### 19.5.4 Kinematics

Evaluate the distance from a resonance. The distance is given by  $|p^2 - m^2|/(m\Gamma)$ . For  $\Gamma \ll m$ , this is the relative distance from the resonance peak in units of the half-width.

```

<Resonances: resonance info: TBP>+≡
  procedure :: evaluate_distance => resonance_info_evaluate_distance

<Resonances: procedures>+≡
  subroutine resonance_info_evaluate_distance (res_info, p, dist)
    class(resonance_info_t), intent(in) :: res_info
    type(vector4_t), dimension(:), intent(in) :: p
    real(default), intent(out) :: dist
    real(default) :: m, w
    type(vector4_t) :: q
    m = res_info%flavor%get_mass ()
    w = res_info%flavor%get_width ()
    q = sum (p(res_info%contributors%c))
    dist = abs (q**2 - m**2) / (m * w)
  end subroutine resonance_info_evaluate_distance

```

Evaluate the array of distances from a resonance history. We assume that the array has been allocated with correct size, namely the number of resonances in this history.

```

<Resonances: resonance history: TBP>+≡
  procedure :: evaluate_distances => resonance_history_evaluate_distances

<Resonances: procedures>+≡
  subroutine resonance_history_evaluate_distances (res_hist, p, dist)
    class(resonance_history_t), intent(in) :: res_hist
    type(vector4_t), dimension(:), intent(in) :: p
    real(default), dimension(:), intent(out) :: dist
    integer :: i
    do i = 1, res_hist%n_resonances
      call res_hist%resonances(i)%evaluate_distance (p, dist(i))
    end do
  end subroutine resonance_history_evaluate_distances

```

Use the distance to determine a Gaussian turnoff factor for a resonance. The factor is given by a Gaussian function  $e^{-d^2/\sigma^2}$ , where  $\sigma$  is the **gw** parameter multiplied by the resonance width, and  $d$  is the distance (see above). So, for  $d = \sigma$ , the factor is 0.37, and for  $d = 2\sigma$  we get 0.018.

If the **gw** factor is less or equal to zero, return 1.

```

<Resonances: resonance info: TBP>+≡
  procedure :: evaluate_gaussian => resonance_info_evaluate_gaussian

<Resonances: procedures>+≡
  function resonance_info_evaluate_gaussian (res_info, p, gw) result (factor)
    class(resonance_info_t), intent(in) :: res_info

            if (i > 1) string = string // " && "
            string = string // res_hist%resonances(i)%as_omega_string (n_in)
        end do
    end function resonance_history_as_omega_string

```

### 19.5.6 Resonance history as tree

If we want to organize the resonances and their decay products, it can be useful to have them explicitly as a tree structure. We implement this in the tradi-

tional event-record form with the resonances sorted by decreasing number of contributors, and their decay products added as an extra array.

```

<Resonances: public>+≡
    public :: resonance_tree_t

<Resonances: types>+≡
    type :: resonance_branch_t
        integer :: i = 0
        type(flavor_t) :: flv
        integer, dimension(:), allocatable :: r_child
        integer, dimension(:), allocatable :: o_child
    end type resonance_branch_t

    type :: resonance_tree_t
        private
        integer :: n = 0
        type(resonance_branch_t), dimension(:), allocatable :: branch
    contains
        <Resonances: resonance tree: TBP>
    end type resonance_tree_t

<Resonances: resonance tree: TBP>≡
    procedure :: write => resonance_tree_write

<Resonances: procedures>+≡

        integer :: nr, no
        associate (branch => tree%branch(i))
            nr = size (branch%r_child)
            no = size (branch%o_child)
            allocate (child (nr + no))
            child(1:nr) = branch%r_child + offset_r
            child(nr+1:nr+no) = branch%o_child + offset_o
        end associate
    end function resonance_tree_get_children

```

Transform a resonance history into a resonance tree. Algorithm:

1. Determine a mapping of the resonance array, such that in the new array the resonances are ordered by decreasing number of contributors.
2. Copy the flavor entries to the mapped array.

3. Scan all resonances and, for each one, find a resonance that is its parent. Since the resonances are ordered, later matches overwrite earlier ones. The last match is the correct one. Then scan again and, for each resonance, collect the resonances that have it as parent. This is the set of child resonances.
4. Analogously, scan all outgoing particles that appear in any of the contributors list. Determine their immediate parent as above, and set the child outgoing parents for the resonances, as above.

```

### 19.5.7 Resonance history set

This is an array of resonance histories. The elements are supposed to be unique. That is, entering a new element is successful only if the element does not already exist.

The current implementation uses a straightforward linear search for comparison. If this should become an issue, we may change the implementation to a hash table. To keep this freedom, the set should be an opaque object. In fact, we expect to use it as a transient data structure. Once the set is complete, we transform it into a contiguous array.

```

<Resonances: public>+≡
    public :: resonance_history_set_t

<Resonances: types>+≡
    type :: index_array_t
        integer, dimension(:), allocatable :: i

## 19.6 Mappings

Mappings are objects that encode the transformation of the interval  $(0,1)$  to a physical variable  $m^2$  or  $\cos\theta$  (and back), as it is used in the phase space parameterization. The mapping objects contain fixed parameters, the associated methods implement the mapping and inverse mapping operations, including the computation of the Jacobian (phase space factor).

```
<mappings.f90>≡  
  <File header>  
  
  module mappings  
  
    <Use kinds>  
    use kinds, only: TC  
    <Use strings>  
    use io_units  
    use constants, only: pi  
    use format_defs, only: FMT_19  
    use diagnostics  
    use md5  
    use model_data  
    use flavors  
  
    <Standard module head>  
  
    <Mappings: public>  
  
    <Mappings: parameters>  
  
    <Mappings: types>  
  
    <Mappings: interfaces>  
  
    contains  
  
    <Mappings: procedures>  
  
  end module mappings
```

### 19.6.1 Default parameters

This type holds the default parameters, needed for setting the scale in cases where no mass parameter is available. The contents are public.

```
<Mappings: public>≡  
  public :: mapping_defaults_t  
  
<Mappings: types>≡  
  type :: mapping_defaults_t  
    real(default) :: energy_scale = 10  
    real(default) :: invariant_mass_scale = 10  
    real(default) :: momentum_transfer_scale = 10  
    logical :: step_mapping = .true.  
    logical :: step_mapping_exp = .true.
```

```

        logical :: enable_s_mapping = .false.
contains
    <Mappings: mapping defaults: TBP>
end type mapping_defaults_t

```

Output.

```

<Mappings: mapping defaults: TBP>≡

    end function mapping_defaults_md5sum

```

## 19.6.2 The Mapping type

Each mapping has a type (e.g., s-channel, infrared), a binary code (redundant, but useful for debugging), and a reference particle. The flavor code of this particle is stored for bookkeeping reasons, what matters are the mass and width of this particle. Furthermore, depending on the type, various mapping parameters can be set and used.

The parameters **a1** to **a3** (for  $m^2$  mappings) and **b1** to **b3** (for  $\cos \theta$  mappings) are values that are stored once to speed up the calculation, if **variable\_limits** is false. The exact meaning of these parameters depends on the mapping type. The limits are fixed if there is a fixed c.m. energy.

```

⟨Mappings: public⟩+≡
    public :: mapping_t

⟨Mappings: types⟩+≡
    type :: mapping_t
    private

```

⟨Mappings: parameters⟩≡
    ⟨Mapping modes⟩

```

## 19.6.3 Screen output

Do not write empty mappings.

```

⟨Mappings: public⟩+≡
    public :: mapping_write

⟨Mappings: procedures⟩+≡
    subroutine mapping_write (map, unit, verbose)
        type(mapping_t), intent(in) :: map
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: verbose
        integer :: u
        character(len=9) :: str
        u = given_output_unit (unit); if (u < 0) return
    end subroutine mapping_write

```

```

select case(map%type)
case(S_CHANNEL); str = "s_channel"
case(COLLINEAR); str = "collinear"
case(INFRARED); str = "infrared "
case(RADIATION); str = "radiation"
case(T_CHANNEL); str = "t_channel"
case(U_CHANNEL); str = "u_channel"
case(STEP_MAPPING_E); str = "step_exp"
case(STEP_MAPPING_H); str = "step_hyp"
case(ON_SHELL); str = "on_shell"
case default; str = "??????"
end select
if (map%type /= NO_MAPPING) then
write (u, '(1x,A,I4,A)') &
"Branch #", map%bincode, ": " // &
"Mapping (" // str // ") for particle " // &
',' // char (map%flv%get_name ()) // ''
if (present (verbose)) then
if (verbose) then
select case (map%type)
case (S_CHANNEL, RADIATION, STEP_MAPPING_E, STEP_MAPPING_H)
write (u, "(1x,A,3(" // FMT_19 // "))" ) &
" m/w = ", map%mass, map%width
case default
write (u, "(1x,A,3(" // FMT_19 // "))" ) &
" m = ", map%mass
end select
select case (map%type)
case (S_CHANNEL, T_CHANNEL, U_CHANNEL, &
STEP_MAPPING_E, STEP_MAPPING_H, &
COLLINEAR, INFRARED, RADIATION)
write (u, "(1x,A,3(" // FMT_19 // "))" ) &
" a1/2/3 = ", map%a1, map%a2, map%a3
end select
select case (map%type)
case (T_CHANNEL, U_CHANNEL, COLLINEAR)
write (u, "(1x,A,3(" // FMT_19 // "))" ) &
" b1/2/3 = ", map%b1, map%b2, map%b3
end select
end if
end if
end if
end subroutine mapping_write

```

#### 19.6.4 Define a mapping

The initialization routine sets the mapping type and the particle (binary code and flavor code) for which the mapping applies (e.g., a  $Z$  resonance in branch #3).

```

<Mappings: public>+≡
public :: mapping_init

```

```

<Mappings: procedures>+≡
subroutine mapping_init (mapping, brcode, type, f, model)
  type(mapping_t), intent(inout) :: mapping
  integer(TC), intent(in) :: brcode
  type(string_t), intent(in) :: type
  integer, intent(in), optional :: f
  class(model_data_t), intent(in), optional, target :: model
  mapping%brcode = brcode
  select case (char (type))
    case ("s_channel"); mapping%type = S_CHANNEL
    case ("collinear"); mapping%type = COLLINEAR
    case ("infrared"); mapping%type = INFRARED
    case ("radiation"); mapping%type = RADIATION
    case ("t_channel"); mapping%type = T_CHANNEL
    case ("u_channel"); mapping%type = U_CHANNEL
    case ("step_exp"); mapping%type = STEP_MAPPING_E
    case ("step_hyp"); mapping%type = STEP_MAPPING_H
    case ("on_shell"); mapping%type = ON_SHELL
    case default
      call msg_bug ("Mappings: encountered undefined mapping key '" &
        // char (type) // "'")
  end select
  if (present (f) .and. present (model)) call mapping%flv%init (f, model)
end subroutine mapping_init

```

This sets the actual mass and width, using a parameter set. Since the auxiliary parameters will only be determined when the mapping is first called, they are marked as unknown.

```

<Mappings: public>+≡
public :: mapping_set_parameters

<Mappings: procedures>+≡
subroutine mapping_set_parameters (map, mapping_defaults, variable_limits)
  type(mapping_t), intent(inout) :: map
  type(mapping_defaults_t), intent(in) :: mapping_defaults
  logical, intent(in) :: variable_limits
  if (map%type /= NO_MAPPING) then
    map%mass = map%flv%get_mass ()
    map%width = map%flv%get_width ()
    map%variable_limits = variable_limits
    map%a_unknown = .true.
    map%b_unknown = .true.
    select case (map%type)
      case (S_CHANNEL)
        if (map%mass <= 0) then
          call mapping_write (map)
          call msg_fatal &
            & (" S-channel resonance must have positive mass")
        else if (map%width <= 0) then
          call mapping_write (map)
          call msg_fatal &
            & (" S-channel resonance must have positive width")
        end if
      case (RADIATION)
    end select
  end if
end subroutine mapping_set_parameters

```

```

        map%width = max (map%width, mapping_defaults%energy_scale)
    case (INFRARED, COLLINEAR)
        map%mass = max (map%mass, mapping_defaults%invariant_mass_scale)
    case (T_CHANNEL, U_CHANNEL)
        map%mass = max (map%mass, mapping_defaults%momentum_transfer_scale)
    end select
end if
end subroutine mapping_set_parameters

```

For a step mapping the mass and width are set directly, instead of being determined from the flavor parameter (which is meaningless here). They correspond to the effective upper bound of phase space due to a resonance, as opposed to the absolute upper bound.

```

<Mappings: public>+≡
    public :: mapping_set_step_mapping_parameters

<Mappings: procedures>+≡
    subroutine mapping_set_step_mapping_parameters (map, &
        mass, width, variable_limits)
        type(mapping_t), intent(inout) :: map
        real(default), intent(in) :: mass, width
        logical, intent(in) :: variable_limits
        select case (map%type)
        case (STEP_MAPPING_E, STEP_MAPPING_H)
            map%variable_limits = variable_limits
            map%a_unknown = .true.
            map%b_unknown = .true.
            map%mass = mass
            map%width = width
        end select
    end subroutine mapping_set_step_mapping_parameters

```

    function mapping_equal (m1, m2) result (equal)
        type(mapping_t), intent(in) :: m1, m2
        logical :: equal
        if (m1%type == m2%type) then
            select case (m1%type)
            case (NO_MAPPING)
                equal = .true.
            case (S_CHANNEL, RADIATION, STEP_MAPPING_E, STEP_MAPPING_H)
                equal = (m1%mass == m2%mass) .and. (m1%width == m2%width)
            case default
                equal = (m1%mass == m2%mass)
            end select
        else
            equal = .false.
        end if
    end function mapping_equal

```

### 19.6.7 Mappings of the invariant mass

Inserting an  $x$  value between 0 and 1, we want to compute the corresponding invariant mass  $m^2(x)$  and the jacobian, aka phase space factor  $f(x)$ . We also need the reverse operation.

In general, the phase space factor  $f$  is defined by

$$\frac{1}{s} \int_{m_{\min}^2}^{m_{\max}^2} dm^2 g(m^2) = \int_0^1 dx \frac{1}{s} \frac{dm^2}{dx} g(m^2(x)) = \int_0^1 dx f(x) g(x), \quad (19.8)$$

where thus

$$f(x) = \frac{1}{s} \frac{dm^2}{dx}. \quad (19.9)$$

With this mapping, a function of the form

$$g(m^2) = c \frac{dx(m^2)}{dm^2} \quad (19.10)$$

is mapped to a constant:

$$\frac{1}{s} \int_{m_{\min}^2}^{m_{\max}^2} dm^2 g(m^2) = \int_0^1 dx f(x) g(m^2(x)) = \int_0^1 dx \frac{c}{s}. \quad (19.11)$$

Here is the mapping routine. Input are the available energy squared  $s$ , the limits for  $m^2$ , and the  $x$  value. Output are the  $m^2$  value and the phase space factor  $f$ .

```

end subroutine mapping_compute_x_from_msq

```

### Trivial mapping

We simply map the boundaries of the interval  $(m_{\min}, m_{\max})$  to  $(0, 1)$ :

$$m^2 = (1 - x)m_{\min}^2 + xm_{\max}^2; \quad (19.12)$$

the inverse is

$$x = \frac{m^2 - m_{\min}^2}{m_{\max}^2 - m_{\min}^2}. \quad (19.13)$$

Hence

$$f(x) = \frac{m_{\max}^2 - m_{\min}^2}{s}, \quad (19.14)$$

and we have, as required,

$$f(x) \frac{dx}{dm^2} = \frac{1}{s}. \quad (19.15)$$

We store the constant parameters the first time the mapping is called – or, if limits vary, recompute them each time.

```

⟨Constants for trivial msq mapping⟩≡

  else
    x = 0
  end if
  f = map%a3

```

Resonance or step mapping does not make much sense if the resonance mass is outside the kinematical bounds. If this is the case, revert to `NO_MAPPING`. This is possible even if the kinematical bounds vary from event to event.

```

⟨Modify mapping type if necessary⟩≡
  select case (type)
  case (S_CHANNEL, STEP_MAPPING_E, STEP_MAPPING_H)
    msq0 = map%mass**2
    if (msq0 < msq_min .or. msq0 > msq_max) type = NO_MAPPING
  end select

```

### Breit-Wigner mapping

A Breit-Wigner resonance with mass  $M$  and width  $\Gamma$  is flattened by the following mapping:

This mapping does not make much sense if the resonance mass is too low. If this is the case, revert to `NO_MAPPING`. There is a tricky point with this if the mass is too high: `msq_max` is not a constant if structure functions are around. However, switching the type depending on the overall energy does not change the integral, it is just another branching point.

$$m^2 = M(M + t\Gamma), \quad (19.16)$$

where

$$t = \tan \left[ (1-x) \arctan \frac{m_{\min}^2 - M^2}{M\Gamma} + x \arctan \frac{m_{\max}^2 - M^2}{M\Gamma} \right]. \quad (19.17)$$

The inverse:

$$x = \frac{\arctan \frac{m^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma}}{\arctan \frac{m_{\max}^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma}} \quad (19.18)$$

The phase-space factor of this transformation is

$$f(x) = \frac{M\Gamma}{s} \left( \arctan \frac{m_{\max}^2 - M^2}{M\Gamma} - \arctan \frac{m_{\min}^2 - M^2}{M\Gamma} \right) (1 + t^2). \quad (19.19)$$

This maps any function proportional to

$$g(m^2) = \frac{M\Gamma}{(m^2 - M^2)^2 + M^2\Gamma^2} \quad (19.20)$$

to a constant times  $1/s$ .

f = map%a3 * (1 + tmp**2)

```

### Mapping for massless splittings

This mapping accounts for approximately scale-invariant behavior where  $\ln M^2$  is evenly distributed.

$$m^2 = m_{\min}^2 + M^2 (\exp(xL) - 1) \quad (19.21)$$

where

$$L = \ln \left( \frac{m_{\max}^2 - m_{\min}^2}{M^2} + 1 \right). \quad (19.22)$$

The inverse:

$$x = \frac{1}{L} \ln \left( \frac{m^2 - m_{\min}^2}{M^2} + 1 \right) \quad (19.23)$$

The constant  $M$  is a characteristic scale. Above this scale ( $m^2 - m_{\min}^2 \gg M^2$ ), this mapping behaves like  $x \propto \ln m^2$ , while below the scale it reverts to a linear mapping.

The phase-space factor is

$$f(x) = \frac{M^2}{s} \exp(xL) L. \quad (19.24)$$

A function proportional to

$$g(m^2) = \frac{1}{(m^2 - m_{\min}^2) + M^2} \quad (19.25)$$

is mapped to a constant, i.e., a simple pole near  $m_{\min}$  with a regulator mass  $M$ .

This type of mapping is useful for massless collinear and infrared singularities, where the scale is stored as the mass parameter. In the radiation case

(IR radiation off massive particle), the heavy particle width is the characteristic scale.

```

### Mapping for t-channel poles

This is also approximately scale-invariant, and we use the same type of mapping as before. However, we map  $1/x$  singularities at both ends of the interval; again, the mapping becomes linear when the distance is less than  $M^2$ :

$$m^2 = \begin{cases} m_{\min}^2 + M^2 (\exp(xL) - 1) & \text{for } 0 < x < \frac{1}{2} \\ m_{\max}^2 - M^2 (\exp((1-x)L) - 1) & \text{for } \frac{1}{2} \leq x < 1 \end{cases} \quad (19.26)$$

where

$$L = 2 \ln \left( \frac{m_{\max}^2 - m_{\min}^2}{2M^2} + 1 \right). \quad (19.27)$$

The inverse:

$$x = \begin{cases} \frac{1}{L} \ln \left( \frac{m^2 - m_{\min}^2}{M^2} + 1 \right) & \text{for } m^2 < (m_{\max}^2 - m_{\min}^2)/2 \\ 1 - \frac{1}{L} \ln \left( \frac{m_{\max}^2 - m^2}{M^2} + 1 \right) & \text{for } m^2 \geq (m_{\max}^2 - m_{\min}^2)/2 \end{cases} \quad (19.28)$$

The phase-space factor is

$$f(x) = \begin{cases} \frac{M^2}{s} \exp(xL) L. & \text{for } 0 < x < \frac{1}{2} \\ \frac{M^2}{s} \exp((1-x)L) L. & \text{for } \frac{1}{2} \leq x < 1 \end{cases} \quad (19.29)$$

A (continuous) function proportional to

$$g(m^2) = \begin{cases} 1/(m^2 - m_{\min}^2) + M^2 & \text{for } m^2 < (m_{\max}^2 - m_{\min}^2)/2 \\ 1/((m_{\max}^2 - m^2) + M^2) & \text{for } m^2 \geq (m_{\max}^2 - m_{\min}^2)/2 \end{cases} \quad (19.30)$$

is mapped to a constant by this mapping, i.e., poles near both ends of the interval.

```

  f = map%a3 * msq1

```

### 19.6.8 Step mapping

Step mapping is useful when the allowed range for a squared-mass variable is large, but only a fraction at the lower end is populated because the particle in question is an (off-shell) decay product of a narrow resonance. I.e., if the resonance was forced to be on-shell, the upper end of the range would be the resonance mass, minus the effective (real or resonance) mass of the particle(s) in the sibling branch of the decay.

The edge of this phase space section has a width which is determined by the width of the parent, plus the width of the sibling branch. (The widths might be added in quadrature, but this precision is probably not important.)

#### Fermi function

A possible mapping is derived from the Fermi function which has precisely this behavior. The Fermi function is given by

$$f(x) = \frac{1}{1 + \exp \frac{x-\mu}{\gamma}} \quad (19.31)$$

where  $x$  is taken as the invariant mass squared,  $\mu$  is the invariant mass squared of the edge, and  $\gamma$  is the effective width which is given by the widths of the

parent and the sibling branch. (Widths might be added in quadrature, but we do not require this level of precision.)

$$x = \frac{m^2 - m_{\min}^2}{\Delta m^2} \quad (19.32)$$

$$\mu = \frac{m_{\max, \text{eff}}^2 - m_{\min}^2}{\Delta m^2} \quad (19.33)$$

$$\gamma = \frac{2m_{\max, \text{eff}}\Gamma}{\Delta m^2} \quad (19.34)$$

with

$$\Delta m^2 = m_{\max}^2 - m_{\min}^2 \quad (19.35)$$

$m^2$  is thus given by

$$m^2(x) = xm_{\max}^2 + (1-x)m_{\min}^2 \quad (19.36)$$

For the mapping, we compute the integral  $g(x)$  of the Fermi function, normalized such that  $g(0) = 0$  and  $g(1) = 1$ . We introduce the abbreviations

$$\alpha = 1 - \gamma \ln \frac{1 + \beta e^{1/\gamma}}{1 + \beta} \quad (19.37)$$

$$\beta = e^{-\mu/\gamma} \quad (19.38)$$

and obtain

$$g(x) = \frac{1}{\alpha} \left( x - \gamma \ln \frac{1 + \beta e^{x/\gamma}}{1 + \beta} \right) \quad (19.39)$$

The actual mapping is the inverse function  $h(y) = g^{-1}(y)$ ,

$$h(y) = -\gamma \ln \left( e^{-\alpha y/\gamma} (1 + \beta) - \beta \right) \quad (19.40)$$

The Jacobian is

$$\frac{dh}{dy} = \alpha \left( 1 - e^{\alpha y/\gamma} \frac{\beta}{1 + \beta} \right)^{-1} \quad (19.41)$$

which is equal to  $1/(dg/dx)$ , namely

$$\frac{dg}{dx} = \frac{1}{\alpha} \frac{1}{1 + \beta e^{x/\gamma}} \quad (19.42)$$

The final result is

$$\int_{m_{\min}^2}^{m_{\max}^2} dm^2 F(m^2) = \Delta m^2 \int_0^1 dx F(m^2(x)) \quad (19.43)$$

$$= \Delta m^2 \int_0^1 dy F(m^2(h(y))) \frac{dh}{dy} \quad (19.44)$$

Here is the implementation. We fill **a1**, **a2**, **a3** with  $\alpha, \beta, \gamma$ , respectively.

```

    / map%a1
  f = map%a1 * tmp * (msq_max - msq_min) / s

```

## Hyperbolic mapping

The Fermi function has the drawback that it decreases exponentially. It might be preferable to take a function with a power-law decrease, such that the high-mass region is not completely depopulated.

Here, we start with the actual mapping which we take as

$$h(y) = \frac{b}{a-y} - \frac{b}{a} + \mu y \quad (19.45)$$

with the abbreviation

$$a = \frac{1}{2} \left( 1 + \sqrt{1 + \frac{4b}{1-\mu}} \right) \quad (19.46)$$

This is a hyperbola in the  $xy$  plane. The derivative is

$$\frac{dh}{dy} = \frac{b}{(a-y)^2} + \mu \quad (19.47)$$

The constants correspond to

$$\mu = \frac{m_{\text{max,eff}}^2 - m_{\text{min}}^2}{\Delta m^2} \quad (19.48)$$

$$b = \frac{1}{\mu} \left( \frac{2m_{\text{max,eff}}\Gamma}{\Delta m^2} \right)^2 \quad (19.49)$$

The inverse function is the solution of a quadratic equation,

$$g(x) = \frac{1}{2} \left[ \left( a + \frac{x}{\mu} + \frac{b}{a\mu} \right) - \sqrt{\left( a - \frac{x}{\mu} \right)^2 + 2\frac{b}{a\mu} \left( a + \frac{x}{\mu} \right) + \left( \frac{b}{a\mu} \right)^2} \right] \quad (19.50)$$

The constants  $a_{1,2,3}$  are identified with  $a, b, \mu$ .

```

⟨Constants for hyperbolic step mapping⟩≡

  msq = z * msq_max + (1 - z) * msq_min
  f = (map%a2 / (map%a1 - x)**2 + map%a3) * (msq_max - msq_min) / s

⟨Apply inverse hyperbolic step mapping⟩≡
  z = (msq - msq_min) / (msq_max - msq_min)
  tmp = map%a2 / (map%a1 * map%a3)
  x = ((map%a1 + z / map%a3 + tmp) &
        - sqrt((map%a1 - z / map%a3)**2 + 2 * tmp * (map%a1 + z / map%a3) &
              + tmp**2)) / 2
  f = (map%a2 / (map%a1 - x)**2 + map%a3) * (msq_max - msq_min) / s

```

### 19.6.9 Mappings of the polar angle

The other type of singularity, a simple pole just outside the integration region, can occur in the integration over  $\cos\theta$ . This applies to exchange of massless (or light) particles.

Double poles (Coulomb scattering) are also possible, but only in certain cases. These are also handled by the single-pole mapping.

The mapping is analogous to the previous  $m^2$  pole mapping, but with a different normalization and notation of variables:

$$\frac{1}{2} \int_{-1}^1 d\cos\theta g(\theta) = \int_0^1 dx \frac{d\cos\theta}{dx} g(\theta(x)) = \int_0^1 dx f(x) g(x), \quad (19.51)$$

where thus

$$f(x) = \frac{1}{2} \frac{d\cos\theta}{dx}. \quad (19.52)$$

With this mapping, a function of the form

$$g(\theta) = c \frac{dx(\cos\theta)}{d\cos\theta} \quad (19.53)$$

is mapped to a constant:

$$\int_{-1}^1 d\cos\theta g(\theta) = \int_0^1 dx f(x) g(\theta(x)) = \int_0^1 dx c. \quad (19.54)$$

```

## Trivial mapping

This is just the mapping of the interval  $(-1, 1)$  to  $(0, 1)$ :

$$\cos \theta = -1 + 2x \quad (19.55)$$

and

$$f(x) = 1 \quad (19.56)$$

with the inverse

$$x = \frac{1 + \cos \theta}{2} \quad (19.57)$$

```

<Apply trivial ct mapping>≡
    tmp = 2 * (1-x)
    ct = 1 - tmp
    st = sqrt (tmp * (2-tmp))
    f = 1

<Apply inverse trivial ct mapping>≡
    x = (ct + 1) / 2
    f = 1

```

### Pole mapping

As above for  $m^2$ , we simultaneously map poles at both ends of the  $\cos \theta$  interval. The formulae are completely analogous:

$$\cos \theta = \begin{cases} \frac{M^2}{s} [\exp(xL) - 1] - 1 & \text{for } x < \frac{1}{2} \\ -\frac{M^2}{s} [\exp((1-x)L) - 1] + 1 & \text{for } x \geq \frac{1}{2} \end{cases} \quad (19.58)$$

where

$$L = 2 \ln \frac{M^2 + s}{M^2}. \quad (19.59)$$

Inverse:

$$x = \begin{cases} \frac{1}{2L} \ln \frac{1 + \cos \theta + M^2/s}{M^2/s} & \text{for } \cos \theta < 0 \\ 1 - \frac{1}{2L} \ln \frac{1 - \cos \theta + M^2/s}{M^2/s} & \text{for } \cos \theta \geq 0 \end{cases} \quad (19.60)$$

The phase-space factor:

$$f(x) = \begin{cases} \frac{M^2}{s} \exp(xL) L & \text{for } x < \frac{1}{2} \\ \frac{M^2}{s} \exp((1-x)L) L & \text{for } x \geq \frac{1}{2} \end{cases} \quad (19.61)$$

```

⟨Constants for ct pole mapping⟩≡

  f = ct1 * map%b2

```

## 19.7 Phase-space trees

The phase space evaluation is organized in terms of trees, where each branch corresponds to three integrations:  $m^2$ ,  $\cos\theta$ , and  $\phi$ . The complete tree thus makes up a specific parameterization of the multidimensional phase-space integral. For the multi-channel integration, the phase-space tree is a single channel.

The trees imply mappings of formal Feynman tree graphs into arrays of integer numbers: Each branch, corresponding to a particular line in the graph, is assigned an integer code  $c$  (with kind value  $\text{TC} = \text{tree code}$ ).

In this integer, each bit determines whether a particular external momentum flows through the line. The external branches therefore have codes 1, 2, 4, 8, ... An internal branch has those bits ORed corresponding to the momenta flowing through it. For example, a branch with momentum  $p_1 + p_4$  has code  $2^0 + 2^3 = 1 + 8 = 9$ .

There is a two-fold ambiguity: Momentum conservation implies that the branch with code

$$c_0 = \sum_{i=1}^{n(\text{ext})} 2^{i-1} \quad (19.62)$$

i.e. the branch with momentum  $p_1 + p_2 + \dots p_n$  has momentum zero, which is equivalent to tree code 0 by definition. Correspondingly,

$$c \quad \text{and} \quad c_0 - c = c \text{ XOR } c_0 \quad (19.63)$$

are equivalent. E.g., if there are five externals with codes  $c = 1, 2, 4, 8, 16$ , then  $c = 9$  and  $\bar{c} = 31 - 9 = 22$  are equivalent.

This ambiguity may be used to assign a direction to the line: If all momenta are understood as outgoing,  $c = 9$  in the example above means  $p_1 + p_4$ , but  $c = 22$  means  $p_2 + p_3 + p_5 = -(p_1 + p_4)$ .

Here we make use of the ambiguity in a slightly different way. First, the initial particles are singled out as those externals with the highest bits, the IN-bits. (Here: 8 and 16 for a  $2 \rightarrow 3$  scattering process, 16 only for a  $1 \rightarrow 4$  decay.) Then we invert those codes where all IN-bits are set. For a decay process this maps each tree of an equivalence class onto a unique representative (that one with the smallest integer codes). For a scattering process we proceed further:

The ambiguity remains in all branches where only one IN-bit is set, including the initial particles. If there are only externals with this property, we have an  $s$ -channel graph which we leave as it is. In all other cases, an internal with only one IN-bit is a  $t$ -channel line, which for phase space integration should be associated with one of the initial momenta as a reference axis. We take that one whose bit is set in the current tree code. (E.g., for branch  $c = 9$  we use the initial particle  $c = 8$  as reference axis, whereas for the same branch we would take  $c = 16$  if it had been assigned  $\bar{c} = 31 - 9 = 22$  as tree code.) Thus, different ways of coding the same  $t$ -channel graph imply different phase space parameterizations.

$s$ -channel graphs have a unique parameterization. The same sets of parameterizations are used for  $t$ -channel graphs, except for the reference frames of their angular parts. We map each  $t$ -channel graph onto an  $s$ -channel graph as follows:

Working in ascending order, for each  $t$ -channel line (whose code has exactly one IN-bit set) the attached initial line is flipped upstream, while the outgoing

line is flipped downstream. (This works only if  $t$ -channel graphs are always parameterized beginning at their outer vertices, which we require as a restriction.) After all possible flips have been applied, we have an  $s$ -channel graph. We only have to remember the initial particle a vertex was originally attached to.

## 19.7.2 The phase-space tree type

### Definition

In the concrete implementation, each branch  $c$  may have two *daughters*  $c_1$  and  $c_2$  such that  $c_1 + c_2 = c$ , a *sibling*  $c_s$  and a *mother*  $c_m$  such that  $c + c_s = c_m$ , and a *friend* which is kept during flips, such that it can indicate a fixed reference frame. Absent entries are set  $c = 0$ .

First, declare the branch type. There is some need to have this public. Give initializations for all components, so no `init` routine is necessary. The branch has some information about the associated coordinates and about connections.

```

(PHS trees: types)+≡
  type :: phs_branch_t
  private
    logical :: set = .false.
    logical :: inverted_decay = .false.
    logical :: inverted_axis = .false.
    integer(TC) :: mother = 0
    integer(TC) :: sibling = 0
    integer(TC) :: friend = 0
    integer(TC) :: origin = 0
    integer(TC), dimension(2) :: daughter = 0
    integer :: firstborn = 0
    logical :: has_children = .false.
    logical :: has_friend = .false.
    logical :: is_real = .false.
  end type phs_branch_t

```

The tree type: No initialization, this is done by `phs_tree_init`. In addition to the branch array which

The branches are collected in an array which holds all possible branches, of which only a few are set. After flips have been applied, the branch  $c_M = \sum_{i=1}^{n(\text{fin})} 2^{i-1}$  must be there, indicating the mother of all decay products. In addition, we should check for consistency at the beginning.

`n_branches` is the number of those actually set. `n externals` defines the number of significant bit, and `mask` is a code where all bits are set. Analogous: `n_in` and `mask_in` for the incoming particles.

The `mapping` array contains the mappings associated to the branches (corresponding indices). The array `mass_sum` contains the sum of the real masses of the external final-state particles associated to the branch. During phase-space evaluation, this determines the boundaries.

```

(PHS trees: public)+≡
  public :: phs_tree_t
(PHS trees: types)+≡
  type :: phs_tree_t
  private
    integer :: n_branches, n externals, n_in, n_msq, n_angles
    integer(TC) :: n_branches_tot, n_branches_out
    integer(TC) :: mask, mask_in, mask_out
    type(phs_branch_t), dimension(:), allocatable :: branch
    type(mapping_t), dimension(:), allocatable :: mapping
    real(default), dimension(:), allocatable :: mass_sum
    real(default), dimension(:), allocatable :: effective_mass
    real(default), dimension(:), allocatable :: effective_width
    logical :: real_phsp = .false.
    integer, dimension(:), allocatable :: momentum_link
  contains
    (PHS trees: phs tree: TBP)
  end type phs_tree_t

```

The maximum number of external particles that can be represented is related to the bit size of the integer that stores binary codes. With the default integer of 32 bit on common machines, this is more than enough space. If TC is actually the default integer kind, there is no need to keep it separate, but doing so marks this as a special type of integer. So, just state that the maximum number is 32:

```
<Limits: public parameters>≡
    integer, parameter, public :: MAX_EXTERNAL = 32
```

### Constructor and destructor

Allocate memory for a phase-space tree with given number of externals and incoming. The number of allocated branches can easily become large, but appears manageable for realistic cases, e.g., for `n_in=2` and `n_out=8` we get  $2^{10}-1 = 1023$ .

```
<PHS trees: public>+≡
    public :: phs_tree_init
    public :: phs_tree_final
```

Here we set the masks for incoming and for all externals.

```
<PHS trees: phs tree: TBP>≡
    procedure :: init => phs_tree_init
    procedure :: final => phs_tree_final
```

```
<PHS trees: procedures>+≡
    elemental subroutine phs_tree_init (tree, n_in, n_out, n_masses, n_angles)
        class(phs_tree_t), intent(inout) :: tree
        integer, intent(in) :: n_in, n_out, n_masses, n_angles
        integer(TC) :: i
        tree%n_externals = n_in + n_out
        tree%n_branches_tot = 2**(n_in+n_out) - 1
        tree%n_branches_out = 2**n_out - 1
        tree%mask = 0
        do i = 0, n_in + n_out - 1
            tree%mask = ibset (tree%mask, i)
        end do
        tree%n_in = n_in
        tree%mask_in = 0
        do i = n_out, n_in + n_out - 1
            tree%mask_in = ibset (tree%mask_in, i)
        end do
        tree%mask_out = ieor (tree%mask, tree%mask_in)
        tree%n_msq = n_masses
        tree%n_angles = n_angles
        allocate (tree%branch (tree%n_branches_tot))
        tree%n_branches = 0
        allocate (tree%mapping (tree%n_branches_out))
        allocate (tree%mass_sum (tree%n_branches_out))
        allocate (tree%effective_mass (tree%n_branches_out))
        allocate (tree%effective_width (tree%n_branches_out))
    end subroutine phs_tree_init

    elemental subroutine phs_tree_final (tree)
        class(phs_tree_t), intent(inout) :: tree
        deallocate (tree%branch)
        deallocate (tree%mapping)
```

```

deallocate (tree%mass_sum)
deallocate (tree%effective_mass)

end if
end subroutine phs_branch_write

```

### 19.7.3 PHS tree setup

#### Transformation into an array of branch codes and back

Assume that the tree/array has been created before with the appropriate length and is empty.

