```

Subroutine of the initialization above: initialize the beam and structure-function chain template. We establish pointers to the configuration data, so `beam_config` must have a `target` attribute.

The resulting chain is not used directly for calculation. It will acquire instances which are stored in the process-component instance objects.

```

<Instances: process instance: TBP>+≡
  procedure :: setup_sf_chain => process_instance_setup_sf_chain

<Instances: procedures>+≡
  subroutine process_instance_setup_sf_chain (instance, config)
    class(process_instance_t), intent(inout) :: instance
    type(process_beam_config_t), intent(in), target :: config
    integer :: n_strfun
    n_strfun = config%n_strfun
    if (n_strfun /= 0) then
      call instance%sf_chain%init (config%data, config%sf)
    else
      call instance%sf_chain%init (config%data)
    end if
    if (config%sf_trace) then
      call instance%sf_chain%setup_tracing (config%sf_trace_file)
    end if
  end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

<Instances: process instance: TBP>+≡
  procedure :: setup_event_data => process_instance_setup_event_data

<Instances: procedures>+≡
  subroutine process_instance_setup_event_data (instance, model, i_core)
    class(process_instance_t), intent(inout), target :: instance
    class(model_data_t), intent(in), optional, target :: model

            call term%setup_event_data (core, current_model)
        end if
    end associate
end do
core => null ()
end subroutine process_instance_setup_event_data

```

Choose a MC parameter set and the corresponding integrator. The choice persists beyond calls of the `reset` method above. This method is automatically called here.

```

<Instances: process instance: TBP>+≡
    procedure :: choose_mci => process_instance_choose_mci

<Instances: procedures>+≡
    subroutine process_instance_choose_mci (instance, i_mci)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci
        instance%i_mci = i_mci
        call instance%reset ()
    end subroutine process_instance_choose_mci

```

Explicitly set a MC parameter set. Works only if we are in initial state. We assume that the length of the parameter set is correct.

After setting the parameters, activate the components and terms that correspond to the chosen MC parameter set.

The `warmup_flag` is used when a dummy phase-space point is computed for the warmup of e.g. OpenLoops helicities. The setting of the `evaluation_status` has to be avoided then.

```

<Instances: process instance: TBP>+≡
    procedure :: set_mcpair => process_instance_set_mcpair

<Instances: procedures>+≡
    subroutine process_instance_set_mcpair (instance, x, warmup_flag)
        class(process_instance_t), intent(inout) :: instance
        real(default), dimension(:), intent(in) :: x
        logical, intent(in), optional :: warmup_flag
        logical :: activate
        activate = .true.; if (present (warmup_flag)) activate = .not. warmup_flag
        if (instance%evaluation_status == STAT_INITIAL) then
            associate (mci_work => instance%mci_work(instance%i_mci))
                call mci_work%set (x)
            end associate
            if (activate) call instance%activate ()
        end if
    end subroutine process_instance_set_mcpair

```

```

    end if
end subroutine process_instance_set_mcpair

```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The `sf_chain` instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```

<Instances: process instance: TBP>+≡
  procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

<Instances: procedures>+≡
  subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%receive_beam_momenta ()
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_receive_beam_momenta

```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```

<Instances: process instance: TBP>+≡
  procedure :: set_beam_momenta => process_instance_set_beam_momenta

<Instances: procedures>+≡
  subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%set_beam_momenta (p)
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_set_beam_momenta

```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```

<Instances: process instance: TBP>+≡
  procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

<Instances: procedures>+≡
  subroutine process_instance_recover_beam_momenta (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    if (.not. instance%process%lab_is_cm ()) then
      if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
        call instance%term(i_term)%return_beam_momenta ()
      end if
    end if
  end subroutine process_instance_recover_beam_momenta

```

```

        end if
    end subroutine process_instance_recover_beam_momenta

```

Explicitly choose MC integration channel. We assume here that the channel count is identical for all active components.

```

<Instances: process instance: TBP>+=
    procedure :: select_channel => process_instance_select_channel

<Instances: procedures>+=
    subroutine process_instance_select_channel (instance, channel)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
        instance%selected_channel = channel
    end subroutine process_instance_select_channel

```

First step of process evaluation: set up seed kinematics. That is, for each active process component, compute a momentum array from the MC input parameters.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Instances: process instance: TBP>+=
    procedure :: compute_seed_kinematics => &

Calculates and then saves the ratio of the value of the (rescaled) real structure function chain of each ISR alpha region over the value of the corresponding underlying born flavor structure. In the case of emitter 0 we also need the rescaled ratio for emitter 1 and 2 in that region for the (soft-)collinear limits. Although this procedure is implying functionality for general structure functions, it should be reviewed for anything else besides PDFs, as there might be complications in the details. The general idea of getting the ratio in this way should hold up in these cases as well, however.

```

Final step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

If **weight** is provided, we already know the kinematical event weight (the MCI weight which depends on the kinematics sampling algorithm, but not on the matrix element), so we do not need to take it from the MCI record.

```

Computes the real-emission matrix element for externally supplied momenta for the term instance with index `i_term` and a phase space point set with index `i_phs`. In addition, for the real emission, each term instance corresponds to one emitter. Also, e.g. for Powheg, there is the possibility to supply an external  $\alpha_s$ .

    end if
  end subroutine process_instance_normalize_weight

```

This is a convenience routine that performs the computations of the steps 1 to 5 in a single step. The arguments are the input for `set_mcpair`. After this, the evaluation status should be either `STAT_FAILED_KINEMATICS`, `STAT_FAILED_CUTS` or `STAT_EVALUATED_TRACE`.

Before calling this, we should call `choose_mci`.

```

<Instances: process instance: TBP>+≡
  procedure :: evaluate_sqme => process_instance_evaluate_sqme

<Instances: procedures>+≡
  subroutine process_instance_evaluate_sqme (instance, channel, x)
    class(process_instance_t), intent(inout) :: instance

    call instance%compute_eff_kinematics ()
    call instance%evaluate_expressions ()
    call instance%compute_other_channels ()
    call instance%evaluate_trace ()
  end subroutine process_instance_evaluate_sqme

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

```

<Instances: process instance: TBP>+≡
  procedure :: recover => process_instance_recover

<Instances: procedures>+≡
  subroutine process_instance_recover &
    (instance, channel, i_term, update_sqme, recover_phs, scale_forced)

```

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the  $x$  array, and the  $f$  Jacobian array are exposed by the `sampler_t` object.

We allow for the additional `hook` to be called, if associated, for outlying object to access information from the current state of the `sampler`.

*(Instances: process instance: TBP)* +=

```

procedure :: evaluate => process_instance_evaluate

```

*(Instances: procedures)* +=

```

subroutine process_instance_evaluate (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call sampler%evaluate_sqme (c, x_in)
    if (sampler%is_valid ()) then
        call sampler%fetch (val, x, f)
    end if
    call sampler%record_call ()
    call sampler%evaluate_after_hook ()
end subroutine process_instance_evaluate

```

The phase-space point is valid if the event has valid kinematics and has passed the cuts.

```

<Instances: process instance: TBP>+=
  procedure :: is_valid => process_instance_is_valid

<Instances: procedures>+=
  function process_instance_is_valid (sampler) result (valid)
    class(process_instance_t), intent(in) :: sampler
    logical :: valid
    valid = sampler%evaluation_status >= STAT_PASSED_CUTS
  end function process_instance_is_valid

```

Add a process\_instance\_hook object..

```

<Instances: process instance: TBP>+=
  procedure :: append_after_hook => process_instance_append_after_hook

<Instances: procedures>+=
  subroutine process_instance_append_after_hook (sampler, new_hook)
    class(process_instance_t), intent(inout), target :: sampler
    class(process_instance_hook_t), intent(inout), target :: new_hook
    class(process_instance_hook_t), pointer :: last
    if (associated (new_hook%next)) then
      call msg_bug ("process_instance_append_after_hook: reuse of SAME hook object is forbidden.")
    end if
    if (associated (sampler%hook)) then

```

## Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

If `n_incoming` is provided, the status code of the first `n_incoming` particles will be reset to incoming. Otherwise, they would be classified as virtual.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

NB: The `recover_beams` option should be used only when the particle set originates from an external event file, and the user has asked for it. It should be switched off when reading from raw event file.

*(Instances: process instance: TBP)+≡*

```
procedure :: get_trace => process_instance_get_trace
procedure :: set_trace => process_instance_set_trace
```

*(Instances: procedures)+≡*

```
subroutine process_instance_get_trace (instance, pset, i_term, n_incoming)
  class(process_instance_t), intent(in), target :: instance
  type(particle_set_t), intent(out) :: pset
  integer, intent(in) :: i_term
  integer, intent(in), optional :: n_incoming
  type(interaction_t), pointer :: int
  logical :: ok
  int => instance%get_trace_int_ptr (i_term)
  call pset%init (ok, int, int, FM_IGNORE_HELICITY, &
    [0._default, 0._default], .false., .true., n_incoming)
end subroutine process_instance_get_trace
```

```
subroutine process_instance_set_trace &
  (instance, pset, i_term, recover_beams, check_match, success)
  class(process_instance_t), intent(inout), target :: instance
  type(particle_set_t), intent(in) :: pset
  integer, intent(in) :: i_term
  logical, intent(in), optional :: recover_beams, check_match
  logical, intent(out), optional :: success
  type(interaction_t), pointer :: int
  integer :: n_in
  int => instance%get_trace_int_ptr (i_term)
  n_in = instance%process%get_n_in ()
  call pset%fill_interaction (int, n_in, &
    recover_beams = recover_beams, &
    check_match = check_match, &
    state_flg = instance%get_state_flg (i_term), &
    success = success)
end subroutine process_instance_set_trace
```

This procedure allows us to override any QCD setting of the WHIZARD process and directly set the coupling value that comes together with a particle set.

```

## Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```

<Processes: execute tests>+≡
  call test (processes_8, "processes_8", &
    "process evaluation with structure functions", &
    u, results)

## Complete events

For the purpose of simplifying further tests, we implement a convenience routine that initializes a process and prepares a single event. This is a wrapup of the test `processes_10`.

The procedure is re-exported by the `processes_ut` module.

```
<Processes: public test auxiliary>≡
  public :: prepare_test_process
<Processes: test auxiliary>+≡
  subroutine prepare_test_process &
    (process, process_instance, model, var_list, run_id)
    type(process_t), intent(out), target :: process
    type(process_instance_t), intent(out), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(var_list_t), intent(inout), optional :: var_list
    type(string_t), intent(in), optional :: run_id
    type(process_library_t), target :: lib
    type(string_t) :: libname
    type(string_t) :: procname
    type(os_data_t) :: os_data
    type(model_t), allocatable, target :: process_model
    class(mci_t), pointer :: mci
    class(phs_config_t), allocatable :: phs_config_template
    real(default) :: sqrts
    libname = "processes_test"
    procname = libname
    call os_data%init ()
    call prc_test_create_library (libname, lib)
    call reset_interaction_counter ()
    allocate (process_model)
    call process_model%init (model%get_name (), &
      model%get_n_real (), &
      model%get_n_complex (), &
      model%get_n_field (), &
      model%get_n_vtx ())
    call process_model%copy_from (model)
    call process%init (procname, lib, os_data, process_model, var_list)
    if (present (run_id)) call process%set_run_id (run_id)
    call process%setup_test_cores ()
    allocate (phs_test_config_t :: phs_config_template)
    call process%init_components (phs_config_template)
    sqrts = 1000
    call process%setup_beams_sqrts (sqrts, i_core = 1)
    call process%configure_phs ()
    call process%setup_mci (dispatch_mci_test10)
    call process%setup_terms ()
    call process_instance%init (process)
    call process%test_get_mci_ptr (mci)

## Resonances in Phase Space

This test demonstrates the extraction of the resonance-history set from the generated phase space. We need a nontrivial process, but no matrix element. This is provided by the `prc.template` method, using the SM model. We also

need the `phs_wood` method, otherwise we would not have resonances in the phase space configuration.

```

<Processes: execute tests>+≡
    call test (processes_18, "processes_18", &
               "extract resonance history set", &
               u, results)

## 30.12 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

```

<process_stacks.f90>≡
<File header>

module process_stacks

  <Use kinds>
  <Use strings>
  use io_units
  use format_utils, only: write_separator
  use diagnostics
  use os_interface
  use sm_qcd
  use model_data
  use rng_base
  use variables
  use observables
  use process_libraries
  use process

  <Standard module head>

  <Process stacks: public>

  <Process stacks: types>

contains

  <Process stacks: procedures>

end module process_stacks

```

### 30.12.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```
<Process stacks: public>≡
    public :: process_entry_t

<Process stacks: types>≡
    type, extends (process_t) :: process_entry_t
        type(process_entry_t), pointer :: next => null ()
    end type process_entry_t
```

### 30.12.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

The process stack can be linked to another one. This allows us to work with stacks of local scope.

```
<Process stacks: public>+≡
    public :: process_stack_t

<Process stacks: types>+≡
    type :: process_stack_t
        integer :: n = 0
        type(process_entry_t), pointer :: first => null ()
        type(var_list_t), pointer :: var_list => null ()
        type(process_stack_t), pointer :: next => null ()
    contains
        <Process stacks: process stack: TBP>
    end type process_stack_t
```

Finalize partly: deallocate the process stack and variable list entries, but keep the variable list as an empty object. This way, the variable list links are kept.

```
<Process stacks: process stack: TBP>≡
    procedure :: clear => process_stack_clear

<Process stacks: procedures>≡
    subroutine process_stack_clear (stack)
        class(process_stack_t), intent(inout) :: stack
        type(process_entry_t), pointer :: process
        if (associated (stack%var_list)) then
            call stack%var_list%final ()
        end if
        do while (associated (stack%first))
            process => stack%first
            stack%first => process%next
            call process%final ()
            deallocate (process)
        end do
```

```

        stack%n = 0
    end subroutine process_stack_clear

```

Finalizer. Clear and deallocate the variable list.

```

<Process stacks: process stack: TBP>+≡
    procedure :: final => process_stack_final

<Process stacks: procedures>+≡
    subroutine process_stack_final (object)
        class(process_stack_t), intent(inout) :: object
        call object%clear ()
        if (associated (object%var_list)) then
            deallocate (object%var_list)
        end if
    end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write => process_stack_write

<Process stacks: procedures>+≡
    recursive subroutine process_stack_write (object, unit, pacify)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: pacify
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)
        call write_separator (u, 2)
        select case (object%n)
        case (0)
            write (u, "(1x,A)") "Process stack: [empty]"
            call write_separator (u, 2)
        case default
            write (u, "(1x,A)") "Process stack:"
            process => object%first
            do while (associated (process))
                call process%write (.false., u, pacify = pacify)
                process => process%next
            end do
        end select
        if (associated (object%next)) then
            write (u, "(1x,A)") "[Processes from context environment:]"
            call object%next%write (u, pacify)
        end if
    end subroutine process_stack_write

```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write_var_list => process_stack_write_var_list

```

```

<Process stacks: procedures>+≡
  subroutine process_stack_write_var_list (object, unit)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    if (associated (object%var_list)) then
      call var_list_write (object%var_list, unit)
    end if
  end subroutine process_stack_write_var_list

```

Short output.

Since this is a stack, the default output ordering for each stack will be last-in, first-out. To enable first-in, first-out, which is more likely to be requested, there is an optional `fifo` argument.

```

<Process stacks: process stack: TBP>+≡
  procedure :: show => process_stack_show

<Process stacks: procedures>+≡
  recursive subroutine process_stack_show (object, unit, fifo)
    class(process_stack_t), intent(in) :: object

  end subroutine process_stack_show

```

### 30.12.3 Link

Link the current process stack to a global one.

```

<Process stacks: process stack: TBP>+≡

```

```

    procedure :: link => process_stack_link
  <Process stacks: procedures>+≡
    subroutine process_stack_link (local_stack, global_stack)
      class(process_stack_t), intent(inout) :: local_stack
      type(process_stack_t), intent(in), target :: global_stack
      local_stack%next => global_stack
    end subroutine process_stack_link

```

Initialize the process variable list and link the main variable list to it.

```

  <Process stacks: process stack: TBP>+≡
    procedure :: init_var_list => process_stack_init_var_list
  <Process stacks: procedures>+≡
    subroutine process_stack_init_var_list (stack, var_list)
      class(process_stack_t), intent(inout) :: stack
      type(var_list_t), intent(inout), optional :: var_list
      allocate (stack%var_list)
      if (present (var_list)) call var_list%link (stack%var_list)
    end subroutine process_stack_init_var_list

```

Link the process variable list to a global variable list.

```

  <Process stacks: process stack: TBP>+≡
    procedure :: link_var_list => process_stack_link_var_list
  <Process stacks: procedures>+≡
    subroutine process_stack_link_var_list (stack, var_list)
      class(process_stack_t), intent(inout) :: stack
      type(var_list_t), intent(in), target :: var_list
      call stack%var_list%link (var_list)
    end subroutine process_stack_link_var_list

```

### 30.12.4 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

  <Process stacks: process stack: TBP>+≡
    procedure :: push => process_stack_push
  <Process stacks: procedures>+≡
    subroutine process_stack_push (stack, process)
      class(process_stack_t), intent(inout) :: stack
      type(process_entry_t), intent(inout), pointer :: process
      process%next => stack%first
      stack%first => process
      process => null ()
      stack%n = stack%n + 1
    end subroutine process_stack_push

```

Inverse: Remove the last process pointer in the list and return it.

```

  <Process stacks: process stack: TBP>+≡
    procedure :: pop_last => process_stack_pop_last

```

```

(Process stacks: procedures)+≡
subroutine process_stack_pop_last (stack, process)
  class(process_stack_t), intent(inout) :: stack
  type(process_entry_t), intent(inout), pointer :: process
  type(process_entry_t), pointer :: previous
  integer :: i
  select case (stack%n)
  case (:0)
    process => null ()
  case (1)
    process => stack%first
    stack%first => null ()
    stack%n = 0
  case (2:)
    process => stack%first
    do i = 2, stack%n
      previous => process
      process => process%next
    end do
    previous%next => null ()
    stack%n = stack%n - 1
  end select
end subroutine process_stack_pop_last

```

Initialize process variables for a given process ID, without setting values.

```

(Process stacks: process stack: TBP)+≡
procedure :: init_result_vars => process_stack_init_result_vars

(Process stacks: procedures)+≡
subroutine process_stack_init_result_vars (stack, id)
  class(process_stack_t), intent(inout) :: stack
  type(string_t), intent(in) :: id
  call var_list_init_num_id (stack%var_list, id)
  call var_list_init_process_results (stack%var_list, id)
end subroutine process_stack_init_result_vars

```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```

(Process stacks: process stack: TBP)+≡
procedure :: fill_result_vars => process_stack_fill_result_vars

(Process stacks: procedures)+≡
subroutine process_stack_fill_result_vars (stack, id)
  class(process_stack_t), intent(inout) :: stack
  type(string_t), intent(in) :: id
  type(process_t), pointer :: process
  process => stack%get_process_ptr (id)
  if (associated (process)) then
    call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
    if (process%has_integral ()) then
      call var_list_init_process_results (stack%var_list, id, &
        integral = process%get_integral (), &

```

```

        error = process%get_error ()
    end if
else
    call msg_bug ("process_stack_fill_result_vars: unknown process ID")
end if
end subroutine process_stack_fill_result_vars

```

If one of the result variables has a local image in `var_list_local`, update the value there as well.

```

(Process stacks: process stack: TBP)+≡
    procedure :: update_result_vars => process_stack_update_result_vars

(Process stacks: procedures)+≡
    subroutine process_stack_update_result_vars (stack, id, var_list_local)
        class(process_stack_t), intent(inout) :: stack
        type(string_t), intent(in) :: id
        type(var_list_t), intent(inout) :: var_list_local
        call update ("integral(" // id // ")")
        call update ("error(" // id // ")")
    contains
        subroutine update (var_name)
            type(string_t), intent(in) :: var_name
            real(default) :: value
            if (var_list_local%contains (var_name, follow_link = .false.)) then
                value = stack%var_list%get_rval (var_name)
                call var_list_local%set_real (var_name, value, is_known = .true.)
            end if
        end subroutine update
    end subroutine process_stack_update_result_vars

```

### 30.12.5 Data Access

Tell if a process exists.

```

(Process stacks: process stack: TBP)+≡
    procedure :: exists => process_stack_exists

(Process stacks: procedures)+≡
    function process_stack_exists (stack, id) result (flag)
        class(process_stack_t), intent(in) :: stack
        type(string_t), intent(in) :: id
        logical :: flag
        type(process_t), pointer :: process
        process => stack%get_process_ptr (id)
        flag = associated (process)
    end function process_stack_exists

```

Return a pointer to a process with specific ID. Look also at a linked stack, if necessary.

```

(Process stacks: process stack: TBP)+≡
    procedure :: get_process_ptr => process_stack_get_process_ptr

```

```

<Process stacks: procedures>+≡
  recursive function process_stack_get_process_ptr (stack, id) result (ptr)
    class(process_stack_t), intent(in) :: stack
    type(string_t), intent(in) :: id
    type(process_t), pointer :: ptr
    type(process_entry_t), pointer :: entry
    ptr => null ()
    entry => stack%first
    do while (associated (entry))
      if (entry%get_id () == id) then
        ptr => entry%process_t
        return
      end if
      entry => entry%next
    end do
    if (associated (stack%next)) ptr => stack%next%get_process_ptr (id)
  end function process_stack_get_process_ptr

```

### 30.12.6 Unit tests

Test module, followed by the corresponding implementation module.

```

<process_stacks_ut.f90>≡
  <File header>

  module process_stacks_ut
    use unit_tests
    use process_stacks_uti

    <Standard module head>

    <Process stacks: public test>

    contains

    <Process stacks: test driver>

  end module process_stacks_ut

<process_stacks_uti.f90>≡
  <File header>

  module process_stacks_uti

    <Use strings>
    use os_interface
    use sm_qcd
    use models
    use model_data
    use variables, only: var_list_t
    use process_libraries
    use rng_base
    use prc_test, only: prc_test_create_library
    use process, only: process_t

```

```

    use instances, only: process_instance_t
    use processes_ut, only: prepare_test_process

    use process_stacks

    use rng_base_ut, only: rng_test_factory_t

    <Standard module head>

    <Process stacks: test declarations>

contains

    <Process stacks: tests>

end module process_stacks_ut

API: driver for the unit tests below.
<Process stacks: public test>≡
    public :: process_stacks_test
<Process stacks: test driver>≡
    subroutine process_stacks_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Process stacks: execute tests>
    end subroutine process_stacks_test

```

## Write an empty process stack

The most trivial test is to write an uninitialized process stack.

```

<Process stacks: execute tests>≡
    call test (process_stacks_1, "process_stacks_1", &
        "write an empty process stack", &
        u, results)
<Process stacks: test declarations>≡
    public :: process_stacks_1
<Process stacks: tests>≡

*⟨Matching base: interfaces⟩*

contains

*⟨Matching base: procedures⟩*

end module matching\_base

## 31.1 Abstract Matching Type

A matching will need access to the `shower` as well as matrix elements that we currently get over `process_instace`. The `model` is intended for the backup `model_hadrons`.

*⟨Matching base: public⟩*≡

public :: matching\_t

*⟨Matching base: types⟩*≡

type, abstract :: matching\_t

logical :: is\_hadron\_collision = .false.

type(qcd\_t) :: qcd

class(shower\_base\_t), pointer :: shower => null ()

type(process\_instance\_t), pointer :: process\_instance => null ()

class(model\_data\_t), pointer :: model => null ()

class(rng\_t), allocatable :: rng

type(string\_t) :: process\_name

contains

*⟨Matching base: matching: TBP⟩*

end type matching\_t

*⟨Matching base: matching: TBP⟩*≡

procedure (matching\_init), deferred :: init

*⟨Matching base: interfaces⟩*≡

abstract interface

subroutine matching\_init (matching, var\_list, process\_name)

import

class(matching\_t), intent(out) :: matching

type(var\_list\_t), intent(in) :: var\_list

type(string\_t), intent(in) :: process\_name

end subroutine matching\_init

end interface

If we use a polymorphic settings type, this boilerplate wouldn't be necessary but then we introduce `select type` statements all over the place.

*⟨default matching init⟩*≡

type(var\_list\_t), intent(in) :: var\_list

type(string\_t), intent(in) :: process\_name

if (debug\_on) call msg\_debug (D\_MATCHING, "matching\_init")

### 31.3 CKKW matching

This module contains the CKKW matching.

The type `ckkw_pseudo_shower_weights_t` gives the (relative) weights for different clusterings of the final particles, as given in Eq. (2.7) of hep-ph/0503281v1. Each particle has a binary labelling (power of 2) (first particle = 1, second particle = 2, third particle = 4, ...). Each recombination therefore corresponds to an integer, that is not a power of 2. For multiple subsequent recombinations, no different weights for different sequences of clustering are stored. It is assumed that the weight of a multiply recombined state is a combination of the states with one fewer recombination and that these states' contributions are proportional to their weights. For a  $2 - > n$  event, the weights array thus has the size  $2^{(2+n)-1}$ . The `weights_by_type` array gives the weights depending on the type of the particle, the first index is the same as for weights, the second index gives the type of the new mother particle:

- 0: uncolored ( $\gamma$ ,  $Z$ ,  $W$ , Higgs)
- 1: colored (quark)
- 2: gluon
- 3: squark

#### 4: gluino

`alphaS` gives the value for  $\alpha_s$  used in the generation of the matrix element. This is needed for the reweighting using the values for a running  $\alpha_s$  at the scales of the clusterings.

```

## 31.4 POWHEG

This module generates radiation according to the POWHEG Sudakov form factor

$$\Delta^{f_b}(\Phi_n, p_T) = \prod_{\alpha_r \in \{\alpha_r | f_b\}} \Delta_{\alpha_r}^{f_b}(\Phi_n, p_T), \quad (31.1)$$

with

$$\Delta_{\alpha_r}^{f_b}(\Phi_n, p_T) = \exp \left\{ - \left[ \int d\Phi_{\text{rad}} \frac{R(\Phi_{n+1})}{B^{f_b}(\Phi_n)} \theta(k_T(\Phi_{n+1}) - p_T) \right]_{\alpha_r}^{\tilde{\Phi}_n^{\alpha_r} = \Phi_n} \right\} \quad (31.2)$$

We expect that an underlying Born flavor structure  $f_b$  has been generated with a probability proportional to its contribution to the  $\tilde{B}$  at the given kinematic point.

```

To generate the transverse momentum, we have to solve the equation

$$\frac{\Delta^{(U)}(p_T)}{\Delta^{(U)}(p_T^{\max})} = r_1$$

iteratively for  $p_T$ . In log space and with initially  $\Delta^{(U)}(p_T^{\max}) = 1$ , this is

$$\log \Delta^{(U)}(p_T) = \log r_1$$

If no solution is found, we set  $p_T = p_T^{\min}$  to exit the event generation loop and generate an emissionless event. If a solution is found but the current emission is not accepted, we set  $p_T = p_T^{\max}$  and thus in the next step it is  $\Delta^{(U)}(p_T^{\max}) = r_1$ , so that we have to solve the equation

$$\log \Delta^{(U)}(p_T) = \log r_1 + \log r_2$$

using another random number  $r_2$ . We use `sum_log_rands` to remember the sum of the logarithms of all previous random numbers used for this event.

Generates the FKS variables  $(\xi, y, \phi)$  and sets the emission hardness scale. In debug mode, we assert that the `pt2` saved in the `radiation_t` and the massive hardness scale are equal. This should hold as we compute `kt2` with the `y` we got from generating `pt2` so that this is a full circle. It then initiates the generation of the transverse momentum followed by a sequence of veto steps to get the correct distribution.

    (sudakov%i_phs, sudakov%associated_emitter(), UBF_FSR_MASSLESS_RECOIL, xi, y)
end function sudakov_eeqq_fsr_kt2

```

For eeqq, the shower starts at  $k_{\max} = \frac{q^0}{2}$ . (c.f. eq. (7.86) in [0709.2092].)

```

<POWHEG matching: sudakov eeqq fsr: TBP>+=
procedure :: kt2_max => sudakov_eeqq_fsr_kt2_max

<POWHEG matching: procedures>+=
pure function sudakov_eeqq_fsr_kt2_max (sudakov) result (kt2_max)
  real(default) :: kt2_max
  class(sudakov_eeqq_fsr_t), intent(in) :: sudakov
  kt2_max = 0.25_default * sudakov%event_deps%s_hat
end function sudakov_eeqq_fsr_kt2_max

```

This covers also the singularity at  $(\xi, y) \rightarrow (1, -1)$  that occurs for a massless recoiling system.

```

<POWHEG matching: sudakov eeqq fsr: TBP>+=
procedure :: upper_bound_func => sudakov_eeqq_fsr_upper_bound_func

<POWHEG matching: procedures>+=
pure function sudakov_eeqq_fsr_upper_bound_func (sudakov, xi, y, alpha_s) result (u)
  real(default) :: u
  class(sudakov_eeqq_fsr_t), intent(in) :: sudakov
  real(default), intent(in) :: xi, y, alpha_s
  u = alpha_s / (xi * (1 - y**2))
end function sudakov_eeqq_fsr_upper_bound_func

```

The logarithmic integrated UBF in the eeqq case as explained in [0709.2092], eq. (7.98), is given by

$$\begin{aligned}
-\frac{1}{N} \log [\Delta^U(p_T)] &= 2\pi \int_0^{k_{\max}} \alpha_s(k_T) \log \left[ \frac{4k_{\max}^2}{k_T^2} \right] \theta(k_T - p_T) \frac{dk_T}{k_T} \\
&= \frac{\pi}{b_0} \left( \log \left[ \frac{4k_{\max}^2}{k_T^2} \right] \log \left[ \frac{\log(k_{\max}^2/\Lambda^2)}{\log(p_T^2/\Lambda^2)} \right] - \log \left[ \frac{k_{\max}^2}{p_T^2} \right] \right)
\end{aligned} \tag{31.7}$$

with  $k_{\max} = \frac{q^0}{2}$ . We see that for these logarithms to be well defined, we need to set a lower bound for the transverse momentum  $p_{T,\min} > \Lambda = \text{lambda2\_gen}$ .

```

<POWHEG matching: sudakov eeqq fsr: TBP>+=
procedure :: log_integrated_ubf => sudakov_eeqq_fsr_log_integrated_ubf

<POWHEG matching: procedures>+=
pure function sudakov_eeqq_fsr_log_integrated_ubf (sudakov, pt2) result (log_sudakov)
  real(default) :: log_sudakov
  class(sudakov_eeqq_fsr_t), intent(in) :: sudakov
  real(default), intent(in) :: pt2

```

```

real(default) :: k_max2, Lambda2
logical :: within_boundaries
k_max2 = sudakov%kt2_max ()
within_boundaries = pt2 >= sudakov%powheg_settings%pt2_min &
    .and. pt2 <= k_max2
if (within_boundaries) then
    Lambda2 = sudakov%process_deps%lambda2_gen
    log_sudakov = pi / b0rad * ( log (4 * k_max2 / Lambda2) * &
        log (log (k_max2/Lambda2) / log (pt2/Lambda2)) - log(k_max2/pt2) )
else
    log_sudakov = 0
end if
end function sudakov_eeqq_fsr_log_integrated_ubf

```

In order to arrive at the log integrated Sudakov implemented in `sudakov_eeqq_fsr_log_integrated_ubf`, we overestimated

$$\log \left[ \frac{1 + \sqrt{1 - (k_T/k_{\max})^2}}{1 - \sqrt{1 - (k_T/k_{\max})^2}} \right] \leq \log \left[ \frac{4k_{\max}^2}{k_T^2} \right]. \quad (31.8)$$

We correct for this in this veto step.

## Massive FSR

```

<POWHEG matching: public>+=
public :: sudakov_massive_fsr_t

<POWHEG matching: types>+=
type, extends (sudakov_t) :: sudakov_massive_fsr_t
  real(default) :: z, z1, z2 = 0._default
  real(default) :: xi_1, xi_min, xi_m = 0._default
  real(default) :: xi_max_extended = 1._default
contains
  <POWHEG matching: sudakov massive fsr: TBP>
end type sudakov_massive_fsr_t

```

According to eq. A.42 1202.0465, during the radiation generation, an alternative expression for  $\xi_{\max}$ ,

$$\xi_{\max} = 1 - \frac{(m + m_{\text{rec}})^2}{q^2},$$

is used, which corresponds to an extended Dalitz region. Phase space points outside of the original Dalitz region will be vetoed afterwards in `sudakov_massive_fsr_reweight_xi_max`.

