The routine `make_factorized_particle_set` will setup the subevent momenta from the `connected%matrix`. Its initial state momenta correspond to the Born process without IS splitting and thus need to be updated with the real momenta from the `int_hard` to get correct momenta in the events with real radiation.

Ideally the `int_hard` and the `connected` would be setup with correct `source_links` to real momenta so that we would not need to replace momenta of the `connected` here.

The parameter `n_in` from the `int_matrix` is still 0 as it has been shifted to `n_vir`. We thus take `n_in` from the `particle_set`.

Boosts the given four vector `p_lab` to the Born or real CMS depending on the number of given momenta. Unfortunately, all boosts available via `get_boost_to_cms` are Born-like, so we need to compute the boost to the real CMS here manually. We cannot rely on `i_term` in order to determine whether to apply a Born-like or a real boost as we also need a real boost to compute the weights of the Born-like subevents as implemented in `evt_nlo_generate_weighted`.

Selects a flavor structure for Born subevents, such that each possible flavor structure is as probable as its portion of the sum of Born matrix elements over all flavors. For non-Born Born-like subevents, no Born matrix elements are available. We always choose `i_flv = 1` in this case. If all terms are active, i.e. in a full NLO calculation, the flavors of Born-like subevents will be distributed according to the Born matrix elements only, to avoid issues with matrix elements of different sign and assure a LO flavor distribution.

Likewise, the real-like event flavors are distributed according to the real matrix elements. Here, we need to make sure to not mix matrix elements from different real terms and instead determine the flavor for each subevent based on just the matrix elements for one of the terms. The implementation below assumes that in the sequence of NLO terms, the Born term is immediately followed by all the real terms which are again followed by the subtraction, the virtual and the DGLAP term.

Both flavor structures can be determined without correlation as the flavors will only become important for events to be matched to a parton shower and in this case we will only generate either a single Born-like or a single real-like event which are not part of an event group.

In case all subevents failed the cuts, all `sqmes` were set to 0 so we cannot determine the flavor in this way. In this case, we always choose the first flavor structure given by the matrix-element generator with `i_flv = 1`.

Ideally, having to choose a particle set here would not be necessary as it is also chosen in `particle_set_init_interaction` which in the current approach is disabled by supplying `qn_select` explicitly based on the flavors chosen here.

### 32.10.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The `safety_factor` reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The `sigma` and `n` values, if nontrivial, allow for reweighting the events according to the requested `norm_mode`.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the `event_expr_t` objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

```

<Events: types>≡

### 32.10.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event_base` module. The core manages the main (dressed) particle set pointer and the current values for weights and sqme. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

The `sqme` and `weight` values mirror corresponding values in the `expr` subobject. The idea is that when generating or reading events, the event record is filled first, then the `expr` object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the `expr` subobject. In particular, evaluating the event-selection expression sets the `passed` flag. Furthermore, the `expr` subobject collects data that can be used in the analysis and should be written to file, including copies of `sqme` and `weight`.

```

### 32.10.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one. Gfortran 7/8/9 bug, has to remain in the main module:

```

<Events: event: TBP>+≡
  procedure :: basic_init => event_init

<Events: main procedures>≡
  subroutine event_init (event, var_list, n_alt)
    class(event_t), intent(out) :: event

```

```

type(var_list_t), intent(in), optional :: var_list
integer, intent(in), optional :: n_alt
type(string_t) :: norm_string, mode_string
logical :: polarized_events
if (present (n_alt)) then
call event%base_init (n_alt)
call event%expr%init (n_alt)
else
call event%base_init (0)
end if
if (present (var_list)) then
event%config%unweighted = var_list%get_lval (&
var_str ("?unweighted"))
norm_string = var_list%get_sval (&
var_str ("sample_normalization"))
event%config%norm_mode = &
event_normalization_mode (norm_string, event%config%unweighted)
polarized_events = &
var_list%get_lval (var_str ("?polarized_events"))
if (polarized_events) then
mode_string = &
var_list%get_sval (var_str ("polarization_mode"))
select case (char (mode_string))
case ("ignore")
event%config%factorization_mode = FM_IGNORE_HELICITY
case ("helicity")
event%config%factorization_mode = FM_SELECT_HELICITY
case ("factorized")
event%config%factorization_mode = FM_FACTOR_HELICITY
case ("correlated")
event%config%factorization_mode = FM_CORRELATED_HELICITY
case default
call msg_fatal ("Polarization mode " &
// char (mode_string) // " is undefined")
end select
else
event%config%factorization_mode = FM_IGNORE_HELICITY
end if
event%config%colorize_subevt = &
var_list%get_lval (var_str ("?colorize_subevt"))
if (event%config%unweighted) then
event%config%safety_factor = var_list%get_rval (&
var_str ("safety_factor"))
end if
else
event%config%norm_mode = NORM_SIGMA
end if
allocate (evt_trivial_t :: event%transform_first)
event%transform_last => event%transform_first
end subroutine event_init

```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the de-

fault value for both is unity, and event renormalization has no effect.

```

<Events: event: TBP>+≡
  procedure :: set_sigma => event_set_sigma
  procedure :: set_n => event_set_n

<Events: sub interfaces>+≡
  elemental module subroutine event_set_sigma (event, sigma)
  class(event_t), intent(inout) :: event
  real(default), intent(in) :: sigma
  end subroutine event_set_sigma
  elemental module subroutine event_set_n (event, n)
  class(event_t), intent(inout) :: event
  integer, intent(in) :: n
  end subroutine event_set_n

<Events: procedures>+≡
  elemental module subroutine event_set_sigma (event, sigma)
  class(event_t), intent(inout) :: event
  real(default), intent(in) :: sigma
  event%config%sigma = sigma
  end subroutine event_set_sigma

  elemental module subroutine event_set_n (event, n)
  class(event_t), intent(inout) :: event
  integer, intent(in) :: n
  event%config%n = n
  end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
  procedure :: import_transform => event_import_transform

<Events: sub interfaces>+≡
  module subroutine event_import_transform (event, evt)
  class(event_t), intent(inout) :: event
  class(evt_t), intent(inout), pointer :: evt
  end subroutine event_import_transform

<Events: procedures>+≡
  module subroutine event_import_transform (event, evt)
  class(event_t), intent(inout) :: event
  class(evt_t), intent(inout), pointer :: evt
  event%transform_last%next => evt
  evt%previous => event%transform_last
  event%transform_last => evt
  evt => null ()
  end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

<Events: sub interfaces>+≡
  module subroutine event_connect &
    (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event

call event%expr%colorize (event%config%colorize_subevt)
end subroutine event_setup_expressions

```

### 32.10.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

.and. event%weight_alt_is_known ()
end if
end subroutine event_check

```

### 32.10.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we accept the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
  procedure :: generate => event_generate

<Events: sub interfaces>+≡
  module subroutine event_generate (event, i_mci, r, i_nlo)

### 32.10.8 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
  procedure :: select => event_select

<Events: sub interfaces>+≡
  module subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
  end subroutine event_select

<Events: procedures>+≡
  module subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
    if (associated (event%instance)) then
      event%selected_i_mci = i_mci
      event%selected_i_term = i_term
      event%selected_channel = channel
    else
      event%selected_i_mci = 0
      event%selected_i_term = 0
      event%selected_channel = 0
    end if
  end subroutine event_select

