+≡
  subroutine model_set_scheme (model, scheme)
    class(model_t), intent(inout) :: model
    type(string_t), intent(in), optional :: scheme
    logical :: ok
    integer :: i
    if (model%has_schemes ()) then
      if (present (scheme)) then
        ok = .false.
        CHECK_SCHEME: do i = 1, size (model%schemes)
          if (scheme == model%schemes(i)) then
            allocate (model%selected_scheme, source = scheme)
            call model%set_scheme_num (i)
            ok = .true.
            exit CHECK_SCHEME
          end if
        end do CHECK_SCHEME
      if (.not. ok) then
        call msg_fatal &
          ("Model '" // char (model%get_name ()) &
           // "': scheme '" // char (scheme) // "' not supported")
      end if
    else
      allocate (model%selected_scheme, source = model%schemes(1))
      call model%set_scheme_num (1)
    end if
  else
    if (present (scheme)) then
      call msg_error &
        ("Model '" // char (model%get_name ()) &

```

```

// '' does not support schemes")
    end if
  end if
end subroutine model_set_scheme

```

Get the scheme. Note that the base `model_data_t` provides a `get_scheme_num` getter function.

```

<Models: model: TBP>+≡
  procedure :: get_scheme => model_get_scheme

<Models: procedures>+≡
  function model_get_scheme (model) result (scheme)
    class(model_t), intent(in) :: model
    type(string_t) :: scheme
    if (allocated (model%selected_scheme)) then
      scheme = model%selected_scheme
    else
      scheme = ""
    end if
  end function model_get_scheme

```

Check if a model has been set up with a specific name and (if applicable) scheme. This helps in determining whether we need a new model object.

A UFO model is considered to be distinct from a non-UFO model. We assume that if `ufo` is asked for, there is no scheme argument. Furthermore, if there is an `ufo_path` requested, it must coincide with the `ufo_path` of the model. If not, the model `ufo_path` is not checked.

```

<Models: model: TBP>+≡

    else
        flag = .true.
    end if
end function model_matches

```

### 28.4.8 SLHA-type interface

Abusing the original strict SUSY Les Houches Accord (SLHA), we support reading parameter data from some custom SLHA-type input file. To this end, the `model` object stores a list of model-specific block names together with information how to find a parameter in the model record, given a block name and index vector.

Check if the model supports custom SLHA block info. This is the case if `n_slha_block` is nonzero, i.e., after SLHA block names have been parsed and registered.

```

<Models: model: TBP>+≡
    procedure :: supports_custom_slha => model_supports_custom_slha

<Models: procedures>+≡
    function model_supports_custom_slha (model) result (flag)
        class(model_t), intent(in) :: model
        logical :: flag

        flag = model%n_slha_block > 0

    end function model_supports_custom_slha

```

Return the block names for all SLHA block references.

```

<Models: model: TBP>+≡
    procedure :: get_custom_slha_blocks => model_get_custom_slha_blocks

<Models: procedures>+≡
    subroutine model_get_custom_slha_blocks (model, block_name)
        class(model_t), intent(in) :: model
        type(string_t), dimension(:), allocatable :: block_name

        integer :: i

        allocate (block_name (model%n_slha_block))
        do i = 1, size (block_name)
            block_name(i) = model%slha_block(i)%name
        end do

    end subroutine model_get_custom_slha_blocks

```

This routine registers a SLHA block reference. We have the index of a (new) parameter entry and a parse node from the model file which specifies a block name and an index array.

*(Models: procedures)*+≡

```

subroutine model_record_slha_block_entry (model, i_par, node)
  class(model_t), intent(inout) :: model
  integer, intent(in) :: i_par
  type(parse_node_t), intent(in), target :: node

  type(parse_node_t), pointer :: node_block_name, node_index

  model%par(i_par)%block_index = block_index
end subroutine model_record_slha_block_entry

```

Add a new entry to the SLHA block register, increasing the array size if necessary

*(Models: procedures)*+≡

```

subroutine model_add_slha_block (model, block_name)
  class(model_t), intent(inout) :: model

```

```

type(string_t), intent(in) :: block_name

if (.not. allocated (model%slha_block)) allocate (model%slha_block (1))
if (model%n_slha_block == size (model%slha_block)) call grow
model%n_slha_block = model%n_slha_block + 1
associate (b => model%slha_block(model%n_slha_block))
    b%name = block_name
    allocate (b%entry (1))
end associate

contains

subroutine grow
    type(slha_block_t), dimension(:), allocatable :: b_tmp
    call move_alloc (model%slha_block, b_tmp)
    allocate (model%slha_block (2 * size (b_tmp)))
    model%slha_block(:size (b_tmp)) = b_tmp(:)
end subroutine grow

end subroutine model_add_slha_block

```

Add a new entry to a block-register record. The entry establishes a pointer-target relation between an index array within the SLHA block and a parameter-data record. We increase the entry array as needed.

*(Models: procedures)+≡*

```

subroutine add_slha_block_entry (b, block_index, i_par)
    type(slha_block_t), intent(inout) :: b
    integer, dimension(:), intent(in) :: block_index
    integer, intent(in) :: i_par

    if (b%n_entry == size (b%entry)) call grow
    b%n_entry = b%n_entry + 1
    associate (entry => b%entry(b%n_entry))
        entry%block_index = block_index
        entry%i_par = i_par
    end associate

contains

subroutine grow
    type(slha_entry_t), dimension(:), allocatable :: entry_tmp
    call move_alloc (b%entry, entry_tmp)
    allocate (b%entry (2 * size (entry_tmp)))
    b%entry(:size (entry_tmp)) = entry_tmp(:)
end subroutine grow

end subroutine add_slha_block_entry

```

The lookup routine returns a pointer to the appropriate `par_data` record, if `block_name` and `block_index` are valid. The latter point to the `slha_block_t` register within the `model_t` object, if it is allocated.

This should only be needed during I/O (i.e., while reading the SLHA file), so a simple linear search for each parameter should not be a performance problem.

```

<Models: model: TBP>+≡
  procedure :: slha_lookup => model_slha_lookup

```

Read a model from file. Handle all syntax and respect the provided scheme.

The `ufo` flag just says that the model object should be tagged as being derived from an UFO model. The UFO model path may be requested by the caller. If not, we use a standard path search for UFO models. There is no difference in the contents of the file or the generated model object.

            model_list%context => context
        end subroutine model_list_link

```

(Private, used below:) Append an existing model, for which we have allocated a pointer entry, to the model list. The original pointer becomes disassociated, and the model should now be considered as part of the list. We assume that this model is not yet part of the list.

If we provide a `model` argument, this returns a pointer to the new entry.

```

<Models: model list: TBP>+≡
  procedure, private :: import => model_list_import

<Models: procedures>+≡
  subroutine model_list_import (model_list, current, model)
    class(model_list_t), intent(inout) :: model_list
    type(model_entry_t), pointer, intent(inout) :: current
    type(model_t), optional, pointer, intent(out) :: model
    if (associated (current)) then
      if (associated (model_list%first)) then
        model_list%last%next => current
      else
        model_list%first => current
      end if
      model_list%last => current
      if (present (model)) model => current%model_t
      current => null ()
    end if
  end subroutine model_list_import

```

Currently test only:

Add a new model with given `name` to the list, if it does not yet exist. If successful, return a pointer to the new model.

```

<Models: model list: TBP>+≡
  procedure :: add => model_list_add

<Models: procedures>+≡
  subroutine model_list_add (model_list, &
    name, os_data, n_par, n_prt, n_vtx, model)
    class(model_list_t), intent(inout) :: model_list
    type(string_t), intent(in) :: name
    type(os_data_t), intent(in) :: os_data
    integer, intent(in) :: n_par, n_prt, n_vtx
    type(model_t), pointer :: model
    type(model_entry_t), pointer :: current
    if (model_list%model_exists (name, follow_link=.false.)) then
      model => null ()
    else
      allocate (current)
      call current%init (name, var_str (""), os_data, &
        n_par, n_prt, n_vtx)
      call model_list%import (current, model)
    end if
  end subroutine model_list_add

```

Read a new model from file and add to the list, if it does not yet exist. Finalize the model by allocating the vertex table. Return a pointer to the new model. If unsuccessful, return the original pointer.

The model is always inserted in the last link of a chain of model lists. This way, we avoid loading models twice from different contexts. When a model is modified, we should first allocate a local copy.

```

```

## 28.4.12 Model instances

A model instance is a copy of a model object. The parameters are true copies. The particle data and the variable list pointers should point to the copy, so modifying the parameters has only a local effect. Hence, we build them up explicitly. The vertex array is also rebuilt, it contains particle pointers. Finally, the vertex hash table can be copied directly since it contains no pointers.

The `multiplicity` entry depends on the association of the `mass_data` entry and therefore has to be set at the end.

The instance must carry the `target` attribute.

Parameters: the `copy_parameter` method essentially copies the parameter decorations (parse node, expression etc.). The current parameter values are part of the `model_data_t` base type and are copied afterwards via its `copy_from` method.

Note: the parameter set is initialized for real parameters only.

In order for the local model to be able to use the correct UFO model setup, UFO model information has to be transferred.

```

<Models: model: TBP>+≡
  procedure :: init_instance => model_copy

<Models: procedures>+≡
  subroutine model_copy (model, orig)
    class(model_t), intent(out), target :: model
    type(model_t), intent(in) :: orig
    integer :: n_par, n_prt, n_vtx
    integer :: i
    n_par = orig%get_n_real ()
    n_prt = orig%get_n_field ()
    n_vtx = orig%get_n_vtx ()

## 28.5 The SUSY Les Houches Accord

The SUSY Les Houches Accord defines a standard interfaces for storing the physics data of SUSY models. Here, we provide the means for reading, storing, and writing such data.

```
(slha_interface.f90)≡  
  <File header>  
  
  module slha_interface  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use constants  
    use string_utils, only: upper_case  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF  
    use diagnostics  
    use os_interface  
    use ifiles  
    use lexers  
    use syntax_rules  
    use parser  
    use variables  
    use models  
  
    <Standard module head>  
  
    <SLHA: public>  
  
    <SLHA: parameters>  
  
    <SLHA: variables>  
  
    save  
  
    contains  
  
    <SLHA: procedures>  
  
    <SLHA: tests>  
  
  end module slha_interface
```

### 28.5.1 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the

parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

A name clash occurs if the block name is identical to a keyword. This can happen for custom SLHA models and files. In that case, we prepend an underscore, which will be silently suppressed where needed.

$\langle SLHA: parameters \rangle \equiv$

```
integer, parameter :: MODE_SKIP = 0, MODE_DATA = 1, MODE_INFO = 2
```

$\langle SLHA: procedures \rangle \equiv$

```
subroutine slha_preprocess (stream, custom_block_name, ifile)
  type(stream_t), intent(inout), target :: stream
  type(string_t), dimension(:), intent(in) :: custom_block_name
  type(ifile_t), intent(out) :: ifile
  type(string_t) :: buffer, line, item
  integer :: iostat
  integer :: mode
  mode = MODE
  SCAN_FILE: do
    call stream_get_record (stream, buffer, iostat)
    select case (iostat)
    case (0)
      call split (buffer, line, "#")
      if (len_trim (line) == 0) cycle SCAN_FILE
      select case (char (extract (line, 1, 1)))
      case ("B", "b")
        call check_block_handling (line, custom_block_name, mode)
        call ifile_append (ifile, line // "$")
      case ("D", "d")
        mode = MODE_DATA
        call ifile_append (ifile, line // "$")
      case (" " )
        select case (mode)
        case (MODE_DATA)
          call ifile_append (ifile, "DATA" // line // "$")
        case (MODE_INFO)
          line = adjustl (line)
          call split (line, item, " ")
          call ifile_append (ifile, "INFO" // " " // item // " " &
            // ' ' // trim (adjustl (line)) // ' ' $)
          end select
        case default
          call msg_message (char (line))
          call msg_fatal ("SLHA: Incomprehensible line")
        end select
      case (EOF)
        exit SCAN_FILE
      case default
        call msg_fatal ("SLHA: I/O error occurred while reading SLHA input")
        end select
    end do SCAN_FILE
```

```
end subroutine slha_preprocess
```

Return the mode that we should treat this block with. We add the `custom_block_name` array to the set of supported blocks, which otherwise includes only hard-coded block names. Those custom blocks are data blocks.

Unknown blocks will be skipped altogether. The standard does not specify their internal format at all, so we must not parse their content.

If the name of a (custom) block clashes with a keyword of the SLHA syntax, we append an underscore to the block name, modifying the current line string. This should be silently suppressed when actually parsing block names.

(*SLHA: procedures*) +=

```
subroutine check_block_handling (line, custom_block_name, mode)
  type(string_t), intent(inout) :: line
  type(string_t), dimension(:), intent(in) :: custom_block_name
  integer, intent(out) :: mode
  type(string_t) :: buffer, key, block_name
  integer :: i
  buffer = trim (line)
  call split (buffer, key, " ")
  buffer = adjustl (buffer)
  call split (buffer, block_name, " ")
  buffer = adjustl (buffer)
  block_name = trim (adjustl (upper_case (block_name)))
  select case (char (block_name))
    case ("MODESEL", "MINPAR", "SMINPUTS")
      mode = MODE_DATA
    case ("MASS")
      mode = MODE_DATA
    case ("NMIX", "UMIX", "VMIX", "STOPMIX", "SBOTMIX", "STAUMIX")
      mode = MODE_DATA
    case ("NMHMIX", "NMAMIX", "NMNMIX", "NMSSMRUN")
      mode = MODE_DATA
    case ("ALPHA", "HMIX")
      mode = MODE_DATA
    case ("AU", "AD", "AE")
      mode = MODE_DATA
    case ("SPINFO", "DCINFO")
      mode = MODE_INFO
    case default
      mode = MODE_SKIP
      CHECK_CUSTOM_NAMES: do i = 1, size (custom_block_name)
        if (block_name == custom_block_name(i)) then
          mode = MODE_DATA
          call mangle_keywords (block_name)
          line = key // " " // block_name // " " // trim (buffer)
          exit CHECK_CUSTOM_NAMES
        end if
      end do CHECK_CUSTOM_NAMES
    end select
end subroutine check_block_handling
```

Append an underscore to specific block names:

```

<SLHA: procedures>+=
  subroutine mangle_keywords (name)
    type(string_t), intent(inout) :: name
    select case (char (name))
      case ("BLOCK", "DATA", "INFO", "DECAY")
        name = name // "_"
    end select
  end subroutine mangle_keywords

```

Remove the underscore again:

```

<SLHA: procedures>+=
  subroutine demangle_keywords (name)
    type(string_t), intent(inout) :: name
    select case (char (name))
      case ("BLOCK_", "DATA_", "INFO_", "DECAY_")
        name = extract (name, 1, len(name)-1)
    end select
  end subroutine demangle_keywords

```

  call ifile_append (ifile, "SEQ decay_line = data_item integer pdg_code+")
end subroutine define_slha_syntax

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

```

<SLHA: public> +=
public :: lexer_init_slha

<SLHA: procedures> +=
subroutine lexer_init_slha (lexer)
  type(lexer_t), intent(out) :: lexer
  call lexer_init (lexer, &

```

```

        comment_chars = "#", &
        quote_chars = "'", &
        quote_match = "'", &

    write (u, 1) code1, code2, item, comment
end subroutine write_real_matrix_element

```

## The concrete SLHA interpreter

SLHA codes for particular physics models

*<SLHA: parameters>+≡*

```
integer, parameter :: MDL_MSSM = 0
integer, parameter :: MDL_NMSSM = 1
```

Take the parse tree and extract relevant data. Select the correct model and store all data that is present in the appropriate variable list. Finally, update the variable record.

We assume that if the model contains custom SLHA block names, we just have to scan those to get complete information. Block names could coincide with the SLHA standard block names, but we do not have to assume this. This will be the situation for an UFO-generated file. In particular, an UFO file should contain all expressions necessary for computing dependent parameters, so we can forget about the strict SLHA standard and its hard-coded conventions.

If there are no custom SLHA block names, we should assume that the model is a standard SUSY model, and the parameters and hard-coded blocks can be read as specified by the original SLHA standard. There are hard-coded block names and parameter calculations.

Public for use in unit test.

*<SLHA: public>+≡*

```

end subroutine slha_handle_info_block

```

## MODSEL

Handle the overall model definition. Only certain models are recognized. The soft-breaking model templates that determine the set of input parameters.

This block used to be required, but for generic UFO model support we should allow for its absence. In that case, `mssm_type` will be set to a negative value. If the block is present, the model must be one of the following, or parsing ends with an error.

*(SLHA: parameters)+≡*

```

## SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is not defined in the block, we use the previous value from the model variable list. For the basic parameters we have to do a small recalculation, since SLHA uses the  $G_F$ - $\alpha$ - $m_Z$  scheme, while WHIZARD derives them from  $G_F$ ,  $m_W$ , and  $m_Z$ .