```

<PHS trees: public>+≡
public :: phs_tree_from_array

```

```

<PHS trees: phs tree: TBP>+≡
  procedure :: from_array => phs_tree_from_array

<PHS trees: procedures>+≡
  subroutine phs_tree_from_array (tree, a)
    class(phs_tree_t), intent(inout) :: tree
    integer(TC), dimension(:), intent(in) :: a
    integer :: i
    integer(TC) :: k
    <Set branches from array a>
    <Set external branches if necessary>
    <Check number of branches>
    <Determine the connections>
    contains
    <Subroutine: set relatives>
    end subroutine phs_tree_from_array

```

First, set all branches specified by the user. If all IN-bits are set, we invert the branch code.

```

<Set branches from array a>≡
  do i=1, size(a)
    k = a(i)
    if (iand(k, tree%mask_in) == tree%mask_in) k = ieor(tree%mask, k)
    tree%branch(k)%set = .true.
    tree%n_branches = tree%n_branches+1
  end do

```

The external branches are understood, so set them now if not yet done. In all cases ensure that the representative with one bit set is used, except for decays where the in-particle is represented by all OUT-bits set instead.

```

<Set external branches if necessary>≡
  do i=0, tree%n externals-1
    k = ibset(0,i)
    if (iand(k, tree%mask_in) == tree%mask_in) k = ieor(tree%mask, k)
    if (tree%branch(ieor(tree%mask, k))%set) then
      tree%branch(ieor(tree%mask, k))%set = .false.
      tree%branch(k)%set = .true.
    else if (.not.tree%branch(k)%set) then
      tree%branch(k)%set = .true.
      tree%n_branches = tree%n_branches+1
    end if
  end do

```

Now the number of branches set can be checked. Here we assume that the tree is binary. For three externals there are three branches in total, and for each additional external branches we get another internal one.

```

<Check number of branches>≡
  if (tree%n_branches /= tree%n externals*2-3) then
    call phs_tree_write (tree)
    call msg_bug &
      & (" Wrong number of branches set in phase space tree")
  end if

```

For all branches that are set, except for the externals, we try to find the daughter branches:

```

<Determine the connections>≡
do k=1, size (tree%branch)
  if (tree%branch(k)%set .and. tc_decay_level (k) /= 1) then
    call branch_set_relatives(k)
  end if
end do

```

To this end, we scan all codes less than the current code, whether we can find two branches which are set and which together give the current code. After that, the tree may still not be connected, but at least we know if a branch does not have daughters: This indicates some inconsistency.

The algorithm ensures that, at this stage, the first daughter has a smaller code value than the second one.

```

<Subroutine: set relatives>≡
subroutine branch_set_relatives (k)
  integer(TC), intent(in) :: k
  integer(TC) :: m,n
  do m=1, k-1
    if (iand(k,m)==m) then
      n = ieor(k,m)
      if ( tree%branch(m)%set .and. tree%branch(n)%set ) then
        tree%branch(k)%daughter(1) = m; tree%branch(k)%daughter(2) = n
        tree%branch(m)%mother      = k; tree%branch(n)%mother      = k
        tree%branch(m)%sibling      = n; tree%branch(n)%sibling      = m
        tree%branch(k)%has_children = .true.
        return
      end if
    end if
  end do
  call phs_tree_write (tree)
  call msg_bug &
    & (" Missing daughter branch(es) in phase space tree")
end subroutine branch_set_relatives

```

The inverse: this is trivial, fortunately.

### Flip $t$ -channel into $s$ -channel

Flipping the tree is done upwards, beginning from the decay products. First we select a  $t$ -channel branch  $k$ : one which is set, which does have an IN-bit, and which is not an external particle.

Next, we determine the adjacent in-particle (called the 'friend'  $f$  here, since it will provide the reference axis for the angular integration). In addition, we look for the 'mother' and 'sibling' of this particle. If the latter field is empty, we select the (unique) other out-particle which has no mother, calling the internal subroutine `find_orphan`.

The flip is done as follows: We assume that the first daughter  $d$  is an  $s$ -channel line, which is true if the daughters are sorted. This will stay the first daughter. The second one is a  $t$ -channel line; it is exchanged with the 'sibling'

s. The new line which replaces the branch k is just the sum of s and d. In addition, we have to rearrange the relatives of s and d, as well of f.

Finally, we flip 'sibling' and 'friend' and set the new s-channel branch n which replaces the t-channel branch k. After this is complete, we are ready to execute another flip.

[Although the friend is not needed for the final flip, since it would be an initial particle anyway, we need to know whether we have t- or u-channel.]

```

<PHS trees: public>+≡
    public :: phs_tree_flip_t_to_s_channel

<PHS trees: procedures>+≡
    subroutine phs_tree_flip_t_to_s_channel (tree)
        type(phs_tree_t), intent(inout) :: tree
        integer(TC) :: k, f, m, n, d, s
        if (tree%n_in == 2) then
            FLIP: do k=3, tree%mask-1
                if (.not. tree%branch(k)%set) cycle FLIP
                f = iand(k,tree%mask_in)
                if (f==0 .or. f==k) cycle FLIP
                m = tree%branch(k)%mother
                s = tree%branch(k)%sibling
                if (s==0) call find_orphan(s)
                d = tree%branch(k)%daughter(1)
                n = ior(d,s)
                tree%branch(k)%set = .false.
                tree%branch(n)%set = .true.
                tree%branch(n)%origin = k
                tree%branch(n)%daughter(1) = d; tree%branch(d)%mother = n
                tree%branch(n)%daughter(2) = s; tree%branch(s)%mother = n
                tree%branch(n)%has_children = .true.
                tree%branch(d)%sibling = s; tree%branch(s)%sibling = d
                tree%branch(n)%sibling = f; tree%branch(f)%sibling = n
                tree%branch(n)%mother = m
                tree%branch(f)%mother = m
                if (m/=0) then
                    tree%branch(m)%daughter(1) = n

            do s=1, tree%mask_out
                if (tree%branch(s)%set .and. tree%branch(s)%mother==0) return
            end do
            call phs_tree_write (tree)
            call msg_bug (" Can't flip phase space tree to channel")
        end subroutine find_orphan
    end subroutine phs_tree_flip_t_to_s_channel

```

After the tree has been flipped, one may need to determine what has become of a particular  $t$ -channel branch. This function gives the bincode of the flipped tree. If the original bincode does not contain IN-bits, we leave it as it is.

```

<PHS trees: procedures>+≡
function tc_flipped (tree, kt) result (ks)
  type(phs_tree_t), intent(in) :: tree
  integer(TC), intent(in) :: kt
  integer(TC) :: ks
  if (iand (kt, tree%mask_in) == 0) then
    ks = kt
  else
    ks = tree%branch(iand (kt, tree%mask_out))%mother
  end if
end function tc_flipped

```

Scan a tree and make sure that the first daughter has always a smaller code than the second one. Furthermore, delete any **friend** entry in the root branch – this branching has the incoming particle direction as axis anyway. Keep track of reordering by updating **inverted\_axis**, **inverted\_decay** and **firstborn**.

```

```

```
end subroutine phs_tree_canonicalize
```

## Mappings

Initialize a mapping for the current tree. This is done while reading from file, so the mapping parameters are read, but applied to the flipped tree. Thus, the size of the array of mappings is given by the number of outgoing particles only.

```
<PHS trees: public>+≡
  public :: phs_tree_init_mapping

<PHS trees: phs tree: TBP>+≡
  procedure :: init_mapping => phs_tree_init_mapping

<PHS trees: procedures>+≡
  subroutine phs_tree_init_mapping (tree, k, type, pdg, model)
    class(phs_tree_t), intent(inout) :: tree
    integer(TC), intent(in) :: k
    type(string_t), intent(in) :: type
    integer, intent(in) :: pdg
    class(model_data_t), intent(in), target :: model
    integer(TC) :: kk
    kk = tc_flipped (tree, k)
    call mapping_init (tree%mapping(kk), kk, type, pdg, model)
  end subroutine phs_tree_init_mapping
```

Set the physical parameters for the mapping, using a specific parameter set. Also set the mass sum array.

```
<PHS trees: public>+≡
  public :: phs_tree_set_mapping_parameters

<PHS trees: phs tree: TBP>+≡
  procedure :: set_mapping_parameters => phs_tree_set_mapping_parameters

<PHS trees: procedures>+≡
  subroutine phs_tree_set_mapping_parameters &
    (tree, mapping_defaults, variable_limits)
    class(phs_tree_t), intent(inout) :: tree
    type(mapping_defaults_t), intent(in) :: mapping_defaults
    logical, intent(in) :: variable_limits
    integer(TC) :: k
    do k = 1, tree%n_branches_out
      call mapping_set_parameters &
        (tree%mapping(k), mapping_defaults, variable_limits)
    end do
  end subroutine phs_tree_set_mapping_parameters
```

Return the mapping for the sum of all outgoing particles. This should either be no mapping or a global s-channel mapping.

```
<PHS trees: public>+≡
  public :: phs_tree_assign_s_mapping
```

```

<PHS trees: procedures>+≡
  subroutine phs_tree_assign_s_mapping (tree, mapping)
    type(phs_tree_t), intent(in) :: tree
    type(mapping_t), intent(out) :: mapping
    mapping = tree%mapping(tree%mask_out)
  end subroutine phs_tree_assign_s_mapping

```

## Kinematics

Fill the mass sum array, starting from the external particles and working down to the tree root. For each bincode  $k$  we scan the bits in  $k$ ; if only one is set, we take the physical mass of the corresponding external particle; if more than one is set, we sum up the two masses (which we know have already been set).

```

<PHS trees: public>+≡
  public :: phs_tree_set_mass_sum

<PHS trees: phs tree: TBP>+≡
  procedure :: set_mass_sum => phs_tree_set_mass_sum

<PHS trees: procedures>+≡
  subroutine phs_tree_set_mass_sum (tree, flv)
    class(phs_tree_t), intent(inout) :: tree
    type(flavor_t), dimension(:), intent(in) :: flv
    integer(TC) :: k
    integer :: i
    tree%mass_sum = 0
    do k = 1, tree%n_branches_out
      do i = 0, size(flav) - 1
        if (btest(k,i)) then
          if (ibclr(k,i) == 0) then
            tree%mass_sum(k) = flv(i+1)%get_mass ()
          else
            tree%mass_sum(k) = &
              tree%mass_sum(ibclr(k,i)) + tree%mass_sum(ibset(0,i))
          end if
        end if
      end do
    end do
  end subroutine phs_tree_set_mass_sum

```

Set the effective masses and widths. For each non-resonant branch in a tree, the effective mass is equal to the sum of the effective masses of the children (and analogous for the width). External particles have their real mass and width zero. For resonant branches, we insert mass and width from the corresponding mapping.

This routine has `phs_tree_set_mass_sum` and `phs_tree_set_mapping_parameters` as prerequisites.

```

<PHS trees: public>+≡
  public :: phs_tree_set_effective_masses

<PHS trees: phs tree: TBP>+≡
  procedure :: set_effective_masses => phs_tree_set_effective_masses

```

```

<PHS trees: procedures>+≡

        k2 = tree%branch(k)%daughter(2)
        call set_masses_x (k1)
        call set_masses_x (k2)
        if (mapping_is_s_channel (tree%mapping(k))) then
          tree%effective_mass(k) = mapping_get_mass (tree%mapping(k))
          tree%effective_width(k) = mapping_get_width (tree%mapping(k))
        else
          tree%effective_mass(k) = &
            tree%effective_mass(k1) + tree%effective_mass(k2)
          tree%effective_width(k) = &
            tree%effective_width(k1) + tree%effective_width(k2)
        end if
      else
        tree%effective_mass(k) = tree%mass_sum(k)
      end if
    end subroutine set_masses_x
  end subroutine phs_tree_set_effective_masses

```

Define step mappings, recursively, for the decay products of all intermediate resonances. Step mappings account for the fact that a branch may originate from a resonance, which almost replaces the upper limit on the possible invariant mass. The step mapping implements a smooth cutoff that interpolates between the resonance and the real kinematic limit. The mapping width determines the sharpness of the cutoff.

Step mappings are inserted only for branches that are not mapped otherwise.

At each branch, we record the mass that is effectively available for phase space, by taking the previous limit and subtracting the effective mass of the sibling branch. Widths are added, not subtracted.

If we encounter a resonance decay, we discard the previous limit and replace it by the mass and width of the resonance, also subtracting the sibling branch.

Initially, the limit is zero, so it becomes negative at any branch. Only if there is a resonance, the limit becomes positive. Whenever the limit is positive, and the current branch decays, we activate a step mapping for the current branch.

As a result, step mappings are implemented for all internal lines that originate from an intermediate resonance decay.

The flag `variable_limits` applies to the ultimate limit from the available energy, not to the intermediate resonances whose masses are always fixed.

This routine requires `phs_tree_set_effective_masses`

                    end if
                end associate
            end do
        end if
    end subroutine phs_tree_extract_resonance_history

```

## Structural comparison

This function allows to check whether one tree is the permutation of another one. The permutation is applied to the second tree in the argument list. We do not make up a temporary permuted tree, but compare the two trees directly. The branches are scanned recursively, where for each daughter we check the friend and the mapping as well. Once a discrepancy is found, the recursion is exited immediately.

```

## 19.7.4 Phase-space evaluation

### Phase-space volume

We compute the phase-space volume recursively, following the same path as for computing other kinematical variables. However, the volume depends just on  $\sqrt{\hat{s}}$ , not on the momentum configuration.

Note: counting branches, we may replace this by a simple formula.

```

<PHS trees: public>+≡
  public :: phs_tree_compute_volume

<PHS trees: procedures>+≡
  subroutine phs_tree_compute_volume (tree, sqrts, volume)
    type(phs_tree_t), intent(in) :: tree

else
  volume = v1 * v2 * sqrts**2 / (4 * twopi2)
end if
end subroutine compute_volume_x
end subroutine phs_tree_compute_volume

```

### Determine momenta

This is done in two steps: First the masses are determined. This step may fail, in which case `ok` is set to false. If successful, we generate angles and the actual momenta. The array `decay_p` serves for transferring the individual three-momenta of the daughter particles in their mother rest frame from the mass generation to the momentum generation step.

```

    (tree, prt, factor, volume, decay_p, sqrts, x(1:n1), ok)
if (ok) call phs_tree_set_angles &
    (tree, prt, factor, decay_p, sqrts, x(n1+1:n2))
end subroutine phs_tree_compute_momenta_from_x

```

Mass generation is done recursively. The `ok` flag causes the filled tree to be discarded if set to `.false.`. This happens if a three-momentum turns out to be imaginary, indicating impossible kinematics. The index `ix` tells us how far we have used up the input array `x`.

The heart of phase space generation: Now we have the invariant masses, let us generate angles. At each branch, we take a Lorentz transformation and augment it by a boost to the current particle rest frame, and by rotations  $\phi$  and  $\theta$  around the  $z$  and  $y$  axis, respectively. This transformation is passed down to the daughter particles, if present.

```

This subroutine is the most time-critical part of the whole program. Therefore, we do not exactly parallel the angle generation routine above but make sure that things get evaluated only if they are really needed, at the expense of

readability. Particularly important is to have as few multiplications of Lorentz transformations as possible.

## 19.8 The phase-space forest

Simply stated, a phase-space forest is a collection of phase-space trees. More precisely, a `phs_forest` object contains all parameterizations of phase space that **WHIZARD** will use for a single hard process, prepared in the form of `phs_tree` objects. This is suitable for evaluation by the **VAMP** integration package: each parameterization (tree) is a valid channel in the multi-channel adaptive integration, and each variable in a tree corresponds to an integration dimension, defined by an appropriate mapping of the  $(0, 1)$  interval to the allowed range of the integration variable.

The trees are grouped in groves. The trees (integration channels) within a grove share a common weight, assuming that they are related by some approximate symmetry.

Trees/channels that are related by an exact symmetry are connected by an array of equivalences; each equivalence object holds the data that relate one channel to another.

The phase-space setup, i.e., the detailed structure of trees and forest, are read from a file. Therefore, this module also contains the syntax definition and the parser needed for interpreting this file.

### 19.8.1 Phase-space setup parameters

This transparent container holds the parameters that the algorithm needs for phase-space setup, with reasonable defaults.

The threshold mass (for considering a particle as effectively massless) is specified separately for s- and t-channel. The default is to treat  $W$  and  $Z$  bosons as massive in the s-channel, but as massless in the t-channel. The  $b$ -quark is treated always massless, the  $t$ -quark always massive.

```

```

## 19.8.2 Equivalences

This type holds information about equivalences between phase-space trees. We make a linked list, where each node contains the two trees which are equivalent and the corresponding permutation of external particles. Two more arrays are to be filled: The permutation of mass variables and the permutation of angular variables, where the signature indicates a necessary exchange of daughter branches.

```
(PHS forests: types)+≡
  type :: equivalence_t
  private
  integer :: left, right
  type(permutation_t) :: perm
  type(permutation_t) :: msq_perm, angle_perm
  logical, dimension(:), allocatable :: angle_sig
  type(equivalence_t), pointer :: next => null ()
end type equivalence_t
```

```
(PHS forests: types)+≡
  type :: equivalence_list_t
  private
  integer :: length = 0
  type(equivalence_t), pointer :: first => null ()
  type(equivalence_t), pointer :: last => null ()
end type equivalence_list_t
```

Append an equivalence to the list

```
(PHS forests: procedures)+≡
  subroutine equivalence_list_add (eql, left, right, perm)
  type(equivalence_list_t), intent(inout) :: eql
  integer, intent(in) :: left, right
  type(permutation_t), intent(in) :: perm
  type(equivalence_t), pointer :: eq
  allocate (eq)
  eq%left = left
  eq%right = right
  eq%perm = perm
  if (associated (eql%last)) then
    eql%last%next => eq
  else
    eql%first => eq
  end if
  eql%last => eq
  eql%length = eql%length + 1
end subroutine equivalence_list_add
```

Delete the list contents. Has to be pure because it is called from an elemental subroutine.

```
(PHS forests: procedures)+≡
  pure subroutine equivalence_list_final (eql)
  type(equivalence_list_t), intent(inout) :: eql
  type(equivalence_t), pointer :: eq
```

```

do while (associated (eql%first))
  eq => eql%first
  eql%first => eql%first%next
  deallocate (eq)
end do
eql%last => null ()
eql%length = 0
end subroutine equivalence_list_final

```

Make a deep copy of the equivalence list. This allows for deep copies of groves and forests.

```

<PHS forests: interfaces>+≡
interface assignment(=)
  module procedure equivalence_list_assign
end interface

<PHS forests: procedures>+≡
subroutine equivalence_list_assign (eql_out, eql_in)
  type(equivalence_list_t), intent(out) :: eql_out
  type(equivalence_list_t), intent(in) :: eql_in
  type(equivalence_t), pointer :: eq, eq_copy
  eq => eql_in%first
  do while (associated (eq))
    allocate (eq_copy)
    eq_copy = eq
    eq_copy%next => null ()
    if (associated (eql_out%first)) then
      eql_out%last%next => eq_copy
    else
      eql_out%first => eq_copy
    end if
    eql_out%last => eq_copy
    eq => eq%next
  end do
end subroutine equivalence_list_assign

```

The number of list entries

```

<PHS forests: procedures>+≡
elemental function equivalence_list_length (eql) result (length)
  integer :: length
  type(equivalence_list_t), intent(in) :: eql
  length = eql%length
end function equivalence_list_length

```

Recursively write the equivalences list

```

<PHS forests: procedures>+≡
subroutine equivalence_list_write (eql, unit)
  type(equivalence_list_t), intent(in) :: eql
  integer, intent(in), optional :: unit
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  if (associated (eql%first)) then

```

```

        call equivalence_write_rec (eq1%first, u)
    else
        write (u, *) " [empty]"
    end if
contains
recursive subroutine equivalence_write_rec (eq, u)
    type(equivalence_t), intent(in) :: eq
    integer, intent(in) :: u
    integer :: i
    write (u, "(3x,A,1x,I0,1x,I0,2x,A)", advance="no") &
        "Equivalence:", eq%left, eq%right, "Final state permutation:"
    call permutation_write (eq%perm, u)
    write (u, "(1x,12x,1x,A,1x)", advance="no") &
        "      msq permutation:  "
    call permutation_write (eq%msq_perm, u)
    write (u, "(1x,12x,1x,A,1x)", advance="no") &
        "      angle permutation:"
    call permutation_write (eq%angle_perm, u)
    write (u, "(1x,12x,1x,26x)", advance="no")
    do i = 1, size (eq%angle_sig)
        if (eq%angle_sig(i)) then
            write (u, "(1x,A)", advance="no") "+"
        else
            write (u, "(1x,A)", advance="no") "-"
        end if
    end do
    write (u, *)
    if (associated (eq%next)) call equivalence_write_rec (eq%next, u)
end subroutine equivalence_write_rec
end subroutine equivalence_list_write

```

### 19.8.3 Groves

A grove is a group of trees (phase-space channels) that share a common weight in the integration. Within a grove, channels can be declared equivalent, so they also share their integration grids (up to symmetries). The grove contains a list of equivalences. The `tree_count_offset` is the total number of trees of the preceding groves; when the trees are counted per forest (integration channels), the offset has to be added to all tree indices.

```

<PHS forests: types>+≡
    type :: phs_grove_t
    private
    integer :: tree_count_offset
    type(phs_tree_t), dimension(:), allocatable :: tree
    type(equivalence_list_t) :: equivalence_list
end type phs_grove_t

```

Call `phs_tree_init` which is also elemental:

```

<PHS forests: procedures>+≡
    elemental subroutine phs_grove_init &
        (grove, n_trees, n_in, n_out, n_masses, n_angles)

```

```

    type(phs_grove_t), intent(inout) :: grove
    integer, intent(in) :: n_trees, n_in, n_out, n_masses, n_angles
    grove%tree_count_offset = 0
    allocate (grove%tree (n_trees))
    call phs_tree_init (grove%tree, n_in, n_out, n_masses, n_angles)
end subroutine phs_grove_init

```

The trees do not have pointer components, thus no call to `phs_tree_final`:

```

<PHS forests: procedures>+≡
    elemental subroutine phs_grove_final (grove)
        type(phs_grove_t), intent(inout) :: grove
        deallocate (grove%tree)
        call equivalence_list_final (grove%equivalence_list)
    end subroutine phs_grove_final

```

Deep copy.

```

<PHS forests: interfaces>+≡
    interface assignment(=)
        module procedure phs_grove_assign0
        module procedure phs_grove_assign1
    end interface

<PHS forests: procedures>+≡
    subroutine phs_grove_assign0 (grove_out, grove_in)
        type(phs_grove_t), intent(out) :: grove_out
        type(phs_grove_t), intent(in) :: grove_in
        grove_out%tree_count_offset = grove_in%tree_count_offset
        if (allocated (grove_in%tree)) then
            allocate (grove_out%tree (size (grove_in%tree)))
            grove_out%tree = grove_in%tree
        end if
        grove_out%equivalence_list = grove_in%equivalence_list
    end subroutine phs_grove_assign0

    subroutine phs_grove_assign1 (grove_out, grove_in)
        type(phs_grove_t), dimension(:), intent(out) :: grove_out
        type(phs_grove_t), dimension(:), intent(in) :: grove_in
        integer :: i
        do i = 1, size (grove_in)
            call phs_grove_assign0 (grove_out(i), grove_in(i))
        end do
    end subroutine phs_grove_assign1

```

Get the global (s-channel) mappings. Implemented as a subroutine which returns an array (slice).

```

<PHS forests: procedures>+≡
    subroutine phs_grove_assign_s_mappings (grove, mapping)
        type(phs_grove_t), intent(in) :: grove
        type(mapping_t), dimension(:), intent(out) :: mapping
        integer :: i
        if (size (mapping) == size (grove%tree)) then
            do i = 1, size (mapping)

```

```

        call phs_tree_assign_s_mapping (grove%tree(i), mapping(i))
    end do
else
    call msg_bug ("phs_grove_assign_s_mappings: array size mismatch")
end if
end subroutine phs_grove_assign_s_mappings

```

#### 19.8.4 The forest type

This is a collection of trees and associated particles. In a given tree, each branch code corresponds to a particle in the `prt` array. Furthermore, we have an array of mass sums which is independent of the decay tree and of the particular event. The mappings directly correspond to the decay trees, and the decay groves collect the trees in classes. The permutation list consists of all permutations of outgoing particles that map the decay forest onto itself.

The particle codes `flv` (one for each external particle) are needed for determining masses and such. The trees and associated information are collected in the `grove` array, together with a lookup table that associates tree indices to groves. Finally, the `prt` array serves as workspace for phase-space evaluation.

The `prt_combination` is a list of index pairs, namely the particle momenta pairs that need to be combined in order to provide all momentum combinations that the phase-space trees need to know.

```

(PHS forests: public)+≡
    public :: phs_forest_t

(PHS forests: types)+≡
    type :: phs_forest_t
    private
        integer :: n_in, n_out, n_tot
        integer :: n_masses, n_angles, n_dimensions
        integer :: n_trees, n_equivalences
        type(flavor_t), dimension(:), allocatable :: flv
        type(phs_grove_t), dimension(:), allocatable :: grove
        integer, dimension(:), allocatable :: grove_lookup
        type(phs_prt_t), dimension(:), allocatable :: prt_in
        type(phs_prt_t), dimension(:), allocatable :: prt_out
        type(phs_prt_t), dimension(:), allocatable :: prt
        integer(TC), dimension(:,:), allocatable :: prt_combination
        type(mapping_t), dimension(:), allocatable :: s_mapping
    contains
        (PHS forests: phs_forest: TBP)
    end type phs_forest_t

```

The initialization merely allocates memory. We have to know how many trees there are in each grove, so we can initialize everything. The number of groves is the size of the `n_tree` array.

In the `grove_lookup` table we store the grove index that belongs to each absolute tree index. The difference between the absolute index and the relative (to the grove) index is stored, for each grove, as `tree_count_offset`.

The particle array is allocated according to the total number of branches each tree has, but not filled.

```

### 19.8.7 Read the phase space setup from file

The phase space setup is stored in a file. The file may be generated by the `cascades` module below, or by other means. This file has to be read and parsed to create the PHS forest as the internal phase-space representation.

Create lexer and syntax:

(*PHS forests: procedures*) +=

```

subroutine define_phs_forest_syntax (ifile)
    type(ifile_t) :: ifile
    call ifile_append (ifile, "SEQ phase_space_list = process_phase_space*")
    call ifile_append (ifile, "SEQ process_phase_space = " &
        // "process_def process_header phase_space")
    call ifile_append (ifile, "SEQ process_def = process process_list")
    call ifile_append (ifile, "KEY process")
    call ifile_append (ifile, "LIS process_list = process_tag*")
    call ifile_append (ifile, "IDE process_tag")
    call ifile_append (ifile, "SEQ process_header = " &
        // "md5sum_process = md5sum " &
        // "md5sum_model_par = md5sum " &
        // "md5sum_phs_config = md5sum " &
        // "sqrts = real " &
        // "m_threshold_s = real " &
        // "m_threshold_t = real " &
        // "off_shell = integer " &
        // "t_channel = integer " &
        // "keep_nonresonant = logical")
    call ifile_append (ifile, "KEY '='")
    call ifile_append (ifile, "KEY '-'")
    call ifile_append (ifile, "KEY md5sum_process")
    call ifile_append (ifile, "KEY md5sum_model_par")
    call ifile_append (ifile, "KEY md5sum_phs_config")
    call ifile_append (ifile, "KEY sqrts")
    call ifile_append (ifile, "KEY m_threshold_s")
    call ifile_append (ifile, "KEY m_threshold_t")
    call ifile_append (ifile, "KEY off_shell")
    call ifile_append (ifile, "KEY t_channel")
    call ifile_append (ifile, "KEY keep_nonresonant")
    call ifile_append (ifile, "QUO md5sum = '""' ... '""'")
    call ifile_append (ifile, "REA real")
    call ifile_append (ifile, "INT integer")
    call ifile_append (ifile, "IDE logical")
    call ifile_append (ifile, "SEQ phase_space = grove_def+")
    call ifile_append (ifile, "SEQ grove_def = grove tree_def+")
    call ifile_append (ifile, "KEY grove")
end subroutine

```

```

call ifile_append (ifile, "SEQ tree_def = tree bincodes mapping*")
call ifile_append (ifile, "KEY tree")
call ifile_append (ifile, "SEQ bincodes = bincodes*")
call ifile_append (ifile, "INT bincodes")
call ifile_append (ifile, "SEQ mapping = map bincodes channel signed_pdg")
call ifile_append (ifile, "KEY map")
call ifile_append (ifile, "ALT channel = &
    &s_channel | t_channel | u_channel | &
    &collinear | infrared | radiation | on_shell")
call ifile_append (ifile, "KEY s_channel")
! call ifile_append (ifile, "KEY t_channel")    !!! Key already exists
call ifile_append (ifile, "KEY u_channel")
call ifile_append (ifile, "KEY collinear")
call ifile_append (ifile, "KEY infrared")
call ifile_append (ifile, "KEY radiation")
call ifile_append (ifile, "KEY on_shell")
call ifile_append (ifile, "ALT signed_pdg = &
    &pdg | negative_pdg")
call ifile_append (ifile, "SEQ negative_pdg = '-' pdg")
call ifile_append (ifile, "INT pdg")
end subroutine define_phs_forest_syntax

```

The model-file syntax and lexer are fixed, therefore stored as module variables:

```

<PHS forests: variables>≡
    type(syntax_t), target, save :: syntax_phs_forest

<PHS forests: public>+≡
    public :: syntax_phs_forest_init

<PHS forests: procedures>+≡
    subroutine syntax_phs_forest_init ()
        type(ifile_t) :: ifile
        call define_phs_forest_syntax (ifile)
        call syntax_init (syntax_phs_forest, ifile)
        call ifile_final (ifile)
    end subroutine syntax_phs_forest_init

<PHS forests: procedures>+≡
    subroutine lexer_init_phs_forest (lexer)
        type(lexer_t), intent(out) :: lexer
        call lexer_init (lexer, &
            comment_chars = "#!", &
            quote_chars = "'", &
            quote_match = "'", &
            single_chars = "-", &
            special_class = ["="] , &
            keyword_list = syntax_get_keyword_list_ptr (syntax_phs_forest))
    end subroutine lexer_init_phs_forest

<PHS forests: public>+≡
    public :: syntax_phs_forest_final

<PHS forests: procedures>+≡

```

```

subroutine syntax_phs_forest_final ()
  call syntax_final (syntax_phs_forest)
end subroutine syntax_phs_forest_final

```

*<PHS forests: public>+≡*

```

public :: syntax_phs_forest_write

```

*<PHS forests: procedures>+≡*

```

subroutine syntax_phs_forest_write (unit)
  integer, intent(in), optional :: unit
  call syntax_write (syntax_phs_forest, unit)
end subroutine syntax_phs_forest_write

```

The concrete parser and interpreter. Generate an input stream for the external `unit`, read the parse tree (with given `syntax` and `lexer`) from this stream, and transfer the contents of the parse tree to the PHS forest.

We look for the matching `process` tag, count groves and trees for initializing the forest, and fill the trees.

If the optional parameters are set, compare the parameters stored in the file to those. Set `match` true if everything agrees.

*<PHS forests: public>+≡*

```

public :: phs_forest_read

```

*<PHS forests: interfaces>+≡*

### 19.8.8 Preparation

The trees that we read from file do not carry flavor information. This is set separately:

The flavor list must be unique for a unique set of masses; if a given particle can have different flavor, the mass must be degenerate, so we can choose one of the possible flavor combinations.

*(PHS forests: public)*+≡

```
public :: phs_forest_set_flavors
```

*(PHS forests: procedures)*+≡

```

subroutine phs_forest_set_flavors (forest, flv, reshuffle, flv_extra)
    type(phs_forest_t), intent(inout) :: forest
    type(flavor_t), dimension(:), intent(in) :: flv

    do t = 1, size (forest%grove(g)%tree)
      associate (tree => forest%grove(g)%tree(t))
        call phs_tree_set_momentum_links (tree, list)
      !!! call phs_tree_reshuffle_mappings (tree)
      end associate
    end do
  end do
end subroutine phs_forest_set_momentum_links

```

Once the parameter set is fixed, the masses and the widths of the particles are known and the `mass_sum` arrays as well as the mapping parameters can be computed. Note that order is important: we first compute the mass sums, then the ordinary mappings. The resonances obtained here determine the effective masses, which in turn are used to implement step mappings for resonance decay products that are not mapped otherwise.

*(PHS forests: public)*+≡

```
public :: phs_forest_set_parameters
```

*(PHS forests: procedures)*+≡

```

subroutine phs_forest_set_parameters &
  (forest, mapping_defaults, variable_limits)
  type(phs_forest_t), intent(inout) :: forest

        end if
    end do
end do
end subroutine phs_forest_set_parameters

```

Generate the particle combination table. Scan all trees and merge their individual combination tables. At the end, valid entries are non-zero, and they indicate the indices of a pair of particles to be combined to a new particle. If a particle is accessible by more than one tree (this is usual), only keep the first possibility.

### 19.8.10 Find equivalences among phase-space trees

Scan phase space for equivalences. We generate the complete set of unique permutations for the given list of outgoing particles, and use this for scanning equivalences within each grove. We scan all pairs of trees, using all permutations. This implies that trivial equivalences are included, and equivalences between different trees are recorded twice. This is intentional.

```

```

### 19.8.12 Phase-space evaluation

Given one row of the **x** parameter array and the corresponding channel index, compute first all relevant momenta and then recover the remainder of the **x** array, the Jacobians **phs\_factor**, and the phase-space volume.

The output argument **ok** indicates whether this was successful.

*(PHS forests: public)+≡*

```
public :: phs_forest_evaluate_selected_channel
```

*(PHS forests: procedures)+≡*

```

subroutine phs_forest_evaluate_selected_channel &
  (forest, channel, active, sqrts, x, phs_factor, volume, ok)
  type(phs_forest_t), intent(inout) :: forest
  integer, intent(in) :: channel
  logical, dimension(:), intent(in) :: active
  real(default), intent(in) :: sqrts
  real(default), dimension(:,:), intent(inout) :: x
  real(default), dimension(:), intent(out) :: phs_factor
  real(default), intent(out) :: volume
  logical, intent(out) :: ok
  integer :: g, t

```

```

integer(TC) :: k, k_root, k_in

g = forest%grove_lookup (channel)
t = channel - forest%grove(g)%tree_count_offset
call phs_prt_set_undefined (forest%prt)
call phs_prt_set_undefined (forest%prt_out)
k_in = forest%n_tot

do k = 1, forest%n_in
    forest%prt(ibset(0,k_in-k)) = forest%prt_in(k)
end do

do k = 1, forest%n_out
    call phs_prt_set_msq (forest%prt(ibset(0,k-1)), &
        forest%flv(forest%n_in+k)%get_mass () ** 2)
end do

k_root = 2**forest%n_out - 1
select case (forest%n_in)
case (1)
    forest%prt(k_root) = forest%prt_in(1)
case (2)
    call phs_prt_combine &
        (forest%prt(k_root), forest%prt_in(1), forest%prt_in(2))
end select
call phs_tree_compute_momenta_from_x (forest%grove(g)%tree(t), &
    forest%prt, phs_factor(channel), volume, sqrts, x(:,channel), ok)

## 19.9 Finding phase space parameterizations

If the phase space configuration is not found in the appropriate file, we should generate one.

The idea is to construct all Feynman diagrams subject to certain constraints which eliminate everything that is probably irrelevant for the integration. These Feynman diagrams (cascades) are grouped in groves by finding equivalence classes related by symmetry and ordered with respect to their importance (resonances). Finally, the result (or part of it) is written to file and used for the integration.

This module may eventually disappear and be replaced by CAML code. In particular, we need here a set of Feynman rules (vertices with particle codes,

but not the factors). Thus, the module works for the Standard Model only.

Note that this module is stand-alone, it communicates to the main program only via the generated ASCII phase-space configuration file.

```

<cascades.f90>≡

### 19.9.2 The cascade type

A cascade is essentially the same as a decay tree (both definitions may be merged in a later version). It contains a linked tree of nodes, each of which representing an internal particle. In contrast to decay trees, each node has a definite particle code. These nodes need not be modified, therefore we can use pointers and do not have to copy them. Thus, physically each cascades has only a single node, the mother particle. However, to be able to compare trees quickly, we store in addition an array of binary codes which is always sorted in ascending order. This is accompanied by a corresponding list of particle codes. The index is the location of the corresponding cascade in the cascade set, this may be used to access the daughters directly.

The real mass is the particle mass belonging to the particle code. The minimal mass is the sum of the real masses of all its daughters; this is the kinematical cutoff. The effective mass may be zero if the particle mass is below a certain threshold; it may be the real mass if the particle is resonant; or it may be some other value.

The logical `t_channel` is set if this a  $t$ -channel line, while `initial` is true only for an initial particle. Note that both initial particles are also `t_channel` by definition, and that they are distinguished by the direction of the tree: One of them decays and is the root of the tree, while the other one is one of the leaves.

The cascade is a list of nodes (particles) which are linked via the `daughter` entries. The node is the mother particle of the decay cascade. Much of the information in the nodes is repeated in arrays, to be accessible more easily. The arrays will be kept sorted by binary codes.

The counter `n_off_shell` is increased for each internal line that is neither resonant nor log-enhanced. It is set to zero if the current line is resonant, since this implies on-shell particle production and subsequent decay.

The counter `n_t_channel` is non-negative once an initial particle is included in the tree: then, it counts the number of  $t$ -channel lines.

The `multiplicity` is the number of branchings to follow until all daughters are on-shell. A resonant or non-decaying particle has multiplicity one. Merging nodes, the multiplicities add unless the mother is a resonance. An initial or final node has multiplicity zero.

The arrays correspond to the subnode tree `tree` of the current cascade. PDG codes are stored only for those positions which are resonant, with the exception of the last entry, i.e., the current node. Other positions, in particular external legs, are assigned undefined PDG code.

A cascade is uniquely identified by its tree, the tree of PDG codes, and the tree of mappings. The tree of resonances is kept only to mask the PDG tree as

described above.

### 19.9.3 Creating new cascades

This initializes a single-particle cascade (external, final state). The PDG entry in the tree is set undefined because the cascade is not resonant. However, the flavor entry is set, so the cascade flavor is identified nevertheless.