```

```

end if
end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. The event reader may either read in the transformed event separately, or apply all event transforms to the hard particle set to (re)generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
  procedure :: set_hard_particle_set => event_set_hard_particle_set

<Events: sub interfaces>+≡
  module subroutine event_set_hard_particle_set (event, particle_set)
    class(event_t), intent(inout) :: event
    type(particle_set_t), intent(in) :: particle_set
  end subroutine event_set_hard_particle_set

<Events: procedures>+≡
  module subroutine event_set_hard_particle_set (event, particle_set)
    class(event_t), intent(inout) :: event
    type(particle_set_t), intent(in) :: particle_set
    class(evt_t), pointer :: evt
    evt => event%transform_first
    call evt%set_particle_set (particle_set, &
      event%selected_i_mci, event%selected_i_term)
    call event%link_particle_set (evt%particle_set)
    evt => evt%next
    do while (associated (evt))
      call evt%reset ()
      evt => evt%next
    end do
  end subroutine event_set_hard_particle_set

```

Set the  $\alpha_s$  value that should be used in a recalculation. This should be called only if we explicitly want to override the QCD setting of the process core.

```

<Events: event: TBP>+≡
  procedure :: set_alpha_qcd_forced => event_set_alpha_qcd_forced

<Events: sub interfaces>+≡
  module subroutine event_set_alpha_qcd_forced (event, alpha_qcd)

    class(event_t), intent(inout) :: event
    real(default), intent(in) :: alpha_qcd
    if (allocated (event%alpha_qcd_forced)) then
      event%alpha_qcd_forced = alpha_qcd
    else
      allocate (event%alpha_qcd_forced, source = alpha_qcd)
    end if
  end subroutine event_set_alpha_qcd_forced

```

```

end if
end subroutine event_set_alpha_qcd_forced

```

Analogously, for the common scale. This forces also renormalization and factorization scale.

```

<Events: event: TBP>+≡
  procedure :: set_scale_forced => event_set_scale_forced

<Events: sub interfaces>+≡
  module subroutine event_set_scale_forced (event, scale)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: scale
  end subroutine event_set_scale_forced

<Events: procedures>+≡
  module subroutine event_set_scale_forced (event, scale)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: scale
    if (allocated (event%scale_forced)) then
      event%scale_forced = scale
    else
      allocate (event%scale_forced, source = scale)
    end if
  end subroutine event_set_scale_forced

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have a `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

If `recover_phs` is set (and false), do not attempt any phase-space calculation, including MCI evaluation. Useful if we need only matrix elements.

```

<Events: event: TBP>+≡
  procedure :: recalculate => event_recalculate

## 32.11 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the `events` module which provides the concrete implementation of `event_base`. The other I/O formats access only the methods that are defined in `event_base`.

```

<eio_raw.f90>≡
  <File header>

  module eio_raw

    <Use kinds>
    <Use strings>
    use event_base
    use event_handles, only: event_handle_t
    use eio_data
    use eio_base
    use events

    <Standard module head>

    <EIO raw: public>

    <EIO raw: parameters>

```

```

    <EIO raw: types>

    interface
    <EIO raw: sub interfaces>
    end interface

    end module eio_raw

    <eio_raw_sub.f90>≡
    <File header>

    submodule (eio_raw) eio_raw_s

    use io_units
    use diagnostics
    use model_data
    use particles
    !!! Intel oneAPI 2022/23 regression workaround
    use event_handles, only: event_handle_t

    implicit none

    contains

    <EIO raw: procedures>

    end submodule eio_raw_s

```

### 32.11.1 File Format Version

This is the current default file version.

```

    <EIO raw: parameters>≡
    integer, parameter :: CURRENT_FILE_VERSION = 2

```

The user may change this number; this should force some compatibility mode for reading and writing. In any case, the file version stored in a event file that we read has to match the expected file version.

History of version numbers:

1. Format for WHIZARD 2.2.0 to 2.2.3. No version number stored in the raw file.
2. Format from 2.2.4 on. File contains version number. The file contains the transformed particle set (if applicable) after the hard-process particle set.

### 32.11.2 Type

Note the file version number. The default may be reset during initialization, which should enforce some compatibility mode.

```

    <EIO raw: public>≡
    public :: eio_raw_t

```

```

  end subroutine eio_raw_switch_inout

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

The `passed` flag is not written. This allow us to apply different selection criteria upon rereading.

```

## 32.12 Dispatch

An event transform is responsible for dressing a partonic event. Since event transforms are not mutually exclusive but are concatenated, we provide individual dispatchers for each of them.

Due to the gfortran 7/8/9 bug that leads to segmentation violation if polymorphic user-defined derived types are allocated in routines within submodules, this module remains without submodule until we can switch to gfortran v10 or newer.

```

## Chapter 33

# Integration and Simulation

### 33.1 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```
<user_files.f90>≡  
<File header>  
  
module user_files  
  
  <Use strings>  
  use ifiles  
  
  <Standard module head>  
  
  <User files: public>  
  
  <User files: types>  
  
  <User files: interfaces>  
  
  interface  
    <User files: sub interfaces>  
  end interface  
  
end module user_files  
  
<user_files_sub.f90>≡  
<File header>  
  
submodule (user_files) user_files_s  
  
  use io_units  
  use diagnostics  
  use analysis
```

```

implicit none

contains

<User files: procedures>

end submodule user_files_s

```

### 33.1.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```

<User files: types>≡
  type :: file_t
  private
  type(string_t) :: name
  integer :: unit = -1
  logical :: reading = .false.
  logical :: writing = .false.
  type(file_t), pointer :: prev => null ()
  type(file_t), pointer :: next => null ()
end type file_t

```

The initializer opens the file.

```

<User files: procedures>≡
  subroutine file_init (file, name, action, status, position)
  type(file_t), intent(out) :: file
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position
  file%unit = free_unit ()
  file%name = name
  open (unit = file%unit, file = char (file%name), &
    action = action, status = status, position = position)
  select case (action)
  case ("read")
    file%reading = .true.
  case ("write")
    file%writing = .true.
  case ("readwrite")
    file%reading = .true.
    file%writing = .true.
  end select
end subroutine file_init

```

The finalizer closes it.

```

<User files: procedures>+≡
  subroutine file_final (file)
  type(file_t), intent(inout) :: file
  close (unit = file%unit)
  file%unit = -1
end subroutine file_final

```

Check if a file is open with correct status.

```
<User files: procedures>+≡  
function file_is_open (file, action) result (flag)  
  logical :: flag  
  type(file_t), intent(in) :: file  
  character(*), intent(in) :: action  
  select case (action)  
  case ("read")  
    flag = file%reading  
  case ("write")  
    flag = file%writing  
  case ("readwrite")  
    flag = file%reading .and. file%writing  
  case default  
    call msg_bug ("Checking file '" // char (file%name) &  
    // "': illegal action specifier")  
  end select  
end function file_is_open
```

Return the unit number of a file for direct access. It should be checked first whether the file is open.

```
<User files: procedures>+≡  
function file_get_unit (file) result (unit)  
  integer :: unit  
  type(file_t), intent(in) :: file  
  unit = file%unit  
end function file_get_unit
```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the **advancing** option.