(*SLHA: procedures*)+≡

        pn_decay => slha_get_next_decay_ptr (pn_decay)
    end do
end subroutine slha_handle_decays

```

## Mixing matrices

Read mixing matrices. We can treat all matrices by a single procedure if we just know the block name, variable prefix, and matrix dimension. The matrix dimension must be less than 10. For the pseudoscalar Higgses in NMSSM-type models we need off-diagonal matrices, so we generalize the definition.

*(SLHA: procedures)* +=

```

subroutine slha_handle_matrix_block &
    (parse_tree, block_name, var_prefix, dim1, dim2, model)
    type(parse_tree_t), intent(in) :: parse_tree
    character(*), intent(in) :: block_name, var_prefix
    integer, intent(in) :: dim1, dim2
    type(model_t), intent(inout), target :: model
    type(parse_node_t), pointer :: pn_block
    type(var_list_t), pointer :: var_list
    integer :: i, j
    character(len=len(var_prefix)+2) :: var_name

```

```

var_list => model%get_var_list_ptr ()
pn_block => slha_get_block_ptr &
    (parse_tree, var_str (block_name), required=.false.)
if (.not. (associated (pn_block))) return
do i = 1, dim1
    do j = 1, dim2
        write (var_name, "(A,I1,I1)") var_prefix, i, j
        call set_matrix_element (pn_block, i, j, var_str (var_name), var_list)
    end do
end do
end subroutine slha_handle_matrix_block

```

## Higgs data

Read the block ALPHA which holds just the Higgs mixing angle.

```

<SLHA: procedures>+≡
subroutine slha_handle_ALPHA (parse_tree, model)
    type(parse_tree_t), intent(in) :: parse_tree
    type(model_t), intent(inout), target :: model
    type(parse_node_t), pointer :: pn_block, pn_line, pn_data, pn_item

  var_list => model%get_var_list_ptr ()
  pn_block => slha_get_block_ptr &
    (parse_tree, var_str ("NMSSMRUN"), required=.false.)
  if (.not. (associated (pn_block))) return
  call set_data_item (pn_block, 1, var_str ("ls"), var_list)
  call set_data_item (pn_block, 2, var_str ("ks"), var_list)
  call set_data_item (pn_block, 3, var_str ("a_ls"), var_list)
  call set_data_item (pn_block, 4, var_str ("a_ks"), var_list)
  call set_data_item (pn_block, 5, var_str ("nmu"), var_list)
end subroutine slha_handle_NMSSMRUN
```

### 28.5.5 Parsing custom SLHA files

With the introduction of UFO models, we support custom files in generic SLHA format that reset model parameters. In contrast to strict SLHA files, the order and naming of blocks is arbitrary.

We scan the complete file (i.e., preprocessed parse tree), parsing all blocks that contain data lines. For each data line, we identify index array and associated value. Then we set the model parameter that is associated with that block name and index array, if it exists.

*(SLHA: procedures)*+≡

```
subroutine slha_handle_custom_file (parse_tree, model)
  type(parse_tree_t), intent(in) :: parse_tree
  type(model_t), intent(inout), target :: model

  type(parse_node_t), pointer :: pn_root, pn_block
  type(parse_node_t), pointer :: pn_block_spec, pn_block_name
  type(parse_node_t), pointer :: pn_data, pn_line, pn_code, pn_item
  type(string_t) :: block_name
  integer, dimension(:), allocatable :: block_index
  integer :: n_index, i
  real(default) :: value

  pn_root => parse_tree%get_root_ptr ()
  pn_block => pn_root%get_sub_ptr ()
  HANDLE_BLOCKS: do while (associated (pn_block))
    select case (char (pn_block%get_rule_key ()))
      case ("block_def")
        call slha_handle_custom_block (pn_block, model)
    end select
    pn_block => pn_block%get_next_ptr ()
  end do HANDLE_BLOCKS

end subroutine slha_handle_custom_file
```

```

  end do HANDLE_LINES

end subroutine slha_handle_custom_block

```

## 28.5.6 Parser

Read a SLHA file from stream, including preprocessing, and make up a parse tree.

*<SLHA: procedures>+≡*

```

subroutine slha_parse_stream (stream, custom_block_name, parse_tree)
  type(stream_t), intent(inout), target :: stream
  type(string_t), dimension(:), intent(in) :: custom_block_name
  type(parse_tree_t), intent(out) :: parse_tree
  type(ifile_t) :: ifile
  type(lexer_t) :: lexer
  type(stream_t), target :: stream_tmp
  call slha_preprocess (stream, custom_block_name, ifile)
  call stream_init (stream_tmp, ifile)
  call lexer_init_slha (lexer)
  call lexer_assign_stream (lexer, stream_tmp)
  call parse_tree_init (parse_tree, syntax_slha, lexer)
  call lexer_final (lexer)
  call stream_final (stream_tmp)
  call ifile_final (ifile)
end subroutine slha_parse_stream

```

Read a SLHA file chosen by name. Check first the current directory, then the directory where SUSY input files should be located.

The `default_mode` applies to unknown blocks in the SLHA file: this is either `MODE_SKIP` or `MODE_DATA`, corresponding to genuine SUSY and custom file content, respectively.

*<SLHA: public>+≡*

```

public :: slha_parse_file

```

*<SLHA: procedures>+≡*

```

subroutine slha_parse_file (file, custom_block_name, os_data, parse_tree)
  type(string_t), intent(in) :: file
  type(string_t), dimension(:), intent(in) :: custom_block_name
  type(os_data_t), intent(in) :: os_data
  type(parse_tree_t), intent(out) :: parse_tree

  inquire (file=char(filename), exist=exist)
  if (.not. exist) then
    filename = os_data%whizard_susypath // "/" // file
    inquire (file=char(filename), exist=exist)
    if (.not. exist) then
      call msg_fatal ("SLHA input file '" // char (file) // "' not found")
      return
    end if
  end if
  call stream_init (stream, char (filename))
  call slha_parse_stream (stream, custom_block_name, parse_tree)
  call stream_final (stream)
end subroutine slha_parse_file

```

## 28.5.7 API

Read the SLHA file, parse it, and interpret the parse tree. The model parameters retrieved from the file will be inserted into the appropriate model, which is loaded and modified in the background. The pointer to this model is returned as the last argument.

```

<SLHA: public>+≡
    public :: slha_read_file

<SLHA: procedures>+≡
    subroutine slha_read_file &
        (file, os_data, model, input, spectrum, decays)
        type(string_t), intent(in) :: file
        type(os_data_t), intent(in) :: os_data
        type(model_t), intent(inout), target :: model
        logical, intent(in) :: input, spectrum, decays
        type(string_t), dimension(:), allocatable :: custom_block_name
        type(parse_tree_t) :: parse_tree
        call model%get_custom_slha_blocks (custom_block_name)
        call slha_parse_file (file, custom_block_name, os_data, parse_tree)
        if (associated (parse_tree%get_root_ptr ())) then
            call slha_interpret_parse_tree &
                (parse_tree, model, input, spectrum, decays)
            call parse_tree_final (parse_tree)
            call model%update_parameters ()
        end if
    end subroutine slha_read_file

```

Write the SLHA contents, as far as possible, to external file.

```

<SLHA: public>+≡
    public :: slha_write_file

<SLHA: procedures>+≡
    subroutine slha_write_file (file, model, input, spectrum, decays)
        type(string_t), intent(in) :: file
        type(model_t), target, intent(in) :: model
        logical, intent(in) :: input, spectrum, decays
        integer :: mssm_type
        integer :: u
        u = free_unit ()
        call msg_message ("Writing SLHA output file '" // char (file) // "'")
        open (unit=u, file=char(file), action="write", status="replace")
        write (u, "(A)")  "# SUSY Les Houches Accord"
        write (u, "(A)")  "# Output generated by " // trim (VERSION_STRING)
        call slha_write_MODSEL (u, model, mssm_type)
        if (input) then

c Correction function for non-constant (energy and momentum dependent) width:
      FUNCTION GTPCOR1(TOPP,ETOT)
C
C      TOPP - momentum of t quark = - momentum of tbar
C      ETOT - total energy of t-tbar system
C      calls: GENWDS, RAN2
C
C      Evaluates a correction factor to the width of t-tbar system.
C      in future has to be replaced by a function evaluating
C      width including radiative corrections and GTPCOR.
C      I include two factors reducing the width:

```

```

c      a - time dilatation: for decay in flight lifetime
c      increased accordingly to relativistic kinematics
c      b - overall energy-momentum conservation: I assume that
c      t and tbar decay in flight and in this decays energies
c      of Ws follow from 2-body kinematics. Then I calculate
c      effective mass squared of b-bar system (it may be
c      negative!) from en-momentum conservation.
c      If effective mass is < 2*Mb + 2 GeV configuration
c      is rejected. The weight is acceptance.

C *****
C      Version tuned to provide 0(1%) relative accuracy for Coulomb axial
C      vertex function at first and second order (search for 'cctt'):
C      - integrals A(p), Vhat, Vhhat provided analytically w/out cut-off
C      - grid range fixed to 0.1 ... 10**6 absolut
C      - and grid size enhanced to 600 points (900 foreseen in arrays).
C
C      This provides a compromise between stability and accuracy:
C      We need a relatively high momentum resolution and large maximal
C      momenta to achieve a ~1 percent accuracy, but the method of
C      direct inversion of the discretised integral equation for objects
C      whose integral is divergent induces instabilities at small
C      momenta. As the behaviour there is known, they can be cut off and
C      the vertex function fixed by hand; but limiting the grid
C      further would impact on the accuracy.
C      22.3.2017, tt

c -- Calculation of the Green function in momentum space by solving the
c   Lippmann-Schwinger equation
c   
$$F(p) = G_0(p) + G_0(p) \int_0^{xcutn} V(p,q) q \cdot p / p^2 F(q) dq$$

c
c -- Written by Thomas Teubner, Hamburg, November 1998
c   * Based on TOPPIK Version 1.1
c     from M. Jezabek and TT, Karlsruhe, June 1992
c   * Version originally for non-constant top-width
c   * Constant width supplied here
c   * No generator included
c
c -- Use of double precision everywhere
c
c -- All masses, momenta, energies, widths in GeV
c
c -- Input parameters:
c
c   xenergy  :  $E = \sqrt{s} - 2 \cdot \text{topmass}$ 
c   xtm      : topmass (in the Pole scheme)
c   xtg      : top-width
c   xalphas  :  $\alpha_s^{\{MSbar, n_f=5\}}(xscale)$ 
c   xscale   : soft scale  $\mu_{\{soft\}}$ 
c   xcutn    : numerical UV cutoff on all momenta
c              (UV cutoff of the Gauss-Legendre grid)
c   xcutv    : renormalization cutoff on the
c              delta-, the  $(p^2+q^2)/(p-q)^2$ -, and the
c               $1/r^2 - [1/|p-q|]$ -potential:
c              if (max(p,q).ge.xcutv) then the three potentials
c              are set to zero in the Lippmann-Schwinger equation
c   xc0      : 0th order coefficient for the Coulomb potential,
c              see calling example above
c   xc1      : 1st order coefficient for the Coulomb potential
c   xc2      : 2nd order coefficient for the Coulomb potential
c   xcdeltc  : constant of the delta(r)-

```

```

c          [= constant in momentum space-] potential
c  xcdeltl : constant for the additional  $\log(q^2/\mu^2)$ -part of the
c            delta-potential:
c             $xcdeltc*1 + xcdeltl*\log(q^2/\mu^2)$ 
c  xcfullc : constant of the  $(p^2+q^2)/(p-q)^2$ -potential
c  xcfulll : constant for the additional  $\log(q^2/\mu^2)$ -part of the
c             $(p^2+q^2)/(p-q)^2$ -potential
c  xcrm2   : constant of the  $1/r^2-[1/|p-q|]$ -potential
c  xkincm  : } kinetic corrections in the 0th order Green function:
c  xkinca  : }  $G_0(p) := 1/[E+i\Gamma_t-p^2/m_t]*(1+xkincm)+xkinca$ 
c            !!! WATCH THE SIGN IN  $G_0$  !!!
c  jknflg  : flag for these kinetic corrections:
c            0 : no kinetic corrections applied
c            1 : kinetic corrections applied with cutoff xcutv
c              for xkinca only
c            2 : kinetic corrections applied with cutoff xcutv
c              for xkinca AND xkincm
c  jgcflg  : flag for  $G_0(p)$  in the LS equation:
c            0 (standard choice) :  $G_0(p)$  as given above
c            1 (for TIPT)         :  $G_0(p) = G_c^{\{0\}}(p)$  the 0th
c                                  order Coulomb Green function
c                                  in analytical form; not for
c                                  momenta  $p > 1000*topmass$ 
c  xkincv  : additional kinematic vertexcorrection in  $G_0$ , see below:
c  jvflg   : flag for the additional vertexcorrection xkincv in the
c            'zeroth order'  $G_0(p)$  in the LS-equation:
c            0 : no correction, means  $G = G_0 + G_0 \int V G$ 
c              with  $G_0 = 1/[E+i\Gamma_t-p^2/m_t]*(1+xkincm)+xkinca$ 
c            1 : apply the correction in the LS equation as
c               $G = G_0 + xkincv*p^2/m_t^2/[E+i\Gamma_t-p^2/m_t] +$ 
c               $G_0 \int V G$ 
c              and correct the integral over  $\text{Im}[G(p)]$  to get  $\sigma_{tot}$ 
c              from the optical theorem by the same factor.
c              The cutoff xcutv is applied for these corrections.
c
c -- Output:
c
c  xim      :  $R^{\{P \text{ wave}\}}_{\{ttbar\}}$  from the imaginary part of the Green
c            function
c  xdi      :  $R^{\{P \text{ wave}\}}_{\{ttbar\}}$  from the integral over the momentum
c            distribution:  $\int_0^{xcutv} dp p^3/m_t * |F(p,E)|^2$ 
c  np       : number of points used for the grid; fixed in tttoppik
c  xpp      : 1-dim array (max. 900 elements) giving the momenta of
c            the Gauss-Legendre grid (pp(i) in the code)
c  xww      : 1-dim array (max. 900 elements) giving the corresponding
c            Gauss-Legendre weights for the grid
c  xdsdp    : 1-dim array (max. 900 elements) giving the
c            momentum distribution of top:  $d\sigma^{\{P \text{ wave}\}}/dp$ ,
c            normalized to R,
c            at the momenta of the Gauss-Legendre grid xpp(i)
c  zftild   : 1-dim array (max. 900 elements) of COMPLEX*16 numbers
c            giving the vertex function  $K_A$  for the P-wave
c            at the momenta of the grid.
c            Then  $F(p) = K_A(p) * G_0(p)$  corresponding to  $G = K_V * G_0$ .

        if ((npot.eq.1).or.(npot.eq.3).or.(npot.eq.4).or.
            u      (npot.eq.5)) then
c For pure coulomb and fixed order potentials there is no delta-part:
        consde = 0.d0

```