```

(Cascades: procedures)+≡
subroutine cascade_init_outgoing (cascade, flv, pos, m_thr)
  type(cascade_t), intent(out) :: cascade
  type(flavor_t), intent(in) :: flv
  integer, intent(in) :: pos
  real(default), intent(in) :: m_thr
  call cascade_init (cascade, 1)
  cascade%bincode = ibset (0_TC, pos-1)
  cascade%flv = flv
  cascade%pdg = cascade%flv%get_pdg ()
  cascade%is_vector = flv%get_spin_type () == VECTOR
  cascade%m_min = flv%get_mass ()
  cascade%m_rea = cascade%m_min
  if (cascade%m_rea >= m_thr) then
    cascade%m_eff = cascade%m_rea
  end if
  cascade%on_shell = .true.
  cascade%multiplicity = 1
  cascade%tree(1) = cascade%bincode
  cascade%tree_pdg(1) = cascade%pdg
  cascade%tree_mapping(1) = EXTERNAL_PRT
  cascade%tree_resonant(1) = .false.
end subroutine cascade_init_outgoing

```

The same for an incoming line:

```

(Cascades: procedures)+≡
subroutine cascade_init_incoming (cascade, flv, pos, m_thr)
  type(cascade_t), intent(out) :: cascade

```

```

type(flavor_t), intent(in) :: flv
integer, intent(in) :: pos
real(default), intent(in) :: m_thr
call cascade_init (cascade, 1)
cascade%incoming = .true.
cascade%bincode = ibset (0_TC, pos-1)
cascade%flv = flv%anti ()
cascade%pdg = cascade%flv%get_pdg ()
cascade%is_vector = flv%get_spin_type () == VECTOR
cascade%m_min = flv%get_mass ()
cascade%m_rea = cascade%m_min
if (cascade%m_rea >= m_thr) then
    cascade%m_eff = cascade%m_rea
end if
cascade%on_shell = .true.
cascade%n_t_channel = 0
cascade%n_off_shell = 0
cascade%tree(1) = cascade%bincode
cascade%tree_pdg(1) = cascade%pdg
cascade%tree_mapping(1) = EXTERNAL_PRT
cascade%tree_resonant(1) = .false.
end subroutine cascade_init_incoming

```

#### 19.9.4 Tools

This function returns true if the two cascades share no common external particle. This is a requirement for joining them.

```

<Cascades: interfaces>≡
interface operator(.disjunct.)
    module procedure cascade_disjunct
end interface

<Cascades: procedures>+≡
function cascade_disjunct (cascade1, cascade2) result (flag)
    logical :: flag
    type(cascade_t), intent(in) :: cascade1, cascade2
    flag = iand (cascade1%bincode, cascade2%bincode) == 0
end function cascade_disjunct

```

Compute a hash code for the resonance pattern of a cascade. We count the number of times each particle appears as a resonance.

We pack the PDG codes of the resonances in two arrays (s-channel and t-channel), sort them both, concatenate the results, transfer to i8 integers, and compute the hash code from this byte stream.

For t/u-channel, we remove the sign for antiparticles since this is not well-defined.

```

<Cascades: procedures>+≡
subroutine cascade_assign_resonance_hash (cascade)
    type(cascade_t), intent(inout) :: cascade
    integer(i8), dimension(1) :: mold
    cascade%res_hash = hash (transfer &

```

```

        ([sort (pack (cascade%tree_pdg, &
                    cascade%tree_resonant)), &
         sort (pack (abs (cascade%tree_pdg), &
                    cascade%tree_mapping == T_CHANNEL .or. &
                    cascade%tree_mapping == U_CHANNEL))), &
        mold))
end subroutine cascade_assign_resonance_hash

```

### 19.9.5 Hash entries for cascades

We will set up a hash array which contains keys of and pointers to cascades. We hold a list of cascade (pointers) within each bucket. This is not for collision resolution, but for keeping similar, but unequal cascades together.

```

<Cascades: types>+≡
  type :: cascade_p
    type(cascade_t), pointer :: cascade => null ()
    type(cascade_p), pointer :: next => null ()
  end type cascade_p

```

Here is the bucket or hash entry type:

```

<Cascades: types>+≡
  type :: hash_entry_t
    integer(i32) :: hashval = 0
    integer(i8), dimension(:), allocatable :: key
    type(cascade_p), pointer :: first => null ()
    type(cascade_p), pointer :: last => null ()
  end type hash_entry_t

```

```

<Cascades: public>≡
  public :: hash_entry_init

```

```

<Cascades: procedures>+≡
  subroutine hash_entry_init (entry, entry_in)
    type(hash_entry_t), intent(out) :: entry
    type(hash_entry_t), intent(in) :: entry_in
    type(cascade_p), pointer :: casc_iter, casc_copy
    entry%hashval = entry_in%hashval
    entry%key = entry_in%key
    casc_iter => entry_in%first
    do while (associated (casc_iter))
      allocate (casc_copy)
      casc_copy = casc_iter
      casc_copy%next => null ()
      if (associated (entry%first)) then

    end if
    hash_entry%last => current
end subroutine hash_entry_add_cascade_ptr

```

This function checks whether a cascade is already in the bucket. For incomplete cascades, we look for an exact match. It should suffice to verify the tree, the PDG codes, and the mapping modes. This is the information that is written to the phase space file.

For complete cascades, we ignore the PDG code at positions with mappings infrared, collinear, or t/u-channel. Thus a cascade which is distinguished only by PDG code at such places, is flagged existent. If the convention is followed that light particles come before heavier ones (in the model definition), this ensures that the lightest particle is kept in the appropriate place, corresponding to the strongest peak.

For external cascades (incoming/outgoing) we take the PDG code into account even though it is zeroed in the PDG-code tree.

```

```

### 19.9.6 The cascade set

The cascade set will later be transformed into the decay forest. It is set up as a linked list. In addition to the usual **first** and **last** pointers, there is a **first\_t** pointer which points to the first t-channel cascade (after all s-channel cascades), and a **first\_k** pointer which points to the first final cascade (with a keystone).

As an auxiliary device, the object contains a hash array with associated parameters where an additional pointer is stored for each cascade. The keys are made from the relevant cascade data. This hash is used for fast detection (and thus avoidance) of double entries in the cascade list.

```

### 19.9.7 Adding cascades

Add a deep copy of a cascade to the set. The copy has all content of the original, but the pointers are nullified. We do not care whether insertion was successful or not. The pointer argument, if present, is assigned to the input cascade, or to the hash entry if it is already present.

The procedure is recursive: any daughter or mother entries are also deep-copied and added to the cascade set before the current copy is added.

*(Cascades: procedures)+≡*

```

recursive subroutine cascade_set_add_copy &
  (cascade_set, cascade_in, cascade_ptr)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in) :: cascade_in
  type(cascade_t), optional, pointer :: cascade_ptr
  type(cascade_t), pointer :: cascade
  logical :: ok
  allocate (cascade)
  cascade = cascade_in
  if (associated (cascade_in%daughter1)) call cascade_set_add_copy &
    (cascade_set, cascade_in%daughter1, cascade%daughter1)
  if (associated (cascade_in%daughter2)) call cascade_set_add_copy &
    (cascade_set, cascade_in%daughter2, cascade%daughter2)
  if (associated (cascade_in%mother)) call cascade_set_add_copy &
    (cascade_set, cascade_in%mother, cascade%mother)
  cascade%next => null ()
  call cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
  if (.not. ok) deallocate (cascade)
end subroutine cascade_set_add_copy

```

Add a cascade to the set. This does not deep-copy. We first try to insert it in the hash array. If successful, add it to the list. Failure indicates that it is already present, and we drop it.

The hash key is built solely from the tree array, so neither particle codes nor resonances count, just topology.

Technically, hash and list receive only pointers, so the cascade can be considered as being in either of both. We treat it as part of the list.

*(Cascades: procedures)+≡*

```

subroutine cascade_set_add (cascade_set, cascade, ok, cascade_ptr)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in), target :: cascade
  logical, intent(out) :: ok
  type(cascade_t), optional, pointer :: cascade_ptr

```

```

integer(i8), dimension(1) :: mold
call cascade_set_hash_insert &
    (cascade_set, transfer (cascade%tree, mold), cascade, ok, cascade_ptr)
if (ok) call cascade_set_list_add (cascade_set, cascade)
end subroutine cascade_set_add

```

Add a new cascade to the list:

```

<Cascades: procedures>+=
subroutine cascade_set_list_add (cascade_set, cascade)
type(cascade_set_t), intent(inout) :: cascade_set
type(cascade_t), intent(in), target :: cascade
if (associated (cascade_set%last)) then
    cascade_set%last%next => cascade
else
    cascade_set%first => cascade
end if
cascade_set%last => cascade
end subroutine cascade_set_list_add

```

Add a cascade entry to the hash array:

```

<Cascades: procedures>+=
subroutine cascade_set_hash_insert &
    (cascade_set, key, cascade, ok, cascade_ptr)
type(cascade_set_t), intent(inout), target :: cascade_set
integer(i8), dimension(:), intent(in) :: key
type(cascade_t), intent(in), target :: cascade
logical, intent(out) :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i32) :: h
if (cascade_set%n_entries >= cascade_set%n_entries_max) &
    call cascade_set_hash_expand (cascade_set)
h = hash (key)
call cascade_set_hash_insert_rec &
    (cascade_set, h, h, key, cascade, ok, cascade_ptr)
end subroutine cascade_set_hash_insert

```

Double the hashtable size when necessary:

```

<Cascades: procedures>+=
subroutine cascade_set_hash_expand (cascade_set)
type(cascade_set_t), intent(inout), target :: cascade_set
type(hash_entry_t), dimension(:), allocatable, target :: table_tmp
type(cascade_p), pointer :: current
integer :: i, s
allocate (table_tmp (0:cascade_set%mask))
table_tmp = cascade_set%entry
deallocate (cascade_set%entry)
s = 2 * size (table_tmp)
cascade_set%n_entries = 0
cascade_set%n_entries_max = s * cascade_set%fill_ratio
cascade_set%mask = s - 1
allocate (cascade_set%entry (0:cascade_set%mask))
do i = 0, ubound (table_tmp, 1)

```

```

        current => table_tmp(i)%first
    do while (associated (current))
        call cascade_set_hash_insert_rec &
            (cascade_set, table_tmp(i)%hashval, table_tmp(i)%hashval, &
             table_tmp(i)%key, current%cascade)
        current => current%next
    end do
end do
end subroutine cascade_set_hash_expand

```

Insert the cascade at the bucket determined by the hash value. If the bucket is filled, check first for a collision (unequal keys). In that case, choose the following bucket and repeat. Otherwise, add the cascade to the bucket.

If the bucket is empty, record the hash value, allocate and store the key, and then add the cascade to the bucket.

If ok is present, before insertion we check whether the cascade is already stored, and return failure if yes.

(*Cascades: procedures*) +=

```

recursive subroutine cascade_set_hash_insert_rec &
    (cascade_set, h, hashval, key, cascade, ok, cascade_ptr)
type(cascade_set_t), intent(inout) :: cascade_set
integer(i32), intent(in) :: h, hashval
integer(i8), dimension(:), intent(in) :: key
type(cascade_t), intent(in), target :: cascade
logical, intent(out), optional :: ok
type(cascade_t), optional, pointer :: cascade_ptr
integer(i32) :: i
i = iand (h, cascade_set%mask)
if (allocated (cascade_set%entry(i)%key)) then
    if (size (cascade_set%entry(i)%key) /= size (key)) then
        call cascade_set_hash_insert_rec &
            (cascade_set, h + 1, hashval, key, cascade, ok, cascade_ptr)
    else if (any (cascade_set%entry(i)%key /= key)) then
        call cascade_set_hash_insert_rec &
            (cascade_set, h + 1, hashval, key, cascade, ok, cascade_ptr)
    else
        call hash_entry_add_cascade_ptr &
            (cascade_set%entry(i), cascade, ok, cascade_ptr)
    end if
else
    cascade_set%entry(i)%hashval = hashval
    allocate (cascade_set%entry(i)%key (size (key)))
    cascade_set%entry(i)%key = key
    call hash_entry_add_cascade_ptr &
        (cascade_set%entry(i), cascade, ok, cascade_ptr)
    cascade_set%n_entries = cascade_set%n_entries + 1
end if
end subroutine cascade_set_hash_insert_rec

```

### 19.9.8 External particles

We want to initialize the cascade set with the outgoing particles. In case of multiple processes, initial cascades are prepared for all of them. The hash array check ensures that no particle appears more than once at the same place.

```
(Cascades: interfaces) +=  
    interface cascade_set_add_outgoing  
        module procedure cascade_set_add_outgoing1  
        module procedure cascade_set_add_outgoing2  
    end interface  
  
(Cascades: procedures) +=  
    subroutine cascade_set_add_outgoing2 (cascade_set, flv)  
        type(cascade_set_t), intent(inout), target :: cascade_set  
        type(flavor_t), dimension(:,:), intent(in) :: flv  
        integer :: pos, prc, n_out, n_prc  
        type(cascade_t), pointer :: cascade  
        logical :: ok  
        n_out = size (flv, dim=1)  
        n_prc = size (flv, dim=2)  
        do prc = 1, n_prc  
            do pos = 1, n_out  
                allocate (cascade)  
                call cascade_init_outgoing &  
                    (cascade, flv(pos,prc), pos, cascade_set%m_threshold_s)  
                call cascade_set_add (cascade_set, cascade, ok)  
                if (.not. ok) then  
                    deallocate (cascade)  
                end if  
            end do  
        end do  
    end subroutine cascade_set_add_outgoing2  
  
    subroutine cascade_set_add_outgoing1 (cascade_set, flv)  
        type(cascade_set_t), intent(inout), target :: cascade_set  
        type(flavor_t), dimension(:), intent(in) :: flv  
        integer :: pos, n_out  
        type(cascade_t), pointer :: cascade  
        logical :: ok  
        n_out = size (flv, dim=1)  
        do pos = 1, n_out  
            allocate (cascade)  
            call cascade_init_outgoing &  
                (cascade, flv(pos), pos, cascade_set%m_threshold_s)  
            call cascade_set_add (cascade_set, cascade, ok)  
            if (.not. ok) then  
                deallocate (cascade)  
            end if  
        end do  
    end subroutine cascade_set_add_outgoing1
```

The incoming particles are added one at a time. Nevertheless, we may have several processes which are looped over. At the first opportunity, we set the

pointer `first_t` in the cascade set which should point to the first t-channel cascade.

Return the indices of the first and last cascade generated.

        end if
    else
        deallocate (cascade)
    end if
end subroutine cascade_set_add_incoming0

```

### 19.9.9 Cascade combination I: flavor assignment

We have two disjunct cascades, now use the vertex table to determine the possible flavors of the combination cascade. For each possibility, try to generate a new cascade. The total cascade depth has to be one less than the limit, because this is reached by setting the keystone.

```

<Cascades: procedures>+=
subroutine cascade_match_pair (cascade_set, cascade1, cascade2, s_channel)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(cascade_t), intent(in), target :: cascade1, cascade2
    logical, intent(in) :: s_channel
    integer, dimension(:), allocatable :: pdg3
    integer :: i, depth_max
    type(flavor_t) :: flv
    if (s_channel) then
        depth_max = cascade_set%depth_out
    else
        depth_max = cascade_set%depth_tot
    end if
    if (cascade1%depth + cascade2%depth < depth_max) then
        call cascade_set%model%match_vertex ( &
            cascade1%flv%get_pdg (), &
            cascade2%flv%get_pdg (), &
            pdg3)
        do i = 1, size (pdg3)
            call flv%init (pdg3(i), cascade_set%model)
            if (s_channel) then
                call cascade_combine_s (cascade_set, cascade1, cascade2, flv)
            else
                call cascade_combine_t (cascade_set, cascade1, cascade2, flv)
            end if
        end do
        deallocate (pdg3)
    end if
end subroutine cascade_match_pair

```

The triplet version takes a third cascade, and we check whether this triplet has a matching vertex in the database. If yes, we make a keystone cascade.

```

<Cascades: procedures>+=
subroutine cascade_match_triplet &
    (cascade_set, cascade1, cascade2, cascade3, s_channel)
    type(cascade_set_t), intent(inout), target :: cascade_set

```

```

type(cascade_t), intent(in), target :: cascade1, cascade2, cascade3
logical, intent(in) :: s_channel
integer :: depth_max
depth_max = cascade_set%depth_tot
if (cascade1%depth + cascade2%depth + cascade3%depth == depth_max) then
  if (cascade_set%model%check_vertex ( &
    cascade1%flv%get_pdg (), &
    cascade2%flv%get_pdg (), &
    cascade3%flv%get_pdg ())) then
    call cascade_combine_keystone &
      (cascade_set, cascade1, cascade2, cascade3, s_channel)
  end if
end if
end subroutine cascade_match_triplet

```

### 19.9.10 Cascade combination II: kinematics setup and check

Having three matching flavors, we start constructing the combination cascade. We look at the mass hierarchies and determine whether the cascade is to be kept. In passing we set mapping modes, resonance properties and such.

If successful, the cascade is finalized. For a resonant cascade, we prepare in addition a copy without the resonance.

```

(Cascades: procedures)+≡
subroutine cascade_combine_s (cascade_set, cascade1, cascade2, flv)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), intent(in), target :: cascade1, cascade2
  type(flavor_t), intent(in) :: flv
  type(cascade_t), pointer :: cascade3, cascade4
  logical :: keep
  keep = .false.
  allocate (cascade3)
  call cascade_init (cascade3, cascade1%depth + cascade2%depth + 1)
  cascade3%bincode = ior (cascade1%bincode, cascade2%bincode)

Here we complete a decay cascade. The third input is the single-particle cascade for the initial particle. There is no resonance or mapping assignment. The only condition for keeping the cascade is the mass sum of the final state, which must be less than the available energy.

Two modifications are necessary for scattering cascades: a pure s-channel diagram (cascade1 is the incoming particle) do not have a logarithmic mapping at top-level. And in a t-channel diagram, the last line exchanged is mapped t-channel, not u-channel. Finally, we can encounter the case of a  $2 \rightarrow 1$  process, where cascade1 is incoming, and cascade2 is the outgoing particle. In all three cases we register a new cascade with the modified mapping.

### 19.9.11 Cascade combination III: node connections and tree fusion

Here we assign global tree properties. If the allowed number of off-shell lines is exceeded, discard the new cascade. Otherwise, assign the trees, sort them, and assign connections. Finally, append the cascade to the list. This may fail (because in the hash array there is already an equivalent cascade). On failure, discard the cascade.

```

    resonant(i) = resonant_tmp (pos(1))
    tree_tmp(pos(1)) = 0
end do
end subroutine tree_sort

```

### 19.9.12 Cascade set generation

These procedures loop over cascades and build up the cascade set. After each iteration of the innermost loop, we set a breakpoint.

s-channel: We use a nested scan to combine all cascades with all other cascades.

```

(Cascades: procedures)+≡
subroutine cascade_set_generate_s (cascade_set)
    type(cascade_set_t), intent(inout), target :: cascade_set
    type(cascade_t), pointer :: cascade1, cascade2
    cascade1 => cascade_set%first
    LOOP1: do while (associated (cascade1))
        cascade2 => cascade_set%first
        LOOP2: do while (associated (cascade2))
            if (cascade2%index >= cascade1%index) exit LOOP2
            if (cascade1 .disjunct. cascade2) then
                call cascade_match_pair (cascade_set, cascade1, cascade2, .true.)
            end if
            call terminate_now_if_signal ()
            cascade2 => cascade2%next
        end do LOOP2
        cascade1 => cascade1%next
    end do LOOP1
end subroutine cascade_set_generate_s

```

The t-channel cascades are directed and have a seed (one of the incoming particles) and a target (the other one). We loop over all possible seeds and targets. Inside this, we loop over all t-channel cascades (*cascade1*) and s-channel cascades (*cascade2*) and try to combine them.

```

(Cascades: procedures)+≡
subroutine cascade_set_generate_t (cascade_set, pos_seed, pos_target)
    type(cascade_set_t), intent(inout), target :: cascade_set
    integer, intent(in) :: pos_seed, pos_target

```

```

end subroutine cascade_set_generate_scattering

```

### 19.9.13 Groves

Before assigning groves, assign hashcodes to the resonance patterns, so they can easily be compared.

*(Cascades: procedures)* +=

```

subroutine cascade_set_assign_resonance_hash (cascade_set)
  type(cascade_set_t), intent(inout) :: cascade_set
  type(cascade_t), pointer :: cascade
  cascade => cascade_set%first_k
  do while (associated (cascade))
    call cascade_assign_resonance_hash (cascade)
    cascade => cascade%next
  end do
end subroutine cascade_set_assign_resonance_hash

```

After all cascades are recorded, we group the complete cascades in groves. A grove consists of cascades with identical multiplicity, number of resonances, log-enhanced, t-channel lines, and resonance flavors.

*(Cascades: procedures)* +=

```

subroutine cascade_set_assign_groves (cascade_set)
  type(cascade_set_t), intent(inout), target :: cascade_set
  type(cascade_t), pointer :: cascade1, cascade2
  integer :: multiplicity
  integer :: n_resonances, n_log_enhanced, n_t_channel, n_off_shell
  integer :: res_hash
  integer :: grove
  grove = 0
  cascade1 => cascade_set%first_k
  do while (associated (cascade1))
    if (cascade1%active .and. cascade1%complete &
      .and. cascade1%grove == 0) then
      grove = grove + 1
      cascade1%grove = grove
    end if
    cascade1 => cascade1%next
  end do
end subroutine cascade_set_assign_groves

```

```

multiplicity = cascade1%multiplicity
n_resonances = cascade1%n_resonances
n_log_enhanced = cascade1%n_log_enhanced
n_off_shell = cascade1%n_off_shell
n_t_channel = cascade1%n_t_channel
res_hash = cascade1%res_hash
cascade2 => cascade1%next
do while (associated (cascade2))
  if (cascade2%grove == 0) then
    if (cascade2%multiplicity == multiplicity &
        .and. cascade2%n_resonances == n_resonances &
        .and. cascade2%n_log_enhanced == n_log_enhanced &
        .and. cascade2%n_off_shell == n_off_shell &
        .and. cascade2%n_t_channel == n_t_channel &
        .and. cascade2%res_hash == res_hash) then
      cascade2%grove = grove
    end if
  end if
  call terminate_now_if_signal ()
  cascade2 => cascade2%next
end do
end if
call terminate_now_if_signal ()
cascade1 => cascade1%next
end do
cascade_set%n_groves = grove
end subroutine cascade_set_assign_groves

```

#### 19.9.14 Generate the phase space file

Generate a complete phase space configuration.

For each flavor assignment: First, all s-channel graphs that can be built up from the outgoing particles. Then we distinguish (1) decay, where we complete the s-channel graphs by connecting to the input line, and (2) scattering, where we now generate t-channel graphs by introducing an incoming particle, and complete this by connecting to the other incoming particle.

After all cascade sets have been generated, merge them into a common set. This eliminates redundancies between flavor assignments.

```

<Cascades: public>+≡
  public :: cascade_set_generate

<Cascades: procedures>+≡
  subroutine cascade_set_generate &
    (cascade_set, model, n_in, n_out, flv, phs_par, fatal_beam_decay)
    type(cascade_set_t), intent(out) :: cascade_set
    class(model_data_t), intent(in), target :: model
    integer, intent(in) :: n_in, n_out
    type(flavor_t), dimension(:,:), intent(in) :: flv
    type(phs_parameters_t), intent(in) :: phs_par
    logical, intent(in) :: fatal_beam_decay
    type(cascade_set_t), dimension(:), allocatable :: cset
    type(cascade_t), pointer :: cascade

```

```

integer :: i
if (phase_space_vanishes (phs_par%sqrts, n_in, flv)) return
call cascade_set_init (cascade_set, model, n_in, n_out, phs_par, &
    fatal_beam_decay, flv)
allocate (cset (size (flv, 2)))
do i = 1, size (cset)
    call cascade_set_generate_single (cset(i), &
        model, n_in, n_out, flv(:,i), phs_par, fatal_beam_decay)
    cascade => cset(i)%first_k
    do while (associated (cascade))
        if (cascade%active .and. cascade%complete) then
            call cascade_set_add_copy (cascade_set, cascade)
        end if
        cascade => cascade%next
    end do
    call cascade_set_final (cset(i))
end do
cascade_set%first_k => cascade_set%first
call cascade_set_assign_resonance_hash (cascade_set)
call cascade_set_assign_groves (cascade_set)
end subroutine cascade_set_generate

```

This generates phase space for a single channel, without assigning groves.

*(Cascades: procedures)+≡*

```

## 19.10 WOOD phase space

This is the module that interfaces the `phs_forests` phase-space treatment and the `cascades` module for generating phase-space channels. As an extension of the `phs_base` abstract type, the phase-space configuration and instance implement the standard API.

(Currently, this is the only generic phase-space implementation of WHIZARD. For trivial two-particle phase space, there is `phs_wood` as an alternative.)

```

<phs_wood.f90>≡
  <File header>

  module phs_wood

    <Use kinds>
    <Use strings>
    use io_units
    use constants
    use numeric_utils
    use diagnostics
    use os_interface
    use md5
    use physics_defs
    use lorentz
    use model_data
    use flavors
    use process_constants
    use sf_mappings
    use sf_base
    use phs_base
    use mappings
    use resonances, only: resonance_history_set_t
    use phs_forests
    use cascades
    use cascades2

    <Standard module head>

    <PHS wood: public>

    <PHS wood: types>

    contains

    <PHS wood: procedures>

  end module phs_wood

```

### 19.10.1 Configuration

```

### 19.10.3 Phase-space configuration

We read the phase-space configuration from the stored I/O unit. If this is not set, we assume that we have to generate a phase space configuration. When done, we open a scratch file and write the configuration.

If `rebuild` is set, we should trash any existing phase space file and build a new one. Otherwise, we try to use an old one, which we check for existence and integrity. If `ignore_mismatch` is set, we reuse an existing file even if it does not match the current setup.

```

```

The MD5 sum of the forest is computed in addition to the MD5 sum of the configuration. The reason is that the forest may depend on a user-provided external file. On the other hand, this MD5 sum encodes all information that is relevant for further processing. Therefore, the `get_md5sum` method returns this result, once it is available.

```

Create filenames according to standard conventions. The `id` is the process name including the suffix `_iX` where `X` stands for the component identifier (an integer). The `run_id` may be set or unset.

The convention for file names that include the run ID is to separate prefix, run ID, and any extensions by dots. We construct the file name by concatenating the individual elements accordingly. If there is no run ID, we nevertheless replace `_iX` by `.iX`.

      end if
    end select
  end subroutine phs_wood_init

```

### 19.10.5 Evaluation

We compute the outgoing momenta from the incoming momenta and the input parameter set `r_in` in channel `r_in`. We also compute the `r` parameters and Jacobians `f` for all other channels.

We do *not* need to apply a transformation from/to the c.m. frame, because in `phs_base` the momenta are already boosted to the c.m. frame before assigning them in the `phs` object, and inversely boosted when extracting them.

```

<PHS wood: phs wood: TBP>+≡

```

The boost to the center-of-mass system only has a reasonable meaning above the threshold. Below the threshold, we do not apply boost at all, so that the top quarks stay in the rest frame. However, with top quarks exactly at rest, problems arise in the matrix elements (e.g. in the computation of angles). Therefore, we apply a boost which is not exactly 1, but has a tiny value differing from that.

Very soft or collinear phase-space points can become a problem for matrix elements providers, as some scalar products cannot be evaluated properly. Here, a nonsensical result can spoil the whole integration. We therefore check the scalar products appearing to be below a certain tolerance.

Naturally, this happens very rarely but for some processes, setting `?test_coll_limit = true` and/or `?test_soft_limit = true` leads to all phase space points being discarded by this routine.

The fks phase space type contains the wood phase space and separately the in- and outgoing momenta for the real process and the corresponding Born momenta. Additionally, there are the variables  $\xi, \xi_{max}, y$  and  $\phi$  which are used to create the real phase space, as well as the jacobian and its corresponding soft and collinear limit. Lastly, the array `ch_to_em` connects each channel with an emitter.

### 19.11.1 Creation of the real phase space - FSR

At this point, the Born phase space has been generated, as well as the three random variables  $\xi$ ,  $y$  and  $\phi$ . The question is how the real phase space is generated for a final-state emission configuration. We work with two different sets of momenta, the Born configuration  $\{\bar{k}_\oplus, \bar{k}_\ominus, \bar{k}_1, \dots, \bar{k}_n\}$  and the real configuration  $\{k_\oplus, k_\ominus, k_1, \dots, k_n, k_{n+1}\}$ . We define the momentum of the emitter to be on the  $n$ -th position and the momentum of the radiated particle to be at position  $n+1$ . The magnitude of the spatial component of  $\mathbf{k}$  is denoted by  $\underline{k}$ .

For final-state emissions, it is  $\bar{k}_\oplus = k_\oplus$  and  $\bar{k}_\ominus = k_\ominus$ . Thus, the center-of-mass systems coincide and it is

$$q = \sum_{i=1}^n \bar{k}_i = \sum_{i=1}^{n+1} k_i, \quad (19.65)$$

with  $\vec{q} = 0$  and  $q^2 = (q^0)^2$ .

We want to construct the real phase space from the Born phase space using three random numbers. They are defined as follows:

- $\xi = \frac{2k_{n+1}^0}{\sqrt{s}} \in [0, \xi_{max}]$ , where  $k_{n+1}$  denotes the four-momentum of the radiated particle.
- $y = \cos \theta = \frac{\vec{k}_n \cdot \vec{k}_{n+1}}{\underline{k}_n \underline{k}_{n+1}}$  is the splitting angle.
- The angle between the two splitting particles in the transversal plane,  $\phi \in [0, 2\pi]$ .

Further,  $k_{rec} = \sum_{i=1}^{n-1} k_i$  denotes the sum of all recoiling momenta.

Construction of the recoiling momenta. The reshuffling of momenta must not change the invariant mass of the recoiling system, which means  $k_{\text{rec}}^2 = \bar{k}_{\text{rec}}^{-2}$ . Therefore, the momenta are related by a boost,  $\bar{k}_i = \Lambda k_i$ . The boost parameter is

$$\beta = \frac{q^2 - (k_{\text{rec}}^0 + \bar{k}_{\text{rec}})^2}{q^2 + (k_{\text{rec}}^0 + \bar{k}_{\text{rec}})^2}$$

```

The momentum of the radiated particle is computed according to

$$\underline{k}_n = \frac{q^2 - M_{\text{rec}}^2 - 2q^0 \underline{k}_{n+1}}{2(q^0 - \underline{k}_{n+1}(1 - y))}, \quad (19.66)$$

with  $k = k_n + k_{n+1}$  and  $M_{\text{rec}}^2 = k_{\text{rec}}^2 = (q - k)^2$ . Because of  $\bar{\mathbf{k}}_n \parallel \mathbf{k}_n + \mathbf{k}_{n+1}$  we find  $M_{\text{rec}}^2 = (q - \bar{k}_n)^2$ . Equation 19.66 follows from the fact that  $(\mathbf{k} - \mathbf{k}_n)^2 = \mathbf{k}_{n+1}^2$ , which is equivalent to  $\mathbf{k}_n \cdot \mathbf{k} = \frac{1}{2}(\underline{k}_n^2 + \underline{k}^2 - \underline{k}_{n+1}^2)$ .  $\mathbf{k}_n$  and  $\mathbf{k}_{n+1}$  are obtained by first setting up vectors parallel to  $\bar{\mathbf{k}}_n$ ,

$$\mathbf{k}'_n = \underline{k}_n \frac{\bar{\mathbf{k}}_n}{\bar{k}_n}, \quad \mathbf{k}'_{n+1} = \underline{k}_{n+1} \frac{\bar{\mathbf{k}}_n}{\bar{k}_n},$$

and then rotating these vectors by an amount of  $\cos \psi_n = \frac{\mathbf{k}_n \cdot \mathbf{k}}{\bar{k}_n \bar{k}}$ . The emitted particle cannot have more momentum than the emitter has in the Born phase space. Thus, there is an upper bound for  $\xi$ , determined by the condition  $k_{n+1}^0 = \bar{k}_n$ , which is equal to

$$\xi_{\text{max}} = \frac{2}{\bar{k}_n} q^0.$$

```

The computation of  $\xi_{\max}$  for massive emitters is described in arXiv:1202.0465. Let's recapitulate it here.

We consider the Dalitz-domain created by  $k_{n+1}^0$ ,  $k_n^0$  and  $k_{\text{rec}}^0$  and introduce the parameterization

$$k_n^0 = \bar{k}_n^0 - z k_{n+1}^0$$

Then, for each value of  $z$ , there exists a maximum value of  $\underline{k}_{n+1}$  from which  $\xi_{\max}$  can be extracted via  $\xi_{\max} = 2k_{n+1}^0/q$ . It is determined by the condition

$$\underline{k}_{n+1} \pm \underline{k}_n \pm \underline{k}_{\text{rec}} = 0.$$

This can be manipulated to yield

$$(\underline{k}_{n+1}^2 + \underline{k}_n^2 - \underline{k}_{\text{rec}}^2)^2 = 4\underline{k}_{n+1}^2 \underline{k}_n^2.$$

Here we can use  $\underline{k}_n^2 = (k_n^0)^2 - m^2$  and  $\underline{k}_{\text{rec}}^2 = (q - k_n^0 - k_{n+1}^0)^2 - M_{\text{rec}}^2$ , as well as the above parameterization of  $k_n^0$ , to obtain

$$4\underline{k}_{n+1}^2 (2\underline{k}_{n+1} q z (1 - z) + q^2 z^2 - 2q \bar{k}_{\text{rec}}^0 z + M_{\text{rec}}^2) = 0.$$

Solving for  $k_{n+1}^0$  gives

$$k_{n+1}^0 = \frac{2q \bar{k}_{\text{rec}}^0 z - q^2 z^2 - M_{\text{rec}}^2}{2q z (1 - z)}. \quad (19.67)$$

It is still open how to compute  $z$ . For this, consider that the right-hand-side of equation (19.67) vanishes for

$$z_{1,2} = \left( \bar{k}_{\text{rec}}^0 \pm \sqrt{(\bar{k}_{\text{rec}}^0)^2 - M_{\text{rec}}^2} \right) / q,$$

which corresponds to the borders of the Dalitz-region where the gluon momentum vanishes. Thus we define

$$z = z_2 - \frac{1}{2}(z_2 - z_1)(1 + y).$$

The real phase space for an initial-state emission involved in a decay process is generated by first setting the gluon momentum like in the scattering case by using its angular coordinates  $y$  and  $\phi$  and then adjusting the gluon energy with  $\xi$ . The emitter momentum is kept identical to the Born case, i.e.  $p_{\text{in}} = \bar{p}_{\text{in}}$ , so that after the emission it has momentum  $p_{\text{virt}} = p_{\text{in}} - p_g$  and invariant mass  $m^2 = p_{\text{virt}}^2$ . Note that the final state momenta have to remain on-shell, so that  $p_1^2 = \bar{p}_1^2 = m_1^2$  and  $p_2^2 = \bar{p}_2^2 = m_2^2$ . Let  $\Lambda$  be the boost from into the rest frame of the emitter after emission, i.e.  $\Lambda p_{\text{virt}} = (m, 0, 0, 0)$ . In this reference frame, the spatial components of the final-state momenta sum up to zero, and their magnitude is

$$p = \frac{\sqrt{\lambda(m^2, m_1^2, m_2^2)}}{2m},$$

a fact already used in the evaluation of the phase space trees of `phs_forest`. Obviously, from this, the final-state energies can be deferred via  $E_i^2 = m_i^2 - p^2$ . In the next step, the  $p_{1,2}$  are set up as vectors  $(E, 0, 0, \pm p)$  along the z-axis and then rotated about the same azimuthal and polar angles as in the Born system. Finally, the momenta are boosted out of the rest frame by multiplying with  $\Lambda$ .

Construction of the real momenta `p_real` in case of ISR. Follows the discussion in [0709.2092] sec. 5.1. The sequence of Lorentz boosts required to construct `p_real` from `p_born` is as follows:

- We construct the IS momenta of `p_real` from the Born momenta via rescaling:  $\mathbf{p\_real}(1:2) = \frac{x}{\bar{x}} \cdot \mathbf{p\_born}(1:2)$ . If the Born momenta are imported in the lab frame, these will define the real lab frame.
- We construct the momentum of the radiated particle in the real CMS:  $k_{n+1} = \frac{s\xi}{2} \cdot (1, \sin(\theta) \sin(\phi), \sin(\theta) \cos(\phi), \cos(\theta))$
- 0. We first boost the momentum of the radiated particle from the real CMS to the real lab frame determined from `p_real(1:2)`.
- 1. We initialize the non-radiated real FS momenta by a longitudinal boost of `p_born` to a system with zero rapidity, i.e. zero longitudinal momentum. This is  $\mathbb{B}_L$ .
- 2. We boost these momenta in a transverse direction to compensate the transverse momentum of the radiation. This is  $\mathbb{B}_T$ . Note: we switched  $\mathbb{B}_T$  and  $\mathbb{B}_T^{-1}$  in Eq. (5.16) and their definition w.r.t. [0709.2092].
- 3. We restore longitudinal momentum conservation by applying the inverse boost of  $\mathbb{B}_L$  to all non-radiated real FS momenta.