```
<User files: procedures>+≡  
subroutine file_write_string (file, string, advancing)  
  type(file_t), intent(in) :: file  
  type(string_t), intent(in), optional :: string  
  logical, intent(in), optional :: advancing  
  if (file%writing) then  
    if (present (string)) then  
      if (present (advancing)) then  
        if (advancing) then  
          write (file%unit, "(A)") char (string)  
        else  
          write (file%unit, "(A)", advance="no") char (string)  
        end if  
      else  
        write (file%unit, "(A)") char (string)  
      end if  
    else  
      write (file%unit, *)  
    end if  
  else  
    call msg_error ("Writing to file: File '" // char (file%name) &
```

```

// '' is not open for writing.")
end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
subroutine file_write_ifile (file, ifile)
type(file_t), intent(in) :: file
type(ifile_t), intent(in) :: ifile
type(line_p) :: line
call line_init (line, ifile)
do while (line_is_associated (line))
call file_write_string (file, line_get_string_advance (line))
end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
subroutine file_write_analysis (file, tag)
type(file_t), intent(in) :: file
type(string_t), intent(in), optional :: tag
if (file%writing) then
if (present (tag)) then
call analysis_write (tag, unit = file%unit)
else
call analysis_write (unit = file%unit)
end if
else
call msg_error ("Writing analysis to file: File '' // char (file%name) &
// '' is not open for writing.")
end if
end subroutine file_write_analysis

```

### 33.1.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
public :: file_list_t

<User files: types>+≡
type :: file_list_t
type(file_t), pointer :: first => null ()
type(file_t), pointer :: last => null ()
end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
public :: file_list_final

```

```

<User files: sub interfaces>≡
module subroutine file_list_final (file_list)
type(file_list_t), intent(inout) :: file_list
end subroutine file_list_final

<User files: procedures>+≡
module subroutine file_list_final (file_list)
type(file_list_t), intent(inout) :: file_list
type(file_t), pointer :: current
do while (associated (file_list%first))
current => file_list%first
file_list%first => current%next
call file_final (current)
deallocate (current)
end do
file_list%last => null ()
end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```

<User files: procedures>+≡
function file_list_get_file_ptr (file_list, name) result (current)
type(file_t), pointer :: current
type(file_list_t), intent(in) :: file_list
type(string_t), intent(in) :: name
current => file_list%first
do while (associated (current))
if (current%name == name) return
current => current%next
end do
end function file_list_get_file_ptr

```

Check if a file is open, public version:

```

<User files: public>+≡
public :: file_list_is_open

<User files: sub interfaces>+≡
module function file_list_is_open (file_list, name, action) result (flag)
logical :: flag
type(file_list_t), intent(in) :: file_list
type(string_t), intent(in) :: name
character(len=*), intent(in) :: action
end function file_list_is_open

<User files: procedures>+≡
module function file_list_is_open (file_list, name, action) result (flag)
logical :: flag
type(file_list_t), intent(in) :: file_list
type(string_t), intent(in) :: name
character(len=*), intent(in) :: action
type(file_t), pointer :: current
current => file_list_get_file_ptr (file_list, name)
if (associated (current)) then
flag = file_is_open (current, action)
else
flag = .false.

```

```

end if
end function file_list_is_open

```

Return the unit number for a file. It should be checked first whether the file is open.

```

<User files: public>+≡
  public :: file_list_get_unit

<User files: sub interfaces>+≡
  module function file_list_get_unit (file_list, name) result (unit)
    integer :: unit
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
  end function file_list_get_unit

<User files: procedures>+≡
  module function file_list_get_unit (file_list, name) result (unit)
    integer :: unit
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    type(file_t), pointer :: current
    current => file_list_get_file_ptr (file_list, name)
    if (associated (current)) then
      unit = file_get_unit (current)
    else
      unit = -1
    end if
  end function file_list_get_unit

```

Append a new file entry, i.e., open this file. Error if it is already open.

```

<User files: public>+≡
  public :: file_list_open

<User files: sub interfaces>+≡
  module subroutine file_list_open (file_list, name, action, status, position)
    type(file_list_t), intent(inout) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
  end subroutine file_list_open

<User files: procedures>+≡
  module subroutine file_list_open (file_list, name, action, status, position)
    type(file_list_t), intent(inout) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    type(file_t), pointer :: current
    if (.not. associated (file_list_get_file_ptr (file_list, name))) then
      allocate (current)
      call msg_message ("Opening file '" // char (name) // "' for output")
      call file_init (current, name, action, status, position)
      if (associated (file_list%last)) then
        file_list%last%next => current
        current%prev => file_list%last
      else
        file_list%first => current
      end if
    end if
  end subroutine file_list_open

```

```

end if
file_list%last => current
else
call msg_error ("Opening file: File '" // char (name) &
// "' is already open.")
end if
end subroutine file_list_open

### 33.2.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn, is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

### 33.2.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```
<RT data: types>≡
```

```

type :: rt_parse_nodes_t
type(parse_node_t), pointer :: cuts_lexpr => null ()
type(parse_node_t), pointer :: scale_expr => null ()
type(parse_node_t), pointer :: fac_scale_expr => null ()
type(parse_node_t), pointer :: ren_scale_expr => null ()
type(parse_node_t), pointer :: weight_expr => null ()
type(parse_node_t), pointer :: selection_lexpr => null ()
type(parse_node_t), pointer :: reweight_expr => null ()
type(parse_node_t), pointer :: analysis_lexpr => null ()
type(parse_node_p), dimension(:), allocatable :: alt_setup
contains
<RT data: rt parse nodes: TBP>
end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

<RT data: sub interfaces>≡
  module subroutine rt_parse_nodes_clear (rt_pn, name)
    class(rt_parse_nodes_t), intent(inout) :: rt_pn
    type(string_t), intent(in) :: name
  end subroutine rt_parse_nodes_clear

<RT data: procedures>≡
  module subroutine rt_parse_nodes_clear (rt_pn, name)
    class(rt_parse_nodes_t), intent(inout) :: rt_pn
    type(string_t), intent(in) :: name
    select case (char (name))
    case ("cuts")
      rt_pn%cuts_lexpr => null ()
    case ("scale")
      rt_pn%scale_expr => null ()
    case ("factorization_scale")
      rt_pn%fac_scale_expr => null ()
    case ("renormalization_scale")
      rt_pn%ren_scale_expr => null ()
    case ("weight")
      rt_pn%weight_expr => null ()
    case ("selection")
      rt_pn%selection_lexpr => null ()
    case ("reweight")
      rt_pn%reweight_expr => null ()
    case ("analysis")
      rt_pn%analysis_lexpr => null ()
    end select
  end subroutine rt_parse_nodes_clear

```

Output for the parse nodes.

```

<RT data: rt parse nodes: TBP>+≡
  procedure :: write => rt_parse_nodes_write

```

```

<RT data: sub interfaces>+≡

end if
end subroutine rt_parse_nodes_show

```

### 33.2.3 The data type

This is a big data container which contains everything that is used and modified during the command flow. A local copy of this can be used to temporarily override defaults. The data set is transparent.

```

<RT data: public>≡
public :: rt_data_t

<RT data: types>+≡
type :: rt_data_t
type(lexer_t), pointer :: lexer => null ()
type(rt_data_t), pointer :: context => null ()
type(string_t), dimension(:), allocatable :: export

```

```

type(var_list_t) :: var_list
type(iterations_list_t) :: it_list
type(os_data_t) :: os_data
type(model_list_t) :: model_list
type(model_t), pointer :: model => null ()
logical :: model_is_copy = .false.
type(model_t), pointer :: preload_model => null ()
type(model_t), pointer :: fallback_model => null ()
type(prclib_stack_t) :: prclib_stack
type(process_library_t), pointer :: prclib => null ()
type(beam_structure_t) :: beam_structure
type(rt_parse_nodes_t) :: pn
type(process_stack_t) :: process_stack
type(string_t), dimension(:), allocatable :: sample_fmt
class(event_callback_t), allocatable :: event_callback
type(file_list_t), pointer :: out_files => null ()
logical :: quit = .false.
integer :: quit_code = 0
type(string_t) :: logfile
logical :: nlo_fixed_order = .false.
logical, dimension(0:5) :: selected_nlo_parts = .false.
integer, dimension(:), allocatable :: nlo_component
contains
<RT data: rt data: TBP>
end type rt_data_t