```

<POWHEG matching: sudakov massive fsr: TBP>=
procedure :: compute_xi_max_extended &
=> sudakov_massive_fsr_compute_xi_max_extended

<POWHEG matching: procedures>+=
subroutine sudakov_massive_fsr_compute_xi_max_extended (sudakov, i_phs)
  class(sudakov_massive_fsr_t), intent(inout) :: sudakov
  integer, intent(in) :: i_phs
  real(default) :: m, mrec
  real(default) :: q0
  type(vector4_t) :: p
  q0 = sqrt(sudakov%event_deps%s_hat)
  p = sudakov%event_deps%p_born_lab%get_momentum (1, sudakov%associated_emitter())
  m = p**1
  mrec = sqrt ((q0 - p%p(0))**2 - p%p(1)**2 - p%p(2)**2 - p%p(3)**2)
  sudakov%xi_max_extended = one - (m + mrec)**2 / q0**2
end subroutine sudakov_massive_fsr_compute_xi_max_extended

```

As described in 1202.0465, App. A.5., for massive emitters, the radiation variable  $\xi$  is constructed as follows. First,

$$\xi_{\min}(K_T^2) = \frac{\sqrt{K_T^2 (K_T^2 z_2^2 + 8\bar{p}^0 q (1 - z_2))} - K_T^2 z_2}{2q^2(1 - z_2)} \quad (31.12)$$

is computed where  $K_T$  is a hardness scale for the radiation that determines the upper limit of the integral for the Sudakov form factor and coincides with the usual one, i.e. the transverse momentum of the radiated particle, in the massless limit. Then  $\xi_1$  is computed according to the same equation with  $z_2 \leftrightarrow z_1$ . Finally,  $\xi$  is generated according to

$$\xi = \frac{1}{q^2} \left( \exp \left[ \log (\xi_{\min} q^2 - K_T^2) + r \log \frac{\xi_m q^2 - K_T^2}{\xi_{\min} q^2 - K_T^2} \right] + K_T^2 \right), \quad (31.13)$$

where  $\xi_m = \min (\xi_{\max}, \xi_1)$ .

*(POWHEG matching: sudakov massive fsr: TBP)+≡*

Finalization of the POWHEG matching. It creates a log file showing how many events failed at which stage of the POWHEG veto algorithm. It also issues a warning if too many POWHEG excess events occurred. If this is the case, the chosen upper-bounding function is unsuitable for the considered process.

This is the last step of the Sudakov veto algorithm removing the dependence on the normalization factor  $N$  and the upper bounding function  $U$  from the final result.

In cases where the Born kinematic failed the cuts,  $\mathcal{B}$  was artificially set to zero, so we cannot use it in a denominator. We assume that the generator cuts applied for parton showering are weak cuts to avoid divergent phase space regions, thus  $\mathcal{B}$  would have been large and the reweighting would have failed.

This routine implements the Sudakov veto algorithm as explained in [1002.2581], Sec. 7.1 and Bijans thesis, Sec. 3.3 and B.2. Here, we veto in order to correct for

1. an overestimation of parts of the upper bounding function for complicated UBFs in `reweight_ubf`
2. the usage of  $\alpha_s^{\text{rad}}$  instead of  $\alpha_s^{\text{true}}$  in `reweight_alpha_s`
3. the usage of `xi_max_extended` instead of `xi_max` in `reweight_xi_max` which is only non-trivial for massive FSR.
4. using the maximum of the entire POWHEG normalization grid  $N_{\text{max}}$  when generating  $p_T$  instead of the correct bin value  $N(\xi_i, y_i)$  in `reweight_norm`.
5. the normalization grid and the upper bounding function in the first place in `reweight_matrix_elements` to retrieve the correct fraction  $\frac{\mathcal{R}(\xi, y) \mathcal{J}(\xi, y)}{\mathcal{B}}$ .

By keeping the radiation with the largest `pt2`, we are effectively implementing the highest bid procedure. This means that we generate values  $(f_B)$ .

We need to compute `xi2_max` before `kt2_max` here. In the simple case, it is given by  $\xi_{\text{max}} = \frac{s - M_{\text{rec}}^2}{s}$  but we can also take the  $\xi_{\text{max}}$  from the phase space computed before; they coincide. In the eeqq case,  $M_{\text{rec}} = 0$ , so  $x_{i_{\text{max}}} = 1$  and in the massive case, we compute an extended  $\xi_{\text{max}} = 1 - \frac{(m + M_{\text{rec}})^2}{q^2}$ .

Retrieves the value of the norm for given  $\xi$  and  $y$  from the pre-computed POWHEG grid. To find the correct bin in the grid, we need to invert the generation of  $\xi$  and  $y$  from their corresponding random numbers. As the grid is filled during integration, the formulas here are the inverse of those in `compute_y_from_emitter` instead of those specific for POWHEG matching. There, we coompute  $y$  with  $y = (\text{one} - \text{two} * r_y)$  and  $y = 1.5\_default * (y - y**3 / 3)$ . The inverse of this operation is given by

$$r_y = \begin{cases} \frac{1}{4} \left[ (i\sqrt{3} - 1)A^{\frac{1}{3}} - (i\sqrt{3} + 1)A^{-\frac{1}{3}} + 2 \right] & \text{for } y < 0 \\ \frac{1}{4} \left[ -(i\sqrt{3} + 1)A^{\frac{1}{3}} + (i\sqrt{3} - 1)A^{-\frac{1}{3}} + 2 \right] & \text{for } y > 0 \end{cases}$$

with  $A = \sqrt{y^2 - 1} + y$  (31.18)

#### 31.4.4 $\alpha_s$ and its reweighting

The main point to ensure here is that the simple fixed-flavor-1-loop expression  $\alpha_s^{\text{rad}}$  is larger than the more accurate  $\alpha_s$  such that we can use a reweighting veto and use  $\alpha_s^{\text{rad}}$  for the generation of the emission. This can be done by setting

$$\alpha_s^{\text{rad}}(\mu_0) = \alpha_s(\mu_0) \quad (31.19)$$

whereby  $\mu_0^2$  is the `scale_to_relate2` that is taken to be  $p_{T,\text{min}}^2$ .

### 31.4.5 POWHEG hook

We provide a POWHEG hook to be called by `process_instance_evaluate` to prefill the adaptation grid.

We store the actual `powheg` object, which does the computations.

```

<POWHEG matching: public>+≡
public :: powheg_matching_hook_t

<POWHEG matching: types>+≡
type, extends(process_instance_hook_t) :: powheg_matching_hook_t
  type(string_t) :: process_name
  type(powheg_matching_t) :: powheg
contains
  <POWHEG matching: powheg matching hook: TBP>
end type powheg_matching_hook_t

```

Init the hook. The init procedure will be called in `setup_process`, after everything is set up.

Additionally, we have to include `var_list` in order to retrieve the grid size in `xi` and `y`.

```

<POWHEG matching: powheg matching hook: TBP>≡
procedure :: init => powheg_matching_hook_init

```

```

<POWHEG matching: procedures>+≡

```

This routine fills each bin of the POWHEG normalization grid  $\{\tilde{\xi}, \tilde{y}\}$  such that

$$N(\{\tilde{\xi}, \tilde{y}\}) = \max_{\forall \xi, y \in \{\tilde{\xi}, \tilde{y}\}} \frac{\mathcal{R}(\xi, y) \mathcal{J}(\xi, y)}{\mathcal{B} U(\xi, y, \alpha_s^{\text{true}})} \quad (31.20)$$

where  $\mathcal{R}(\xi, y)$  is the real cross section `sqme_real`,  $\mathcal{B}$  is the Born cross section `sqme_born`,  $\mathcal{J}$  is the Jacobian and  $U$  the upper bounding function `ubf`.

For each underlying Born  $f_b$ , there is a number of radiation regions. A radiation region `rr` may correspond to multiple  $\alpha_r$ s. The phase space only depends upon the radiation region kinematics `rr` and not on the specific  $\alpha_r$ .  $\alpha_r$  can be picked in the set  $\{\alpha_r | f_b, rr\}$  proportional to their  $R_{\alpha_r}$ . For now, we simplify things though and just work with the  $\alpha_r$ .

References:

, Sec. 7.1

- Bijans Thesis, Sec. 3.3 and B.2

In cases where just the Born kinematic failed the cuts,  $\mathcal{B}$  was artificially set to zero. Unfortunately, we lost information about the value of `sqme_born` in these cases but we assume that the generator cuts applied for parton showering are weak cuts to avoid divergent phase space regions, thus  $\mathcal{B}$  is large and does not influence  $N$  so we can skip these phase space points.

In cases where just the real kinematic failed the cuts,  $\mathcal{R}$  was artificially set to zero and we have no way to recover it. These cases will have no influence on  $N$ . It might be possible that this leads to an underestimate of  $N$  in some bins. The number of POWHEG excess events will be an indicator for the severity of this effect.

### Initialization

There are no Powheg unit tests so far.

### Compare generated emission with Sudakov form factor

This is a nontrivial test of the generation algorithm and should be independent of the used upper bounding function (as long as all singularities are included).

It runs for an extensive amount of time generating a file **sudakov.dat** containing a histogram for the Sudakov factor in bins of the radiation's transverse momentum  $p_T^2$ .

So far, it is only designed to work for lepton collisions without beam spectra and cuts. In its current state however, it fills the histogram with either 1 or NaN as the **p\_hard** received in **term\_instance\_evaluate\_interaction** is identically zero.

## Chapter 32

# Event Implementation

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

**event\_transforms** Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

**resonance\_insertion** Insert a resonance history into an event record, based on kinematical and matrix-element information.

**recoil\_kinematics** Common kinematics routines for the ISR and EPA handlers.

**isr\_photon\_handler** Transform collinear kinematics, as it results from applying ISR radiation, to non-collinear kinematics with a reasonable transverse-momentum distribution of the radiated photons, and also of the recoiling partonic event.

**epa\_beam\_handler** For photon-initiated processes where the effective photon approximation is used in integration, to add in beam-particle recoil. Analogous to the ISR handler.

**decays** Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

**showers** Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

**hadrons** (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

**tau\_decays** (not implemented yet) Let  $\tau$  leptons decay taking full spin correlations into account.

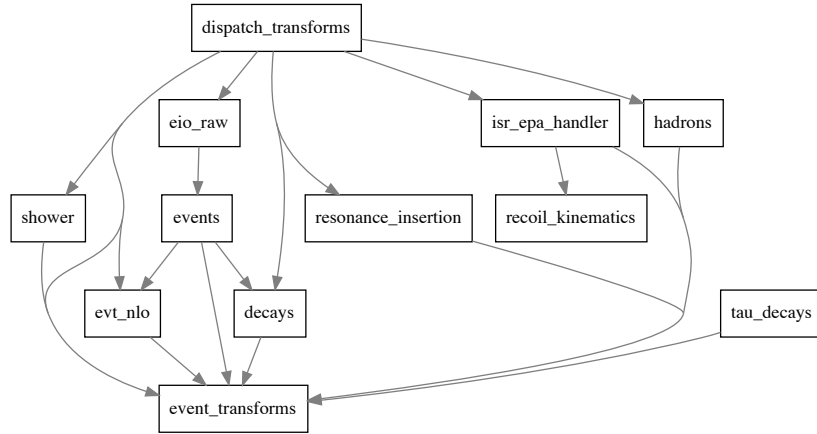

Figure 32.1: Module dependencies in `src/transforms`.

**evt\_nlo** Handler for fixed-order NLO events.

**events** Combine all pieces to generate full events.

**eio\_raw** Raw I/O for complete events.

## 32.1 Abstract Event Transforms

`<event_transforms.f90>`≡  
*<File header>*

    <Event transforms: interfaces>

    contains

    <Event transforms: procedures>

    end module event_transforms

```

### 32.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified settings that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include `previous` and `next` pointers.

```

<Event transforms: public>≡
    public :: evt_t

<Event transforms: types>≡
    type, abstract :: evt_t
        type(process_t), pointer :: process => null ()
        type(process_instance_t), pointer :: process_instance => null ()
        class(model_data_t), pointer :: model => null ()
        class(rng_t), allocatable :: rng
        integer :: rejection_count = 0
        logical :: particle_set_exists = .false.
        type(particle_set_t) :: particle_set
        class(evt_t), pointer :: previous => null ()
        class(evt_t), pointer :: next => null ()
        logical :: only_weighted_events = .false.
    contains
        <Event transforms: evt: TBP>
    end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

        evt%process_instance => process_instance
        evt%model => model
        call evt%process%make_rng (evt%rng)
    end subroutine evt_connect

```

Reset internal state.

```

<Event transforms: evt: TBP>+≡
    procedure :: reset => evt_reset
    procedure :: base_reset => evt_reset

<Event transforms: procedures>+≡
    subroutine evt_reset (evt)
        class(evt_t), intent(inout) :: evt
        evt%rejection_count = 0
        call evt%particle_set%final ()
        evt%particle_set_exists = .false.
    end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

<Event transforms: evt: TBP>+≡
    procedure (evt_prepare_new_event), deferred :: prepare_new_event

<Event transforms: interfaces>+≡
    interface
        subroutine evt_prepare_new_event (evt, i_mci, i_term)
            import
            class(evt_t), intent(inout) :: evt
            integer, intent(in) :: i_mci, i_term
        end subroutine evt_prepare_new_event
    end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)
      import
      class(evt_t), intent(inout) :: evt
      real(default), intent(inout) :: probability
    end subroutine evt_generate_weighted
  end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted

(Event transforms: procedures)+≡
  subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set

(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
  end interface

```

```

        integer, intent(in) :: factorization_mode
        logical, intent(in) :: keep_correlations
        real(default), dimension(:), intent(in), optional :: r
    end subroutine evt_make_particle_set
end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

<Event transforms: evt: TBP>+≡
    procedure :: set_particle_set => evt_set_particle_set

<Event transforms: procedures>+≡
    subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
        class(evt_t), intent(inout) :: evt
        type(particle_set_t), intent(in) :: particle_set
        integer, intent(in) :: i_term, i_mci
        call evt%prepare_new_event (i_mci, i_term)
        evt%particle_set = particle_set
        evt%particle_set_exists = .true.
    end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. We need two interactions, one with color summed over, the `int_matrix`, and one with the probability distributed among flows, the `int_flows`.

We use the two values from the random number generator saved in `r` for factorizing the state. For testing purposes, we can provide those numbers explicitly.

The optional `qn_select` allows to limit the number of quantum numbers to choose from when factorizing. If only a single set of quantum numbers is given, it effectively dictates the quantum numbers chosen for the event.

```

<Event transforms: evt: TBP>+≡
    procedure :: factorize_interactions => evt_factorize_interactions

<Event transforms: procedures>+≡
    subroutine evt_factorize_interactions &
        (evt, int_matrix, int_flows, factorization_mode, &

    call evt%tag_incoming ()
else
    call msg_bug ("Event factorization: event is incomplete")
end if
end subroutine make_factorized_particle_set

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

*<Event transforms: evt: TBP>+≡*

```

procedure :: tag_incoming => evt_tag_incoming

```

*<Event transforms: procedures>+≡*

```

subroutine evt_tag_incoming (evt)
class(evt_t), intent(inout) :: evt
integer :: i_term, n_in
integer, dimension(:), allocatable :: beam_index, in_index

```

```

n_in = evt%process%get_n_in ()
i_term = 1
allocate (beam_index (n_in))
call evt%process_instance%get_beam_index (i_term, beam_index)
call evt%particle_set%reset_status (beam_index, PRT_BEAM)
allocate (in_index (n_in))
call evt%process_instance%get_in_index (i_term, in_index)
call evt%particle_set%reset_status (in_index, PRT_INCOMING)
end subroutine evt_tag_incoming

```

### 32.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

<Event transforms: public>+≡
  public :: evt_trivial_t

<Event transforms: types>+≡
  type, extends (evt_t) :: evt_trivial_t
  contains
    <Event transforms: evt trivial: TBP>
  end type evt_trivial_t

<Event transforms: evt trivial: TBP>≡
  procedure :: write_name => evt_trivial_write_name

<Event transforms: procedures>+≡
  subroutine evt_trivial_write_name (evt, unit)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event transform: trivial (hard process)"
  end subroutine evt_trivial_write_name

```

The finalizer is trivial. Some output:

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: write => evt_trivial_write

<Event transforms: procedures>+≡
  subroutine evt_trivial_write (evt, unit, verbose, more_verbose, testflag)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, more_verbose, testflag
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    call evt%write_name (u)
    call write_separator (u)
    call evt%base_write (u, testflag = testflag)
    !!! More readable but wider output; in line with evt_resonance_write
    !   if (verbose .and. evt%particle_set_exists) then

```

```

!      call evt%particle_set%write &
!      (u, summary = .true., compressed = .true., testflag = testflag)
!      call write_separator (u)
!      end if
end subroutine evt_trivial_write

```

Nothing to do here:

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: prepare_new_event => evt_trivial_prepare_new_event

<Event transforms: procedures>+≡
  subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
  end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: generate_weighted => evt_trivial_generate_weighted

<Event transforms: procedures>+≡
  subroutine evt_trivial_generate_weighted (evt, probability)
    class(evt_trivial_t), intent(inout) :: evt
    real(default), intent(inout) :: probability
    probability = 1
  end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is. Note that it is a potential risk to tolerate a non-existent particle set at this point. We should remove it once the flavors are determined correctly in all cases. It is currently necessary if we are keeping failed events `?keep_failed_events = .true..` For these events, we do not compute the matrix elements, so the factorization fails trying to determine the quantum numbers. Additionally, it is necessary for the trivial event transformation preceeding the event transformations required for POWHEG matching.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: make_particle_set => evt_trivial_make_particle_set

<Event transforms: procedures>+≡
  subroutine evt_trivial_make_particle_set &
    (evt, factorization_mode, keep_correlations, r)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    call make_factorized_particle_set (evt, factorization_mode, &
      keep_correlations, r)
    evt%particle_set_exists = .true.
  end subroutine evt_trivial_make_particle_set

```

Here we take the particle set from the previous event transform and apply the hadronization. The result is stored in the `evt%hadrons` object. We always return a probability of unity as we don't have the analytic weight of the hadronization. Invalid events have to be discarded by the caller which is why

we mark the particle set as invalid.

end if
end subroutine evt_resonance_write

```

### 32.3.2 Set contained data

Insert the resonance data, in form of a pre-generated resonance history set. Accumulate the number of histories for each set, to initialize an array of index offsets for lookup.

```

(Resonance insertion: evt resonance: TBP)+≡
    procedure :: set_resonance_data => evt_resonance_set_resonance_data

(Resonance insertion: procedures)+≡
    subroutine evt_resonance_set_resonance_data (evt, res_history_set)
        class(evt_resonance_t), intent(inout) :: evt
        type(resonance_history_set_t), dimension(:), intent(in) :: res_history_set
        integer :: i
        evt%res_history_set = res_history_set
        allocate (evt%index_offset (size (evt%res_history_set)), source = 0)
        do i = 2, size (evt%res_history_set)
            evt%index_offset(i) = &
                evt%index_offset(i-1) + evt%res_history_set(i-1)%get_n_history ()
        end do
    end subroutine evt_resonance_set_resonance_data

```

Set the library that contains the resonant subprocesses.

```

(Resonance insertion: evt resonance: TBP)+≡
    procedure :: set_library => evt_resonance_set_library

(Resonance insertion: procedures)+≡
    subroutine evt_resonance_set_library (evt, libname)
        class(evt_resonance_t), intent(inout) :: evt
        type(string_t), intent(in) :: libname
        evt%libname = libname
    end subroutine evt_resonance_set_library

```

Assign pointers to subprocess instances. Once a subprocess has been selected, the instance is used for generating the particle set with valid quantum-number assignments, ready for resonance insertion.

```

(Resonance insertion: evt resonance: TBP)+≡
    procedure :: set_subprocess_instances &
        => evt_resonance_set_subprocess_instances

(Resonance insertion: procedures)+≡
    subroutine evt_resonance_set_subprocess_instances (evt, instance)
        class(evt_resonance_t), intent(inout) :: evt
        type(process_instance_ptr_t), dimension(:), intent(in) :: instance
        evt%instance = instance
    end subroutine evt_resonance_set_subprocess_instances

```

Set the on-shell limit, the relative distance from a resonance that is still considered to be on-shell. The probability for being considered on-shell can be reduced by the turnoff parameter below. For details, see the **resonances** module.

```

(Resonance insertion: evt resonance: TBP)+≡
    procedure :: set_on_shell_limit => evt_resonance_set_on_shell_limit

```

```

⟨Resonance insertion: procedures⟩+≡
  subroutine evt_resonance_set_on_shell_limit (evt, on_shell_limit)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_limit
    evt%on_shell_limit = on_shell_limit
  end subroutine evt_resonance_set_on_shell_limit

```

Set the Gaussian on-shell turnoff parameter, the width of the weighting factor for the resonance squared matrix element. If the resonance is off shell, this factor reduces the weight of the matrix element in the selector, such that the probability for considered resonant is reduced. The factor is applied only if the offshellness is less than the `on_shell_limit` above. For details, see the `resonances` module.

```

⟨Resonance insertion: evt resonance: TBP⟩+≡
  procedure :: set_on_shell_turnoff => evt_resonance_set_on_shell_turnoff

⟨Resonance insertion: procedures⟩+≡
  subroutine evt_resonance_set_on_shell_turnoff (evt, on_shell_turnoff)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_turnoff
    evt%on_shell_turnoff = on_shell_turnoff
  end subroutine evt_resonance_set_on_shell_turnoff

```

Reweight (suppress) the background contribution if there is a resonance history that applies. The event will be registered as background if there is no applicable resonance history, or if the background configuration has been selected based on (reweighted) squared matrix elements.

```

⟨Resonance insertion: evt resonance: TBP⟩+≡
  procedure :: set_background_factor => evt_resonance_set_background_factor

⟨Resonance insertion: procedures⟩+≡
  subroutine evt_resonance_set_background_factor (evt, background_factor)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: background_factor
    evt%background_factor = background_factor
  end subroutine evt_resonance_set_background_factor

```

### 32.3.3 Selector

Manually import a random-number generator object. This should be done only for testing purposes. The standard procedure is to `connect` a process to an event transform; this will create an appropriate `rng` from the RNG factory in the process object.

```

⟨Resonance insertion: evt resonance: TBP⟩+≡
  procedure :: import_rng => evt_resonance_import_rng

⟨Resonance insertion: procedures⟩+≡
  subroutine evt_resonance_import_rng (evt, rng)
    class(evt_resonance_t), intent(inout) :: evt
    class(rng_t), allocatable, intent(inout) :: rng
    call move_alloc (from = rng, to = evt%rng)
  end subroutine evt_resonance_import_rng

```

```
end subroutine evt_resonance_import_rng
```

We use a standard selector object to choose from the available resonance histories. If the selector is inactive, we do not insert resonances.

```
<Resonance insertion: evt resonance: TBP>+≡
  procedure :: write_selector => evt_resonance_write_selector

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_write_selector (evt, unit, testflag)
    class(evt_resonance_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: u
    u = given_output_unit (unit)
    if (evt%selector_active) then
      call evt%selector%write (u, testflag)
    else
      write (u, "(1x,A)") "Selector: [inactive]"
    end if
  end subroutine evt_resonance_write_selector
```

The selector is initialized with relative weights of histories which need not be normalized. Channels with weight zero are ignored.

The `offset` will normally be  $-1$ , so we count from zero, and zero is a valid result from the selector. Selecting the zero entry implies no resonance insertion. However, this behavior is not hard-coded here (without `offset`, no resonance is not possible as a result).

```
<Resonance insertion: evt resonance: TBP>+≡
  procedure :: init_selector => evt_resonance_init_selector

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_init_selector (evt, weight, offset)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), dimension(:), intent(in) :: weight
    integer, intent(in), optional :: offset
    if (any (weight > 0)) then
      call evt%selector%init (weight, offset = offset)
      evt%selector_active = .true.
    else
      evt%selector_active = .false.
    end if
  end subroutine evt_resonance_init_selector
```

Return all selector weights, for inspection. Note that the index counts from zero.

```
<Resonance insertion: evt resonance: TBP>+≡
  procedure :: get_selector_weights => evt_resonance_get_selector_weights

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_get_selector_weights (evt, weight)
    class(evt_resonance_t), intent(in) :: evt
    real(default), dimension(0:), intent(out) :: weight
    integer :: i
```

```

do i = 0, ubound (weight,1)
  weight(i) = evt%selector%get_weight (i)
end do
end subroutine evt_resonance_get_selector_weights

```

### 32.3.4 Runtime calculations

Use the associated master process instance and the subprocess instances to distribute the current momentum set, then compute the squared matrix elements weights for all subprocesses.

NOTE: Procedures in this subsection are not covered by unit tests in this module, but by unit tests of the `restricted_subprocesses` module.

Fill the particle set, so the momentum configuration can be used by the subprocess instances. The standard workflow is to copy from the previous particle set.

```

<Resonance insertion: evt_resonance: TBP>+≡
  procedure :: fill_momenta => evt_resonance_fill_momenta

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_fill_momenta (evt)
    class(evt_resonance_t), intent(inout) :: evt
    integer :: i, n
    if (associated (evt%previous)) then
      evt%particle_set = evt%previous%particle_set
    else if (associated (evt%process_instance)) then
      ! this branch only for unit test
      call evt%process_instance%get_trace &
        (evt%particle_set, i_term=1, n_incoming=evt%process%get_n_in ())
    end if
  end subroutine evt_resonance_fill_momenta

```

Return the indices of those subprocesses which can be considered on-shell. The result depends on the stored particle set (outgoing momenta) and on the on-shell limit value.

The index `evt%selected_component` identifies the particular history set that corresponds to the given process component. Recall that process components may have different external particles, so they have distinct history sets.

```

<Resonance insertion: evt_resonance: TBP>+≡
  procedure :: determine_on_shell_histories &
    => evt_resonance_determine_on_shell_histories

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_determine_on_shell_histories &
    (evt, index_array)
    class(evt_resonance_t), intent(in) :: evt
    integer, dimension(:), allocatable, intent(out) :: index_array
    integer :: i
    i = evt%selected_component
    call evt%res_history_set(i)%determine_on_shell_histories &
      (evt%particle_set%get_outgoing_momenta (), &
        evt%on_shell_limit, &

```

```

        index_array)
    end subroutine evt_resonance_determine_on_shell_histories

```

Evaluate selected subprocesses. (In actual operation, the ones that have been tagged as on-shell.)

We assume that the MCI, term, and channel indices for the subprocesses can all be set to 1.

```

<Resonance insertion: evt resonance: TBP>+≡

    end subroutine evt_resonance_apply_turnoff_factor

```

We use the calculations of resonant matrix elements to determine probabilities for all applicable resonance configurations. This method combines the steps implemented above.

First, we determine the selected process component.

TODO: the version below selects the first component which is found active. This make sense only for standard LO process components, where exactly one component corresponds to a MCI set.

For the selected process component, we query the kinematics and determine the applicable resonance histories. We collect squared matrix elements for those resonance histories and compare them to the master-process squared matrix element.

The result is the probability for each resonance history together with the probability for non-resonant background (zeroth entry). The latter is defined as the difference between the complete process result and the sum of the resonances, ignoring the possibility for interference. If the complete process result is actually undershooting the sum of resonances, we nevertheless count the background with positive probability.

When looking up the subprocess `sqme`, we must add the `index_offset` to the resulting array, since the indices returned by the individual history set all count

from one, while the subprocess instances that belong to process components are collected in one flat array.

After determining matrix elements and background, we may reduce the weight of the matrix elements in the selector by applying a turnoff factor.

The factor **background\_factor** indicates whether to include the background contribution at all, as long as there is a nonvanishing resonance contribution. Note that instead of setting background to zero, we just multiply it by a very small number. This ensures that indices are assigned correctly, and that background will eventually be selected if smooth turnoff is chosen.

```

  end subroutine evt_resonance_select_component

```

### 32.3.5 Sanity check

Check the color assignment, which may be wrong for the inserted resonances. Delegated to the particle-set component. Return offending particle indices and, optionally, particles as arrays.

This is done in a unit test. The current algorithm, i.e., selecting the color assignment from the resonant-subprocess instance, should not generate invalid color assignments.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: find_prt_invalid_color => evt_resonance_find_prt_invalid_color

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_find_prt_invalid_color (evt, index, prt)
    class(evt_resonance_t), intent(in) :: evt

    else
      allocate (prt (0))
    end if
  end subroutine evt_resonance_find_prt_invalid_color

```

### 32.3.6 API implementation

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: prepare_new_event => evt_resonance_prepare_new_event

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_prepare_new_event (evt, i_mci, i_term)
    class(evt_resonance_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
  end subroutine evt_resonance_prepare_new_event

```

Select one of the histories, based on the momentum array from the current particle set. Compute the probabilities for all resonant subprocesses and initialize the selector accordingly. Then select one resonance history, or none.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: generate_weighted => evt_resonance_generate_weighted

```

```

<Resonance insertion: procedures>+≡
  subroutine evt_resonance_generate_weighted (evt, probability)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(inout) :: probability
    call evt%fill_momenta ()
    call evt%compute_probabilities ()
    call evt%selector%generate (evt%rng, evt%selected_history)
    probability = 1
  end subroutine evt_resonance_generate_weighted

```

Here take the current particle set and insert resonance intermediate states if applicable. The resonance history has already been chosen by the generator above. If no resonance history applies, just retain the particle set.

If a resonance history applies, we factorize the exclusive interaction of the selected (resonance-process) process instance. With a temporary particle set `prt_set` as workspace, we insert the resonances, reinstate parent-child relations and set colors and momenta for the resonances. The temporary is then copied back.

Taking the event data from the resonant subprocess instead of the master process, guarantees that all flavor, helicity, and color assignments are valid for the selected resonance history. Note that the transform may thus choose a quantum-number combination that is different from the one chosen by the master process.

The `i_term` value for the selected subprocess instance is always 1. We support only LO process. For those, the master process may have several terms (= components) that correspond to different external states. The subprocesses are distinct, each one corresponds to a definite master component, and by itself it consists of a single component/term.

However, if the selector chooses resonance history #0, i.e., no resonance, we just copy the particle set from the previous (i.e., trivial) event transform and ignore all subprocess data.

<Standard module head>

<Recoil kinematics: public>

<Recoil kinematics: parameters>

<Recoil kinematics: types>

contains

<Recoil kinematics: procedures>

end module recoil_kinematics

```

### 32.4.1 $\phi$ sampler

This is trivial. Generate an azimuthal angle, given a  $(0,1)$  RNG parameter.

```

<Recoil kinematics: procedures>≡
  elemental subroutine generate_phi_recoil (r, phi)
    real(default), intent(in) :: r
    real(default), intent(out) :: phi

    phi = r * twopi

  end subroutine generate_phi_recoil

```

### 32.4.2 $Q^2$ sampler

The dynamics of factorization suggests to generate a flat  $Q^2$  distribution from a (random) number, event by event.

At the lowest momentum transfer values, the particle (electron) mass sets a smooth cutoff. The formula can produce  $Q$  values below the electron mass, down to zero, but with a power distribution that eventually evolves into the expected logarithmic distribution for  $Q^2 > m^2$ .

We are talking about the absolute value here, so all  $Q^2$  values are positive. For the actual momentum transfer,  $q^2 = -Q^2$ .

```

<Recoil kinematics: public>≡

```

```

public :: generate_q2_recoil
<Recoil kinematics: procedures>+≡
elemental subroutine generate_q2_recoil (s, x_bar, q2_max, m2, r, q2)
  real(default), intent(in) :: s
  real(default), intent(in) :: q2_max
  real(default), intent(in) :: x_bar
  real(default), intent(in) :: m2
  real(default), intent(in) :: r
  real(default), intent(out) :: q2

  real(default) :: q2_max_evt

  q2_max_evt = q2_max_event (s, x_bar, q2_max)

  q2 = m2 * (exp (r * log (1 + (q2_max_evt / m2))) - 1)

end subroutine generate_q2_recoil

```

The  $Q$  distribution is cut off from above by the kinematic limit, which depends on the energy that is available for the radiated photon, or by a user-defined cutoff – whichever is less. The kinematic limit fits the formulas for recoil momenta (see below), and it also implicitly enters the ISR collinear structure function, so the normalization of the distribution should be correct.

```

<Recoil kinematics: procedures>+≡
elemental function q2_max_event (s, x_bar, q2_max) result (q2)
  real(default), intent(in) :: s
  real(default), intent(in) :: x_bar
  real(default), intent(in) :: q2_max
  real(default) :: q2

  q2 = min (x_bar * s, q2_max)

end function q2_max_event

```

### 32.4.3 Kinematics functions

Given values for energies,  $Q_{1,2}^2$ , azimuthal angle, compute the matching polar angle of the radiating particle. The subroutine returns  $\sin \theta$  and  $\cos \theta$ .

```

<Recoil kinematics: procedures>+≡
subroutine polar_angles (s, xb, rho, ee, q2, sin_th, cos_th, ok)
  real(default), intent(in) :: s
  real(default), intent(in) :: xb
  real(default), intent(in) :: rho
  real(default), dimension(2), intent(in) :: ee
  real(default), dimension(2), intent(in) :: q2
  real(default), dimension(2), intent(out) :: sin_th
  real(default), dimension(2), intent(out) :: cos_th
  logical, intent(out) :: ok

  real(default), dimension(2) :: sin2_th_2

```

```

sin2_th_2 = q2 / (ee * rho * xb * s)

if (all (sin2_th_2 <= 1)) then
  sin_th = 2 * sqrt (sin2_th_2 * (1 - sin2_th_2))
  cos_th = 1 - 2 * sin2_th_2
  ok = .true.
else
  sin_th = 0
  cos_th = 1
  ok = .false.
end if

end subroutine polar_angles

```

Compute the acollinearity parameter  $\lambda$  from azimuthal and polar angles. The result is a number between 0 and 1.

*<Recoil kinematics: procedures>+≡*

```

function lambda_factor (sin_th, cos_th, cphi) result (lambda)
  real(default), dimension(2), intent(in) :: sin_th
  real(default), dimension(2), intent(in) :: cos_th
  real(default), intent(in) :: cphi
  real(default) :: lambda

  lambda = (1 - cos_th(1) * cos_th(2) - cphi * sin_th(1) * sin_th(2)) / 2

end function lambda_factor

```

Compute the factor that rescales photon energies, such that the radiation angles match the kinematics parameters.

For small values of  $\bar{x}/\cosh\eta$ , we have to use the Taylor expansion if we do not want to lose precision. The optional argument allows for a unit test that compares exact and approximate.

*<Recoil kinematics: procedures>+≡*

```

function scale_factor (che, lambda, xb0, approximate) result (rho)
  real(default), intent(in) :: che
  real(default), intent(in) :: lambda
  real(default), intent(in) :: xb0
  logical, intent(in), optional :: approximate
  real(default) :: rho

  real(default), parameter :: &
    e0 = (100 * epsilon (1._default)) ** (0.3_default)
  logical :: approx

  if (present (approximate)) then
    approx = approximate
  else
    approx = (xb0/che) < e0
  end if

  if (approx) then

  end subroutine scaled_x

```

#### 32.4.4 Iterative solution of kinematics constraints

Find a solution of the kinematics constraints. We know the parameters appropriate for collinear kinematics  $\sqrt{s}$ ,  $x_{1,2}^c$ . We have picked values for the momentum transfer  $Q_{1,2}$  and the azimuthal angles  $\phi_{1,2}$ . The solution consists of modified energy fractions  $x_{1,2}$  and polar angles  $\theta_{1,2}$ .

If the computation fails, which can happen for large momentum transfer, the flag ok will indicate this.

  end subroutine initial_transformation
```

### 32.4.5 Generate recoil event

Combine the above kinematics calculations. First generate azimuthal angles and momentum transfer, solve kinematics and compute momenta for the radiated photons and the on-shell projected, recoiling partons.

The `mo` masses are used for the on-shell projection of the partons after radiation. They may be equal to `m`, or set to zero.

If `ok` is false, the data point has failed and we should repeat the procedure for a new set of RNG parameters `r`.

```

## 32.5 Transverse momentum for the ISR and EPA approximations

The ISR and EPA handler takes an event with a single radiated collinear particle (photon for ISR, beam particle for EPA) for each beam, respectively, and inserts transverse momentum for both. The four-particle kinematics allows us to generate  $Q^2$  and azimuthal angles independently, without violating energy-momentum conservation. The  $Q^2$  distribution is logarithmic, as required by the effective particle approximation, and reflected in the inclusive ISR/EPA structure functions. We also conserve the invariant mass of the partonic system after radiation. The total transverse-momentum kick is applied in form of a Lorentz transformation to the elementary process, both in- and out-particles. In fact, the incoming partons (beam particle for ISR, photon for EPA) which would be virtual space-like in the exact kinematics configuration, are replaced by on-shell incoming partons, such that energy, momentum, and invariant mass  $\sqrt{\hat{s}}$  are conserved.

Regarding kinematics, we treat all particles as massless. The beam-particle mass only appears as the parameter `isr_mass` or `epa_mass`, respectively, and cuts off the logarithmic distribution. The upper cutoff is `isr_q_max` (`epa_q_max`), which defaults to the available energy  $\sqrt{s}$ .

The only differences between ISR and EPA, in this context, are the particle types, and an extra  $\bar{x}$  factor in the lower cutoff for EPA, see below.

### 32.5.1 Event transform type

Convention: **beam** are the incoming partons before ISR – not necessarily the actual beams, need not be in c.m. frame. **radiated** are the radiated particles (photon for ISR), and **parton** are the remainders which initiate the elementary process. These particles are copied verbatim from the event record, and must be collinear.

The kinematical parameters are **sqrts** = invariant mass of the **beam** particles, **q\_max** and **m** determining the  $Q^2$  distribution, and **xc/xcb** as the energy

fraction (complement) of the partons, relative to the beams.

Transformations: `lti` is the Lorentz transformation that would boosts `pi` (c.m. frame) back to the original `beam` momenta (lab frame). `lto` is the recoil transformation, transforming the partons after ISR from the collinear frame to the recoiling frame. `lt` is the combination of both, which is to be applied to all particles after the hard interaction.

Momenta: `pi` are the beams transformed to their common c.m. frame. `ki` and `qi` are the photon/parton momenta in the `pi` c.m. frame. `km` and `qm` are the photon/parton momenta with the  $Q$  distribution applied, and finally `qo` are the partons `qm` projected on-shell.