This way, all components of `p_real` are constructed in the real Lab frame.

```

Configure channel mappings, using some conditions from the phase space configuration. If there are no structure functions, we enable a default setup with a single (dummy) structure-function channel. Otherwise, we look at the channel collection that we got from the phase-space configuration step. Each entry should be translated into an independent structure-function channel, where typically there is one default entry, which could be mapped using a standard s-channel mapping if the structure function setup recommends this, and other entries with s-channel resonances. The latter need to be translated into global mappings from the structure-function chain.

## 19.13 A lexer for O'Mega's phase-space output

This module provides three data types. One of them is the type `dag_string_t` which should contain the information of all Feynman diagrams in the factorized form which is provided by O'Mega in its phase-space output. This output is translated into a string of tokens (in the form of an array of the type `dag_token_t`) which have a certain meaning. The purpose of this module is only to identify these tokens correctly and to provide some procedures and interfaces which allow us to use these strings in a similar way as variables of the basic character type or the type `iso_varying_string`. Both `character` and `iso_varying_string` have some disadvantages at least if one wants to keep support for some older compiler versions. These can be circumvented by the `dag_string_t` type. Finally the `dag_chain_t` type is used to create a larger string in several steps without always recreating the string, which is done in the form of a simple linked list. In the end one can create a single `dag_string` out of this list, which is more useful.

```

(cascades2_lexer.f90)≡
  <File header>

```

```

module cascades2_lexer

  <Use kinds>
    use kinds, only: TC, i8

  <Standard module head>

  <Cascades2 lexer: public>

  <Cascades2 lexer: parameters>

  <Cascades2 lexer: types>

  <Cascades2 lexer: interfaces>

  contains

  <Cascades2 lexer: procedures>

end module cascades2_lexer

```

This is the token type. By default the variable `type` is `EMPTY_TK` but can obtain other values corresponding to the parameters defined below. The type of the token corresponds to a particular sequence of characters. When the token corresponds to a node of a tree, i.e. some particle in the Feynman diagram, the type is `NODE_TK` and the `particle_name` variable is holding the name of the particle. O'Megas output contains in addition to the particle name some numbers which indicate the external momenta that are flowing through this line. These numbers are translated into a binary code and saved in the variable `bincode`. In this case the number 1 corresponds to a bit set at position 0, 2 corresponds to a bit set at position 1, etc. Instead of numbers which are composed out of several digits, letters are used, i.e. A instead of 10 (bit at position 9), B instead of 11 (bit at position 10), etc.

When the DAG is reconstructed from a `dag_string` which was built from O'Mega's output, this string is modified such that a substring (a set of tokens) is replaced by a single token where the type variable is one of the three parameters `DAG_NODE_TK`, `DAG_OPTIONS_TK` and `DAG_COMBINATION_TK`. These parameters correspond to the three types `dag_node_t`, `dag_options_t` and `dag_combination_t` (see `cascades2` for more information. In this case, since these objects are organized in arrays, the `index` variable holds the corresponding position in the array.

In any case, we want to be able to reproduce the character string from which a token (or a string) has been created. The variable `char_len` is the length of this string. For tokens with the type `DAG_NODE_TK`, `DAG_OPTIONS_TK` and `DAG_COMBINATION_TK` we use output of the form `<N23>`, `<O23>` or `<C23>` which is useful for debugging the parser. Here 23 is the `index` and N, O or C obviously corresponds to the `type`.

```

<Cascades2 lexer: parameters>≡
  integer, parameter :: PRT_NAME_LEN = 20
<Cascades2 lexer: public>≡

```

```

    public :: dag_token_t
  <Cascades2 lexer: types>≡
    type :: dag_token_t
      integer :: type = EMPTY_TK
      integer :: char_len = 0
      integer(TC) :: bincode = 0
      character (PRT_NAME_LEN) :: particle_name=""
      integer :: index = 0
    contains
      <Cascades2 lexer: dag token: TBP>
    end type dag_token_t

```

This is the string type. It also holds the number of characters in the corresponding character string. It contains an array of tokens. If the `dag_string` is constructed using the type `dag_chain_t`, which creates a linked list, we also need the pointer `next`.

```

  <Cascades2 lexer: public>+≡
    public :: dag_string_t
  <Cascades2 lexer: types>+≡
    type :: dag_string_t
      integer :: char_len = 0
      type (dag_token_t), dimension(:), allocatable :: t
      type (dag_string_t), pointer :: next => null ()
    contains
      <Cascades2 lexer: dag string: TBP>
    end type dag_string_t

```

This is the chain of `dag_strings`. It allows us to construct a large string by appending new strings to the linked list, which can later be merged to a single string. This is very useful because the file written by O'Mega contains large strings where each string contains all Feynman diagrams in a factorized form, but these large strings are cut into several pieces and distributed over many lines. As the file can become large, rewriting a new `dag_string` (or `iso_varying_string`) would consume more and more time with each additional line. For recreating a single `dag_string` out of this chain, we need the total character length and the sum of all sizes of the `dag_token` arrays `t`.

```

  <Cascades2 lexer: public>+≡
    public :: dag_chain_t
  <Cascades2 lexer: types>+≡
    type :: dag_chain_t
      integer :: char_len = 0
      integer :: t_size = 0
      type (dag_string_t), pointer :: first => null ()
      type (dag_string_t), pointer :: last => null ()
    contains
      <Cascades2 lexer: dag chain: TBP>
    end type dag_chain_t

```

We define two parameters holding the characters corresponding to a backslash and a blanc space.

```
<Cascades2 lexer: parameters>+≡
    character(len=1), parameter, public :: BACKSLASH_CHAR = "\\"
    character(len=1), parameter :: BLANC_CHAR = " "
```

These are the parameters which correspond to meaningful types of token.

```
<Cascades2 lexer: parameters>+≡
    integer, parameter, public :: NEW_LINE_TK = -2
    integer, parameter :: BLANC_SPACE_TK = -1
    integer, parameter :: EMPTY_TK = 0
    integer, parameter, public :: NODE_TK = 1
    integer, parameter, public :: DAG_NODE_TK = 2
    integer, parameter, public :: DAG_OPTIONS_TK = 3
    integer, parameter, public :: DAG_COMBINATION_TK = 4
    integer, parameter, public :: COLON_TK = 11
    integer, parameter, public :: COMMA_TK = 12
    integer, parameter, public :: VERTICAL_BAR_TK = 13
    integer, parameter, public :: OPEN_PAR_TK = 21
    integer, parameter, public :: CLOSED_PAR_TK = 22
    integer, parameter, public :: OPEN_CURLY_TK = 31
    integer, parameter, public :: CLOSED_CURLY_TK = 32
```

Different sorts of assignment. This contains the conversion of a character variable into a dag\_token or dag\_string.

```

Compare strings/tokens/characters. Each character is relevant, including all blanc spaces. An exception is the **newline** character which is not treated by the types used in this module (not to confused with the type parameter **NEW\_LINE\_TK** which corresponds to the backslash character and simply tells us that the string continues on the next line in the file).

## 19.14 An alternative cascades module

This module might replace the module `cascades`, which generates suitable phase space parametrizations and generates the phase space file. The mappings, as well as the criteria to determine these, do not change.

The advantage of this module is that it makes use of the `O'Mega` matrix element generator which provides the relevant Feynman diagrams (the ones which can be constructed only from 3-vertices). In principle, the construction of these diagrams is also one of the tasks of the existing `cascades` module, in which the diagrams would correspond to a set of cascades. It starts by creating cascades which correspond to the outgoing particles. These are combined to a new cascade using the vertices of the model. In this way, since each cascade knows the daughter cascades from which it is built, complete Feynman diagrams are represented by sets of cascades, as soon as the existing cascades can be recombined with the incoming particle(s).

In this module, the Feynman diagrams are represented by the type `feyngraph.t`, which represents the Feynman diagrams as a tree of nodes. The object which contains the necessary kinematical information to determine mappings, and hence sensible phase space parametrizations is of another type, called `kingraph.t`, which is built from a corresponding `feyngraph` object.

There are two types of output which can be produced by `O'Mega` and are potentially relevant here. The first type contains all tree diagrams for the process under consideration, where each line of the output corresponds to one Feynman diagram. This output is easy to read, but can be very large, depending on the number of particles involved in the process. Moreover, it repeats substructures of the diagrams which are part of more than one diagram. One could in principle work with this output and construct a `feyngraph` from each line, if allowed, i.e. if there are only 3-vertices.

The other output contains also all of these Feynman diagrams, but in a factorized form. This means that the substructures which appear in several Feynman diagrams, are written only once, if possible. This leads to a much shorter input file, which speeds up the parsing process. Furthermore it makes it possible to reconstruct the `feyngraphs` in such a way that the calculations concerning subdiagrams which reappear in other `feyngraphs` have to be performed only once. This is already the case in the existing `cascades` module but can be exploited more efficiently here because the possible graphs are well known from the input file, whereas the `cascades` module would create a large number of `cascades` which do not lead to a complete Feynman diagram of the given process.

```
<cascades2.f90>≡

<Cascades2: parameters>

<Cascades2: types>

<Cascades2: interfaces>

contains

<Cascades2: procedures>

end module cascades2

```

### 19.14.1 Particle properties

We define a type holding the properties of the particles which are needed for parsing and finding the phase space parametrizations and mappings. The properties of all particles which appear in the parsed Feynman diagrams for the given process will be stored in a central place, and only pointers to these objects are used.

```

<Cascades2: types>≡
  type :: part_prop_t
    character (len=LABEL_LEN) :: particle_label
    integer :: pdg = 0
    real(default) :: mass = 0.
    real :: width = 0.
    integer :: spin_type = 0
    logical :: is_vector = .false.
    logical :: empty = .true.
    type (part_prop_t), pointer :: anti => null ()
    type (string_t) :: tex_name
  contains
  <Cascades2: part prop: TBP>
end type part_prop_t

```

The `particle_label` in `part_prop_t` is simply the particle name (e.g. 'W+'). The corresponding variable in the type `f_node_t` contains some additional infor-

mation related to the external momenta, see below. The length of the `character` variable is fixed as:

```

<Cascades2: parameters>≡
    integer, parameter :: LABEL_LEN=30

<Cascades2: part prop: TBP>≡
    procedure :: final => part_prop_final

<Cascades2: procedures>≡
    subroutine part_prop_final (part)
        class(part_prop_t), intent(inout) :: part
        part%anti => null ()
    end subroutine part_prop_final

```

### 19.14.2 The mapping modes

The possible mappings are essentially the same as in `cascades`, but we introduce in addition the mapping constant `NON_RESONANT`, which does not refer to a new mapping; it corresponds to the nonresonant version of a potentially resonant particle (or `k_node`). This becomes relevant when we compare `k_nodes` to eliminate equivalences.

```

<Cascades2: parameters>+≡
    integer, parameter :: &
        & NONRESONANT = -2, EXTERNAL_PRT = -1, &
        & NO_MAPPING = 0, S_CHANNEL = 1, T_CHANNEL = 2, U_CHANNEL = 3, &
        & RADIATION = 4, COLLINEAR = 5, INFRARED = 6, &
        & STEP_MAPPING_E = 11, STEP_MAPPING_H = 12, &
        & ON_SHELL = 99

```

### 19.14.3 Grove properties

The channels or `kingraphs` will be grouped in groves, i.e. sets of channels, which share some characteristic numbers. These numbers are stored in the following type:

```

<Cascades2: types>+≡
    type :: grove_prop_t
        integer :: multiplicity = 0
        integer :: n_resonances = 0
        integer :: n_log_enhanced = 0
        integer :: n_off_shell = 0
        integer :: n_t_channel = 0
        integer :: res_hash = 0
    end type grove_prop_t

```

### 19.14.4 The tree type

This type contains all the information which is needed to reconstruct a `feyngraph` or `kingraph`. We store bincodes, pdg codes and mappings for all nodes of a valid `kingraph`. If we label the external particles as given in the process definition with integer numbers representing their position in the process definition, the

bincode would be the number that one obtains by setting the bit at the position that is given by this number. If we combine two particles/nodes to a third one (using a three-vertex of the given model), the bincode is the number which one obtains by setting all the bits which are set for the two particles. The **pdg** and **mapping** are simply the pdg-code and mapping at the position (i.e. propagator or external particle) which is specified by the corresponding bincode. We use **tree\_t** not only for completed **kingraphs**, but also for all **k\_nodes**, which are a subtree of a **kingraph**.

```

<Cascades2: types>+≡
  type :: tree_t
    integer(TC), dimension(:), allocatable :: bc
    integer, dimension(:), allocatable :: pdg
    integer, dimension(:), allocatable :: mapping
    integer :: n_entries = 0
    logical :: keep = .true.
    logical :: empty = .true.
  contains
    <Cascades2: tree: TBP>
  end type tree_t

<Cascades2: tree: TBP>≡
  procedure :: final => tree_final

<Cascades2: procedures>+≡
  subroutine tree_final (tree)
    class (tree_t), intent (inout) :: tree
    if (allocated (tree%bc)) deallocate (tree%bc)
    if (allocated (tree%pdg)) deallocate (tree%pdg)
    if (allocated (tree%mapping)) deallocate (tree%mapping)
  end subroutine tree_final

<Cascades2: interfaces>≡
  interface assignment (=)
    module procedure tree_assign
  end interface assignment (=)

<Cascades2: procedures>+≡
  subroutine tree_assign (tree1, tree2)
    type (tree_t), intent (inout) :: tree1
    type (tree_t), intent (in) :: tree2
    if (allocated (tree2%bc)) then
      allocate (tree1%bc(size(tree2%bc)))
      tree1%bc = tree2%bc
    end if
    if (allocated (tree2%pdg)) then
      allocate (tree1%pdg(size(tree2%pdg)))
      tree1%pdg = tree2%pdg
    end if
    if (allocated (tree2%mapping)) then
      allocate (tree1%mapping(size(tree2%mapping)))
      tree1%mapping = tree2%mapping
    end if
    tree1%n_entries = tree2%n_entries

```

```

    tree1%keep = tree2%keep
    tree1%empty = tree2%empty
end subroutine tree_assign

```

### 19.14.5 Add entries to the tree

The following procedures fill the arrays in `tree_t` with entries resulting from the bincode and mapping assignment.

```

<Cascades2: tree: TBP>+≡
  procedure :: add_entry_from_numbers => tree_add_entry_from_numbers
  procedure :: add_entry_from_node => tree_add_entry_from_node
  generic :: add_entry => add_entry_from_numbers, add_entry_from_node

```

Here we add a single entry to each of the arrays. This will exclusively be used for external particles.

```

<Cascades2: procedures>+≡
  subroutine tree_add_entry_from_numbers (tree, bincode, pdg, mapping)
    class (tree_t), intent (inout) :: tree
    integer(TC), intent (in) :: bincode
    integer, intent (in) :: pdg
    integer, intent (in) :: mapping
    integer :: pos
    if (tree%empty) then
      allocate (tree%bc(1))
      allocate (tree%pdg(1))
      allocate (tree%mapping(1))
      pos = tree%n_entries + 1
      tree%bc(pos) = bincode
      tree%pdg(pos) = pdg
      tree%mapping(pos) = mapping
      tree%n_entries = pos
      tree%empty = .false.
    end if
  end subroutine tree_add_entry_from_numbers

```

Here we merge two existing subtrees and a single entry (bc, pdg and mapping).

```

<Cascades2: procedures>+≡
  subroutine tree_merge (tree, tree1, tree2, bc, pdg, mapping)
    class (tree_t), intent (inout) :: tree
    type (tree_t), intent (in) :: tree1, tree2
    integer(TC), intent (in) :: bc
    integer, intent (in) :: pdg, mapping
    integer :: tree_size
    integer :: i1, i2
    if (tree%empty) then
      i1 = tree1%n_entries
      i2 = tree1%n_entries + tree2%n_entries
      !! Proof: tree_size > 0 (always)
      tree_size = tree1%n_entries + tree2%n_entries + 1
      allocate (tree%bc (tree_size))
      allocate (tree%pdg (tree_size))
      allocate (tree%mapping (tree_size))
    end if
  end subroutine tree_merge

```

```

      if (.not. tree1%empty) then
        tree%bc(:i1) = tree1%bc
        tree%pdg(:i1) = tree1%pdg
        tree%mapping(:i1) = tree1%mapping
      end if
      if (.not. tree2%empty) then
        tree%bc(i1+1:i2) = tree2%bc
        tree%pdg(i1+1:i2) = tree2%pdg
        tree%mapping(i1+1:i2) = tree2%mapping
      end if
      tree%bc(tree_size) = bc
      tree%pdg(tree_size) = pdg
      tree%mapping(tree_size) = mapping
      tree%n_entries = tree_size
      tree%empty = .false.
    end if
  end subroutine tree_merge

```

Here we add entries to a tree for a given `k_node`, which means that we first have to determine whether the node is external or internal. The arrays are sorted after the entries have been added (see below for details).

```

<Cascades2: procedures>+≡
  subroutine tree_add_entry_from_node (tree, node)
    class (tree_t), intent (inout) :: tree
    type (k_node_t), intent (in) :: node
    integer :: pdg
    if (node%t_line) then
      pdg = abs (node%particle%pdg)
    else
      pdg = node%particle%pdg
    end if
    if (associated (node%daughter1) .and. &
        associated (node%daughter2)) then
      call tree_merge (tree, node%daughter1%subtree, &
        node%daughter2%subtree, node%bincode, &
        node%particle%pdg, node%mapping)
    else
      call tree_add_entry_from_numbers (tree, node%bincode, &
        node%particle%pdg, node%mapping)
    end if
    call tree%sort ()
  end subroutine tree_add_entry_from_node

```

For a well-defined order of the elements of the arrays in `tree_t`, the elements can be sorted. The bincodes (entries of `bc`) are simply ordered by size, the `pdg` and `mapping` entries go to the positions of the corresponding `bc` values.

```

<Cascades2: tree: TBP>+≡
  procedure :: sort => tree_sort

<Cascades2: procedures>+≡
  subroutine tree_sort (tree)
    class (tree_t), intent (inout) :: tree
    integer(TC), dimension(size(tree%bc)) :: bc_tmp

```

```

integer, dimension(size(tree%pdg)) :: pdg_tmp, mapping_tmp
integer, dimension(1) :: pos
integer :: i
bc_tmp = tree%bc
pdg_tmp = tree%pdg
mapping_tmp = tree%mapping
do i = size(tree%bc),1,-1
  pos = maxloc (bc_tmp)
  tree%bc(i) = bc_tmp (pos(1))
  tree%pdg(i) = pdg_tmp (pos(1))
  tree%mapping(i) = mapping_tmp (pos(1))
  bc_tmp(pos(1)) = 0
end do
end subroutine tree_sort

```

### 19.14.6 Graph types

We define an abstract type which will give rise to two different types: The type `feyngraph_t` contains the pure information of the corresponding Feynman diagram, but also a list of objects of the `kingraph` type which contain the kinematically relevant data for the mapping calculation as well as the mappings themselves. Every graph should have an index which is unique. Graphs which are not needed any more can be disabled by setting the `keep` variable to `false`.

```

<Cascades2: types>+≡
type, abstract :: graph_t
  integer :: index = 0
  integer :: n_nodes = 0
  logical :: keep = .true.
end type graph_t

```

This is the type representing the Feynman diagrams which are read from an input file created by O'Mega. It is a tree of nodes, which we call `f_nodes`, so that `feyngraph_t` contains a pointer to the root of this tree, and each node can have two daughter nodes. The case of only one associated daughter should never appear, because in the method of phase space parametrization which is used here, we combine always two particle momenta to a third one. The `feyngraphs` will be arranged in a linked list. This is why we have a pointer to the next graph. The `kingraphs` on the other hand are arranged in linked lists which are attached to the corresponding `feyngraph`. In general, a `feyngraph` can give rise to more than one `kingraph` because we make a copy every time a particle can be resonant, so that in the copy we keep the particle nonresonant.

```

<Cascades2: types>+≡
type, extends (graph_t) :: feyngraph_t
  type (string_t) :: omega_feyngraph_output
  type (f_node_t), pointer :: root => null ()
  type (feyngraph_t), pointer :: next => null ()
  type (kingraph_t), pointer :: kin_first => null ()
  type (kingraph_t), pointer :: kin_last => null ()
contains
  <Cascades2: feyngraph: TBP>

```

```
end type feyngraph_t
```

A container for a pointer of type `feyngraph_t`. This is used to realize arrays of these pointers.

```
<Cascades2: types>+≡
  type :: feyngraph_ptr_t
    type (feyngraph_t), pointer :: graph => null ()
  end type feyngraph_ptr_t
```

The length of a string describing a Feynman diagram which is produced by O'Mega is fixed by the parameter

```
<Cascades2: parameters>+≡
  integer, parameter :: FEYNGRAPH_LEN=300

<Cascades2: feyngraph: TBP>≡
  procedure :: final => feyngraph_final

<Cascades2: procedures>+≡
  subroutine feyngraph_final (graph)
    class(feyngraph_t), intent(inout) :: graph
    type (kingraph_t), pointer :: current
    graph%root => null ()
    graph%kin_last => null ()
    do while (associated (graph%kin_first))
      current => graph%kin_first
      graph%kin_first => graph%kin_first%next
      call current%final ()
      deallocate (current)
    enddo
  end subroutine feyngraph_final
```

This is the type of graph which is used to find the phase space channels, or in other words, each kingraph could correspond to a channel, if it is not eliminated for kinematical reasons or due to an equivalence. For the linked list which is attached to the corresponding `feyngraph`, we need the `next` pointer, whereas `grove_next` points to the next kingraph within a grove. The information which is relevant for the specification of a channel is stored in `tree`. We use `grove_prop` to sort the `kingraph` in a grove in which all `kingraphs` are characterized by the numbers contained in `grove_prop`. Later these groves are further subdivided using the resonance hash. A `kingraph` which is constructed directly from the output of O'Mega, is not `inverse`. In this case the first incoming particle is the root of the tree. In a scattering process, we can also construct a `kingraph` where the root of the tree is the second incoming particle. In this case the value of `inverse` is `.true..`

```
<Cascades2: types>+≡
  type, extends (graph_t) :: kingraph_t
    type (k_node_t), pointer :: root => null ()
    type (kingraph_t), pointer :: next => null()
    type (kingraph_t), pointer :: grove_next => null ()
    type (tree_t) :: tree
    type (grove_prop_t) :: grove_prop
    logical :: inverse = .false.
```

```

        integer :: prc_component = 0
        contains
        <Cascades2: kingraph: TBP>
    end type kingraph_t

```

Another container for a pointer to emulate arrays of pointers:

```

<Cascades2: types>+≡
    type :: kingraph_ptr_t
        type (kingraph_t), pointer :: graph => null ()
    end type kingraph_ptr_t

<Cascades2: kingraph: TBP>≡
    procedure :: final => kingraph_final

<Cascades2: procedures>+≡
    subroutine kingraph_final (graph)
        class(kingraph_t), intent(inout) :: graph
        graph%root => null ()
        graph%next => null ()
        graph%grove_next => null ()
        call graph%tree%final ()
    end subroutine kingraph_final

```

### 19.14.7 The node types

We define an abstract type containing variables which are needed for `f_node_t` as well as `k_node_t`. We say that a node is on the t-line if it lies between the two nodes which correspond to the two incoming particles. `incoming` and `tline` are used only for scattering processes and remain `.false.` in decay processes. The variable `n_subtree_nodes` holds the number of nodes (including the node itself) of the subtree of which the node is the root.

```

<Cascades2: types>+≡
    type, abstract :: node_t
        type (part_prop_t), pointer :: particle => null ()
        logical :: incoming = .false.
        logical :: t_line = .false.
        integer :: index = 0
        logical :: keep = .true.
        integer :: n_subtree_nodes = 1
    end type node_t

```

We use two different list types for the different kinds of nodes. We therefore start with an abstract type:

```

<Cascades2: types>+≡
    type, abstract :: list_t
        integer :: n_entries = 0
    end type list_t

```

Since the contents of the lists are different, we introduce two different entry types. Since the trees of nodes use pointers, the nodes should only be allocated by a type-bound procedure of the corresponding list type, such that we can keep track of all nodes, eventually reuse and in the end deallocate nodes correctly, without forgetting any nodes. Here is the type for the `k_nodes`. The list is a linked list. We want to reuse (recycle) the `k_nodes` which are neither incoming nore `t_line`.

```

<Cascades2: types>+≡
  type :: k_node_entry_t
    type (k_node_t), pointer :: node => null ()
    type (k_node_entry_t), pointer :: next => null ()
    logical :: recycle = .false.
  contains
    <Cascades2: k node entry: TBP>
  end type k_node_entry_t

<Cascades2: k node entry: TBP>≡
  procedure :: final => k_node_entry_final

<Cascades2: procedures>+≡
  subroutine k_node_entry_final (entry)
    class(k_node_entry_t), intent(inout) :: entry
    if (associated (entry%node)) then
      call entry%node%final
      deallocate (entry%node)
    end if
    entry%next => null ()
  end subroutine k_node_entry_final

<Cascades2: k node entry: TBP>+≡
  procedure :: write => k_node_entry_write

<Cascades2: procedures>+≡
  subroutine k_node_entry_write (k_node_entry, u)
    class (k_node_entry_t), intent (in) :: k_node_entry
    integer, intent (in) :: u
  end subroutine k_node_entry_write

```

Here is the list type for `k_nodes`. A `k_node_list` can be declared to be an observer. In this case it does not create any nodes by itself, but the entries set their pointers to existing nodes. In this way we can use the list structure and the type bound procedures for existing nodes.

```

<Cascades2: types>+≡
  type, extends (list_t) :: k_node_list_t
    type (k_node_entry_t), pointer :: first => null ()
    type (k_node_entry_t), pointer :: last => null ()
    integer :: n_recycle
    logical :: observer = .false.
  contains
    <Cascades2: k node list: TBP>
  end type k_node_list_t

```

```

<Cascades2: k node list: TBP>≡
  procedure :: final => k_node_list_final

<Cascades2: procedures>+≡
  subroutine k_node_list_final (list)
    class(k_node_list_t), intent(inout) :: list
    type (k_node_entry_t), pointer :: current
    do while (associated (list%first))
      current => list%first
      list%first => list%first%next
      if (list%observer) current%node => null ()
      call current%final ()
      deallocate (current)
    enddo
  end subroutine k_node_list_final

```

The `f_node_t` type contains the `particle_label` variable which is extracted from the input file. It consists not only of the particle name, but also of some numbers in brackets. These numbers indicate which external particles are part of the subtree of this node. The `f_node` contains also a list of `k_nodes`. Therefore, if the nodes are not incoming or t\_line, the mapping calculations for these `k_nodes` which can appear in several kingraphs have to be performed only once.

```

<Cascades2: types>+≡
  type, extends (node_t) :: f_node_t
    type (f_node_t), pointer :: daughter1 => null ()
    type (f_node_t), pointer :: daughter2 => null ()
    character (len=LABEL_LEN) :: particle_label
    type (k_node_list_t) :: k_node_list
  contains
    <Cascades2: f node: TBP>
  end type f_node_t

```

The finalizer nullifies the daughter pointers, since they are deallocated, like the `f_node` itself, with the finalizer of the `f_node_list`.

```

<Cascades2: f node: TBP>≡
  procedure :: final => f_node_final

<Cascades2: procedures>+≡
  recursive subroutine f_node_final (node)
    class(f_node_t), intent(inout) :: node
    call node%k_node_list%final ()
    node%daughter1 => null ()
    node%daughter2 => null ()
  end subroutine f_node_final

```

Finaliser for `f_node_entry`.

```

<Cascades2: f node entry: TBP>≡
  procedure :: final => f_node_entry_final

<Cascades2: procedures>+≡
  subroutine f_node_entry_final (entry)
    class(f_node_entry_t), intent(inout) :: entry

```

```

    if (associated (entry%node)) then
        call entry%node%final ()
        deallocate (entry%node)
    end if
    entry%next => null ()
end subroutine f_node_entry_final

```

Set index if not yet done, i.e. if it is zero.

```

<Cascades2: f node: TBP>+≡
    procedure :: set_index => f_node_set_index

<Cascades2: procedures>+≡
    subroutine f_node_set_index (f_node)
        class (f_node_t), intent (inout) :: f_node
        integer, save :: counter = 0
        if (f_node%index == 0) then
            counter = counter + 1
            f_node%index = counter
        end if
    end subroutine f_node_set_index

```

Type for the nodes of the tree (lines of the Feynman diagrams). We also need a type containing a pointer to a node, which is needed for creating arrays of pointers. This will be used for scattering processes where we can take either the first or the second particle to be the root of the tree. Since we need both cases for the calculations and O'Mega only gives us one of these, we have to perform a transformation of the graph in which some nodes (on the line which we hereafter call t-line) need to know their mother and sister nodes, which become their daughters within this transformation.

```

<Cascades2: types>+≡
    type :: f_node_ptr_t
        type (f_node_t), pointer :: node => null ()
        contains
            <Cascades2: f node ptr: TBP>
    end type f_node_ptr_t

<Cascades2: f node ptr: TBP>≡
    procedure :: final => f_node_ptr_final

<Cascades2: procedures>+≡
    subroutine f_node_ptr_final (f_node_ptr)
        class (f_node_ptr_t), intent (inout) :: f_node_ptr
        f_node_ptr%node => null ()
    end subroutine f_node_ptr_final

<Cascades2: interfaces>+≡
    interface assignment (=)
        module procedure f_node_ptr_assign
    end interface assignment (=)

<Cascades2: procedures>+≡
    subroutine f_node_ptr_assign (ptr1, ptr2)
        type (f_node_ptr_t), intent (out) :: ptr1

```

```

    type (f_node_ptr_t), intent (in) :: ptr2
    ptr1%node => ptr2%node
end subroutine f_node_ptr_assign

```

*<Cascades2: types>+≡*

```

type :: k_node_ptr_t
    type (k_node_t), pointer :: node => null ()
end type k_node_ptr_t

```

*<Cascades2: types>+≡*

```

type, extends (node_t) :: k_node_t

end type f_node_list_t

```

Add an entry to the `f_node_list`. If the node might be reused, we check first using the `subtree_string` if there is already a node in the list which is the root of exactly the same subtree. Otherwise we add an entry to the list and allocate the node. In both cases we return a pointer to the node which allows to access the node.

```

<Cascades2: f node list: TBP>≡
  procedure :: add_entry => f_node_list_add_entry

<Cascades2: procedures>+≡
  subroutine f_node_list_add_entry (list, subtree_string, ptr_to_node, &
    recycle, subtree_size)

      list%first%subtree_string = trim(subtree_string)
      list%first%string_len = subtree_len
      if (present (subtree_size)) list%first%subtree_size = subtree_size
    end if
  end subroutine

```

```

        allocate (list%first%node)
        call list%first%node%set_index ()
        ptr_to_node => list%first%node
    end if
end subroutine f_node_list_add_entry

```

A write method for debugging.

```

<Cascades2: f node list: TBP>+≡
    procedure :: write => f_node_list_write

<Cascades2: procedures>+≡
    subroutine f_node_list_write (f_node_list, u)
        class (f_node_list_t), intent (in) :: f_node_list
        integer, intent (in) :: u
        type (f_node_entry_t), pointer :: current
        integer :: pos = 0
        current => f_node_list%first
        do while (associated (current))
            pos = pos + 1
            write (unit=u, fmt='(A,I10)') 'entry #: ', pos
            call current%write (u)
            write (unit=u, fmt=*)
            current => current%next
        enddo
    end subroutine f_node_list_write

```

```

<Cascades2: interfaces>+≡
    interface assignment (=)
        module procedure k_node_entry_assign
    end interface assignment (=)

```

```

<Cascades2: procedures>+≡
    subroutine k_node_entry_assign (entry1, entry2)
        type (k_node_entry_t), intent (out) :: entry1
        type (k_node_entry_t), intent (in) :: entry2
        entry1%node => entry2%node
        entry1%recycle = entry2%recycle
    end subroutine k_node_entry_assign

```

Add an entry to the `k_node_list`. We have to specify if the node can be reused. The check for existing reusable nodes happens with `k_node_list_get_nodes` (see below).

```

<Cascades2: k node list: TBP>+≡
    procedure :: add_entry => k_node_list_add_entry

<Cascades2: procedures>+≡
    recursive subroutine k_node_list_add_entry (list, ptr_to_node, recycle)
        class (k_node_list_t), intent (inout) :: list
        type (k_node_t), pointer, intent (out) :: ptr_to_node
        logical, intent (in) :: recycle
        if (list%n_entries == 0) then
            allocate (list%first)
            list%last => list%first
        else

```

```

        allocate (list%last%next)
        list%last => list%last%next
    end if
    list%n_entries = list%n_entries + 1
    list%last%recycle = recycle
    allocate (list%last%node)
    call list%last%node%set_index ()
    ptr_to_node => list%last%node
end subroutine k_node_list_add_entry

```

We need a similar subroutine for adding only a pointer to a list. This is needed for a `k_node_list` which is only an observer, i.e. it does not create any nodes by itself.

```

<Cascades2: k node list: TBP>+≡
    procedure :: add_pointer => k_node_list_add_pointer

<Cascades2: procedures>+≡
    subroutine k_node_list_add_pointer (list, ptr_to_node, recycle)
        class (k_node_list_t), intent (inout) :: list
        type (k_node_t), pointer, intent (in) :: ptr_to_node
        logical, optional, intent (in) :: recycle
        logical :: rec
        if (present (recycle)) then
            rec = recycle
        else
            rec = .false.
        end if
        if (list%n_entries == 0) then
            allocate (list%first)
            list%last => list%first
        else
            allocate (list%last%next)
            list%last => list%last%next
        end if
        list%n_entries = list%n_entries + 1
        list%last%recycle = rec
        list%last%node => ptr_to_node
    end subroutine k_node_list_add_pointer

```

The `k_node_list` can also be used to collect `k_nodes` which belong to different `f_nodes` in order to compare these. This is done only for nodes which have the same number of subtree nodes. We compare all nodes of the list with each other (as long as the node is not deactivated, i.e. if the `keep` variable is set to `.true.`) using the subroutine `subtree_select`. If it turns out that two nodes are equivalent, we keep only one of them. The term equivalent in this module refers to trees or subtrees which differ in the pdg codes at positions where the trivial mapping is used (`NO_MAPPING` or `NON_RESONANT`) so that the mass of the particle does not matter. Depending on the available couplings, two equivalent subtrees could eventually lead to the same phase space channels, which is why only one of them is kept.

```

<Cascades2: k node list: TBP>+≡
    procedure :: check_subtree_equivalences => k_node_list_check_subtree_equivalences

```

```

<Cascades2: procedures>+≡
subroutine k_node_list_check_subtree_equivalences (list, model)
  class (k_node_list_t), intent (inout) :: list
  type (model_data_t), intent (in) :: model
  type (k_node_ptr_t), dimension (:), allocatable :: set
  type (k_node_entry_t), pointer :: current
  integer :: pos
  integer :: i,j
  if (list%n_entries == 0) return
  allocate (set (list%n_entries))
  current => list%first
  pos = 0
  do while (associated (current))
    pos = pos + 1
    set(pos)%node => current%node
    current => current%next
  enddo
  do i=1, list%n_entries
    if (set(i)%node%keep) then
      do j=i+1, list%n_entries
        if (set(j)%node%keep) then
          if (set(i)%node%bincode == set(j)%node%bincode) then
            call subtree_select (set(i)%node%subtree,set(j)%node%subtree, model)
            if (.not. set(i)%node%subtree%keep) then
              set(i)%node%keep = .false.
              exit
            else if (.not. set(j)%node%subtree%keep) then
              set(j)%node%keep = .false.
            end if
          end if
        end if
      enddo
    end if
  enddo
  deallocate (set)
end subroutine k_node_list_check_subtree_equivalences

```

This subroutine is used to obtain all `k_nodes` of a `k_node_list` which can be recycled and are not disabled for some reason. We pass an allocatable array of the type `k_node_ptr_t` which will be allocated if there are any such nodes in the list and the pointers will be associated with these nodes.

```

<Cascades2: k node list: TBP>+≡
  procedure :: get_nodes => k_node_list_get_nodes

<Cascades2: procedures>+≡
subroutine k_node_list_get_nodes (list, nodes)
  class (k_node_list_t), intent (inout) :: list
  type (k_node_ptr_t), dimension(:), allocatable, intent (out) :: nodes
  integer :: n_nodes
  integer :: pos
  type (k_node_entry_t), pointer :: current, garbage
  n_nodes = 0
  current => list%first
  do while (associated (current))

```

```

        if (current%recycle .and. current%node%keep) n_nodes = n_nodes + 1
        current => current%next
    enddo
    if (n_nodes /= 0) then
        pos = 1
        allocate (nodes (n_nodes))
        do while (associated (list%first) .and. .not. list%first%node%keep)
            garbage => list%first
            list%first => list%first%next
            call garbage%final ()
            deallocate (garbage)
        enddo
        current => list%first
        do while (associated (current))
            do while (associated (current%next))
                if (.not. current%next%node%keep) then
                    garbage => current%next
                    current%next => current%next%next
                    call garbage%final
                    deallocate (garbage)
                else
                    exit
                end if
            enddo
            if (current%recycle .and. current%node%keep) then
                nodes(pos)%node => current%node
                pos = pos + 1
            end if
            current => current%next
        enddo
    end if
end subroutine k_node_list_get_nodes

```

```

<Cascades2: f node list: TBP>+≡
    procedure :: final => f_node_list_final

<Cascades2: procedures>+≡
    subroutine f_node_list_final (list)
        class (f_node_list_t) :: list
        type (f_node_entry_t), pointer :: current
        list%k_node_list => null ()
        do while (associated (list%first))
            current => list%first
            list%first => list%first%next
            call current%final ()
            deallocate (current)
        enddo
    end subroutine f_node_list_final

```

### 19.14.8 The grove list

First a type is introduced in order to speed up the comparison of kingraphs with the purpose to quickly find the graphs that might be equivalent. This is

done solely on the basis of a number (which is given by the value of **depth** in **compare\_tree\_t**) of bincodes, which are the highest ones that do not belong to external particles. The highest such value determines the index of the element in the **entry** array of the **compare\_tree**. The next lower such value determines the index of the element in the **entry** array of this **entry**, and so on and so forth. This results in a tree structure where the number of levels is given by **depth** and should not be too large for reasons of memory. This is the entry type.

```

<Cascades2: types>+≡
  type :: compare_tree_entry_t
    type (compare_tree_entry_t), dimension(:), pointer :: entry => null ()
    type (kingraph_ptr_t), dimension(:), allocatable :: graph_entry
  contains
    <Cascades2: compare tree entry: TBP>
  end type compare_tree_entry_t

```

This is the tree type.

```

<Cascades2: types>+≡
  type :: compare_tree_t
    integer :: depth = 3
    type (compare_tree_entry_t), dimension(:), pointer :: entry => null ()
  contains
    <Cascades2: compare tree: TBP>
  end type compare_tree_t

```

Finalizers for both types. The one for the entry type has to be recursive.

```

<Cascades2: compare tree: TBP>≡
  procedure :: final => compare_tree_final

<Cascades2: procedures>+≡
  subroutine compare_tree_final (ctree)
    class (compare_tree_t), intent (inout) :: ctree
    integer :: i
    if (associated (ctree%entry)) then
      do i=1, size (ctree%entry)
        call ctree%entry(i)%final ()
        deallocate (ctree%entry)
      end do
    end if
  end subroutine compare_tree_final

<Cascades2: compare tree entry: TBP>≡
  procedure :: final => compare_tree_entry_final

<Cascades2: procedures>+≡
  recursive subroutine compare_tree_entry_final (ct_entry)
    class (compare_tree_entry_t), intent (inout) :: ct_entry
    integer :: i
    if (associated (ct_entry%entry)) then
      do i=1, size (ct_entry%entry)
        call ct_entry%entry(i)%final ()
      enddo
    deallocate (ct_entry%entry)
  end subroutine compare_tree_entry_final

```

```

else
  deallocate (ct_entry%graph_entry)
end if
end subroutine compare_tree_entry_final

```

Check the presence of a graph which is considered as equivalent and select between the two. If there is no such graph, the current one is added to the list. First the entry has to be found:

*<Cascades2: compare tree: TBP>+≡*

```

  procedure :: check_kingraph => compare_tree_check_kingraph

```

*<Cascades2: procedures>+≡*

```

subroutine compare_tree_check_kingraph (ctree, kingraph, model, preliminary)
  class (compare_tree_t), intent (inout) :: ctree
  type (kingraph_t), intent (inout), pointer :: kingraph
  type (model_data_t), intent (in) :: model
  logical, intent (in) :: preliminary
  integer :: i
  integer :: pos
  integer(TC) :: sz
  integer(TC), dimension(:), allocatable :: identifier
  if (.not. associated (ctree%entry)) then
    sz = 0_TC
    do i = size(kingraph%tree%bc), 1, -1
      sz = ior (sz, kingraph%tree%bc(i))
    enddo
    if (sz > 0) then
      allocate (ctree%entry (sz))
    else
      call msg_bug ("Compare tree could not be created")
    end if
  end if
  allocate (identifier (ctree%depth))
  pos = 0
  do i = size(kingraph%tree%bc), 1, -1
    if (popcnt (kingraph%tree%bc(i)) /= 1) then
      pos = pos + 1
      identifier(pos) = kingraph%tree%bc(i)
      if (pos == ctree%depth) exit
    end if
  enddo
  if (size (identifier) > 1) then
    call ctree%entry(identifier(1))%check_kingraph (kingraph, model, &
      preliminary, identifier(1), identifier(2:))
  else if (size (identifier) == 1) then
    call ctree%entry(identifier(1))%check_kingraph (kingraph, model, preliminary)
  end if
  deallocate (identifier)
end subroutine compare_tree_check_kingraph

```

Then the graphs of the entry are checked.