```

### 33.2.5 Clear

The `clear` command can remove the contents of various subobjects. The objects themselves should stay.

```

<RT data: rt data: TBP>+≡
  procedure :: clear_beams => rt_data_clear_beams

<RT data: sub interfaces>+≡
  module subroutine rt_data_clear_beams (global)
    class(rt_data_t), intent(inout) :: global
  end subroutine rt_data_clear_beams

<RT data: procedures>+≡
  module subroutine rt_data_clear_beams (global)
    class(rt_data_t), intent(inout) :: global
    call global%beam_structure%final_sf ()
    call global%beam_structure%final_pol ()
    call global%beam_structure%final_mom ()
  end subroutine rt_data_clear_beams

```

### 33.2.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

```

<RT data: rt data: TBP>+≡
  procedure :: global_init => rt_data_global_init

<RT data: sub interfaces>+≡
  module subroutine rt_data_global_init (global, paths, logfile)
    class(rt_data_t), intent(out), target :: global
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
  end subroutine rt_data_global_init

```

```

<RT data: procedures>+≡
module subroutine rt_data_global_init (global, paths, logfile)
class(rt_data_t), intent(out), target :: global
type(paths_t), intent(in), optional :: paths
type(string_t), intent(in), optional :: logfile
integer :: seed
call global%os_data%init (paths)
if (present (logfile)) then
global%logfile = logfile
else
global%logfile = ""
end if
allocate (global%out_files)
call system_clock (seed)
call global%var_list%init_defaults (seed, paths)
call global%init_pointer_variables ()
call global%process_stack%init_var_list (global%var_list)
end subroutine rt_data_global_init

```

### 33.2.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
procedure :: local_init => rt_data_local_init

<RT data: sub interfaces>+≡
module subroutine rt_data_local_init (local, global, env)
class(rt_data_t), intent(inout), target :: local
type(rt_data_t), intent(in), target :: global
integer, intent(in), optional :: env
end subroutine rt_data_local_init

<RT data: procedures>+≡
module subroutine rt_data_local_init (local, global, env)
class(rt_data_t), intent(inout), target :: local
type(rt_data_t), intent(in), target :: global
integer, intent(in), optional :: env
local%context => global
call local%process_stack%link (global%process_stack)
call local%process_stack%init_var_list (local%var_list)
call local%process_stack%link_var_list (global%var_list)
call local%var_list%append_string (var_str ("model_name"), &
var_str (""), intrinsic=.true.)
call local%init_pointer_variables ()
local%fallback_model => global%fallback_model
local%os_data = global%os_data
local%logfile = global%logfile
call local%model_list%link (global%model_list)
local%model => global%model

```

```

if (associated (local%model)) then
call local%model%link_var_list (local%var_list)
end if
if (allocated (global%event_callback)) then
allocate (local%event_callback, source = global%event_callback)
end if
end subroutine rt_data_local_init

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
  procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: sub interfaces>+≡
  module subroutine rt_data_init_pointer_variables (local)
  class(rt_data_t), intent(inout), target :: local
  end subroutine rt_data_init_pointer_variables

<RT data: procedures>+≡
  module subroutine rt_data_init_pointer_variables (local)
  class(rt_data_t), intent(inout), target :: local
  logical, target, save :: known = .true.
  call local%var_list%append_string_ptr (var_str ("%fc"), &
local%os_data%fc, known, intrinsic=.true., &

'within \whizard. It can only be accessed, not set by ' // &
'the user. (cf. also \ttt{\%fc}, \ttt{\%fcflags}'))
  end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

Gfortran 7/8/9 bug, has to remain in the main module:

```

<RT data: rt data: TBP>+≡
  procedure :: activate => rt_data_activate

<RT data: main procedures>≡
  subroutine rt_data_activate (local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), pointer :: global
    global => local%context
    if (associated (global)) then
      local%lexer => global%lexer
      call global%copy_globals (local)
      local%os_data = global%os_data
      local%logfile = global%logfile
      if (associated (global%prclib)) then
        local%prclib => &
        local%prclib_stack%get_library_ptr (global%prclib%get_name ())
      end if
      call local%import_values ()
      call local%process_stack%link (global%process_stack)
      local%it_list = global%it_list
      local%beam_structure = global%beam_structure
      local%pn = global%pn
      if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
      if (allocated (global%sample_fmt)) then
        allocate (local%sample_fmt (size (global%sample_fmt)), &
          source = global%sample_fmt)
      end if
      local%out_files => global%out_files
      local%model => global%model
      local%model_is_copy = .false.
      else if (.not. associated (local%model)) then
        local%model => local%preload_model
        local%model_is_copy = .false.
      end if
      if (associated (local%model)) then
        call local%model%link_var_list (local%var_list)
        call local%var_list%set_string (var_str ("model_name"), &
          local%model%get_name (), is_known = .true.)
      else
        call local%var_list%set_string (var_str ("model_name"), &
          var_str (""), is_known = .false.)
      end if
    end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
  procedure :: deactivate => rt_data_deactivate

<RT data: sub interfaces>+≡
  module subroutine rt_data_deactivate (local, global, keep_local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), optional, target :: global
    logical, intent(in), optional :: keep_local
  end subroutine rt_data_deactivate

<RT data: procedures>+≡
  module subroutine rt_data_deactivate (local, global, keep_local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), optional, target :: global
    logical, intent(in), optional :: keep_local
    type(string_t) :: local_model, local_scheme
    logical :: same_model, delete
    delete = .true.; if (present (keep_local)) delete = .not. keep_local
    if (present (global)) then
      if (associated (global%model) .and. associated (local%model)) then
        local_model = local%model%get_name ()
        if (global%model%has_schemes ()) then
          local_scheme = local%model%get_scheme ()
          same_model = &
            global%model%matches (local_model, local_scheme)
        else
          same_model = global%model%matches (local_model)
        end if
      else
        same_model = .false.
      end if
    if (delete) then
      call local%process_stack%clear ()
      call local%unselect_model ()
      call local%unset_values ()
    else if (associated (local%model)) then
      call local%ensure_model_copy ()
    end if
    if (.not. same_model .and. associated (global%model)) then
      if (global%model%has_schemes ()) then
        call msg_message ("Restoring model '" // &
          char (global%model%get_name ()) // "'", scheme '" // &
          char (global%model%get_scheme ()) // "'")
      else
        call msg_message ("Restoring model '" // &
          char (global%model%get_name ()) // "'")
      end if
    end if

    end if
    call global%restore_globals (local)
  else
    call local%unselect_model ()
  end if
end if

```

```
end subroutine rt_data_deactivate
```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```
<RT data: rt data: TBP>+≡
  procedure :: copy_globals => rt_data_copy_globals

<RT data: sub interfaces>+≡
  module subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
  end subroutine rt_data_copy_globals

<RT data: procedures>+≡
  module subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
    local%prclib_stack = global%prclib_stack
  end subroutine rt_data_copy_globals
```

This restores global objects for which local modifications should be kept. May also modify (remove) the local objects.

```
<RT data: rt data: TBP>+≡
  procedure :: restore_globals => rt_data_restore_globals

<RT data: sub interfaces>+≡
  module subroutine rt_data_restore_globals (global, local)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(inout) :: local
  end subroutine rt_data_restore_globals

<RT data: procedures>+≡
  module subroutine rt_data_restore_globals (global, local)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(inout) :: local
    global%prclib_stack = local%prclib_stack
    call local%handle_exports (global)
  end subroutine rt_data_restore_globals
```

### 33.2.8 Exported objects

Exported objects are transferred to the global state when a local environment is closed. (For the top-level global data set, there is no effect.)

The current implementation handles only the **results** object, which resolves to the local process stack. The stack elements are appended to the global stack without modification, the local stack becomes empty.

Write names of objects to be exported:

```
<RT data: rt data: TBP>+≡
  procedure :: write_exports => rt_data_write_exports
```

```

<RT data: sub interfaces>+≡
  module subroutine rt_data_write_exports (rt_data, unit)
    class(rt_data_t), intent(in) :: rt_data
    integer, intent(in), optional :: unit
  end subroutine rt_data_write_exports

```

```

<RT data: procedures>+≡
  module subroutine rt_data_write_exports (rt_data, unit)
    class(rt_data_t), intent(in) :: rt_data
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    do i = 1, rt_data%get_n_export ()
      write (u, "(A)") char (rt_data%export(i))
    end do
  end subroutine rt_data_write_exports

```

The number of entries in the export list.