### 32.5.5 Initialization

Manually import a random-number generator object. This should be done only for testing purposes. The standard procedure is to **connect** a process to an event transform; this will create an appropriate **rng** from the RNG factory in the process object.

```

<ISR/EPA handler: evt_isr: TBP>+≡
    procedure :: import_rng => evt_isr_epa_import_rng

<ISR/EPA handler: procedures>+≡
    subroutine evt_isr_epa_import_rng (evt, rng)
        class(evt_isr_epa_t), intent(inout) :: evt
        class(rng_t), allocatable, intent(inout) :: rng
        call move_alloc (from = rng, to = evt%rng)
    end subroutine evt_isr_epa_import_rng

```

Set constant kinematics limits and initialize for ISR. Note that **sqrts** is used only as the fallback value for **q\_max**. The actual **sqrts** value for the transform object is inferred from the incoming particles, event by event.

```

<ISR/EPA handler: evt_isr: TBP>+≡
    procedure :: set_data_isr => evt_isr_epa_set_data_isr

<ISR/EPA handler: procedures>+≡
    subroutine evt_isr_epa_set_data_isr (evt, sqrts, q_max, m, keep_mass)
        class(evt_isr_epa_t), intent(inout) :: evt

```

```

real(default), intent(in) :: sqrts
real(default), intent(in) :: q_max
real(default), intent(in) :: m
logical, intent(in) :: keep_mass
if (sqrts <= 0) then
  call msg_fatal ("ISR handler: sqrts value must be positive")
end if
if (q_max <= 0 .or. q_max > sqrts) then
  evt%isr_q_max = sqrts
else
  evt%isr_q_max = q_max
end if
if (m > 0) then
  evt%isr_mass = m
else
  call msg_fatal ("ISR handler: ISR_mass value must be positive")
end if
evt%isr_active = .true.
evt%isr_keep_mass = keep_mass
end subroutine evt_isr_epa_set_data_isr

```

Set constant kinematics limits and initialize for EPA. Note that `sqrts` is used only as the fallback value for `q_max`. The actual `sqrts` value for the transform object is inferred from the incoming particles, event by event.

*(ISR/EPA handler: evt\_isr: TBP)*+≡

```

  end if
  evt%epa_active = .true.
end subroutine evt_isr_epa_set_data_epa

```

### 32.5.6 Fetch event data

Identify the radiated particles and the recoil momenta in the particle set. Without much sophistication, start from the end and find particles with the “remnant” status. Their parents should point to the recoiling parton. If successful, set the particle indices in the `evt` object, for further processing.

```

<ISR/EPA handler: evt isr: TBP>+≡
  procedure, private :: identify_radiated

<ISR/EPA handler: procedures>+≡
  subroutine identify_radiated (evt)
    class(evt_isr_epa_t), intent(inout) :: evt
    integer :: i, k

### 32.5.7 Two-parton recoil

For transforming partons into recoil momenta, we make use of the routines in the `recoil_kinematics` module. In addition to the collinear momenta, we use the  $x$  energy fractions, and four numbers from the RNG.

There is one subtle difference w.r.t. ISR case: the EPA mass parameter is multiplied by the energy fraction  $x$ , separately for each beam. This is the effective lower  $Q$  cutoff.

For certain kinematics, close to the  $Q_{\max}$  endpoint, this may fail, and `ok` is set to false. In that case, we should generate new recoil momenta for the same event. This is handled by the generic unweighting procedure.

```

<ISR/EPA handler: evt isr: TBP>+≡
    procedure, private :: generate_recoil => evt_generate_recoil

```

```

<ISR/EPA handler: procedures>+≡
subroutine evt_generate_recoil (evt, ok)
  class(evt_isr_epa_t), intent(inout) :: evt
  logical, intent(out) :: ok
  real(default), dimension(4) :: r
  real(default), dimension(2) :: m, mo
  integer :: i
  call evt%rng%generate (r)
  m = 0
  mo = 0
  do i = 1, 2
    select case (evt%rad_mode(i))
    case (BEAM_RAD_ISR)
      m(i) = evt%m(i)
      if (evt%isr_keep_mass) mo(i) = m(i)
    case (BEAM_RAD_EPA)
      m(i) = evt%xc(i) * evt%m(i)
    end select
  end do
  call generate_recoil (evt%sqrts, evt%q_max, m, mo, evt%xc, evt%xcb, r, &
    evt%km, evt%qm, evt%qo, ok)
end subroutine evt_generate_recoil

```

Replace the collinear radiated (incoming) parton momenta by the momenta that we have generated, respectively. Recall that the recoil has been applied in the c.m. system of the partons before ISR, so we apply the stored Lorentz transformation to boost them to the lab frame.

```

<ISR/EPA handler: evt isr: TBP>+≡
procedure, private :: replace_radiated
procedure, private :: replace_partons

<ISR/EPA handler: procedures>+≡
subroutine replace_radiated (evt)
  class(evt_isr_epa_t), intent(inout) :: evt
  integer :: i
  do i = 1, 2
    associate (prt => evt%particle_set%prt(evt%i_radiated(i)))
      call prt%set_momentum (evt%lti * evt%km(i))
    end associate
  end do
end subroutine replace_radiated

subroutine replace_partons (evt)
  class(evt_isr_epa_t), intent(inout) :: evt
  integer :: i
  do i = 1, 2
    associate (prt => evt%particle_set%prt(evt%i_parton(i)))
      call prt%set_momentum (evt%lti * evt%qo(i))
    end associate
  end do
end subroutine replace_partons

```

### 32.5.8 Transform the event

Knowing the new incoming partons for the elementary process, we can make use of another procedure in `recoil_kinematics` to determine the Lorentz transformation that transforms the collinear frame into the frame with transverse momentum. We apply this transformation, recursively, to all particles that originate from those incoming partons in the original particle set.

We have to allow for the pre-ISR partons being not in their common c.m. frame. Taking into account non-commutativity, we actually have to first transform the outgoing particles to that c.m. frame, then apply the recoil transformation, then boost back to the lab frame.

The `mask` keep track of particles that we transform, just in case the parent-child tree is multiply connected.

```

<ISR/EPA handler: evt isr: TBP>+≡
  procedure :: transform_outgoing => evt_transform_outgoing

<ISR/EPA handler: procedures>+≡
  subroutine evt_transform_outgoing (evt)
    class(evt_isr_epa_t), intent(inout) :: evt
    logical, dimension(:), allocatable :: mask
    call recoil_transformation (evt%sqrts, evt%xc, evt%qo, evt%lto)
    evt%lt = evt%lti * evt%lto * inverse (evt%lti)
    allocate (mask (evt%particle_set%get_n_tot ()), source=.false.)
    call transform_children (evt%i_parton(1))
  contains
    recursive subroutine transform_children (i)
      integer, intent(in) :: i
      integer :: j, n_child, c
      integer, dimension(:), allocatable :: child
      child = evt%particle_set%prt(i)%get_children ()
      do j = 1, size (child)
        c = child(j)
        if (.not. mask(c)) then
          associate (prt => evt%particle_set%prt(c))
            call prt%set_momentum (evt%lt * prt%get_momentum ())
            mask(c) = .true.
            call transform_children (c)
          end associate
        end if
      end do
    end subroutine transform_children
  end subroutine evt_transform_outgoing

```

### 32.5.9 Implemented methods

Here we take the particle set from the previous event transform and copy it, then generate the transverse momentum for the radiated particles and for the incoming partons. If this fails (rarely, for large  $p_T$ ), return zero for the probability, to trigger another try.

NOTE: The boost for the initial partonic system, if not in the c.m. frame, has not been implemented yet.

```

<ISR/EPA handler: evt isr: TBP>+≡

```

```

    procedure :: generate_weighted => &
        evt_isr_epa_generate_weighted
<ISR/EPA handler: procedures>+≡
    subroutine evt_isr_epa_generate_weighted (evt, probability)
        class(evt_isr_epa_t), intent(inout) :: evt
        real(default), intent(inout) :: probability
        logical :: valid
        call evt%particle_set%final ()
        evt%particle_set = evt%previous%particle_set
        evt%particle_set_exists = .true.
        select case (evt%mode)
        case (ISR_TRIVIAL_COLLINEAR)
            probability = 1
            valid = .true.
        case (ISR_PAIR_RECOIL)
            call evt%identify_radiated ()
            call evt%identify_partons ()

    use numeric_utils
    use diagnostics
    use flavors
    use helicities
    use quantum_numbers

```

```

    use interactions
    use evaluators
    use variables, only: var_list_t
    use model_data
    use rng_base
    use selectors
    use parton_states
    use process, only: process_t
    use instances, only: process_instance_t, pacify
    use process_stacks
    use event_transforms

    <Standard module head>

    <Decays: public>

    <Decays: types>

    <Decays: interfaces>

contains

    <Decays: procedures>

end module decays

```

### 32.6.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

<Decays: types>≡
    type, abstract :: any_config_t
    private
    contains
    <Decays: any config: TBP>
    end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
    procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
    interface
    subroutine any_config_final (object)
    import
    class(any_config_t), intent(inout) :: object
    end subroutine any_config_final
    end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
    procedure (any_config_write), deferred :: write

```

```

<Decays: interfaces>+≡
  interface
    subroutine any_config_write (object, unit, indent, verbose)
      import
      class(any_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
    end subroutine any_config_write
  end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_config_t
  private
    class(any_config_t), allocatable :: c
  end type particle_config_t

```

### 32.6.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above.

```

<Decays: types>+≡
  type, abstract :: any_t
  private
    contains
    <Decays: any: TBP>
  end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final
<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
      class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write
<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
      import
      class(any_t), intent(in) :: object

```

```

        integer, intent(in), optional :: unit, indent
    end subroutine any_write
end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
    type :: particle_out_t
    private
    class(any_t), allocatable :: c
end type particle_out_t

```

### 32.6.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+≡
    type :: decay_term_config_t
    private
    type(particle_config_t), dimension(:), allocatable :: prt
    contains
    <Decays: decay term config: TBP>
end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>≡
    procedure :: final => decay_term_config_final

<Decays: procedures>≡
    recursive subroutine decay_term_config_final (object)
    class(decay_term_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%prt)) then
        do i = 1, size (object%prt)
            if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
        end do
    end if
end subroutine decay_term_config_final

```

Output, with optional indentation

```

<Decays: decay term config: TBP>+≡
    procedure :: write => decay_term_config_write

<Decays: procedures>+≡
    recursive subroutine decay_term_config_write (object, unit, indent, verbose)
    class(decay_term_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: i, j, u, ind
    logical :: verb

```

```

u = given_output_unit (unit)
ind = 0; if (present (indent)) ind = indent
verb = .true.; if (present (verbose)) verb = verbose
call write_indent (u, ind)
write (u, "(1x,A)", advance="no") "Final state:"

  select type (prt_config => object%prt(i)%c)
  type is (stable_config_t)
    write (u, "(1x,A)", advance="no") &
      char (prt_config%flv(1)%get_name ())
    do j = 2, size (prt_config%flv)
      write (u, "(:',A)", advance="no") &
        char (prt_config%flv(j)%get_name ())
    end do
  type is (unstable_config_t)
    write (u, "(1x,A)", advance="no") &
      char (prt_config%flv%get_name ())
  end select
end do
write (u, *)
if (verb) then
  do i = 1, size (object%prt)
    call object%prt(i)%c%write (u, ind)
  end do
end if
end subroutine decay_term_config_write

```

Initialize, given a set of flavors. For each flavor, we must indicate whether the particle is stable. The second index of the flavor array runs over alternatives for each decay product; alternatives are allowed only if the decay product is itself stable.

```

<Decays: decay term config: TBP>+≡
  procedure :: init => decay_term_config_init

<Decays: procedures>+≡
  recursive subroutine decay_term_config_init &
    (term, flv, stable, model, process_stack, var_list)
    class(decay_term_config_t), intent(out) :: term
    type(flavor_t), dimension(:,:), intent(in) :: flv

### 32.6.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```

<Decays: public>≡
  public :: decay_root_config_t

```

```

<Decays: types>+≡
  type :: decay_root_config_t
  private
    type(string_t) :: process_id
    type(process_t), pointer :: process => null ()
    class(model_data_t), pointer :: model => null ()
    type(decay_term_config_t), dimension(:), allocatable :: term_config
  contains
    <Decays: decay root config: TBP>
  end type decay_root_config_t

```

The finalizer is recursive since there may be cascade decays.

```

<Decays: decay root config: TBP>≡
  procedure :: final => decay_root_config_final

<Decays: procedures>+≡
  recursive subroutine decay_root_config_final (object)
    class(decay_root_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%term_config)) then
      do i = 1, size (object%term_config)
        call object%term_config(i)%final ()
      end do
    end if
  end subroutine decay_root_config_final

```

The output routine is also recursive, and it contains an adjustable indentation.

```

<Decays: decay root config: TBP>+≡
  procedure :: write => decay_root_config_write
  procedure :: write_header => decay_root_config_write_header
  procedure :: write_terms => decay_root_config_write_terms

<Decays: procedures>+≡
  recursive subroutine decay_root_config_write (object, unit, indent, verbose)
    class(decay_root_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent

        decay%process_id = process_id
        if (present (n_terms)) then
            allocate (decay%term_config (n_terms))
        end if
    end subroutine decay_root_config_init

```

Declare a decay term, given an array of flavors.

```

<Decays: decay root config: TBP>+≡
    procedure :: init_term => decay_root_config_init_term

<Decays: procedures>+≡
    recursive subroutine decay_root_config_init_term &
        (decay, i, flv, stable, model, process_stack, var_list)
        class(decay_root_config_t), intent(inout) :: decay
        integer, intent(in) :: i
        type(flavor_t), dimension(:, :), intent(in) :: flv
        logical, dimension(:), intent(in) :: stable
        class(model_data_t), intent(in), target :: model

```

```

    type(process_stack_t), intent(in), optional :: process_stack
    type(var_list_t), intent(in), optional, target :: var_list
    call decay%term_config(i)%init (flv, stable, model, process_stack, var_list)
end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

For the unstable particles, we have to check whether their masses match between the production and the decay. Fortunately, both versions are available for comparison.

The optional `var_list` argument may override integral/error values for decay processes.

```

<Decays: decay root config: TBP>+=
  procedure :: connect => decay_root_config_connect

<Decays: procedures>+=
  recursive subroutine decay_root_config_connect &

### 32.6.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle

settings may be updated w.r.t. the parent process object.

```

<Decays: types>+≡
  type, abstract :: decay_gen_t
  private
    type(decay_term_t), dimension(:), allocatable :: term
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
  contains
    <Decays: decay gen: TBP>
  end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

<Decays: public>+≡
  public :: decay_root_t

<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_root_t
  private
    type(decay_root_config_t), pointer :: config => null ()
  contains
    <Decays: decay root: TBP>
  end type decay_root_t

```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```

<Decays: decay gen: TBP>≡
  procedure :: base_final => decay_gen_final

<Decays: procedures>+≡
  recursive subroutine decay_gen_final (object)
    class(decay_gen_t), intent(inout) :: object
    integer :: i
    if (allocated (object%term)) then
      do i = 1, size (object%term)
        call object%term(i)%final ()
      end do
    end if
  end subroutine decay_gen_final

```

No extra finalization for the decay root.

```

<Decays: decay root: TBP>≡
  procedure :: final => decay_root_final

<Decays: procedures>+≡
  subroutine decay_root_final (object)
    class(decay_root_t), intent(inout) :: object
    call object%base_final ()
  end subroutine decay_root_final

```

Output.

```

<Decays: decay root: TBP>+≡

```

### 32.6.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

The flavor component should be identical to the flavor component of the parent particle (`unstable` object).

```

⟨Decays: types⟩+≡
  type, extends (decay_root_config_t) :: decay_config_t
  private
  type(flavor_t) :: flv
  real(default) :: weight = 0
  real(default) :: integral = 0
  real(default) :: abs_error = 0
  real(default) :: rel_error = 0
  type(selector_t) :: mci_selector
  contains
  ⟨Decays: decay config: TBP⟩
end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
  procedure :: write => decay_config_write

<Decays: procedures>+≡
  recursive subroutine decay_config_write (object, unit, indent, verbose)

    call write_indent (u, ind)
    write (u, 1) "error (abs)      =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel)       =", object%rel_error
1   format (3x,A,ES19.12)
2   format (3x,A,F11.6,1x,'%')
    call object%write_terms (unit, indent, verbose)
  end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should be used instead.

If there is an optional `var_list`, check if the stored values for the decay partial width and error have been overridden there.

```

<Decays: decay config: TBP>+≡
  procedure :: connect => decay_config_connect

<Decays: procedures>+≡
  recursive subroutine decay_config_connect &
    (decay, process, model, process_stack, process_instance, var_list)
    class(decay_config_t), intent(out) :: decay
    type(process_t), intent(in), target :: process
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(process_instance_t), intent(in), optional, target :: process_instance
    type(var_list_t), intent(in), optional, target :: var_list
    real(default), dimension(:), allocatable :: integral_mci
    type(string_t) :: process_id
    integer :: i, n_mci
    call decay%decay_root_config_t%connect &
      (process, model, process_stack, var_list=var_list)

```

```

process_id = process%get_id ()
if (process%lab_is_cm ()) then
    call msg_fatal ("Decay process " // char (process_id) &
        // ": unusable because rest frame is fixed.")
end if
decay%integral = process%get_integral ()
decay%abs_error = process%get_error ()
if (present (var_list)) then
    call update (decay%integral, "integral(" // process_id // ")")
    call update (decay%abs_error, "error(" // process_id // ")")
end if
n_mci = process%get_n_mci ()

        else
            decay%rel_error = 0
        end if
    end subroutine decay_config_compute

```

### 32.6.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```
<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_t
  private
    type(decay_config_t), pointer :: config => null ()
    class(rng_t), allocatable :: rng
  contains
    <Decays: decay: TBP>
  end type decay_t
```

The finalizer is recursive.

```
<Decays: decay: TBP>≡
  procedure :: final => decay_final

<Decays: procedures>+≡
  recursive subroutine decay_final (object)
    class(decay_t), intent(inout) :: object
    integer :: i
    call object%base_final ()
    do i = 1, object%config%process%get_n_mci ()
      call object%process_instance%final_simulation (i)
    end do
    call object%process_instance%final ()
    deallocate (object%process_instance)
  end subroutine decay_final
```

Output.

```
<Decays: decay: TBP>+≡
  procedure :: write => decay_write

<Decays: procedures>+≡
  recursive subroutine decay_write (object, unit, indent, recursive)
    class(decay_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent, recursive
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call object%config%write (unit, indent, verbose = .false.)
    if (allocated (object%rng)) then
      call object%rng%write (u, ind + 1)
    end if
    call write_indent (u, ind)
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI    = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI    = [undefined]"
    end if
    call write_indent (u, ind)
```

```

    if (object%selected_term > 0) then
      write (u, "(3x,A,I0)") "Selected term  = ", object%selected_term
      call object%term(object%selected_term)%write (u, ind + 1)
    else
      write (u, "(3x,A)") "Selected term  = [undefined]"
    end if
  end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
  procedure :: init => decay_init

<Decays: procedures>+≡
  recursive subroutine decay_init (decay, config)
    class(decay_t), intent(out) :: decay
    type(decay_config_t), intent(in), target :: config
    integer :: i
    call decay%base_init (config%term_config)
    decay%config => config
    allocate (decay%process_instance)
    call decay%process_instance%init (decay%config%process)
    call decay%process_instance%setup_event_data (decay%config%model)
    do i = 1, decay%config%process%get_n_mci ()
      call decay%process_instance%init_simulation (i)
    end do
    call decay%config%process%make_rng (decay%rng)
    call decay%make_term_rng (decay%config%process)
  end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
  procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
  recursive subroutine decay_link_interactions (decay, i_prt, trace)
    class(decay_t), intent(inout) :: decay
    integer, intent(in) :: i_prt
    type(interaction_t), intent(in), target :: trace
    type(interaction_t), pointer :: beam_int
    integer :: n_in, n_vir
    beam_int => decay%process_instance%get_beam_int_ptr ()
    n_in = trace%get_n_in ()
    n_vir = trace%get_n_vir ()
    call beam_int%set_source_link (1, trace, &
      n_in + n_vir + i_prt)
    call decay%link_term_interactions ()
  end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
  procedure :: select_chain => decay_select_chain

<Decays: procedures>+≡
  recursive subroutine decay_select_chain (decay)
    class(decay_t), intent(inout) :: decay
    real(default) :: x
    integer :: i
    call decay%rng%generate (x)
    decay%selected_mci = decay%config%mci_selector%select (x)
    call decay%process_instance%choose_mci (decay%selected_mci)
    decay%selected_term = decay%process_instance%select_i_term ()
    do i = 1, size (decay%term)
      call decay%term(i)%select_chain ()
    end do
  end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

<Decays: decay: TBP>+≡
  procedure :: generate => decay_generate

<Decays: procedures>+≡
  recursive subroutine decay_generate (decay)
    class(decay_t), intent(inout) :: decay
    type(isolated_state_t), pointer :: isolated_state
    integer :: i
    call decay%process_instance%receive_beam_momenta ()
    call decay%process_instance%generate_unweighted_event (decay%selected_mci)
    if (signal_is_pending ()) return
    call decay%process_instance%evaluate_event_data ()
    isolated_state => &
      decay%process_instance%get_isolated_state_ptr (decay%selected_term)
    call isolated_state%normalize_matrix_by_trace ()
    do i = 1, size (decay%term)
      call decay%term(i)%generate ()
      if (signal_is_pending ()) return
    end do
  end subroutine decay_generate

```

### 32.6.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```

<Decays: types>+≡
  type, extends (any_config_t) :: stable_config_t
  private
    type(flavor_t), dimension(:), allocatable :: flv
  contains
    <Decays: stable config: TBP>
  end type stable_config_t

```

The finalizer is empty:

```

<Decays: stable config: TBP>≡
  procedure :: final => stable_config_final

<Decays: procedures>+≡
  subroutine stable_config_final (object)
    class(stable_config_t), intent(inout) :: object
  end subroutine stable_config_final

```

Output.

```

<Decays: stable config: TBP>+≡
  procedure :: write => stable_config_write

<Decays: procedures>+≡
  recursive subroutine stable_config_write (object, unit, indent, verbose)
    class(stable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"
    write (u, "(1x,A)", advance = "no") char (object%flv(1)%get_name ())
    do i = 2, size (object%flv)
      write (u, "(:',A)", advance = "no") &
        char (object%flv(i)%get_name ())
    end do
    write (u, *)
  end subroutine stable_config_write

```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```

<Decays: stable config: TBP>+≡
  procedure :: init => stable_config_init

<Decays: procedures>+≡
  subroutine stable_config_init (config, flv)
    class(stable_config_t), intent(out) :: config
    type(flavor_t), dimension(:), intent(in) :: flv
    integer, dimension (size (flv)) :: pdg
    logical, dimension (size (flv)) :: mask
    integer :: i
    pdg = flv%get_pdg ()
    mask(1) = .true.
    forall (i = 2 : size (pdg))

```

```

        mask(i) = all (pdg(i) /= pdg(1:i-1))
    end forall
    allocate (config%flv (count (mask)))
    config%flv = pack (flv, mask)
end subroutine stable_config_init

```

Here is the corresponding object instance. Except for the pointer to the configuration, there is no content.

```

<Decays: types>+≡
    type, extends (any_t) :: stable_t
    private
        type(stable_config_t), pointer :: config => null ()
    contains
        <Decays: stable: TBP>
    end type stable_t

```

The finalizer does nothing.

```

<Decays: stable: TBP>≡
    procedure :: final => stable_final

<Decays: procedures>+≡
    subroutine stable_final (object)
        class(stable_t), intent(inout) :: object
    end subroutine stable_final

```

We can delegate output to the configuration object.

```

<Decays: stable: TBP>+≡
    procedure :: write => stable_write

<Decays: procedures>+≡
    subroutine stable_write (object, unit, indent)
        class(stable_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        call object%config%write (unit, indent)
    end subroutine stable_write

```

Initializer: just assign the configuration.

```

<Decays: stable: TBP>+≡
    procedure :: init => stable_init

<Decays: procedures>+≡
    subroutine stable_init (stable, config)
        class(stable_t), intent(out) :: stable
        type(stable_config_t), intent(in), target :: config
        stable%config => config
    end subroutine stable_init

```

### 32.6.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: public>+≡
    public :: unstable_config_t

<Decays: types>+≡
    type, extends (any_config_t) :: unstable_config_t
    private
    type(flavor_t) :: flv
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: selector
    type(decay_config_t), dimension(:), allocatable :: decay_config
    contains
    <Decays: unstable config: TBP>
    end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
    procedure :: final => unstable_config_final

<Decays: procedures>+≡
    recursive subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay_config)) then
        do i = 1, size (object%decay_config)
            call object%decay_config(i)%final ()
        end do
    end if
    end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
    procedure :: write => unstable_config_write

<Decays: procedures>+≡
    recursive subroutine unstable_config_write (object, unit, indent, verbose)
    class(unstable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    logical :: verb
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
        char (object%flv%get_name ())
    call write_indent (u, ind)
    write (u, 1) "total width =", object%integral
    call write_indent (u, ind)

```

```

write (u, 1) "error (abs) =", object%abs_error
call write_indent (u, ind)
write (u, 1) "error (rel) =", object%rel_error
1 format (5x,A,ES19.12)
if (verb .and. allocated (object%decay_config)) then
  do i = 1, size (object%decay_config)
    call object%decay_config(i)%write (u, ind + 1)
  end do
end if
end subroutine unstable_config_write

```

Initializer. For the unstable particle, the flavor is unique.

```

<Decays: unstable config: TBP>+≡
  procedure :: init => unstable_config_init

<Decays: procedures>+≡
  subroutine unstable_config_init (unstable, flv, set_decays, model)
    class(unstable_config_t), intent(out) :: unstable
    type(flavor_t), intent(in) :: flv
    logical, intent(in), optional :: set_decays
    class(model_data_t), intent(in), optional, target :: model
    type(string_t), dimension(:), allocatable :: decay
    unstable%flv = flv
    if (present (set_decays)) then
      call unstable%flv%get_decays (decay)
      call unstable%init_decays (decay, model)
    end if
  end subroutine unstable_config_init

```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```

<Decays: unstable config: TBP>+≡
  procedure :: init_decays => unstable_config_init_decays

<Decays: procedures>+≡
  recursive subroutine unstable_config_init_decays &
    (unstable, decay_id, model, process_stack, var_list)
    class(unstable_config_t), intent(inout) :: unstable
    type(string_t), dimension(:), intent(in) :: decay_id
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(var_list_t), intent(in), optional :: var_list
    integer :: i
    allocate (unstable%decay_config (size (decay_id)))
    do i = 1, size (decay_id)
      associate (decay => unstable%decay_config(i))
        if (present (process_stack)) then
          call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
            model, process_stack, var_list=var_list)
        else
          call decay%init (model, decay_id(i))
        end if
      end associate
    end do
  end subroutine unstable_config_init_decays

```

```

        call decay%set_flg (unstable%flv)
    end associate
end do
end subroutine unstable_config_init_decays

```

Explicitly connect a specific decay with a process. This is used only in unit tests.

```

<Decays: unstable config: TBP>+≡
    procedure :: connect_decay => unstable_config_connect_decay

<Decays: procedures>+≡
    subroutine unstable_config_connect_decay (unstable, i, process, model)
        class(unstable_config_t), intent(inout) :: unstable
        integer, intent(in) :: i
        type(process_t), intent(in), target :: process
        class(model_data_t), intent(in), target :: model
        associate (decay => unstable%decay_config(i))
            call decay%connect (process, model)
        end associate
    end subroutine unstable_config_connect_decay

```

Compute the total width and branching ratios, initializing the decay selector.

```

<Decays: unstable config: TBP>+≡
    procedure :: compute => unstable_config_compute

<Decays: procedures>+≡
    recursive subroutine unstable_config_compute (unstable)
        class(unstable_config_t), intent(inout) :: unstable
        integer :: i
        do i = 1, size (unstable%decay_config)
            call unstable%decay_config(i)%compute ()
        end do
        unstable%integral = sum (unstable%decay_config%integral)
        if (unstable%integral <= 0) then
            call unstable%write ()
            call msg_fatal ("Decay configuration: computed total width is zero")
        end if
        unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
        unstable%rel_error = unstable%abs_error / unstable%integral
        call unstable%selector%init (unstable%decay_config%integral)
        do i = 1, size (unstable%decay_config)
            unstable%decay_config(i)%weight &
                = unstable%selector%get_weight (i)
        end do
    end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: public>+≡
    public :: unstable_t

<Decays: types>+≡
    type, extends (any_t) :: unstable_t
    private

```

```

    type(unstable_config_t), pointer :: config => null ()
    class(rng_t), allocatable :: rng
    integer :: selected_decay = 0
    type(decay_t), dimension(:), allocatable :: decay
contains
  <Decays: unstable: TBP>
end type unstable_t

```

Recursive finalizer.

```

<Decays: unstable: TBP>≡
  procedure :: final => unstable_final
<Decays: procedures>+≡
  recursive subroutine unstable_final (object)
    class(unstable_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay)) then
      do i = 1, size (object%decay)
        call object%decay(i)%final ()
      end do
    end if
  end subroutine unstable_final

```

Output.

```

<Decays: unstable: TBP>+≡
  procedure :: write => unstable_write
<Decays: procedures>+≡
  recursive subroutine unstable_write (object, unit, indent)
    class(unstable_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call object%config%write (u, ind, verbose=.false.)
    if (allocated (object%rng)) then
      call object%rng%write (u, ind + 2)
    end if
    call write_indent (u, ind)
    if (object%selected_decay > 0) then
      write (u, "(5x,A,I0)") "Sel. decay = ", object%selected_decay
      call object%decay(object%selected_decay)%write (u, ind + 1)
    else
      write (u, "(5x,A)") "Sel. decay = [undefined]"
    end if
  end subroutine unstable_write

```

Write the embedded process instances.

```

<Decays: unstable: TBP>+≡
  procedure :: write_process_instances => unstable_write_process_instances
<Decays: procedures>+≡
  recursive subroutine unstable_write_process_instances &
    (unstable, unit, verbose)

```

```

    call unstable%decay(unstable%selected_decay)%select_chain ()
  end subroutine unstable_select_chain

```

Generate a decay event.

```

<Decays: unstable: TBP>+≡
  procedure :: generate => unstable_generate

<Decays: procedures>+≡
  recursive subroutine unstable_generate (unstable)
    class(unstable_t), intent(inout) :: unstable
    call unstable%decay(unstable%selected_decay)%generate ()
  end subroutine unstable_generate

```

### 32.6.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+≡
  type, extends (connected_state_t) :: decay_chain_entry_t
  private
  integer :: index = 0
  type(decay_config_t), pointer :: config => null ()
  integer :: selected_mci = 0
  integer :: selected_term = 0
  type(decay_chain_entry_t), pointer :: previous => null ()
  end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: public>+≡
    public :: decay_chain_t

<Decays: types>+≡
    type :: decay_chain_t
    private
        type(process_instance_t), pointer :: process_instance => null ()
        integer :: selected_term = 0
        type(evaluator_t) :: correlated_trace
        type(decay_chain_entry_t), pointer :: last => null ()
    contains
        <Decays: decay chain: TBP>
    end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay chain: TBP>≡
    procedure :: final => decay_chain_final

<Decays: procedures>+≡
    subroutine decay_chain_final (object)
        class(decay_chain_t), intent(inout) :: object
        type(decay_chain_entry_t), pointer :: entry
        do while (associated (object%last))
            entry => object%last
            object%last => entry%previous
            call entry%final ()
            deallocate (entry)
        end do
        call object%correlated_trace%final ()
    end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

<Decays: decay chain: TBP>+≡
    procedure :: write => decay_chain_write

<Decays: procedures>+≡
    subroutine decay_chain_write (object, unit)
        class(decay_chain_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)

```

```

call write_separator (u, 2)
write (u, "(1x,A)") "Decay chain:"
call write_entries (object%last)
call write_separator (u, 2)
write (u, "(1x,A)") "Evaluator (correlated trace of the decay chain):"
call write_separator (u)
call object%correlated_trace%write (u)
call write_separator (u, 2)
contains
recursive subroutine write_entries (entry)
  type(decay_chain_entry_t), intent(in), pointer :: entry
  if (associated (entry)) then
    call write_entries (entry%previous)
    call write_separator (u, 2)
    write (u, "(1x,A,I0)") "Decay #", entry%index
    call entry%config%write_header (u)
    write (u, "(3x,A,I0)") "Selected MCI    = ", entry%selected_mci
    write (u, "(3x,A,I0)") "Selected term  = ", entry%selected_term
    call entry%config%term_config(entry%selected_term)%write (u, indent=1)
    call entry%write (u)
  end if
end subroutine write_entries
end subroutine decay_chain_write

```

Build a decay chain, recursively following the selected decays and terms in a decay tree. Before start, we finalize the chain, deleting any previous contents.

```

<Decays: decay chain: TBP>+≡
  procedure :: build => decay_chain_build

<Decays: procedures>+≡
  subroutine decay_chain_build (chain, decay_root)
    class(decay_chain_t), intent(inout), target :: chain
    type(decay_root_t), intent(in) :: decay_root
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    type(interaction_t), pointer :: int_last_decay
    call chain%final ()
    if (decay_root%selected_term > 0) then
      chain%process_instance => decay_root%process_instance
      chain%selected_term = decay_root%selected_term
      call chain%build_term_entries (decay_root%term(decay_root%selected_term))
    end if
    int_last_decay => chain%last%get_matrix_int_ptr ()
    allocate (qn_mask (int_last_decay%get_n_tot ()))
    call qn_mask%init (mask_f = .true., mask_c = .true., mask_h = .true.)
    call chain%correlated_trace%init_qn_sum (int_last_decay, qn_mask)
  end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable particles.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_term_entries (chain, term)

```

```

class(decay_chain_t), intent(inout) :: chain
type(decay_term_t), intent(in) :: term
integer :: i
do i = 1, size (term%particle_out)
  select type (unstable => term%particle_out(i)%c)
  type is (unstable_t)
    if (unstable%selected_decay > 0) then
      call chain%build_decay_entries &
        (unstable%decay(unstable%selected_decay))
    end if
  end select
end do
end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_decay_entries => decay_chain_build_decay_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_decay_entries (chain, decay)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_t), intent(in) :: decay
    type(decay_chain_entry_t), pointer :: entry
    type(connected_state_t), pointer :: previous_state
    type(isolated_state_t), pointer :: current_decay
    type(helicity_t) :: hel
    type(quantum_numbers_t) :: qn_filter_conn
    allocate (entry)
    if (associated (chain%last)) then
      entry%previous => chain%last
      entry%index = entry%previous%index + 1
      previous_state => entry%previous%connected_state_t
    else
      entry%index = 1
      previous_state => &
        chain%process_instance%get_connected_state_ptr (chain%selected_term)
    end if
    entry%config => decay%config
    entry%selected_mci = decay%selected_mci
    entry%selected_term = decay%selected_term
  end subroutine

```

```

current_decay => decay%process_instance%get_isolated_state_ptr &
    (decay%selected_term)
call entry%setup_connected_trace &
    (current_decay, previous_state%get_trace_int_ptr (), resonant=.true.)
if (entry%config%flv%has_decay_helicity ()) then
    call hel%init (entry%config%flv%get_decay_helicity ())
    call qn_filter_conn%init (hel)
    call entry%setup_connected_matrix &
        (current_decay, previous_state%get_matrix_int_ptr (), &
        resonant=.true., qn_filter_conn = qn_filter_conn)
    call entry%setup_connected_flows &
        (current_decay, previous_state%get_flows_int_ptr (), &
        resonant=.true., qn_filter_conn = qn_filter_conn)
else
    call entry%setup_connected_matrix &
        (current_decay, previous_state%get_matrix_int_ptr (), &
        resonant=.true.)
    call entry%setup_connected_flows &

        resonant=.true.)
end if
chain%last => entry
call chain%build_term_entries (decay%term(decay%selected_term))
end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

```

<Decays: decay chain: TBP>+≡
    procedure :: evaluate => decay_chain_evaluate

<Decays: procedures>+≡
    subroutine decay_chain_evaluate (chain)
        class(decay_chain_t), intent(inout) :: chain
        call evaluate (chain%last)
        call chain%correlated_trace%receive_momenta ()
        call chain%correlated_trace%evaluate ()
    contains
        recursive subroutine evaluate (entry)
            type(decay_chain_entry_t), intent(inout), pointer :: entry
            if (associated (entry)) then
                call evaluate (entry%previous)
                call entry%receive_kinematics ()
                call entry%evaluate_trace ()
                call entry%evaluate_event_data ()
            end if
        end subroutine evaluate
    end subroutine decay_chain_evaluate

```

Return the probability of a decay chain. This is given as the trace of the density

matrix with intermediate helicity correlations, normalized by the product of the uncorrelated density matrix traces. This works only if an event has been evaluated and the `correlated_trace` evaluator is filled. By definition, this evaluator has only one matrix element, and this must be real.

```

<Decays: decay chain: TBP>+≡
  procedure :: get_probability => decay_chain_get_probability

<Decays: procedures>+≡
  function decay_chain_get_probability (chain) result (x)
    class(decay_chain_t), intent(in) :: chain
    real(default) :: x
    x = real (chain%correlated_trace%get_matrix_element (1))
  end function decay_chain_get_probability

```

### 32.6.12 Decay as Event Transform

The `evt_decay` object combines decay configuration, decay tree, and chain in a single object, as an implementation of the `evt` (event transform) abstract type.