*<Cascades2: compare tree entry: TBP>+≡*

```

  procedure :: check_kingraph => compare_tree_entry_check_kingraph

```

*<Cascades2: procedures>+≡*

```

recursive subroutine compare_tree_entry_check_kingraph (ct_entry, kingraph, &
    model, preliminary, subtree_size, identifier)
    class (compare_tree_entry_t), intent (inout) :: ct_entry
    type (kingraph_t), pointer, intent (inout) :: kingraph
    type (model_data_t), intent (in) :: model
    logical, intent (in) :: preliminary
    integer, intent (in), optional :: subtree_size
    integer, dimension (:), intent (in), optional :: identifier
    if (present (identifier)) then
        if (.not. associated (ct_entry%entry)) &
            allocate (ct_entry%entry(subtree_size))
        if (size (identifier) > 1) then
            call ct_entry%entry(identifier(1))%check_kingraph (kingraph, &
                model, preliminary, identifier(1), identifier(2:))
        else if (size (identifier) == 1) then
            call ct_entry%entry(identifier(1))%check_kingraph (kingraph, &
                model, preliminary)
        end if
    else
        if (allocated (ct_entry%graph_entry)) then
            call perform_check
        else
            allocate (ct_entry%graph_entry(1))
            ct_entry%graph_entry(1)%graph => kingraph
        end if
    end if
end if

```

contains

```

subroutine perform_check
    integer :: i
    logical :: rebuild
    rebuild = .true.
    do i=1, size(ct_entry%graph_entry)
        if (ct_entry%graph_entry(i)%graph%keep) then
            if (preliminary .or. &
                ct_entry%graph_entry(i)%graph%prc_component /= kingraph%prc_component) then
                call kingraph_select (ct_entry%graph_entry(i)%graph, kingraph, model, preliminary)
            if (.not. kingraph%keep) then
                return
            else if (rebuild .and. .not. ct_entry%graph_entry(i)%graph%keep) then
                ct_entry%graph_entry(i)%graph => kingraph
                rebuild = .false.
            end if
        end if
    end if
end if
enddo
if (rebuild) call rebuild_graph_entry
end subroutine perform_check

subroutine rebuild_graph_entry
    type (kingraph_ptr_t), dimension(:), allocatable :: tmp_ptr
    integer :: i

```

```

integer :: pos
allocate (tmp_ptr(size(ct_entry%graph_entry)+1))
pos = 0
do i=1, size(ct_entry%graph_entry)
    pos = pos + 1
    tmp_ptr(pos)%graph => ct_entry%graph_entry(i)%graph
enddo
pos = pos + 1
tmp_ptr(pos)%graph => kingraph
deallocate (ct_entry%graph_entry)
allocate (ct_entry%graph_entry (pos))
do i=1, pos
    ct_entry%graph_entry(i)%graph => tmp_ptr(i)%graph
enddo
deallocate (tmp_ptr)
end subroutine rebuild_graph_entry
end subroutine compare_tree_entry_check_kingraph

```

The grove to which a completed `kingraph` will be added is determined by the entries of `grove_prop`. We use another list type (linked list) to arrange the groves. Each grove contains again a linked list of `kingraphs`.

```

<Cascades2: types>+≡
type :: grove_t
    type (grove_prop_t) :: grove_prop
    type (grove_t), pointer :: next => null ()
    type (kingraph_t), pointer :: first => null ()
    type (kingraph_t), pointer :: last => null ()
    type (compare_tree_t) :: compare_tree
contains
    <Cascades2: grove: TBP>
end type grove_t

```

Container for a pointer of type `grove_t`:

```

<Cascades2: types>+≡
type :: grove_ptr_t
    type (grove_t), pointer :: grove => null ()
end type grove_ptr_t

```

```

<Cascades2: grove: TBP>≡
procedure :: final => grove_final

```

```

<Cascades2: procedures>+≡
subroutine grove_final (grove)
    class(grove_t), intent(inout) :: grove
    grove%first => null ()
    grove%last  => null ()
    grove%next => null ()
end subroutine grove_final

```

This is the list type:

```

<Cascades2: types>+≡
type :: grove_list_t

```

```

        type (grove_t), pointer :: first => null ()
contains
    <Cascades2: grove list: TBP>
end type grove_list_t

<Cascades2: grove list: TBP>≡
    procedure :: final => grove_list_final

<Cascades2: procedures>+≡
    subroutine grove_list_final (list)
        class(grove_list_t), intent(inout) :: list
        class(grove_t), pointer :: current
        do while (associated (list%first))
            current => list%first
            list%first => list%first%next
            call current%final ()
            deallocate (current)
        end do
    end subroutine grove_list_final

```

### 19.14.9 The feyngraph set

The fundament of the module is the public type `feyngraph_set_t`. It is not only a linked list of all `feyngraphs` but contains an array of all particle properties (`particle`), an `f_node_list` and a pointer of the type `grove_list_t`, since several `feyngraph_sets` can share a common `grove_list`. In addition it keeps the data which unambiguously specifies the process, as well as the model which provides information which allows us to choose between equivalent subtrees or complete `kingraphs`.

```

<Cascades2: public>+≡
    public :: feyngraph_set_t

<Cascades2: types>+≡
    type :: feyngraph_set_t
        type (model_data_t), pointer :: model => null ()
        type(flavor_t), dimension(:, :), allocatable :: flv
        integer :: n_in = 0
        integer :: n_out = 0
        integer :: process_type = DECAY
        type (phs_parameters_t) :: phs_par
        logical :: fatal_beam_decay = .true.
        type (part_prop_t), dimension (:), pointer :: particle => null ()
        type (f_node_list_t) :: f_node_list
        type (feyngraph_t), pointer :: first => null ()
        type (feyngraph_t), pointer :: last => null ()
        integer :: n_graphs = 0
        type (grove_list_t), pointer :: grove_list => null ()
        logical :: use_dag = .true.
        type (dag_t), pointer :: dag => null ()
        type (feyngraph_set_t), dimension (:), pointer :: fset => null ()
contains
    <Cascades2: feyngraph set: TBP>

```

```
end type feyngraph_set_t
```

This final procedure contains calls to all other necessary final procedures.

```
<Cascades2: feyngraph set: TBP>≡

### 19.14.10 Construct the feyngraph set

We construct the `feyngraph_set` from an input file. Therefore we pass a unit to `feyngraph_set_build`. The parsing subroutines are chosen depending on the value of `use_dag`. In the DAG output, which is the one that is produced by default, we have to work on a string of one line, where the length of this string becomes larger the more particles are involved in the process. The other output (which is now only used in a unit test) contains one Feynman diagram per line and each line starts with an open parenthesis so that we read the file line per line and create a `feyngraph` for every line. Only after this, nodes are created. In both decay and scattering processes the diagrams are represented like in a decay process, i.e. in a scattering process one of the incoming particles appears as an outgoing particle.

```

```

Read the string from the file. The output which is produced by O'Mega contains the DAG in a factorised form as a long string, distributed over several lines (in addition, in the case of a scattering process, it contains a similar string for the same process, but with the other incoming particle as the root of the tree structure). In general, such a file can contain many of these strings, belonging to different process components. Therefore we first have to find the correct position of the string for the process in question. Therefore we look for a line containing a pair of colons, in which case the line contains a process string. Then we check if the process string describes the correct process, which is done by checking for all the incoming and outgoing particle names. If the process is correct, the dag output should start in the following line. As long as we do not find the correct process string, we continue searching. If we reach the end of the file, we rewind the unit once, and repeat searching. If the process is still not found, there must be some sort of error.

```

<Cascades2: dag: TBP>≡
    procedure :: read_string => dag_read_string

<Cascades2: procedures>+≡
    subroutine dag_read_string (dag, u_in, flv)
        class (dag_t), intent (inout) :: dag
        integer, intent (in) :: u_in
        type(flavor_t), dimension(:), intent(in) :: flv
        character (len=BUFFER_LEN) :: process_string
        logical :: process_found
        logical :: rewind
    !!! find process string in file
        process_found = .false.
        rewind = .false.

```

```

do while (.not. process_found)
  process_string = ""
  read (unit=u_in, fmt='(A)') process_string
  if (len_trim(process_string) /= 0) then
    if (index (process_string, "::") > 0) then
      process_found = process_string_match (trim (process_string), flv)
    end if
  else if (.not. rewind) then
    rewind (u_in)
    rewind = .true.
  else
    call msg_bug ("Process string not found in O'Mega input file.")
  end if
enddo
call fds_file_get_line (u_in, dag%string)
call dag%string%clean ()
if (.not. allocated (dag%string%t) .or. dag%string%char_len == 0) &
  call msg_bug ("Process string not found in O'Mega input file.")
end subroutine dag_read_string

```

The output of factorized Feynman diagrams which is created by O'Mega for a given process could in principle be written to a single line in the file. This can however lead to different problems with different compilers as soon as such lines become too long. This is the reason why the line is cut into smaller pieces. This means that a new line starts after each vertical bar. For this long string the type `dag_string_t` has been introduced. In order to read the file quickly into such a `dag_string` we use another type, `dag_chain_t` which is a linked list of such `dag_strings`. This has the advantage that we do not have to recreate a new `dag_string` for every line which has been read from file. Only in the end of this operation we compress the list of strings to a single string, removing useless `dag_tokens`, such as blanc space tokens. This subroutine reads all lines starting from the position in the file the unit is connected to, until no backslash character is found at the end of a line (the backslash means that the next line also belongs to the current string).

```

<Cascades2: parameters>+≡
  integer, parameter :: BUFFER_LEN = 1000
  integer, parameter :: STACK_SIZE = 100

<Cascades2: procedures>+≡
  subroutine fds_file_get_line (u, string)
    integer, intent (in) :: u
    type (dag_string_t), intent (out) :: string
    type (dag_chain_t) :: chain
    integer :: string_size, current_len
    character (len=BUFFER_LEN) :: buffer
    integer :: fragment_len
    integer :: stat
    current_len = 0
    stat = 0
    string_size = 0
    do while (stat == 0)
      read (unit=u, fmt='(A)', iostat=stat) buffer
      if (stat /= 0) exit
    enddo
  end subroutine

```

```

        fragment_len = len_trim (buffer)
        if (fragment_len == 0) then
            exit
        else if (buffer (fragment_len:fragment_len) == BACKSLASH_CHAR) then
            fragment_len = fragment_len - 1
        end if
        call chain%append (buffer(:fragment_len))
        if (buffer(fragment_len+1:fragment_len+1) /= BACKSLASH_CHAR) exit
    enddo
    if (associated (chain%first)) then
        call chain%compress ()
        string = chain%first
        call chain%final ()
    end if
end subroutine fds_file_get_line

```

We check, if the process string which has been read from file corresponds to the process for which we want to extract the Feynman diagrams.

```

Initialize a `part_prop` object by passing a `particle_label`, which is simply the particle name. `part_prop` should be part of the `particle` array of `feyngraph_set`. We use the `model` of `feyngraph_set` to obtain the relevant data of the particle which is needed to find `phase_space` parametrizations. When a `part_prop` is initialized, we add and initialize also the corresponding anti- particle `part_prop` if it is not yet in the array.

```

```

This subroutine assigns to a node the particle properties. Since these properties do not change and are simply read from the model file, we use pointers to the elements of the `particle` array of the `feyngraph_set`. If there is no corresponding array element, we have to initialize the first empty element of the array.

```

        !!! Since the O'Mega output uses the anti-particles instead of the particles specified
        !!! in the process definition, we revert this here. An exception is the first particle
        !!! in the parsable DAG output
        node%particle => node%particle%anti
    end subroutine f_node_assign_particle_properties

```

From the output of a Feynman diagram (in the non-factorized output) we need to find out how many daughter nodes would be required to reconstruct it cor-

rectly, to make sure that we keep only those **feyngraphs** which are constructed solely on the basis of the 3-vertices which are provided by the model. The number of daughter particles can easily be determined from the syntax of O'Mega's output: The particle which appears before the colon ':' is the mother particle. The particles or subtrees (i.e. whole parentheses) follow after the colon and are separated by commas.

```

    end if
end if
end function get_n_daughters

```

### 19.14.12 Reconstruction of trees

The reconstruction of a tree or subtree with the non-factorized input can be done recursively, i.e. we first find the root of the tree in the string and create an **f\_node**. Then we look for daughters, which in the string appear either as single particles or subtrees (which are of the same form as the tree which we want to reconstruct. Therefore the subroutine can simply be called again and again until there are no more daughter nodes to create. When we meet a vertex which requires more than two daughter particles, we stop the recursion and disable the node using its **keep** variable. Whenever a daughter node is not kept, we do not keep the mother node as well.

```

<Cascades2: procedures>+≡
recursive subroutine node_construct_subtree_rec (feyngraph_set, &
    feyngraph, subtree_string, mother_node)
type (feyngraph_set_t), intent (inout) :: feyngraph_set

end if
end subroutine node_construct_subtree_rec

```

When the non-factorized version of the O'Mega output is used, the `feyngraph` is reconstructed from the contents of its `string_t` variable `omega_feyngraph_output`. This can be used for the recursive reconstruction of the tree of `k_nodes` with `node_construct_subtree_rec`.

```

<Cascades2: procedures>+≡
subroutine feyngraph_construct (feyngraph_set, feyngraph)
  type (feyngraph_set_t), intent (inout) :: feyngraph_set
  type (feyngraph_t), pointer, intent (inout) :: feyngraph
  call node_construct_subtree_rec (feyngraph_set, feyngraph, &
    char(feyngraph%omega_feyngraph_output), feyngraph%root)
  feyngraph%n_nodes = feyngraph%root%n_subtree_nodes
end subroutine feyngraph_construct

```

We introduce another node type, which is called `dag_node_t` and is used to reproduce the dag structure which is represented by the input. The `dag_nodes` can have several combinations of daughters 1 and 2. The `dag` type contains an array of `dag_nodes` and is only used for the reconstruction of `feyngraphs` which are factorized as well, but in the other direction as the original output. This means in particular that the outgoing particles in the output file (which there can appear many times) exist only once as `f_nodes`. To represent combinations of daughters and alternatives (options), we further use the types `dag_options_t` and `dag_combination_t`. The `dag_nodes`, `dag_options` and `dag_combinations` correspond to a substring of the string which has been read from file (and transformed into an object of type `dag_string_t`, which is simply another compact representation of this string), or a modified version of this substring. The aim is to create only one object for a given substring, even if it appears several times in the original string and then create trees of `f_nodes`, which build up the `feyngraph`, such that as many `f_nodes` as possible can be reused. An outgoing particle (always interpreting the input as a decay) is called a `leaf` in the context of a `dag`.

```

<Cascades2: types>+≡
type :: dag_node_t
  integer :: string_len
  type (dag_string_t) :: string

```

```

        logical :: leaf = .false.
        type (f_node_ptr_t), dimension (:), allocatable :: f_node
        integer :: subtree_size = 0
    contains
        <Cascades2: dag node: TBP>
    end type dag_node_t

```

```

<Cascades2: dag node: TBP>≡
    procedure :: final => dag_node_final

<Cascades2: procedures>+≡
    subroutine dag_node_final (dag_node)
        class (dag_node_t), intent (inout) :: dag_node
        integer :: i
        call dag_node%string%final ()
        if (allocated (dag_node%f_node)) then
            do i=1, size (dag_node%f_node)
                if (associated (dag_node%f_node(i)%node)) then
                    call dag_node%f_node(i)%node%final ()
                    deallocate (dag_node%f_node(i)%node)

            enddo
            deallocate (dag_node%f_node)
        end if
    end subroutine dag_node_final

```

Whenever there are more than one possible subtrees (represented by a `dag_node`) or combinations of subtrees to daughters (represented by `dag_combination_t`), we use the type `dag_options_t`. In the syntax of the factorized output, options are listed within curly braces, separated by horizontal bars.

```

<Cascades2: types>+≡
    type :: dag_options_t
        integer :: string_len
        type (dag_string_t) :: string
        type (f_node_ptr_t), dimension (:), allocatable :: f_node_ptr1
        type (f_node_ptr_t), dimension (:), allocatable :: f_node_ptr2
    contains
        <Cascades2: dag options: TBP>
    end type dag_options_t

```

```

<Cascades2: dag options: TBP>≡
    procedure :: final => dag_options_final

<Cascades2: procedures>+≡
    subroutine dag_options_final (dag_options)
        class (dag_options_t), intent (inout) :: dag_options
        integer :: i
        call dag_options%string%final ()
        if (allocated (dag_options%f_node_ptr1)) then
            do i=1, size (dag_options%f_node_ptr1)
                dag_options%f_node_ptr1(i)%node => null ()
            enddo
            deallocate (dag_options%f_node_ptr1)
        end if
    end subroutine dag_options_final

```

```

end if
  if (allocated (dag_options%f_node_ptr2)) then
    do i=1, size (dag_options%f_node_ptr2)
      dag_options%f_node_ptr2(i)%node => null ()
    enddo
    deallocate (dag_options%f_node_ptr2)
  end if
end subroutine dag_options_final

```

A pair of two daughters (which can be `dag_nodes` or `dag_options`) is represented by the type `dag_combination_t`. In the original string, a `dag_combination` appears between parentheses, which contain a comma, but not a colon. If we find a colon between these parentheses, it is a `dag_node` instead.

```

<Cascades2: types>+≡
type :: dag_combination_t
  integer :: string_len
  type (dag_string_t) :: string
  integer, dimension (2) :: combination
  type (f_node_ptr_t), dimension (:), allocatable :: f_node_ptr1
  type (f_node_ptr_t), dimension (:), allocatable :: f_node_ptr2
contains
  <Cascades2: dag combination: TBP>
end type dag_combination_t

```

```

<Cascades2: dag combination: TBP>≡
procedure :: final => dag_combination_final

```

```

<Cascades2: procedures>+≡
subroutine dag_combination_final (dag_combination)
  class (dag_combination_t), intent (inout) :: dag_combination

    end subroutine dag_final

```

We construct the DAG from the given `dag_string` which is modified several times so that in the end the remaining string corresponds to a simple `dag_node`, the root of the factorized tree. This means that we first identify the leaves, i.e. outgoing particles. Then we identify `dag_nodes`, `dag_combinations` and `options` until the number of these objects does not change any more. Identifying means that we add a corresponding object to the array (if not yet present), which can be identified with the corresponding substring, and replace the substring in the original `dag_string` by a `dag_token` of the corresponding type (in the char output of this token, this corresponds to a place holder like e.g. `'iO23i'` which in this particular case corresponds to an option and can be found at the position 23 in the array). The character output of the substrings turns out to be very useful for debugging.

Identify `dag_nodes` and `dag_combinations`. Leaves are simply nodes (i.e. of type `NODE_TK`) where only one bit in the bincode is set. The `dag_nodes` and `dag_combinations` have in common that they are surrounded by parentheses. There is however a way to distinguish between them because the corresponding substring contains a colon (or `dag_token` with type `COLON_TK`) if it is a `dag_node`. Otherwise it is a `dag_combination`. The string of the `dag_node` or `dag_combination` should not contain curly braces, because these correspond to `dag_options` and should be identified before.

For a given `dag_node` we want to create all `f_nodes`. If the node is not a leaf, it contains in its string placeholders for options or combinations. For these

objects there are similar subroutines which are needed here to obtain the sets of daughter nodes. If the `dag_node` is a leaf, it corresponds to an external particle and the token contains the particle name.

In `dag_options.make_f_nodes.single` we obtain all `f_nodes` for `dag_nodes` which correspond to a set of rival subtrees or nodes, which is the first possibility for which `dag_options` can appear. In `dag_options.make_f_nodes.pair` the options are rival pairs (`daughter1`, `daughter2`). Therefore we have to pass two allocatable arrays of type `f_node_ptr_t` to the subroutine.

We create all combinations of daughter **f\_nodes** for a combination. In the combination each daughter can be either a single **dag\_node** or **dag\_options** which are a set of single **dag\_nodes**. Therefore, we first create all possible **f\_nodes** for daughter1, then all possible **f\_nodes** for daughter2. In the end we combine all **daughter1** nodes with all **daughter2** nodes.

Here we create the **feyngraphs**. After the construction of the **dag** the remaining **dag.string** should contain a token for a single **dag\_node** which corresponds to the roots of the **feyngraphs**. Therefore we make all **f\_nodes** for this **dag\_node** and create a **feyngraph** for each **f\_node**. Note that only 3-vertices are accepted. All other vertices are rejected. The starting point is the last dag node which has been added to the list, since this corresponds to the root of the tree. Is is important to understand that the structure of feyngraphs is not the same as the structure of the dag which is read from file, because for the calculations which are performed in this module we want to reuse the nodes for the outgoing particles, which means that they appear only once. In O'Mega's output, it is the first incoming particle which appears only once and the outgoing particles appear many times. This transition is incorporated in the subroutines which create **f\_nodes** from the different dag objects.

end subroutine k_node_make_nonresonant_copy

```

For a given `feyngraph` we create all possible `kingraphs`. Here we use existing `k_nodes` which have already been created when the mapping calculations of the pure s-channel subgraphs are performed. The nodes for the incoming particles or the nodes on the t-line will have to be created in all cases because they are not used in several graphs. To obtain the existing `k_nodes`, we use the subroutine `k_node_init_from_f_node` which itself uses `f_node_list.get_nodes` to obtain all active `k_nodes` in the `k_node_list` of the `f_node`. The created `kingraphs` are attached to the linked list of the `feyngraph`. For scattering processes we have to split up the t-line, because since all graphs are represented as a decay, different nodes can share daughter nodes. This happens also for the t-line or the incoming particle which appears as an outgoing particle. For the `t_line` or `incoming` nodes we do not want to recycle nodes but rather create a copy of this line for each `kingraph`.

end subroutine k_node_init_from_f_node

```

The graphs resulting from `k_node_init_from_f_node` are fine if they are used only in one direction. This is however not the case when one wants to invert the graphs, i.e. take the other incoming particle of a scattering process as the decaying particle, because the outgoing `f_nodes` (and hence also the `k_nodes`) exist only once. This problem is solved here by creating a distinct t-line for each of the graphs. The following subroutine disentangles the data structure by creating new nodes such that the different t-lines are not connected any more.

(*Cascades2: procedures*) +=

```

recursive subroutine split_up_t_lines (t_node)
    type (k_node_ptr_t), dimension(:), intent (inout) :: t_node
    type (k_node_t), pointer :: ref_node => null ()

else
    return
end if
enddo
call split_up_t_lines (t_daughter)
deallocate (t_daughter)
end subroutine split_up_t_lines

```

This subroutine sets the `inverse_daughters` of a `k_node`. If we invert a kingraph such that not the first but the second incoming particle appears as the root of the tree, the `incoming` and `t_line` particles obtain other daughters. These are the former mother node and the sister node `s_daughter`. Here we set only the pointers for the `inverse_daughters`. The inversion happens in `kingraph_make_inverse_copy` and `node_inverse_deep_copy`.

(*Cascades2: procedures*) +=

```

subroutine kingraph_set_inverse_daughters (kingraph)
    type (kingraph_t), intent (inout) :: kingraph
    type (k_node_t), pointer :: mother
    type (k_node_t), pointer :: t_daughter
    type (k_node_t), pointer :: s_daughter
    mother => kingraph%root
    do while (associated (mother))
        if (associated (mother%daughter1) .and. &
            associated (mother%daughter2)) then
            if (mother%daughter1%t_line .or. mother%daughter1%incoming) then
                t_daughter => mother%daughter1; s_daughter => mother%daughter2
            else if (mother%daughter2%t_line .or. mother%daughter2%incoming) then
                t_daughter => mother%daughter2; s_daughter => mother%daughter1
            else
                exit
            end if
            t_daughter%inverse_daughter1 => mother
            t_daughter%inverse_daughter2 => s_daughter
            mother => t_daughter
        else
            exit
        end if
    enddo
end subroutine kingraph_set_inverse_daughters

```

Set the bincode of an `f_node` which corresponds to an external particle. This

is done on the basis of the `particle_label` which is a substring of the input file. Here it is not the particle name which is important, but the number(s) in brackets which in general indicate the external particles which are connected to the current node. This function is however only used for external particles, so there can either be one or `n_out + 1` particles in the brackets (in the DAG input file always one, because also for the root there is only a single number). In all cases we check the number of particles (in the DAG input the numbers are separated by a slash).

*(Cascades2: procedures)*+≡

```
function f_node_get_external_bincode (feyngraph_set, f_node) result (bincode)
  type (feyngraph_set_t), intent (in) :: feyngraph_set
  type (f_node_t), intent (in) :: f_node
  integer (TC) :: bincode
  character (len=LABEL_LEN) :: particle_label
  integer :: start_pos, end_pos, n_out_decay
  integer :: n_prt ! for DAG
  integer :: i
  bincode = 0
  if (feyngraph_set%process_type == DECAY) then
    n_out_decay = feyngraph_set%n_out
  else
    n_out_decay = feyngraph_set%n_out + 1
  end if
  particle_label = f_node%particle_label
  start_pos = index (particle_label, '[') + 1
  end_pos = index (particle_label, ']') - 1
  particle_label = particle_label(start_pos:end_pos)
  !!! n_out_decay is the number of outgoing particles in the
  !!! 0'Mega output, which is always represented as a decay
  if (feyngraph_set%use_dag) then
    n_prt = 1
    do i=1, len(particle_label)
      if (particle_label(i:i) == '/') n_prt = n_prt + 1
    enddo
  else
    n_prt = end_pos - start_pos + 1
  end if
  if (n_prt == 1) then
    bincode = calculate_external_bincode (particle_label, &
      feyngraph_set%process_type, n_out_decay)
  else if (n_prt == n_out_decay) then
    bincode = ibset (0, n_out_decay)
  end if
end function f_node_get_external_bincode
```

Assign a bincode to an internal node, which is calculated from the bincodes of `daughter1` and `daughter2`.

*(Cascades2: procedures)*+≡

```
subroutine node_assign_bincode (node)
  type (k_node_t), intent (inout) :: node
  if (associated (node%daughter1) .and. associated (node%daughter2) &
    .and. .not. node%incoming) then
    node%bincode = ior(node%daughter1%bincode, node%daughter2%bincode)
```

```

    end if
end subroutine node_assign_bincode

```

Calculate the `bincode` from the number in the brackets of the `particle_label`, if the node is external. For the root in the non-factorized output, this is calculated directly in `f_node_get_external_bincode` because in this case all the other external particle numbers appear between the brackets.

*(Cascades2: procedures)*+≡

```

function calculate_external_bincode (label_number_string, process_type, n_out_decay) result (bin
character (len=*), intent (in) :: label_number_string
integer, intent (in) :: process_type
integer, intent (in) :: n_out_decay
character :: number_char
integer :: number_int
integer (kind=TC) :: bincode
bincode = 0
read (label_number_string, fmt='(A)') number_char
!!! check if the character is a letter (A,B,C,...) or a number (1...9)
!!! numbers 1 and 2 are special cases
select case (number_char)
case ('1')
    if (process_type == SCATTERING) then
        number_int = n_out_decay + 3

    end if
case ('2')
    if (process_type == SCATTERING) then
        number_int = n_out_decay + 2
    else
        number_int = 2
    end if
case ('A')
    number_int = 10
case ('B')
    number_int = 11
case ('C')
    number_int = 12
case ('D')
    number_int = 13
case default
    read (number_char, fmt='(I1)') number_int
end select
bincode = ibset (bincode, number_int - process_type - 1)
end function calculate_external_bincode

```

### 19.14.13 Mapping calculations

Once a `k_node` and its subtree nodes have been created, we can perform the kinematical calculations and assign mappings, depending on the particle properties and the results for the subtree nodes. This could in principle be done recursively, calling the procedure first for the daughter nodes and then perform

the calculations for the actual node. But for parallization and comparing the nodes, this will be done simultaneously for all nodes with the same number of subtree nodes, and the number of subtree nodes increases, starting from one, in steps of two. The actual mapping calculations are done in complete analogy to cascades.

```
(Cascades2: procedures)+≡

  end if
end subroutine

```

```

end if
if (kingraph%keep) kingraph%tree = kingraph%root%subtree
end subroutine kingraph_compute_mappings_t_line

```

Perform the kinematical calculations and mapping assignment for a node which is either `incoming` or `t_line`. This is done recursively, going first to the daughter node which has this property. Therefore we first set the pointer `t_node` to this daughter node and `s_node` to the other one. The mapping determination happens again in the same way as in `cascades`.

```

After all pure s-channel subdiagrams have already been created from the corresponding **f\_nodes** and mappings have been determined for their nodes, we complete the calculations here. In a first step, the **kingraphs** have to be created on the basis of the existing **k\_nodes**, which means in particular that a **feyngraph** can give rise to several **kingraphs** which will all be attached to the linked list of the **feyngraph**. The calculations which remain are of different

kinds for decay and scattering processes. In a decay process the kinematical calculations have to be done for the `root` node. In a scattering process, after the creation of `kingraphs` in the first step, there will be only `kingraphs` with the first incoming particle as the `root` of the tree. For these graphs the `inverse` variable has the value `.false..` Before performing any calculations on these graphs we make a so-called inverse copy of the graph (see below), which will also be attached to the linked list. Since the s-channel subgraph calculations have already been completed, only the t-line computations remain.

```

<Cascades2: feyngraph: TBP>+≡
  procedure :: make_inverse_kingraphs => feyngraph_make_inverse_kingraphs

<Cascades2: procedures>+≡
  subroutine feyngraph_make_inverse_kingraphs (feyngraph)

    enddo
  end subroutine feyngraph_compute_mappings

```

Here we control the mapping calculations for the nodes of s-channel subgraphs. We start with the nodes with the smallest number of subtree nodes and always increase this number by two because nodes have exactly zero or two daughter nodes. We create the `k_nodes` using the `k_node_list` of each `f_node`. The number of nodes which have to be created depends of the number of existing daughter nodes, which means that we have to create a node for each combination of existing and valid (the ones which we `keep`) daughter nodes. If the node corresponds to an external particle, we create only one node, since there are no daughter nodes. If the particle is not external and the daughter `f_nodes` do not contain any valid `k_nodes`, we do not create a new `k_nodes` either. When

the calculations for all nodes with the same number of subtree nodes have been completed, we compare the valid nodes to eliminate equivalences (see below).

### 19.14.14 Fill the grove list

Find the **grove** within the **grove\_list** for a **kingraph** for which the kinematical calculations and mapping assignments have been completed. The **groves** are defined by the **grove\_prop** entries and the value of the resonance hash (**res\_hash**). Whenever a matching grove does not exist, we create one. In a first step we consider only part of the grove properties (see **grove\_prop\_match**) and the resonance hash is ignored, which leads to a preliminary grove list. In the end all numbers in **grove\_prop** as well as the resonance hash are compared, i.e. we create a new **grove\_list**.

  end if
enddo
end if
end subroutine grove_list_add_feyngraph

```

Compare two `grove_prop` objects. The `.match.` operator is used for preliminary groves in which the `kingraphs` share only the 3 numbers `n_resonances`, `n_log_enhanced` and `n_t_channel`. These groves are only used for comparing the kingraphs, because only graphs within these preliminary groves can be equivalent (the numbers which are compared here are unambiguously fixed by the combination of mappings in these channels).

```

<Cascades2: interfaces>+≡
  interface operator (.match.)
    module procedure grove_prop_match
  end interface operator (.match.)

<Cascades2: procedures>+≡
  function grove_prop_match (grove_prop1, grove_prop2) result (gp_match)
    type (grove_prop_t), intent (in) :: grove_prop1
    type (grove_prop_t), intent (in) :: grove_prop2
    logical :: gp_match
    gp_match = (grove_prop1%n_resonances == grove_prop2%n_resonances) &
      .and. (grove_prop1%n_log_enhanced == grove_prop2%n_log_enhanced) &
      .and. (grove_prop1%n_t_channel == grove_prop2%n_t_channel)
  end function grove_prop_match

```

The equal operator on the other hand will be used when all valid `kingraphs` have been created and mappings have been determined, to split up the existing (preliminary) grove list, i.e. to create new groves which are determined by all entries in `grove_prop_t`.

```

<Cascades2: interfaces>+≡
  interface operator (==)
    module procedure grove_prop_equal
  end interface operator (==)

<Cascades2: procedures>+≡
  function grove_prop_equal (grove_prop1, grove_prop2) result (gp_equal)
    type (grove_prop_t), intent (in) :: grove_prop1
    type (grove_prop_t), intent (in) :: grove_prop2
    logical :: gp_equal
    gp_equal = (grove_prop1%res_hash == grove_prop2%res_hash) &
      .and. (grove_prop1%n_resonances == grove_prop2%n_resonances) &
      .and. (grove_prop1%n_log_enhanced == grove_prop2%n_log_enhanced) &
      .and. (grove_prop1%n_off_shell == grove_prop2%n_off_shell) &

```

```

        .and. (grove_prop1%multiplicity == grove_prop2%multiplicity) &
        .and. (grove_prop1%n_t_channel == grove_prop2%n_t_channel)
    end function grove_prop_equal

```

### 19.14.15 Remove equivalent channels

Here we define the equivalence condition for completed **kingraphs**. The aim is to keep those **kingraphs** which describe the strongest peaks of the amplitude. The **bincodes** and **mappings** have to be the same for an equivalence, but the **pdgs** can be different. At the same time we check if the trees are exactly the same (up to the sign of pdg codes) in which case we do not keep both of them. This can be the case when the incoming particles are the same or their mutual anti-particles and there are no t-channel lines in the Feynman diagram to which the kingraph belongs.

```

<Cascades2: parameters>+=

```

        eqv = .true.
    end if
end function kingraph_eqv

```

Select between two **kingraphs** which fulfill the equivalence condition above. This is done by comparing the **pdg** values of the **tree** for increasing bincode. If the particles are different at some place, we usually choose the one which would be returned first by the subroutine **match\_vertex** of the model for the daughter **pdg** codes. Since we work here only on the basis of the **trees** of the completed **kingraphs**, we have to use the **bc** array to determine the positions of the daughter nodes' entries in the array. The graph which has to be kept should correspond to the stronger peak at the place which is compared.

end subroutine kinggraph_select

```

At the beginning we do not care about the resonance hash, but only about part of the grove properties, which is defined in `grove_prop_match`. In these resulting preliminary groves the kingraphs can be equivalent, i.e. we do not have to compare all graphs with each other but only all graphs within each of these preliminary groves. In the end we create a new grove list where the grove properties of the `kingraphs` within a `grove` have to be exactly the same and in addition the groves are distinguished by the resonance hash values. Here the kingraphs are not compared any more, which means that the number of channels is not reduced any more.