```

<RT data: rt data: TBP>+≡
  procedure :: get_n_export => rt_data_get_n_export

<RT data: sub interfaces>+≡
  module function rt_data_get_n_export (rt_data) result (n)
    class(rt_data_t), intent(in) :: rt_data
    integer :: n
  end function rt_data_get_n_export

<RT data: procedures>+≡
  module function rt_data_get_n_export (rt_data) result (n)
    class(rt_data_t), intent(in) :: rt_data
    integer :: n
    if (allocated (rt_data%export)) then
      n = size (rt_data%export)
    else
      n = 0
    end if
  end function rt_data_get_n_export

```

Return a specific export Append new names to the export list. If a duplicate occurs, do not transfer it.

```

<RT data: rt data: TBP>+≡
  procedure :: append_exports => rt_data_append_exports

<RT data: sub interfaces>+≡
  module subroutine rt_data_append_exports (rt_data, export)
    class(rt_data_t), intent(inout) :: rt_data
    type(string_t), dimension(:), intent(in) :: export
  end subroutine rt_data_append_exports

<RT data: procedures>+≡
  module subroutine rt_data_append_exports (rt_data, export)
    class(rt_data_t), intent(inout) :: rt_data
    type(string_t), dimension(:), intent(in) :: export
    logical, dimension(:), allocatable :: mask
    type(string_t), dimension(:), allocatable :: tmp

```

```

integer :: i, j, n
if (.not. allocated (rt_data%export)) allocate (rt_data%export (0))
n = size (rt_data%export)
allocate (mask (size (export)), source=.false.)
do i = 1, size (export)
mask(i) = all (export(i) /= rt_data%export) &
.and. all (export(i) /= export(:i-1))
end do
if (count (mask) > 0) then
allocate (tmp (n + count (mask)))
tmp(1:n) = rt_data%export(:)
j = n
do i = 1, size (export)
if (mask(i)) then
j = j + 1
tmp(j) = export(i)
end if
end do
call move_alloc (from=tmp, to=rt_data%export)
end if
end subroutine rt_data_append_exports

```

Transfer export-objects from the local rt data to the global rt data, as far as supported.

```

<RT data: rt data: TBP>+≡
  procedure :: handle_exports => rt_data_handle_exports

<RT data: sub interfaces>+≡
  module subroutine rt_data_handle_exports (local, global)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), target :: global
  end subroutine rt_data_handle_exports

<RT data: procedures>+≡
  module subroutine rt_data_handle_exports (local, global)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), target :: global
    type(string_t) :: export
    integer :: i
    if (local%get_n_export () > 0) then
      do i = 1, local%get_n_export ()
        export = local%export(i)
        select case (char (export))
        case ("results")
          call msg_message ("Exporting integration results &
&to outer environment")
          call local%transfer_process_stack (global)
        case default
          call msg_bug ("handle exports: '" &
// char (export) // "' unsupported")
        end select
      end do
    end if
  end subroutine rt_data_handle_exports

```

Export the process stack. One-by-one, take the last process from the local stack and push it on the global stack. Also handle the corresponding result variables: append if the process did not exist yet in the global stack, otherwise update.

TODO: result variables do not work that way yet, require initialization in the global variable list.

```

<RT data: rt data: TBP>+≡
  procedure :: transfer_process_stack => rt_data_transfer_process_stack

<RT data: sub interfaces>+≡
  module subroutine rt_data_transfer_process_stack (local, global)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), target :: global
  end subroutine rt_data_transfer_process_stack

<RT data: procedures>+≡
  module subroutine rt_data_transfer_process_stack (local, global)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), target :: global
    type(process_entry_t), pointer :: process
    type(string_t) :: process_id
  do
    call local%process_stack%pop_last (process)
    if (.not. associated (process)) exit
    process_id = process%get_id ()
    call global%process_stack%push (process)
    call global%process_stack%fill_result_vars (process_id)
    call global%process_stack%update_result_vars &
      (process_id, global%var_list)
  end do
end subroutine rt_data_transfer_process_stack

```

### 33.2.9 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
  procedure :: final => rt_data_global_final

<RT data: sub interfaces>+≡
  module subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
  end subroutine rt_data_global_final

<RT data: procedures>+≡
  module subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
    call global%model_list%final ()
    call global%var_list%final (follow_link=.false.)
    if (associated (global%out_files)) then
      call file_list_final (global%out_files)
    deallocate (global%out_files)
  end subroutine rt_data_global_final

```

```

end if
end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: local_final => rt_data_local_final

<RT data: sub interfaces>+≡
  module subroutine rt_data_local_final (local)
    class(rt_data_t), intent(inout) :: local
  end subroutine rt_data_local_final

<RT data: procedures>+≡
  module subroutine rt_data_local_final (local)
    class(rt_data_t), intent(inout) :: local
    call local%process_stack%clear ()
    call local%model_list%final ()
    call local%var_list%final (follow_link=.false.)
  end subroutine rt_data_local_final

```

### 33.2.10 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
  procedure :: read_model => rt_data_read_model

<RT data: sub interfaces>+≡
  module subroutine rt_data_read_model (global, name, model, scheme)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(string_t), intent(in), optional :: scheme
    type(model_t), pointer, intent(out) :: model
  end subroutine rt_data_read_model

<RT data: procedures>+≡
  module subroutine rt_data_read_model (global, name, model, scheme)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(string_t), intent(in), optional :: scheme
    type(model_t), pointer, intent(out) :: model
    type(string_t) :: filename
    filename = name // ".mdl"
    call global%model_list%read_model &
      (name, filename, global%os_data, model, scheme)
  end subroutine rt_data_read_model

```

Read a UFO model. Create it on the fly if necessary.

```

<RT data: rt data: TBP>+≡
  procedure :: read_ufo_model => rt_data_read_ufo_model

<RT data: sub interfaces>+≡
  module subroutine rt_data_read_ufo_model (global, name, model, ufo_path)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(model_t), pointer, intent(out) :: model
    type(string_t), intent(in), optional :: ufo_path
  end subroutine rt_data_read_ufo_model

<RT data: procedures>+≡
  module subroutine rt_data_read_ufo_model (global, name, model, ufo_path)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(model_t), pointer, intent(out) :: model
    type(string_t), intent(in), optional :: ufo_path
    type(string_t) :: filename
    filename = name // ".ufo.mdl"
    call global%model_list%read_model &
      (name, filename, global%os_data, model, ufo=.true., ufo_path=ufo_path)
  end subroutine rt_data_read_ufo_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
  procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: sub interfaces>+≡
  module subroutine rt_data_init_fallback_model (global, name, filename)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name, filename
  end subroutine rt_data_init_fallback_model

<RT data: procedures>+≡
  module subroutine rt_data_init_fallback_model (global, name, filename)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name, filename
    call global%model_list%read_model &
      (name, filename, global%os_data, global%fallback_model)
  end subroutine rt_data_init_fallback_model

```

Activate a model: assign the current-model pointer and set the model name in the variable list. If necessary, read the model from file. Link the global variable list to the model variable list.