The `var_list` may be a pointer to the user variable list, which could contain overridden parameters for the decay processes.

```

<Decays: public>+≡
  public :: evt_decay_t

<Decays: types>+≡
  type, extends (evt_t) :: evt_decay_t
    private
      type(decay_root_config_t) :: decay_root_config
      type(decay_root_t) :: decay_root
      type(decay_chain_t) :: decay_chain
      type(var_list_t), pointer :: var_list => null ()
    contains
      <Decays: evt decay: TBP>
  end type evt_decay_t

<Decays: evt decay: TBP>≡
  procedure :: write_name => evt_decay_write_name

<Decays: procedures>+≡
  subroutine evt_decay_write_name (evt, unit)
    class(evt_decay_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event transform: partonic decays"
  end subroutine evt_decay_write_name

```

Output. We display the currently selected decay tree, which includes configuration data, and the decay chain, i.e., the evaluators.

```

<Decays: evt decay: TBP>+≡
  procedure :: write => evt_decay_write

```

```

<Decays: procedures>+≡
subroutine evt_decay_write (evt, unit, verbose, more_verbose, testflag)
  class(evt_decay_t), intent(in) :: evt
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: verbose, more_verbose, testflag
  logical :: verb, verb2
  integer :: u
  u = given_output_unit (unit)
  verb = .true.; if (present (verbose)) verb = verbose
  verb2 = .false.; if (present (more_verbose)) verb2 = more_verbose
  call write_separator (u, 2)
  call evt%write_name (u)
  call write_separator (u, 2)
  call evt%base_write (u, testflag = testflag)
  if (associated (evt%var_list)) then
    call write_separator (u)
    write (u, "(1x,A)" "Variable list for simulation: &
      &[associated, not shown]"
  end if
  if (verb) then
    call write_separator (u)
    call evt%decay_root%write (u)
    if (verb2) then
      call evt%decay_chain%write (u)
      call evt%decay_root%write_process_instances (u, verb)
    end if
  else
    call write_separator (u, 2)
  end if
end subroutine evt_decay_write

```

Set the pointer to a user variable list.

```

<Decays: evt decay: TBP>+≡
  procedure :: set_var_list => evt_decay_set_var_list

<Decays: procedures>+≡
subroutine evt_decay_set_var_list (evt, var_list)
  class(evt_decay_t), intent(inout) :: evt
  type(var_list_t), intent(in), target :: var_list
  evt%var_list => var_list
end subroutine evt_decay_set_var_list

```

Connect with a process instance and process. This initializes the decay configuration. The process stack is used to look for process objects that implement daughter decays.

When all processes are assigned, configure the decay tree instance, using the decay tree configuration. First obtain the branching ratios, then allocate the decay tree. This is done once for all events.

```

<Decays: evt decay: TBP>+≡
  procedure :: connect => evt_decay_connect

<Decays: procedures>+≡
subroutine evt_decay_connect (evt, process_instance, model, process_stack)

```

```

class(evt_decay_t), intent(inout), target :: evt
type(process_instance_t), intent(in), target :: process_instance
class(model_data_t), intent(in), target :: model
type(process_stack_t), intent(in), optional :: process_stack
call evt%base_connect (process_instance, model)
if (associated (evt%var_list)) then
    call evt%decay_root_config%connect (process_instance%process, &
        model, process_stack, process_instance, evt%var_list)
else
    call evt%decay_root_config%connect (process_instance%process, &
        model, process_stack, process_instance)
end if
call evt%decay_root_config%compute ()
call evt%decay_root%init (evt%decay_root_config, evt%process_instance)
end subroutine evt_decay_connect

```

Prepare a new event: Select a decay chain and build the corresponding chain object.

```

<Decays: evt decay: TBP>+≡
    procedure :: prepare_new_event => evt_decay_prepare_new_event

<Decays: procedures>+≡
    subroutine evt_decay_prepare_new_event (evt, i_mci, i_term)
        class(evt_decay_t), intent(inout) :: evt
        integer, intent(in) :: i_mci, i_term
        call evt%reset ()
        evt%decay_root%selected_mci = i_mci
        evt%decay_root%selected_term = i_term
        call evt%decay_root%select_chain ()
        call evt%decay_chain%build (evt%decay_root)
    end subroutine evt_decay_prepare_new_event

```

Generate a weighted event and assign the resulting weight (probability). We use a chain initialized by the preceding subroutine, fill it with momenta and evaluate.

```

<Decays: evt decay: TBP>+≡
    procedure :: generate_weighted => evt_decay_generate_weighted

<Decays: procedures>+≡
    subroutine evt_decay_generate_weighted (evt, probability)
        class(evt_decay_t), intent(inout) :: evt
        real(default), intent(inout) :: probability
        call evt%decay_root%generate ()
        if (signal_is_pending ()) return
        call evt%decay_chain%evaluate ()
        probability = evt%decay_chain%get_probability ()
    end subroutine evt_decay_generate_weighted

```

To create a usable event, we have to transform the interaction into a particle set; this requires factorization for the correlated density matrix, according to the factorization mode.

```

<Decays: evt decay: TBP>+≡
    procedure :: make_particle_set => evt_decay_make_particle_set

```

```

<Decays: procedures>+≡
  subroutine evt_decay_make_particle_set &
    (evt, factorization_mode, keep_correlations, r)
    class(evt_decay_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    type(interaction_t), pointer :: int_matrix, int_flows
    type(decay_chain_entry_t), pointer :: last_entry
    last_entry => evt%decay_chain%last
    int_matrix => last_entry%get_matrix_int_ptr ()
    int_flows => last_entry%get_flows_int_ptr ()

```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations is under construction. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid. This procedure directly

takes the (MLM) matching into account.

## 32.9 Fixed Order NLO Events

This section deals with the generation of weighted event samples which take into account next-to-leading order corrections. An approach generating unweighted events is not possible here, because negative weights might occur due to subtraction. Note that the events produced this way are not physical in the sense that they will not keep NLO-accuracy when interfaced to a parton shower. They are rather useful for theoretical consistency checks and a fast estimate of NLO effects.

We generate NLO events in the following way: First, the integration is carried out using the complete divergence-subtracted NLO matrix element. In the subsequent simulation,  $N$ -particle kinematics are generated using  $\mathcal{B} + \mathcal{V} + \mathcal{C}$  as weight. After that, the program loops over all singular regions and for each of them generates an event with  $N + 1$ -particle kinematics. The weight for those events corresponds to the real matrix element  $\mathcal{R}^\alpha$  evaluated at the  $\alpha$ -region's emitter's phase space point, multiplied with  $S_\alpha$ . This procedure is implemented using the `evt_nlo` transform.

```

  integer :: n_phs = 0
end type nlo_event_deps_t
```

This event transformation is for the generation of fixed-order NLO events. It takes an event with Born kinematics and creates  $N_\alpha + 1$  modified weighted events. The first one has Born kinematics and its weight is the sum of Born, virtual, subtraction and, if present, also DGLAP matrix elements. The other  $N_\alpha$  events have a weight which is equal to the real matrix element, evaluated with the phase space corresponding to the emitter of the  $\alpha$ -region.

As the NLO event transforms have different kinematics, they also differ in their `particle_sets`. The NLO `event_t` object carries a single pointer to a `particle_set`. To avoid interference between the different NLO `particle_sets`, we save the `particle_set` of the current  $\alpha$ -region in the array `particle_set_nlo`. Otherwise it would be unretrievable if the usual particle set of the event object was used.

```

The event transform has a variable which counts the number of times it has already been called for one generation point. If this variable, `i_evaluation`, is zero, this means that `evt_nlo_generate_weighted` is called for the first time, so that the generation of an  $N$ -particle event is required. In all other cases, emission events are generated.

During a separate integration of the real component, the first event of each event group will become the counterevent. In this case, we return the sum of all subtraction matrix elements.

During a combined integration, the first event will be a combination of all Born-like events. To get the sum of their matrix elements, we subtract the sum of all real emissions from the sum of all matrix elements as the real contribution is the only non-Born contribution.

Note that the argument named `probability`, the use of the routine `generate_weighted` and the procedure we use to generate NLO events via an event transformation is an abuse of the interface which should be refactored.

The routine `make_factorized_particle_set` will setup the subevent momenta from the `connected%matrix`. Its initial state momenta correspond to the Born process without IS splitting and thus need to be updated with the real momenta from the `int_hard` to get correct momenta in the events with real radiation.

Ideally the `int_hard` and the `connected` would be setup with correct `source_links` to real momenta so that we would not need to replace momenta of the `connected` here.

The parameter `n_in` from the `int_matrix` is still 0 as it has been shifted to `n_vir`. We thus take `n_in` from the `particle_set`.

```

Selects a flavor structure for Born subevents, such that each possible flavor structure is as probable as its portion of the sum of Born matrix elements over all flavors. For non-Born Born-like subevents, no Born matrix elements are available. We always choose `i_flv = 1` in this case. If all terms are active, i.e.

in a full NLO calculation, the flavors of Born-like subevents will be distributed according to the Born matrix elements only, to avoid issues with matrix elements of different sign and assure a LO flavor distribution.

Likewise, the real-like event flavors are distributed according to the real matrix elements. Here, we need to make sure to not mix matrix elements from different real terms and instead determine the flavor for each subevent based on just the matrix elements for one of the terms. The implementation below assumes that in the sequence of NLO terms, the Born term is immediately followed by all the real terms which are again followed by the subtraction, the virtual and the DGLAP term.

Both flavor structures can be determined without correlation as the flavors will only become important for events to be matched to a parton shower and in this case we will only generate either a single Born-like or a single real-like event which are not part of an event group.

In case all subevents failed the cuts, all `sqmes` were set to 0 so we cannot determine the flavor in this way. In this case, we always choose the first flavor structure given by the matrix-element generator with `i_flv = 1`.

Ideally, having to choose a particle set here would not be necessary as it is also chosen in `particle_set_init_interaction` which in the current approach is disabled by supplying `qn_select` explicitly based on the flavors chosen here.

### 32.10.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The **safety\_factor** reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The **sigma** and **n** values, if nontrivial, allow for reweighting the events according to the requested **norm\_mode**.

Various **parse\_node\_t** objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the **event\_expr\_t** objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

```

### 32.10.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event_base` module. The core manages the main (dressed) particle set pointer and the current values for weights and sqme. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers

should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

The `sqme` and `weight` values mirror corresponding values in the `expr` subobject. The idea is that when generating or reading events, the event record is filled first, then the `expr` object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the `expr` subobject. In particular, evaluating the event-selection expression sets the `passed` flag. Furthermore, the `expr` subobject collects data that can be used in the analysis and should be written to file, including copies of `sqme` and `weight`.

```

### 32.10.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```

(Events: event: TBP) +=
  procedure :: basic_init => event_init

(Events: procedures) +=
  subroutine event_init (event, var_list, n_alt)
    class(event_t), intent(out) :: event
    type(var_list_t), intent(in), optional :: var_list
    integer, intent(in), optional :: n_alt
    type(string_t) :: norm_string, mode_string
    logical :: polarized_events
    if (present (n_alt)) then
      call event%base_init (n_alt)
      call event%expr%init (n_alt)
    else
      call event%base_init (0)
    end if
    if (present (var_list)) then
      event%config%unweighted = var_list%get_lval (&
        var_str ("?unweighted"))
      norm_string = var_list%get_sval (&
        var_str ("$_sample_normalization"))
      event%config%norm_mode = &
        event_normalization_mode (norm_string, event%config%unweighted)
      polarized_events = &
        var_list%get_lval (var_str ("?polarized_events"))
      if (polarized_events) then
        mode_string = &
          var_list%get_sval (var_str ("$_polarization_mode"))
        select case (char (mode_string))
          case ("ignore")
            event%config%factorization_mode = FM_IGNORE_HELICITY
          case ("helicity")
            event%config%factorization_mode = FM_SELECT_HELICITY
          case ("factorized")
            event%config%factorization_mode = FM_FACTOR_HELICITY
          case ("correlated")
            event%config%factorization_mode = FM_CORRELATED_HELICITY
          case default
            call msg_fatal ("Polarization mode " &
              // char (mode_string) // " is undefined")
        end select
      else
        event%config%factorization_mode = FM_IGNORE_HELICITY
      end if
      event%config%colorize_subevt = &

```

```

        var_list%get_lval (var_str ("?colorize_subevt"))
    if (event%config%unweighted) then
        event%config%safety_factor = var_list%get_rval (&
            var_str ("safety_factor"))
    end if
else
    event%config%norm_mode = NORM_SIGMA
end if
allocate (evt_trivial_t :: event%transform_first)
event%transform_last => event%transform_first
end subroutine event_init

```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

```

<Events: event: TBP>+≡
    procedure :: set_sigma => event_set_sigma
    procedure :: set_n => event_set_n

<Events: procedures>+≡
    elemental subroutine event_set_sigma (event, sigma)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: sigma
        event%config%sigma = sigma
    end subroutine event_set_sigma

    elemental subroutine event_set_n (event, n)
        class(event_t), intent(inout) :: event
        integer, intent(in) :: n
        event%config%n = n
    end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
    procedure :: import_transform => event_import_transform

<Events: procedures>+≡
    subroutine event_import_transform (event, evt)
        class(event_t), intent(inout) :: event
        class(evt_t), intent(inout), pointer :: evt
        event%transform_last%next => evt
        evt%previous => event%transform_last
        event%transform_last => evt
        evt => null ()
    end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

<Events: procedures>+≡
  subroutine event_connect (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(string_t) :: id
    integer :: num_id
    class(evt_t), pointer :: evt
    event%process => process_instance%process
    event%instance => process_instance
    id = event%process%get_id ()
    if (id /= "") call event%expr%set_process_id (id)
    num_id = event%process%get_num_id ()
    if (num_id /= 0) call event%expr%set_process_num_id (num_id)
    call event%expr%setup_vars (event%process%get_sqrts ())
    call event%expr%link_var_list (event%process%get_var_list_ptr ())
    call event%process%make_rng (event%rng)
    evt => event%transform_first
    do while (associated (evt))
      call evt%connect (process_instance, model, process_stack)
      evt => evt%next
    end do
  end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
  procedure :: set_selection => event_set_selection
  procedure :: set_reweight => event_set_reweight
  procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡
  subroutine event_set_selection (event, ef_selection)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_selection
    allocate (event%config%ef_selection, source = ef_selection)
  end subroutine event_set_selection

  subroutine event_set_reweight (event, ef_reweight)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_reweight
    allocate (event%config%ef_reweight, source = ef_reweight)

```

```

end subroutine event_set_reweight

subroutine event_set_analysis (event, ef_analysis)
  class(event_t), intent(inout) :: event
  class(expr_factory_t), intent(in) :: ef_analysis
  allocate (event%config%ef_analysis, source = ef_analysis)
end subroutine event_set_analysis

```

Create evaluation trees from the parse trees. The `target` attribute is required because the expressions contain pointers to event subobjects.

```

<Events: event: TBP>+≡
  procedure :: setup_expressions => event_setup_expressions

<Events: procedures>+≡
  subroutine event_setup_expressions (event)
    class(event_t), intent(inout), target :: event
    call event%expr%setup_selection (event%config%ef_selection)
    call event%expr%setup_analysis (event%config%ef_analysis)
    call event%expr%setup_reweight (event%config%ef_reweight)
    call event%expr%colorize (event%config%colorize_subevt)
  end subroutine event_setup_expressions

```

### 32.10.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

<Events: event: TBP>+≡
  procedure :: evaluate_transforms => event_evaluate_transforms

<Events: procedures>+≡

```

```

end do
end subroutine event_reset_contents

subroutine event_reset_index (event)
  class(event_t), intent(inout) :: event
  call event%expr%reset_event_index ()
end subroutine event_reset_index

```

### 32.10.6 Squared Matrix Element and Weight

Transfer the result of the process instance calculation to the event record header.

```

<Events: event: TBP>+≡
  procedure :: import_instance_results => event_import_instance_results

<Events: procedures>+≡
  subroutine event_import_instance_results (event)
    class(event_t), intent(inout) :: event
    if (associated (event%instance)) then
      if (event%instance%has_evaluated_trace ()) then
        call event%set ( &
          sqme_prc = event%instance%get_sqme (), &
          weight_prc = event%instance%get_weight (), &
          excess_prc = event%instance%get_excess (), &
          n_dropped = event%instance%get_n_dropped () &
        )
      end if
    end if
  end subroutine event_import_instance_results

```

Duplicate the instance result / the reference result in the event record.

```

<Events: event: TBP>+≡
  procedure :: accept_sqme_ref => event_accept_sqme_ref
  procedure :: accept_sqme_prc => event_accept_sqme_prc
  procedure :: accept_weight_ref => event_accept_weight_ref
  procedure :: accept_weight_prc => event_accept_weight_prc

<Events: procedures>+≡
  subroutine event_accept_sqme_ref (event)
    class(event_t), intent(inout) :: event
    if (event%sqme_ref_is_known ()) then
      call event%set (sqme_prc = event%get_sqme_ref ())
    end if
  end subroutine event_accept_sqme_ref

  subroutine event_accept_sqme_prc (event)
    class(event_t), intent(inout) :: event
    if (event%sqme_prc_is_known ()) then
      call event%set (sqme_ref = event%get_sqme_prc ())
    end if
  end subroutine event_accept_sqme_prc

  subroutine event_accept_weight_ref (event)
    class(event_t), intent(inout) :: event

```

```

        if (event%weight_ref_is_known ()) then
            call event%set (weight_prc = event%get_weight_ref ())
        end if
    end subroutine event_accept_weight_ref

    subroutine event_accept_weight_prc (event)
        class(event_t), intent(inout) :: event
        if (event%weight_prc_is_known ()) then
            call event%set (weight_ref = event%get_weight_prc ())
        end if
    end subroutine event_accept_weight_prc

```

Update the weight normalization, just after generation. Unweighted and weighted events are generated with a different default normalization. The intended normalization is stored in the configuration record.

```

<Events: event: TBP>+≡
    procedure :: update_normalization => event_update_normalization

```

### 32.10.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we **accept** the latter.

The explicit random number argument **r** should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
    procedure :: generate => event_generate

<Events: procedures>+≡
    subroutine event_generate (event, i_mci, r, i_nlo)
        class(event_t), intent(inout) :: event
        integer, intent(in) :: i_mci
        real(default), dimension(:), intent(in), optional :: r
        integer, intent(in), optional :: i_nlo
        logical :: generate_new
        generate_new = .true.
        if (present (i_nlo)) generate_new = (i_nlo == 1)
        if (generate_new) call event%reset_contents ()
        event%selected_i_mci = i_mci
        if (event%config%unweighted) then

        call event%update_normalization ()
        call event%accept_weight_prc ()
    end subroutine event_generate

```

```

    call event%evaluate_transforms (r)
    if (signal_is_pending ()) return
    call event%check ()
end subroutine event_generate

```

Get a copy of the particle set belonging to the hard process.

```

<Events: event: TBP>+≡
  procedure :: get_hard_particle_set => event_get_hard_particle_set

<Events: procedures>+≡
  subroutine event_get_hard_particle_set (event, pset)
    class(event_t), intent(in) :: event
    type(particle_set_t), intent(out) :: pset
    class(evt_t), pointer :: evt
    evt => event%transform_first
    pset = evt%particle_set
  end subroutine event_get_hard_particle_set

```

### 32.10.8 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
  procedure :: select => event_select

<Events: procedures>+≡
  subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
    if (associated (event%instance)) then
      event%selected_i_mci = i_mci
      event%selected_i_term = i_term
      event%selected_channel = channel
    else
      event%selected_i_mci = 0
      event%selected_i_term = 0
      event%selected_channel = 0
    end if
  end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. The event reader may either read in the transformed event separately, or apply all event transforms to the hard particle set to (re)generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
  procedure :: set_hard_particle_set => event_set_hard_particle_set

```

```

<Events: procedures>+≡
subroutine event_set_hard_particle_set (event, particle_set)
  class(event_t), intent(inout) :: event
  type(particle_set_t), intent(in) :: particle_set
  class(evt_t), pointer :: evt
  evt => event%transform_first
  call evt%set_particle_set (particle_set, &
    event%selected_i_mci, event%selected_i_term)
  call event%link_particle_set (evt%particle_set)
  evt => evt%next
  do while (associated (evt))
    call evt%reset ()
    evt => evt%next
  end do
end subroutine event_set_hard_particle_set

```

Set the  $\alpha_s$  value that should be used in a recalculation. This should be called only if we explicitly want to override the QCD setting of the process core.

```

<Events: event: TBP>+≡
  procedure :: set_alpha_qcd_forced => event_set_alpha_qcd_forced

<Events: procedures>+≡
subroutine event_set_alpha_qcd_forced (event, alpha_qcd)
  class(event_t), intent(inout) :: event
  real(default), intent(in) :: alpha_qcd
  if (allocated (event%alpha_qcd_forced)) then
    event%alpha_qcd_forced = alpha_qcd
  else
    allocate (event%alpha_qcd_forced, source = alpha_qcd)
  end if
end subroutine event_set_alpha_qcd_forced

```

Analogously, for the common scale. This forces also renormalization and factorization scale.

```

<Events: event: TBP>+≡
  procedure :: set_scale_forced => event_set_scale_forced

<Events: procedures>+≡
subroutine event_set_scale_forced (event, scale)
  class(event_t), intent(inout) :: event
  real(default), intent(in) :: scale
  if (allocated (event%scale_forced)) then
    event%scale_forced = scale
  else
    allocate (event%scale_forced, source = scale)
  end if
end subroutine event_set_scale_forced

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have a `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

If `recover_phs` is set (and false), do not attempt any phase-space calculation, including MCI evaluation. Useful if we need only matrix elements.

```

<Events: event: TBP>+≡
  procedure :: recalculate => event_recalculate

<Events: procedures>+≡
  subroutine event_recalculate (event, update_sqme, weight_factor, &

## 32.11 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the `events` module which provides the concrete implementation of `event_base`. The other I/O formats access only the methods that are defined in `event_base`.

```

<eio_raw.f90>≡
  <File header>

  module eio_raw

    <Use kinds>
    <Use strings>
    use io_units
    use diagnostics
    use model_data
    use particles
    use event_base
    use event_handles, only: event_handle_t
    use eio_data
    use eio_base
    use events

    <Standard module head>

    <EIO raw: public>

    <EIO raw: parameters>

    <EIO raw: types>

    contains

    <EIO raw: procedures>

  end module eio_raw

```

### 32.11.1 File Format Version

This is the current default file version.

```

<EIO raw: parameters>≡
  integer, parameter :: CURRENT_FILE_VERSION = 2

```

The user may change this number; this should force some compatibility mode for reading and writing. In any case, the file version stored in a event file that we read has to match the expected file version.

History of version numbers:

1. Format for WHIZARD 2.2.0 to 2.2.3. No version number stored in the raw file.
2. Format from 2.2.4 on. File contains version number. The file contains the transformed particle set (if applicable) after the hard-process particle set.

### 32.11.2 Type

Note the file version number. The default may be reset during initialization, which should enforce some compatibility mode.

```

<EIO raw: public>≡

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

The `passed` flag is not written. This allow us to apply different selection criteria upon rereading.

```

Initialize the ISR/EPA handler, depending on active settings.

The activation is independent for both handlers, since only one may be needed at a time. However, if both handlers are active, the current implementation requires the handler modes of ISR and EPA to coincide.

## Chapter 33

# Integration and Simulation

### 33.1 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```
<user_files.f90>≡  
<File header>  
  
module user_files  
  
  <Use strings>  
  use io_units  
  use diagnostics  
  use ifiles  
  use analysis  
  
  <Standard module head>  
  
  <User files: public>  
  
  <User files: types>  
  
  <User files: interfaces>  
  
  contains  
  
  <User files: procedures>  
  
end module user_files
```

#### 33.1.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡
```

```

type :: file_t
  private
  type(string_t) :: name
  integer :: unit = -1
  logical :: reading = .false.
  logical :: writing = .false.
  type(file_t), pointer :: prev => null ()
  type(file_t), pointer :: next => null ()
end type file_t

```

The initializer opens the file.

```

<User files: procedures>≡
subroutine file_init (file, name, action, status, position)
  type(file_t), intent(out) :: file
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position
  file%unit = free_unit ()
  file%name = name
  open (unit = file%unit, file = char (file%name), &
        action = action, status = status, position = position)
  select case (action)
  case ("read")
    file%reading = .true.
  case ("write")
    file%writing = .true.
  case ("readwrite")
    file%reading = .true.
    file%writing = .true.
  end select
end subroutine file_init

```

The finalizer closes it.

```

<User files: procedures>+≡
subroutine file_final (file)
  type(file_t), intent(inout) :: file
  close (unit = file%unit)
  file%unit = -1
end subroutine file_final

```

Check if a file is open with correct status.

```

<User files: procedures>+≡
function file_is_open (file, action) result (flag)
  logical :: flag
  type(file_t), intent(in) :: file
  character(*), intent(in) :: action
  select case (action)
  case ("read")
    flag = file%reading
  case ("write")
    flag = file%writing
  case ("readwrite")
    flag = file%reading .and. file%writing
  end select
end function file_is_open

```

```

        case default
            call msg_bug ("Checking file '" // char (file%name) &
                // "' : illegal action specifier")
        end select
    end function file_is_open

```

Return the unit number of a file for direct access. It should be checked first whether the file is open.

```

<User files: procedures>+≡
    function file_get_unit (file) result (unit)
        integer :: unit
        type(file_t), intent(in) :: file
        unit = file%unit
    end function file_get_unit

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the `advancing` option.

```

<User files: procedures>+≡
    subroutine file_write_string (file, string, advancing)
        type(file_t), intent(in) :: file
        type(string_t), intent(in), optional :: string
        logical, intent(in), optional :: advancing
        if (file%writing) then
            if (present (string)) then
                if (present (advancing)) then
                    if (advancing) then
                        write (file%unit, "(A)") char (string)
                    else
                        write (file%unit, "(A)", advance="no") char (string)
                    end if
                else
                    write (file%unit, "(A)") char (string)
                end if
            else
                write (file%unit, *)
            end if
        else
            call msg_error ("Writing to file: File '" // char (file%name) &
                // "' is not open for writing.")
        end if
    end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
    subroutine file_write_ifile (file, ifile)
        type(file_t), intent(in) :: file
        type(ifile_t), intent(in) :: ifile
        type(line_p) :: line
        call line_init (line, ifile)
        do while (line_is_associated (line))
            call file_write_string (file, line_get_string_advance (line))
        end do
    end subroutine

```

```
end subroutine file_write_ifile
```

Write an analysis object (or all objects) to an open file.

*<User files: procedures>+≡*

```
subroutine file_write_analysis (file, tag)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: tag
  if (file%writing) then
    if (present (tag)) then
      call analysis_write (tag, unit = file%unit)
    else
      call analysis_write (unit = file%unit)
    end if
  else
    call msg_error ("Writing analysis to file: File ' " // char (file%name) &
      // "' is not open for writing.")
  end if
end subroutine file_write_analysis
```

### 33.1.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

*<User files: public>≡*

```
public :: file_list_t
```

*<User files: types>+≡*

```
type :: file_list_t
  type(file_t), pointer :: first => null ()
  type(file_t), pointer :: last => null ()
end type file_list_t
```

There is no initialization routine, but a finalizer which deletes all:

*<User files: public>+≡*

```
public :: file_list_final
```

*<User files: procedures>+≡*

```
subroutine file_list_final (file_list)
  type(file_list_t), intent(inout) :: file_list
  type(file_t), pointer :: current
  do while (associated (file_list%first))
    current => file_list%first
    file_list%first => current%next
    call file_final (current)
    deallocate (current)
  end do
  file_list%last => null ()
end subroutine file_list_final
```

Find an entry in the list. Return null pointer on failure.

```
<User files: procedures>+≡  
function file_list_get_file_ptr (file_list, name) result (current)  
  type(file_t), pointer :: current  
  type(file_list_t), intent(in) :: file_list  
  type(string_t), intent(in) :: name  
  current => file_list%first  
  do while (associated (current))  
    if (current%name == name) return  
    current => current%next  
  end do  
end function file_list_get_file_ptr
```

Check if a file is open, public version:

```
<User files: public>+≡  
public :: file_list_is_open  
  
<User files: procedures>+≡  
function file_list_is_open (file_list, name, action) result (flag)  
  logical :: flag  
  type(file_list_t), intent(in) :: file_list  
  type(string_t), intent(in) :: name  
  character(len=*), intent(in) :: action  
  type(file_t), pointer :: current  
  current => file_list_get_file_ptr (file_list, name)  
  if (associated (current)) then  
    flag = file_is_open (current, action)  
  else  
    flag = .false.  
  end if  
end function file_list_is_open
```

Return the unit number for a file. It should be checked first whether the file is open.

```
<User files: public>+≡

### 33.2.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn, is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

### 33.2.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()
    type(parse_node_t), pointer :: fac_scale_expr => null ()
    type(parse_node_t), pointer :: ren_scale_expr => null ()
    type(parse_node_t), pointer :: weight_expr => null ()
    type(parse_node_t), pointer :: selection_lexpr => null ()
    type(parse_node_t), pointer :: reweight_expr => null ()
    type(parse_node_t), pointer :: analysis_lexpr => null ()
    type(parse_node_p), dimension(:), allocatable :: alt_setup
  contains
    <RT data: rt parse nodes: TBP>
  end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

```

```

<RT data: procedures>≡
subroutine rt_parse_nodes_clear (rt_pn, name)
  class(rt_parse_nodes_t), intent(inout) :: rt_pn
  type(string_t), intent(in) :: name
  select case (char (name))
  case ("cuts")
    rt_pn%cuts_lexpr => null ()
  case ("scale")

```

### 33.2.5 Clear

The `clear` command can remove the contents of various subobjects. The objects themselves should stay.

```

<RT data: rt data: TBP>+≡
    procedure :: clear_beams => rt_data_clear_beams

<RT data: procedures>+≡
    subroutine rt_data_clear_beams (global)
        class(rt_data_t), intent(inout) :: global
        call global%beam_structure%final_sf ()
        call global%beam_structure%final_pol ()
        call global%beam_structure%final_mom ()
    end subroutine rt_data_clear_beams

```

### 33.2.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

```

<RT data: rt data: TBP>+≡
    procedure :: global_init => rt_data_global_init

```

```

<RT data: procedures>+≡
subroutine rt_data_global_init (global, paths, logfile)
  class(rt_data_t), intent(out), target :: global
  type(paths_t), intent(in), optional :: paths
  type(string_t), intent(in), optional :: logfile
  integer :: seed
  call global%os_data%init (paths)
  if (present (logfile)) then
    global%logfile = logfile
  else
    global%logfile = ""
  end if
  allocate (global%out_files)
  call system_clock (seed)
  call global%var_list%init_defaults (seed, paths)
  call global%init_pointer_variables ()
  call global%process_stack%init_var_list (global%var_list)
end subroutine rt_data_global_init

```

### 33.2.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init

<RT data: procedures>+≡
subroutine rt_data_local_init (local, global, env)
  class(rt_data_t), intent(inout), target :: local
  type(rt_data_t), intent(in), target :: global
  integer, intent(in), optional :: env
  local%context => global
  call local%process_stack%link (global%process_stack)
  call local%process_stack%init_var_list (local%var_list)
  call local%process_stack%link_var_list (global%var_list)
  call local%var_list%append_string (var_str ("model_name"), &
    var_str (""), intrinsic=.true.)
  call local%init_pointer_variables ()
  local%fallback_model => global%fallback_model
  local%os_data = global%os_data
  local%logfile = global%logfile
  call local%model_list%link (global%model_list)
  local%model => global%model
  if (associated (local%model)) then
    call local%model%link_var_list (local%var_list)
  end if
  if (allocated (global%event_callback)) then
    allocate (local%event_callback, source = global%event_callback)
  end if

```

```
end subroutine rt_data_local_init
```

These variables point to objects which get local copies:

```
<RT data: rt data: TBP>+≡
  procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: procedures>+≡
  subroutine rt_data_init_pointer_variables (local)
    class(rt_data_t), intent(inout), target :: local
    logical, target, save :: known = .true.
    call local%var_list%append_string_ptr (var_str ("f_c"), &
      local%os_data%f_c, known, intrinsic=.true., &
      description=var_str('This string variable gives the ' // &
        '\ttt{Fortran} compiler used within \whizard. It can ' // &
        'only be accessed, not set by the user. (cf. also ' // &
        '\ttt{\$f_cflags}, \ttt{\$f_clibs}'))
    call local%var_list%append_string_ptr (var_str ("f_cflags"), &
      local%os_data%f_cflags, known, intrinsic=.true., &
      description=var_str('This string variable gives the ' // &
        'compiler flags for the \ttt{Fortran} compiler used ' // &
        'within \whizard. It can only be accessed, not set by ' // &
        'the user. (cf. also \ttt{\$f_c}, \ttt{\$f_clibs}'))
    call local%var_list%append_string_ptr (var_str ("f_clibs"), &
      local%os_data%f_clibs, known, intrinsic=.true., &
      description=var_str('This string variable gives the ' // &
        'linked libraries for the \ttt{Fortran} compiler used ' // &
        'within \whizard. It can only be accessed, not set by ' // &
        'the user. (cf. also \ttt{\$f_c}, \ttt{\$f_cflags}'))
  end subroutine rt_data_init_pointer_variables
```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```
<RT data: rt data: TBP>+≡
  procedure :: activate => rt_data_activate

<RT data: procedures>+≡
  subroutine rt_data_activate (local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), pointer :: global
    global => local%context
    if (associated (global)) then
      local%lexer => global%lexer
      call global%copy_globals (local)
```

```

local%os_data = global%os_data
local%logfile = global%logfile
if (associated (global%prclib)) then
  local%prclib => &
    local%prclib_stack%get_library_ptr (global%prclib%get_name ())
end if
call local%import_values ()
call local%process_stack%link (global%process_stack)
local%it_list = global%it_list
local%beam_structure = global%beam_structure
local%pn = global%pn
if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
if (allocated (global%sample_fmt)) then
  allocate (local%sample_fmt (size (global%sample_fmt)), &
    source = global%sample_fmt)
end if
local%out_files => global%out_files
local%model => global%model
local%model_is_copy = .false.
else if (.not. associated (local%model)) then
  local%model => local%preload_model
  local%model_is_copy = .false.
end if
if (associated (local%model)) then
  call local%model%link_var_list (local%var_list)
  call local%var_list%set_string (var_str (" $model_name"), &
    local%model%get_name (), is_known = .true.)
else
  call local%var_list%set_string (var_str (" $model_name"), &
    var_str (""), is_known = .false.)
end if
end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
  procedure :: deactivate => rt_data_deactivate

<RT data: procedures>+≡
  subroutine rt_data_deactivate (local, global, keep_local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), optional, target :: global
    logical, intent(in), optional :: keep_local
    type(string_t) :: local_model, local_scheme
    logical :: same_model, delete
    delete = .true.; if (present (keep_local)) delete = .not. keep_local
    if (present (global)) then

```

```

if (associated (global%model) .and. associated (local%model)) then
  local_model = local%model%get_name ()
  if (global%model%has_schemes ()) then
    local_scheme = local%model%get_scheme ()
    same_model = &
      global%model%matches (local_model, local_scheme)
  else
    same_model = global%model%matches (local_model)
  end if
else
  same_model = .false.
end if
if (delete) then
  call local%process_stack%clear ()
  call local%unselect_model ()
  call local%unset_values ()
else if (associated (local%model)) then
  call local%ensure_model_copy ()
end if
if (.not. same_model .and. associated (global%model)) then
  if (global%model%has_schemes ()) then
    call msg_message ("Restoring model '" // &
      char (global%model%get_name ()) // "', scheme '" // &
      char (global%model%get_scheme ()) // "'")
  else
    call msg_message ("Restoring model '" // &
      char (global%model%get_name ()) // "'")
  end if
end if
if (associated (global%model)) then
  call global%model%link_var_list (global%var_list)
end if
call global%restore_globals (local)
else
  call local%unselect_model ()
end if
end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
  procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
  subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
    local%prclib_stack = global%prclib_stack
  end subroutine rt_data_copy_globals

```

This restores global objects for which local modifications should be kept. May also modify (remove) the local objects.