### 19.14.17 Invert a graph

All Feynman diagrams given by O'Mega look like a decay. The `feyngraph` which is constructed from this output also looks like a decay, where one of the incoming particles is the decaying particle (or the root of the tree). The calculations can in principle be done on this data structure. However, it is also performed with the other incoming particle as the root. The first part of the calculation is the same for both cases. For the second part we need to transform/turn the graphs such that the other incoming particle becomes the root. This is done by identifying the incoming particles from the O'Mega output (the first one is simply the root of the existing tree, the second contains [2] in the `particle_label`) and the nodes/particles which connect both incoming particles (here we set `t.line = .true.`). At the same time we set the pointers `inverse_daughter1` and `inverse_daughter2` for the corresponding node, which

point to the mother node and the other daughter of the mother node; these will be the daughters of the node in the inverted feyngraph.

```

## Chapter 20

# VEGAS Integration

The backbone integrator of WHIZARD is a object-oriented implemetation of the VEGAS algorithm.

```
<vegas.f90>≡  
  <File header>  
  
  module vegas  
    <Use kinds>  
  
    <vegas: modules>  
  
    <Standard module head>  
  
    <vegas: public>  
  
    <vegas: parameters>  
  
    <vegas: types>  
  
    <vegas: interfaces>  
  
    contains  
  
    <vegas: procedures>  
  
  end module vegas  
<vegas: modules>≡  
  use diagnostics  
  use io_units  
  use format_utils, only: write_indent  
  use format_defs, only: FMT_17  
  use rng_base, only: rng_t  
  use rng_stream, only: rng_stream_t  
  
MPI Module.  
<MPI: vegas: modules>≡  
  use request_callback, only: request_handler_t  
  use mpi_f08 !NODEP!
```

## 20.1 Integration modes

VEGAS operates in three different modes: `vegas_mode_importance_only`, `vegas_mode_importance` or `vegas_mode_stratified`. The default mode is `vegas_mode_importance`, where the algorithm decides whether if it is possible to use importance sampling or stratified sampling. In low dimensions VEGAS uses strict stratified sampling.

```
<vegas: parameters>≡  
  integer, parameter, public :: VEGAS_MODE_IMPORTANCE = 0, &  
    & VEGAS_MODE_STRATIFIED = 1, VEGAS_MODE_IMPORTANCE_ONLY = 2
```

## 20.2 Type: `vegas_func_t`

We define a abstract `func` type which only gives an interface to an `evaluate` procedure. The inside of implementation and also the optimization of are not a concern of the `vegas` implementation.

```
<vegas: public>≡  
  public :: vegas_func_t  
  
<vegas: types>≡  
  type, abstract :: vegas_func_t  
    !  
    contains  
    procedure(vegas_func_evaluate), deferred, pass, public :: evaluate  
  end type vegas_func_t
```

The only procedure called in `vegas` is `vegas_func_evaluate`. It takes a real value `x` and returns a real value `f`.

```
<vegas: interfaces>≡  
  abstract interface  
    real(default) function vegas_func_evaluate (self, x) result (f)  
      import :: default, vegas_func_t  
      class(vegas_func_t), intent(inout) :: self  
      real(default), dimension(:), intent(in) :: x  
    end function vegas_func_evaluate  
  end interface
```

## 20.3 Type: `vegas_config_t`

We store the complete configuration in a transparent container. The `vegas_config_t` object inside VEGAS must not be directly accesible. We provide a `get` method which returns a copy of the `vegas_config_t` object.

Apart from the options which can be set by the constructor of `vegas_t` object, we store the run-time configuration `n_calls`, `calls_per_box`, `n_bins` and `n_boxes`. Those are calculated and set accordingly by VEGAS.

```
<vegas: public>+≡  
  public :: vegas_config_t
```

```

<vegas: types>+≡
  type :: vegas_config_t
    integer :: n_dim = 0
    real(default) :: alpha = 1.5
    integer :: n_bins_max = 50
    integer :: iterations = 5
    integer :: mode = VEGAS_MODE_STRATIFIED
    integer :: calls_per_box = 0
    integer :: n_calls = 0
    integer :: n_calls_min = 20
    integer :: n_boxes = 1
    integer :: n_bins = 1
  contains
    <vegas: vegas config: TBP>
  end type vegas_config_t

```

Write out the configuration of the grid.

```

<vegas: vegas config: TBP>≡
  procedure, public :: write => vegas_config_write

<vegas: procedures>≡
  subroutine vegas_config_write (self, unit, indent)
    class(vegas_config_t), intent(in) :: self
    integer, intent(in), optional :: unit
    integer, intent(in), optional :: indent
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent

    write (u, "(2x,A,I0)" &
        & "Number of boxes" = ", self%n_boxes
end subroutine vegas_config_write

```

## 20.4 Type: vegas\_grid\_t

We provide a simple and transparent grid container. The container can then later be used, to export the actual grid.

```

<vegas: public>+≡
    public :: vegas_grid_t

<vegas: types>+≡
    type :: vegas_grid_t
        integer :: n_dim = 1
        integer :: n_bins = 1
        real(default), dimension(:), allocatable :: x_lower
        real(default), dimension(:), allocatable :: x_upper
        real(default), dimension(:), allocatable :: delta_x
        real(default), dimension(:,:), allocatable :: xi
    contains
        <vegas: vegas_grid: TBP>
    end type vegas_grid_t

```

Initialise grid.

```

<vegas: interfaces>+≡
    interface vegas_grid_t
        module procedure vegas_grid_init
    end interface vegas_grid_t

<vegas: procedures>+≡
    type(vegas_grid_t) function vegas_grid_init (n_dim, n_bins_max) result (self)
        integer, intent(in) :: n_dim
        integer, intent(in) :: n_bins_max
        self%n_dim = n_dim
        self%n_bins = 1
        allocate (self%x_upper(n_dim), source=1.0_default)
        allocate (self%x_lower(n_dim), source=0.0_default)
        allocate (self%delta_x(n_dim), source=1.0_default)

    yorn = yorn .and. all (grid_a%xi == grid_b%xi)
  end function vegas_grid_equal

```

Resize each bin accordingly to its corresponding weight  $w$ . Can be used to resize the grid to a new size of bins or refinement.

The procedure expects two arguments, firstly, `n_bins` and, secondly, the refinement weights  $w$ . If `n_bins` differs from the internally stored one, we resize the grid under consideration of  $w$ . If each element of  $w$  equals one, then the bins are resized preserving their original bin density.

Anytime else, we refine the grid accordingly to  $w$ .

```

<vegas: vegas_grid: TBP>+≡
  procedure, private :: resize => vegas_grid_resize

<vegas: procedures>+≡

        ! Move division to the end, which is more efficient.
        if (g /= 0) g = 1 / g
    end function vegas_grid_get_probability

```

Broadcast the grid information. As safety measure, we get the actual grid object from VEGAS (correctly allocated, but for non-root unfilled) and broadcast the root object. On success, we set grid into VEGAS.

We use the non-blocking broadcast routine, because we have to send quite a bunch of integers and reals.

We have to be very careful with `n_bins`, the number of bins can actually change during different iterations. If we reuse a grid, we have to take that, every grid uses the same `n_bins`. We expect, that the number of dimension does not change, which is in principle possible, but will be checked onto in `vegas_set_grid`.

## 20.5 Type: vegas\_result\_t

We store the result of the latest iteration(s) in a transparent container. The `vegas_result_t` object inside VEGAS must not be directly accessible. We export the a copy of the result via a get-method of the `vegas_t` object.

We store latest event weight in `evt_weight` and a (possible) evebt weight excess in `evt_weight_excess`, if the event weight is larger than `max_abs_f`.

```

<vegas: public>+≡
  public :: vegas_result_t

Update results and efficiency.

We define

$$\max_x w(x) = \frac{f(x)}{p(x)} \Delta_{\text{jac}}. \quad (20.1)$$

In the implementation we have to factor out `n_calls` in the jacobian. Also, during event generation.

## 20.7 Type: vegas\_t

The VEGAS object contains the methods for integration and grid resize- and refinement. We store the grid configuration and the (current) result in transparent

containers alongside with the actual grid and the distribution.

The values of the distribution depend on the chosen mode whether the function value or the variance is stored. The distribution is used after each iteration to refine the grid.

```

<vegas: public>+≡
    public :: vegas_t

<vegas: types>+≡
    type :: vegas_t
    private
    type(vegas_config_t) :: config
    real(default) :: hypercube_volume = 0.
    real(default) :: jacobian = 0.
    real(default), dimension(:, :), allocatable :: d
    type(vegas_grid_t) :: grid
    integer, dimension(:), allocatable :: bin
    integer, dimension(:), allocatable :: box
    type(vegas_result_t) :: result
<vegas: vegas: type>
    contains
<vegas: vegas: TBP>
end type vegas_t

```

Add members for MPI communication and parallel mode. Must be set before calling to `vegas_integrate`, likewise `vegas_set_calls`.

```

<MPI: vegas: vegas: type>≡
    type(MPI_COMM) :: comm
    logical :: parallel_mode = .false.

```

We overload the type constructor of `vegas_t` which initialises the mandatory argument `n_dim` and allocate memory for the grid.

```

<vegas: interfaces>+≡
    interface vegas_t
        module procedure vegas_init
    end interface vegas_t

<vegas: procedures>+≡

```

## 20.9 Grid resize- and refinement

Before integration the grid itself must be initialised. Given the number of `n_calls` and `n_dim` we prepare the grid for the integration.

The grid is binned according to the VEGAS mode and `n_calls`. If the mode is not set to `vegas_importance_only`, the grid is divided in to equal boxes. We try for 2 calls per box

$$boxes = \sqrt[n_{dim}]{\frac{calls}{2}}. \quad (20.2)$$

If the numbers of boxes exceeds the number of bins, which is the case for low dimensions, the algorithm switches to stratified sampling. Otherwise, we are still using importance sampling, but keep the boxes for book keeping. If the number of bins changes from the previous invocation, bins are expanded or contracted accordingly, while preserving bin density.

```

(vegas: vegas: TBP)+≡
  procedure, private :: init_grid => vegas_init_grid

(vegas: procedures)+≡
  subroutine vegas_init_grid (self)
    class(vegas_t), intent(inout) :: self
    integer :: n_bins, n_boxes, box_per_bin, n_total_boxes
    real(default), dimension(:, :), allocatable :: w
    n_bins = self%config%n_bins_max
    n_boxes = 1
    if (self%config%mode /= VEGAS_MODE_IMPORTANCE_ONLY) then
      ! We try for 2 calls per box
      n_boxes = max (floor ((self%config%n_calls / 2.)*(1. / self%config%n_dim)), 1)
      self%config%mode = VEGAS_MODE_IMPORTANCE
      if (2 * n_boxes >= self%config%n_bins_max) then
        ! if n_bins/box < 2
        box_per_bin = max (n_boxes / self%config%n_bins_max, 1)
        n_bins = min (n_boxes / box_per_bin, self%config%n_bins_max)
        n_boxes = box_per_bin * n_bins
        self%config%mode = VEGAS_MODE_STRATIFIED
      end if
    end if
  end subroutine vegas_init_grid

```

```

end if
n_total_boxes = n_boxes**self%config%n_dim
self%config%calls_per_box = max (floor (real (self%config%n_calls) / n_total_boxes), 2)
self%config%n_calls = self%config%calls_per_box * n_total_boxes
! Total volume of x-space/(average n_calls per bin)

  call self%grid%resize (n_bins, w)
  self%config%n_bins = n_bins
end if
end subroutine vegas_init_grid

```

Reset the cumulative result, and efficiency and max. grid values.

```

<vegas: vegas: TBP>+≡
  procedure, public :: reset_result => vegas_reset_result

<vegas: procedures>+≡
  subroutine vegas_reset_result (self)
    class(vegas_t), intent(inout) :: self
    call self%result%reset ()
  end subroutine vegas_reset_result

```

Reset the grid. Purge the adapted grid and the distribution. Furthermore, reset the results. The maximal size of the grid remains.

Note: Handle `vegas_reset_grid` with great care! Instead of reusing an old object, create a new one.

```

<vegas: vegas: TBP>+≡
  procedure, public :: reset_grid => vegas_reset_grid

<vegas: procedures>+≡
  subroutine vegas_reset_grid (self)
    class(vegas_t), intent(inout) :: self
    self%config%n_bins = 1
    self%d = 0._default
    self%grid%xi = 0._default
    self%grid%xi(1, :) = 0._default
    self%grid%xi(2, :) = 1._default
    call self%reset_result ()
  end subroutine vegas_reset_grid

```

Refine the grid to match the distribution `d`.

Average the distribution over neighbouring bins, then contract or expand the bins. The averaging dampens high fluctuations among the integrand or the variance.

We make the type-bound procedure public accessible because the multi-channel integration refines each grid after integration over all grids.

```

<vegas: vegas: TBP>+≡
  procedure, public :: refine => vegas_refine_grid

```

```

<vegas: procedures>+≡
  subroutine vegas_refine_grid (self, average)
    class(vegas_t), intent(inout) :: self
    logical, intent(in), optional :: average
    logical :: opt_average
    opt_average = .true.; if (present (average)) opt_average = average
    if (opt_average) call self%average_distribution ()
    call self%grid%resize (self%config%n_bins, self%d(:self%config%n_bins, :))
  end subroutine vegas_refine_grid

```

We average the collected values  $d$  of the (sq.) weighted  $f$  over neighbouring bins. The averaged  $d$  are then again damped by a logarithm to enhance numerical stability. The results are then the refinement weights  $w$ .

We have to take care of the special case where we have a very low sampling rate. In those cases we can not be sure that the distribution is satisfying filled, although we have already averaged over neighbouring bins. This will lead to a squashing of the unfilled bins and such the boundaries of those will be pushed together. We circumvent this problem by setting those unfilled bins to the smallest representable value of a default real.

The problem becomes very annoying in the multi-channel formulae where have to look up via binary search the corresponding probability of  $x$  and if the width is zero, the point will be neglected.

Another issue arises when NaNs appear during sampling. A single NaN may spoil the complete adaption as the refinement depends on all weights for a single axis, c.f. `vegas_grid_resize` for the details of the mechanism. Therefore, if we find a single (or more) NaNs in the distribution of an axis, then we won't adapt that specific axis by setting the weights to one. Hence, we skip the adaption for parts of the grid, where NaN appeared during evaluation.

```

```

## 20.10 Integration

Integrate `func`, in the previous set bounds `x.lower` to `x.upper`, with `n.calls`. Use results from previous invocations of `integrate` with `opt.reset.result = .false.` and better with subsequent calls.

Before we walk through the hybercube, we initialise the grid (at a central position).

We step through the (equidistant) boxes which ensure we do not miss any place in the  $n$ -dim. hypercube. In each box we sample `calls_per_box` random points and transform them to bin coordinates. The total integral and the total (sample) variance over each box  $i$  is then calculated by

$$E(I)_i = \sum_j^{\text{calls per box}} I_{i,j},$$

$$V(I)_i = \text{calls per box} \frac{\sum_j^{\text{calls per box}^2} I_{i,j}^2}{I} - \left( \sum_j^{\text{calls per box}} I_{i,j} \right) * 2 \frac{\text{calls per box}}{\text{calls per box} - 1}.$$

The stratification of the  $n$ -dimensional hybercube allows a simple parallelisation of the algorithm (R. Kreckel, "Parallelization of adaptive MC integrators", Computer Physics Communications, vol. 106, no. 3, pp. 258–266, Nov. 1997.). We have to ensure that all boxes are sampled, but the number of boxes to distribute is too large. We allow each thread to sample a fraction  $r$  of all boxes  $k$  such that  $r \ll k$ . Furthermore, we constrain that the number of process  $p$  is much smaller than  $r$ .

The overall constraint is

$$p \ll r \ll k. \quad (20.3)$$

We divide the integration into a parallel and a perpendicular subspace. The number of parallel dimensions is  $D_{\parallel} = \lfloor \frac{D}{2} \rfloor$ .

end subroutine increment_box_coord

```

We parallelize VEGAS in simple forward manner. The hyper-cube is dissambled in to equidistant boxes in which we sample the integrand `calls_per_box` times. The workload of calculating those boxes is distributed along the worker.

The number of dimensions which will be parallelised are  $\lfloor \frac{D}{2} \rfloor$ , such MPI Variables for `vegas_integrate`. We have to duplicate all buffers for `MPI_Ireduce`, because we cannot use the same send or receive buffer.

We temporarily store a (empty) grid, before communicating.

*(MPI: vegas: vegas integrate: variables)*≡

```

integer :: rank
logical :: parallel_mode
type(vegas_grid_t) :: grid

```

MPI procedure-specific initialization.

Allow for (external) veto on parallel mode.

*(MPI: vegas: vegas integrate: init)*≡

```

parallel_mode = self%parallel_mode .and. self%is_parallelizable ()
if (parallel_mode) then
  call MPI_Comm_size (self%comm, n_size)
  call MPI_Comm_rank (self%comm, rank)
else
  n_size = 1
  rank = 0
end if

```

Pre-sampling communication.

We make a copy of the (actual) grid, which is unfilled when non-root. The actual grid is then broadcasted among the workers and inserted into the VEGAS object.

*(MPI: vegas: vegas integrate: presampling)*≡

```

if (parallel_mode) then
  grid = self%get_grid ()
  call grid%broadcast (self%comm)
  call self%set_grid (grid)

```

Start index of the boxes for different ranks. If the random number generator is `RngStream`, we can advance the current stream in such a way, that we will getting matching numbers. Iff `n_boxes` is larger than 2, otherwise parallelization is useless.

```

Generate weighted random event.

The weight given by the overall jacobian

$$\Delta_{\text{jac}} = \prod_{j=1}^d (x_j^+ - x_j^-) \frac{N_{\text{bins}}^d}{N_{\text{calls}}} \quad (20.4)$$

includes the overall non-changing factors  $\frac{1}{N_{\text{calls}}}$ -factor (divisions are expensive) and  $N_{\text{bins}}^d$ , the latter combined with `bin_volume` gives rise to the probability, see `vegas_init_grid` for details. We have to factor out  $N_{\text{calls}}$  to retrieve the correct weight.

*<vegas: vegas: TBP>+≡*

Test module, followed by the corresponding implementation module.

(`vegas.ut.f90`)≡

```

    <File header>

    module vegas_ut
        use unit_tests
        use vegas_util

    <Standard module head>

    <vegas: public test>

    contains
    <vegas: test driver>
    end module vegas_ut

<vegas_util.f90>≡
    <File header>

    module vegas_util
    <Use kinds>
        use io_units
        use constants, only: pi
        use format_defs, only: FMT_10, FMT_12
        use rng_base
        use rng_stream
        use vegas

    <Standard module head>

    <vegas: test declaration>

    <vegas: test types>

    contains
    <vegas: tests>
    end module vegas_util
API: driver for the unit tests below.
<vegas: public test>≡
    public :: vegas_test
<vegas: test driver>≡
    subroutine vegas_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
        <vegas: execute tests>
    end subroutine vegas_test

```

## Test function

We use the example from the Monte Carlo Examples of the GSL library

$$I = \int_{-pi}^{+pi} dk_x / (2pi) \int_{-pi}^{+pi} dk_y / (2pi) \int_{-pi}^{+pi} dk_z / (2pi) 1 / (1 - \cos(k_x) \cos(k_y) \cos(k_z)). \quad (20.6)$$

The integral is reduced to region  $(0,0,0) \rightarrow (\pi, \pi, \pi)$  and multiplied by 8.

```

<vegas: test types>≡
  type, extends (vegas_func_t) :: vegas_test_func_t
  !
  contains
    <vegas: vegas test func: TBP>
  end type vegas_test_func_t

```

Evaluate the integrand.

```

<vegas: vegas test func: TBP>≡
  procedure, public :: evaluate => vegas_test_func_evaluate

<vegas: tests>≡
  real(default) function vegas_test_func_evaluate (self, x) result (f)
    class(vegas_test_func_t), intent(inout) :: self
    real(default), dimension(:), intent(in) :: x
    f = 1.0 / (pi**3)
    f = f / ( 1.0 - cos (x(1)) * cos (x(2)) * cos (x(3)))
  end function vegas_test_func_evaluate

```

The second test function is the normalised n-dim. gaussian distribution.

```

<vegas: test types>+≡
  type, extends (vegas_func_t) :: vegas_gaussian_test_func_t
  !
  contains
    <vegas: vegas gaussian test func: TBP>
  end type vegas_gaussian_test_func_t

```

Evaluate the integrand.

```

<vegas: vegas gaussian test func: TBP>≡
  procedure, public :: evaluate => vegas_gaussian_evaluate

<vegas: tests>+≡
  real(default) function vegas_gaussian_evaluate (self, x) result (f)
    class(vegas_gaussian_test_func_t), intent(inout) :: self
    real(default), dimension(:), intent(in) :: x
    real(default), parameter :: inv_sqrt_pi = 1._default / sqrt(pi)
    f = inv_sqrt_pi**size (x)
    f = f * exp (- dot_product(x, x))
  end function vegas_gaussian_evaluate

```

The third test function is a three-dimensional polynomial function which factorises. The function is defined in such a way that the integral in the unit range is normalised to zero.

$$f(x) = -\frac{8}{3}(x+1)*(y-1)*z \quad (20.7)$$

```

<vegas: test types>+≡
  type, extends (vegas_func_t) :: vegas_polynomial_func_t
  !
  contains
    <vegas: vegas polynomial func: TBP>
  end type vegas_polynomial_func_t

```

```

<vegas: vegas polynomial func: TBP>≡
    procedure, public :: evaluate => vegas_polynomial_evaluate

<vegas: tests>+≡
    real(default) function vegas_polynomial_evaluate (self, x) result (f)
        class(vegas_polynomial_func_t), intent(inout) :: self
        real(default), dimension(:), intent(in) :: x
        f = - 8. / 3. * (x(1) + 1.) * (x(2) - 1.) * x(3)
    end function vegas_polynomial_evaluate

```

## MC Integrator check

Initialise the VEGAS MC integrator and call to `vegas_init_grid` for the initialisation of the grid.

### 20.13.1 Type: `vamp2_func_t`

We extend `vegas_func_t` with the multi-channel weights and the `vegas_grid_t`, such that, the overall multi-channel weight can be calculated by the function itself.

We add an additional logical `valid_x`, if it is set to `.false.`, we do not compute weighted function and just set the weighted integrand to zero. This behavior is in particular very useful, if a mapping is prohibited or fails. Or in the case of WHIZARD, a phase cut is applied.

```

### 20.13.2 Type: `vamp2_config_t`

This is a transparent container which incorporates and extends the definitions in `vegas_config`. The parent object can then be used to parametrise the VEGAS grids directly, where the new parameters are exclusively used in

the multi-channel implementation of VAMP2. `n_calls_min` is calculated by `n_calls_min_per_channel` and `n_channel`. The channels weights (and the result `n_calls` for each channel) are calculated regarding `n_calls_threshold`.

```

Adapt. We adapt the weights due the contribution of variances with  $\beta > 0$ .

$$\alpha_i = \frac{\alpha_i V_i^\beta}{\sum_i \alpha_i V_i^\beta} \quad (20.9)$$

If `n.calls.threshold` is set, we rescale the weights in such a way, that the `n.calls` for each channel are greater than `n.calls.threshold`. We calculate the distance of the weights to the `weight_min` and reset those weights which are less than `weight_mins` to this value. The other values are accordingly resized to fit the boundary condition of the partition of unity.

```

Integrate. We integrate each channel separately and combine the results

$$I = \sum_i \alpha_i I_i, \quad (20.10)$$

$$\sigma^2 = \sum_i \alpha_i^2 \sigma_i^2. \quad (20.11)$$

Although, the (population) variance is given by

$$\begin{aligned}
\sigma^2 &= \frac{1}{N} \left( \sum_i \alpha_i I_i^2 - I^2 \right) \\
&= \frac{1}{N-1} \left( \sum_i (N_i \sigma_i^2 + I_i^2) - I^2 \right) \\
&= \frac{1}{N-1} \left( \sum_i \alpha_i \sigma_i^2 + \alpha_i I_i^2 - I^2 \right),
\end{aligned} \tag{20.12}$$

where we used  $\sigma_i^2 = \frac{1}{N} (\langle I_i^2 \rangle - \langle I_i \rangle^2)$ , we use the approximation for numeric stability. The population variance relates to sample variance

$$s^2 = \frac{n}{n-1} \sigma^2, \tag{20.13}$$

which gives an unbiased error estimate.

Beside those adaption to multichannel, the overall processing of `total_integral`, `total_sq_integral` and `total_variance` is the same as in `vegas_integrate`.

      !! Do not descent into channel integration (later on).
      call req%handle_workload ()
    end select
  end if
```

Conditional handling for the MPI-version of sampling.

We have a request object and an advanced `channel_iterator` and have to consider three cases:

1. `channel_iterator` drained,
2. `request` terminated,
3. `request` received.

When the `channel_iterator` is drained by `update_iter_and_rng`, we send a terminate request to the master and await in the next cycle of channel loop the terminated request. When the request is terminated, we can gracefully exit the channel loop as `channel_iterator` and `rng` are already advanced by `update_iter_and_rng`. When we received a genuine request, then, we proceed as prophesied.

Generate unweighted events.

After selecting a channel  $ch$  by the inversion method using a random number  $r \in [0, 1]$

$$F^{-1}(r) := \inf\{c \in \{1, \dots, N_c\} | F(c) \geq r\}, F(c) = \sum_{c' \leq c} \alpha'_{c'}, \quad (20.14)$$

we try for an event from the previously selected channel. If the event is rejected, we also reject the selected channel.

The inversion method is implemented as a loop over the channel weights  $\alpha_i$  until  $\sum_c^{c^{prime}} \alpha_c - r \leq 0$ , the last value of the loop index `ch` is then  $c'$ .

```

Prepare event generation. We have to set the channel weights and the grids for

the integrand's object.

We use an ansatz proposed by T. Ohl in the original VAMP code where we do not have to accept on

$$\frac{w_i(x)}{\sum_i \alpha_i \max_x w_i(x)},$$

after we have selected a channel by the weights  $\alpha_i$ . But rather, we use a more efficient way where we rescale the channel weights  $\alpha_i$

$$\alpha_i \rightarrow \alpha_i \frac{\max_x w_i(x)}{\sum_i \alpha_i \max_x w_i(x)}.$$

The overall magic is to insert a "1" and to move the uneasy part into the channel selection, such that we can generate events likewise in the single channel mode. We generate an unweighted event by

$$\frac{w_i(x)}{\max_x w_i x},$$

after we have selected a channel by the rescaled event channel weights. The overall normalization  $\max_{i,x}$  is not needed because we normalize the event channel weights to one and therefore the overall normalization cancels.

```
<vamp2: vamp2 generate event: procedures>≡
subroutine prepare_event ()
  integer :: i
  self%event_prepared = .false.
  do i = 1, self%config%n_channel
    func%wi(i) = self%weight(i)
    func%grids(i) = self%integrator(i)%get_grid ()
  end do
  if (any (self%integrator%get_max_abs_f () > 0)) then
    self%event_weight = self%weight * self%integrator%get_max_abs_f ()
  else
    self%event_weight = self%weight
  end if
  self%event_weight = self%event_weight / sum (self%event_weight)
  self%event_prepared = .true.
end subroutine prepare_event
```

## Test function

We use the example from the Monte Carlo Examples of the GSL library

$$I = \int_{-pi}^{+pi} dk_x / (2pi) \int_{-pi}^{+pi} dk_y / (2pi) \int_{-pi}^{+pi} dk_z / (2pi) 1 / (1 - \cos(k_x) \cos(k_y) \cos(k_z)). \quad (20.15)$$

The integral is reduced to region  $(0,0,0) \rightarrow (\pi, \pi, \pi)$  and multiplied by 8.

```

<vamp2: test types>≡
    type, extends (vamp2_func_t) :: vamp2_test_func_t
    !
    contains
    <vamp2: vamp2 test func: TBP>

## 20.15 MPI Request

**Request** Direct interface for requests.

**Balancer** Subliary interfaces and types for implementation into **request**.

**Callback** Direct interface for non-blocking communication in callback fashion used in subsidiary in **request**.

### 20.15.1 Request Base

**request** Container type for current request, contains handler index and status of request.

**request group cache** Caching for communicator groups, tries to reduce the costly calls to `MPI_CREATE_COMM_GROUP`.

**request base** Base type for request handling, defines procedures and basic request scheme for direct implementation into **VAMP2**.

When a data type has an associated communicator field, it always must duplicate the communicator in order to ensure communication encapsulation. Only in special case (e.g. outside of object communication is required) the parent communicator should be directly used. For example, that is the case for the group cache, as it exports its newly created communicator to the outside of the request library.

!> Base type for requesting and back calling.
!!
!! A short remark on the semantics of point-to-point communication (as its intended use in this
!! MPI is strict regarding the order of the messages (for blocking communication), as those can
!! For non-blocking communication, the standard extends it such that the order depends on "the e
!! The non-overtaking requirement is then extended to this definition of order.
!!
!! Color method for tracking communication?
!! We restrict each slave to a single callback (at once), which can communicate during the next
!! Before handling the next (current) callback, the former one has to finish (with a wait call o
!! On the server-side, we only test on the finishing, reporting a communication failure.
!!
!! Furthermore, the implementation has to take care that the order of the communication calls on
!!
!! Therefore, we need to secure the order of communication calls.
!! First, we let the master initiate all callback communication *before* polling.
!! This fixiates the order.
!! Second, we require that the implementation of the polling honors this order.

### 20.15.7 Request Callback

**request handler** Base type and interface for providing two-sided communication in a callback fashion.

**request handler manager** Manages handler with a binary tree.

(request\_callback.f90)≡

```

module request_callback
  use, intrinsic :: iso_fortran_env, only: ERROR_UNIT
  use binary_tree
  use diagnostics

  use mpi_f08 !NODEP!

  implicit none

  private

  !> Request handler.
  !!
  !! A request handler allows to dispatch an object for communication a priori
  !! for a slave and a master.
  !! Typically, each slave register its own request handles, whereas the master
  !! requests all possible requests handles matching those of the slaves.
  !! The requests can then be used later on, e.g. during a computation, a slave
  !! may add a request to the master worker and starts sending an object.
  !! The master worker looks up the appropriate request handler, which then
  !! closes the communication, i.e. by a receive call.
  !! Most important: Only a pointer to the buffer object is stored, therefore, the calling function
  !! has to ensure, that the communication object (buffer) will not be changed
  !! during a request handle (receive or send).
  !!
  !! Remark: The handler allows for a tag offset which allows to unify the the communication.
  !!         The problem occurs when multiple callback need to be handled simultaneously and MPI needs
  !!         Each message has a tuple of (source, tag, comm) associated, we can unify this tuple
  !!         tag = tag_offset + {1, ..., N_requests} where tag_offsets are multiple of N_requests.
  !!         The latter condition should be checked by a modulo.
  !! What happens if the communication is out of order (is this a problem? check with standard)?

## Chapter 21

# Multi-Channel Integration

The abstract representation of multi-channel Monte Carlo algorithms for integration and event generation.

**Module `mci_base`:** The abstract types and their methods. It provides a test integrator that is referenced in later unit tests.

**iterations** Container for defining integration call and pass settings.

**integration\_results** This module handles results from integrating processes. It records passes and iterations, calculates statistical averages, and provides the user output of integration results.

These are the implementations:

**Module `mci_midpoint`:** A simple integrator that uses the midpoint rule to sample the integrand uniformly over the unit hypercube. There is only one integration channel, so this can be matched only to single-channel phase space.

**Module `mci_vamp`:** Interface for the VAMP package.

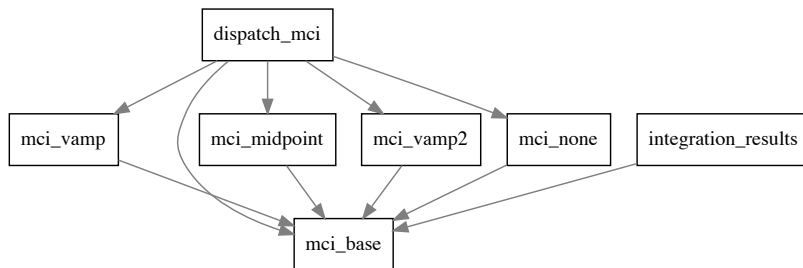

Figure 21.1: Module dependencies in `src/mci`.

## 21.1 Generic Integrator

This module provides a multi-channel integrator (MCI) base type, a corresponding configuration type, and methods for integration and event generation.

```
<mci_base.f90>≡  
  <File header>  
  
  module mci_base  
  
    use kinds  
    use io_units  
    use format_utils, only: pac_fmt  
    use format_defs, only: FMT_14, FMT_17  
    use diagnostics  
    use cputime  
    use phs_base  
    use rng_base  
  
    <Standard module head>  
  
    <MCI base: public>  
  
    <MCI base: types>  
  
    <MCI base: interfaces>  
  
    contains  
  
    <MCI base: procedures>  
  
  end module mci_base
```

### 21.1.1 MCI: integrator

The MCI object contains the methods for integration and event generation. For the actual work and data storage, it spawns an MCI instance object.

The base object contains the number of integration dimensions and the number of channels as configuration data. Further configuration data are stored in the concrete extensions.

The MCI sum contains all relevant information about the integrand. It can be used for comparing the current configuration against a previous one. If they match, we can skip an actual integration. (Implemented only for the VAMP version.)

There is a random-number generator (its state with associated methods) available as `rng`. It may or may not be used for integration. It will be used for event generation.

```
<MCI base: public>≡  
  public :: mci_t  
  
<MCI base: types>≡  
  type, abstract :: mci_t  
    integer :: n_dim = 0
```

```

integer :: n_channel = 0
integer :: n_chain = 0
integer, dimension(:), allocatable :: chain
real(default), dimension(:), allocatable :: chain_weights
character(32) :: md5sum = ""
logical :: integral_known = .false.
logical :: error_known = .false.
logical :: efficiency_known = .false.
real(default) :: integral = 0
real(default) :: error = 0
real(default) :: efficiency = 0
logical :: use_timer = .false.
type(timer_t) :: timer
class(rng_t), allocatable :: rng
contains
  <MCI base: mci: TBP>
end type mci_t

```

Finalizer: the random-number generator may need one.

```

```

Print an informative message when starting integration.

```

<MCI base: mci: TBP>+≡
  procedure (mci_startup_message), deferred :: startup_message
  procedure :: base_startup_message => mci_startup_message

<MCI base: procedures>+≡
  subroutine mci_startup_message (mci, unit, n_calls)
    class(mci_t), intent(in) :: mci
    integer, intent(in), optional :: unit, n_calls
    if (mci%n_chain > 0) then
      write (msg_buffer, "(A,3(1x,I0,1x,A))") &
        "Integrator:", mci%n_chain, "chains,", &
        mci%n_channel, "channels,", &
        mci%n_dim, "dimensions"
    else
      write (msg_buffer, "(A,3(1x,I0,1x,A))") &
        "Integrator:", &
        mci%n_channel, "channels,", &
        mci%n_dim, "dimensions"
    end if
    call msg_message (unit = unit)
  end subroutine mci_startup_message

```

Dump type-specific info to a logfile.

```

<MCI base: mci: TBP>+≡
  procedure(mci_write_log_entry), deferred :: write_log_entry

<MCI base: interfaces>≡
  abstract interface

```

```

subroutine mci_write_log_entry (mci, u)
  import
  class(mci_t), intent(in) :: mci
  integer, intent(in) :: u
end subroutine mci_write_log_entry
end interface

```

In order to avoid dependencies on definite MCI implementations, we introduce a MD5 sum calculator.

```

⟨MCI base: mci: TBP⟩+≡
  procedure(mci_compute_md5sum), deferred :: compute_md5sum
⟨MCI base: interfaces⟩+≡
  abstract interface
    subroutine mci_compute_md5sum (mci, pacify)
      import
      class(mci_t), intent(inout) :: mci
      logical, intent(in), optional :: pacify
    end subroutine mci_compute_md5sum
  end interface

```

Record the index of the MCI object within a process. For multi-component processes with more than one integrator, the integrator should know about its own index, so file names can be unique, etc. The default implementation does nothing, however.

```

⟨MCI base: mci: TBP⟩+≡
  procedure :: record_index => mci_record_index
⟨MCI base: procedures⟩+≡
  subroutine mci_record_index (mci, i_mci)
    class(mci_t), intent(inout) :: mci
    integer, intent(in) :: i_mci
  end subroutine mci_record_index

```

There is no Initializer for the abstract type, but a generic setter for the number of channels and dimensions. We make two aliases available, to be able to override it.

```

⟨MCI base: mci: TBP⟩+≡
  procedure :: set_dimensions => mci_set_dimensions
  procedure :: base_set_dimensions => mci_set_dimensions
⟨MCI base: procedures⟩+≡
  subroutine mci_set_dimensions (mci, n_dim, n_channel)
    class(mci_t), intent(inout) :: mci
    integer, intent(in) :: n_dim
    integer, intent(in) :: n_channel
    mci%n_dim = n_dim
    mci%n_channel = n_channel
  end subroutine mci_set_dimensions

```

Declare particular dimensions as flat. This information can be used to simplify integration. When generating events, the flat dimensions should be sampled with uniform and uncorrelated distribution. It depends on the integrator what to do with that information.