```

        else if (npot.eq.2) then
c Initialize QCD-potential common-blocks and calculate constant multiplying
c the delta-part of the 'qcutted' potential in momentum-space:
c         call iniphc(1)
c         call vqdelt(consde)
c         write(*,*) ' Not supplied with this version. Stop.'
c         stop
        else
c         write (*,*) ' Potential not implemented! Stop. 1'
c         stop
        endif
c Delta-part of potential is absorbed by subtracting vzero from the
c original energy (shift from the potential to the free Hamiltonian):
c         vzero = consde / (2.d0*pi)**3
c         write (*,*) 'vzero=', vzero
c
c Find x-values pp(i) and weights w1(i) for the gaussian quadrature;
c care about large number of points in the important intervals:
c         if (energy-vzero.le.0.d0) then
cc         call gauleg(0.d0, 1.d0, pp, w1, n/3)
cc         call gauleg(1.d0, 5.d0, pp(n/3+1), w1(n/3+1), n/3)
cc         call gauleg(0.d0, 0.2d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c         call gauleg(0.d0, 5.d0, pp, w1, n/3)
c         call gauleg(5.d0, 20.d0, pp(n/3+1), w1(n/3+1), n/3)
c         call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c         else
cc Avoid numerical singular points in the inner of the intervals:
c         critp = sqrt((energy-vzero)*tmass)
c         if (critp.le.1.d0) then
cc Gauss-Legendre is symmetric => automatically principal-value prescription:
c         call gauleg(0.d0, 2.d0*critp, pp, w1, n/3)
c         call gauleg(2.d0*critp, 20.d0, pp(n/3+1),
c         u         w1(n/3+1), n/3)
c         call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c         else
cc Better behaviour at the border of the intervals:
c         call gauleg(0.d0, critp, pp, w1, n/3)
c         call gauleg(critp, 2.d0*critp, pp(n/3+1),
c         u         w1(n/3+1), n/3)
c         call gauleg(0.d0, 1.d0/(2.d0*critp), pp(2*n/3+1),
c         u         w1(2*n/3+1), n/3)
c         endif
c         endif
c
c Or different (simpler) method, good for V_JKT:
c         if (energy.le.0.d0) then
c         critp=tmass/3.d0
c         else
c         critp=max(tmass/3.d0,2.d0*sqrt(energy*tmass))
c         endif
c         call gauleg(0.d0, critp, pp, w1, 2*n/3)
c         call gauleg(1.d0/xpmax, 1.d0/critp, pp(2*n/3+1),
c         u         w1(2*n/3+1), n/3)
cctt Tuned March 2017 for best possible numerical behaviour of P-wave

```

```

        call gauleg(0.1d0, 2.d0, pp, w1, 10)
        call gauleg(2.d0, critp, pp(11), w1(11), 2*n/3-10)
        call gauleg(1.d-6, 1.d0/critp, pp(2*n/3+1),
u           w1(2*n/3+1), n/3)
c
c Do substitution  $p \Rightarrow 1/p$  for the last interval explicitly:
        do 10 i=2*n/3+1,n
            pp(i) = 1.d0/pp(i)
10         continue
c
c Reorder the arrays for the third interval:
        do 20 i=1,n/3
            xx(i) = pp(2*n/3+i)
            w2(i) = w1(2*n/3+i)
20         continue
        do 30 i=1,n/3
            pp(n-i+1) = xx(i)
            w1(n-i+1) = w2(i)
30         continue
c
c Calculate the integrals aax(p) for the given momenta pp(i)
c and store weights and momenta for the output arrays:
        do 40 i=1,n
            a1(i) = aax(pp(i)) !!! FB: can get stuck in original Toppik!
            !!! FB: abuse 'np' as a flag to communicate unstable runs
            if ( abs(a1(i)) .gt. 1d10 ) then
                np = -1
                return
            endif
            xpp(i)=pp(i)
            xww(i)=w1(i)
40         continue
        do 41 i=n+1,nmax
            xpp(i)=0.d0
            xww(i)=0.d0
41         continue
c
c Solve the integral-equation by solving a system of algebraic equations:
        call saeax(pp, w1, bb, vec, a1, n)
c
c (The substitution for the integration to infinity  $pp \Rightarrow 1/pp$ 
c is done already.)
        do 50 i=1,n
            zvfct(i)=bb(i)
            zftild(i)=vec(i)
            gg(i) = bb(i)*g0c(pp(i))
cc         gg(i) = (1.d0 + bb(i))*g0c(pp(i))
cc Urspruenglich anderes (Minus) VZ hier, dafuer kein Minus mehr bei der
cc Definition des Wqs ueber Im G, 2.6.1998, tt.
cc         gg(i) = - (1.d0 + bb(i))*g0c(pp(i))
50         continue
c
c Normalisation on R:
        const = 8.d0*pi/tmass**2

```

```

## Chapter 30

# Integration and Process Objects

This is the central part of the WHIZARD package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

**subevt\_expr** This enables process observables as (abstract) expressions, to be evaluated for each process call.

**parton\_states** A `parton_state_t` object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

**process** Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: `prc_core` for matrix-element evaluation, `prc_core_def` for the associated configuration and driver, `sf_base` for beams and structure-functions, `phs_base` for phase space, and `mci_base` for integration and event generation.

**process\_config**

**process\_counter** Very simple object for statistics

**process\_mci**

**pcm**

**kinematics**

**instances** While the above modules set up all static information, the instances have the changing event data. There are term and process instances but no component instances.

**process\_stacks** Process stacks collect process objects.

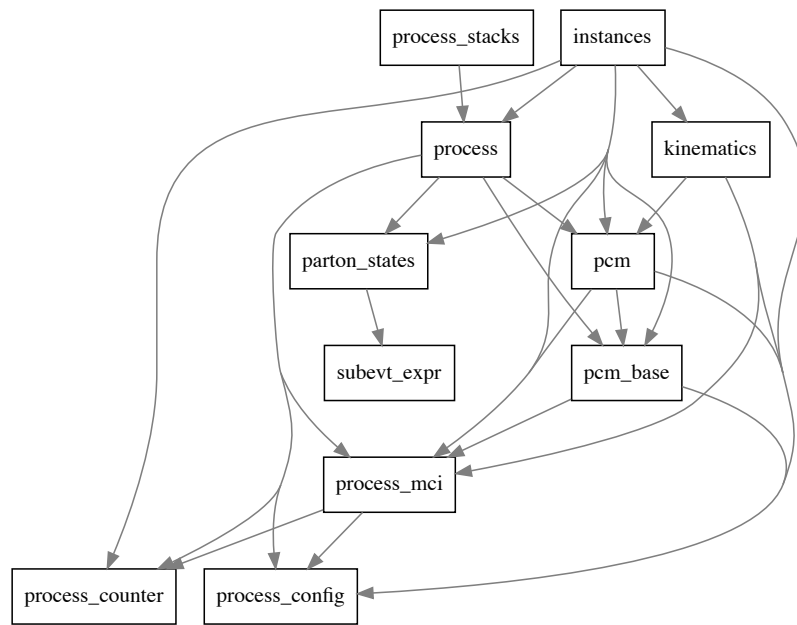

Figure 30.1: Module dependencies in `src/process_integration`.

We combine here hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the **computed** state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the **observed** state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible subsequent decay processes on the parton level, which are full-fledged process objects themselves.

## 30.1 Process observables

We define an abstract **subevt\_expr\_t** object as an extension of the **subevt\_t** type. The object contains a local variable list, variable instances (as targets for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the **subevt**.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression **selection** which determines whether the object passes user-defined cuts.

The intention is that we fill the **subevt\_t** base object and compute the variables once we have evaluated a kinematical phase space point (or a complete event). We then evaluate the expressions and can use the results in further calculations.

The **process\_expr\_t** extension contains furthermore scale and weight expressions. The **event\_expr\_t** extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the

variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

Note that there are unit tests, but they are deferred to the `expr_tests` module.

    end if
  end subroutine subevt_expr_final
```

### 30.1.2 Initialization

Initialization: define local variables and establish pointers.

The common variables are `sqrts` (the nominal beam energy, fixed), `sqrts_hat` (the actual energy), `n.in`, `n.out`, and `n_tot` for the `subevt`. With the exception

of `sqrts`, all are implemented as pointers to subobjects.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure (subevt_expr_setup_vars), deferred :: setup_vars
  procedure :: base_setup_vars => subevt_expr_setup_vars

<Subevt expr: procedures>+≡
  subroutine subevt_expr_setup_vars (expr, sqrts)
    class(subevt_expr_t), intent(inout), target :: expr
    real(default), intent(in) :: sqrts
    call expr%var_list%final ()
    call var_list_append_real (expr%var_list, &
      var_str ("sqrts"), sqrts, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_real_ptr (expr%var_list, &
      var_str ("sqrts_hat"), expr%sqrts_hat, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_in"), expr%n_in, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &

    logical, intent(in) :: colorize_subvt
    expr%colorize_subvt = colorize_subvt
  end subroutine subvt_expr_colorize

```

### 30.1.3 Evaluation

Reset to initial state, i.e., mark the subvt as invalid.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: reset_contents => subvt_expr_reset_contents
  procedure :: base_reset_contents => subvt_expr_reset_contents

<Subvt expr: procedures>+≡
  subroutine subvt_expr_reset_contents (expr)
    class(subvt_expr_t), intent(inout) :: expr
    expr%subvt_filled = .false.
  end subroutine subvt_expr_reset_contents

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: base_evaluate => subvt_expr_evaluate

```

```

<Subvt expr: procedures>+≡
  subroutine subvt_expr_evaluate (expr, passed)
    class(subvt_expr_t), intent(inout) :: expr
    logical, intent(out) :: passed
    if (expr%has_selection) then
      call expr%selection%evaluate ()
      if (expr%selection%is_known ()) then
        passed = expr%selection%get_log ()
      else
        call msg_error ("Evaluate selection expression: result undefined")
        passed = .false.
      end if
    else
      passed = .true.
    end if
  end subroutine subvt_expr_evaluate

```

### 30.1.4 Implementation for partonic events

This implementation contains the expressions that we can evaluate for the partonic process during integration.

```

<Subvt expr: public>≡
  public :: parton_expr_t

<Subvt expr: types>+≡
  type, extends (subvt_expr_t) :: parton_expr_t
    integer, dimension(:), allocatable :: i_beam
    integer, dimension(:), allocatable :: i_in
    integer, dimension(:), allocatable :: i_out
    logical :: has_scale = .false.
    logical :: has_fac_scale = .false.
    logical :: has_ren_scale = .false.
    logical :: has_weight = .false.
    class(expr_t), allocatable :: scale
    class(expr_t), allocatable :: fac_scale
    class(expr_t), allocatable :: ren_scale
    class(expr_t), allocatable :: weight
  contains
    <Subvt expr: parton expr: TBP>
  end type parton_expr_t

```

Finalizer.

```

<Subvt expr: parton expr: TBP>≡
  procedure :: final => parton_expr_final

<Subvt expr: procedures>+≡
  subroutine parton_expr_final (object)
    class(parton_expr_t), intent(inout) :: object
    call object%base_final ()
    if (object%has_scale) then
      call object%scale%final ()
    end if
    if (object%has_fac_scale) then

```

```

        call object%fac_scale%final ()
    end if
    if (object%has_ren_scale) then

      end if
    end subroutine parton_expr_setup_weight

```

Filling the partonic state consists of two parts. The first routine prepares the subvt without assigning momenta. It takes the particles from an `interaction_t`. It needs the indices and flavors for the beam, incoming, and outgoing particles.

We can assume that the particle content of the subvt does not change. Therefore, we set the event variables `n_in`, `n_out`, `n_tot` already in this initialization step.

```

### 30.1.5 Implementation for full events

This implementation contains the expressions that we can evaluate for the full event. It also contains data that pertain to the event, suitable for communication with external event formats. These data simultaneously serve as pointer targets for the variable lists hidden in the expressions (eval trees).

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

```

  <Subvt expr: public>+≡
    public :: event_expr_t

  <Subvt expr: types>+≡

end subroutine event_expr_evaluate

```

## 30.2 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states, depending on the the beam setup allows. The result is used for integration.

The `matrix` evaluator is the counterpart of `trace` which is kept exclusive in all observable quantum numbers. The `flows` evaluator is furthermore exclusive in colors, but neglecting all color interference. The `matrix` and `flows` evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. The extra `has_XXX` flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the `processes` module below.

```

<Standard module head>

<Parton states: public>

<Parton states: types>

contains

<Parton states: procedures>

end module parton_states

```

### 30.2.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

<Parton states: types>≡
  type, abstract :: parton_state_t
    logical :: has_trace = .false.
    logical :: has_matrix = .false.
    logical :: has_flows = .false.
    type(evaluator_t) :: trace
    type(evaluator_t) :: matrix
    type(evaluator_t) :: flows
  contains
    <Parton states: parton state: TBP>
  end type parton_state_t

```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both are implemented as a pointer. The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```

(Parton states: public)≡
  public :: isolated_state_t

(Parton states: types)+≡
  type, extends (parton_state_t) :: isolated_state_t
    logical :: sf_chain_is_allocated = .false.
    type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()
    logical :: int_is_allocated = .false.
    type(interaction_t), pointer :: int_eff => null ()
  contains
    (Parton states: isolated state: TBP)
  end type isolated_state_t

```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

### 30.2.2 Common Initialization

Initialize the isolated parton state. In this version, the effective structure-function chain `sf_chain_eff` and the effective interaction `int_eff` both are trivial pointers to the seed structure-function chain and to the hard interaction, respectively.

```

(Parton states: isolated state: TBP)≡
  procedure :: init => isolated_state_init

(Parton states: procedures)+≡
  subroutine isolated_state_init (state, sf_chain, int)
    class(isolated_state_t), intent(out) :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(interaction_t), intent(in), target :: int
    state%sf_chain_eff => sf_chain

```

```

state%int_eff => int
end subroutine isolated_state_init

```

### 30.2.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask.in`.

There are two options: explicitly computing the color factor table (`use_cf` false; `nc` defined), or taking the color factor table from the hard matrix element data.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_square_trace => isolated_state_setup_square_trace

(Parton states: procedures)+≡
  subroutine isolated_state_setup_square_trace (state, core, &
    qn_mask_in, col, keep_fs_flavor)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), intent(in), dimension(:) :: qn_mask_in
    !!! Actually need allocatable attribute here for once because col might
    !!! enter the subroutine non-allocated.
    integer, intent(in), dimension(:), allocatable :: col
    logical, intent(in) :: keep_fs_flavor
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    associate (data => core%data)
      allocate (qn_mask (data%n_in + data%n_out))
      qn_mask( : data%n_in) = &
        quantum_numbers_mask (.false., .true., .false.) &
        .or. qn_mask_in
      qn_mask(data%n_in + 1 : ) = &
        quantum_numbers_mask (.not. keep_fs_flavor, .true., .true.)
      if (core%use_color_factors) then
        call state%trace%init_square (state%int_eff, qn_mask, &
          col_flow_index = data%cf_index, &
          col_factor = data%color_factors, &
          col_index_hi = col, &
          nc = core%nc)
      else
        call state%trace%init_square (state%int_eff, qn_mask, nc = core%nc)
      end if
    end associate
    state%has_trace = .true.
  end subroutine isolated_state_setup_square_trace

```

Set up an identity-evaluator for the trace. This implies that `me` is considered to be a squared amplitude, as for example for BLHA matrix elements.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_identity_trace => isolated_state_setup_identity_trace

```

*(Parton states: procedures)*+≡

```

subroutine isolated_state_setup_identity_trace (state, core, qn_mask_in, &
    keep_fs_flavors, keep_colors)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), intent(in), dimension(:) :: qn_mask_in
    logical, intent(in), optional :: keep_fs_flavors, keep_colors
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    logical :: fs_flv_flag, col_flag
    fs_flv_flag = .true.; col_flag = .true.
    if (present(keep_fs_flavors)) fs_flv_flag = .not. keep_fs_flavors
    if (present(keep_colors)) col_flag = .not. keep_colors
    associate (data => core%data)
        allocate (qn_mask (data%n_in + data%n_out))
        qn_mask( : data%n_in) = &
            quantum_numbers_mask (.false., col_flag, .false.) .or. qn_mask_in
        qn_mask(data%n_in + 1 : ) = &
            quantum_numbers_mask (fs_flv_flag, col_flag, .true.)
    end associate
    call state%int_eff%set_mask (qn_mask)
    call state%trace%init_identity (state%int_eff)
    state%has_trace = .true.
end subroutine isolated_state_setup_identity_trace

```

Set up the evaluator for the transition matrix, exclusive in helicities where this is requested.