```

<RT data: rt data: TBP>+≡

```

```

    procedure :: restore_globals => rt_data_restore_globals
<RT data: procedures>+≡
    subroutine rt_data_restore_globals (global, local)
        class(rt_data_t), intent(inout) :: global
        class(rt_data_t), intent(inout) :: local
        global%prclib_stack = local%prclib_stack
        call local%handle_exports (global)
    end subroutine rt_data_restore_globals

```

### 33.2.8 Exported objects

Exported objects are transferred to the global state when a local environment is closed. (For the top-level global data set, there is no effect.)

The current implementation handles only the **results** object, which resolves to the local process stack. The stack elements are appended to the global stack without modification, the local stack becomes empty.

Write names of objects to be exported:

```

<RT data: rt data: TBP>+≡
    procedure :: write_exports => rt_data_write_exports
<RT data: procedures>+≡
    subroutine rt_data_write_exports (rt_data, unit)
        class(rt_data_t), intent(in) :: rt_data
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        do i = 1, rt_data%get_n_export ()
            write (u, "(A)") char (rt_data%export(i))
        end do
    end subroutine rt_data_write_exports

```

The number of entries in the export list.

```

<RT data: rt data: TBP>+≡
    procedure :: get_n_export => rt_data_get_n_export
<RT data: procedures>+≡
    function rt_data_get_n_export (rt_data) result (n)
        class(rt_data_t), intent(in) :: rt_data
        integer :: n
        if (allocated (rt_data%export)) then
            n = size (rt_data%export)
        else
            n = 0
        end if
    end function rt_data_get_n_export

```

Return a specific export Append new names to the export list. If a duplicate occurs, do not transfer it.

```

<RT data: rt data: TBP>+≡
    procedure :: append_exports => rt_data_append_exports

```

*<RT data: procedures>+≡*

```

subroutine rt_data_append_exports (rt_data, export)
  class(rt_data_t), intent(inout) :: rt_data
  type(string_t), dimension(:), intent(in) :: export
  logical, dimension(:), allocatable :: mask
  type(string_t), dimension(:), allocatable :: tmp
  integer :: i, j, n
  if (.not. allocated (rt_data%export)) allocate (rt_data%export (0))
  n = size (rt_data%export)
  allocate (mask (size (export)), source=.false.)
  do i = 1, size (export)
    mask(i) = all (export(i) /= rt_data%export) &
      .and. all (export(i) /= export(:i-1))
  end do
  if (count (mask) > 0) then
    allocate (tmp (n + count (mask)))
    tmp(1:n) = rt_data%export(:)
    j = n
    do i = 1, size (export)
      if (mask(i)) then
        j = j + 1
        tmp(j) = export(i)
      end if
    end do
    call move_alloc (from=tmp, to=rt_data%export)
  end if
end subroutine rt_data_append_exports

```

Transfer export-objects from the local rt data to the global rt data, as far as supported.

*<RT data: rt data: TBP>+≡*

```

procedure :: handle_exports => rt_data_handle_exports

```

*<RT data: procedures>+≡*

```

subroutine rt_data_handle_exports (local, global)
  class(rt_data_t), intent(inout), target :: local
  class(rt_data_t), intent(inout), target :: global
  type(string_t) :: export
  integer :: i
  if (local%get_n_export () > 0) then
    do i = 1, local%get_n_export ()
      export = local%export(i)
      select case (char (export))
      case ("results")
        call msg_message ("Exporting integration results &
          &to outer environment")
        call local%transfer_process_stack (global)
      case default
        call msg_bug ("handle exports: '" &
          // char (export) // "' unsupported")
      end select
    end do
  end if
end subroutine rt_data_handle_exports

```

Export the process stack. One-by-one, take the last process from the local stack and push it on the global stack. Also handle the corresponding result variables: append if the process did not exist yet in the global stack, otherwise update.

TODO: result variables do not work that way yet, require initialization in the global variable list.

```

<RT data: rt data: TBP>+≡
  procedure :: transfer_process_stack => rt_data_transfer_process_stack

<RT data: procedures>+≡
  subroutine rt_data_transfer_process_stack (local, global)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), target :: global
    type(process_entry_t), pointer :: process
    type(string_t) :: process_id
    do
      call local%process_stack%pop_last (process)
      if (.not. associated (process)) exit
      process_id = process%get_id ()
      call global%process_stack%push (process)
      call global%process_stack%fill_result_vars (process_id)
      call global%process_stack%update_result_vars &
        (process_id, global%var_list)
    end do
  end subroutine rt_data_transfer_process_stack

```

### 33.2.9 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
  procedure :: final => rt_data_global_final

<RT data: procedures>+≡
  subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
    call global%model_list%final ()
    call global%var_list%final (follow_link=.false.)
    if (associated (global%out_files)) then
      call file_list_final (global%out_files)
      deallocate (global%out_files)
    end if
  end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡

```

```

    procedure :: local_final => rt_data_local_final
<RT data: procedures>+≡
    subroutine rt_data_local_final (local)
        class(rt_data_t), intent(inout) :: local
        call local%process_stack%clear ()
        call local%model_list%final ()
        call local%var_list%final (follow_link=.false.)
    end subroutine rt_data_local_final

```

### 33.2.10 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
    procedure :: read_model => rt_data_read_model
<RT data: procedures>+≡
    subroutine rt_data_read_model (global, name, model, scheme)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name
        type(string_t), intent(in), optional :: scheme
        type(model_t), pointer, intent(out) :: model
        type(string_t) :: filename
        filename = name // ".mdl"
        call global%model_list%read_model &
            (name, filename, global%os_data, model, scheme)
    end subroutine rt_data_read_model

```

Read a UFO model. Create it on the fly if necessary.

```

<RT data: rt data: TBP>+≡
    procedure :: read_ufo_model => rt_data_read_ufo_model
<RT data: procedures>+≡
    subroutine rt_data_read_ufo_model (global, name, model, ufo_path)
        class(rt_data_t), intent(inout) :: global
        type(string_t), intent(in) :: name
        type(model_t), pointer, intent(out) :: model
        type(string_t), intent(in), optional :: ufo_path
        type(string_t) :: filename
        filename = name // ".ufo.mdl"
        call global%model_list%read_model &
            (name, filename, global%os_data, model, ufo=.true., ufo_path=ufo_path)
    end subroutine rt_data_read_ufo_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
    procedure :: init_fallback_model => rt_data_init_fallback_model

```

```

<RT data: procedures>+=
subroutine rt_data_init_fallback_model (global, name, filename)
class(rt_data_t), intent(inout) :: global
type(string_t), intent(in) :: name, filename
call global%model_list%read_model &
    (name, filename, global%os_data, global%fallback_model)
end subroutine rt_data_init_fallback_model

```

Activate a model: assign the current-model pointer and set the model name in the variable list. If necessary, read the model from file. Link the global variable list to the model variable list.

```

<RT data: rt data: TBP>+=
procedure :: select_model => rt_data_select_model

<RT data: procedures>+=
subroutine rt_data_select_model (global, name, scheme, ufo, ufo_path)
class(rt_data_t), intent(inout), target :: global
type(string_t), intent(in) :: name
type(string_t), intent(in), optional :: scheme
logical, intent(in), optional :: ufo
type(string_t), intent(in), optional :: ufo_path
logical :: same_model, ufo_model
ufo_model = .false.; if (present (ufo)) ufo_model = ufo
if (associated (global%model)) then
    same_model = global%model%matches (name, scheme, ufo)
else
    same_model = .false.
end if
if (.not. same_model) then
    global%model => global%model_list%get_model_ptr (name, scheme, ufo)
    if (.not. associated (global%model)) then
        if (ufo_model) then
            call global%read_ufo_model (name, global%model, ufo_path)
        else
            call global%read_model (name, global%model)
        end if
        global%model_is_copy = .false.
    else if (associated (global%context)) then
        global%model_is_copy = &
            global%model_list%model_exists (name, scheme, ufo, &
                follow_link=.false.)
    else
        global%model_is_copy = .false.
    end if
end if
if (associated (global%model)) then
    call global%model%link_var_list (global%var_list)
    call global%var_list%set_string (var_str (" $model_name"), &
        name, is_known = .true.)
    if (global%model%is_ufo_model ()) then
        call msg_message ("Switching to model '" // char (name) // "' " &
            // "(generated from UFO source)")
    else if (global%model%has_schemes ()) then
        call msg_message ("Switching to model '" // char (name) // "', " &

```

```

        // "scheme ' " // char (global%model%get_scheme ()) // "'")
    else
        call msg_message ("Switching to model ' " // char (name) // "'")
    end if
else
    call global%var_list%set_string (var_str ("$model_name"), &
        var_str (""), is_known = .false.)
end if
end subroutine rt_data_select_model

```

Remove the model link. Do not unset the model name variable, because this may unset the variable in a parent `rt_data` object (via linked var lists).

```

<RT data: rt_data: TBP>+≡
    procedure :: unselect_model => rt_data_unselect_model

<RT data: procedures>+≡
    subroutine rt_data_unselect_model (global)
        class(rt_data_t), intent(inout), target :: global
        if (associated (global%model)) then
            global%model => null ()
            global%model_is_copy = .false.
        end if
    end subroutine rt_data_unselect_model

```

Create a copy of the currently selected model and append it to the local model list. The model pointer is redirected to the copy. (Not applicable for the global model list, those models will be modified in-place.)

```

<RT data: rt_data: TBP>+≡
    procedure :: ensure_model_copy => rt_data_ensure_model_copy

<RT data: procedures>+≡
    subroutine rt_data_ensure_model_copy (global)
        class(rt_data_t), intent(inout), target :: global
        if (associated (global%context)) then
            if (.not. global%model_is_copy) then
                call global%model_list%append_copy (global%model, global%model)
                global%model_is_copy = .true.
                call global%model%link_var_list (global%var_list)
            end if
        end if
    end subroutine rt_data_ensure_model_copy

```

Modify a model variable. The update mechanism will ensure that the model parameter set remains consistent. This has to take place in a local copy of the current model. If there is none yet, create one.

```

<RT data: rt_data: TBP>+≡
    procedure :: model_set_real => rt_data_model_set_real

<RT data: procedures>+≡
    subroutine rt_data_model_set_real (global, name, rval, verbose, pacified)
        class(rt_data_t), intent(inout), target :: global
        type(string_t), intent(in) :: name
        real(default), intent(in) :: rval

```

```

    logical, intent(in), optional :: verbose, pacified
    call global%ensure_model_copy ()
    call global%model%set_real (name, rval, verbose, pacified)
end subroutine rt_data_model_set_real

```

Modify particle properties. This has to take place in a local copy of the current model. If there is none yet, create one.

```

<RT data: rt data: TBP>+≡
    procedure :: modify_particle => rt_data_modify_particle

<RT data: procedures>+≡

### 33.2.11 Managing Variables

Return a pointer to the currently active variable list. If there is no model, this is the global variable list. If there is one, it is the model variable list, which should be linked to the former.

```

<RT data: rt data: TBP>+≡
    procedure :: get_var_list_ptr => rt_data_get_var_list_ptr

<RT data: procedures>+≡
    function rt_data_get_var_list_ptr (global) result (var_list)
    class(rt_data_t), intent(in), target :: global
    type(var_list_t), pointer :: var_list

```

```

    if (associated (global%model)) then
        var_list => global%model%get_var_list_ptr ()
    else
        var_list => global%var_list
    end if
end function rt_data_get_var_list_ptr

```

Initialize a local variable: append it to the current variable list. No initial value, yet.

```

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```

### 33.3 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

We would like to put this in the `me_methods` folder but it also depends on `gosam` and `openloops`, so it is unclear where to put it.

```
<dispatch_me_methods.f90>≡  
  <File header>  
  
  module dispatch_me_methods  
  
    <Use strings>  
    <Use debug>  
    use physics_defs, only: BORN  
    use diagnostics  
    use sm_qcd  
    use variables, only: var_list_t  
    use models  
    use model_data  
  
    use prc_core_def  
    use prc_core  
    use prc_test_core  
    use prc_template_me  
    use prc_test  
    use prc_omega  
    use prc_external  
    use prc_gosam  
    use prc_openloops  
    use prc_recola  
    use prc_threshold  
  
    <Standard module head>  
  
    <Dispatch me methods: public>  
  
    contains  
  
    <Dispatch me methods: procedures>  
  
  end module dispatch_me_methods
```

#### 33.3.1 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable.

```
<Dispatch me methods: public>≡  
  public :: dispatch_core_def  
  
<Dispatch me methods: procedures>≡  
  subroutine dispatch_core_def (core_def, prt_in, prt_out, &
```

```

### 33.3.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```

(Dispatch me methods: public)+≡
    public :: dispatch_core

(Dispatch me methods: procedures)+≡
    subroutine dispatch_core (core, core_def, model, &
        helicity_selection, qcd, use_color_factors, has_beam_pol)
        class(prc_core_t), allocatable, intent(inout) :: core
        class(prc_core_def_t), intent(in) :: core_def
        class(model_data_t), intent(in), target, optional :: model
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        type(qcd_t), intent(in), optional :: qcd
        logical, intent(in), optional :: use_color_factors
        logical, intent(in), optional :: has_beam_pol
        select type (core_def)
            type is (prc_test_def_t)
                allocate (test_t :: core)
            type is (template_me_def_t)
                allocate (prc_template_me_t :: core)
                select type (core)
                    type is (prc_template_me_t)
                        call core%set_parameters (model)
                    end select
            class is (omega_def_t)
                if (.not. allocated (core)) allocate (prc_omega_t :: core)
                select type (core)
                    type is (prc_omega_t)
                        call core%set_parameters (model, &
                            helicity_selection, qcd, use_color_factors)
                    end select
            type is (gosam_def_t)
                if (.not. allocated (core)) allocate (prc_gosam_t :: core)

            call msg_bug ("Process core: unexpected process definition type")
        end select
    end subroutine dispatch_core

```

### 33.3.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

```

<Dispatch me methods: public>+≡
    public :: dispatch_core_update
    public :: dispatch_core_restore

<Dispatch me methods: procedures>+≡
    subroutine dispatch_core_update &
        (core, model, helicity_selection, qcd, saved_core)

        class(prc_core_t), allocatable, intent(inout) :: core
        class(model_data_t), intent(in), optional, target :: model
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        type(qcd_t), intent(in), optional :: qcd
        class(prc_core_t), allocatable, intent(inout), optional :: saved_core

        if (present (saved_core)) then
            allocate (saved_core, source = core)
        end if
        select type (core)
            type is (test_t)
            type is (prc_omega_t)
                call core%set_parameters (model, helicity_selection, qcd)
                call core%activate_parameters ()
            class is (prc_external_t)
                call msg_message ("Updating user defined cores is not implemented yet.")
            class default
                call msg_bug ("Process core update: unexpected process definition type")
            end select
    end subroutine dispatch_core_update

    subroutine dispatch_core_restore (core, saved_core)

```

```

class(prc_core_t), allocatable, intent(inout) :: core
class(prc_core_t), allocatable, intent(inout) :: saved_core

call move_alloc (from = saved_core, to = core)

## 33.4 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

```
<process_configurations.f90>≡  
  <File header>  
  
  module process_configurations  
  
    <Use strings>  
    <Use debug>  
    use diagnostics  
    use io_units  
    use physics_defs, only: BORN, NLO_VIRTUAL, NLO_REAL, NLO_DGLAP, &  
      NLO_SUBTRACTION, NLO_MISMATCH  
    use models  
    use prc_core_def  
    use particle_specifiers  
    use process_libraries  
    use rt_data  
    use variables, only: var_list_t  
  
    use dispatch_me_methods, only: dispatch_core_def  
    use prc_external, only: prc_external_def_t  
  
    <Standard module head>  
  
    <Process configurations: public>  
  
    <Process configurations: types>  
  
    contains  
  
    <Process configurations: procedures>  
  
  end module process_configurations
```

### 33.4.1 Data Type

```
<Process configurations: public>≡  
  public :: process_configuration_t  
  
<Process configurations: types>≡  
  type :: process_configuration_t  
    type(process_def_entry_t), pointer :: entry => null ()  
    type(string_t) :: id  
    integer :: num_id = 0  
  contains  
    <Process configurations: process configuration: TBP>  
  end type process_configuration_t
```

Output (for unit tests).

```

<Process configurations: process configuration: TBP>≡
  procedure :: write => process_configuration_write

<Process configurations: procedures>≡
  subroutine process_configuration_write (config, unit)
    class(process_configuration_t), intent(in) :: config

    negative_sf = neg_sf, &
    requires_resonances = requires_resonances)
end if
end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

    <Process configurations: execute tests>
    end subroutine process_configurations_test

```

## Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

This is re-exported by the UT module.

```

<Process configurations: public test auxiliary>≡

## 33.5 Compilation

This module manages compilation and loading of process libraries. It is needed as a separate module because integration depends on it.

```
<compilations.f90>≡  
  <File header>  
  
  module compilations  
  
    <Use strings>  
    use io_units  
    use system_defs, only: TAB  
    use system_dependencies, only: OS_IS_DARWIN  
    use diagnostics  
    use os_interface  
    use variables, only: var_list_t  
    use model_data  
    use process_libraries  
    use prclib_stacks  
    use rt_data  
  
    <Standard module head>  
  
    <Compilations: public>  
  
    <Compilations: types>  
  
    <Compilations: parameters>  
  
    contains  
  
    <Compilations: procedures>  
  
  end module compilations
```

### 33.5.1 The data type

The compilation item handles the compilation and loading of a single process library.

```
<Compilations: public>≡  
  public :: compilation_item_t  
  
<Compilations: types>≡  
  type :: compilation_item_t  
  private  
  type(string_t) :: libname  
  type(string_t) :: static_external_tag  
  type(process_library_t), pointer :: lib => null ()  
  logical :: recompile_library = .false.  
  logical :: verbose = .false.  
  logical :: use_workspace = .false.  
  type(string_t) :: workspace  
  contains  
  <Compilations: compilation item: TBP>
```

```
end type compilation_item_t
```

Initialize.

Set flags and global properties of the library. Establish the workspace name, if defined.

*<Compilations: compilation item: TBP>*≡

```
procedure :: init => compilation_item_init
```

*<Compilations: procedures>*≡

```
subroutine compilation_item_init (comp, libname, stack, var_list)
  class(compilation_item_t), intent(out) :: comp
  type(string_t), intent(in) :: libname
  type(prclib_stack_t), intent(inout) :: stack
  type(var_list_t), intent(in) :: var_list
  comp%libname = libname
  comp%lib => stack%get_library_ptr (comp%libname)
  if (.not. associated (comp%lib)) then
    call msg_fatal ("Process library '" // char (comp%libname) &
      // "' has not been declared.")
  end if
  comp%recompile_library = &
    var_list%get_lval (var_str ("?recompile_library"))
  comp%verbose = &
    var_list%get_lval (var_str ("?me_verbose"))
  comp%use_workspace = &
    var_list%is_known (var_str ("$_compile_workspace"))
  if (comp%use_workspace) then
    comp%workspace = &
      var_list%get_sval (var_str ("$_compile_workspace"))
    if (comp%workspace == "") comp%use_workspace = .false.
  else
    comp%workspace = ""
  end if
end subroutine compilation_item_init
```

Compile the current library. The force flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

*<Compilations: compilation item: TBP>*+≡

```
procedure :: compile => compilation_item_compile
```

*<Compilations: procedures>*+≡

```
subroutine compilation_item_compile (comp, model, os_data, force, recompile)
  class(compilation_item_t), intent(inout) :: comp
  class(model_data_t), intent(in), target :: model
  type(os_data_t), intent(in) :: os_data
  logical, intent(in) :: force, recompile
  if (associated (comp%lib)) then
    if (comp%use_workspace) call setup_workspace (comp%workspace, os_data)
    call msg_message ("Process library '" &
      // char (comp%libname) // "': compiling ...")
    call comp%lib%configure (os_data)
    if (signal_is_pending ()) return
```

```

call comp%lib%compute_md5sum (model)
call comp%lib%write_makefile &
    (os_data, force, verbose=comp%verbose, workspace=comp%workspace)
if (signal_is_pending ()) return
if (force) then
    call comp%lib%clean &
        (os_data, distclean = .false., workspace=comp%workspace)
    if (signal_is_pending ()) return
end if
call comp%lib%write_driver (force, workspace=comp%workspace)
if (signal_is_pending ()) return
if (recompile) then
    call comp%lib%load &
        (os_data, keep_old_source = .true., workspace=comp%workspace)
    if (signal_is_pending ()) return
end if
call comp%lib%update_status (os_data, workspace=comp%workspace)
end if
end subroutine compilation_item_compile

```

The workspace directory is created if it does not exist. (Applies only if the use has set the workspace directory.)

*<Compilations: parameters>+≡*

```

character(*), parameter :: ALLOWED_IN_DIRNAME = &
    "abcdefghijklmnopqrstuvwxyz&
    &ABCDEFGHIJKLMNOPQRSTUVWXYZ&
    &1234567890&
    &.,_-= "

```

*<Compilations: procedures>+≡*

```

subroutine setup_workspace (workspace, os_data)
    type(string_t), intent(in) :: workspace
    type(os_data_t), intent(in) :: os_data
    if (verify (workspace, ALLOWED_IN_DIRNAME) == 0) then
        call msg_message ("Compile: preparing workspace directory '" &
            // char (workspace) // "'")
        call os_system_call ("mkdir -p '" // workspace // "'")
    else
        call msg_fatal ("compile: workspace name '" &
            // char (workspace) // "' contains illegal characters")
    end if
end subroutine setup_workspace

```

Load the current library, just after compiling it.

*<Compilations: compilation item: TBP>+≡*

```

procedure :: load => compilation_item_load

```

*<Compilations: procedures>+≡*

```

subroutine compilation_item_load (comp, os_data)
    class(compilation_item_t), intent(inout) :: comp
    type(os_data_t), intent(in) :: os_data
    if (associated (comp%lib)) then
        call comp%lib%load (os_data, workspace=comp%workspace)
    end if

```

```
end subroutine compilation_item_load
```

Message as a separate call:

```
<Compilations: compilation item: TBP>+≡
  procedure :: success => compilation_item_success

<Compilations: procedures>+≡
  subroutine compilation_item_success (comp)
    class(compilation_item_t), intent(in) :: comp
    if (associated (comp%lib)) then
      call msg_message ("Process library '" // char (comp%libname) &
        // "': ... success.")
    else
      call msg_fatal ("Process library '" // char (comp%libname) &
        // "': ... failure.")
    end if
  end subroutine compilation_item_success
```

### 33.5.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```
<Compilations: public>+≡
  public :: compile_library

<Compilations: procedures>+≡
  subroutine compile_library (libname, global)
    type(string_t), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
    type(compilation_item_t) :: comp
    logical :: force, recompile
    force = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    recompile = &
      global%var_list%get_lval (var_str ("?recompile_library"))
    if (associated (global%model)) then
      call comp%init (libname, global%prclib_stack, global%var_list)
      call comp%compile (global%model, global%os_data, force, recompile)
      if (signal_is_pending ()) return
      call comp%load (global%os_data)
      if (signal_is_pending ()) return
    else
      call msg_fatal ("Process library compilation: " &
        // " model is undefined.")
    end if
    call comp%success ()
  end subroutine compile_library
```

### 33.5.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```
<Compilations: public>+≡
    public :: compilation_t
<Compilations: types>+≡
    type :: compilation_t
        private
            type(string_t) :: exe_name
            type(string_t), dimension(:), allocatable :: lib_name
        contains
            <Compilations: compilation: TBP>
        end type compilation_t
```

Output.

```
<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write
<Compilations: procedures>+≡
    subroutine compilation_write (object, unit)
        class(compilation_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Compilation object:"
        write (u, "(3x,3A)") "executable      = '", &
            char (object%exe_name), "'"
        write (u, "(3x,A)", advance="no") "process libraries ="
        do i = 1, size (object%lib_name)
            write (u, "(1x,3A)", advance="no") " '", char (object%lib_name(i)), "'"
        end do
        write (u, *)
    end subroutine compilation_write
```

Initialize: we know the names of the executable and of the libraries. Optionally, we may provide a workspace directory.

```
<Compilations: compilation: TBP>+≡
    procedure :: init => compilation_init
<Compilations: procedures>+≡
    subroutine compilation_init (compilation, exe_name, lib_name)
        class(compilation_t), intent(out) :: compilation
        type(string_t), intent(in) :: exe_name
        type(string_t), dimension(:), intent(in) :: lib_name
        compilation%exe_name = exe_name
        allocate (compilation%lib_name (size (lib_name)))
        compilation%lib_name = lib_name
    end subroutine compilation_init
```

Write the dispatcher subroutine for the compiled libraries. Also write a subroutine which returns the names of the compiled libraries.

```
<Compilations: compilation: TBP>+≡
```

```

procedure :: write_dispatcher => compilation_write_dispatcher
{Compilations: procedures}+=
subroutine compilation_write_dispatcher (compilation)
  class(compilation_t), intent(in) :: compilation
  type(string_t) :: file
  integer :: u, i
  file = compilation%exe_name // "_prclib_dispatcher.f90"
  call msg_message ("Static executable '" // char (compilation%exe_name) &
    // "' : writing library dispatcher")
  u = free_unit ()
  open (u, file = char (file), status="replace", action="write")
  write (u, "(3A)" ) "! Whizard: process libraries for executable '", &
    char (compilation%exe_name), "'"
  write (u, "(A)" ) "! Automatically generated file, do not edit"
  write (u, "(A)" ) "subroutine dispatch_prclib_static " // &
    "(driver, basename, modellibs_ldflags)"
  write (u, "(A)" ) " use iso_varying_string, string_t => varying_string"
  write (u, "(A)" ) " use prclib_interfaces"
  do i = 1, size (compilation%lib_name)
    associate (lib_name => compilation%lib_name(i))
      write (u, "(A)" ) " use " // char (lib_name) // "_driver"
    end associate
  end do
  write (u, "(A)" ) " implicit none"
  write (u, "(A)" ) " class(prclib_driver_t), intent(inout), allocatable &
    &:: driver"

// " -f " // compilation%exe_name // ".makefile")
  end subroutine compilation_make_clean_exe

```

### 33.5.4 API for executable compilation

This is a shorthand for compiling and loading an executable, including the enclosed libraries. The `compilation` object is used only internally.

The global data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
  public :: compile_executable

<Compilations: procedures>+≡
  subroutine compile_executable (exename, libname, global)
    type(string_t), intent(in) :: exename
    type(string_t), dimension(:), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
    type(compilation_t) :: compilation
    type(compilation_item_t) :: item
    type(string_t) :: ext_libtag
    logical :: force, recompile, verbose
    integer :: i
    ext_libtag = ""
    force = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    recompile = &
      global%var_list%get_lval (var_str ("?recompile_library"))
    verbose = &
      global%var_list%get_lval (var_str ("?me_verbose"))
    call compilation%init (exename, [libname])
    if (signal_is_pending ()) return
    call compilation%write_dispatcher ()
    if (signal_is_pending ()) return
    do i = 1, size (libname)
      call item%init (libname(i), global%prclib_stack, global%var_list)
      call item%compile (global%model, global%os_data, &

```

```

        force=force, recompile=recompile)
    ext_libtag = "" // item%lib%get_static_modelname (global%os_data)
    if (signal_is_pending ()) return
    call item%success ()
end do
call compilation%write_makefile &
    (global%os_data, ext_libtag=ext_libtag, verbose=verbose)
if (signal_is_pending ()) return
call compilation%make_compile (global%os_data)
if (signal_is_pending ()) return
call compilation%make_link (global%os_data)
end subroutine compile_executable

```

### 33.5.5 Unit Tests

Test module, followed by the stand-alone unit-test procedures.

`<compilations_ut.f90>`≡

*<File header>*

```

module compilations_ut
  use unit_tests
  use compilations_uti

```

*<Standard module head>*

*<Compilations: public test>*

`contains`

*<Compilations: test driver>*

```

end module compilations_ut

```

`<compilations_uti.f90>`≡

*<File header>*

```

module compilations_uti

```

*<Use strings>*

```

  use io_units
  use models
  use rt_data
  use process_configurations_ut, only: prepare_test_library

```

```

  use compilations

```

*<Standard module head>*

*<Compilations: test declarations>*

`contains`

*<Compilations: tests>*

```
end module compilations_util
```

API: driver for the unit tests below.

```
<Compilations: public test>≡
  public :: compilations_test

<Compilations: test driver>≡
  subroutine compilations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Compilations: execute tests>
  end subroutine compilations_test
```

## Intrinsic Matrix Element

Compile an intrinsic test matrix element (`prc_test` type).

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```
<Compilations: execute tests>≡
  call test (compilations_1, "compilations_1", &
    "intrinsic test processes", &
    u, results)

<Compilations: test declarations>≡
  public :: compilations_1

<Compilations: tests>≡
  subroutine compilations_1 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname
    type(rt_data_t), target :: global

    write (u, "(A)")  "* Test output: compilations_1"
    write (u, "(A)")  "* Purpose: configure and compile test process"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()

    libname = "compilation_1"
    procname = "prc_comp_1"
    call prepare_test_library (global, libname, 1, [procname])

    call compile_library (libname, global)

    call global%write_libraries (u)

    call global%final ()
    call syntax_model_file_final ()

    write (u, "(A)")
```

```

        write (u, "(A)")  "* Test output end: compilations_1"

    end subroutine compilations_1

```

## External Matrix Element

Compile an external test matrix element (omega type)

```

<Compilations: execute tests>+≡
    call test (compilations_2, "compilations_2", &
        "external process (omega)", &
        u, results)

<Compilations: test declarations>+≡
    public :: compilations_2

<Compilations: tests>+≡
    subroutine compilations_2 (u)
        integer, intent(in) :: u
        type(string_t) :: libname, procname
        type(rt_data_t), target :: global

        write (u, "(A)")  "* Test output: compilations_2"
        write (u, "(A)")  "* Purpose: configure and compile test process"
        write (u, "(A)")

        call syntax_model_file_init ()

        call global%global_init ()
        call global%set_log (var_str ("?omega_openmp"), &
            .false., is_known = .true.)

        libname = "compilation_2"
        procname = "prc_comp_2"
        call prepare_test_library (global, libname, 2, [procname,procname])

        call compile_library (libname, global)

        call global%write_libraries (u, libpath = .false.)

        call global%final ()
        call syntax_model_file_final ()

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: compilations_2"

    end subroutine compilations_2

```

## External Matrix Element

Compile an external test matrix element (omega type) and create driver files for a static executable.

```

<Compilations: execute tests>+≡

```

```

call test (compilations_3, "compilations_3", &

```

## External Matrix Element

Compile an external test matrix element ( $\omega$  type) and incorporate this in a new static WHIZARD executable. In this version, we use the wrapper `compile_executable` procedure.

```

<Compilations: static tests>+=
  call test (compilations_static_2, "compilations_static_2", &
    "static executable: shortcut", &
    u, results)

```

```

<Compilations: test declarations>+≡
    public :: compilations_static_2

<Compilations: tests>+≡
    subroutine compilations_static_2 (u)
        integer, intent(in) :: u
        type(string_t) :: libname, procname, exename
        type(rt_data_t), target :: global
        logical :: exist
        integer :: u_file

        write (u, "(A)")  "* Test output: compilations_static_2"
        write (u, "(A)")  "*   Purpose: make static executable"
        write (u, "(A)")

        write (u, "(A)")  "* Initialize library and compile"
        write (u, "(A)")

        call syntax_model_file_init ()

        call global%global_init ()
        call global%set_log (var_str ("?omega_openmp"), &
            .false., is_known = .true.)

        libname = "compilations_static_2_lib"
        procname = "prc_comp_stat_2"
        exename = "compilations_static_2"

        call prepare_test_library (global, libname, 2, [procname,procname])

        call compile_executable (exename, [libname], global)

        write (u, "(A)")  "* Check executable (should be present)"
        write (u, "(A)")

        inquire (file = char (exename), exist = exist)

## 33.6 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

### 33.6.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

<Integrations: public>≡
    public :: integration_t

<Integrations: types>≡
    type :: integration_t
        private
            type(string_t) :: process_id
            type(string_t) :: run_id
            type(process_t), pointer :: process => null ()
            logical :: rebuild_phs = .false.
            logical :: ignore_phs_mismatch = .false.
            logical :: phs_only = .false.
            logical :: process_has_me = .true.
            integer :: n_calls_test = 0
            logical :: vis_history = .true.
            type(string_t) :: history_filename
            type(string_t) :: log_filename
            type(helicity_selection_t) :: helicity_selection
            logical :: use_color_factors = .false.
            logical :: has_beam_pol = .false.
            logical :: combined_integration = .false.
            type(iteration_multipliers_t) :: iteration_multipliers
            type(nlo_settings_t) :: nlo_settings
        contains
            <Integrations: integration: TBP>
    end type integration_t

```

### 33.6.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied.