```

<MCI base: mci: TBP>+≡
  procedure (mci_declare_flat_dimensions), deferred :: declare_flat_dimensions

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_declare_flat_dimensions (mci, dim_flat)
      import
      class(mci_t), intent(inout) :: mci
      integer, dimension(:), intent(in) :: dim_flat
    end subroutine mci_declare_flat_dimensions
  end interface

```

Declare particular channels as equivalent, possibly allowing for permutations or reflections of dimensions. We use the information stored in the `phs_channel_t` object array that the phase-space module provides.

(We do not test this here, deferring the unit test to the `mci_vamp` implementation where we actually use this feature.)

```

<MCI base: mci: TBP>+≡
  procedure (mci_declare_equivalences), deferred :: declare_equivalences

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_declare_equivalences (mci, channel, dim_offset)
      import
      class(mci_t), intent(inout) :: mci
      type(phs_channel_t), dimension(:), intent(in) :: channel
      integer, intent(in) :: dim_offset
    end subroutine mci_declare_equivalences
  end interface

```

Declare particular channels as chained together. The implementation may use this array for keeping their weights equal to each other, etc.

The chain array is an array sized by the number of channels. For each channel, there is an integer entry that indicates the corresponding chains. The total number of chains is the maximum value of this entry.

```

<MCI base: mci: TBP>+≡
  procedure :: declare_chains => mci_declare_chains

<MCI base: procedures>+≡
  subroutine mci_declare_chains (mci, chain)
    class(mci_t), intent(inout) :: mci
    integer, dimension(:), intent(in) :: chain
    allocate (mci%chain (size (chain)))
    mci%n_chain = maxval (chain)
    allocate (mci%chain_weights (mci%n_chain), source = 0._default)
    mci%chain = chain
  end subroutine mci_declare_chains

```

Collect channel weights according to chains and store them in the `chain_weights` for output. We sum up the weights for all channels that share the same `chain` index and store the results in the `chain_weights` array.

```

(MCI base: mci: TBP)+≡
  procedure :: collect_chain_weights => mci_collect_chain_weights

(MCI base: procedures)+≡
  subroutine mci_collect_chain_weights (mci, weight)
    class(mci_t), intent(inout) :: mci
    real(default), dimension(:), intent(in) :: weight
    integer :: i, c
    if (allocated (mci%chain)) then
      mci%chain_weights = 0
      do i = 1, size (mci%chain)
        c = mci%chain(i)
        mci%chain_weights(c) = mci%chain_weights(c) + weight(i)
      end do
    end if
  end subroutine mci_collect_chain_weights

```

Check if there are chains.

```

(MCI base: mci: TBP)+≡
  procedure :: has_chains => mci_has_chains

(MCI base: procedures)+≡
  function mci_has_chains (mci) result (flag)
    class(mci_t), intent(in) :: mci
    logical :: flag
    flag = allocated (mci%chain)
  end function mci_has_chains

```

Output of the chain weights, kept separate from the main `write` method.

[The formatting will work as long as the number of chains is less than  $10^{10}$ ...]

```

(MCI base: mci: TBP)+≡
  procedure :: write_chain_weights => mci_write_chain_weights

(MCI base: procedures)+≡
  subroutine mci_write_chain_weights (mci, unit)
    class(mci_t), intent(in) :: mci
    integer, intent(in), optional :: unit
    integer :: u, i, n, n_digits
    character(4) :: ifmt
    u = given_output_unit (unit)
    if (allocated (mci%chain_weights)) then
      write (u, "(1x,A)") "Weights of channel chains (groves):"
      n_digits = 0
      n = size (mci%chain_weights)
      do while (n > 0)
        n = n / 10
        n_digits = n_digits + 1
      end do
      write (ifmt, "(A1,I1)") "I", n_digits
      do i = 1, size (mci%chain_weights)
        write (u, "(3x," // ifmt // ",F13.10)") i, mci%chain_weights(i)
      end do
    end if
  end subroutine mci_write_chain_weights

```

```

        end do
    end if
end subroutine mci_write_chain_weights

```

Set the MD5 sum, independent of initialization.

```

<MCI base: mci: TBP>+≡
    procedure :: set_md5sum => mci_set_md5sum
<MCI base: procedures>+≡
    subroutine mci_set_md5sum (mci, md5sum)
        class(mci_t), intent(inout) :: mci
        character(32), intent(in) :: md5sum
        mci%md5sum = md5sum
    end subroutine mci_set_md5sum

```

Initialize a new integration pass. This is not necessarily meaningful, so we provide an empty base method. The `mci_vamp` implementation overrides this.

```

<MCI base: mci: TBP>+≡
    procedure :: add_pass => mci_add_pass
<MCI base: procedures>+≡
    subroutine mci_add_pass (mci, adapt_grids, adapt_weights, final_pass)

    end subroutine mci_add_pass

```

Allocate an instance with matching type. This must be deferred.

```

<MCI base: mci: TBP>+≡
    procedure (mci_allocate_instance), deferred :: allocate_instance
<MCI base: interfaces>+≡
    abstract interface
        subroutine mci_allocate_instance (mci, mci_instance)
            import
            class(mci_t), intent(in) :: mci
            class(mci_instance_t), intent(out), pointer :: mci_instance
        end subroutine mci_allocate_instance
    end interface

```

Import a random-number generator. We transfer the allocation of an existing generator state into the object. The generator state may already be initialized, or we can reset it by its `init` method.

```

<MCI base: mci: TBP>+≡
    procedure :: import_rng => mci_import_rng
<MCI base: procedures>+≡
    subroutine mci_import_rng (mci, rng)
        class(mci_t), intent(inout) :: mci
        class(rng_t), intent(inout), allocatable :: rng
        call move_alloc (rng, mci%rng)
    end subroutine mci_import_rng

```

Activate or deactivate the timer.

```

<MCI base: mci: TBP>+≡
  procedure :: set_timer => mci_set_timer

<MCI base: procedures>+≡
  subroutine mci_set_timer (mci, active)
    class(mci_t), intent(inout) :: mci
    logical, intent(in) :: active
    mci%use_timer = active
  end subroutine mci_set_timer

```

Start and stop signal for the timer, if active. The elapsed time can then be retrieved from the MCI record.

```

<MCI base: mci: TBP>+≡
  procedure :: start_timer => mci_start_timer
  procedure :: stop_timer => mci_stop_timer

<MCI base: procedures>+≡
  subroutine mci_start_timer (mci)
    class(mci_t), intent(inout) :: mci
    if (mci%use_timer) call mci%timer%start ()
  end subroutine mci_start_timer

  subroutine mci_stop_timer (mci)
    class(mci_t), intent(inout) :: mci
    if (mci%use_timer) call mci%timer%stop ()
  end subroutine mci_stop_timer

```

Sampler test. Evaluate the sampler a given number of times. Results are discarded, so we don't need the MCI instance which would record them.

The evaluation channel is iterated, and the *x* parameters are randomly chosen.

```

<MCI base: mci: TBP>+≡
  procedure :: sampler_test => mci_sampler_test

<MCI base: procedures>+≡
  subroutine mci_sampler_test (mci, sampler, n_calls)
    class(mci_t), intent(inout) :: mci
    class(mci_sampler_t), intent(inout), target :: sampler
    integer, intent(in) :: n_calls
    real(default), dimension(:), allocatable :: x_in, f
    real(default), dimension(:,:), allocatable :: x_out
    real(default) :: val
    integer :: i, c
    allocate (x_in (mci%n_dim))
    allocate (f (mci%n_channel))
    allocate (x_out (mci%n_dim, mci%n_channel))
    do i = 1, n_calls
      c = mod (i, mci%n_channel) + 1
      call mci%rng%generate_array (x_in)
      call sampler%evaluate (c, x_in, val, x_out, f)
    end do
  end subroutine mci_sampler_test

```

Integrate: this depends on the implementation. We foresee a pacify flag to take care of small numerical noise on different platforms.

```

(MCI base: mci: TBP)+≡
  procedure (mci_integrate), deferred :: integrate

(MCI base: interfaces)+≡
  abstract interface
    subroutine mci_integrate (mci, instance, sampler, &
      n_it, n_calls, results, pacify)
    import
    class(mci_t), intent(inout) :: mci
    class(mci_instance_t), intent(inout), target :: instance
    class(mci_sampler_t), intent(inout), target :: sampler
    integer, intent(in) :: n_it
    integer, intent(in) :: n_calls
    logical, intent(in), optional :: pacify
    class(mci_results_t), intent(inout), optional :: results
  end subroutine mci_integrate
end interface

```

Event generation. Depending on the implementation, event generation may or may not require a previous integration pass.

Instead of a black-box `simulate` method, we require an initializer, a finalizer, and procedures for generating a single event. This allows us to interface simulation event by event from the outside, and it facilitates the further processing of an event after successful generation. For integration, this is not necessary.

The initializer has `intent(inout)` for the `mci` passed object. The reason is that the initializer can read integration results and grids from file, where the results can modify the `mci` record.

```

(MCI base: mci: TBP)+≡
  procedure (mci_prepare_simulation), deferred :: prepare_simulation

(MCI base: interfaces)+≡
  abstract interface
    subroutine mci_prepare_simulation (mci)
    import
    class(mci_t), intent(inout) :: mci
  end subroutine mci_prepare_simulation
end interface

```

The generated event will reside in in the `instance` object (overall results and weight) and in the `sampler` object (detailed data). In the real application, we can subsequently call methods of the `sampler` in order to further process the generated event.

The `target` attributes are required by the VAMP implementation, which uses pointers to refer to the instance and sampler objects from within the integration function.

```

(MCI base: mci: TBP)+≡
  procedure (mci_generate), deferred :: generate_weighted_event
  procedure (mci_generate), deferred :: generate_unweighted_event

```

```

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_generate (mci, instance, sampler)
      import
      class(mci_t), intent(inout) :: mci
      class(mci_instance_t), intent(inout), target :: instance
      class(mci_sampler_t), intent(inout), target :: sampler
    end subroutine mci_generate
  end interface

```

This is analogous, but we rebuild the event from the information stored in `state` instead of generating it.

Note: currently unused outside of tests, might be deleted later.

```

<MCI base: mci: TBP>+≡
  procedure (mci_rebuild), deferred :: rebuild_event

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_rebuild (mci, instance, sampler, state)
      import
      class(mci_t), intent(inout) :: mci
      class(mci_instance_t), intent(inout) :: instance
      class(mci_sampler_t), intent(inout) :: sampler
      class(mci_state_t), intent(in) :: state
    end subroutine mci_rebuild
  end interface

```

Pacify: reduce numerical noise. The base implementation does nothing.

```

<MCI base: mci: TBP>+≡
  procedure :: pacify => mci_pacify

<MCI base: procedures>+≡
  subroutine mci_pacify (object, efficiency_reset, error_reset)
    class(mci_t), intent(inout) :: object
    logical, intent(in), optional :: efficiency_reset, error_reset
  end subroutine mci_pacify

```

Return the value of the integral, error, efficiency, and time per call.

```

```

### 21.1.2 MCI instance

The base type contains an array of channel weights. The value `mci_weight` is the combined MCI weight that corresponds to a particular sampling point.

For convenience, we also store the `x` and Jacobian values for this sampling point.

```

<MCI base: public>+≡

```

```

    public :: mci_instance_t
<MCI base: types>+≡
    type, abstract :: mci_instance_t
        logical :: valid = .false.
        real(default), dimension(:), allocatable :: w
        real(default), dimension(:), allocatable :: f
        real(default), dimension(:,:), allocatable :: x
        integer :: selected_channel = 0
        real(default) :: mci_weight = 0
        real(default) :: integrand = 0
        logical :: negative_weights = .false.
        integer :: n_dropped = 0
    contains
        <MCI base: mci instance: TBP>
    end type mci_instance_t

```

Output: deferred

```

<MCI base: mci instance: TBP>≡
    procedure (mci_instance_write), deferred :: write
<MCI base: interfaces>+≡
    abstract interface
        subroutine mci_instance_write (object, unit, pacify)
            import
            class(mci_instance_t), intent(in) :: object
            integer, intent(in), optional :: unit
            logical, intent(in), optional :: pacify

            call mci%record_integrand (val)
        end if
    end subroutine mci_instance_fetch

```

The value, i.e., the weighted integrand, is the integrand (which should be taken as-is from the sampler) multiplied by the MCI weight.

```

⟨MCI base: mci instance: TBP⟩+≡
    procedure :: get_value => mci_instance_get_value

⟨MCI base: procedures⟩+≡
    function mci_instance_get_value (mci) result (value)
        class(mci_instance_t), intent(in) :: mci
        real(default) :: value
        if (mci%valid) then
            value = mci%integrand * mci%mci_weight
        else
            value = 0
        end if
    end function mci_instance_get_value

```

This is an extra routine. By default, the event weight is equal to the value returned by the previous routine. However, if we select a channel for event generation not just based on the channel weights, the event weight has to account for this bias, so the event weight that applies to event generation is different. In that case, we should override the default routine.

```

⟨MCI base: mci instance: TBP⟩+≡
    procedure :: get_event_weight => mci_instance_get_value

```

Excess weight can occur during unweighted event generation, if the assumed maximum value of the integrand is too small. This excess should be normalized in the same way as the event weight above (which for unweighted events becomes unity).

```

(MCI base: mci instance: TBP)+≡
  procedure (mci_instance_get_event_excess), deferred :: get_event_excess

(MCI base: interfaces)+≡
  abstract interface
    function mci_instance_get_event_excess (mci) result (excess)
      import
      class(mci_instance_t), intent(in) :: mci
      real(default) :: excess
    end function mci_instance_get_event_excess
  end interface

```

Dropped events (i.e., events with zero weight that are not retained) are counted within the `mci_instance` object.

```

(MCI base: mci instance: TBP)+≡
  procedure :: get_n_event_dropped => mci_instance_get_n_event_dropped
  procedure :: reset_n_event_dropped => mci_instance_reset_n_event_dropped
  procedure :: record_event_dropped => mci_instance_record_event_dropped

(MCI base: procedures)+≡
  function mci_instance_get_n_event_dropped (mci) result (n_dropped)
    class(mci_instance_t), intent(in) :: mci
    integer :: n_dropped
    n_dropped = mci%n_dropped
  end function mci_instance_get_n_event_dropped

  subroutine mci_instance_reset_n_event_dropped (mci)
    class(mci_instance_t), intent(inout) :: mci
    mci%n_dropped = 0
  end subroutine mci_instance_reset_n_event_dropped

  subroutine mci_instance_record_event_dropped (mci)
    class(mci_instance_t), intent(inout) :: mci
    mci%n_dropped = mci%n_dropped + 1
  end subroutine mci_instance_record_event_dropped

```

### 21.1.3 MCI state

This object can hold the relevant information that allows us to reconstruct the MCI instance without re-evaluating the sampler completely.

We store the `x_in` MC input parameter set, which coincides with the section of the complete `x` array that belongs to a particular channel. We also store the MC function value. When we want to reconstruct the state, we can use the input array to recover the complete `x` and `f` arrays (i.e., the kinematics), but do not need to recompute the MC function value (the dynamics).

The `mci_state_t` may be extended, to allow storing/recalling more information. In that case, we would override the type-bound procedures. However, the

base type is also a concrete type and self-contained.

```

<MCI base: public>+≡
    public :: mci_state_t

<MCI base: types>+≡
    type :: mci_state_t
        integer :: selected_channel = 0
        real(default), dimension(:), allocatable :: x_in
        real(default) :: val
    contains
        <MCI base: mci state: TBP>
    end type mci_state_t

```

Output:

```

<MCI base: mci state: TBP>≡
    procedure :: write => mci_state_write

<MCI base: procedures>+≡
    subroutine mci_state_write (object, unit)
        class(mci_state_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)
        write (u, "(1x,A)") "MCI state:"
        write (u, "(3x,A,I0)") "Channel   = ", object%selected_channel
        write (u, "(3x,A,999(1x,F12.10))") "x (in)   =", object%x_in
        write (u, "(3x,A,ES19.12)") "Integrand = ", object%val
    end subroutine mci_state_write

```

To store the object, we take the relevant section of the **x** array. The channel used for storing data is taken from the **instance** object, but it could be arbitrary in principle.

```

<MCI base: mci instance: TBP>+≡
    procedure :: store => mci_instance_store

<MCI base: procedures>+≡
    subroutine mci_instance_store (mci, state)
        class(mci_instance_t), intent(in) :: mci
        class(mci_state_t), intent(out) :: state
        state%selected_channel = mci%selected_channel
        allocate (state%x_in (size (mci%x, 1)))
        state%x_in = mci%x(:,mci%selected_channel)
        state%val = mci%integrand
    end subroutine mci_instance_store

```

Recalling the state, we must consult the sampler in order to fully reconstruct the **x** and **f** arrays. The integrand value is known, and we also give it to the sampler, bypassing evaluation.

The final steps are equivalent to the **evaluate** method above.

```

<MCI base: mci instance: TBP>+≡
    procedure :: recall => mci_instance_recall

```

```

<MCI base: procedures>+≡
subroutine mci_instance_recall (mci, sampler, state)
  class(mci_instance_t), intent(inout) :: mci
  class(mci_sampler_t), intent(inout) :: sampler
  class(mci_state_t), intent(in) :: state
  if (size (state%x_in) == size (mci%x, 1) &
      .and. state%selected_channel <= size (mci%x, 2)) then
    call sampler%rebuild (state%selected_channel, &
        state%x_in, state%val, mci%x, mci%f)
    call mci%compute_weight (state%selected_channel)
    call mci%record_integrand (state%val)
  else
    call msg_fatal ("Recalling event: mismatch in channel or dimension")
  end if
end subroutine mci_instance_recall

```

#### 21.1.4 MCI sampler

A sampler is an object that implements a multi-channel parameterization of the unit hypercube. Specifically, it is able to compute, given a channel and a set of  $x$  MC parameter values, the complete set of  $x$  values and associated Jacobian factors  $f$  for all channels.

Furthermore, the sampler should return a single real value, the integrand, for the given point in the hypercube.

It must implement a method `evaluate` for performing the above computations.

```

<MCI base: public>+≡
public :: mci_sampler_t

<MCI base: types>+≡
type, abstract :: mci_sampler_t
contains
  <MCI base: mci sampler: TBP>
end type mci_sampler_t

```

Output, deferred to the implementation.

```

<MCI base: mci sampler: TBP>≡
procedure (mci_sampler_write), deferred :: write

<MCI base: interfaces>+≡
abstract interface
  subroutine mci_sampler_write (object, unit, testflag)
    import
    class(mci_sampler_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
  end subroutine mci_sampler_write
end interface

```

The evaluation routine. Input is the channel index `c` and the one-dimensional parameter array `x_in`. Output are the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

```

(MCI base: mci_sampler: TBP)+≡
  procedure (mci_sampler_evaluate), deferred :: evaluate

(MCI base: interfaces)+≡
  abstract interface
    subroutine mci_sampler_evaluate (sampler, c, x_in, val, x, f)
      import
      class(mci_sampler_t), intent(inout) :: sampler
      integer, intent(in) :: c
      real(default), dimension(:), intent(in) :: x_in
      real(default), intent(out) :: val
      real(default), dimension(:, :), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_evaluate
  end interface

```

Query the validity of the sampling point. Can be called after `evaluate`.

```

(MCI base: mci_sampler: TBP)+≡
  procedure (mci_sampler_is_valid), deferred :: is_valid

(MCI base: interfaces)+≡
  abstract interface
    function mci_sampler_is_valid (sampler) result (valid)
      import
      class(mci_sampler_t), intent(in) :: sampler
      logical :: valid
    end function mci_sampler_is_valid
  end interface

```

The shortcut. Again, the channel index `c` and the parameter array `x_in` are input. However, we also provide the integrand value `val`, and we just require that the complete parameter array `x` and Jacobian array `f` are recovered.

```

(MCI base: mci_sampler: TBP)+≡
  procedure (mci_sampler_rebuild), deferred :: rebuild

(MCI base: interfaces)+≡
  abstract interface
    subroutine mci_sampler_rebuild (sampler, c, x_in, val, x, f)
      import
      class(mci_sampler_t), intent(inout) :: sampler
      integer, intent(in) :: c
      real(default), dimension(:), intent(in) :: x_in
      real(default), intent(in) :: val
      real(default), dimension(:, :), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_rebuild
  end interface

```

This routine should extract the important data from a sampler that has been filled by other means. We fetch the integrand value `val`, the two-dimensional parameter array `x` and the Jacobian array `f`.

```

<MCI base: mci_sampler: TBP>+≡
  procedure (mci_sampler_fetch), deferred :: fetch

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_sampler_fetch (sampler, val, x, f)
      import
      class(mci_sampler_t), intent(in) :: sampler
      real(default), intent(out) :: val
      real(default), dimension(:,:), intent(out) :: x
      real(default), dimension(:), intent(out) :: f
    end subroutine mci_sampler_fetch
  end interface

```

### 21.1.5 Results record

This is an abstract type which allows us to implement callback: each integration results can optionally be recorded to an instance of this object. The actual object may store a new result, average results, etc. It may also display a result on-line or otherwise, whenever the `record` method is called.

```

<MCI base: public>+≡
  public :: mci_results_t

<MCI base: types>+≡
  type, abstract :: mci_results_t
  contains
    <MCI base: mci_results: TBP>
  end type mci_results_t

```

The output routine is deferred. We provide an extra `verbose` flag, which could serve any purpose.

```

<MCI base: mci_results: TBP>≡
  procedure (mci_results_write), deferred :: write
  procedure (mci_results_write_verbose), deferred :: write_verbose

<MCI base: interfaces>+≡
  abstract interface
    subroutine mci_results_write (object, unit, suppress)
      import
      class(mci_results_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: suppress
    end subroutine mci_results_write

    subroutine mci_results_write_verbose (object, unit)
      import
      class(mci_results_t), intent(in) :: object
      integer, intent(in), optional :: unit
    end subroutine mci_results_write_verbose

```

```
end interface
```

This is the generic `record` method, which can be called directly from the integrator. The `record_extended` procedure store additionally the valid calls, positive and negative efficiency.

```
<MCI base: mci results: TBP>+=
  generic :: record => record_simple, record_extended
  procedure (mci_results_record_simple), deferred :: record_simple
  procedure (mci_results_record_extended), deferred :: record_extended

<MCI base: interfaces>+=
  abstract interface
    subroutine mci_results_record_simple (object, n_it, &
      n_calls, integral, error, efficiency, chain_weights, suppress)
      import
      class(mci_results_t), intent(inout) :: object
      integer, intent(in) :: n_it
      integer, intent(in) :: n_calls
      real(default), intent(in) :: integral
      real(default), intent(in) :: error
      real(default), intent(in) :: efficiency
      real(default), dimension(:), intent(in), optional :: chain_weights
      logical, intent(in), optional :: suppress
    end subroutine mci_results_record_simple

    subroutine mci_results_record_extended (object, n_it, n_calls,&
      & n_calls_valid, integral, error, efficiency, efficiency_pos,&
      & efficiency_neg, chain_weights, suppress)
      import
      class(mci_results_t), intent(inout) :: object
      integer, intent(in) :: n_it
      integer, intent(in) :: n_calls
      integer, intent(in) :: n_calls_valid
      real(default), intent(in) :: integral
      real(default), intent(in) :: error
      real(default), intent(in) :: efficiency
      real(default), intent(in) :: efficiency_pos
      real(default), intent(in) :: efficiency_neg
      real(default), dimension(:), intent(in), optional :: chain_weights
      logical, intent(in), optional :: suppress
    end subroutine mci_results_record_extended
  end interface
```

### 21.1.6 Unit tests

Test module, followed by the corresponding implementation module.

```
<mci_base.ut.f90>=

## Test implementation of the configuration type

The concrete type contains the number of requested calls and the integral result, to be determined.

The `max_factor` entry is set for the actual test integration, where the integrand is not unity but some other constant value. This value should be set here, such that the actual maximum of the integrand is known when vetoing unweighted events.

```

### Instance of the test MCI type

This instance type simulates the VAMP approach. We implement the VAMP multi-channel formula, but keep the channel-specific probability functions  $g_i$

smooth and fixed. We also keep the weights fixed.

The setup is as follows: we have  $n$  mappings of the unit hypercube

$$x = x(x^{(k)}) \quad \text{where } x = (x_1, \dots). \quad (21.1)$$

The Jacobian factors are the determinants

$$f^{(k)}(x^{(k)}) = \left| \frac{\partial x}{\partial x^{(k)}} \right| \quad (21.2)$$

We introduce arbitrary probability functions

$$g^{(k)}(x^{(k)}) \quad \text{with} \quad \int dx^{(k)} g^{(k)}(x^{(k)}) = 1 \quad (21.3)$$

and weights

$$w_k \quad \text{with} \quad \sum_k w_k = 1 \quad (21.4)$$

and construct the joint probability function

$$g(x) = \sum_k w_k \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \quad (21.5)$$

which also satisfies

$$\int g(x) dx = 1. \quad (21.6)$$

The algorithm implements a resolution of unity as follows

$$\begin{aligned} 1 &= \int dx = \int \frac{g(x)}{g(x)} dx \\ &= \sum_k w_k \int \frac{g^{(k)}(x^{(k)}(x))}{f^{(k)}(x^{(k)}(x))} \frac{dx}{g(x)} \\ &= \sum_k w_k \int g^{(k)}(x^{(k)}) \frac{dx^{(k)}}{g(x^{(k)})} \end{aligned} \quad (21.7)$$

where each of the integrals in the sum is evaluated using the channel-specific variables  $x^{(k)}$ .

We provide two examples: (1) trivial with one channel, one dimension, and all functions unity and (2) two channels and two dimensions with

$$\begin{aligned} x(x^{(1)}) &= (x_1^{(1)}, x_2^{(1)}) \\ x(x^{(2)}) &= (x_1^{(2)2}, x_2^{(2)}) \end{aligned} \quad (21.8)$$

hence

$$f^{(1)} \equiv 1, \quad f^{(2)}(x^{(2)}) = 2x_1^{(2)} \quad (21.9)$$

The probability functions are

$$g^{(1)} \equiv 1, \quad g^{(2)}(x^{(2)}) = 2x_2^{(2)} \quad (21.10)$$

In the concrete implementation of the integrator instance we store values for the channel probabilities  $g_i$  and the accumulated probability  $g$ .

We also store the result (product of integrand and MCI weight), the expected maximum for the result in each channel.

```

## Test sampler

The test sampler implements a fixed configuration, either trivial (one-channel, one-dimension), or slightly nontrivial (two-channel, two-dimension). In the second channel, the first parameter is mapped according to  $x_1 = x_1^{(2)2}$ , so we have  $f^{(2)}(x^{(2)}) = 2x_1^{(2)}$ .

For display purposes, we store the return values inside the object. This is not strictly necessary.

```

## 21.2 Iterations

This module defines a container for the list of iterations and calls, to be submitted to integration.

*<iterations.f90>*≡  
*<File header>*

**module iterations**

*<Use kinds>*

*<Use strings>*

**use io\_units**

**use diagnostics**

*<Standard module head>*

*<Iterations: public>*

*<Iterations: types>*

```
contains

<Iterations: procedures>

end module iterations
```

### 21.2.1 The iterations list

Each integration pass has a number of iterations and a number of calls per iteration. The last pass produces the end result; the previous passes are used for adaptation.

The flags `adapt_grid` and `adapt_weight` are used only if `custom_adaptation` is set. Otherwise, default settings are used that depend on the integration pass.

```
<Iterations: types>≡
  type :: iterations_spec_t
    private
    integer :: n_it = 0
    integer :: n_calls = 0
    logical :: custom_adaptation = .false.
    logical :: adapt_grids = .false.
    logical :: adapt_weights = .false.
  end type iterations_spec_t
```

We build up a list of iterations.

```
<Iterations: public>≡
  public :: iterations_list_t

<Iterations: types>+≡
  type :: iterations_list_t
    private
    integer :: n_pass = 0
    type(iterations_spec_t), dimension(:), allocatable :: pass
  contains
    <Iterations: iterations list: TBP>
  end type iterations_list_t
```

Initialize an iterations list. For each pass, we have to specify the number of iterations and calls. We may provide the adaptation conventions explicitly, either as character codes or as logicals.

For passes where the adaptation conventions are not specified, we use the following default setting: adapt weights and grids for all passes except the last one.

```
<Iterations: iterations list: TBP>≡
  procedure :: init => iterations_list_init

<Iterations: procedures>≡
  subroutine iterations_list_init &
    (it_list, n_it, n_calls, adapt, adapt_code, adapt_grids, adapt_weights)
    class(iterations_list_t), intent(inout) :: it_list
    integer, dimension(:), intent(in) :: n_it, n_calls
    logical, dimension(:), intent(in), optional :: adapt
```

```

type(string_t), dimension(:), intent(in), optional :: adapt_code
logical, dimension(:), intent(in), optional :: adapt_grids, adapt_weights
integer :: i
it_list%n_pass = size (n_it)
if (allocated (it_list%pass)) deallocate (it_list%pass)
allocate (it_list%pass (it_list%n_pass))
it_list%pass%n_it = n_it
it_list%pass%n_calls = n_calls
if (present (adapt)) then
    it_list%pass%custom_adaptation = adapt
    do i = 1, it_list%n_pass
        if (adapt(i)) then
            if (verify (adapt_code(i), "wg") /= 0) then
                call msg_error ("iteration specification: " &
                    // "adaptation code letters must be 'w' or 'g'")
            end if
            it_list%pass(i)%adapt_grids = scan (adapt_code(i), "g") /= 0
            it_list%pass(i)%adapt_weights = scan (adapt_code(i), "w") /= 0
        end if
    end do
else if (present (adapt_grids) .and. present (adapt_weights)) then
    it_list%pass%custom_adaptation = .true.
    it_list%pass%adapt_grids = adapt_grids
    it_list%pass%adapt_weights = adapt_weights
end if
do i = 1, it_list%n_pass - 1
    if (.not. it_list%pass(i)%custom_adaptation) then
        it_list%pass(i)%adapt_grids = .true.
        it_list%pass(i)%adapt_weights = .true.
    end if

## 21.2.2 Tools

Return the total number of passes.

*<Iterations: iterations list: TBP>+≡*

```
procedure :: get_n_pass => iterations_list_get_n_pass
```

*<Iterations: procedures>+≡*

```
function iterations_list_get_n_pass (it_list) result (n_pass)
  class(iterations_list_t), intent(in) :: it_list
  integer :: n_pass
  n_pass = it_list%n_pass
end function iterations_list_get_n_pass
```

Return the number of calls for a specific pass.

*<Iterations: iterations list: TBP>+≡*

```
procedure :: get_n_calls => iterations_list_get_n_calls
```

```

<Iterations: procedures>+≡
function iterations_list_get_n_calls (it_list, pass) result (n_calls)
  class(iterations_list_t), intent(in) :: it_list
  integer :: n_calls
  integer, intent(in) :: pass
  if (pass <= it_list%n_pass) then
    n_calls = it_list%pass(pass)%n_calls
  else
    n_calls = 0
  end if
end function iterations_list_get_n_calls

```

```

<Iterations: iterations list: TBP>+≡
procedure :: set_n_calls => iterations_list_set_n_calls

```

```

<Iterations: procedures>+≡
subroutine iterations_list_set_n_calls (it_list, pass, n_calls)
  class(iterations_list_t), intent(inout) :: it_list
  integer, intent(in) :: pass, n_calls
  it_list%pass(pass)%n_calls = n_calls
end subroutine iterations_list_set_n_calls

```

Get the adaptation mode (automatic/custom) and, for custom adaptation, the flags for a specific pass.

```

<Iterations: iterations list: TBP>+≡
procedure :: adapt_grids => iterations_list_adapt_grids
procedure :: adapt_weights => iterations_list_adapt_weights

<Iterations: procedures>+≡
function iterations_list_adapt_grids (it_list, pass) result (flag)

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: iterations_2"

    end subroutine iterations_2

```

## 21.3 Integration results

We record integration results and errors in a dedicated type. This allows us to do further statistics such as weighted average, chi-squared, grouping by integration

passes, etc.

Note WHIZARD 2.2.0: This code is taken from the previous `processes` module essentially unchanged and converted into a separate module. It lacks an overhaul and, in particular, self-tests.

```
<integration_results.f90>≡
  module integration_results

    <Use kinds>
    <Use strings>
    use io_units
    use format_utils, only: mp_format, pac_fmt
    use format_defs, only: FMT_10, FMT_14
    use diagnostics
    use md5
    use os_interface
    use mci_base

    <Standard module head>

    <Integration results: public>

    <Integration results: parameters>

    <Integration results: types>

    <Integration results: interfaces>

    contains

    <Integration results: procedures>

  end module integration_results
```

### 21.3.1 Integration results entry

This object collects the results of an integration pass and makes them available to the outside.

The results object has to distinguish the process type:

We store the process type, the index of the integration pass and the absolute iteration index, the number of iterations contained in this result (for averages), and the integral (cross section or partial width), error estimate, efficiency.

For intermediate results, we set a flag if this result is an improvement w.r.t. previous ones.

The process type indicates decay or scattering. Dummy entries (skipped iterations) have a process type of `PRC_UNKNOWN`.

The additional information `n_calls_valid`, `efficiency_pos` and `efficiency_neg` are stored, but only used in verbose mode.

```
<Integration results: public>≡
  public :: integration_entry_t

<Integration results: types>≡
  type :: integration_entry_t
```

```

private
integer :: process_type = PRC_UNKNOWN
integer :: pass = 0
integer :: it = 0
integer :: n_it = 0
integer :: n_calls = 0
integer :: n_calls_valid = 0
logical :: improved = .false.
real(default) :: integral = 0
real(default) :: error = 0
real(default) :: efficiency = 0
real(default) :: efficiency_pos = 0
real(default) :: efficiency_neg = 0
real(default) :: chi2 = 0
real(default), dimension(:), allocatable :: chain_weights
contains
<Integration results: integration entry: TBP>
end type integration_entry_t

```

The possible values of the type indicator:

```

<Integration results: parameters>≡
integer, parameter, public :: PRC_UNKNOWN = 0
integer, parameter, public :: PRC_DECAY = 1
integer, parameter, public :: PRC_SCATTERING = 2

```

Initialize with all relevant data.

```

<Integration results: interfaces>≡
interface integration_entry_t
module procedure integration_entry_init
end interface integration_entry_t

```

```

<Integration results: procedures>≡
type(integration_entry_t) function integration_entry_init (process_type, pass,&
& it, n_it, n_calls, n_calls_valid, improved, integral, error,&
& efficiency, efficiency_pos, efficiency_neg, chi2, chain_weights)&
& result (entry)
integer, intent(in) :: process_type, pass, it, n_it, n_calls, n_calls_valid
logical, intent(in) :: improved
real(default), intent(in) :: integral, error, efficiency, efficiency_pos, efficiency_neg
real(default), intent(in), optional :: chi2
real(default), dimension(:), intent(in), optional :: chain_weights
entry%process_type = process_type
entry%pass = pass
entry%it = it
entry%n_it = n_it
entry%n_calls = n_calls
entry%n_calls_valid = n_calls_valid
entry%improved = improved
entry%integral = integral
entry%error = error
entry%efficiency = efficiency
entry%efficiency_pos = efficiency_pos

```

```

entry%efficiency_neg = efficiency_neg
if (present (chi2)) entry%chi2 = chi2
if (present (chain_weights)) then
    allocate (entry%chain_weights (size (chain_weights)))
    entry%chain_weights = chain_weights
end if
end function integration_entry_init

```

Access values, some of them computed on demand:

### 21.3.2 Combined integration results

We collect a list of results which grows during the execution of the program. This is implemented as an array which grows if necessary; so we can easily compute averages.

We implement this as an extension of the `mci_results_t` which is defined in `mci_base` as an abstract type. We thus decouple the implementation of the integrator from the implementation of the results display, but nevertheless can record intermediate results during integration. This implies that the present extension implements a `record` method.

```

<Integration results: public>+≡
    public :: integration_results_t

```

```

<Integration results: types>+≡
type, extends (mci_results_t) :: integration_results_t
  private
  integer :: process_type = PRC_UNKNOWN
  integer :: current_pass = 0
  integer :: n_pass = 0
  integer :: n_it = 0
  logical :: screen = .false.
  integer :: unit = 0
  integer :: verbosity = 0
  real(default) :: error_threshold = 0
  type(integration_entry_t), dimension(:), allocatable :: entry
  type(integration_entry_t), dimension(:), allocatable :: average
contains
  <Integration results: integration results: TBP>
end type integration_results_t

```

The array is extended in chunks of 10 entries.

```

<Integration results: parameters>+≡
integer, parameter :: RESULTS_CHUNK_SIZE = 10

```

```

<Integration results: integration results: TBP>≡
procedure :: init => integration_results_init

```

```

<Integration results: procedures>+≡
subroutine integration_results_init (results, process_type)

```

During integration, we do not want to print all results at once, but each intermediate result as soon as we get it. Thus, the previous procedure is chopped in pieces. First piece: store the output unit and a flag whether we want to print to standard output as well. Then write the header if the results are still empty, i.e., before integration has started. The second piece writes a single result to the saved output channels. We call this from the `record` method, which can be called from the integrator directly. The third piece writes the average result, once a pass has been completed. The fourth piece writes a footer (if any), assuming that this is the final result.

```

Compute the average for all entries in the specified integration pass. The integrals are weighted w.r.t. their individual errors.

The quoted error of the result is the expected error, computed from the weighted average of the given individual errors.

This should be compared to the actual distribution of the results, from which we also can compute an error estimate if there is more than one iteration. The ratio of the distribution error and the averaged error, is the  $\chi^2$  value.

All error distributions are assumed Gaussian, of course. The  $\chi^2$  value is a partial check for this assumption. If it is significantly greater than unity, there is something wrong with the individual errors.

The efficiency returned is the one of the last entry in the integration pass.

If any error vanishes, averaging by this algorithm would fail. In this case, we simply average the entries and use the deviations from this average (if any) to estimate the error.

*(Integration results: procedures)+≡*

### 21.3.3 Access results

Return true if the results object has entries.

*<Integration results: integration results: TBP>+≡*

```
procedure :: exist => integration_results_exist
```

*<Integration results: procedures>+≡*

```

function integration_results_exist (results) result (flag)
  logical :: flag
  class(integration_results_t), intent(in) :: results
  flag = results%n_pass > 0
end function integration_results_exist

```

Retrieve information from the results record. If **last** is set and true, take the last iteration. If it is set instead, take this iteration. If **pass** is set, take this average. If none is set, take the final average.

If the result would be invalid, the entry is not assigned. Due to default initialization, this returns a null entry.

*(Integration results: integration results: TBP)+≡*

```

procedure :: get_entry => results_get_entry

```

*(Integration results: procedures)+≡*

```

function results_get_entry (results, last, it, pass) result (entry)

  <MCI none: public>  
  
  <MCI none: types>  
  
  contains  
  
  <MCI none: procedures>  
  
end module mci_none
```

### 21.4.1 Integrator

The object contains the methods for integration and event generation. For the actual work and data storage, it spawns an instance object.

After an integration pass, we update the `max` parameter to indicate the maximum absolute value of the integrand that the integrator encountered. This is required for event generation.