For all unstable final-state particles we keep polarization according to the applicable decay options. If the process is a decay itself, this applies also to the initial state.

For all polarized final-state particles, we keep polarization including off-diagonal entries. We drop helicity completely for unpolarized final-state particles.

For the initial state, if the particle has not been handled yet, we apply the provided `qn_mask_in` which communicates the beam properties.

*(Parton states: isolated state: TBP)*+≡

```

procedure :: setup_square_matrix => isolated_state_setup_square_matrix

```

*(Parton states: procedures)*+≡

```

subroutine isolated_state_setup_square_matrix &

### 30.2.4 Evaluator initialization: connected state

Set up a trace evaluator as a product of two evaluators (incoming state, effective interaction). In the result, all quantum numbers are summed over.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`.

The `resonant` flag applies if we want to construct a decay chain. The resonance property can propagate to the final event output.

If an extended structure function is required `requires_extended_sf`, we have to not consider `sub` as a quantum number.

```

<Parton states: connected state: TBP>≡
    procedure :: setup_connected_trace => connected_state_setup_connected_trace

<Parton states: procedures>+≡
    subroutine connected_state_setup_connected_trace &
        (state, isolated, int, resonant, undo_helicities, &
         keep_fs_flavors, requires_extended_sf)

  end function connected_state_get_state_flv

```

### 30.2.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

```

  class(connected_state_t), intent(inout), target :: state
  class(expr_factory_t), intent(in) :: ef_weight
  call state%expr%setup_weight (ef_weight)
end subroutine connected_state_setup_weight

```

Reset the expression object: invalidate the subevt.

```

⟨Parton states: connected state: TBP⟩+≡
  procedure :: reset_expressions => connected_state_reset_expressions

⟨Parton states: procedures⟩+≡
  subroutine connected_state_reset_expressions (state)
    class(connected_state_t), intent(inout) :: state
    if (state%has_expr) call state%expr%reset_contents ()
  end subroutine connected_state_reset_expressions

```

### 30.2.6 Evaluation

Transfer momenta to the trace evaluator and fill the `subevt` with this effective kinematics, if applicable.

Note: we may want to apply a boost for the `subevt`.

```

⟨Parton states: parton state: TBP⟩+≡
  procedure :: receive_kinematics => parton_state_receive_kinematics

⟨Parton states: procedures⟩+≡
  subroutine parton_state_receive_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
    if (state%has_trace) then
      call state%trace%receive_momenta ()
      select type (state)
      class is (connected_state_t)
        if (state%has_expr) then
          call state%expr%fill_subevt (state%trace%interaction_t)
        end if
      end select
    end if
  end subroutine parton_state_receive_kinematics

```

Recover kinematics: We assume that the trace evaluator is filled with momenta. Send those momenta back to the sources, then fill the variables and subevent as above.

The incoming momenta of the connected state are not connected to the isolated state but to the beam interaction. Therefore, the incoming momenta within the isolated state do not become defined, yet. Instead, we reconstruct the beam (and ISR) momentum configuration.

```

⟨Parton states: parton state: TBP⟩+≡
  procedure :: send_kinematics => parton_state_send_kinematics

```

```

<Parton states: procedures>+≡
subroutine parton_state_send_kinematics (state)
  class(parton_state_t), intent(inout), target :: state
  if (state%has_trace) then
    call interaction_send_momenta (state%trace%interaction_t)
    select type (state)
    class is (connected_state_t)
      call state%expr%fill_subevt (state%trace%interaction_t)
    end select
  end if
end subroutine parton_state_send_kinematics

```

Evaluate the expressions. The routine evaluates first the cut expression. If the event passes, it evaluates the other expressions. Where no expressions are defined, default values are inserted.

```

<Parton states: connected state: TBP>+≡
procedure :: evaluate_expressions => connected_state_evaluate_expressions

<Parton states: procedures>+≡
subroutine connected_state_evaluate_expressions (state, passed, &
  scale, fac_scale, ren_scale, weight, scale_forced, force_evaluation)
  class(connected_state_t), intent(inout) :: state
  logical, intent(out) :: passed
  real(default), intent(out) :: scale, fac_scale, ren_scale, weight

end module pcm_base

```

### 30.3.2 Core management

This object holds information about the cores used by the components and allocates the corresponding manager instance.

`i_component` is the index of the process component which this core belongs to. The pointer to the core definition is a convenient help in configuring the core itself.

We allow for a `blha_config` configuration object that covers BLHA cores. The BLHA standard is suitable generic to warrant support outside of specific type extension (i.e., applies to LO and NLO if requested). The BLHA configuration is allocated only if the core requires it.

```

<PCM base: public>≡
    public :: core_entry_t

<PCM base: types>≡
    type :: core_entry_t
        integer :: i_component = 0
        logical :: active = .false.
        class(prc_core_def_t), pointer :: core_def => null ()
        type(blha_template_t), allocatable :: blha_config
        class(prc_core_t), allocatable :: core
    contains
        <PCM base: core entry: TBP>
    end type core_entry_t

<PCM base: core entry: TBP>≡
    procedure :: get_core_ptr => core_entry_get_core_ptr

<PCM base: procedures>≡
    function core_entry_get_core_ptr (core_entry) result (core)
        class(core_entry_t), intent(in), target :: core_entry
        class(prc_core_t), pointer :: core
        if (allocated (core_entry%core)) then
            core => core_entry%core
        else
            core => null ()
        end if
    end function core_entry_get_core_ptr

```

Configure the core object after allocation with correct type. The `core_def` object pointer and the index `i_component` of the associated process component are already there.

```

<PCM base: core entry: TBP>+≡
    procedure :: configure => core_entry_configure

<PCM base: procedures>+≡
    subroutine core_entry_configure (core_entry, lib, id)
        class(core_entry_t), intent(inout) :: core_entry
        type(process_library_t), intent(in), target :: lib
        type(string_t), intent(in) :: id
        call core_entry%core%init &
            (core_entry%core_def, lib, id, core_entry%i_component)
    end subroutine core_entry_configure

```

### 30.3.3 Process component manager

This object may hold process and method-specific data, and it should allocate the corresponding manager instance.

The number of components determines the `component_selected` array.

`i_phs_config` is a lookup table that returns the PHS configuration index for a given component index.

`i_core` is a lookup table that returns the core-entry index for a given component index.

```

<PCM base: public>+≡
    public :: pcm_t

<PCM base: types>+≡
    type, abstract :: pcm_t
        logical :: initialized = .false.
        logical :: has_pdfs = .false.
        integer :: n_components = 0
        integer :: n_cores = 0
        integer :: n_mci = 0
        logical, dimension(:), allocatable :: component_selected
        logical, dimension(:), allocatable :: component_active
        integer, dimension(:), allocatable :: i_phs_config
        integer, dimension(:), allocatable :: i_core
        integer, dimension(:), allocatable :: i_mci
        type(blha_template_t) :: blha_defaults
        logical :: uses_blha = .false.
        type(os_data_t) :: os_data
    contains
    <PCM base: pcm: TBP>
    end type pcm_t

```

The factory method. We use the `inout` intent, so calling this again is an error.

```

<PCM base: pcm: TBP>≡
    procedure(pcm_allocate_instance), deferred :: allocate_instance

<PCM base: interfaces>≡
    abstract interface
        subroutine pcm_allocate_instance (pcm, instance)
            import
            class(pcm_t), intent(in) :: pcm
            class(pcm_instance_t), intent(inout), allocatable :: instance
        end subroutine pcm_allocate_instance
    end interface

<PCM base: pcm: TBP>+≡
    procedure(pcm_is_nlo), deferred :: is_nlo

<PCM base: interfaces>+≡
    abstract interface
        function pcm_is_nlo (pcm) result (is_nlo)
            import
            logical :: is_nlo
            class(pcm_t), intent(in) :: pcm
        end function pcm_is_nlo
    end interface

<PCM base: pcm: TBP>+≡
    procedure(pcm_final), deferred :: final

```

```

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_final (pcm)
      import
      class(pcm_t), intent(inout) :: pcm
    end subroutine pcm_final
  end interface

```

### 30.3.4 Initialization methods

The PCM has the duty to coordinate and configure the process-object components.

Initialize the PCM configuration itself, using environment data.

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_init), deferred :: init

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_init (pcm, env, meta)
      import
      class(pcm_t), intent(out) :: pcm
      type(process_environment_t), intent(in) :: env
      type(process_metadata_t), intent(in) :: meta
    end subroutine pcm_init
  end interface

```

Initialize the BLHA configuration block, the component-independent default settings. This is to be called by `pcm_init`. We use the provided variable list.

This block is filled regardless of whether BLHA is actually used, because why not? We use a default value for the scheme (not set in unit tests).

```

<PCM base: pcm: TBP>+≡
  procedure :: set_blha_defaults => pcm_set_blha_defaults

<PCM base: procedures>+≡
  subroutine pcm_set_blha_defaults (pcm, polarized_beams, var_list)
    class(pcm_t), intent(inout) :: pcm
    type(var_list_t), intent(in) :: var_list
    logical, intent(in) :: polarized_beams
    logical :: muon_yukawa_off
    real(default) :: top_yukawa
    type(string_t) :: ew_scheme
    muon_yukawa_off = &
      var_list%get_lval (var_str ("?openloops_switch_off_muon_yukawa"))
    top_yukawa = &
      var_list%get_rval (var_str ("blha_top_yukawa"))
    ew_scheme = &
      var_list%get_sval (var_str ("blha_ew_scheme"))
    if (ew_scheme == "") ew_scheme = "Gmu"
    call pcm%blha_defaults%init &
      (polarized_beams, muon_yukawa_off, top_yukawa, ew_scheme)
  end subroutine pcm_set_blha_defaults

```

Read the method settings from the variable list and store them in the BLHA master. The details depend on the pcm concrete type.

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_set_blha_methods), deferred :: set_blha_methods

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_set_blha_methods (pcm, blha_master, var_list)
      import
      class(pcm_t), intent(inout) :: pcm
      type(blha_master_t), intent(inout) :: blha_master
      type(var_list_t), intent(in) :: var_list
    end subroutine pcm_set_blha_methods
  end interface

```

Produce the LO and NLO flavor-state tables (as far as available), as appropriate for BLHA configuration. We may inspect either the PCM itself or the array of process cores.

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_get_blha_flv_states), deferred :: get_blha_flv_states

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_get_blha_flv_states (pcm, core_entry, flv_born, flv_real)
      import
      class(pcm_t), intent(in) :: pcm
      type(core_entry_t), dimension(:), intent(in) :: core_entry
      integer, dimension(:,:), allocatable, intent(out) :: flv_born
      integer, dimension(:,:), allocatable, intent(out) :: flv_real
    end subroutine pcm_get_blha_flv_states
  end interface

```

Allocate the right number of process components. The number is also stored in the process meta. Initially, all components are active but none are selected.

```

<PCM base: pcm: TBP>+≡
  procedure :: allocate_components => pcm_allocate_components

<PCM base: procedures>+≡
  subroutine pcm_allocate_components (pcm, comp, meta)
    class(pcm_t), intent(inout) :: pcm
    type(process_component_t), dimension(:), allocatable, intent(out) :: comp
    type(process_metadata_t), intent(in) :: meta
    pcm%n_components = meta%n_components
    allocate (comp (pcm%n_components))
    allocate (pcm%component_selected (pcm%n_components), source = .false.)
    allocate (pcm%component_active (pcm%n_components), source = .true.)
  end subroutine pcm_allocate_components

```

Each process component belongs to a category/type, which we identify by a universal integer constant. The categories can be taken from the process definition. For easy lookup, we store the categories in an array.

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_categorize_components), deferred :: categorize_components

```

*<PCM base: interfaces>+≡*

```
abstract interface
  subroutine pcm_categorize_components (pcm, config)
    import
    class(pcm_t), intent(inout) :: pcm
    type(process_config_data_t), intent(in) :: config
  end subroutine pcm_categorize_components
end interface
```

Allocate the right number and type(s) of process-core objects, i.e., the interface object between the process and matrix-element code.

Within the `pcm` block, also associate cores with components and store relevant configuration data, including the `i_core` lookup table.

*<PCM base: pcm: TBP>+≡*

```
procedure(pcm_allocate_cores), deferred :: allocate_cores
```

*<PCM base: interfaces>+≡*

```
abstract interface
  subroutine pcm_allocate_cores (pcm, config, core_entry)
    import
    class(pcm_t), intent(inout) :: pcm
    type(process_config_data_t), intent(in) :: config
    type(core_entry_t), dimension(:), allocatable, intent(out) :: core_entry
  end subroutine pcm_allocate_cores
end interface
```

Generate and interface external code for a single core, if this is required.

*<PCM base: pcm: TBP>+≡*

```
procedure(pcm_prepare_any_external_code), deferred :: &
  prepare_any_external_code
```

*<PCM base: interfaces>+≡*

```
abstract interface
  subroutine pcm_prepare_any_external_code &
    (pcm, core_entry, i_core, libname, model, var_list)
    import
    class(pcm_t), intent(in) :: pcm
    type(core_entry_t), intent(inout) :: core_entry
    integer, intent(in) :: i_core
    type(string_t), intent(in) :: libname
    type(model_data_t), intent(in), target :: model
    type(var_list_t), intent(in) :: var_list
  end subroutine pcm_prepare_any_external_code
end interface
```

Prepare the BLHA configuration for a core object that requires it. This does not affect the core object, which may not yet be allocated.

*<PCM base: pcm: TBP>+≡*

```
procedure(pcm_setup_blha), deferred :: setup_blha
```

*<PCM base: interfaces>+≡*

```
abstract interface
  subroutine pcm_setup_blha (pcm, core_entry)
```

```

import
class(pcm_t), intent(in) :: pcm
type(core_entry_t), intent(inout) :: core_entry
end subroutine pcm_setup_blha
end interface

```

Configure the BLHA interface for a core object that requires it. This is separate from the previous method, assuming that the pcm has to allocate the actual cores and acquire some data in-between.

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_prepare_blha_core), deferred :: prepare_blha_core
<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_prepare_blha_core (pcm, core_entry, model)
      import
      class(pcm_t), intent(in) :: pcm
      type(core_entry_t), intent(inout) :: core_entry
      class(model_data_t), intent(in), target :: model
    end subroutine pcm_prepare_blha_core
  end interface

```

Allocate and configure the MCI (multi-channel integrator) records and their relation to process components, appropriate for the algorithm implemented by pcm.