```

<RT data: rt data: TBP>+≡
  procedure :: select_model => rt_data_select_model

<RT data: sub interfaces>+≡
  module subroutine rt_data_select_model (global, name, scheme, ufo, ufo_path)
    class(rt_data_t), intent(inout), target :: global
    type(string_t), intent(in) :: name
    type(string_t), intent(in), optional :: scheme

```

```

logical, intent(in), optional :: ufo
type(string_t), intent(in), optional :: ufo_path
end subroutine rt_data_select_model

```

*(RT data: procedures)*+≡

```

### 33.2.11 Managing Variables

Return a pointer to the currently active variable list. If there is no model, this is the global variable list. If there is one, it is the model variable list, which should be linked to the former.

```

<RT data: rt data: TBP>+≡
  procedure :: get_var_list_ptr => rt_data_get_var_list_ptr

<RT data: sub interfaces>+≡
  module function rt_data_get_var_list_ptr (global) result (var_list)
    class(rt_data_t), intent(in), target :: global
    type(var_list_t), pointer :: var_list
  end function rt_data_get_var_list_ptr

<RT data: procedures>+≡
  module function rt_data_get_var_list_ptr (global) result (var_list)
    class(rt_data_t), intent(in), target :: global
    type(var_list_t), pointer :: var_list
    if (associated (global%model)) then
      var_list => global%model%get_var_list_ptr ()
    else
      var_list => global%var_list
    end if
  end function rt_data_get_var_list_ptr

```

Initialize a local variable: append it to the current variable list. No initial value, yet.

```

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

### 33.3 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

We would like to put this in the `me_methods` folder but it also depends on `gosam` and `openloops`, so it is unclear where to put it.

```
<dispatch_me_methods.f90>≡
  <File header>

  module dispatch_me_methods

    <Use strings>
    <Use debug>
    use physics_defs, only: BORN
    use diagnostics
    use sm_qcd
    use variables, only: var_list_t
    use models
    use model_data

    use prc_core_def
    use prc_core
    use prc_test_core
    use prc_template_me
    use prc_test
    use prc_omega
    use prc_external
    use prc_gosam
    use prc_openloops
    use prc_recola
    use prc_threshold

    <Standard module head>

    <Dispatch ME methods: public>

    interface
      <Dispatch ME methods: sub interfaces>
    end interface

    contains

    <Dispatch ME methods: main procedures>

  end module dispatch_me_methods

### 33.3.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model. Gfortran 7/8/9 bug, has to remain in the main module:

```

<Dispatch ME methods: public>+≡
public :: dispatch_core

<Dispatch ME methods: main procedures>+≡
subroutine dispatch_core (core, core_def, model, &
helicity_selection, qcd, use_color_factors, has_beam_pol)
class(prc_core_t), allocatable, intent(inout) :: core
class(prc_core_def_t), intent(in) :: core_def
class(model_data_t), intent(in), target, optional :: model
type(helicity_selection_t), intent(in), optional :: helicity_selection
type(qcd_t), intent(in), optional :: qcd
logical, intent(in), optional :: use_color_factors
logical, intent(in), optional :: has_beam_pol
select type (core_def)
type is (prc_test_def_t)
allocate (test_t :: core)
type is (template_me_def_t)
allocate (prc_template_me_t :: core)
select type (core)
type is (prc_template_me_t)
call core%set_parameters (model)
end select
class is (omega_def_t)
if (.not. allocated (core)) allocate (prc_omega_t :: core)
select type (core)
type is (prc_omega_t)
call core%set_parameters (model, &
helicity_selection, qcd, use_color_factors)
end select
type is (gosam_def_t)
if (.not. allocated (core)) allocate (prc_gosam_t :: core)
select type (core)
type is (prc_gosam_t)
call core%set_parameters (qcd)

```

```

end select
type is (openloops_def_t)
if (.not. allocated (core)) allocate (prc_openloops_t :: core)
select type (core)
type is (prc_openloops_t)
call core%set_parameters (qcd)
end select
type is (recola_def_t)
if (.not. allocated (core)) allocate (prc_recola_t :: core)
select type (core)
type is (prc_recola_t)
call core%set_parameters (qcd, model)
end select
type is (prc_external_test_def_t)
if (.not. allocated (core)) allocate (prc_external_test_t :: core)
select type (core)
type is (prc_external_test_t)
call core%set_parameters (qcd, model)
end select
type is (threshold_def_t)
if (.not. allocated (core)) allocate (prc_threshold_t :: core)
select type (core)
type is (prc_threshold_t)
call core%set_parameters (qcd, model)
call core%set_beam_pol (has_beam_pol)
end select
class default
call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

### 33.3.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

*(Dispatch ME methods: public)* +≡

```

public :: dispatch_core_update
public :: dispatch_core_restore

```

*(Dispatch ME methods: sub interfaces)* ≡

```

module subroutine dispatch_core_update &
  (core, model, helicity_selection, qcd, saved_core)
class(prc_core_t), allocatable, intent(inout) :: core
class(model_data_t), intent(in), optional, target :: model
type(helicity_selection_t), intent(in), optional :: helicity_selection
type(qcd_t), intent(in), optional :: qcd
class(prc_core_t), allocatable, intent(inout), optional :: saved_core
end subroutine dispatch_core_update
module subroutine dispatch_core_restore (core, saved_core)

```

```

class(prc_core_t), allocatable, intent(inout) :: core
class(prc_core_t), allocatable, intent(inout) :: saved_core
end subroutine dispatch_core_restore

<Dispatch ME methods: procedures>≡
module subroutine dispatch_core_update &

end if
end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method,

which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

## Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

This is re-exported by the UT module.

```

<Process configurations: public test auxiliary>≡
  public :: prepare_test_library

<Process configurations: test auxiliary>≡
  subroutine prepare_test_library (global, libname, mode, procname)
    type(rt_data_t), intent(inout), target :: global

## 33.5 Compilation

This module manages compilation and loading of of process libraries. It is needed as a separate module because integration depends on it.

```
<compilations.f90>≡  
  <File header>  
  
  module compilations  
  
    <Use strings>  
    use os_interface  
    use variables, only: var_list_t  
    use model_data  
    use process_libraries  
    use prclib_stacks  
    use rt_data  
  
    <Standard module head>  
  
    <Compilations: public>  
  
    <Compilations: types>  
  
    <Compilations: parameters>  
  
    interface  
    <Compilations: sub interfaces>  
    end interface  
  
  end module compilations  
  
<compilations_sub.f90>≡  
  <File header>  
  
  submodule (compilations) compilations_s  
  
    use io_units  
    use system_defs, only: TAB  
    use system_dependencies, only: OS_IS_DARWIN  
    use diagnostics  
    !!! Intel oneAPI 2022/23 regression workaround  
    use variables, only: var_list_t  
  
    implicit none  
  
    contains  
  
    <Compilations: procedures>  
  
  end submodule compilations_s
```

### 33.5.1 The data type

The compilation item handles the compilation and loading of a single process library.

```
<Compilations: public>≡
  public :: compilation_item_t

<Compilations: types>≡
  type :: compilation_item_t
  private
  type(string_t) :: libname
  type(string_t) :: static_external_tag
  type(process_library_t), pointer :: lib => null ()
  logical :: recompile_library = .false.
  logical :: verbose = .false.
  logical :: use_workspace = .false.
  type(string_t) :: workspace
  contains
  <Compilations: compilation item: TBP>
  end type compilation_item_t
```

Initialize.

Set flags and global properties of the library. Establish the workspace name, if defined.