```

<Integrations: integration: TBP>≡
    procedure :: create_process => integration_create_process

```

```

<Integrations: procedures>≡
subroutine integration_create_process (intg, process_id, global)
  class(integration_t), intent(out) :: intg
  type(rt_data_t), intent(inout), optional, target :: global
  type(string_t), intent(in) :: process_id
  type(process_entry_t), pointer :: process_entry
  if (debug_on) call msg_debug (D_CORE, "integration_create_process")
  intg%process_id = process_id
  if (present (global)) then
    allocate (process_entry)
    intg%process => process_entry%process_t
    call global%process_stack%push (process_entry)
  else
    allocate (process_t :: intg%process)
  end if
end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the local stack directly. The intent(inout) attribute for the local data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

```

<Integrations: integration: TBP>+≡
  procedure :: init_process => integration_init_process

<Integrations: procedures>+≡
subroutine integration_init_process (intg, local)
  class(integration_t), intent(inout) :: intg
  type(rt_data_t), intent(inout), target :: local
  type(string_t) :: model_name
  type(model_t), pointer :: model
  class(model_data_t), pointer :: model_instance
  type(var_list_t), pointer :: var_list
  if (debug_on) call msg_debug (D_CORE, "integration_init_process")
  if (.not. local%prclib%contains (intg%process_id)) then
    call msg_fatal ("Process '" // char (intg%process_id) // "' not found" &
      // " in library '" // char (local%prclib%get_name ()) // "'")
    return
  end if
  model_name = local%prclib%get_model_name (intg%process_id)
  if (local%get_sval (var_str ("$model_name")) == model_name) then
    model => local%model
  else
    model => local%model_list%get_model_ptr (model_name)
  end if

### 33.6.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

<Integrations: integration: TBP>+≡
    procedure :: evaluate => integration_evaluate

<Integrations: procedures>+≡
    subroutine integration_evaluate &
        (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
    integer :: n_calls, n_it
    logical :: adapt_grids, adapt_weights, final
    n_it = it_list%get_n_it (pass)
    n_calls = it_list%get_n_calls (pass)
    adapt_grids = it_list%adapt_grids (pass)
    adapt_weights = it_list%adapt_weights (pass)
    final = pass == it_list%get_n_pass ()
    call process_instance%integrate ( &
        i_mci, n_it, n_calls, adapt_grids, adapt_weights, &

```

```

        final, pacify)
    end subroutine integration_evaluate

```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

```

<Integrations: integration: TBP>+≡
    procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: procedures>+≡
    subroutine integration_make_iterations_list (intg, it_list)
        class(integration_t), intent(in) :: intg
        type(iterations_list_t), intent(out) :: it_list
        integer :: pass, n_pass
        integer, dimension(:), allocatable :: n_it, n_calls
        logical, dimension(:), allocatable :: adapt_grids, adapt_weights
        n_pass = intg%process%get_n_pass_default ()
        allocate (n_it (n_pass), n_calls (n_pass))
        allocate (adapt_grids (n_pass), adapt_weights (n_pass))
        do pass = 1, n_pass
            n_it(pass)      = intg%process%get_n_it_default (pass)
            n_calls(pass)   = intg%process%get_n_calls_default (pass)
            adapt_grids(pass) = intg%process%adapt_grids_default (pass)
            adapt_weights(pass) = intg%process%adapt_weights_default (pass)
        end do
        call it_list%init (n_it, n_calls, &
            adapt_grids = adapt_grids, adapt_weights = adapt_weights)
    end subroutine integration_make_iterations_list

```

In NLO calculations, the individual components might scale very differently with the number of calls. This especially applies to the real-subtracted component, which usually fluctuates more than the Born and virtual component, making it a bottleneck of the calculation. Thus, the calculation is throttled twice, first by the number of calls for the real component, second by the number of surplus calls of computation-intense virtual matrix elements. Therefore, we want to set a different number of calls for each component, which is done by the subroutine `integration.apply.call_multipliers`.

```

<Integrations: integration: TBP>+≡
    procedure :: init_iteration_multipliers => integration_init_iteration_multipliers

<Integrations: procedures>+≡
    subroutine integration_init_iteration_multipliers (intg, local)

### 33.6.4 API for integration objects

This initializer does everything except assigning cuts/scale/weight expressions.

*<Integrations: integration: TBP>+≡*

```

procedure :: init => integration_init

```

*<Integrations: procedures>+≡*

```

subroutine integration_init &
    (intg, process_id, local, global, local_stack, init_only)
    class(integration_t), intent(out) :: intg
    type(string_t), intent(in) :: process_id
    type(rt_data_t), intent(inout), target :: local
    type(rt_data_t), intent(inout), optional, target :: global
    logical, intent(in), optional :: init_only
    logical, intent(in), optional :: local_stack
    logical :: use_local
    use_local = .false.; if (present (local_stack)) use_local = local_stack
    if (present (global)) then
        call intg%create_process (process_id, global)
    else if (use_local) then
        call intg%create_process (process_id, local)
    else
        call intg%create_process (process_id)
    end if
    call intg%init_process (local)
    call intg%setup_process (local, init_only = init_only)
    call intg%init_iteration_multipliers (local)
end subroutine integration_init

```

Do the integration for a single process, both warmup and final evaluation. The `eff_reset` flag is to suppress numerical noise in the graphical output of the integration history.

Return the process pointer (needed by simulate):

```

<Integrations: integration: TBP>+≡
    procedure :: get_process_ptr => integration_get_process_ptr

<Integrations: procedures>+≡
    function integration_get_process_ptr (intg) result (ptr)
        class(integration_t), intent(in) :: intg
        type(process_t), pointer :: ptr
        ptr => intg%process
    end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the `global` environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the `process` object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

```

<Integrations: public>+=
    public :: integrate_process

```

### Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the  $2 \rightarrow 2$  process  $ss \rightarrow ss$  with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (33.1)$$

$c$  is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (33.2)$$

$f$  is the flux of the incoming particles with mass  $m = 125 \text{ GeV}$  and energy  $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (33.3)$$

$\Phi_2$  is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (33.4)$$

The squared matrix element  $|M|^2$  is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (33.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

## Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function  $f(x) = x$  for both beams. Together with the  $1/x_1 x_2$  factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the  $m_s$  mass which we set to zero here.

```

<Integrations: execute tests>+≡

## Integration with sign change

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`. The weight that is applied changes the sign in half of phase space. The weight is  $-3$  and  $1$ , respectively, so the total result is equal to the original, but negative sign.

The efficiency should (approximately) become the average of  $1$  and  $1/3$ , that is  $2/3$ .

```

## 33.7 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
(event_streams.f90)≡  
  <File header>  
  
  module event_streams  
  
    <Use strings>  
    use io_units  
    use diagnostics  
    use events  
    use event_handles, only: event_handle_t  
    use eio_data  
    use eio_base  
    use rt_data  
  
    use dispatch_transforms, only: dispatch_eio  
  
    <Standard module head>  
  
    <Event streams: public>  
  
    <Event streams: types>  
  
    contains  
  
    <Event streams: procedures>  
  
  end module event_streams
```

### 33.7.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡  
  type :: event_stream_entry_t  
    class(eio_t), allocatable :: eio  
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```
<Event streams: public>≡  
  public :: event_stream_array_t  
  
<Event streams: types>+≡  
  type :: event_stream_array_t  
    type(event_stream_entry_t), dimension(:), allocatable :: entry  
    integer :: i_in = 0  
  contains  
    <Event streams: event stream array: TBP>
```

```
end type event_stream_array_t
```

Output.

```
<Event streams: event stream array: TBP>≡
  procedure :: write => event_stream_array_write

<Event streams: procedures>≡
  subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event stream array:"
    if (allocated (object%entry)) then
      select case (size (object%entry))
      case (0)
        write (u, "(3x,A)") "[empty]"
      case default
        do i = 1, size (object%entry)
          if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
          call object%entry(i)%eio%write (u)
        end do
      end select
    else
      write (u, "(3x,A)") "[undefined]"
    end if
  end subroutine event_stream_array_write
```

Check if there is content.

```
<Event streams: event stream array: TBP>+≡
  procedure :: is_valid => event_stream_array_is_valid

<Event streams: procedures>+≡
  function event_stream_array_is_valid (es_array) result (flag)
    class(event_stream_array_t), intent(in) :: es_array
    logical :: flag

    flag = allocated (es_array%entry)

  end function event_stream_array_is_valid
```

Finalize all streams.

```
<Event streams: event stream array: TBP>+≡
  procedure :: final => event_stream_array_final

<Event streams: procedures>+≡
  subroutine event_stream_array_final (es_array)
    class(event_stream_array_t), intent(inout) :: es_array
    integer :: i
    if (allocated (es_array%entry)) then
      do i = 1, size (es_array%entry)
        call es_array%entry(i)%eio%final ()
      end do
    end if
  end subroutine
```

```
end subroutine event_stream_array_final
```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

## 33.8 Restricted Subprocesses

This module provides an automatic means to construct restricted subprocesses of a current process object. A restricted subprocess has the same initial and final state as the current process, but a restricted set of Feynman graphs.

The actual application extracts the set of resonance histories that apply to the process and uses this to construct subprocesses that are restricted to one of those histories, respectively. The resonance histories are derived from the phase-space setup. This implies that the method is tied to the OMeGa matrix element generator and to the wood phase space method.

The processes are collected in a new process library that is generated on-the-fly.

The `resonant_subprocess_t` object is intended as a component of the event record, which manages all operations regarding resonance handling.

The run-time calculations are delegated to an event transform (`evt_resonance_t`), as a part of the event transform chain. The transform selects one (or none) of the resonance histories, given the momentum configuration, computes matrix elements and inserts resonances into the particle set.

    <Restricted subprocesses: procedures>

end module restricted_subprocesses

```

### 33.8.1 Process configuration

We extend the `process_configuration_t` by another method for initialization that takes into account a resonance history.

```

<Restricted subprocesses: public>≡
    public :: restricted_process_configuration_t

<Restricted subprocesses: types>≡
    type, extends (process_configuration_t) :: restricted_process_configuration_t
    private
    contains
    <Restricted subprocesses: restricted process configuration: TBP>
end type restricted_process_configuration_t

```

Resonance history as an argument. We use it to override the `restrictions` setting in a local variable list. Since we can construct the restricted process only by using OMega, we enforce it as the ME method. Other settings are taken from the variable list. The model will most likely be set, but we insert a safeguard just in case.

Also, the resonant subprocess should not itself spawn resonant subprocesses, so we unset `?resonance_history`.

We have to create a local copy of the model here, via pointer allocation. The reason is that the model as stored (via pointer) in the base type will be finalized and deallocated.

The current implementation will generate a LO process, the optional `nlo_process` is unset. (It is not obvious whether the construction makes sense beyond LO.)

```

<Restricted subprocesses: restricted process configuration: TBP>≡
    procedure :: init_resonant_process

<Restricted subprocesses: procedures>≡
    subroutine init_resonant_process &
        (prc_config, prc_name, prt_in, prt_out, res_history, model, var_list)
    class(restricted_process_configuration_t), intent(out) :: prc_config
    type(string_t), intent(in) :: prc_name
    type(prt_spec_t), dimension(:), intent(in) :: prt_in
    type(prt_spec_t), dimension(:), intent(in) :: prt_out
    type(resonance_history_t), intent(in) :: res_history
    type(model_t), intent(in), target :: model
    type(var_list_t), intent(in), target :: var_list
    type(model_t), pointer :: local_model

```

```

type(var_list_t) :: local_var_list

call prc_config%setup_component (1, &
    prt_in, prt_out, &
    local_model, local_var_list)
end subroutine init_resonant_process

```

### 33.8.2 Resonant-subprocess set manager

This data type enables generation of a library of resonant subprocesses for a given master process, and it allows for convenient access. The matrix elements from the subprocesses can be used as channel weights to activate a selector, which then returns a preferred channel via some random number generator.

```

<Restricted subprocesses: public>+≡
    public :: resonant_subprocess_set_t

<Restricted subprocesses: types>+≡
    type :: resonant_subprocess_set_t
    private
    integer, dimension(:), allocatable :: n_history

end if
end subroutine resonant_subprocess_set_write

```

### 33.8.3 Resonance history set

Initialize subprocess set with an array of pre-created resonance history sets.

Safeguard: if there are no resonances in the input, initialize the local set as

empty, but complete.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: init => resonant_subprocess_set_init
  procedure :: fill_resonances => resonant_subprocess_set_fill_resonances

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_init (prc_set, n_component)
    class(resonant_subprocess_set_t), intent(out) :: prc_set
    integer, intent(in) :: n_component
    allocate (prc_set%res_history_set (n_component))
    allocate (prc_set%n_history (n_component), source = 0)
  end subroutine resonant_subprocess_set_init

  subroutine resonant_subprocess_set_fill_resonances (prc_set, &
    res_history_set, i_component)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    type(resonance_history_set_t), intent(in) :: res_history_set
    integer, intent(in) :: i_component
    prc_set%n_history(i_component) = res_history_set%get_n_history ()
    if (prc_set%n_history(i_component) > 0) then
      prc_set%res_history_set(i_component) = res_history_set
    else
      call prc_set%res_history_set(i_component)%init (initial_size = 0)
      call prc_set%res_history_set(i_component)%freeze ()
    end if
  end subroutine resonant_subprocess_set_fill_resonances

```

Return the resonance history set.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: get_resonance_history_set &
    => resonant_subprocess_set_get_resonance_history_set

<Restricted subprocesses: procedures>+≡
  function resonant_subprocess_set_get_resonance_history_set (prc_set) &
    result (res_history_set)
    class(resonant_subprocess_set_t), intent(in) :: prc_set
    type(resonance_history_set_t), dimension(:), allocatable :: res_history_set
    res_history_set = prc_set%res_history_set
  end function resonant_subprocess_set_get_resonance_history_set

```

### 33.8.4 Library for the resonance history set

The recommended library name: append `_R` to the process name.

```

<Restricted subprocesses: public>+≡
  public :: get_libname_res

<Restricted subprocesses: procedures>+≡
  elemental function get_libname_res (proc_id) result (libname)
    type(string_t), intent(in) :: proc_id
    type(string_t) :: libname
    libname = proc_id // "_R"
  end function get_libname_res

```

Here we scan the global process library whether any processes require resonant subprocesses to be constructed. If yes, create process objects with phase space and construct the process libraries as usual. Then append the library names to the array.

The temporary integration objects should carry the `phs_only` flag. We set this in the local environment.

Once a process object with resonance histories (derived from phase space) has been created, we extract the resonance histories and use them, together with the process definition, to create the new library.

Finally, compile the library.

```

<Restricted subprocesses: public>+=
  public :: spawn_resonant_subprocess_libraries

<Restricted subprocesses: procedures>+=
  subroutine spawn_resonant_subprocess_libraries &
    (libname, local, global, libname_res)

### 33.8.5 Process objects and instances

Prepare process objects for all entries in the resonant-subprocesses library. The process objects are appended to the global process stack. A local environment can be used where we place temporary variable settings that affect process-object generation. We initialize the processes, such that we can evaluate matrix elements, but we do not need to integrate them.

The internal procedure `prepare_process` is an abridged version of the procedure with this name in the `simulations` module.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: prepare_process_objects &
    => resonant_subprocess_set_prepare_process_objects

<Restricted subprocesses: procedures>+≡

end subroutine resonant_subprocess_set_prepare_process_instances

```

### 33.8.6 Event transform connection

The idea is that the resonance-insertion event transform has been allocated somewhere (namely, in the standard event-transform chain), but we maintain a link such that we can inject matrix-element results event by event. The event transform holds a selector, to choose one of the resonance histories (or none), and it manages resonance insertion for the particle set.

The data that the event transform requires can be provided here. The resonance history set has already been assigned with the `dispatch` initializer. Here, we supply the set of subprocess instances that we have generated (see above). The master-process instance is set when we `connect` the transform by the standard method.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: connect_transform => &
    resonant_subprocess_set_connect_transform

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_connect_transform (prc_set, evt)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    class(evt_t), intent(in), target :: evt
    select type (evt)
    type is (evt_resonance_t)
      prc_set%evt => evt
      call prc_set%evt%set_subprocess_instances (prc_set%instance)
    class default
      call msg_bug ("Resonant subprocess set: event transform has wrong type")
    end select
  end subroutine resonant_subprocess_set_connect_transform

```

Set the on-shell limit value in the connected transform.

    call prc_set%evt%set_background_factor (background_factor)
  end subroutine resonant_subprocess_set_background_factor

```

### 33.8.7 Wrappers for runtime calculations

All runtime calculations are delegated to the event transform. The following procedures are essentially redundant wrappers. We retain them for a unit test below.

Debugging aid:

```

<Restricted subprocesses: resonant subprocess set: TBP>+=
  procedure :: dump_instances => resonant_subprocess_set_dump_instances

<Restricted subprocesses: procedures>+=
  subroutine resonant_subprocess_set_dump_instances (prc_set, unit, testflag)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: i, n, u
    u = given_output_unit (unit)
    write (u, "(A)")  "*** Process instances of resonant subprocesses"
    write (u, *)
    n = size (prc_set%subprocess)
    do i = 1, n
      associate (instance => prc_set%instance(i)%p)
        call instance%write (u, testflag)
        write (u, *)
        write (u, *)
      end associate
    end do
  end subroutine resonant_subprocess_set_dump_instances

```

Inject the current kinematics configuration, reading from the previous event transform or from the process instance.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: fill_momenta => resonant_subprocess_set_fill_momenta

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_fill_momenta (prc_set)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    integer :: i, n
    call prc_set%evt%fill_momenta ()
  end subroutine resonant_subprocess_set_fill_momenta

```

Determine the indices of the resonance histories that can be considered on-shell for the current kinematics.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: determine_on_shell_histories &
    => resonant_subprocess_set_determine_on_shell_histories

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_determine_on_shell_histories &
    (prc_set, i_component, index_array)
    class(resonant_subprocess_set_t), intent(in) :: prc_set
    integer, intent(in) :: i_component
    integer, dimension(:), allocatable, intent(out) :: index_array
    call prc_set%evt%determine_on_shell_histories (index_array)
  end subroutine resonant_subprocess_set_determine_on_shell_histories

```

Evaluate selected subprocesses. (In actual operation, the ones that have been tagged as on-shell.)

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: evaluate_subprocess &
    => resonant_subprocess_set_evaluate_subprocess

<Restricted subprocesses: procedures>+≡
  subroutine resonant_subprocess_set_evaluate_subprocess (prc_set, index_array)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
    integer, dimension(:), intent(in) :: index_array
    call prc_set%evt%evaluate_subprocess (index_array)
  end subroutine resonant_subprocess_set_evaluate_subprocess

```

Extract the matrix elements of the master process / the resonant subprocesses. After the previous routine has been executed, they should be available and stored in the corresponding process instances.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: get_master_sqme &
    => resonant_subprocess_set_get_master_sqme
  procedure :: get_subprocess_sqme &
    => resonant_subprocess_set_get_subprocess_sqme

<Restricted subprocesses: procedures>+≡
  function resonant_subprocess_set_get_master_sqme (prc_set) result (sqme)
    class(resonant_subprocess_set_t), intent(in) :: prc_set
    real(default) :: sqme

```

```

    sqme = prc_set%evt%get_master_sqme ()
end function resonant_subprocess_set_get_master_sqme

subroutine resonant_subprocess_set_get_subprocess_sqme (prc_set, sqme)
    class(resonant_subprocess_set_t), intent(in) :: prc_set

```

If events have been dropped during simulation of weighted events, issue a message here. If a fraction `n_dropped / n_total` of the events fail the cuts, we keep generating new ones until we have `n_total` events with `weight > 0`. Thus, the total sum of weights will be a fraction of `n_dropped / n_total` too large. However, we do not know how many events will pass or fail the cuts prior to generating them so we leave it to the user to correct for this factor.

  end if
end subroutine counter_show_mean_and_variance
```

Count an event. The weight and event source are optional; by default we assume that the event has been generated and has positive weight.

The optional integer `n_dropped` counts weighted events with weight zero that were encountered while generating the current event, but dropped (because of their zero weight). Accumulating this number allows for renormalizing event weight sums in histograms, after the generation step has been completed.

### 33.9.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

*<Simulations: types>+≡*

```

type :: core_safe_t
  class(prc_core_t), allocatable :: core
end type core_safe_t

```

### 33.9.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. `use_process` implies that the process should already exist as an object in the process stack. If integration is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

*<Simulations: procedures>+≡*

```

subroutine prepare_process &

```

### 33.9.5 Simulation-entry object

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array

is used for selecting a component set (which shares an MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocates the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

For the purpose of NLO events, `entry_t` contains a pointer list to other simulation-entries. This is due to the fact that we have to associate an event for each component of the fixed order simulation, i.e. one  $N$ -particle event and  $N_{\text{phs}}$   $N + 1$ -particle events. However, all entries share the same event transforms.

```

<Simulations: types>+≡
  type, extends (event_t) :: entry_t

## Simulation-entry initialization

Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the `process_instance` pointer. Assign data by looking at the process object and at the environment.

If `n_alt` is set, we prepare for additional alternate sqme and weight entries.

The `compile` flag is only false if we do not need the Whizard process at all, just its definition. In that case, we skip process initialization.

Otherwise, and if the process object is not found initially: if `integrate` is set, attempt an integration pass and try again. Otherwise, just initialize the

object.

If **generate** is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

If **resonance\_history** is set, we create a separate process library which contains all possible restricted subprocesses with distinct resonance histories. These processes will not be integrated, but their matrix element codes are used for determining probabilities of resonance histories. Note that this can work only if the process method is OMega, and the phase-space method is 'wood'.

When done, we assign the **instance** and **process** pointers of the base type by the **connect** method, so we can reference them later.

TODO: In case of NLO event generation, copying the configuration from the master process is rather intransparent. For instance, we override the process var list by the global var list.

## Event-transform initialization

Part of simulation-entry initialization: dispatch event transforms (decay, shower) as requested. If a transform is not applicable or switched off via some variable, it will be skipped.

Regarding resonances/decays: these two transforms are currently mutually exclusive. Resonance insertion will not be applied if there is an unstable particle in the game.

The initial particle set is the output of the trivial transform; this has already been applied when the transforms listed here are encountered. Each transform takes a particle set and produces a new one, with one exception: the decay module takes its input from the process object, ignoring the trivial transform. (Reason: spin correlations.) Therefore, the decay module must be first in line.

Settings that we don't or can't support (yet) are rejected by the embedded call to `event_transforms_check`.

```

  if (i_mci > 0) then
    call entry%mc_i_sets(i_mci)%counter%record (weight, excess)
  end if
end subroutine entry_record
```

Update and restore the process core that this entry accesses, when parameters change. If explicit arguments `model`, `qcd`, or `helicity_selection` are provided, use those. Otherwise use the parameters stored in the process object.

These two procedures come with a caching mechanism which guarantees that the current core object is saved when calling `update_process`, and restored by calling `restore_process`. If the flag `saved` is unset, saving is skipped, and the `restore` procedure should not be called.

*<Simulations: entry: TBP>+≡*

### 33.9.6 Handling resonant subprocesses

Resonant subprocesses are required if we want to determine resonance histories when generating events. The feature is optional, to be switched on by the user.

This procedure initializes a new, separate process library that contains copies of the current process, restricted to the relevant resonance histories. (If this library exists already, it is just kept.) The histories can be extracted from the process object.

The code has to match the assignments in `create_resonant_subprocess_library`. The library may already exist – in that case, here it will be recovered without recompilation.

```

<Simulations: entry: TBP>+≡
    procedure :: setup_resonant_subprocesses &
        => entry_setup_resonant_subprocesses

<Simulations: procedures>+≡
    subroutine entry_setup_resonant_subprocesses (entry, global, process)
        class(entry_t), intent(inout) :: entry

                    (i_component, &
                     process_component_def%get_prt_spec_in (), &
                     process_component_def%get_prt_spec_out (), &

```

```

                                global)
        end if
    end do
    call entry%resonant_subprocess_set%freeze_library (global)
end if
end subroutine entry_setup_resonant_subprocesses

```

Compile the resonant-subprocesses library. The library is assumed to be the current library in the `global` object. This is a simple wrapper.

```

⟨Simulations: entry: TBP⟩+≡
    procedure :: compile_resonant_subprocesses &
        => entry_compile_resonant_subprocesses

⟨Simulations: procedures⟩+≡
    subroutine entry_compile_resonant_subprocesses (entry, global)
        class(entry_t), intent(inout) :: entry
        type(rt_data_t), intent(inout), target :: global
        call entry%resonant_subprocess_set%compile_library (global)
    end subroutine entry_compile_resonant_subprocesses

```

Prepare process objects for the resonant-subprocesses library. The process objects are appended to the global process stack. We initialize the processes, such that we can evaluate matrix elements, but we do not need to integrate them.

```

⟨Simulations: entry: TBP⟩+≡
    procedure :: prepare_resonant_subprocesses &
        => entry_prepare_resonant_subprocesses

⟨Simulations: procedures⟩+≡
    subroutine entry_prepare_resonant_subprocesses (entry, local, global)
        class(entry_t), intent(inout) :: entry
        type(rt_data_t), intent(inout), target :: local
        type(rt_data_t), intent(inout), optional, target :: global
        call entry%resonant_subprocess_set%prepare_process_objects (local, global)
    end subroutine entry_prepare_resonant_subprocesses

```

Prepare process instances. They are linked to their corresponding process objects. Both, process and instance objects, are allocated as anonymous targets inside the `resonant_subprocess_set` component.

NOTE: those anonymous object are likely forgotten during finalization of the parent `event_t` (extended as `entry_t`) object. This should be checked! The memory leak is probably harmless as long as the event object is created once per run, not once per event.

```

⟨Simulations: entry: TBP⟩+≡
    procedure :: prepare_resonant_subprocess_instances &
        => entry_prepare_resonant_subprocess_instances

⟨Simulations: procedures⟩+≡

### 33.9.7 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
  type, extends (entry_t) :: alt_entry_t
  contains
    <Simulations: alt entry: TBP>
  end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

<Simulations: alt entry: TBP>≡
  procedure :: init_alt => alt_entry_init

<Simulations: procedures>+≡
  subroutine alt_entry_init (entry, process_id, master_process, local)
    class(alt_entry_t), intent(inout), target :: entry

### Simulation-object initialization

We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If `integrate` is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If `integrate` is unset, we do not need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If `generate` is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

  end do

```

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the luminosity setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the luminosity, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

```

    class(simulation_t), intent(in) :: simulation
    integer :: n

    n = simulation%n_evt_requested

  end function simulation_get_n_events_requested

```

Generate the number of events that has been set by `simulation_set_n_events_requested`. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

The `begin_it` and `end_it` limits are equal to 1 and the number of events, respectively, in serial mode, but differ for MPI mode.

TODO: When reading from file, event transforms cannot be applied because the process instance will not be complete. (?)

```

<Simulations: simulation: TBP>+≡
  procedure :: generate => simulation_generate

<Simulations: procedures>+≡
  subroutine simulation_generate (simulation, es_array)
    class(simulation_t), intent(inout), target :: simulation

do i = begin_it, end_it
  call simulation%next_event (es_array)
end do
call simulation%after_last_event (begin_it, end_it)

end subroutine simulation_generate

```

The header of the event loop: with all necessary information present in the `simulation` and `es_array` objects, and given a number of events `n` to generate, we prepare for actually generating/reading/writing events.

The procedure returns the real iteration bounds `begin_it` and `end_it` for the event loop. This is nontrivial only for MPI; in serial mode those are equal to 1 and to `n_events`, respectively.

```

## Alternate environments

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

```

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

```

## Rescan-Events Loop

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

## Event index

Here we handle the event index that is kept in the simulation record. The event index is valid for the current sample. When generating or reading events, we initialize the index with the offset that the user provides (if any) and increment it for each event that is generated or read from file. The event index is stored in the event-entry that is current for the event. If an event on file comes with its own index, that index overwrites the predefined one and also resets the index within the simulation record.

The event index is not connected to the `counter` object. The counter is supposed to collect statistical information. The event index is a user-level object that is visible in event records and analysis expressions.

*(Simulations: simulation: TBP)+≡*

```

procedure :: init_event_index => simulation_init_event_index
procedure :: increment_event_index => simulation_increment_event_index
procedure :: set_event_index => simulation_set_event_index
procedure :: get_event_index => simulation_get_event_index

```

*(Simulations: procedures)+≡*

```

    i = simulation%event_index
  else
    i = 0
  end if
end function simulation_get_event_index

```

### 33.9.9 Direct event access

If we want to retrieve event information, we should expose the currently selected event **entry** within the simulation object. We recall that this is an extension of the (generic) **event** type. Assuming that we will restrict this to read access, we return a pointer.

```

<Simulations: simulation: TBP>+≡
  procedure :: get_process_index => simulation_get_process_index
  procedure :: get_event_ptr => simulation_get_event_ptr

<Simulations: procedures>+≡
  function simulation_get_process_index (simulation) result (i_prc)
    class(simulation_t), intent(in), target :: simulation
    integer :: i_prc

    i_prc = simulation%i_prc

  end function simulation_get_process_index

  function simulation_get_event_ptr (simulation) result (event)
    class(simulation_t), intent(in), target :: simulation
    class(event_t), pointer :: event

    event => simulation%entry(simulation%i_prc)

```

```
end function simulation_get_event_ptr
```

### 33.9.10 Event Stream I/O

Write an event to a generic `eio` event stream. The process index must be selected, or the current index must be available.

```
<Simulations: simulation: TBP>+≡
generic :: write_event => write_event_eio
procedure :: write_event_eio => simulation_write_event_eio

<Simulations: procedures>+≡
subroutine simulation_write_event_eio (object, eio, i_prc)
  class(simulation_t), intent(in) :: object
  class(eio_t), intent(inout) :: eio
  integer, intent(in), optional :: i_prc
  logical :: increased
  integer :: current
  if (present (i_prc)) then
    current = i_prc
  else
    current = object%i_prc
  end if
  if (current > 0) then
    if (object%split_n_evt > 0 .and. object%counter%total > 1) then
      if (mod (object%counter%total, object%split_n_evt) == 1) then
        call eio%split_out ()
      end if
    else if (object%split_n_kbytes > 0) then
      call eio%update_split_count (increased)
      if (increased) call eio%split_out ()
    end if
    call eio%output (object%entry(current)%event_t, current, pacify = object%pacify)
  else
    call msg_fatal ("Simulation: write event: no process selected")
  end if
end subroutine simulation_write_event_eio
```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```
<Simulations: simulation: TBP>+≡
generic :: read_event => read_event_eio
procedure :: read_event_eio => simulation_read_event_eio

<Simulations: procedures>+≡
subroutine simulation_read_event_eio (object, eio)
  class(simulation_t), intent(inout) :: object
  class(eio_t), intent(inout) :: eio
```

```

integer :: iostat, current
call eio%input_i_prc (current, iostat)
select case (iostat)
case (0)
    object%i_prc = current
    call eio%input_event (object%entry(current)%event_t, iostat)
end select
select case (iostat)
case (:-1)
    object%i_prc = 0
    object%i_mci = 0
case (1:)
    call msg_error ("Reading events: I/O error, aborting read")
    object%i_prc = 0
    object%i_mci = 0
case default
    object%i_mci = object%entry(current)%get_i_mci ()
end select
end subroutine simulation_read_event_eio

```

### 33.9.11 Event Stream Array

Write an event using an array of event I/O streams. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+=
generic :: write_event => write_event_es_array
procedure :: write_event_es_array => simulation_write_event_es_array

<Simulations: procedures>+=
subroutine simulation_write_event_es_array &
    (object, es_array, passed, event_handle)
class(simulation_t), intent(in), target :: object
class(event_stream_array_t), intent(inout) :: es_array
logical, intent(in), optional :: passed
class(event_handle_t), intent(inout), optional :: event_handle
integer :: i_prc, event_index
integer :: i
type(entry_t), pointer :: current_entry
i_prc = object%i_prc
if (i_prc > 0) then
    event_index = object%counter%total
    current_entry => object%entry(i_prc)%get_first ()
    do i = 1, current_entry%count_nlo_entries ()
        if (i > 1) current_entry => current_entry%get_next ()
        call es_array%output (current_entry%event_t, i_prc, &
            event_index, &
            passed = passed, &
            pacify = object%pacify, &
            event_handle = event_handle)
    end do
else
    call msg_fatal ("Simulation: write event: no process selected")
end if

```

```
end subroutine simulation_write_event_es_array
```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

```
(Simulations: simulation: TBP)+≡
```

```
generic :: read_event => read_event_es_array
```

```
procedure :: read_event_es_array => simulation_read_event_es_array
```

```
(Simulations: procedures)+≡
```

```

end select
else
  fail = .true.
end if
end subroutine simulation_read_event_es_array

```

### 33.9.12 Recover event

Recalculate the process instance contents, given an event with known particle set. The indices for MC, term, and channel must be already set. The `recalculate` method of the selected entry will import the result into `sqme_prc` and `weight_prc`.

If `recover_phs` is set (and false), do not attempt any phase-space calculation. Useful if we need only matrix elements (esp. testing); this flag is not stored in the simulation record.

```

<Simulations: simulation: TBP>+=
  procedure :: recalculate => simulation_recalculate

<Simulations: procedures>+=
  subroutine simulation_recalculate (simulation, recover_phs, check_match)
    class(simulation_t), intent(inout) :: simulation

  integer, intent(in) :: i
  character(32) :: md5sum
  md5sum = simulation%md5sum_alt(i)
end function simulation_get_md5sum_alt

```

Return data that may be useful for writing event files.

Usually we can refer to a previously integrated process, for which we can fetch a process pointer. Occasionally, we do not have this because we are just rescanning an externally generated file without calculation. For that situation, we generate our local beam data object using the current environment, or, in simple cases, just fetch the necessary data from the process definition and environment.

```

## Chapter 34

# More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in init/final hooks that we can set at runtime.)

### 34.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
(expr_tests_ut.f90)≡
  <File header>
  module expr_tests_ut

    use unit_tests
    use expr_tests_util

    <Standard module head>

    <Expr tests: public test>

    contains

    <Expr tests: test driver>

  end module expr_tests_ut
(expr_tests_util.f90)≡
  <File header>

  module expr_tests_util

    <Use kinds>
    <Use strings>
    use format_defs, only: FMT_12
    use format_utils, only: write_separator
```

```

    use os_interface
    use sm_qcd
    use lorentz
    use ifiles
    use lexers
    use parser
    use model_data
    use interactions, only: reset_interaction_counter
    use process_libraries
    use subevents
    use subvt_expr
    use rng_base
    use mci_base
    use phs_base
    use variables, only: var_list_t
    use eval_trees
    use models
    use prc_core
    use prc_test
    use process, only: process_t
    use instances, only: process_instance_t
    use events

    use rng_base_ut, only: rng_test_factory_t
    use phs_base_ut, only: phs_test_config_t

    <Standard module head>

    <Expr tests: test declarations>

contains

    <Expr tests: tests>

    <Expr tests: test auxiliary>

end module expr_tests_util

```

### 34.1.1 Test

This is the master for calling self-test procedures.

```

    <Expr tests: public test>≡
        public :: subvt_expr_test

    <Expr tests: test driver>≡
        subroutine subvt_expr_test (u, results)
            integer, intent(in) :: u
            type(test_results_t), intent(inout) :: results
            <Expr tests: execute tests>
        end subroutine subvt_expr_test

```

## Parton-event expressions

```
<Expr tests: execute tests>≡

## Chapter 35

# Top Level

The top level consists of

**commands** Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

**whizard** This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

**main** The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

**whizard\_c\_interface** Alternative top-level procedures, for use in the context of a C-compatible caller program.

## 35.1 Commands

This module defines the command language of the main input file.