Create a mci\_t template: the procedure `dispatch_mci` is called as a factory method for allocating the mci\_t object with a specific concrete type. The call may depend on the concrete pcm type.

```

<PCM base: public>+≡
  public :: dispatch_mci_proc
<PCM base: interfaces>+≡
  abstract interface
    subroutine dispatch_mci_proc (mci, var_list, process_id, is_nlo)
      import
      class(mci_t), allocatable, intent(out) :: mci
      type(var_list_t), intent(in) :: var_list
      type(string_t), intent(in) :: process_id
      logical, intent(in), optional :: is_nlo
    end subroutine dispatch_mci_proc
  end interface

  <PCM base: pcm: TBP>+≡
    procedure(pcm_setup_mci), deferred :: setup_mci
    procedure(pcm_call_dispatch_mci), deferred :: call_dispatch_mci
  <PCM base: interfaces>+≡
    abstract interface
      subroutine pcm_setup_mci (pcm, mci_entry)
        import
        class(pcm_t), intent(inout) :: pcm
        type(process_mci_entry_t), &
          dimension(:), allocatable, intent(out) :: mci_entry

```

```

        end subroutine pcm_setup_mci
    end interface

    abstract interface
        subroutine pcm_call_dispatch_mci (pcm, &
            dispatch_mci, var_list, process_id, mci_template)
            import
            class(pcm_t), intent(inout) :: pcm
            procedure(dispatch_mci_proc) :: dispatch_mci
            type(var_list_t), intent(in) :: var_list
            type(string_t), intent(in) :: process_id
            class(mci_t), intent(out), allocatable :: mci_template
        end subroutine pcm_call_dispatch_mci
    end interface

```

Proceed with PCM configuration based on the core and component configuration data. Base version is empty.

```

<PCM base: pcm: TBP>+≡
    procedure(pcm_complete_setup), deferred :: complete_setup

<PCM base: interfaces>+≡
    abstract interface
        subroutine pcm_complete_setup (pcm, core_entry, component, model)
            import
            class(pcm_t), intent(inout) :: pcm
            type(core_entry_t), dimension(:), intent(in) :: core_entry
            type(process_component_t), dimension(:), intent(inout) :: component
            type(model_t), intent(in), target :: model
        end subroutine pcm_complete_setup
    end interface

```

## Retrieve information

Return the core index that belongs to a particular component.

```

<PCM base: pcm: TBP>+≡
    procedure :: get_i_core => pcm_get_i_core

<PCM base: procedures>+≡
    function pcm_get_i_core (pcm, i_component) result (i_core)
        class(pcm_t), intent(in) :: pcm
        integer, intent(in) :: i_component
        integer :: i_core
        if (allocated (pcm%i_core)) then
            i_core = pcm%i_core(i_component)
        else
            i_core = 0
        end if
    end function pcm_get_i_core

```

## Phase-space configuration

Allocate and initialize the right number and type(s) of phase-space configuration entries. The `i_phs_config` lookup table must be set accordingly.

```
(PCM base: pcm: TBP)+≡
  procedure(pcm_init_phs_config), deferred :: init_phs_config

(PCM base: interfaces)+≡
  abstract interface
    subroutine pcm_init_phs_config &
      (pcm, phs_entry, meta, env, phs_par, mapping_defs)
    import
    class(pcm_t), intent(inout) :: pcm
    type(process_phs_config_t), &
      dimension(:), allocatable, intent(out) :: phs_entry
    type(process_metadata_t), intent(in) :: meta
    type(process_environment_t), intent(in) :: env
    type(mapping_defaults_t), intent(in) :: mapping_defs
    type(phs_parameters_t), intent(in) :: phs_par
  end subroutine pcm_init_phs_config
end interface
```

Initialize a single component. We require all process-configuration blocks, and specific templates for the phase-space and integrator configuration.

We also provide the current component index `i` and the active flag.

```
(PCM base: pcm: TBP)+≡
  procedure(pcm_init_component), deferred :: init_component

(PCM base: interfaces)+≡
  abstract interface
    subroutine pcm_init_component &
      (pcm, component, i, active, phs_config, env, meta, config)
    import
    class(pcm_t), intent(in) :: pcm
    type(process_component_t), intent(out) :: component
    integer, intent(in) :: i
    logical, intent(in) :: active
    class(phs_config_t), allocatable, intent(in) :: phs_config
    type(process_environment_t), intent(in) :: env
    type(process_metadata_t), intent(in) :: meta
    type(process_config_data_t), intent(in) :: config
  end subroutine pcm_init_component
end interface
```

Record components in the process meta data if they have turned out to be inactive.

```
(PCM base: pcm: TBP)+≡
  procedure :: record_inactive_components => pcm_record_inactive_components

(PCM base: procedures)+≡
  subroutine pcm_record_inactive_components (pcm, component, meta)
    class(pcm_t), intent(inout) :: pcm
    type(process_component_t), dimension(:), intent(in) :: component
    type(process_metadata_t), intent(inout) :: meta
```

```

integer :: i
pcm%component_active = component%active
do i = 1, pcm%n_components
    if (.not. component(i)%active) call meta%deactivate_component (i)
end do
end subroutine pcm_record_inactive_components

```

### 30.3.5 Manager instance

This object deals with the actual (squared) matrix element values.

```

<PCM base: public>+≡
    public :: pcm_instance_t

<PCM base: types>+≡
    type, abstract :: pcm_instance_t
        class(pcm_t), pointer :: config => null ()
        logical :: bad_point = .false.
    contains

  private
end type process_results_t

```

### 30.4.3 The process type

A process object is the workspace for the process instance. After initialization, its contents are filled by integration passes which shape the integration grids and compute cross sections. Processes are set up initially from user-level configuration data. After calculating integrals and thus developing integration grid data, the program may use a process object or a copy of it for the purpose of generating events.

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The **type** determines whether we are considering a decay or a scattering process.

The **meta** object describes the process and its environment. All contents become fixed when the object is initialized.

The **config** object holds physical and technical configuration data that have been obtained during process initialization, and which are common to all process components.

The individual process components are configured in the **component** objects. These objects contain more configuration parameters and workspace, as needed for the specific process variant.

The **term** objects describe parton configurations which are technically used as phase-space points. Each process component may split into several terms with distinct kinematics and particle content. Furthermore, each term may project on a different physical state, e.g., by particle recombination. The **term** object provides the framework for this projection, for applying cuts, weight, and thus completing the process calculation.

The **beam.config** object describes the incoming particles, either the decay mother or the scattering beams. It also contains the structure-function information.

The **mci.entry** objects configure a MC input parameter set and integrator, each. The number of parameters depends on the process component and on the beam and structure-function setup.

The **pcm** component is the process-component manager. This polymorphic object manages and hides the details of dealing with NLO processes where several components have to be combined in a non-trivial way. It also acts as an abstract factory for the corresponding object in **process\_instance**, which does the actual work for this matter.

#### 30.4.4 Process pointer

Wrapper type for storing pointers to process objects in arrays.

```

<Process: public>+≡
    public :: process_ptr_t

<Process: types>+≡
    type :: process_ptr_t
        type(process_t), pointer :: p => null ()
    end type process_ptr_t

```

#### 30.4.5 Output

This procedure is an important debugging and inspection tool; it is not used during normal operation. The process object is written to a file (identified by unit, which may also be standard output). Optional flags determine whether we show everything or just the interesting parts.

The shorthand as a traditional TBP.

```

<Process: process: TBP>≡
    procedure :: write => process_write

```

```

<Process: procedures>+=
  subroutine process_write (process, screen, unit, &
    show_os_data, show_var_list, show_rng, show_expressions, pacify)
    class(process_t), intent(in) :: process
    logical, intent(in) :: screen
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: show_os_data
    logical, intent(in), optional :: show_var_list
    logical, intent(in), optional :: show_rng
    logical, intent(in), optional :: show_expressions
    logical, intent(in), optional :: pacify
    integer :: u, iostat
    character(0) :: iomsg
    integer, dimension(:), allocatable :: v_list
    u = given_output_unit (unit)
    allocate (v_list (0))
    call set_flag (v_list, F_SHOW_OS_DATA, show_os_data)
    call set_flag (v_list, F_SHOW_VAR_LIST, show_var_list)
    call set_flag (v_list, F_SHOW_RNG, show_rng)
    call set_flag (v_list, F_SHOW_EXPRESSIONS, show_expressions)
    call set_flag (v_list, F_PACIFY, pacify)
    if (screen) then
      call process%write_formatted (u, "LISTDIRECTED", v_list, iostat, iomsg)
    else
      call process%write_formatted (u, "DT", v_list, iostat, iomsg)
    end if
  end subroutine process_write

```

Standard DTIO procedure with binding.

For the particular application, the screen format is triggered by the LISTDIRECTED option for the iotype format editor string. The other options activate when the particular parameter value is found in v\_list.

NOTE: The DTIO generic binding is supported by gfortran since 7.0.

TODO wk 2018: The default could be to show everything, and we should have separate switches for all major parts. Currently, there are only a few.

```

<Process: process: TBP>+=
  ! generic :: write (formatted) => write_formatted

```

Finalizer. Explicitly iterate over all subobjects that may contain allocated pointers.

TODO wk 2018 (workaround): The finalizer for the `config_data` component is not called. The reason is that this deletes model data local to the process, but these could be referenced by pointers (flavor objects) from some persistent event record. Obviously, such side effects should be avoided, but this requires refactoring the event-handling procedures.

```

(Process: process: TBP)+≡
    procedure :: final => process_final

(Process: procedures)+≡
    subroutine process_final (process)

  deallocate (process%pcm)
end if
end subroutine process_final

```

## Process setup

Initialize a process. We need a process library `lib` and the process identifier `proc_id` (string). We will fetch the current run ID from the variable list `var_list`.

We collect all important data from the environment and store them in the appropriate places. OS data, model, and variable list are copied into `env` (true snapshot), also the process library (pointer only).

The `meta` subobject is initialized with process ID and attributes taken from the process library.

We initialize the `config` subobject with all data that are relevant for this run, using the settings from `env`. These data determine the MD5 sum for this run, which allows us to identify the setup and possibly skips in a later re-run.

We also allocate and initialize the embedded RNG factory. We take the seed from the `var_list`, and we should return the `var_list` to the caller with a new seed.

Finally, we allocate the process component manager `pcm`, which implements the chosen algorithm for process integration. The first task of the manager is to allocate the component array and to determine the component categories (e.g., Born/Virtual etc.).

TODO wk 2018: The `pcm` dispatcher should be provided by the caller, if we eventually want to eliminate dependencies on concrete `pcm_t` extensions.

```

(Process: process: TBP)+≡
  procedure :: init => process_init

(Process: procedures)+≡

    end associate
end associate
end subroutine process_init

```

### 30.4.6 Process component manager

The `pcm` (read: process-component manager) takes the responsibility of steering the actual algorithm of configuration and integration. Depending on the concrete type, different algorithms can be implemented.

The first version of this supports just two implementations: leading-order (tree-level) integration and event generation, and NLO (QCD/FKS subtraction). We thus can start with a single logical for steering the dispatcher.

TODO wk 2018: Eventually, we may eliminate all references to the extensions of `pcm_t` from this module and therefore move this outside the module as well.

```

(Process: procedures)+≡
subroutine dispatch_pcm (pcm, is_nlo)
    class(pcm_t), allocatable, intent(out) :: pcm
    logical, intent(in) :: is_nlo
    if (.not. is_nlo) then
        allocate (pcm_default_t :: pcm)
    else
        allocate (pcm_nlo_t :: pcm)
    end if
end subroutine dispatch_pcm

```

This step is performed after phase-space and core objects are done: collect all missing information and prepare the process component manager for the appropriate integration algorithm.

```

(Process: process: TBP)+≡

```

```

    procedure :: complete_pcm_setup => process_complete_pcm_setup
  <Process: procedures>+≡
    subroutine process_complete_pcm_setup (process)
      class(process_t), intent(inout) :: process
      call process%pcm%complete_setup &
        (process%core_entry, process%component, process%env%get_model_ptr ())
    end subroutine process_complete_pcm_setup

```

### 30.4.7 Core management

Allocate cores (interface objects to matrix-element code).

The `dispatch_core` procedure is taken as an argument, so we do not depend on the implementation, and thus on the specific core types.

The `helicity_selection` object collects data that the matrix-element code needs for configuring the appropriate behavior.

After the cores have been allocated, and assuming the phs initial configuration has been done before, we proceed with computing the pcm internal data.

```

  <Process: process: TBP>+≡
    procedure :: setup_cores => process_setup_cores
  <Process: procedures>+≡
    subroutine process_setup_cores (process, dispatch_core, &
      helicity_selection, use_color_factors, has_beam_pol)
      class(process_t), intent(inout) :: process
      procedure(dispatch_core_proc) :: dispatch_core

      logical, intent(in), optional :: use_color_factors
      logical, intent(in), optional :: has_beam_pol
      integer :: i
      associate (pcm => process%pcm)
        call pcm%allocate_cores (process%config, process%core_entry)
        do i = 1, size (process%core_entry)
          call dispatch_core (process%core_entry(i)%core, &
            process%core_entry(i)%core_def, &
            process%config%model, &
            helicity_selection, &
            process%config%qcd, &
            use_color_factors, &
            has_beam_pol)
          call process%core_entry(i)%configure &
            (process%env%get_lib_ptr (), process%meta%id)
          if (process%core_entry(i)%core%uses_blha ()) then
            call pcm%setup_blha (process%core_entry(i))
          end if
        end do
      end associate
    end subroutine process_setup_cores

  <Process: interfaces>≡
    abstract interface
      subroutine dispatch_core_proc (core, core_def, model, &

```

```

        helicity_selection, qcd, use_color_factors, has_beam_pol)
import
class(prc_core_t), allocatable, intent(inout) :: core
class(prc_core_def_t), intent(in) :: core_def
class(model_data_t), intent(in), target, optional :: model
type(helicity_selection_t), intent(in), optional :: helicity_selection
type(qcd_t), intent(in), optional :: qcd
logical, intent(in), optional :: use_color_factors
logical, intent(in), optional :: has_beam_pol
end subroutine dispatch_core_proc
end interface

```

Use the pcm to initialize the BLHA interface for each core which requires it.

```

<Process: process: TBP>+≡
    procedure :: prepare_blha_cores => process_prepare_blha_cores

<Process: procedures>+≡
    subroutine process_prepare_blha_cores (process)
        class(process_t), intent(inout), target :: process
        integer :: i
        associate (pcm => process%pcm)
            do i = 1, size (process%core_entry)
                associate (core_entry => process%core_entry(i))
                    if (core_entry%core%uses_blha ()) then
                        pcm%uses_blha = .true.
                        call pcm%prepare_blha_core (core_entry, process%config%model)
                    end if
                end associate
            end do
        end associate
    end subroutine process_prepare_blha_cores

```

Create the BLHA interface data, using PCM for specific data, and write the BLHA contract file(s).

We take various configuration data and copy them to the `blha_master` record, which then creates and writes the contracts.

For assigning the QCD/EW coupling powers, we inspect the first process component only. The other parameters are taken as-is from the process environment variables.

```

<Process: process: TBP>+≡
    procedure :: create_blha_interface => process_create_blha_interface

```

Initialize the process components, one by one. We require templates for the `mci` (integrator) and `phs_config` (phase-space) configuration data.

The `active` flag is set if the component has an associated matrix element, so we can compute it. The case of no core is a unit-test case.

The specifics depend on the algorithm and are delegated to the `pcm` process-component manager.

The optional `phs_config` overrides a pre-generated config array (for unit test).

```

<Process: process: TBP>+≡
  procedure :: init_components => process_init_components
<Process: procedures>+≡

```

```

```

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a

scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam_data_t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by extending the code in the `beams` module.

```

We complete the kinematics configuration after the beam setup, but before we configure the chain of structure functions. The reason is that we need the

total energy `sqrts` for the kinematics, but the structure-function setup requires the number of channels, which depends on the kinematics configuration. For instance, the kinematics module may return the need for parameterizing an s-channel resonance.

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config.data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

## MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

```

### 30.4.8 Default iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

<Process: process: TBP>+=
  procedure :: get_n_pass_default => process_get_n_pass_default
  procedure :: adapt_grids_default => process_adapt_grids_default
  procedure :: adapt_weights_default => process_adapt_weights_default

```

*<Process: procedures>+≡*

```

### 30.4.10 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```

(Process: process: TBP)+≡
  procedure :: compute_amplitude => process_compute_amplitude

    integer, parameter, public :: COMP_SUB = 8
    integer, parameter, public :: COMP_RESUM = 9

```

### 30.5.1 Output selection flags

We declare a number of identifiers for write methods, so they only displays selected parts. The identifiers can be supplied to the `vlist` array argument of the standard F2008 derived-type writer call.