```
<Compilations: compilation item: TBP>≡
  procedure :: init => compilation_item_init

<Compilations: sub interfaces>≡
  module subroutine compilation_item_init (comp, libname, stack, var_list)
    class(compilation_item_t), intent(out) :: comp
    type(string_t), intent(in) :: libname
    type(prclib_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in) :: var_list
  end subroutine compilation_item_init

<Compilations: procedures>≡
  module subroutine compilation_item_init (comp, libname, stack, var_list)
    class(compilation_item_t), intent(out) :: comp
    type(string_t), intent(in) :: libname
    type(prclib_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in) :: var_list
    comp%libname = libname
    comp%lib => stack%get_library_ptr (comp%libname)
    if (.not. associated (comp%lib)) then
      call msg_fatal ("Process library ' " // char (comp%libname) &
        // "' has not been declared.")
    end if
    comp%recompile_library = &
      var_list%get_lval (var_str ("?recompile_library"))
    comp%verbose = &
      var_list%get_lval (var_str ("?me_verbose"))
    comp%use_workspace = &
      var_list%is_known (var_str ("$compile_workspace"))
    if (comp%use_workspace) then
      comp%workspace = &
```

```

var_list%get_sval (var_str (" $compile_workspace"))
if (comp%workspace == "") comp%use_workspace = .false.
else
  comp%workspace = ""
end if
end subroutine compilation_item_init

```

Compile the current library. The force flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

```

<Compilations: compilation item: TBP>+≡
  procedure :: compile => compilation_item_compile

<Compilations: sub interfaces>+≡
  module subroutine compilation_item_compile &
    (comp, model, os_data, force, recompile)
    class(compilation_item_t), intent(inout) :: comp
    class(model_data_t), intent(in), target :: model
    type(os_data_t), intent(in) :: os_data
    logical, intent(in) :: force, recompile
  end subroutine compilation_item_compile

<Compilations: procedures>+≡

  module subroutine compilation_item_success (comp)
    class(compilation_item_t), intent(in) :: comp
  end subroutine compilation_item_success
<Compilations: procedures>+≡
  module subroutine compilation_item_success (comp)
    class(compilation_item_t), intent(in) :: comp
    if (associated (comp%lib)) then

```

```

call msg_message ("Process library '" // char (comp%libname) &
// "': ... success.")
else
call msg_fatal ("Process library '" // char (comp%libname) &
// "': ... failure.")
end if
end subroutine compilation_item_success

```

### 33.5.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
  public :: compile_library

<Compilations: sub interfaces>+≡
  module subroutine compile_library (libname, global)
    type(string_t), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
  end subroutine compile_library

<Compilations: procedures>+≡
  module subroutine compile_library (libname, global)
    type(string_t), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
    type(compilation_item_t) :: comp
    logical :: force, recompile
    force = &
    global%var_list%get_lval (var_str ("?rebuild_library"))
    recompile = &
    global%var_list%get_lval (var_str ("?recompile_library"))
    if (associated (global%model)) then
      call comp%init (libname, global%prclib_stack, global%var_list)
      call comp%compile (global%model, global%os_data, force, recompile)
      if (signal_is_pending ()) return
      call comp%load (global%os_data)
      if (signal_is_pending ()) return
    else
      call msg_fatal ("Process library compilation: " &
// " model is undefined.")
    end if
    call comp%success ()
  end subroutine compile_library

```

### 33.5.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```

<Compilations: public>+≡

```

```

    public :: compilation_t
<Compilations: types>+≡
    type :: compilation_t
    private
    type(string_t) :: exe_name
    type(string_t), dimension(:), allocatable :: lib_name
    contains
    <Compilations: compilation: TBP>
    end type compilation_t

```

Output.

```

<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write

<Compilations: sub interfaces>+≡
    module subroutine compilation_write (object, unit)
    class(compilation_t), intent(in) :: object
    integer, intent(in), optional :: unit
    end subroutine compilation_write

<Compilations: procedures>+≡
    module subroutine compilation_write (object, unit)
    class(compilation_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Compilation object:"
    write (u, "(3x,3A)") "executable          = '", &
    char (object%exe_name), "'"
    write (u, "(3x,A)", advance="no") "process libraries ="
    do i = 1, size (object%lib_name)
    write (u, "(1x,3A)", advance="no") "'", char (object%lib_name(i)), "'"
    end do
    write (u, *)
    end subroutine compilation_write

```

Initialize: we know the names of the executable and of the libraries. Optionally, we may provide a workspace directory.

```

<Compilations: compilation: TBP>+≡
    procedure :: init => compilation_init

<Compilations: sub interfaces>+≡
    module subroutine compilation_init (compilation, exe_name, lib_name)
    class(compilation_t), intent(out) :: compilation
    type(string_t), intent(in) :: exe_name
    type(string_t), dimension(:), intent(in) :: lib_name
    end subroutine compilation_init

<Compilations: procedures>+≡
    module subroutine compilation_init (compilation, exe_name, lib_name)
    class(compilation_t), intent(out) :: compilation
    type(string_t), intent(in) :: exe_name
    type(string_t), dimension(:), intent(in) :: lib_name
    compilation%exe_name = exe_name

```

```

// " -f " // compilation%exe_name // ".makefile")
  end subroutine compilation_make_clean_exe
```

### 33.5.4 API for executable compilation

This is a shorthand for compiling and loading an executable, including the enclosed libraries. The `compile` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```
(Compilations: public) +=  
  public :: compile_executable  
  
(Compilations: sub interfaces) +=  
  module subroutine compile_executable (exename, libname, global)  
    type(string_t), intent(in) :: exename  
    type(string_t), dimension(:), intent(in) :: libname  
    type(rt_data_t), intent(inout), target :: global  
    end subroutine compile_executable  
  
(Compilations: procedures) +=  
  module subroutine compile_executable (exename, libname, global)  
    type(string_t), intent(in) :: exename  
    type(string_t), dimension(:), intent(in) :: libname  
    type(rt_data_t), intent(inout), target :: global  
    type(compilation_t) :: compilation  
    type(compilation_item_t) :: item  
    type(string_t) :: ext_libtag  
    logical :: force, recompile, verbose  
    integer :: i  
    ext_libtag = ""  
    force = &  
    global%var_list%get_lval (var_str ("?rebuild_library"))  
    recompile = &  
    global%var_list%get_lval (var_str ("?recompile_library"))  
    verbose = &  
    global%var_list%get_lval (var_str ("?me_verbose"))  
    call compilation%init (exename, [libname])  
    if (signal_is_pending ()) return  
    call compilation%write_dispatcher ()  
    if (signal_is_pending ()) return  
    do i = 1, size (libname)  
      call item%init (libname(i), global%prclib_stack, global%var_list)  
      call item%compile (global%model, global%os_data, &  
        force=force, recompile=recompile)  
      ext_libtag = "" // item%lib%get_static_modelname (global%os_data)  
      if (signal_is_pending ()) return  
      call item%success ()  
    end do  
    call compilation%write_makefile &  
      (global%os_data, ext_libtag=ext_libtag, verbose=verbose)  
    if (signal_is_pending ()) return  
    call compilation%make_compile (global%os_data)  
    if (signal_is_pending ()) return

    end subroutine compile_executable
```

### 33.5.5 Unit Tests

Test module, followed by the stand-alone unit-test procedures.

```
<compilations_ut.f90>≡  
  <File header>  
  
  module compilations_ut  
    use unit_tests  
    use compilations_uti  
  
    <Standard module head>  
  
    <Compilations: public test>  
  
    contains  
  
    <Compilations: test driver>  
  
  end module compilations_ut  
<compilations_uti.f90>≡  
  <File header>  
  
  module compilations_uti  
  
    <Use strings>  
    use io_units  
    use models  
    use rt_data  
    use process_configurations_ut, only: prepare_test_library  
  
    use compilations  
  
    <Standard module head>  
  
    <Compilations: test declarations>  
  
    contains  
  
    <Compilations: tests>  
  
  end module compilations_uti
```

API: driver for the unit tests below.

```
<Compilations: public test>≡  
  public :: compilations_test  
<Compilations: test driver>≡  
  subroutine compilations_test (u, results)  
    integer, intent(in) :: u  
    type(test_results_t), intent(inout) :: results  
    <Compilations: execute tests>  
  end subroutine compilations_test
```

## Intrinsic Matrix Element

Compile an intrinsic test matrix element (`prc_test` type).