```
<MCI none: public>≡  
  public :: mci_none_t  
  
<MCI none: types>≡  
  type, extends (mci_t) :: mci_none_t  
    contains

call mci%final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: mci_none_1"

end subroutine mci_none_1

```

## 21.5 Simple midpoint integration

This is a most simple implementation of an integrator. The algorithm is the straightforward multi-dimensional midpoint rule, i.e., the integration hypercube is binned uniformly, the integrand is evaluated at the midpoints of each bin, and the result is the average. The binning is equivalent for all integration dimensions.

This rule is accurate to the order  $h^2$ , where  $h$  is the bin width. Given that  $h = N^{-1/d}$ , where  $d$  is the integration dimension and  $N$  is the total number of sampling points, we get a relative error of order  $N^{-2/d}$ . This is superior to MC integration if  $d < 4$ , and equivalent if  $d = 4$ . It is not worse than higher-order formulas (such as Gauss integration) if the integrand is not smooth, e.g., if it contains cuts.

The integrator is specifically single-channel. However, we do not limit the dimension.

```
<mci_midpoint.f90>≡  
  <File header>  
  
  module mci_midpoint  
  
    <Use kinds>  
    use io_units  
    use diagnostics  
    use phs_base  
  
    use mci_base  
  
    <Standard module head>  
  
    <MCI midpoint: public>  
  
    <MCI midpoint: types>  
  
    contains  
  
    <MCI midpoint: procedures>  
  
  end module mci_midpoint
```

### 21.5.1 Integrator

The object contains the methods for integration and event generation. For the actual work and data storage, it spawns an instance object.

After an integration pass, we update the `max` parameter to indicate the maximum absolute value of the integrand that the integrator encountered. This is required for event generation.

```
<MCI midpoint: public>≡  
  public :: mci_midpoint_t  
  
<MCI midpoint: types>≡

Integrate. The number of dimensions is arbitrary. We make sure that the number of calls is evenly distributed among the dimensions. The actual number of calls will typically be smaller than the requested number, but never smaller than 1.

The sampling over a variable number of dimensions implies a variable number of nested loops. We implement this by a recursive subroutine, one loop in each recursion level.

The number of iterations `n_it` is ignored. Also, the error is set to zero in the current implementation.

With this integrator, we allow the calculation to abort immediately when forced by a signal. There is no state that we can save, hence we do not catch an interrupt.

## Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

This is the function  $f(x) = 3x^2$  with integral  $\int_0^1 f(x) dx = 1$  and maximum  $f(1) = 3$ . If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

Mimicking the behavior of a process object, we store the argument and result inside the sampler, so we can fetch results.

*<MCI midpoint: test types>*≡

type, extends (mci\_sampler\_t) :: test\_sampler\_1\_t

real(default), dimension(:), allocatable :: x

real(default) :: val

contains

*<MCI midpoint: test sampler 1: TBP>*

end type test\_sampler\_1\_t

Output: There is nothing stored inside, so just print an informative line.

*<MCI midpoint: test sampler 1: TBP>*≡

procedure :: write => test\_sampler\_1\_write

*<MCI midpoint: tests>*≡

subroutine test\_sampler\_1\_write (object, unit, testflag)

class(test\_sampler\_1\_t), intent(in) :: object

integer, intent(in), optional :: unit

logical, intent(in), optional :: testflag

integer :: u

u = given\_output\_unit (unit)

write (u, "(1x,A)") "Test sampler: f(x) = 3 x^2"

end subroutine test\_sampler\_1\_write

Evaluation: compute the function value. The output  $x$  parameter (only one channel) is identical to the input  $x$ , and the Jacobian is 1.

*<MCI midpoint: test sampler 1: TBP>*+≡

procedure :: evaluate => test\_sampler\_1\_evaluate

```

## 21.6 VAMP interface

The standard method for integration is **VAMP**: the multi-channel version of the VEGAS algorithm. Each parameterization (channel) of the hypercube is binned in each dimension. The binning is equally equidistant, but an iteration of the integration procedure, the binning is updated for each dimension, according to the variance distribution of the integrand, summed over all other dimension. In the next iteration, the binning approximates (hopefully) follows the integrand more closely, and the accuracy of the result is increased. Furthermore, the relative weight of the individual channels is also updated after an iteration.

The bin distribution is denoted as the grid for a channel, which we can write to file and reuse later.

In our implementation we specify the generic **VAMP** algorithm more tightly: the number of bins is equal for all dimensions, the initial weights are all equal. The user controls whether to update bins and/or weights after each iteration. The integration is organized in passes, each one consisting of several iterations with a common number of calls to the integrand. The first passes are intended as warmup, so the results are displayed but otherwise discarded. In the final pass, the integration estimates for the individual iterations are averaged for the final result.

Integrate. Perform a new integration pass (possibly reusing previous results), which may consist of several iterations.

Note: we record the integral once per iteration. The integral stored in the `mci` record itself is the last integral of the current iteration, no averaging done. The `results` record may average results.

In case we read the integration from file and we added new iterations to the pass preserving number of calls, we need to reshape the grids in order to incorporate the correct number of calls. Else the grids would be sampled with the number of calls from the grids file, which does not need to coincide with the number of calls from the pass.

Note: recording the efficiency is not supported yet.

Prepare an event generation pass. Should be called before a sequence of events is generated, then we should call the corresponding finalizer.

The pass-specific data of the previous integration pass are retained, but we reset the number of iterations and calls to zero. The latter now counts the number of events (calls to the sampling function, actually).

Generate weighted event. Note that the event weight (`vamp_weight`) is not just the MCI weight. `vamp_next_event` selects a channel based on the channel weights multiplied by the (previously recorded) maximum integrand value of the channel. The MCI weight is renormalized accordingly, to cancel this effect on the result.

### 21.6.5 Sampler as Workspace

In the full setup, the sampling function requires the process instance object as workspace. We implement this by (i) implementing the process instance as a type extension of the abstract `sampler_t` object used by the MCI implementation and (ii) providing such an object as an extra argument to the sampling function that VAMP can call. To minimize cross-package dependencies, we use an abstract type `vamp_workspace` that VAMP declares and extend this by including a pointer to the `sampler` and `instance` objects. In the body of the sampling function, we dereference this pointer and can then work with the contents.

```
<MCI vamp: types>+≡
  type, extends (vamp_data_t) :: mci_workspace_t
    class(mci_sampler_t), pointer :: sampler => null ()
    class(mci_vamp_instance_t), pointer :: instance => null ()
  end type mci_workspace_t
```

### 21.6.6 Integrator instance

The history entries should point to the corresponding history entry in the `pass_t` object. If there is none, we may allocate a local history, which is then just transient.

```

Prepare a new integration pass: write the pass-specific settings to the **instance** object. This should be called initially, together with the **create\_grids** procedure, and whenever we start a new integration pass.

Set **reshape** if the number of calls is different than previously (unless it was zero, indicating the first pass).

We link VAMP histories to the allocated histories in the current pass object, so the recorded results are persistent. However, if there are no histories present there, we allocate them locally. In that case, the histories will disappear together with the MCI instance object.

Integration: sample the VAMP grids. The number of calls etc. are already stored inside the grids. We provide the random-number generator, the sampling function, and a link to the workspace object, which happens to contain a pointer to the sampler object. The sampler object thus becomes the workspace of the sampling function.

Note: in the current implementation, the random-number generator must be the TAO generator. This explicit dependence should be removed from the VAMP implementation.

    end subroutine mci_vamp_instance_final_simulation

```

### 21.6.7 Sampling function

The VAMP sampling function has a well-defined interface which we have to implement. The `data` argument allows us to pass pointers to the `sampler` and `instance` objects, so we can access configuration data and fill point-dependent contents within these objects.

The `weights` and `channel` argument must be present in the call.

Note: this is the place where we must look for external signals, i.e., interrupt from the OS. We would like to raise a VAMP exception which is then caught by `vamp_sample_grids` as the caller, so it dumps its current state and returns (with the signal still pending). WHIZARD will then terminate gracefully. Of course, VAMP should be able to resume from the dump.

In the current implementation, we handle the exception in place and terminate immediately. The incomplete current integration pass is lost.

```

<MCI vamp: procedures>+=
    function vamp_sampling_function &
        (xi, data, weights, channel, grids) result (f)
    real(default) :: f
    real(default), dimension(:), intent(in) :: xi
    class(vamp_data_t), intent(in) :: data
    real(default), dimension(:), intent(in), optional :: weights
    integer, intent(in), optional :: channel

```

```

type(vamp_grid), dimension(:), intent(in), optional :: grids
type(exception) :: exc
logical :: verbose
character(*), parameter :: FN = "WHIZARD sampling function"
class(mci_instance_t), pointer :: instance
select type (data)
type is (mci_workspace_t)
    instance => data%instance
    select type (instance)
    class is (mci_vamp_instance_t)
        verbose = instance%mci%verbose
        call instance%evaluate (data%sampler, channel, xi)
        if (signal_is_pending ()) then
            call raise_exception (exc, EXC_FATAL, FN, "signal received")
            call handle_vamp_exception (exc, verbose)
            call terminate_now_if_signal ()
        end if
        instance%calls = instance%calls + 1
        if (data%sampler%is_valid ()) &
            & instance%calls_valid = instance%calls_valid + 1
        f = instance%get_value ()
        call terminate_now_if_single_event ()
    class default
        call msg_bug("VAMP: " // FN // ": unknown MCI instance type")
    end select
end select
end function vamp_sampling_function

```

This is supposed to be the mapping between integration channels. The VAMP event generating procedures technically require it, but it is meaningless in our setup where all transformations happen inside the sampler object. So, this implementation is trivial:

```

⟨MCI vamp: procedures⟩+≡
pure function phi_trivial (xi, channel_dummy) result (x)
    real(default), dimension(:), intent(in) :: xi
    integer, intent(in) :: channel_dummy
    real(default), dimension(size(xi)) :: x
    x = xi
end function phi_trivial

```

### 21.6.8 Integrator instance: evaluation

Here, we compute the multi-channel reweighting factor for the current channel, that accounts for the Jacobians of the transformations from/to all other channels.

The computation of the VAMP probabilities may consume considerable time, therefore we enable parallel evaluation. (Collecting the contributions to `mci%g` is a reduction, which we should also implement via OpenMP.)

```

⟨MCI vamp: mci vamp instance: TBP⟩+≡
procedure :: compute_weight => mci_vamp_instance_compute_weight

```

```

<MCI vamp: procedures>+=
subroutine mci_vamp_instance_compute_weight (mci, c)
  class(mci_vamp_instance_t), intent(inout) :: mci
  integer, intent(in) :: c
  integer :: i
  mci%selected_channel = c
  !$OMP PARALLEL PRIVATE(i) SHARED(mci)
  !$OMP DO
  do i = 1, mci%nc
    if (mci%w(i) /= 0) then
      mci%gi(i) = vamp_probability (mci%gids%gids(i), mci%x(:,i))
    else
      mci%gi(i) = 0
    end if
  end do
  !$OMP END DO
  !$OMP END PARALLEL
  mci%g = 0
  if (mci%gi(c) /= 0) then
    do i = 1, mci%nc
      if (mci%w(i) /= 0 .and. mci%f(i) /= 0) then
        mci%g = mci%g + mci%w(i) * mci%gi(i) / mci%f(i)
      end if
    end do
  end if
  if (mci%g /= 0) then
    mci%weight = mci%gi(c) / mci%g
  else
    mci%weight = 0
  end if
end subroutine mci_vamp_instance_compute_weight

```

Record the integrand.

```

<MCI vamp: mci vamp instance: TBP>+=
procedure :: record_integrand => mci_vamp_instance_record_integrand

<MCI vamp: procedures>+=
subroutine mci_vamp_instance_record_integrand (mci, integrand)
  class(mci_vamp_instance_t), intent(inout) :: mci
  real(default), intent(in) :: integrand
  mci%integrand = integrand
end subroutine mci_vamp_instance_record_integrand

```

Get the event weight. The default routine returns the same value that we would use for integration. This is correct if we select the integration channel according to the channel weight. `vamp_next_event` does differently, so we should rather rely on the weight that VAMP returns. This is the value stored in `vamp_weight`. We override the default TBP accordingly.

```

<MCI vamp: mci vamp instance: TBP>+=
procedure :: get_event_weight => mci_vamp_instance_get_event_weight
procedure :: get_event_excess => mci_vamp_instance_get_event_excess

<MCI vamp: procedures>+=

```

```

function mci_vamp_instance_get_event_weight (mci) result (value)
  class(mci_vamp_instance_t), intent(in) :: mci
  real(default) :: value
  if (mci%vamp_weight_set) then
    value = mci%vamp_weight
  else
    call msg_bug ("VAMP: attempt to read undefined event weight")
  end if
end function mci_vamp_instance_get_event_weight

function mci_vamp_instance_get_event_excess (mci) result (value)
  class(mci_vamp_instance_t), intent(in) :: mci
  real(default) :: value
  if (mci%vamp_weight_set) then
    value = mci%vamp_excess
  else
    call msg_bug ("VAMP: attempt to read undefined event excess weight")
  end if
end function mci_vamp_instance_get_event_excess

```

### 21.6.9 VAMP exceptions

A VAMP routine may have raised an exception. Turn this into a WHIZARD error message.

An external signal could raise a fatal exception, but this should be delayed and handled by the correct termination routine.

*(MCI vamp: procedures)+≡*

```

subroutine handle_vamp_exception (exc, verbose)
  type(exception), intent(in) :: exc
  logical, intent(in) :: verbose
  integer :: exc_level
  if (verbose) then
    exc_level = EXC_INFO
  else
    exc_level = EXC_ERROR
  end if
  if (exc%level >= exc_level) then
    write (msg_buffer, "(A,':',1x,A)" trim (exc%origin), trim (exc%message))
    select case (exc%level)
      case (EXC_INFO); call msg_message ()
      case (EXC_WARN); call msg_warning ()
      case (EXC_ERROR); call msg_error ()
      case (EXC_FATAL)
        if (signal_is_pending ()) then
          call msg_message ()
        else
          call msg_fatal ()
        end if
      end select
  end if
end subroutine handle_vamp_exception

```

```

## Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is  $f(x) = 3x^2$  with integral  $\int_0^1 f(x) dx = 1$  and maximum  $f(1) = 3$ . If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is  $11x^{10}$ , also with integral 1.

Mode 4 includes ranges of zero and negative function value, the integral is negative. The results should be identical to the results of `mci_midpoint_4`, where the same function is evaluated. The function is  $f(x) = (1 - 3x^2)\theta(x - 1/2)$  with integral  $\int_0^1 f(x) dx = -3/8$ , minimum  $f(1) = -2$  and maximum  $f(1/2) = 1/4$ .

```

<MCI vamp: test types>≡
type, extends (mci_sampler_t) :: test_sampler_1_t
    real(default), dimension(:), allocatable :: x
    real(default) :: val
    integer :: mode = 1
contains
    <MCI vamp: test sampler 1: TBP>
end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

<MCI vamp: test sampler 1: TBP>≡
    procedure :: write => test_sampler_1_write

<MCI vamp: tests>≡
    subroutine test_sampler_1_write (object, unit, testflag)
        class(test_sampler_1_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: testflag
        integer :: u

## Two-channel, two dimension test sampler

This sampler implements the function

$$f(x, y) = 4 \sin^2(\pi x) \sin^2(\pi y) + 2 \sin^2(\pi v) \quad (21.11)$$

where

$$x = u^v \quad u = xy \quad (21.12)$$

$$y = u^{(1-v)} \quad v = \frac{1}{2} \left( 1 + \frac{\log(x/y)}{\log xy} \right) \quad (21.13)$$

Each term contributes 1 to the integral. The first term in the function is peaked along a cross aligned to the coordinates  $x$  and  $y$ , while the second term is peaked along the diagonal  $x = y$ .

The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = |\log u| \quad (21.14)$$

```

## Two-channel, one dimension test sampler

This sampler implements the function

$$f(x, y) = a * 5x^4 + b * 5(1 - x)^4 \quad (21.15)$$

Each term contributes 1 to the integral, multiplied by  $a$  or  $b$ , respectively. The first term is peaked at  $x = 1$ , the second one at  $x = 0$ .

We implement the two mappings

$$x = u^{1/5} \quad \text{and} \quad x = 1 - v^{1/5}, \quad (21.16)$$

with Jacobians

$$\frac{\partial(x)}{\partial(u)} = u^{-4/5}/5 \quad \text{and} \quad v^{-4/5}/5, \quad (21.17)$$

respectively. The first mapping concentrates points near  $x = 1$ , the second one near  $x = 0$ .

```

  end subroutine test_sampler_3_fetch

```

## One-dimensional integration

Construct an integrator and use it for a one-dimensional sampler.

Note: We would like to check the precise contents of the grid allocated during integration, but the output format for reals is very long (for good reasons), so the last digits in the grid content display are numerical noise. So, we just check the integration results.

```

## 21.7 Multi-channel integration with VAMP2

The multi-channel integration uses VEGAS as backbone integrator. The base interface for the multi-channel integration is given by `mci_base` module.

We interface the VAMP2 interface given by `vamp2` module.

```

⟨mci_vamp2.f90⟩≡
  ⟨File header⟩

```

```

module mci_vamp2

```

```

  ⟨Use kinds⟩

```

```

  ⟨Use strings⟩

```

```

  use io_units

```

```

  use format_utils, only: pac_fmt

```

```

  use format_utils, only: write_separator, write_indent

```

```

  use format_defs, only: FMT_12, FMT_14, FMT_17, FMT_19

```

```

    use constants, only: tiny_13
    use diagnostics
    use md5
    use phs_base
    use rng_base
    use os_interface, only: mpi_get_comm_id
    use rng_stream, only: rng_stream_t

    use mci_base

    use vegas, only: VEGAS_MODE_IMPORTANCE, VEGAS_MODE_IMPORTANCE_ONLY
    use vamp2

```

Update a pass object, given a reference. The parameters must match, except for the `n_it` entry. The number of complete iterations must be less or equal to the reference, and the number of complete iterations in the reference must be no larger than `n_it`. Where results are present in both passes, they must match. Where results are present in the reference only, the pass is updated accordingly.

#### 21.7.4 Integrator

We store the different passes of integration, adaptation and actual sampling, in a linked list.

We store the total number of calls `n_calls` and the minimal number of calls `n_calls_min`. The latter is calculated based on `n_channel` and `min_calls_per_channel`. If `n_calls` is smaller than `n_calls_min`, then we replace `n_calls` with `n_min_calls`.

Read / write grids from / to file.

We split the reading process in two parts. First, we check on the header where we check (and update) all relevant pass data using `mci_vamp2_update`. In the second part we only read the integrator data. We implement `mci_vamp2_read` for completeness.

The writing of the MCI object is split into two parts, a header with the relevant process configuration regarding the integration and the results of the

different passes and their iterations. The other part is the actual grid. The header will always be written in ASCII format, including a md5 hash, in order to testify against unwilling changes to the setup. The grid part can be either added to the ASCII file, or to an additional binary file.

## Interface: VAMP2

We define the interfacing procedures, as such, initialising the VAMP2 integrator or resetting the results.

Initialise the VAMP2 integrator which is stored within the `mci` object, using the data of the current integration pass. Furthermore, reset the counters that track this set of integrator.

```

<MCI vamp2: mci vamp2: TBP>+≡

```

Integrate. Perform a new integration pass (possibly reusing previous results), which may consist of several iterations. We reinitialise the sampling new each time and set the workspace again. Note: we record the integral once per iteration. The integral stored in the mci record itself is the last integral of the current iteration, no averaging done. The results record may average results. Note: recording the efficiency is not supported yet.

We only allow the master to write the grids to file.

<MPI: MCI vamp2: mci vamp2 integrate: post sampling>≡  
 if (rank == 0) &

Write grids to `grid_filename` at a given checkpoint.

We qualify each iteration and pass as possible checkpoint. However, we allow the user to alter the checkpoint behavior:

- after every iteration,
- after every pass,
- after a  $N$  iterations and every pass.

The user sets the Sindarin variable `vamp_grid_checkpoint` to an integer value where the value 0 represents each pass, value 1 each iteration, and a value  $> 1$  means after  $N$  iterations (or at the last iteration of a pass).

### 21.7.6 Integrator instance

We store all information relevant for simulation. The event weight is stored, when a weighted event is generated, and the event excess, when a larger weight occurs than actual stored max. weight.

We give the possibility to rescale the `f_max` within the integrator object with `event_rescale_f_max`.

```
<MCI vamp2: public>+=
  public :: mci_vamp2_instance_t

<MCI vamp2: types>+=
  type, extends (mci_instance_t) :: mci_vamp2_instance_t
    class(mci_vamp2_func_t), allocatable :: func
    real(default), dimension(:), allocatable :: gi
    integer :: n_events = 0
    logical :: event_generated = .false.
    real(default) :: event_weight = 0.
    real(default) :: event_excess = 0.
    real(default) :: event_rescale_f_max = 1.
    real(default), dimension(:), allocatable :: event_x
  contains
    <MCI vamp2: mci vamp2 instance: TBP>
  end type mci_vamp2_instance_t
```

Output.

    mci%integrand = integrand
    call mci%func%set_integrand (integrand)
  end subroutine mci_vamp2_instance_record_integrand

```

## Event simulation

In contrast to VAMP, we reset only counters and set the safety factor, which will then be applied each time an event is generated. In that way we do not rescale the actual values in the integrator, but more the current value!

```

## Test sampler

A test sampler object should implement a function with known integral that we can use to check the integrator.

In mode 1, the function is  $f(x) = 3x^2$  with integral  $\int_0^1 f(x) dx = 1$  and maximum  $f(1) = 3$ . If the integration dimension is greater than one, the function is extended as a constant in the other dimension(s).

In mode 2, the function is  $11x^{10}$ , also with integral 1.

Mode 4 includes ranges of zero and negative function value, the integral is negative. The results should be identical to the results of `mci_midpoint_4`, where the same function is evaluated. The function is  $f(x) = (1 - 3x^2)\theta(x - 1/2)$  with integral  $\int_0^1 f(x) dx = -3/8$ , minimum  $f(1) = -2$  and maximum  $f(1/2) = 1/4$ .

```

<MCI vamp2: test types>≡
type, extends (mci_sampler_t) :: test_sampler_1_t
    real(default), dimension(:), allocatable :: x
    real(default) :: val
    integer :: mode = 1
contains
    <MCI vamp2: test sampler 1: TBP>
end type test_sampler_1_t

```

Output: There is nothing stored inside, so just print an informative line.

```

<MCI vamp2: test sampler 1: TBP>≡
    procedure, public :: write => test_sampler_1_write
<MCI vamp2: tests>≡
    subroutine test_sampler_1_write (object, unit, testflag)
        class(test_sampler_1_t), intent(in) :: object

## Two-channel, two dimension test sampler

This sampler implements the function

$$f(x, y) = 4 \sin^2(\pi x) \sin^2(\pi y) + 2 \sin^2(\pi v) \quad (21.19)$$

where

$$x = u^v \quad u = xy \quad (21.20)$$

$$y = u^{(1-v)} \quad v = \frac{1}{2} \left( 1 + \frac{\log(x/y)}{\log xy} \right) \quad (21.21)$$

Each term contributes 1 to the integral. The first term in the function is peaked along a cross aligned to the coordinates  $x$  and  $y$ , while the second term is peaked along the diagonal  $x = y$ .

The Jacobian is

$$\frac{\partial(x, y)}{\partial(u, v)} = |\log u| \quad (21.22)$$

```

### 22.1.2 Shower settings

These the general shower settings, the settings and parameters for the matching are defined in the corresponding matching modules. The width and the cutoff of the Gaussian primordial  $k_t$  distribution, PARP(91) and PARP(93), in GeV, are called `isr_primordial_kt_width` and `isr_primordial_kt_cutoff` in WHIZARD. The parameter MSTJ(45) gives the maximum number of flavors in gluon decay to quarks, and is here called `max_n_flavors`.

The two parameters `isr_alphas_running` and `[fsr_alphas_running` decide whether to use constant or running  $\alpha_s$  in the form of the function  $D_{\alpha_s}(t)$  for the FSR and ISR (MSTJ(44), MSTP(64)), respectively. The next parameter, `fixed_alpha_s` is the parameter PARU(111), which sets the value for constant  $\alpha_s$ , and the flag whether to use  $P_t$ -ordered ISR is `isr_pt_ordered`. From the entry `min_voirtuality` on, parameters have meanings both for the PYTHIA and WHIZARD parton shower(s), where PYTHIA values are denoted at the end of the line.

    use rng_base

    <Standard module head>

    <Shower partons: public>

    <Shower partons: types>

contains

    <Shower partons: procedures>

end module shower_partons

```

### 22.2.1 The basic type defintions

The type `parton_t` defines a parton for the shower. The `x` value of the parton is only needed for spacelike showers. The pointer `initial` is only needed for partons in initial showers, it points to the hadron the parton is coming from. An auxiliary value for the  $P_t$ -ordered ISR is `aux_pt`. Then, there are two auxiliary entries for the clustering of CKKW pseudo weights and CKKW matching, `ckkwlabel` and `ckkwscale`. In order to make shower settings available to all operations on the shower partons, we endow the `parton_t` type with a pointer to `shower_settings_t`.

```

<Shower partons: public>≡
    public :: parton_t

<Shower partons: types>≡
    type :: parton_t
        integer :: nr = 0
        integer :: type = 0

The parameters of the shower module:

```

<Shower core: parameters>≡
    real(default), save :: alphaspdfmax = 12._default

```

In this routine,  $y$  and  $y_{\min}$  are the jet measures,  $w$  and  $w_{\max}$  are weights,  $s$  is the kinematic energy squared of the interaction. The flag `isr_is_possible_and_allowed` checks whether the initial parton is set, lepton-hadron collisions are not implemented (yet).

As a workaround: as WHIZARD can treat partons as massless, there might be partons with  $E < m$ : if such a parton is found, quarks will be treated massless.

We combine the `particle_set` from the hard interaction with the partons of the shower. For simplicity, we do not maintain the mother-daughter-relations of the shower. Hadronic `beam_remnants` of the old `particle_set` are removed as they are provided, including proper flavor information, by the ISR shower.

!C      KTCLUS: written by Mike Seymour, July 1992.
!C      Last modified November 2000.
!C      Please send comments or suggestions to Mike.Seymour@rl.ac.uk
!C
!C      This is a general-purpose kt clustering package.
!C      It can handle ee, ep and pp collisions.
!C      It is loosely based on the program of Siggi Bethke.
!C
!C      The time taken (on a 10MIP machine) is (0.2microsec)*N**3
!C      where N is the number of particles.
!C      Over 90 percent of this time is used in subroutine KTPMIN, which
!C      simply finds the minimum member of a one-dimensional array.
!C      It is well worth thinking about optimization: on the SPARCstation
!C      a factor of two increase was obtained simply by increasing the
!C      optimization level from its default value.
!C
!C      The approach is to separate the different stages of analysis.
!C      KTCLUS does all the clustering and records a merging history.
!C      It returns a simple list of the y values at which each merging
!C      occurred. Then the following routines can be called to give extra
!C      information on the most recently analysed event.
!C      KTCLUR is identical but includes an R parameter, see below.
!C      KTYCUT gives the number of jets at each given YCUT value.
!C      KTYSUB gives the number of sub-jets at each given YCUT value.
!C      KTBEAM gives same info as KTCLUS but only for merges with the beam
!C      KTJOIN gives same info as KTCLUS but for merges of sub-jets.
!C      KTRECO reconstructs the jet momenta at a given value of YCUT.
!C      It also gives information on which jets at scale YCUT belong to
!C      which macro-jets at scale YMAC, for studying sub-jet properties.
!C      KTINCL reconstructs the jet momenta according to the inclusive jet
!C      definition of Ellis and Soper.
!C      KTISUB, KTIJOI and KTIREC are like KTYSUB, KTJOIN and KTRECO,
!C      except that they only apply to one inclusive jet at a time,
!C      with the pt of that jet automatically used for ECUT.
!C      KTWICH gives a list of which particles ended up in which jets.
!C      KTWCHS gives the same thing, but only for subjets.
!C      Note that the numbering of jets used by these two routines is
!C      guaranteed to be the same as that used by KTRECO.
!C
!C      The collision type and analysis type are indicated by the first
!C      argument of KTCLUS. IMODE=<TYPE><ANGLE><MONO><RECOM> where
!C      TYPE:  1=>ee, 2=>ep with p in -z direction, 3=>pe, 4=>pp
!C      ANGLE: 1=>angular kt def., 2=>DeltaR, 3=>f(DeltaEta,DeltaPhi)
!C              where f()=2(cosh(eta)-cos(phi)) is the QCD emission metric
!C      MONO:  1=>derive relative pseudoparticle angles from jets
!C              2=>monotonic definitions of relative angles
!C      RECOM: 1=>E recombination scheme, 2=>pt scheme, 3=>pt**2 scheme
!C
!C      There are also abbreviated forms for the most common combinations:

```

```

!C      IMODE=1 => E scheme in e+e-                      (=1111)
!C      2 => E scheme in ep                             (=2111)
!C      3 => E scheme in pe                             (=3111)
!C      4 => E scheme in pp                             (=4111)
!C      5 => covariant E scheme in pp                   (=4211)
!C      6 => covariant pt-scheme in pp                  (=4212)
!C      7 => covariant monotonic pt**2-scheme in pp     (=4223)
!C
!C      KTRECO no longer needs to reconstruct the momenta according to the
!C      same recombination scheme in which they were clustered. Its first
!C      argument gives the scheme, taking the same values as RECOM above.
!C
!C      Note that unlike previous versions, all variables which hold y
!C      values have been named in a consistent way:
!C      Y() is the output scale at which jets were merged,
!C      YCUT is the input scale at which jets should be counted, and
!C      jet-momenta reconstructed etc,
!C      YMAC is the input macro-jet scale, used in determining whether
!C      or not each jet is a sub-jet.
!C      The original scheme defined in our papers is equivalent to always
!C      setting YMAC=1.
!C      Whenever a YCUT or YMAC variable is used, it is rounded down
!C      infinitesimally, so that for example, setting YCUT=Y(2) refers
!C      to the scale where the event is 2-jet, even if rounding errors
!C      have shifted its value slightly.
!C
!C      An R parameter can be used in hadron-hadron collisions by
!C      calling KTCLUR instead of KTCLUS. This is as suggested by
!C      Ellis and Soper, but implemented slightly differently,
!C      as in M.H. Seymour, LU TP 94/2 (submitted to Nucl. Phys. B.).
!C      R**2 multiplies the single Kt everywhere it is used.
!C      Calling KTCLUR with R=1 is identical to calling KTCLUS.
!C      R plays a similar role to the jet radius in a cone-type algorithm,
!C      but is scaled up by about 40% (ie R=0.7 in a cone algorithm is
!C      similar to this algorithm with R=1).
!C      Note that R.EQ.1 must be used for the e+e- and ep versions,
!C      and is strongly recommended for the hadron-hadron version.
!C      However, R values smaller than 1 have been found to be useful for
!C      certain applications, particularly the mass reconstruction of
!C      highly-boosted colour-singlets such as high-pt hadronic Ws,
!C      as in M.H. Seymour, LU TP 93/8 (to appear in Z. Phys. C.).
!C      Situations in which R<1 is useful are likely to also be those in
!C      which the inclusive reconstruction method is more useful.
!C
!C      Also included is a set of routines for doing Lorentz boosts:
!C      KTLBST finds the boost matrix to/from the cm frame of a 4-vector
!C      KTRROT finds the rotation matrix from one vector to another
!C      KTMMUL multiplies together two matrices
!C      KTMVUL multiplies a vector by a matrix
!C      KTINVT inverts a transformation matrix (nb NOT a general 4 by 4)
!C      KTFRAM boosts a list of vectors between two arbitrary frames
!C      KTBREI boosts a list of vectors between the lab and Breit frames
!C      KTHADR boosts a list of vectors between the lab and hadronic cmf
!C      The last two need the momenta in the +z direction of the lepton

```

```

!C      and hadron beams, and the 4-momentum of the outgoing lepton.
!C
!C      The main reference is:
!C      S. Catani, Yu.L. Dokshitzer, M.H. Seymour and B.R. Webber,
!C      Nucl.Phys.B406(1993)187.
!C      The ep version was proposed in:
!C      S. Catani, Yu.L. Dokshitzer and B.R. Webber,
!C      Phys.Lett.285B(1992)291.
!C      The inclusive reconstruction method was proposed in:
!C      S.D. Ellis and D.E. Soper,
!C      Phys.Rev.D48(1993)3160.

Setup the user process for the LHA interface.

We fill the user process with the correct information on the beams, and set the strategy of the user process to weighted events. `process_id` and `n_processes`

are not used by LHA user process for weighted (or unweighted) events, but required by the LHA user process interface. Therefore, we choose arbitrary defaults.

## Chapter 23

# Multiple Interactions (MPI) Code

### 23.1 The Multiple Interactions main module

This file contains the module `muli` which is the multiple parton interactions interface module to `WHIZARD`. `muli` is supposed to run together with initial state radiation. Both share a momentum evolution variable and compete for beam momentum, so the generation of this scale variable must be fully transparent to `WHIZARD`. This here is a stub as long as there is no working `WHIZARD` implementation for multiple interactions. It gives an interface for the necessary routines.

```

## Chapter 24

# BLHA Interface

The code in this chapter implements support for the BLHA record that communicates data for NLO processes.

These are the modules:

**blha\_config**

**blha\_interface**

**blha\_driver**

### 24.1 Module definition

These modules implement the communication with one loop matrix element providers according to the Binoth LesHouches Accord Interface. The actual matrix element(s) are loaded as a dynamic library.

This module defines the common OLP-interfaces defined through the Binoth Les-Houches accord.

```
<blha_olp_interfaces.f90>≡  
  <File header>  
  
  module blha_olp_interfaces  
  
    use, intrinsic :: iso_c_binding !NODEP!  
    use, intrinsic :: iso_fortran_env  
  
    use kinds  
    <Use strings>  
    <Use debug>  
    use constants  
    use numeric_utils, only: vanishes  
    use numeric_utils, only: extend_integer_array, crop_integer_array  
    use io_units  
    use string_utils  
    use physics_defs  
    use diagnostics  
    use os_interface
```

Figure 24.1: Module dependencies in `src/blha`.

Computes a virtual matrix element from an interface to an external one-loop provider. The output of `blha_olp_eval2` is an array of `dimension(4)`, corresponding to the  $\epsilon^2$ -,  $\epsilon^1$ - and  $\epsilon^0$ -poles of the virtual matrix element at position `r(1:3)` and the Born matrix element at position `r(4)`. The matrix element is rejected if its accuracy is larger than the maximal allowed accuracy. OpenLoops includes a factor of  $1 / n_{\text{hel}}$  in the amplitudes, which we have to undo if polarized matrix elements are requested (GoSam does not support polarized matrix elements).

In general, the BLHA consists of a virtual matrix element and  $n_{\text{sub}}$  subtraction terms. The subtraction terms can be pure Born matrix elements (to be used in collinear subtraction or in internal color-correlation), color-correlated matrix elements or spin-correlated matrix elements. The numbers should be ordered in such a way that  $\mathcal{V}_{\text{fin}}$  is first, followed by the pure Born, the color-correlated and the spin-correlated matrix elements. This repeats  $n_{\text{flv}}$  times. Let  $\nu_i$  be the position of the  $i$ th virtual matrix element. The next  $\mathcal{V}_{\text{fin}}$  is at position  $\nu_i = \nu_{i-1} + n_{\text{sub}} + 1$ . Obviously,  $\nu_1 = 1$ . This allows us to determine the virtual matrix element positions using the recursive function implemented below.

```
<BLHA OLP interfaces: public>+=
  public :: blha_loop_positions

<BLHA OLP interfaces: procedures>+=
  recursive function blha_loop_positions (i_flg, n_sub) result (index)
    integer :: index
    integer, intent(in) :: i_flg, n_sub
    index = 0
    if (i_flg == 1) then
      index = 1
    else
      index = blha_loop_positions (i_flg - 1, n_sub) + n_sub + 1
    end if
  end function blha_loop_positions
```

The module is split into a configuration interface which manages configuration and handles the request and contract files, a module which interfaces the OLP matrix elements and a driver.