```
<commands.f90>≡

end module commands

```

### 35.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```

<Commands: types>≡
    type, abstract :: command_t
        type(parse_node_t), pointer :: pn => null ()
        class(command_t), pointer :: next => null ()
        type(parse_node_t), pointer :: pn_opt => null ()
        type(command_list_t), pointer :: options => null ()
        type(rt_data_t), pointer :: local => null ()
    contains
    <Commands: command: TBP>
end type command_t

```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```

<Commands: command: TBP>≡
    procedure :: final => command_final

<Commands: procedures>≡
    recursive subroutine command_final (cmd)
        class(command_t), intent(inout) :: cmd
        if (associated (cmd%options)) then
            call cmd%options%final ()
            deallocate (cmd%options)
        end if
    end subroutine command_final

```

```

end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

<Commands: command: TBP>+≡
    procedure (command_write), deferred :: write
<Commands: interfaces>≡
    abstract interface
        subroutine command_write (cmd, unit, indent)
            import
            class(command_t), intent(in) :: cmd
            integer, intent(in), optional :: unit, indent
        end subroutine command_write
    end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

<Commands: command: TBP>+≡
    procedure (command_compile), deferred :: compile
<Commands: interfaces>+≡
    abstract interface
        subroutine command_compile (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_compile
    end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

<Commands: command: TBP>+≡
    procedure (command_execute), deferred :: execute
<Commands: interfaces>+≡
    abstract interface
        subroutine command_execute (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global

```

```

        end subroutine command_execute
    end interface

```

### 35.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```

<Commands: command: TBP>+≡
    procedure :: write_options => command_write_options

<Commands: procedures>+≡
    recursive subroutine command_write_options (cmd, unit, indent)
        class(command_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: ind
        ind = 1; if (present (indent)) ind = indent + 1
        if (associated (cmd%options)) call cmd%options%write (unit, ind)
    end subroutine command_write_options

```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```

<Commands: command: TBP>+≡
    procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
    recursive subroutine command_compile_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%pn_opt)) then
            allocate (cmd%local)
            call cmd%local%local_init (global)
            call global%copy_globals (cmd%local)
            allocate (cmd%options)
            call cmd%options%compile (cmd%pn_opt, cmd%local)
            call global%restore_globals (cmd%local)
            call cmd%local%deactivate ()
        else
            cmd%local => global
        end if
    end subroutine command_compile_options

```

Execute options. First prepare the local environment, then execute the command list.

```

<Commands: command: TBP>+≡
    procedure :: execute_options => cmd_execute_options

```

```

⟨Commands: procedures⟩+≡
recursive subroutine cmd_execute_options (cmd, global)
  class(command_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  if (associated (cmd%options)) then
    call cmd%local%activate ()
    call cmd%options%execute (cmd%local)
  end if
end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

⟨Commands: command: TBP⟩+≡
  procedure :: reset_options => cmd_reset_options

⟨Commands: procedures⟩+≡
subroutine cmd_reset_options (cmd, global)
  class(command_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  if (associated (cmd%options)) then
    call cmd%local%deactivate (global)
  end if
end subroutine cmd_reset_options

```

### 35.1.3 Specific command types

#### Model configuration

The command declares a model, looks for the specified file and loads it.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_model_t
  private
  type(string_t) :: name
  type(string_t) :: scheme
  logical :: ufo_model = .false.
  logical :: ufo_path_set = .false.
  type(string_t) :: ufo_path
  contains
  ⟨Commands: cmd model: TBP⟩
end type cmd_model_t

```

#### Output

```

⟨Commands: cmd model: TBP⟩≡
  procedure :: write => cmd_model_write

⟨Commands: procedures⟩+≡
subroutine cmd_model_write (cmd, unit, indent)
  class(cmd_model_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return

```

```

call write_indent (u, indent)
write (u, "(1x,A,1x,'"',A,'\"')", advance="no") "model =", char (cmd%name)
if (cmd%ufo_model) then
  if (cmd%ufo_path_set) then
    write (u, "(1x,A,A,A)") "(ufo (", char (cmd%ufo_path), ")")
  else
    write (u, "(1x,A)") "(ufo)"
  end if
else if (cmd%scheme /= "") then
  write (u, "(1x,'(,A,')')") char (cmd%scheme)
else
  write (u, *)
end if
end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed. If the model has a scheme argument, take this into account.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

*(Commands: cmd model: TBP)+≡*

    if (associated (lib) .and. .not. rebuild_library) then
      call lib%update_status (global%os_data)
    end if
  end subroutine cmd_library_execute

```

## Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_process_t
  private
  type(string_t) :: id
  integer :: n_in = 0
  type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
  type(parse_node_t), pointer :: pn_out => null ()
  contains
  ⟨Commands: cmd process: TBP⟩
end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

⟨Commands: cmd process: TBP⟩≡
  procedure :: write => cmd_process_write

⟨Commands: procedures⟩+≡
  subroutine cmd_process_write (cmd, unit, indent)
    class(cmd_process_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)") "process: ", char (cmd%id), " (", &
      size (cmd%pn_pdg_in), " -> X)"
    call cmd%write_options (u, indent)
  end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

⟨Commands: cmd process: TBP⟩+≡
  procedure :: compile => cmd_process_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_process_compile (cmd, global)
    class(cmd_process_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_id, pn_in, pn_codes
    integer :: i
    pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_in => parse_node_get_next_ptr (pn_id, 2)
    cmd%pn_out => parse_node_get_next_ptr (pn_in, 2)
    cmd%pn_opt => parse_node_get_next_ptr (cmd%pn_out)
    call cmd%compile_options (global)
    cmd%id = parse_node_get_string (pn_id)

```

```

cmd%n_in = parse_node_get_n_sub (pn_in)
pn_codes => parse_node_get_sub_ptr (pn_in)
allocate (cmd%pn_pdg_in (cmd%n_in))
do i = 1, cmd%n_in
    cmd%pn_pdg_in(i)%ptr => pn_codes
    pn_codes => parse_node_get_next_ptr (pn_codes)
end do
end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

There are two possibilities that a process contains more than one component: by an explicit component statement by the user for inclusive processes, or by having one process at NLO level. The first option is determined in the chunk `scan components`, and determines `n_components`.

```

Command execution. Generate code, write driver, compile and link. Do this for all libraries in the list.

If no library names have been given and stored while compiling this command, we collect all libraries from the current stack and compile those.

As a bonus, a compiled library may be able to spawn new process libraries. For instance, a processes may ask for a set of resonant subprocesses which go into their own library, but this can be determined only after the process is

available as a compiled object. Therefore, the compilation loop is implemented as a recursive internal subroutine.

We can compile static libraries (which actually just loads them). However, we can't incorporate in a generated executable.

```

```

## Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process

object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

## SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_slha_t
    private
    type(string_t) :: file
    logical :: write_mode = .false.
  contains
    <Commands: cmd slha: TBP>
  end type cmd_slha_t
```

Output.

```
<Commands: cmd slha: TBP>≡
  procedure :: write => cmd_slha_write

<Commands: procedures>+≡
  subroutine cmd_slha_write (cmd, unit, indent)
    class(cmd_slha_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "slha: file name = ", char (cmd%file)
    write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
  end subroutine cmd_slha_write
```

Compile. Read the filename and store it.

```
<Commands: cmd slha: TBP>+≡
  procedure :: compile => cmd_slha_compile

<Commands: procedures>+≡
  subroutine cmd_slha_compile (cmd, global)
    class(cmd_slha_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_key, pn_arg, pn_file
    pn_key => parse_node_get_sub_ptr (cmd%pn)
    pn_arg => parse_node_get_next_ptr (pn_key)
    pn_file => parse_node_get_sub_ptr (pn_arg)
    call cmd%compile_options (global)
    cmd%pn_opt => parse_node_get_next_ptr (pn_arg)
    select case (char (parse_node_get_key (pn_key)))
    case ("read_slha")
      cmd%write_mode = .false.
    case ("write_slha")
      cmd%write_mode = .true.
    case default
```

```

        call parse_node_mismatch ("read_slha|write_slha", cmd%pn)
    end select
    cmd%file = parse_node_get_string (pn_file)
end subroutine cmd_slha_compile

```

Execute. Read or write the specified SLHA file. Behind the scenes, this will first read the WHIZARD model file, then read the SLHA file and assign the SLHA parameters as far as determined by `dispatch_slha`. Finally, the global variables are synchronized with the model. This is similar to executing `cmd_model`.

```

                 input = input, spectrum = spectrum, decays = decays)
        end if
    end subroutine cmd_slha_execute

```

## Show values

This command shows the current values of variables or other objects, in a suitably condensed form.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_show_t
        private
        type(string_t), dimension(:), allocatable :: name
    contains
    ⟨Commands: cmd show: TBP⟩

```

```
end type cmd_show_t
```

Output: list the object names, not values.

*<Commands: cmd show: TBP>*≡

```
procedure :: write => cmd_show_write
```

*<Commands: procedures>*+≡

```
subroutine cmd_show_write (cmd, unit, indent)
  class(cmd_show_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u, i
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A)", advance="no") "show: "
  if (allocated (cmd%name)) then
    do i = 1, size (cmd%name)
      write (u, "(1x,A)", advance="no") char (cmd%name(i))
    end do
    write (u, *)
  else
    write (u, "(5x,A)") "[undefined]"
  end if
end subroutine cmd_show_write
```

Compile. Allocate an array which is filled with the names of the variables to show.

## Clear values

This command clears the current values of variables or other objects, where this makes sense. It parallels the `show` command. The objects are cleared, but not deleted.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_clear_t
private
type(string_t), dimension(:), allocatable :: name
contains
<Commands: cmd clear: TBP>
end type cmd_clear_t

```

Output: list the names of the objects to be cleared.

```

<Commands: cmd clear: TBP>≡
procedure :: write => cmd_clear_write

<Commands: procedures>+≡
subroutine cmd_clear_write (cmd, unit, indent)
class(cmd_clear_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u, i
u = given_output_unit (unit); if (u < 0) return

## Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_expect_t
        private
        type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
        <Commands: cmd expect: TBP>
    end type cmd_expect_t

```

Simply tell the status.

```

<Commands: cmd expect: TBP>≡
    procedure :: write => cmd_expect_write

<Commands: procedures>+≡
    subroutine cmd_expect_write (cmd, unit, indent)
        class(cmd_expect_t), intent(in) :: cmd
    end subroutine

```

```

integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
if (associated (cmd%pn_lexpr)) then
    write (u, "(1x,A)") "expect: [expression associated]"
else
    write (u, "(1x,A)") "expect: [undefined]"
end if
end subroutine cmd_expect_write

```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

```

⟨Commands: cmd expect: TBP⟩+≡
    procedure :: compile => cmd_expect_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_expect_compile (cmd, global)
        class(cmd_expect_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_arg
        pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)

## Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

⟨Commands: types⟩+≡
  type :: sentry_expr_t
    type(parse_node_p), dimension(:), allocatable :: expr
  contains
    ⟨Commands: sentry expr: TBP⟩
  end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

⟨Commands: sentry expr: TBP⟩≡
  procedure :: compile => sentry_expr_compile

```

*<Commands: procedures>+≡*

```

subroutine sentry_expr_compile (sentry, pn)
  class(sentry_expr_t), intent(out) :: sentry
  type(parse_node_t), intent(in), target :: pn
  type(parse_node_t), pointer :: pn_expr, pn_extra
  integer :: n_expr, i
  n_expr = parse_node_get_n_sub (pn)
  allocate (sentry%expr (n_expr))
  if (n_expr > 0) then
    i = 0
    pn_expr => parse_node_get_sub_ptr (pn)
    pn_extra => parse_node_get_next_ptr (pn_expr)
    do i = 1, n_expr
      sentry%expr(i)%ptr => pn_expr
      if (associated (pn_extra)) then
        pn_expr => parse_node_get_sub_ptr (pn_extra, 2)
        pn_extra => parse_node_get_next_ptr (pn_extra)
      end if
    end do
  end if
end subroutine sentry_expr_compile

```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

*<Commands: sentry expr: TBP>+≡*

```

procedure :: evaluate => sentry_expr_evaluate

```

*<Commands: procedures>+≡*

```

subroutine sentry_expr_evaluate (sentry, index, value, global)
  class(sentry_expr_t), intent(inout) :: sentry
  integer, dimension(:), intent(out) :: index
  complex(default), intent(out) :: value
  type(rt_data_t), intent(in), target :: global
  type(var_list_t), pointer :: var_list

        end do
    end subroutine smatrix_expr_evaluate

```

## Beam polarization density

The beam polarization command defines spin density matrix for one or two beams (scattering or decay).

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_beams_pol_density_t
        private
        integer :: n_in = 0
        type(smatrix_expr_t), dimension(:), allocatable :: smatrix
    contains
        ⟨Commands: cmd beams pol density: TBP⟩
    end type cmd_beams_pol_density_t

```

Output.

```

⟨Commands: cmd beams pol density: TBP⟩≡
    procedure :: write => cmd_beams_pol_density_write

⟨Commands: procedures⟩+≡
    subroutine cmd_beams_pol_density_write (cmd, unit, indent)
        class(cmd_beams_pol_density_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        select case (cmd%n_in)
        case (1)
            write (u, "(1x,A)") "beams polarization setup: 1 [decay]"
        case (2)
            write (u, "(1x,A)") "beams polarization setup: 2 [scattering]"
        case default
            write (u, "(1x,A)") "beams polarization setup: [undefined]"
        end select
    end subroutine

```

```
end subroutine cmd_beams_pol_density_write
```

Compile. Find and assign the parse nodes.

Note: local environments are not yet supported.

*(Commands: cmd beams pol density: TBP)+≡*

```
procedure :: compile => cmd_beams_pol_density_compile
```

*(Commands: procedures)+≡*

```
subroutine cmd_beams_pol_density_compile (cmd, global)
  class(cmd_beams_pol_density_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_pol_spec, pn_smatrix
  integer :: i
  pn_pol_spec => parse_node_get_sub_ptr (cmd%pn, 3)
  call cmd%compile_options (global)
  cmd%n_in = parse_node_get_n_sub (pn_pol_spec)
  allocate (cmd%smatrix (cmd%n_in))
  pn_smatrix => parse_node_get_sub_ptr (pn_pol_spec)
  do i = 1, cmd%n_in
    call cmd%smatrix(i)%compile (pn_smatrix)
    pn_smatrix => parse_node_get_next_ptr (pn_smatrix)
  end do
end subroutine cmd_beams_pol_density_compile
```

Command execution: Fill polarization density matrices. No check yet, the matrices are checked and normalized when the actual beam object is created, just before integration. For intermediate storage, we use the `beam_structure` object in the `global` data set.

*(Commands: cmd beams pol density: TBP)+≡*

```
procedure :: execute => cmd_beams_pol_density_execute
```

*(Commands: procedures)+≡*

```
subroutine cmd_beams_pol_density_execute (cmd, global)
  class(cmd_beams_pol_density_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(smatrix_t) :: smatrix
  integer :: i
  call global%beam_structure%init_pol (cmd%n_in)
  do i = 1, cmd%n_in
    call cmd%smatrix(i)%evaluate (smatrix, global)
    call global%beam_structure%set_smatrix (i, smatrix)
  end do
end subroutine cmd_beams_pol_density_execute
```

## Beam polarization fraction

In addition to the polarization density matrix, we can independently specify the polarization fraction for one or both beams.

*(Commands: types)+≡*

```
type, extends (command_t) :: cmd_beams_pol_fraction_t
private
integer :: n_in = 0
```

```

        type(parse_node_p), dimension(:), allocatable :: expr
contains
  <Commands: cmd beams pol fraction: TBP>
end type cmd_beams_pol_fraction_t

```

Output.

```

<Commands: cmd beams pol fraction: TBP>≡
  procedure :: write => cmd_beams_pol_fraction_write

<Commands: procedures>+≡
  subroutine cmd_beams_pol_fraction_write (cmd, unit, indent)
    class(cmd_beams_pol_fraction_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    select case (cmd%n_in)
    case (1)
      write (u, "(1x,A)") "beams polarization fraction: 1 [decay]"
    case (2)
      write (u, "(1x,A)") "beams polarization fraction: 2 [scattering]"
    case default
      write (u, "(1x,A)") "beams polarization fraction: [undefined]"
    end select
  end subroutine cmd_beams_pol_fraction_write

```

Compile. Find and assign the parse nodes.

Note: local environments are not yet supported.

```

<Commands: cmd beams pol fraction: TBP>+≡
  procedure :: compile => cmd_beams_pol_fraction_compile

<Commands: procedures>+≡
  subroutine cmd_beams_pol_fraction_compile (cmd, global)
    class(cmd_beams_pol_fraction_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_frac_spec, pn_expr
    integer :: i
    pn_frac_spec => parse_node_get_sub_ptr (cmd%pn, 3)
    call cmd%compile_options (global)
    cmd%n_in = parse_node_get_n_sub (pn_frac_spec)
    allocate (cmd%expr (cmd%n_in))
    pn_expr => parse_node_get_sub_ptr (pn_frac_spec)
    do i = 1, cmd%n_in
      cmd%expr(i)%ptr => pn_expr
      pn_expr => parse_node_get_next_ptr (pn_expr)
    end do
  end subroutine cmd_beams_pol_fraction_compile

```

Command execution: Retrieve the numerical values of the beam polarization fractions. The results are stored in the `beam_structure` component of the `global` data block.

```

<Commands: cmd beams pol fraction: TBP>+≡
  procedure :: execute => cmd_beams_pol_fraction_execute

```

```

<Commands: procedures>+≡
subroutine cmd_beams_pol_fraction_execute (cmd, global)
  class(cmd_beams_pol_fraction_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  real(default), dimension(:), allocatable :: pol_f
  type(eval_tree_t) :: expr
  integer :: i
  var_list => global%get_var_list_ptr ()
  allocate (pol_f (cmd%n_in))
  do i = 1, cmd%n_in
    call expr%init_expr (cmd%expr(i)%ptr, var_list)
    call expr%evaluate ()
    if (expr%is_known ()) then
      pol_f(i) = expr%get_real ()
    else

    end if
    call expr%final ()
  end do
  call global%beam_structure%set_pol_f (pol_f)
end subroutine cmd_beams_pol_fraction_execute

```

## Beam momentum

This is completely analogous to the previous command, hence we can use inheritance.

```

<Commands: types>+≡
type, extends (cmd_beams_pol_fraction_t) :: cmd_beams_momentum_t
contains
  <Commands: cmd beams momentum: TBP>
end type cmd_beams_momentum_t

```

Output.

```

<Commands: cmd beams momentum: TBP>≡
procedure :: write => cmd_beams_momentum_write

<Commands: procedures>+≡
subroutine cmd_beams_momentum_write (cmd, unit, indent)
  class(cmd_beams_momentum_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  select case (cmd%n_in)
  case (1)
    write (u, "(1x,A)") "beams momentum: 1 [decay]"
  case (2)
    write (u, "(1x,A)") "beams momentum: 2 [scattering]"
  case default
    write (u, "(1x,A)") "beams momentum: [undefined]"
  end select

```

```
end subroutine cmd_beams_momentum_write
```

Compile: inherited.

Command execution: Not inherited, but just the error string and the final command are changed.

*<Commands: cmd beams momentum: TBP>+≡*

```
procedure :: execute => cmd_beams_momentum_execute
```

*<Commands: procedures>+≡*

```
subroutine cmd_beams_momentum_execute (cmd, global)
  class(cmd_beams_momentum_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  real(default), dimension(:), allocatable :: p
  type(eval_tree_t) :: expr
  integer :: i
  var_list => global%get_var_list_ptr ()
  allocate (p (cmd%n_in))
  do i = 1, cmd%n_in
    call expr%init_expr (cmd%expr(i)%ptr, var_list)
    call expr%evaluate ()
    if (expr%is_known ()) then
      p(i) = expr%get_real ()
    else
      call msg_fatal ("beams momentum: undefined value")
    end if
    call expr%final ()
  end do
  call global%beam_structure%set_momentum (p)
end subroutine cmd_beams_momentum_execute
```

## Beam angles

Again, this is analogous. There are two angles, polar angle  $\theta$  and azimuthal angle  $\phi$ , which can be set independently for both beams.

*<Commands: types>+≡*

```
type, extends (cmd_beams_pol_fraction_t) :: cmd_beams_theta_t
contains
  <Commands: cmd beams theta: TBP>
end type cmd_beams_theta_t
```

```
type, extends (cmd_beams_pol_fraction_t) :: cmd_beams_phi_t
contains
  <Commands: cmd beams phi: TBP>
end type cmd_beams_phi_t
```

Output.

*<Commands: cmd beams theta: TBP>≡*

```
procedure :: write => cmd_beams_theta_write
```

*<Commands: cmd beams phi: TBP>≡*

```
procedure :: write => cmd_beams_phi_write
```

```

<Commands: procedures>+≡
subroutine cmd_beams_theta_write (cmd, unit, indent)

    allocate (phi (cmd%n_in))
    do i = 1, cmd%n_in
        call expr%init_expr (cmd%expr(i)%ptr, var_list)
        call expr%evaluate ()
        if (expr%is_known ()) then
            phi(i) = expr%get_real ()
        else
            call msg_fatal ("beams phi: undefined value")
        end if
        call expr%final ()
    end do
    call global%beam_structure%set_phi (phi)
end subroutine cmd_beams_phi_execute

```

## Cuts

Define a cut expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the cut expression is used.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_cuts_t
    private
        type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
        <Commands: cmd cuts: TBP>
    end type cmd_cuts_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```

<Commands: cmd cuts: TBP>≡
    procedure :: write => cmd_cuts_write

```

```

<Commands: procedures>+≡
  subroutine cmd_cuts_write (cmd, unit, indent)
    class(cmd_cuts_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "cuts: [defined]"
  end subroutine cmd_cuts_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd cuts: TBP>+≡
  procedure :: compile => cmd_cuts_compile

<Commands: procedures>+≡
  subroutine cmd_cuts_compile (cmd, global)
    class(cmd_cuts_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_cuts_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd cuts: TBP>+≡
  procedure :: execute => cmd_cuts_execute

<Commands: procedures>+≡
  subroutine cmd_cuts_execute (cmd, global)
    class(cmd_cuts_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%cuts_lexpr => cmd%pn_lexpr
  end subroutine cmd_cuts_execute

```

## General, Factorization and Renormalization Scales

Define a scale expression for either the renormalization or the factorization scale. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd scale: TBP>
  end type cmd_scale_t

```

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_fac_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()

```

```

contains
  <Commands: cmd fac scale: TBP>
end type cmd_fac_scale_t

```

```

<Commands: types>+≡
type, extends (command_t) :: cmd_ren_scale_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd ren scale: TBP>
  end type cmd_ren_scale_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd scale: TBP>≡
  procedure :: write => cmd_scale_write

<Commands: procedures>+≡
  subroutine cmd_scale_write (cmd, unit, indent)
    class(cmd_scale_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "scale: [defined]"
  end subroutine cmd_scale_write

<Commands: cmd fac scale: TBP>≡
  procedure :: write => cmd_fac_scale_write

<Commands: procedures>+≡
  subroutine cmd_fac_scale_write (cmd, unit, indent)
    class(cmd_fac_scale_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "factorization scale: [defined]"
  end subroutine cmd_fac_scale_write

    global%pn%ren_scale_expr => cmd%pn_expr
  end subroutine cmd_ren_scale_execute

```

## Weight

Define a weight expression. The weight is applied to a process to be integrated, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

<Commands: types>+=
  type, extends (command_t) :: cmd_weight_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd weight: TBP>
  end type cmd_weight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd weight: TBP>=
  procedure :: write => cmd_weight_write

<Commands: procedures>+=
  subroutine cmd_weight_write (cmd, unit, indent)
    class(cmd_weight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "weight expression: [defined]"
  end subroutine cmd_weight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd weight: TBP>+=
  procedure :: compile => cmd_weight_compile

<Commands: procedures>+=
  subroutine cmd_weight_compile (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_weight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd weight: TBP>+≡
  procedure :: execute => cmd_weight_execute

<Commands: procedures>+≡
  subroutine cmd_weight_execute (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%weight_expr => cmd%pn_expr
  end subroutine cmd_weight_execute

```

## Selection

Define a selection expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_selection_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()
  contains
  <Commands: cmd selection: TBP>
  end type cmd_selection_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd selection: TBP>≡
  procedure :: write => cmd_selection_write

<Commands: procedures>+≡
  subroutine cmd_selection_write (cmd, unit, indent)
    class(cmd_selection_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "selection expression: [defined]"
  end subroutine cmd_selection_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd selection: TBP>+≡
  procedure :: compile => cmd_selection_compile

<Commands: procedures>+≡
  subroutine cmd_selection_compile (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_selection_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd selection: TBP⟩+≡
  procedure :: execute => cmd_selection_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

## Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_reweight_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()
  contains
  ⟨Commands: cmd reweight: TBP⟩
end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

⟨Commands: cmd reweight: TBP⟩≡
  procedure :: write => cmd_reweight_write

⟨Commands: procedures⟩+≡
  subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd reweight: TBP⟩+≡
  procedure :: compile => cmd_reweight_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd reweight: TBP⟩+≡
    procedure :: execute => cmd_reweight_execute

⟨Commands: procedures⟩+≡
    subroutine cmd_reweight_execute (cmd, global)
        class(cmd_reweight_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        global%pn%reweight_expr => cmd%pn_expr
    end subroutine cmd_reweight_execute

```

## Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_alt_setup_t
        private
        type(parse_node_p), dimension(:), allocatable :: setup
    contains
        ⟨Commands: cmd alt setup: TBP⟩
    end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

⟨Commands: cmd alt setup: TBP⟩≡
    procedure :: write => cmd_alt_setup_write

⟨Commands: procedures⟩+≡
    subroutine cmd_alt_setup_write (cmd, unit, indent)
        class(cmd_alt_setup_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
    end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

⟨Commands: cmd alt setup: TBP⟩+≡
    procedure :: compile => cmd_alt_setup_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_alt_setup_compile (cmd, global)
        class(cmd_alt_setup_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_list, pn_setup
        integer :: i
        pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
        if (associated (pn_list)) then

```

```

        allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
        i = 1
        pn_setup => parse_node_get_sub_ptr (pn_list)
        do while (associated (pn_setup))
            cmd%setup(i)%ptr => pn_setup
            i = i + 1
            pn_setup => parse_node_get_next_ptr (pn_setup)
        end do
    else
        allocate (cmd%setup (0))
    end if
end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

<Commands: cmd alt setup: TBP>+≡
    procedure :: execute => cmd_alt_setup_execute

<Commands: procedures>+≡
    subroutine cmd_alt_setup_execute (cmd, global)
        class(cmd_alt_setup_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (allocated (global%pn%alt_setup)) deallocate (global%pn%alt_setup)
        allocate (global%pn%alt_setup (size (cmd%setup)))
        global%pn%alt_setup = cmd%setup
    end subroutine cmd_alt_setup_execute

```

## Integration

Integrate several processes, consecutively with identical parameters.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_integrate_t
    private
    integer :: n_proc = 0
    type(string_t), dimension(:), allocatable :: process_id
    contains
    <Commands: cmd integrate: TBP>
end type cmd_integrate_t

```

Output: we know the process IDs.

```

<Commands: cmd integrate: TBP>≡
    procedure :: write => cmd_integrate_write

<Commands: procedures>+≡
    subroutine cmd_integrate_write (cmd, unit, indent)
        class(cmd_integrate_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u, i
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)", advance="no") "integrate ("
        do i = 1, cmd%n_proc
            if (i > 1) write (u, "(A,1x)", advance="no") ", "

```

```

        write (u, "(A)", advance="no") char (cmd%process_id(i))
    end do
    write (u, "(A)" )"
end subroutine cmd_integrate_write

```

Compile.

```

⟨Commands: cmd integrate: TBP⟩+≡
    procedure :: compile => cmd_integrate_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_integrate_compile (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_proclist, pn_proc
        integer :: i
        pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
        cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
        call cmd%compile_options (global)
        cmd%n_proc = parse_node_get_n_sub (pn_proclist)
        allocate (cmd%process_id (cmd%n_proc))
        pn_proc => parse_node_get_sub_ptr (pn_proclist)
        do i = 1, cmd%n_proc
            cmd%process_id(i) = parse_node_get_string (pn_proc)
            call global%process_stack%init_result_vars (cmd%process_id(i))
            pn_proc => parse_node_get_next_ptr (pn_proc)
        end do
    end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

⟨Commands: cmd integrate: TBP⟩+≡
    procedure :: execute => cmd_integrate_execute

⟨Commands: procedures⟩+≡
    subroutine cmd_integrate_execute (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        integer :: i
        if (debug_on) call msg_debug (D_CORE, "cmd_integrate_execute")
        do i = 1, cmd%n_proc
            if (debug_on) call msg_debug (D_CORE, "cmd%process_id(i) ", cmd%process_id(i))
            call integrate_process (cmd%process_id(i), cmd%local, global)
            call global%process_stack%fill_result_vars (cmd%process_id(i))
            call global%process_stack%update_result_vars &
                (cmd%process_id(i), global%var_list)
        end do
    end subroutine cmd_integrate_execute

```

```

        if (signal_is_pending ()) return
    end do
end subroutine cmd_integrate_execute

```

## Observables

Declare an observable. After the declaration, it can be used to record data, and at the end one can retrieve average and error.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_observable_t
    private
        type(string_t) :: id
    contains
        ⟨Commands: cmd observable: TBP⟩
    end type cmd_observable_t

```

Output. We know the ID.

```

⟨Commands: cmd observable: TBP⟩≡
    procedure :: write => cmd_observable_write

⟨Commands: procedures⟩+≡
    subroutine cmd_observable_write (cmd, unit, indent)
        class(cmd_observable_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A)") "observable: ", char (cmd%id)
    end subroutine cmd_observable_write

```

Compile. Just record the observable ID.

```

⟨Commands: cmd observable: TBP⟩+≡
    procedure :: compile => cmd_observable_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_observable_compile (cmd, global)
        class(cmd_observable_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_tag
        pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
        if (associated (pn_tag)) then
            cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
        end if
        call cmd%compile_options (global)
        select case (char (parse_node_get_rule_key (pn_tag)))
        case ("analysis_id")
            cmd%id = parse_node_get_string (pn_tag)
        case default
            call msg_bug ("observable: name expression not implemented (yet)")
        end select
    end subroutine cmd_observable_compile

```

Command execution. This declares the observable and allocates it in the analysis store.

```

⟨Commands: cmd observable: TBP⟩+≡
    procedure :: execute => cmd_observable_execute
⟨Commands: procedures⟩+≡
    subroutine cmd_observable_execute (cmd, global)
        class(cmd_observable_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(var_list_t), pointer :: var_list

        type(string_t) :: label, unit
        var_list => cmd%local%get_var_list_ptr ()
        label = var_list%get_sval (var_str ("obs_label"))
        unit = var_list%get_sval (var_str ("obs_unit"))
        call graph_options_init (graph_options)
        call set_graph_options (graph_options, var_list)
        call analysis_init_observable (cmd%id, label, unit, graph_options)
    end subroutine cmd_observable_execute

```

## Histograms

Declare a histogram. At minimum, we have to set lower and upper bound and bin width.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_histogram_t
        private
        type(string_t) :: id
        type(parse_node_t), pointer :: pn_lower_bound => null ()
        type(parse_node_t), pointer :: pn_upper_bound => null ()
        type(parse_node_t), pointer :: pn_bin_width => null ()
        contains
        ⟨Commands: cmd histogram: TBP⟩
    end type cmd_histogram_t

```

Output. Just print the ID.

```

⟨Commands: cmd histogram: TBP⟩≡
    procedure :: write => cmd_histogram_write
⟨Commands: procedures⟩+≡
    subroutine cmd_histogram_write (cmd, unit, indent)
        class(cmd_histogram_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,A)") "histogram: ", char (cmd%id)
    end subroutine cmd_histogram_write

```

Compile. Record the histogram ID and initialize lower, upper bound and bin width.

```

⟨Commands: cmd histogram: TBP⟩+≡
    procedure :: compile => cmd_histogram_compile

```

```

{Commands: procedures}+≡
subroutine cmd_histogram_compile (cmd, global)
  class(cmd_histogram_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global

    end if
end subroutine set_drawing_options

```

## Plots

Declare a plot. No mandatory arguments, just options.

*(Commands: types)+≡*

```

type, extends (command_t) :: cmd_plot_t
private
type(string_t) :: id

```

```

contains
  <Commands: cmd plot: TBP>
end type cmd_plot_t

```

Output. Just print the ID.

```

<Commands: cmd plot: TBP>≡
  procedure :: write => cmd_plot_write
<Commands: procedures>+≡
  subroutine cmd_plot_write (cmd, unit, indent)
    class(cmd_plot_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "plot: ", char (cmd%id)
  end subroutine cmd_plot_write

```

Compile. Record the plot ID and initialize lower, upper bound and bin width.

```

<Commands: cmd plot: TBP>+≡
  procedure :: compile => cmd_plot_compile
<Commands: procedures>+≡
  subroutine cmd_plot_compile (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_tag
    pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%init (pn_tag, global)
  end subroutine cmd_plot_compile

```

This init routine is separated because it is reused below for graph initialization.

```

<Commands: cmd plot: TBP>+≡
  procedure :: init => cmd_plot_init
<Commands: procedures>+≡
  subroutine cmd_plot_init (plot, pn_tag, global)
    class(cmd_plot_t), intent(inout) :: plot
    type(parse_node_t), intent(in), pointer :: pn_tag
    type(rt_data_t), intent(inout), target :: global
    call plot%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      plot%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("plot: name expression not implemented (yet)")
    end select
  end subroutine cmd_plot_init

```

Command execution. This declares the plot and allocates it in the analysis store.

```

<Commands: cmd plot: TBP>+≡
  procedure :: execute => cmd_plot_execute

```

```

<Commands: procedures>+≡
subroutine cmd_plot_execute (cmd, global)
  class(cmd_plot_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  type(graph_options_t) :: graph_options
  type(drawing_options_t) :: drawing_options

  var_list => cmd%local%get_var_list_ptr ()
  call graph_options_init (graph_options)
  call set_graph_options (graph_options, var_list)
  call drawing_options_init_plot (drawing_options)
  call set_drawing_options (drawing_options, var_list)

  call analysis_init_plot (cmd%id, graph_options, drawing_options)
end subroutine cmd_plot_execute

```

## Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_graph_t
  private
  type(string_t) :: id
  integer :: n_elements = 0
  type(cmd_plot_t), dimension(:), allocatable :: el
  type(string_t), dimension(:), allocatable :: element_id
  contains
  <Commands: cmd graph: TBP>
end type cmd_graph_t

```

Output. Just print the ID.