```

<Process config: parameters>+≡
    integer, parameter, public :: F_PACIFY = 1
    integer, parameter, public :: F_SHOW_VAR_LIST = 11
    integer, parameter, public :: F_SHOW_EXPRESSIONS = 12
    integer, parameter, public :: F_SHOW_LIB = 13
    integer, parameter, public :: F_SHOW_MODEL = 14
    integer, parameter, public :: F_SHOW_QCD = 15
    integer, parameter, public :: F_SHOW_OS_DATA = 16
    integer, parameter, public :: F_SHOW_RNG = 17
    integer, parameter, public :: F_SHOW_BEAMS = 18

```

This is a simple function that returns true if a flag value is present in `v_list`, but not its negative. If neither is present, it returns `default`.

```

<Process config: public>≡
    public :: flagged

<Process config: procedures>≡
    function flagged(v_list, id, def) result(flag)
        logical :: flag
        integer, dimension(:), intent(in) :: v_list
        integer, intent(in) :: id

```

```

logical, intent(in), optional :: def
logical :: default_result
default_result = .false.; if (present (def)) default_result = def
if (default_result) then
    flag = all (v_list /= -id)
else
    flag = all (v_list /= -id) .and. any (v_list == id)
end if
end function flagged

```

Related: if flag is set (unset), append **value** (its negative) to the **v\_list**, respectively. **v\_list** must be allocated.

```

<Process config: public>+≡
    public :: set_flag

<Process config: procedures>+≡

        integer, dimension(:), intent(inout), allocatable :: v_list
        integer, intent(in) :: value
        logical, intent(in), optional :: flag
        if (present (flag)) then
            if (flag) then
                v_list = [v_list, value]
            else
                v_list = [v_list, -value]
            end if
        end if
    end subroutine set_flag

```

### 30.5.2 Generic configuration data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the variable list.

The number **n.in** is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number **n.components** is the number of components that constitute the current process.

The number **n.terms** is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number **n.mci** is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The **model** pointer identifies the physics model and its parameters. This is a pointer to an external object.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the `effective_state` subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The `md5sum` is taken and used to verify the process configuration when re-reading data from file.

```

(Process config: public)+≡
    public :: process_config_data_t

(Process config: types)≡
    type :: process_config_data_t
        class(process_def_t), pointer :: process_def => null ()

end if
end subroutine process_config_data_write

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

The model pointer references the model data within the `env` record. That should be an instance of the global model.

We initialize the QCD object, unless the environment information is unavailable (unit tests).

The RNG factory object is imported by moving the allocation.

```

(Process config: process config data: TBP)+≡

```

### 30.5.3 Environment

This record stores a snapshot of the process environment at the point where the process object is created.

Model and variable list are implemented as pointer, so they always have the `target` attribute.

For unit-testing purposes, setting the var list is optional. If not set, the pointer is null.

```

<Process config: public>+≡
    public :: process_environment_t

<Process config: types>+≡
    type :: process_environment_t
        private
        type(model_t), pointer :: model => null ()
        type(var_list_t), pointer :: var_list => null ()
        logical :: var_list_is_set = .false.
        type(process_library_t), pointer :: lib => null ()
        type(beam_structure_t) :: beam_structure
        type(os_data_t) :: os_data
    contains
        <Process config: process environment: TBP>
    end type process_environment_t

```

Model and local var list are snapshots and need a finalizer.

```

<Process config: process environment: TBP>≡
    procedure :: final => process_environment_final

<Process config: procedures>+≡
    subroutine process_environment_final (env)
        class(process_environment_t), intent(inout) :: env
        if (associated (env%model)) then
            call env%model%final ()
        end if
    end subroutine process_environment_final

```

```

        deallocate (env%model)
    end if
    if (associated (env%var_list)) then
        call env%var_list%final (follow_link=.true.)
        deallocate (env%var_list)
    end if
end subroutine process_environment_final

```

Output, DTIO compatible.

```

```

Initialize: Make a snapshot of the provided model. Make a link to the current process library.

Also make a snapshot of the variable list, if provided. If none is provided, there is an empty variable list nevertheless, so a pointer lookup does not return null.

If no beam structure is provided, the beam-structure member is empty and will yield a number of zero beams when queried.

### 30.5.4 Metadata

This information describes the process. It is fixed upon initialization.

The `id` string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The `num_id` is meaningful if nonzero. It is used for communication with external programs or file standards which do not support string IDs.

The `run_id` string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and

similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The `lib_name` identifies the process library where the process definition and the process driver are located.

The `lib_index` is the index of entry in the process library that corresponds to the current process.

The `component_id` array identifies the individual process components.

The `component_description` is an array of human-readable strings that characterize the process components, for instance `a, b => c, d`.

The `active` mask array marks those components which are active. The others are skipped.

### 30.5.6 Beam configuration

The object `data` holds all details about the initial beam configuration. The allocatable array `sf` holds the structure-function configuration blocks. There are `n_strfun` entries in the structure-function chain (not counting the initial beam object). We maintain `n_channel` independent parameterizations of this chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is `n_sfpar`.

The flag `azimuthal_dependence` tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag `lab_is_cm` is obvious.

```

<Process config: public>+≡
public :: process_beam_config_t

<Process config: types>+≡

### 30.5.7 Process components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components can have different types. In short, `process_component_t` is a wrapper for the actual process variants.

If the `active` flag is false, we should skip this component. This happens if the associated process has vanishing matrix element.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

(Process config: public)+≡
    public :: process_component_t

(Process config: types)+≡
    type :: process_component_t
        type(process_component_def_t), pointer :: config => null ()

### 30.5.8 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`. In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`. This is the total number of independent entries in the density matrix. For each

combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

This type is public only for use in a unit test.

```

<Process config: public>+≡
  public :: process_term_t
<Process config: types>+≡
  type :: process_term_t
    integer :: i_term_global = 0
    integer :: i_component = 0
    integer :: i_term = 0
    integer :: i_sub = 0
    integer :: i_core = 0
    integer :: n_allowed = 0
    type(process_constants_t) :: data
    real(default) :: alpha_s = 0
    integer, dimension(:), allocatable :: flv, hel, col
    integer :: n_sub, n_sub_color, n_sub_spin
    type(interaction_t) :: int
    type(interaction_t), pointer :: int_eff => null ()
  contains
    <Process config: process term: TBP>
  end type process_term_t

```

For the output, we skip the process constants and the tables of allowed quantum numbers. Those can also be read off from the interaction object.

```

    end do
  end subroutine process_term_write_state_summary

```

Finalizer: the `int` and potentially `int_eff` components have a finalizer that we must call.

```

(Process config: process term: TBP)+≡
  procedure :: final => process_term_final

(Process config: procedures)+≡
  subroutine process_term_final (term)
    class(process_term_t), intent(inout) :: term
    call term%int%final ()
  end subroutine process_term_final

```

Initialize the term. We copy the process constants from the `core` object and set up the `int` hard interaction accordingly.

The `alpha_s` value is useful for writing external event records. This is the constant value which may be overridden by a event-specific running value. If the model does not contain the strong coupling, the value is zero.

The `rearrange` part is commented out; this or something equivalent could become relevant for NLO algorithms.

```

(Process config: process term: TBP)+≡
  procedure :: init => process_term_init

(Process config: procedures)+≡
  subroutine process_term_init &
    (term, i_term_global, i_component, i_term, core, model, &

    logical :: use_internal_color
    term%i_term_global = i_term_global
    term%i_component = i_component
    term%i_term = i_term
    call core%get_constants (term%data, i_term)
    alpha_s_ptr => model%get_par_data_ptr (var_str ("alphas"))
    if (associated (alpha_s_ptr)) then
      term%alpha_s = alpha_s_ptr%get_real ()
    else
      term%alpha_s = -1
    end if
    use_internal_color = .false.
    if (present (subtraction_method)) &
      use_internal_color = (char (subtraction_method) == 'omega') &
        .or. (char (subtraction_method) == 'threshold')
    call term%setup_interaction (core, model, nlo_type = nlo_type, &
      pol_beams = use_beam_pol, use_internal_color = use_internal_color, &
      has_pdfs = has_pdfs, n_emitters = n_emitters)
  end subroutine process_term_init

```

We fetch the process constants which determine the quantum numbers and use those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

**Why are these four subtraction entries for structure-function aware interactions?** Taking the soft or collinear limit of the real-emission matrix element, the behavior of the parton energy fractions has to be taken into account.

In the pure real case,  $x_{\oplus}$  and  $x_{\ominus}$  are given by

$$x_{\oplus} = \frac{\bar{x}_{\oplus}}{\sqrt{1-\xi}} \sqrt{\frac{2-\xi(1-y)}{2-\xi(1+y)}}, \quad x_{\ominus} = \frac{\bar{x}_{\ominus}}{\sqrt{1-\xi}} \sqrt{\frac{2-\xi(1+y)}{2-\xi(1-y)}}.$$

In the soft limit,  $\xi \rightarrow 0$ , this yields  $x_{\oplus} = \bar{x}_{\oplus}$  and  $x_{\ominus} = \bar{x}_{\ominus}$ . In the collinear limit,  $y \rightarrow 1$ , it is  $x_{\oplus} = \bar{x}_{\oplus}/(1-\xi)$  and  $x_{\ominus} = \bar{x}_{\ominus}$ . Likewise, in the anti-collinear limit  $y \rightarrow -1$ , the inverse relation holds. We therefore have to distinguish four cases with the PDF assignments  $f(x_{\oplus}) \cdot f(x_{\ominus})$ ,  $f(\bar{x}_{\oplus}) \cdot f(\bar{x}_{\ominus})$ ,  $f(\bar{x}_{\oplus}/(1-\xi)) \cdot f(\bar{x}_{\ominus})$  and  $f(\bar{x}_{\oplus}) \cdot f(\bar{x}_{\ominus}/(1-\xi))$ .

The `n_emitters` optional argument is provided by the caller if this term requires spin-correlated matrix elements, and thus involves additional subtractions.

end subroutine setup_states_omega

end subroutine process_term_setup_interaction

<Process config: process term: TBP>+≡
    procedure :: get_process_constants => process_term_get_process_constants

<Process config: procedures>+≡
    subroutine process_term_get_process_constants &
        (term, prc_constants)
    class(process_term_t), intent(inout) :: term

```

```

    type(process_constants_t), intent(out) :: prc_constants
    prc_constants = term%data
end subroutine process_term_get_process_constants

```

## 30.6 Process call statistics

Very simple object for statistics. Could be moved to a more basic chapter.

```

<process_counter.f90>≡
  <File header>

  module process_counter

    use io_units

    <Standard module head>

    <Process counter: public>

    <Process counter: parameters>

    <Process counter: types>

    contains

    <Process counter: procedures>

  end module process_counter

```

This object can record process calls, categorized by evaluation status. It is a part of the `mci_entry` component below.

```

<Process counter: public>≡
  public :: process_counter_t

<Process counter: types>≡
  type :: process_counter_t
    integer :: total = 0
    integer :: failed_kinematics = 0
    integer :: failed_cuts = 0
    integer :: has_passed = 0
    integer :: evaluated = 0
    integer :: complete = 0
    contains
    <Process counter: process counter: TBP>
  end type process_counter_t

```

Here are the corresponding numeric codes:

```

<Process counter: parameters>≡
  integer, parameter, public :: STAT_UNDEFINED = 0
  integer, parameter, public :: STAT_INITIAL = 1
  integer, parameter, public :: STAT_ACTIVATED = 2
  integer, parameter, public :: STAT_BEAM_MOMENTA = 3
  integer, parameter, public :: STAT_FAILED_KINEMATICS = 4

```

```

integer, parameter, public :: STAT_SEED_KINEMATICS = 5
integer, parameter, public :: STAT_HARD_KINEMATICS = 6
integer, parameter, public :: STAT_EFF_KINEMATICS = 7
integer, parameter, public :: STAT_FAILED_CUTS = 8
integer, parameter, public :: STAT_PASSED_CUTS = 9
integer, parameter, public :: STAT_EVALUATED_TRACE = 10
integer, parameter, public :: STAT_EVENT_COMPLETE = 11

```

Output.

```

(Process counter: process counter: TBP)≡
  procedure :: write => process_counter_write

(Process counter: procedures)≡
  subroutine process_counter_write (object, unit)
    class(process_counter_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    if (object%total > 0) then
      write (u, "(1x,A)") "Call statistics (current run):"
      write (u, "(3x,A,I0)") "total          = ", object%total
      write (u, "(3x,A,I0)") "failed kin. = ", object%failed_kinematics
      write (u, "(3x,A,I0)") "failed cuts = ", object%failed_cuts
      write (u, "(3x,A,I0)") "passed cuts = ", object%has_passed
      write (u, "(3x,A,I0)") "evaluated   = ", object%evaluated
    else
      write (u, "(1x,A)") "Call statistics (current run): [no calls]"
    end if
  end subroutine process_counter_write

```

Reset. Just enforce default initialization.

```

(Process counter: process counter: TBP)+≡
  procedure :: reset => process_counter_reset

(Process counter: procedures)+≡
  subroutine process_counter_reset (counter)
    class(process_counter_t), intent(out) :: counter
    counter%total = 0
    counter%failed_kinematics = 0
    counter%failed_cuts = 0
    counter%has_passed = 0
    counter%evaluated = 0
    counter%complete = 0
  end subroutine process_counter_reset

```

We record an event according to the lowest status code greater or equal to the actual status. This is actually done by the process instance; the process object just copies the instance counter.

```

(Process counter: process counter: TBP)+≡
  procedure :: record => process_counter_record

(Process counter: procedures)+≡
  subroutine process_counter_record (counter, status)
    class(process_counter_t), intent(inout) :: counter

```

```

integer, intent(in) :: status
if (status <= STAT_FAILED_KINEMATICS) then
    counter%failed_kinematics = counter%failed_kinematics + 1
else if (status <= STAT_FAILED_CUTS) then
    counter%failed_cuts = counter%failed_cuts + 1
else if (status <= STAT_PASSED_CUTS) then
    counter%has_passed = counter%has_passed + 1
else
    counter%evaluated = counter%evaluated + 1
end if
counter%total = counter%total + 1
end subroutine process_counter_record

```

## 30.7 Multi-channel integration

```

<process_mci.f90>≡
  <File header>

  module process_mci

    <Use kinds>
    <Use strings>
    <Use debug>
    use io_units
    use diagnostics
    use physics_defs
    use md5
    use cputime
    use rng_base
    use mci_base
    use variables
    use integration_results
    use process_libraries
    use phs_base
    use process_counter
    use process_config

    <Standard module head>

    <Process mci: public>

    <Process mci: parameters>

    <Process mci: types>

    contains

    <Process mci: procedures>

  end module process_mci

```

### 30.7.1 Process MCI entry

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly the values that apply to the current pass. Previous values are archived in the `results` object.

The `counter` receives the counter statistics from the associated process instance, for diagnostics.

The `results` object records results, broken down in passes and iterations.

```

(Process mci: public)≡
    public :: process_mci_entry_t

(Process mci: types)≡
    type :: process_mci_entry_t
        integer :: i_mci = 0

        end if
    end subroutine process_mci_entry_write

```

Configure the MCI entry. This is intent(inout) since some specific settings may be done before this. The actual *mci\_t* object is an instance of the *mci\_template* argument, which determines the concrete types.

In a unit-test context, the *mci\_template* argument may be unallocated.

We obtain the number of channels and the number of parameters, separately for the structure-function chain and for the associated process component. We assume that the phase-space object has already been configured.

We assume that there is only one process component directly associated with a MCI entry.

    call mci_entry%mci%sampler_test (mci_sampler, n_calls)
  end subroutine process_mci_entry_sampler_test

```

Integrate.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

```

end subroutine process_mci_entry_prepare_simulation

```

Generate an event. The instance should be initialized, otherwise event generation is directed by the *mci* integrator subobject. The integrator instance is contained in a *mci\_work* subobject of the process instance, which simultaneously serves as the sampler object. (We avoid the anti-aliasing rules if we assume that the sampling itself does not involve the integrator instance contained in the process instance.)

Regarding weighted events, we only take events which are valid, which means that they have valid kinematics and have passed cuts. Therefore, we have a rejection loop. For unweighted events, the unweighting routine should already take care of this.

The *keep\_failed* flag determines whether events which failed cuts are nevertheless produced, to be recorded with zero weight. Alternatively, failed events are dropped, and this fact is recorded by the counter *n\_dropped*.

```

### 30.7.2 MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

```

(Process mci: public)+≡
  public :: mci_work_t

(Process mci: types)+≡
  type :: mci_work_t
    type(process_mci_entry_t), pointer :: config => null ()
    real(default), dimension(:), allocatable :: x
    class(mci_instance_t), pointer :: mci => null ()
    type(process_counter_t) :: counter
    logical :: keep_failed_events = .false.
    integer :: n_event_dropped = 0
  contains
    (Process mci: mci work: TBP)
  end type mci_work_t

```

First write configuration data, then the current values.

```

(Process mci: mci work: TBP)≡
  procedure :: write => mci_work_write

(Process mci: procedures)+≡
  subroutine mci_work_write (mci_work, unit, testflag)
    class(mci_work_t), intent(in) :: mci_work
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A,I0,A)") "Active MCI instance #", &
      mci_work%config%i_mci, " ="
    write (u, "(2x)", advance="no")
    do i = 1, mci_work%config%n_par
      write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
      if (i == mci_work%config%n_par_sf) &
        write (u, "(1x,'|')", advance="no")
    end do
    write (u, *)
    if (associated (mci_work%mci)) then
      call mci_work%mci%write (u, pacify = testflag)
      call mci_work%counter%write (u)
    end if
  end subroutine mci_work_write

```

```
end subroutine mci_work_write
```

The mci component may require finalization.

```
<Process mci: mci work: TBP>+≡
  procedure :: final => mci_work_final

<Process mci: procedures>+≡
  subroutine mci_work_final (mci_work)
    class(mci_work_t), intent(inout) :: mci_work
    if (associated (mci_work%mci)) then
      call mci_work%mci%final ()
      deallocate (mci_work%mci)
    end if
  end subroutine mci_work_final
```

Initialize with the maximum length that we will need. Contents are not initialized.

The integrator inside the `mci_entry` object is responsible for allocating and initializing its own instance, which is referred to by a pointer in the `mci_work` object.

```
<Process mci: mci work: TBP>+≡
  procedure :: init => mci_work_init

<Process mci: procedures>+≡
  subroutine mci_work_init (mci_work, mci_entry)

    procedure :: is_nlo => pcm_default_is_nlo

<Pcm: procedures>+≡
    function pcm_default_is_nlo (pcm) result (is_nlo)
        logical :: is_nlo
        class(pcm_default_t), intent(in) :: pcm
        is_nlo = .false.
    end function pcm_default_is_nlo

```

Initialize configuration data, using environment variables.

```

<Pcm: pcm default: TBP>+≡
    procedure :: init => pcm_default_init

<Pcm: procedures>+≡
    subroutine pcm_default_init (pcm, env, meta)
        class(pcm_default_t), intent(out) :: pcm
        type(process_environment_t), intent(in) :: env
        type(process_metadata_t), intent(in) :: meta
        pcm%has_pdfs = env%has_pdfs ()
        call pcm%set_blha_defaults &
            (env%has_polarized_beams (), env%get_var_list_ptr ())
        pcm%os_data = env%get_os_data ()
    end subroutine pcm_default_init

```

```

<Pcm: types>+≡
  type, extends (pcm_instance_t) :: pcm_instance_default_t
  contains
  <Pcm: pcm instance default: TBP>
  end type pcm_instance_default_t

<Pcm: pcm instance default: TBP>≡
  procedure :: final => pcm_instance_default_final

<Pcm: procedures>+≡
  subroutine pcm_instance_default_final (pcm_instance)
    class(pcm_instance_default_t), intent(inout) :: pcm_instance
  end subroutine pcm_instance_default_final

```

### 30.8.2 Implementations for the default manager

Categorize components. Nothing to do here, all components are of Born type.

```

<Pcm: pcm default: TBP>+≡
  procedure :: categorize_components => pcm_default_categorize_components

<Pcm: procedures>+≡
  subroutine pcm_default_categorize_components (pcm, config)
    class(pcm_default_t), intent(inout) :: pcm
    type(process_config_data_t), intent(in) :: config
  end subroutine pcm_default_categorize_components

```

### Phase-space configuration

Default setup for tree processes: a single phase-space configuration that is valid for all components.

```

<Pcm: pcm default: TBP>+≡
  procedure :: init_phs_config => pcm_default_init_phs_config

<Pcm: procedures>+≡
  subroutine pcm_default_init_phs_config &
    (pcm, phs_entry, meta, env, phs_par, mapping_defs)
    class(pcm_default_t), intent(inout) :: pcm
    type(process_phs_config_t), &
      dimension(:), allocatable, intent(out) :: phs_entry
    type(process_metadata_t), intent(in) :: meta
    type(process_environment_t), intent(in) :: env
    type(mapping_defaults_t), intent(in) :: mapping_defs
    type(phs_parameters_t), intent(in) :: phs_par
    allocate (phs_entry (1))
    allocate (pcm%i_phs_config (pcm%n_components), source=1)
    call dispatch_phs (phs_entry(1)%phs_config, &
      env%get_var_list_ptr (), &
      env%get_os_data (), &
      meta%id, &
      mapping_defs, phs_par)
  end subroutine pcm_default_init_phs_config

```

## Core management

The default component manager assigns one core per component. We allocate and configure the core objects, using the process-component configuration data.

```
(Pcm: pcm default: TBP)+≡
    procedure :: allocate_cores => pcm_default_allocate_cores

(Pcm: procedures)+≡
    subroutine pcm_default_allocate_cores (pcm, config, core_entry)
        class(pcm_default_t), intent(inout) :: pcm
        type(process_config_data_t), intent(in) :: config
        type(core_entry_t), dimension(:), allocatable, intent(out) :: core_entry
        type(process_component_def_t), pointer :: component_def
        integer :: i
        allocate (pcm%i_core (pcm%n_components), source = 0)
        pcm%n_cores = pcm%n_components
        allocate (core_entry (pcm%n_cores))
        do i = 1, pcm%n_cores
            pcm%i_core(i) = i
            core_entry(i)%i_component = i
            component_def => config%process_def%get_component_def_ptr (i)
            core_entry(i)%core_def => component_def%get_core_def_ptr ()
            core_entry(i)%active = component_def%can_be_integrated ()
        end do
    end subroutine pcm_default_allocate_cores
```

Extra code is required for certain core types (threshold) or if BLHA uses an external OLP (Born only, this case) for getting its matrix elements.

```
(Pcm: pcm default: TBP)+≡
    procedure :: prepare_any_external_code => &
        pcm_default_prepare_any_external_code

(Pcm: procedures)+≡
    subroutine pcm_default_prepare_any_external_code &
        (pcm, core_entry, i_core, libname, model, var_list)
        class(pcm_default_t), intent(in) :: pcm
        type(core_entry_t), intent(inout) :: core_entry
        integer, intent(in) :: i_core
        type(string_t), intent(in) :: libname
        type(model_data_t), intent(in), target :: model
        type(var_list_t), intent(in) :: var_list
        if (core_entry%active) then
            associate (core => core_entry%core)
                if (core%needs_external_code ()) then
                    call core%prepare_external_code &
                        (core%data%flv_state, &
                         var_list, pcm%os_data, libname, model, i_core, .false.)
                end if
                call core%set_equivalent_flv_hel_indices ()
            end associate
        end if
    end subroutine pcm_default_prepare_any_external_code
```

Allocate and configure the BLHA record for a specific core, assuming that the core type requires it. In the default case, this is a Born configuration.

```

(Pcm: pcm default: TBP)+≡
  procedure :: setup_blha => pcm_default_setup_blha

(Pcm: procedures)+≡
  subroutine pcm_default_setup_blha (pcm, core_entry)
    class(pcm_default_t), intent(in) :: pcm
    type(core_entry_t), intent(inout) :: core_entry
    allocate (core_entry%blha_config, source = pcm%blha_defaults)
    call core_entry%blha_config%set_born ()
  end subroutine pcm_default_setup_blha

```

Apply the configuration, using pcm data.

```

(Pcm: pcm default: TBP)+≡
  procedure :: prepare_blha_core => pcm_default_prepare_blha_core

(Pcm: procedures)+≡
  subroutine pcm_default_prepare_blha_core (pcm, core_entry, model)
    class(pcm_default_t), intent(in) :: pcm
    type(core_entry_t), intent(inout) :: core_entry
    class(model_data_t), intent(in), target :: model

    call dispatch_mci (mci_template, var_list, process_id)
  end subroutine pcm_default_call_dispatch_mci
```

Nothing left to do for the default algorithm.

```

(Pcm: pcm default: TBP)+≡
  procedure :: complete_setup => pcm_default_complete_setup

(Pcm: procedures)+≡
  subroutine pcm_default_complete_setup (pcm, core_entry, component, model)
    class(pcm_default_t), intent(inout) :: pcm
    type(core_entry_t), dimension(:), intent(in) :: core_entry
    type(process_component_t), dimension(:), intent(inout) :: component
    type(model_t), intent(in), target :: model
  end subroutine pcm_default_complete_setup

```

### Component management

Initialize a single component. We require all process-configuration blocks, and specific templates for the phase-space and integrator configuration.

We also provide the current component index `i` and the `active` flag.

In the default mode, all components are marked as master components.

```

(Pcm: pcm default: TBP)+≡
  procedure :: init_component => pcm_default_init_component

(Pcm: procedures)+≡
  subroutine pcm_default_init_component &
    (pcm, component, i, active, &
     phs_config, env, meta, config)
    class(pcm_default_t), intent(in) :: pcm
    type(process_component_t), intent(out) :: component
    integer, intent(in) :: i
    logical, intent(in) :: active
    class(phs_config_t), allocatable, intent(in) :: phs_config
    type(process_environment_t), intent(in) :: env
    type(process_metadata_t), intent(in) :: meta
    type(process_config_data_t), intent(in) :: config
    call component%init (i, &
      env, meta, config, &
      active, &
      phs_config)
    component%component_type = COMP_MASTER
  end subroutine pcm_default_init_component

```

### 30.8.3 NLO process component manager

The NLO-aware version of the process-component manager.

This is the configuration object, which has the duty of allocating the corresponding instance. This is the nontrivial NLO version.

```

(Pcm: public)+≡
  public :: pcm_nlo_t

```

```

  procedure :: init_nlo_settings => pcm_nlo_init_nlo_settings

```

```

(Pcm: procedures)+≡
  subroutine pcm_nlo_init_nlo_settings (pcm, var_list)
    class(pcm_nlo_t), intent(inout) :: pcm
    type(var_list_t), intent(in), target :: var_list
    call pcm%settings%init (var_list)
  end subroutine pcm_nlo_init_nlo_settings

```

As appropriate for the NLO/FKS algorithm, the category defined by the process, is called `nlo_type`. We refine this by setting the component category `component_type` separately.

The component types `COMP_MISMATCH`, `COMP_PDF`, `COMP_SUB` are set only if the algorithm uses combined integration. Otherwise, they are set to `COMP_DEFAULT`.

The component type `COMP_REAL` is further distinguished between `COMP_REAL_SING` or `COMP_REAL_FIN`, if the algorithm uses real partitions. The former acts as a reference component for the latter, and we always assume that it is the first real component.

Each component is assigned its own core. Exceptions: the finite-real component gets the same core as the singular-real component. The mismatch component gets the same core as the subtraction component.

TODO wk 2018: this convention for real components can be improved. Check whether all component types should be assigned, not just for combined integration.

```

```

## Core management

Allocate the core (matrix-element interface) objects that we will need for evaluation. Every component gets an associated core, except for the real-finite and mismatch components (if any). Those components are associated with their previous corresponding real-singular and subtraction cores, respectively.

After cores are allocated, configure the region-data block that is maintained by the NLO process-component manager.

```

(Pcm: pcm nlo: TBP)+≡
  procedure :: allocate_cores => pcm_nlo_allocate_cores

(Pcm: procedures)+≡
  subroutine pcm_nlo_allocate_cores (pcm, config, core_entry)
    class(pcm_nlo_t), intent(inout) :: pcm
    type(process_config_data_t), intent(in) :: config
    type(core_entry_t), dimension(:), allocatable, intent(out) :: core_entry
    type(process_component_def_t), pointer :: component_def
    integer :: i, i_core
    allocate (pcm%i_core (pcm%n_components), source = 0)
    pcm%n_cores = pcm%n_components &
      - count (pcm%component_type(:) == COMP_REAL_FIN) &
      - count (pcm%component_type(:) == COMP_MISMATCH)
  end subroutine

```

```

allocate (core_entry (pcm%n_cores))
allocate (pcm%nlo_type_core (pcm%n_cores), source = BORN)
i_core = 0
do i = 1, pcm%n_components
  select case (pcm%component_type(i))
  case default
    i_core = i_core + 1
    pcm%i_core(i) = i_core
    pcm%nlo_type_core(i_core) = pcm%nlo_type(i)
    core_entry(i_core)%i_component = i

    core_entry(i_core)%core_def => component_def%get_core_def_ptr ()
    select case (pcm%nlo_type(i))
    case default
      core_entry(i)%active = component_def%can_be_integrated ()
    case (NLO_REAL, NLO_SUBTRACTION)
      core_entry(i)%active = .true.
    end select
  case (COMP_REAL_FIN)
    pcm%i_core(i) = pcm%i_core(pcm%i_real)
  case (COMP_MISMATCH)
    pcm%i_core(i) = pcm%i_core(pcm%i_sub)
  end select
end do
end subroutine pcm_nlo_allocate_cores

```

Extra code is required for certain core types (threshold) or if BLHA uses an external OLP for getting its matrix elements. OMega matrix elements, by definition, do not need extra code. NLO-virtual or subtraction matrix elements always need extra code.

More precisely: for the Born and virtual matrix element, the extra code is accessed only if the component is active. The radiation (real) and the subtraction corrections (singular and finite), extra code is accessed in any case.

The flavor state is taken from the `region_data` table in the `pcm` record. We use the Born and real flavor-state tables as appropriate.

```

<Pcm: pcm nlo: TBP>+≡
  procedure :: prepare_any_external_code => &
    pcm_nlo_prepare_any_external_code

<Pcm: procedures>+≡
  subroutine pcm_nlo_prepare_any_external_code &

    case (NLO_DGLAP)
      call core_entry%blha_config%set_dglap ()
    end select
  end subroutine pcm_nlo_setup_blha

```

After phase-space configuration data and core entries are available, we fill tables and compute the remaining NLO data that will steer the integration and subtraction algorithm.

There are three parts: recognize a threshold-type process core (if it exists), prepare the region-data tables (always), and prepare for real partitioning (if requested).

The real-component phase space acts as the source for resonance-history information, required for the region data.

```

    class(pcm_nlo_t), intent(in) :: pcm
    type(core_entry_t), dimension(:), intent(in) :: core_entry
    integer, dimension(:,:), allocatable, intent(out) :: flv_born
    integer, dimension(:,:), allocatable, intent(out) :: flv_real
    call pcm%region_data%get_all_flv_states (flv_born, flv_real)
  end subroutine pcm_nlo_get_blha_flv_states

```

Allocate and configure the MCI (multi-channel integrator) records. The relation depends on the `combined_integration` setting. If we integrate components separately, each component gets its own record, except for the subtraction component. If we do the combination, there is one record for the master (Born) component and a second one for the real-finite component, if present.

Each entry acquires some NLO-specific initialization. Generic configuration follows later.