```

<Commands: cmd graph: TBP>≡
procedure :: write => cmd_graph_write

<Commands: procedures>+≡
subroutine cmd_graph_write (cmd, unit, indent)
  class(cmd_graph_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u

  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,A,A,I0,A)" "graph: ", char (cmd%id), &
    " (" , cmd%n_elements, " entries)"
end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: compile => cmd_graph_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_compile (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
    integer :: i

    pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      cmd%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("graph: name expression not implemented (yet)")
    end select
    pn_def => parse_node_get_next_ptr (pn_term, 2)
    cmd%n_elements = parse_node_get_n_sub (pn_def)
    allocate (cmd%element_id (cmd%n_elements))
    allocate (cmd%el (cmd%n_elements))
    pn_term => parse_node_get_sub_ptr (pn_def)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%el(1)%init (pn_tag, global)
    cmd%element_id(1) = parse_node_get_string (pn_tag)
    pn_app => parse_node_get_next_ptr (pn_term)
    do i = 2, cmd%n_elements
      pn_term => parse_node_get_sub_ptr (pn_app, 2)
      pn_tag => parse_node_get_sub_ptr (pn_term)
      cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
      call cmd%el(i)%init (pn_tag, global)
      cmd%element_id(i) = parse_node_get_string (pn_tag)
      pn_app => parse_node_get_next_ptr (pn_app)
    end do

  end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: execute => cmd_graph_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_execute (cmd, global)

```

```

class(cmd_graph_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(var_list_t), pointer :: var_list
type(graph_options_t) :: graph_options
type(drawing_options_t) :: drawing_options
integer :: i, type

var_list => cmd%local%get_var_list_ptr ()
call graph_options_init (graph_options)
call set_graph_options (graph_options, var_list)
call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

do i = 1, cmd%n_elements
  if (associated (cmd%el(i)%options)) then
    call cmd%el(i)%options%execute (cmd%el(i)%local)
  end if
  type = analysis_store_get_object_type (cmd%element_id(i))
  select case (type)
  case (AN_HISTOGRAM)
    call drawing_options_init_histogram (drawing_options)
  case (AN_PLOT)
    call drawing_options_init_plot (drawing_options)
  end select
  call set_drawing_options (drawing_options, var_list)
  if (associated (cmd%el(i)%options)) then
    call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
  end if
  call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
end do
end subroutine cmd_graph_execute

```

## Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
  type :: analysis_id_t
  type(string_t) :: tag
  type(parse_node_t), pointer :: pn_sexpr => null ()
end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_analysis_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  ⟨Commands: cmd analysis: TBP⟩
end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

⟨Commands: cmd analysis: TBP⟩≡
  procedure :: write => cmd_analysis_write

⟨Commands: procedures⟩+≡
  subroutine cmd_analysis_write (cmd, unit, indent)
    class(cmd_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "analysis: [defined]"
  end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd analysis: TBP⟩+≡
  procedure :: compile => cmd_analysis_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd analysis: TBP⟩+≡
  procedure :: execute => cmd_analysis_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_analysis_execute (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%analysis_lexpr => cmd%pn_lexpr
  end subroutine cmd_analysis_execute

```

## Write histograms and plots

The data type encapsulating the command:

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_write_analysis_t
  private
  type(analysis_id_t), dimension(:), allocatable :: id
  type(string_t), dimension(:), allocatable :: tag
  contains
  ⟨Commands: cmd write analysis: TBP⟩
  end type cmd_write_analysis_t

```

Output. Just the keyword.

```

⟨Commands: cmd write analysis: TBP⟩≡
  procedure :: write => cmd_write_analysis_write

```

```

<Commands: procedures>+≡
subroutine cmd_write_analysis_write (cmd, unit, indent)
  class(cmd_write_analysis_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A)") "write_analysis"
end subroutine cmd_write_analysis_write

```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: compile => cmd_write_analysis_compile

<Commands: procedures>+≡
subroutine cmd_write_analysis_compile (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
  integer :: n, i
  pn_clause => parse_node_get_sub_ptr (cmd%pn)
  pn_args => parse_node_get_sub_ptr (pn_clause, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
  call cmd%compile_options (global)
  if (associated (pn_args)) then
    n = parse_node_get_n_sub (pn_args)
    allocate (cmd%id (n))
    do i = 1, n
      pn_id => parse_node_get_sub_ptr (pn_args, i)
      if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
        cmd%id(i)%tag = parse_node_get_string (pn_id)
      else
        cmd%id(i)%pn_sexpr => pn_id
      end if
    end do
  else
    allocate (cmd%id (0))
  end if
end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

<Commands: parameters>+≡
character(*), parameter, public :: &
  DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
  FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(6), parameter, public :: &
  FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "pg", "lo", "la" ]
character(len=3), dimension(18), parameter, public :: &
  FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
    "f95", "log", "ltp", "mpx", "olc", "olp", "pdf", "phs", "sin", &
    "tex", "vg2", "vgx" ]

```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: execute => cmd_write_analysis_execute

<Commands: procedures>+≡
  subroutine cmd_write_analysis_execute (cmd, global)
    class(cmd_write_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    var_list => cmd%local%get_var_list_ptr ()
    call write_analysis_wrap (var_list, global%out_files, &
      cmd%id, tag = cmd%tag)
  end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

```

<Commands: procedures>+≡
  subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
    type(var_list_t), intent(inout), target :: var_list
    type(file_list_t), intent(inout), target :: out_files
    type(analysis_id_t), dimension(:), intent(in), target :: id
    type(string_t), dimension(:), allocatable, intent(out) :: tag
    type(string_t), intent(out), optional :: data_file
    type(string_t) :: defaultfile, file
    integer :: i
    logical :: keep_open
    type(string_t) :: extension
    logical :: one_file
    defaultfile = var_list%get_sval (var_str ("out_file"))
    if (present (data_file)) then

## Compile analysis results

This command writes files in a form suitable for GAMELAN and executes the appropriate commands to compile them. The first part is identical to `cmd_write_analysis`.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_compile_analysis_t
    private
    type(analysis_id_t), dimension(:), allocatable :: id
    type(string_t), dimension(:), allocatable :: tag
  contains
    <Commands: cmd compile analysis: TBP>
  end type cmd_compile_analysis_t

```

Output. Just the keyword.

```

<Commands: cmd compile analysis: TBP>≡
  procedure :: write => cmd_compile_analysis_write

<Commands: procedures>+≡
  subroutine cmd_compile_analysis_write (cmd, unit, indent)
    class(cmd_compile_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "compile_analysis"
  end subroutine cmd_compile_analysis_write

```

Compile.

```

<Commands: cmd compile analysis: TBP>+≡
  procedure :: compile => cmd_compile_analysis_compile

        call file_expr%evaluate ()
        if (file_expr%is_known ()) then
            file = file_expr%get_string ()
            call file_list_open (global%out_files, file, &
                action = "write", status = "replace", position = "asis")
        else
            call msg_fatal ("open_out: file name argument evaluates to unknown")
        end if
        call file_expr%final ()
    end subroutine cmd_open_out_execute

```

## Open file (output)

Close an output file. Except for the `execute` method, everything is analogous to the open command, so we can just inherit.

```

⟨Commands: types⟩+≡
    type, extends (cmd_open_out_t) :: cmd_close_out_t
    private
    contains
    ⟨Commands: cmd close out: TBP⟩
end type cmd_close_out_t

```

Execute: remove the file from the global list of output files.

```

⟨Commands: cmd close out: TBP⟩≡
    procedure :: execute => cmd_close_out_execute

⟨Commands: procedures⟩+≡
    subroutine cmd_close_out_execute (cmd, global)
        class(cmd_close_out_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(var_list_t), pointer :: var_list
        type(eval_tree_t) :: file_expr
        type(string_t) :: file
        var_list => cmd%local%var_list

```

```

call file_expr%init_sexpr (cmd%file_expr, var_list)
call file_expr%evaluate ()
if (file_expr%is_known ()) then
  file = file_expr%get_string ()
  call file_list_close (global%out_files, file)
else
  call msg_fatal ("close_out: file name argument evaluates to unknown")
end if
call file_expr%final ()
end subroutine cmd_close_out_execute

```

### 35.1.5 Print custom-formatted values

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_printf_t
  private
  type(parse_node_t), pointer :: sexpr => null ()
  type(parse_node_t), pointer :: sprintf_fun => null ()
  type(parse_node_t), pointer :: sprintf_clause => null ()
  type(parse_node_t), pointer :: sprintf => null ()
contains
  ⟨Commands: cmd printf: TBP⟩
end type cmd_printf_t

```

Finalize.

```

⟨Commands: cmd printf: TBP⟩≡
  procedure :: final => cmd_printf_final

⟨Commands: procedures⟩+≡
  subroutine cmd_printf_final (cmd)
    class(cmd_printf_t), intent(inout) :: cmd
    call parse_node_final (cmd%sexpr, recursive = .false.)
    deallocate (cmd%sexpr)
    call parse_node_final (cmd%sprintf_fun, recursive = .false.)
    deallocate (cmd%sprintf_fun)
    call parse_node_final (cmd%sprintf_clause, recursive = .false.)
    deallocate (cmd%sprintf_clause)
    call parse_node_final (cmd%sprintf, recursive = .false.)
    deallocate (cmd%sprintf)
  end subroutine cmd_printf_final

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```

⟨Commands: cmd printf: TBP⟩+≡
  procedure :: write => cmd_printf_write

⟨Commands: procedures⟩+≡
  subroutine cmd_printf_write (cmd, unit, indent)
    class(cmd_printf_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return

```

```

    call write_indent (u, indent)
    write (u, "(1x,A)") "printf:"
end subroutine cmd_printf_write

```

Compile. We create a fake parse node (subtree) with a `sprintf` command with identical arguments which can then be handled by the corresponding evaluation procedure.

```

⟨Commands: cmd printf: TBP⟩+≡
  procedure :: compile => cmd_printf_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_printf_compile (cmd, global)
    class(cmd_printf_t), intent(inout) :: cmd

    allocate (cmd%sprintf_clause)
    call parse_node_create_branch (cmd%sprintf_clause, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf_clause")))
    allocate (cmd%sprintf)
    call parse_node_create_key (cmd%sprintf, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf")))
    call parse_node_append_sub (cmd%sprintf_clause, cmd%sprintf)
    call parse_node_append_sub (cmd%sprintf_clause, pn_format)
    call parse_node_freeze_branch (cmd%sprintf_clause)
    call parse_node_append_sub (cmd%sprintf_fun, cmd%sprintf_clause)
    if (associated (pn_args)) then
      call parse_node_append_sub (cmd%sprintf_fun, pn_args)
    end if
    call parse_node_freeze_branch (cmd%sprintf_fun)
    call parse_node_append_sub (cmd%sexpr, cmd%sprintf_fun)
    call parse_node_freeze_branch (cmd%sexpr)
  end subroutine cmd_printf_compile

```

Execute. Evaluate the string (pretending this is a `sprintf` expression) and print it.

```

⟨Commands: cmd printf: TBP⟩+≡
  procedure :: execute => cmd_printf_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_printf_execute (cmd, global)
    class(cmd_printf_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global

```

```

type(var_list_t), pointer :: var_list
type(string_t) :: string, file
type(eval_tree_t) :: sprintf_expr
logical :: advance
var_list => cmd%local%get_var_list_ptr ()
advance = var_list%get_lval (&
    var_str ("?out_advance"))
file = var_list%get_sval (&
    var_str ("out_file"))
call sprintf_expr%init_sexpr (cmd%sexpr, var_list)
call sprintf_expr%evaluate ()
if (sprintf_expr%is_known ()) then
    string = sprintf_expr%get_string ()
    if (len (file) == 0) then
        call msg_result (char (string))
    else
        call file_list_write (global%out_files, file, string, advance)
    end if
end if
end subroutine cmd_printf_execute

```

## Record data

The expression syntax already contains a **record** keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

⟨Commands: types⟩+=
type, extends (command_t) :: cmd_record_t
private
type(parse_node_t), pointer :: pn_lexpr => null ()
contains
⟨Commands: cmd record: TBP⟩
end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

⟨Commands: cmd record: TBP⟩=
procedure :: write => cmd_record_write

⟨Commands: procedures⟩+=
subroutine cmd_record_write (cmd, unit, indent)
class(cmd_record_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)" "record"
end subroutine cmd_record_write

```

Compile. This is a hack which transforms the **record** command into a **record** expression, which we handle in the expressions module.

```

⟨Commands: cmd record: TBP⟩+=
procedure :: compile => cmd_record_compile

```

```

⟨Commands: procedures⟩+≡
  subroutine cmd_record_compile (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
    call parse_node_create_branch (pn_lexpr, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))
    call parse_node_create_branch (pn_lsinglet, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lsinglet")))
    call parse_node_append_sub (pn_lexpr, pn_lsinglet)
    call parse_node_create_branch (pn_lterm, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lterm")))
    call parse_node_append_sub (pn_lsinglet, pn_lterm)
    pn_record => parse_node_get_sub_ptr (cmd%pn)
    call parse_node_append_sub (pn_lterm, pn_record)
    cmd%pn_lexpr => pn_lexpr
  end subroutine cmd_record_compile

```

Command execution. Again, transfer this to the embedded expression and just forget the logical result.

```

⟨Commands: cmd record: TBP⟩+≡
  procedure :: execute => cmd_record_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_record_execute (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    logical :: lval
    var_list => global%get_var_list_ptr ()
    lval = eval_log (cmd%pn_lexpr, var_list)
  end subroutine cmd_record_execute

```

## Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_unstable_t
  private
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id
  type(parse_node_t), pointer :: pn_prt_in => null ()
  contains
  ⟨Commands: cmd unstable: TBP⟩
  end type cmd_unstable_t

```

Output: we know the process IDs.

```

⟨Commands: cmd unstable: TBP⟩≡
  procedure :: write => cmd_unstable_write

```

```

<Commands: procedures>+≡
subroutine cmd_unstable_write (cmd, unit, indent)
  class(cmd_unstable_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u, i
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,1x,I0,1x,A)", advance="no") &
    "unstable:", 1, "("
  do i = 1, cmd%n_proc
    if (i > 1) write (u, "(A,1x)", advance="no") ", "
    write (u, "(A)", advance="no") char (cmd%process_id(i))
  end do
  write (u, "(A)") ")"
end subroutine cmd_unstable_write

```

Compile. Initiate an eval tree for the decaying particle and determine the decay channel process IDs.

```

<Commands: cmd unstable: TBP>+≡
  procedure :: compile => cmd_unstable_compile

<Commands: procedures>+≡
subroutine cmd_unstable_compile (cmd, global)

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

  end subroutine cmd_simulate_write

```

Compile. In contrast to WHIZARD 1 the confusing option to give the number of unweighted events for weighted events as if unweighting were to take place has been abandoned. (We both use `n_events` for weighted and unweighted events, the variable `n_calls` from WHIZARD 1 has been discarded.

```

<Commands: cmd simulate: TBP>+≡
  procedure :: compile => cmd_simulate_compile

```

*<Commands: procedures>+≡*

```

subroutine cmd_simulate_compile (cmd, global)

  end do
end subroutine cmd_simulate_compile

```

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

*<Commands: cmd simulate: TBP>+≡*

```

procedure :: execute => cmd_simulate_execute

```

*<Commands: procedures>+≡*

```

subroutine cmd_simulate_execute (cmd, global)

## Range expressions

We need a special type for storing and evaluating range expressions.

```

<Commands: parameters>+≡
integer, parameter :: STEP_NONE = 0
integer, parameter :: STEP_ADD = 1
integer, parameter :: STEP_SUB = 2
integer, parameter :: STEP_MUL = 3
integer, parameter :: STEP_DIV = 4
integer, parameter :: STEP_COMP_ADD = 11
integer, parameter :: STEP_COMP_MUL = 13

```

There is an abstract base type and two implementations: scan over integers and scan over reals.

```

<Commands: types>+≡
type, abstract :: range_t
  type(parse_node_t), pointer :: pn_expr => null ()
  type(parse_node_t), pointer :: pn_term => null ()
  type(parse_node_t), pointer :: pn_factor => null ()
  type(parse_node_t), pointer :: pn_value => null ()
  type(parse_node_t), pointer :: pn_literal => null ()
  type(parse_node_t), pointer :: pn_beg => null ()
  type(parse_node_t), pointer :: pn_end => null ()
  type(parse_node_t), pointer :: pn_step => null ()
  type(eval_tree_t) :: expr_beg
  type(eval_tree_t) :: expr_end
  type(eval_tree_t) :: expr_step
  integer :: step_mode = 0
  integer :: n_step = 0
contains

```

```

    <Commands: range: TBP>
end type range_t

```

These are the implementations:

```

<Commands: types>+≡
    type, extends (range_t) :: range_int_t
        integer :: i_beg = 0
        integer :: i_end = 0
        integer :: i_step = 0
    contains
        <Commands: range int: TBP>
    end type range_int_t

    type, extends (range_t) :: range_real_t
        real(default) :: r_beg = 0
        real(default) :: r_end = 0
        real(default) :: r_step = 0
        real(default) :: lr_beg = 0
        real(default) :: lr_end = 0
        real(default) :: lr_step = 0
    contains
        <Commands: range real: TBP>
    end type range_real_t

```

Finalize the allocated dummy node. The other nodes are just pointers.

```

<Commands: range: TBP>≡
    procedure :: final => range_final

<Commands: procedures>+≡
    subroutine range_final (object)
        class(range_t), intent(inout) :: object
        if (associated (object%pn_expr)) then
            call parse_node_final (object%pn_expr, recursive = .false.)
            call parse_node_final (object%pn_term, recursive = .false.)
            call parse_node_final (object%pn_factor, recursive = .false.)
            call parse_node_final (object%pn_value, recursive = .false.)
            call parse_node_final (object%pn_literal, recursive = .false.)
            deallocate (object%pn_expr)
            deallocate (object%pn_term)
            deallocate (object%pn_factor)
            deallocate (object%pn_value)
            deallocate (object%pn_literal)
        end if
    end subroutine range_final

```

Output.

```

<Commands: range: TBP>+≡
    procedure (range_write), deferred :: write
    procedure :: base_write => range_write

<Commands: range int: TBP>≡
    procedure :: write => range_int_write

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

```

  end subroutine range_real_set_value

```

## Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions

in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_scan_t
  private
  type(string_t) :: name
  integer :: n_values = 0
  type(parse_node_p), dimension(:), allocatable :: scan_cmd
  class(range_t), dimension(:), allocatable :: range
  contains
  ⟨Commands: cmd scan: TBP⟩
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

⟨Commands: cmd scan: TBP⟩≡
  procedure :: final => cmd_scan_final

⟨Commands: procedures⟩+≡
  recursive subroutine cmd_scan_final (cmd)
    class(cmd_scan_t), intent(inout) :: cmd
    type(parse_node_t), pointer :: pn_var_single, pn_decl_single
    type(string_t) :: key
    integer :: i
    if (allocated (cmd%scan_cmd)) then
      do i = 1, size (cmd%scan_cmd)
        pn_var_single => parse_node_get_sub_ptr (cmd%scan_cmd(i)%ptr)
        key = parse_node_get_rule_key (pn_var_single)
        select case (char (key))
          case ("scan_string_decl", "scan_log_decl")
            pn_decl_single => parse_node_get_sub_ptr (pn_var_single, 2)
            call parse_node_final (pn_decl_single, recursive=.false.)
            deallocate (pn_decl_single)
          end select
        call parse_node_final (pn_var_single, recursive=.false.)
        deallocate (pn_var_single)
      end do
      deallocate (cmd%scan_cmd)
    end if
    if (allocated (cmd%range)) then
      do i = 1, size (cmd%range)
        call cmd%range(i)%final ()
      end do
    end if
  end subroutine cmd_scan_final

```

Output.

```

⟨Commands: cmd scan: TBP⟩+≡
  procedure :: write => cmd_scan_write

```

```

{Commands: procedures}+≡
subroutine cmd_scan_write (cmd, unit, indent)
  class(cmd_scan_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,1x,A,1x,'(',I0,')')") "scan:", char (cmd%name), &
    cmd%n_values
end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

```

```

## Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of `else if` constructs. A `cmd_if.t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_if_t

    end if
  end subroutine cmd_include_execute

```

## Export values

This command exports the current values of variables or other objects to the surrounding scope. By default, a scope enclosed by braces keeps all objects local to it. The `export` command exports the values that are generated within the scope to the corresponding object in the outer scope.

The allowed set of exportable objects is, in principle, the same as the set of objects that the `show` command supports. This includes some convenience abbreviations.

TODO: The initial implementation inherits syntax from `show`, but supports only the `results` pseudo-object. The results (i.e., the process stack) is appended to the outer process stack instead of being discarded. The behavior of the `export` command for other object kinds is to be defined on a case-by-case basis. It may involve replacing the outer value or, instead, doing some sort of appending or reduction.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_export_t
  private
  type(string_t), dimension(:), allocatable :: name
  contains
  ⟨Commands: cmd export: TBP⟩
end type cmd_export_t

```

Output: list the object names, not values.

```

⟨Commands: cmd export: TBP⟩≡
  procedure :: write => cmd_export_write

⟨Commands: procedures⟩+≡
  subroutine cmd_export_write (cmd, unit, indent)

  allocate (cmd%name (0))
end if
end subroutine cmd_export_compile

```

Execute. Scan the list of objects to export.

```

<Commands: cmd export: TBP>+≡
  procedure :: execute => cmd_export_execute

<Commands: procedures>+≡
  subroutine cmd_export_execute (cmd, global)
    class(cmd_export_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    call global%append_exports (cmd%name)
  end subroutine cmd_export_execute

```

### Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_quit_t
  private
    logical :: has_code = .false.
    type(parse_node_t), pointer :: pn_code_expr => null ()
  contains
    ⟨Commands: cmd quit: TBP⟩
  end type cmd_quit_t

```

Output.

```

⟨Commands: cmd quit: TBP⟩≡
  procedure :: write => cmd_quit_write

⟨Commands: procedures⟩+≡
  subroutine cmd_quit_write (cmd, unit, indent)
    class(cmd_quit_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,L1)") "quit: has_code = ", cmd%has_code
  end subroutine cmd_quit_write

```

Compile: allocate a quit object which serves as a placeholder.

```

⟨Commands: cmd quit: TBP⟩+≡
  procedure :: compile => cmd_quit_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_quit_compile (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_arg
    pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
    if (associated (pn_arg)) then
      cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
      cmd%has_code = .true.
    end if
  end subroutine cmd_quit_compile

```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```

⟨Commands: cmd quit: TBP⟩+≡
  procedure :: execute => cmd_quit_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_quit_execute (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    logical :: is_known
    var_list => global%get_var_list_ptr ()

```

```

    if (cmd%has_code) then
        global%quit_code = eval_int (cmd%pn_code_expr, var_list, &
            is_known=is_known)
        if (.not. is_known) then
            call msg_error ("Undefined return code of quit/exit command")
        end if
    end if
    global%quit = .true.
end subroutine cmd_quit_execute

```

### 35.1.6 The command list

The command list holds a list of commands and relevant global data.

```

<Commands: public>+≡
    public :: command_list_t

<Commands: types>+≡
    type :: command_list_t
        ! not private anymore as required by the whizard-c-interface
        class(command_t), pointer :: first => null ()
        class(command_t), pointer :: last => null ()
    contains
        <Commands: command list: TBP>
    end type command_list_t

```

Output.

```

<Commands: command list: TBP>≡
    procedure :: write => command_list_write

<Commands: procedures>+≡
    recursive subroutine command_list_write (cmd_list, unit, indent)
        class(command_list_t), intent(in) :: cmd_list
        integer, intent(in), optional :: unit, indent
        class(command_t), pointer :: cmd
        cmd => cmd_list%first
        do while (associated (cmd))
            call cmd%write (unit, indent)
            cmd => cmd%next
        end do
    end subroutine command_list_write

```

Append a new command to the list and free the original pointer.

```

<Commands: command list: TBP>+≡
    procedure :: append => command_list_append

<Commands: procedures>+≡
    subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
        if (associated (cmd_list%last)) then
            cmd_list%last%next => command
        else

```

```

        cmd_list%first => command
    end if
    cmd_list%last => command
    command => null ()
end subroutine command_list_append

```

Finalize.

```

<Commands: command list: TBP>+≡
    procedure :: final => command_list_final

<Commands: procedures>+≡
    recursive subroutine command_list_final (cmd_list)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), pointer :: command
        do while (associated (cmd_list%first))
            command => cmd_list%first
            cmd_list%first => cmd_list%first%next
            call command%final ()
            deallocate (command)
        end do
        cmd_list%last => null ()
    end subroutine command_list_final

```

### 35.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```

<Commands: command list: TBP>+≡
    procedure :: compile => command_list_compile

<Commands: procedures>+≡
    recursive subroutine command_list_compile (cmd_list, pn, global)
        class(command_list_t), intent(inout), target :: cmd_list
        type(parse_node_t), intent(in), target :: pn
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_cmd
        class(command_t), pointer :: command
        integer :: i
        pn_cmd => parse_node_get_sub_ptr (pn)
        do i = 1, parse_node_get_n_sub (pn)
            call dispatch_command (command, pn_cmd)
            call command%compile (global)
            call cmd_list%append (command)
            call terminate_now_if_signal ()
            pn_cmd => parse_node_get_next_ptr (pn_cmd)
        end do
    end subroutine command_list_compile

```

### 35.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```
<Commands: command list: TBP>+≡
    procedure :: execute => command_list_execute

<Commands: procedures>+≡
    recursive subroutine command_list_execute (cmd_list, global)
        class(command_list_t), intent(in) :: cmd_list
        type(rt_data_t), intent(inout), target :: global
        class(command_t), pointer :: command
        command => cmd_list%first
        COMMAND_COND: do while (associated (command))
            call command%execute_options (global)
            call command%execute (global)
            call command%reset_options (global)
            call terminate_now_if_signal ()
            if (global%quit) exit COMMAND_COND
            command => command%next
        end do COMMAND_COND
    end subroutine command_list_execute
```

### 35.1.9 Command list syntax

```
<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡
    public :: syntax_cmd_list_init

end subroutine commands_34

```

For this test, we invent a callback object which simply writes the analysis file, using the standard call for this. Here we rely on the fact that the analysis data are stored as a global entity, otherwise we would have to access them via the event object.

```

<Commands: test auxiliary types>≡
type, extends (event_callback_t) :: event_callback_34_t
  private
  integer :: u = 0
contains
  procedure :: write => event_callback_34_write
  procedure :: proc => event_callback_34
end type event_callback_34_t

```

The output routine is unused. The actual callback should write the analysis data to the output unit that we have injected into the callback object.

```

<Commands: test auxiliary>+≡
subroutine event_callback_34_write (event_callback, unit)
  class(event_callback_34_t), intent(in) :: event_callback
  integer, intent(in), optional :: unit
end subroutine event_callback_34_write

subroutine event_callback_34 (event_callback, i, event)
  class(event_callback_34_t), intent(in) :: event_callback
  integer(i64), intent(in) :: i
  class(generic_event_t), intent(in) :: event
  call analysis_write (event_callback%u)
end subroutine event_callback_34

```

## 35.2 Toplevel module WHIZARD

```
<whizard.f90>≡  
  <File header>  
  
  module whizard  
  
    use io_units  
    <Use strings>  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF, BACKSLASH  
    use diagnostics  
    use os_interface  
    use ifiles  
    use lexers  
    use parser  
    use eval_trees  
    use models  
    use phs_forests  
    use prclib_stacks  
    use slha_interface  
    use blha_config  
    use rt_data  
    use commands  
  
    <Standard module head>  
  
    <WHIZARD: public>  
  
    <WHIZARD: types>  
  
    <WHIZARD: variables>  
  
    save  
  
    contains  
  
    <WHIZARD: procedures>  
  
  end module whizard
```

### 35.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```
<WHIZARD: public>≡  
  public :: whizard_options_t  
  
<WHIZARD: types>≡  
  type :: whizard_options_t  
    type(string_t) :: job_id  
    type(string_t), dimension(:), allocatable :: pack_args  
    type(string_t), dimension(:), allocatable :: unpack_args
```

```

    type(string_t) :: preload_model
    type(string_t) :: default_lib
    type(string_t) :: preload_libraries
    logical :: rebuild_library = .false.
    logical :: recompile_library = .false.
    logical :: rebuild_phs = .false.
    logical :: rebuild_grids = .false.
    logical :: rebuild_events = .false.
end type whizard_options_t

```

### 35.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

<WHIZARD: types> +=
    type, extends (parse_tree_t) :: pt_entry_t
        type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the `last` pointer.

```

<WHIZARD: types> +=
    type :: pt_stack_t
        type(pt_entry_t), pointer :: last => null ()
        contains
            <WHIZARD: pt stack: TBP>
    end type pt_stack_t

```

The finalizer is called at the very end.

```

<WHIZARD: pt stack: TBP> =
    procedure :: final => pt_stack_final

<WHIZARD: procedures> =
    subroutine pt_stack_final (pt_stack)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(pt_entry_t), pointer :: current
        do while (associated (pt_stack%last))
            current => pt_stack%last
            pt_stack%last => current%previous
            call parse_tree_final (current%parse_tree_t)
            deallocate (current)
        end do
    end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt stack: TBP> +=
    procedure :: push => pt_stack_push

```

```

<WHIZARD: procedures>+≡
  subroutine pt_stack_push (pt_stack, parse_tree)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(parse_tree_t), intent(out), pointer :: parse_tree
    type(pt_entry_t), pointer :: current
    allocate (current)
    parse_tree => current%parse_tree_t
    current%previous => pt_stack%last
    pt_stack%last => current
  end subroutine pt_stack_push

```

### 35.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a `WHIZARD` instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+≡
  public :: whizard_t

<WHIZARD: types>+≡
  type :: whizard_t
    type(whizard_options_t) :: options
    type(rt_data_t) :: global
    type(pt_stack_t) :: pt_stack
  contains
    <WHIZARD: whizard: TBP>
  end type whizard_t

```

### 35.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>≡
  procedure :: init => whizard_init

<WHIZARD: procedures>+≡
  subroutine whizard_init (whizard, options, paths, logfile)
    class(whizard_t), intent(out), target :: whizard
    type(whizard_options_t), intent(in) :: options
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
    call init_syntax_tables ()
    whizard%options = options
    call whizard%global%global_init (paths, logfile)
  end subroutine whizard_init

```

```

call whizard%init_job_id ()
call whizard%init_rebuild_flags ()
call whizard%unpack_files ()
call whizard%preload_model ()
call whizard%preload_library ()
call whizard%global%init_fallback_model &
    (var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))
end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: final => whizard_final

<WHIZARD: procedures>+≡
  subroutine whizard_final (whizard)
    class(whizard_t), intent(inout), target :: whizard
    call whizard%global%final ()
    call whizard%pt_stack%final ()
    call whizard%pack_files ()
    call final_syntax_tables ()
  end subroutine whizard_final

```

Set the job ID, if nonempty. If the ID string is empty, the value remains undefined.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: init_job_id => whizard_init_job_id

<WHIZARD: procedures>+≡
  subroutine whizard_init_job_id (whizard)
    class(whizard_t), intent(inout), target :: whizard
    associate (var_list => whizard%global%var_list, options => whizard%options)
      if (options%job_id /= "") then
        call var_list%set_string (var_str ("$_job_id"), &
          options%job_id, is_known=.true.)
      end if
    end associate
  end subroutine whizard_init_job_id

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: procedures>+≡
  subroutine whizard_init_rebuild_flags (whizard)
    class(whizard_t), intent(inout), target :: whizard

```

### 35.2.5 Initialization and finalization: syntax tables

Initialize/finalize the syntax tables used by WHIZARD. These are effectively singleton objects. We introduce a module variable that tracks the initialization status.

Without syntax tables, essentially nothing will work. Any initializer has to call this.

```

<WHIZARD: variables>≡
  logical :: syntax_tables_exist = .false.

<WHIZARD: public>+≡
  public :: init_syntax_tables
  public :: final_syntax_tables

<WHIZARD: procedures>+≡
  subroutine init_syntax_tables ()
    if (.not. syntax_tables_exist) then
      call syntax_model_file_init ()
      call syntax_phs_forest_init ()
      call syntax_pexpr_init ()
      call syntax_slha_init ()
      call syntax_cmd_list_init ()
      syntax_tables_exist = .true.
    end if
  end subroutine init_syntax_tables

  subroutine final_syntax_tables ()
    if (syntax_tables_exist) then
      call syntax_model_file_final ()
      call syntax_phs_forest_final ()
      call syntax_pexpr_final ()
      call syntax_slha_final ()
      call syntax_cmd_list_final ()
      syntax_tables_exist = .false.
    end if
  end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
  public :: write_syntax_tables

```

```

{WHIZARD: procedures}+=
subroutine write_syntax_tables ()
integer :: unit
character(*), parameter :: file_model = "whizard.model_file.syntax"
character(*), parameter :: file_phs = "whizard.phase_space_file.syntax"
character(*), parameter :: file_pexpr = "whizard.prt_expressions.syntax"
character(*), parameter :: file_slha = "whizard.slha.syntax"
character(*), parameter :: file_sindarin = "whizard.sindarin.syntax"
if (.not. syntax_tables_exist) call init_syntax_tables ()
unit = free_unit ()
print *, "Writing file '" // file_model // "'"
open (unit=unit, file=file_model, status="replace", action="write")
write (unit, "(A)") VERSION_STRING
write (unit, "(A)") "Syntax definition file: " // file_model

call syntax_cmd_list_write (unit)
close (unit)
end subroutine write_syntax_tables

```

### 35.2.6 Execute command lists

Process commands given on the command line, stored as an ifile. The whole input is read, compiled and executed as a whole.

```

{WHIZARD: whizard: TBP}+=
procedure :: process_ifile => whizard_process_ifile

{WHIZARD: procedures}+=
subroutine whizard_process_ifile (whizard, ifile, quit, quit_code)
class(whizard_t), intent(inout), target :: whizard
type(ifile_t), intent(in) :: ifile

```

```

logical, intent(out) :: quit
integer, intent(out) :: quit_code
type(lexer_t), target :: lexer
type(stream_t), target :: stream
call msg_message ("Reading commands given on the command line")
call lexer_init_cmd_list (lexer)
call stream_init (stream, ifile)
call whizard%process_stream (stream, lexer, quit, quit_code)
call stream_final (stream)
call lexer_final (lexer)
end subroutine whizard_process_ifile

```

Process standard input as a command list. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: process_stdin => whizard_process_stdin
<WHIZARD: procedures>+≡
  subroutine whizard_process_stdin (whizard, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    call msg_message ("Reading commands from standard input")
    call lexer_init_cmd_list (lexer)
    call stream_init (stream, 5)
    call whizard%process_stream (stream, lexer, quit, quit_code)
    call stream_final (stream)
    call lexer_final (lexer)
  end subroutine whizard_process_stdin

```

Process a file as a command list.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: process_file => whizard_process_file
<WHIZARD: procedures>+≡
  subroutine whizard_process_file (whizard, file, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t), intent(in) :: file
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    logical :: exist
    call msg_message ("Reading commands from file '" // char (file) // "'")
    inquire (file=char(file), exist=exist)
    if (exist) then
      call lexer_init_cmd_list (lexer)
      call stream_init (stream, char (file))
      call whizard%process_stream (stream, lexer, quit, quit_code)
      call stream_final (stream)
      call lexer_final (lexer)
    else

```

```

end subroutine whizard_shell

```

## 35.3 Query Feature Support

This module accesses the various optional features (modules) that WHIZARD can support and reports on their availability.

```
<features.f90>≡
  module features

    use string_utils, only: lower_case
    use system_dependencies, only: WHIZARD_VERSION
    <Features: dependencies>

    <Standard module head>

    <Features: public>

    contains

    <Features: procedures>

  end module features
```

### 35.3.1 Output

```
<Features: public>≡
  public :: print_features

<Features: procedures>≡
  subroutine print_features ()
    print "(A)", "WHIZARD " // WHIZARD_VERSION
    print "(A)", "Build configuration:"
    <Features: config>
    print "(A)", "Optional features available in this build:"
    <Features: print>
  end subroutine print_features
```

### 35.3.2 Query function

```
<Features: procedures>+≡
  subroutine check (feature, recognized, result, help)
    character(*), intent(in) :: feature
    logical, intent(out) :: recognized
    character(*), intent(out) :: result, help
    recognized = .true.
    result = "no"
    select case (lower_case (trim (feature)))
    <Features: cases>
    case default
      recognized = .false.
    end select
  end subroutine check
```

Print this result:

```
<Features: procedures>+≡
  subroutine print_check (feature)
    character(*), intent(in) :: feature
    character(16) :: f
    logical :: recognized
    character(10) :: result
    character(48) :: help
    call check (feature, recognized, result, help)
    if (.not. recognized) then
      result = "unknown"
      help = ""
    end if
    f = feature
    print "(2x,A,1x,A,'( ',A,')')", f, result, trim (help)
  end subroutine print_check
```