Second procedure: call the MCI dispatcher with NLO-setup arguments.

```

<Pcm: pcm_nlo: TBP>+≡
  procedure :: setup_mci => pcm_nlo_setup_mci

## 30.9 Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

**sf\_chain** is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

**phs** is an instance of the phase space for the elementary process.

The array **f** contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either **sf\_chain** or **phs** are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component ('owned' by the object) or as a pointer.

```

integer, intent(in) :: phs_channel
integer :: c, c_sf
call k%phs%evaluate_other_channels (phs_channel)
do c = 1, k%n_channel
    c_sf = k%phs%config%get_sf_channel (c)
    k%f(c) = k%sf_chain%get_f (c_sf) * k%phs%get_f (c)
end do
end subroutine kinematics_compute_other_channels

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

```

<Kinematics: kinematics: TBP>+≡
    procedure :: get_incoming_momenta => kinematics_get_incoming_momenta
<Kinematics: procedures>+≡
    subroutine kinematics_get_incoming_momenta (k, p)
        class(kinematics_t), intent(in) :: k
        type(vector4_t), dimension(:), intent(out) :: p
        type(interaction_t), pointer :: int
        integer :: i
        int => k%sf_chain%get_out_int_ptr ()
        do i = 1, k%n_in
            p(i) = int%get_momentum (k%sf_chain%get_out_i (i))
        end do
    end subroutine kinematics_get_incoming_momenta

```

This inverts the remainder of the above `compute` method. We know the momenta and recover the rest, as far as needed. If we select a channel, we can complete the inversion and reconstruct the MC parameter set.

```

### 30.10.1 Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The `k_term` object is the instance of the kinematics setup (structure-function chain, phase space, etc.) that applies specifically to this term. In ordinary cases, it consists of straight pointers to the seed kinematics.

The `amp` array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The `int_hard` interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The `isolated` object holds the effective parton state for the elementary interaction. The amplitude entries are computed from `int_hard`.

The `connected` evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The `checked` flag is set once we have applied cuts on this term. The result of this is stored in the `passed` flag.

Although each `term_instance` carries a `weight`, this currently always keeps the value 1 and is only used to be given to routines to fulfill their signature.

  end subroutine term_instance_final

```

For initialization, we make use of defined assignment for the `interaction_t` type. This creates a deep copy.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (**rearrange**) as effective structure-function chain and interaction, respectively.

Finally, we set up the **subevt** component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

The **rearrange** parts are still commented out; they could become relevant for a NLO algorithm.

Compute the momenta in the hard interactions, one for each term that constitutes this process component. In simple cases this amounts to just copying momenta. In more advanced cases, we may generate distinct sets of momenta from the seed kinematics.

The interactions in the term instances are accessed individually. We may choose to calculate all terms at once together with the seed kinematics, use `component%core_state` for storage, and just fill the interactions here.

```

```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

Color-correlated matrix elements should be obtained from the external BLHA provider. According to the standard, the matrix elements output is a one-dimensional array. For FKS subtraction, we require the matrix  $B_{ij}$ . BLHA prescribes a mapping  $(i, j) \rightarrow k$ , where  $k$  is the index of the matrix element in the output array. It focusses on the off-diagonal entries, i.e.  $i \neq j$ . The subroutine `blha_color_c.fill_offdiag` realizes this mapping. The diagonal entries can simply be obtained as the product of the Born matrix element and either  $C_A$  or  $C_F$ , which is achieved by `blha_color_c.fill_diag`. For simple processes, i.e. those with only one color line, it is  $B_{ij} = C_F \cdot B$ . For those, we keep the possibility of computing color correlations by a multiplication of the Born matrix

element with  $C_F$ . It is triggered by the `use_internal_color_correlations` flag and should be used only for testing purposes. However, it is also used for the threshold computation where the process is well-defined and fixed.

```

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain. (If we have an algorithm that uses rearrangement, it should evaluate `k_term` explicitly.)

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

```

<Instances: term instance: TBP>+≡
  procedure :: compute_eff_kinematics => &
    term_instance_compute_eff_kinematics

<Instances: procedures>+≡
  subroutine term_instance_compute_eff_kinematics (term)
    class(term_instance_t), intent(inout) :: term
    term%checked = .false.
    term%passed = .false.
    call term%isolated%receive_kinematics ()
    call term%connected%receive_kinematics ()
  end subroutine term_instance_compute_eff_kinematics

```

Inverse. Reconstruct the connected state from the momenta in the trace evaluator (which we assume to be set), then reconstruct the isolated state as far as possible. The second part finalizes the momentum configuration, using the incoming seed momenta

```

<Instances: term instance: TBP>+≡
  procedure :: recover_hard_kinematics => &
    term_instance_recover_hard_kinematics

<Instances: procedures>+≡
  subroutine term_instance_recover_hard_kinematics (term)
    class(term_instance_t), intent(inout) :: term
    term%checked = .false.
    term%passed = .false.
    call term%connected%send_kinematics ()
    call term%isolated%send_kinematics ()
  end subroutine term_instance_recover_hard_kinematics

```

Check the term whether it passes cuts and, if successful, evaluate scales and weights. The factorization scale is also given to the term kinematics, enabling structure-function evaluation.

```

<Instances: term instance: TBP>+≡
  procedure :: evaluate_expressions => &
    term_instance_evaluate_expressions

<Instances: procedures>+≡
  subroutine term_instance_evaluate_expressions (term, scale_forced)
    class(term_instance_t), intent(inout) :: term
    real(default), intent(in), allocatable, optional :: scale_forced
    call term%connected%evaluate_expressions (term%passed, &
      term%scale, term%fac_scale, term%ren_scale, term%weight, &
      scale_forced, force_evaluation = .true.)
    term%checked = .true.
  end subroutine term_instance_evaluate_expressions

```

Evaluate the trace: first evaluate the hard interaction, then the trace evaluator. We use the `evaluate_interaction` method of the process component which generated this term. The `subevt` and cut expressions are not yet filled.

The `component` argument is `intent(inout)` because the `compute_amplitude` method may modify the `core_state` workspace object.

Retrieve the matrix elements from a matrix element provider and place them into term%amp.

For the handling of NLO calculations, FKS applies a book keeping handling flavor and/or particle type (e.g. for QCD: quark/gluon and quark flavor) in order to calculate the subtraction terms. Therefore, we have to insert the calculated matrix elements correctly into the state matrix where each entry corresponds to a set of quantum numbers. We apply a mapping `hard_qn_ind` from a list of quantum numbers provided by FKS to the hard process `int_hard`.

The calculated matrix elements are insert into `term%amp` in the following way. The first `n_born` particles are the matrix element of the hard process. In non-trivial beams, we store another `n_beams_rescaled` copies of these matrix elements as the first `n_beams_rescaled` subtractions. This is a remnant from times before the method `term_instance_set_sf_factors` and these entries are not used anymore. However, eliminating these entries involves deeper changes in how the connection tables for the evaluator product are set up and should therefore be part of a larger refactoring of the interactions & state matrices. The next  $n_{\text{born}} \times n_{\text{subcolor}}$  are color-correlated Born matrix elements, with then again the next  $n_{\text{born}} \times n_{\text{emitters}} \times n_{\text{subspin}}$  being spin-correlated Born matrix elements.

If two or more flavor structures would produce the same amplitude we only compute one and use the `eqv_index` determined by the `prc_core` and just copy the result to improve performance.

Same as for `term_instance_evaluate_interaction_userdef_tree`, but for the integrated-subtraction and finite one-loop terms. We only need color-correlated Born matrix elements, but an additional entry per flavor structure for the finite one-loop contribution. We thus have  $2 + n_{sub\_color}$  entries in the `term%amp` for each `i_flv` and `i_hel` combination.

If two or more flavor structures would produce the same amplitude we only compute one and use the `eqv_index` determined by the `prc_core` and just copy the result to improve performance.

  end subroutine term_instance_evaluate_trace

```

Include rescaled structure functions due to NLO calculation. We rescale the structure function for the real subtraction `sf_rescale_collinear`, the collinear counter terms `sf_rescale_dglap_t` and for the case, in which we have an emitter in the initial state, we rescale the kinematics for it using `sf_rescale_real_t`. References: arXiv:0709.2092, (2.35)-(2.42).

Obviously, it is completely irrelevant, which beam is treated. It becomes problematic when handling `e`, `p`-beams.

Evaluate the extra data that we need for processing the object as a physical event.

```

<Instances: term instance: TBP>+≡
    procedure :: evaluate_event_data => term_instance_evaluate_event_data

<Instances: procedures>+≡
    subroutine term_instance_evaluate_event_data (term)
        class(term_instance_t), intent(inout) :: term
        logical :: only_momenta
        only_momenta = term%nlo_type > BORN
        call term%isolated%evaluate_event_data (only_momenta)
        call term%connected%evaluate_event_data (only_momenta)
    end subroutine term_instance_evaluate_event_data

<Instances: term instance: TBP>+≡
    procedure :: set_fac_scale => term_instance_set_fac_scale

<Instances: procedures>+≡
    subroutine term_instance_set_fac_scale (term, fac_scale)
        class(term_instance_t), intent(inout) :: term
        real(default), intent(in) :: fac_scale
        term%fac_scale = fac_scale
    end subroutine term_instance_set_fac_scale

```

Return data that might be useful for external processing. The factorization scale:

```

<Instances: term instance: TBP>+≡
    procedure :: get_fac_scale => term_instance_get_fac_scale

<Instances: procedures>+≡
    function term_instance_get_fac_scale (term) result (fac_scale)
        class(term_instance_t), intent(in) :: term
        real(default) :: fac_scale
        fac_scale = term%fac_scale
    end function term_instance_get_fac_scale

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

### 30.10.2 The process instance

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `count` object records process evaluations, broken down according to status.

The `sqme` value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The `weight` value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the `sqme` value times Jacobian weights from the integration, or unity, respectively.

The `i_mci` index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The `sf_chain` subobject is a realization of the beam and structure-function configuration in the `process` object. It is not used for calculation directly

but serves as the template for the sf-chain instances that are contained in the `component` objects.

The `component` subobjects determine the state of each component.

The `term` subobjects are workspace for evaluating kinematics, matrix elements, cuts etc.

The `mci_work` subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the `mci_work` array is selected by the `i_mci` index above.

The `hook` pointer accesses a list of after evaluate objects which are evaluated after the matrix element.

```

<Instances: public>+≡
    public :: process_instance_t

<Instances: types>+≡
    type, extends (mci_sampler_t) :: process_instance_t
        type(process_t), pointer :: process => null ()
        integer :: evaluation_status = STAT_UNDEFINED
        real(default) :: sqme = 0
        real(default) :: weight = 0
        real(default) :: excess = 0
        integer :: n_dropped = 0
        integer :: i_mci = 0
        integer :: selected_channel = 0
        type(sf_chain_t) :: sf_chain
        type(term_instance_t), dimension(:), allocatable :: term
        type(mci_work_t), dimension(:), allocatable :: mci_work
        class(pcm_instance_t), allocatable :: pcm
        class(process_instance_hook_t), pointer :: hook => null ()
    contains
        <Instances: process_instance: TBP>
    end type process_instance_t

```

Wrapper type for storing pointers to process instance objects in arrays.

```

<Instances: public>+≡
    public :: process_instance_ptr_t

<Instances: types>+≡
    type :: process_instance_ptr_t
        type(process_instance_t), pointer :: p => null ()
    end type process_instance_ptr_t

```

The process hooks are first-in-last-out list of objects which are evaluated after the phase space and matrixelement are evaluated. It is possible to retrieve the sampler object and read the sampler information.

The hook object are part of the `process_instance` and therefore, share a common lifetime. A data transfer, after the usual lifetime of the `process_instance`, is not provided, as such the finalisation procedure has to take care of this! E.g. write the object to file from which later the collected information can then be retrieved.

```

<Instances: public>+≡
    public :: process_instance_hook_t

```

```

<Instances: types>+≡
type, abstract :: process_instance_hook_t
  class(process_instance_hook_t), pointer :: next => null ()
contains
  procedure(process_instance_hook_init), deferred :: init
  procedure(process_instance_hook_final), deferred :: final
  procedure(process_instance_hook_evaluate), deferred :: evaluate
end type process_instance_hook_t

```

We have to provide a `init`, a `final` procedure and, for after evaluation, the `evaluate` procedure.

The `init` procedures accesses `var_list` and current `instance` object.

```

<Instances: public>+≡
public :: process_instance_hook_final, process_instance_hook_evaluate

<Instances: interfaces>≡
abstract interface
  subroutine process_instance_hook_init (hook, var_list, instance)
    import :: process_instance_hook_t, var_list_t, process_instance_t
    class(process_instance_hook_t), intent(inout), target :: hook
    type(var_list_t), intent(in) :: var_list
    class(process_instance_t), intent(in), target :: instance
  end subroutine process_instance_hook_init

  subroutine process_instance_hook_final (hook)
    import :: process_instance_hook_t
    class(process_instance_hook_t), intent(inout) :: hook
  end subroutine process_instance_hook_final

  subroutine process_instance_hook_evaluate (hook, instance)
    import :: process_instance_hook_t, process_instance_t
    class(process_instance_hook_t), intent(inout) :: hook
    class(process_instance_t), intent(in), target :: instance
  end subroutine process_instance_hook_evaluate
end interface

```

The output routine contains a header with the most relevant information about the process, copied from `process.metadata.write`. We mark the active components by an asterisk.

The next section is the MC parameter input. The following sections are written only if the evaluation status is beyond setting the parameters, or if the `verbose` option is set.

```

<Instances: process instance: TBP>≡
procedure :: write_header => process_instance_write_header

    end if
end do
end if
end if
call write_separator (u, 2)
end if
end if
end subroutine process_instance_write

```

Initialization connects the instance with a process. All initial information is transferred from the process object. The process object contains templates for the interaction subobjects (beam and term), but no evaluators. The initialization routine creates evaluators for the matrix element trace, other evaluators are left untouched.

Before we start generating, we double-check if the process library has been updated after the process was initialized (`check_library_sanity`). This may happen if between integration and event generation the library has been recompiled, so all links become broken.

The `instance` object must have the `target` attribute (also in any caller) since the initialization routine assigns various pointers to subobject of `instance`.

        end if
        instance%selected_channel = 0
        instance%evaluation_status = STAT_INITIAL
    end subroutine process_instance_reset

```

## Integration and event generation

The sampler test should just evaluate the squared matrix element `n_calls` times, discarding the results, and return. This can be done before integration, e.g., for timing estimates.

```

<Instances: process instance: TBP>+≡
    procedure :: sampler_test => process_instance_sampler_test

<Instances: procedures>+≡
    subroutine process_instance_sampler_test (instance, i_mci, n_calls)
        class(process_instance_t), intent(inout), target :: instance
        integer, intent(in) :: i_mci
        integer, intent(in) :: n_calls
        integer :: i_mci_work

```

```

i_mci_work = instance%process%get_i_mci_work (i_mci)
call instance%choose_mci (i_mci_work)
call instance%reset_counter ()
call instance%process%sampler_test (instance, n_calls, i_mci_work)
call instance%process%set_counter_mci_entry (i_mci_work, instance%get_counter ())
end subroutine process_instance_sampler_test

```

Generate a weighted event. We select one of the available MCI integrators by its index `i_mci` and thus generate an event for the associated (group of) process component(s). The arguments exactly correspond to the initializer and finalizer above.

The resulting event is stored in the `process_instance` object, which also holds the workspace of the integrator.

Note: The `process` object contains the random-number state, which changes for each event. Otherwise, all volatile data are inside the `instance` object.

*(Instances: process instance: TBP)+≡*

```

procedure :: generate_weighted_event => process_instance_generate_weighted_event

```

*(Instances: procedures)+≡*

```

subroutine process_instance_generate_weighted_event (instance, i_mci)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_mci
  integer :: i_mci_work
  i_mci_work = instance%process%get_i_mci_work (i_mci)
  call instance%choose_mci (i_mci_work)
  associate (mci_work => instance%mci_work(i_mci_work))