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```
<Compilations: execute tests>≡
  call test (compilations_1, "compilations_1", &
    "intrinsic test processes", &
    u, results)

<Compilations: test declarations>≡
  public :: compilations_1

<Compilations: tests>≡
  subroutine compilations_1 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname
    type(rt_data_t), target :: global

    write (u, "(A)")  "* Test output: compilations_1"
    write (u, "(A)")  "* Purpose: configure and compile test process"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()

    libname = "compilation_1"
    procname = "prc_comp_1"
    call prepare_test_library (global, libname, 1, [procname])

    call compile_library (libname, global)

    call global%write_libraries (u)

    call global%final ()
    call syntax_model_file_final ()

    write (u, "(A)")
    write (u, "(A)")  "* Test output end: compilations_1"

  end subroutine compilations_1
```

## External Matrix Element

Compile an external test matrix element (`omega` type)

```
<Compilations: execute tests>+≡
  call test (compilations_2, "compilations_2", &
    "external process (omega)", &
    u, results)

<Compilations: test declarations>+≡
  public :: compilations_2
```

```

<Compilations: tests>+≡
subroutine compilations_2 (u)
integer, intent(in) :: u
type(string_t) :: libname, procname
type(rt_data_t), target :: global

write (u, "(A)")  "* Test output: compilations_2"
write (u, "(A)")  "* Purpose: configure and compile test process"
write (u, "(A)")

call syntax_model_file_init ()

```

## External Matrix Element

Compile an external test matrix element ( $\omega$  type) and incorporate this in a new static WHIZARD executable. In this version, we use the wrapper `compile_executable` procedure.

```

<Compilations: static tests>+≡
  call test (compilations_static_2, "compilations_static_2", &
    "static executable: shortcut", &
    u, results)

<Compilations: test declarations>+≡
  public :: compilations_static_2

<Compilations: tests>+≡
  subroutine compilations_static_2 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    logical :: exist
    integer :: u_file

    write (u, "(A)")  "* Test output: compilations_static_2"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library and compile"

```

```

write (u, "(A)")

call syntax_model_file_init ()

call global%global_init ()
call global%set_log (var_str ("?omega_openmp"), &
.false., is_known = .true.)

libname = "compilations_static_2_lib"
procname = "prc_comp_stat_2"
exename = "compilations_static_2"

call prepare_test_library (global, libname, 2, [procname,procname])

call compile_executable (exename, [libname], global)

write (u, "(A)")  "* Check executable (should be present)"
write (u, "(A)")

inquire (file = char (exename), exist = exist)
write (u, "(A,A,L1)") char (exename), " exists = ", exist

## 33.6 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

```
<integrations.f90>≡  
  <File header>  
  
  module integrations  
  
    <Use kinds>  
    <Use strings>  
    <Use debug>

```

### 33.6.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

<Integrations: public>≡
  public :: integration_t

<Integrations: types>≡
  type :: integration_t
  private
  type(string_t) :: process_id
  type(string_t) :: run_id
  type(process_t), pointer :: process => null ()
  logical :: rebuild_phs = .false.
  logical :: ignore_phs_mismatch = .false.
  logical :: phs_only = .false.
  logical :: process_has_me = .true.
  integer :: n_calls_test = 0
  logical :: vis_history = .true.
  type(string_t) :: history_filename
  type(string_t) :: log_filename
  type(helicity_selection_t) :: helicity_selection
  logical :: use_color_factors = .false.
  logical :: has_beam_pol = .false.
  logical :: combined_integration = .false.
  type(iteration_multipliers_t) :: iteration_multipliers
  type(nlo_settings_t) :: nlo_settings
  contains
  <Integrations: integration: TBP>
end type integration_t

```

### 33.6.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied. Gfortran7/8/9 bug, has to remain in the main module:

```

<Integrations: integration: TBP>≡
  procedure :: create_process => integration_create_process

<Integrations: main procedures>≡
  subroutine integration_create_process (intg, process_id, global)
    class(integration_t), intent(out) :: intg
    type(rt_data_t), intent(inout), optional, target :: global
    type(string_t), intent(in) :: process_id
    type(process_entry_t), pointer :: process_entry
    if (debug_on) call msg_debug (D_CORE, "integration_create_process")
    intg%process_id = process_id
    if (present (global)) then
      allocate (process_entry)
      intg%process => process_entry%process_t
      call global%process_stack%push (process_entry)
    else
      allocate (process_t :: intg%process)
    end if
  end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the local stack directly. The intent(inout) attribute for the local data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

```

<Integrations: integration: TBP>+≡
  procedure :: init_process => integration_init_process

<Integrations: sub interfaces>≡
  module subroutine integration_init_process (intg, local)
    class(integration_t), intent(inout) :: intg
    type(rt_data_t), intent(inout), target :: local
  end subroutine integration_init_process

<Integrations: procedures>≡
  module subroutine integration_init_process (intg, local)
    class(integration_t), intent(inout) :: intg
    type(rt_data_t), intent(inout), target :: local
    type(string_t) :: model_name
    type(model_t), pointer :: model
    class(model_data_t), pointer :: model_instance
    type(var_list_t), pointer :: var_list

```

```

if (debug_on) call msg_debug (D_CORE, "integration_init_process")

### 33.6.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

<Integrations: integration: TBP>+≡
  procedure :: evaluate => integration_evaluate

<Integrations: sub interfaces>+≡
  module subroutine integration_evaluate &
    (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
  end subroutine integration_evaluate

<Integrations: procedures>+≡
  module subroutine integration_evaluate &
    (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
    integer :: n_calls, n_it
    logical :: adapt_grids, adapt_weights, final
    n_it = it_list%get_n_it (pass)
    n_calls = it_list%get_n_calls (pass)
    adapt_grids = it_list%adapt_grids (pass)
    adapt_weights = it_list%adapt_weights (pass)
    final = pass == it_list%get_n_pass ()
    call process_instance%integrate ( &
      i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
      final, pacify)
  end subroutine integration_evaluate

```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

```

<Integrations: integration: TBP>+≡
  procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: sub interfaces>+≡
  module subroutine integration_make_iterations_list (intg, it_list)
    class(integration_t), intent(in) :: intg
    type(iterations_list_t), intent(out) :: it_list
  end subroutine integration_make_iterations_list

<Integrations: procedures>+≡
  module subroutine integration_make_iterations_list (intg, it_list)
    class(integration_t), intent(in) :: intg
    type(iterations_list_t), intent(out) :: it_list
    integer :: pass, n_pass
    integer, dimension(:), allocatable :: n_it, n_calls
    logical, dimension(:), allocatable :: adapt_grids, adapt_weights
    n_pass = intg%process%get_n_pass_default ()
    allocate (n_it (n_pass), n_calls (n_pass))

```

```

allocate (adapt_grids (n_pass), adapt_weights (n_pass))
do pass = 1, n_pass
  n_it(pass)      = intg%process%get_n_it_default (pass)
  n_calls(pass)   = intg%process%get_n_calls_default (pass)
  adapt_grids(pass) = intg%process%adapt_grids_default (pass)
  adapt_weights(pass) = intg%process%adapt_weights_default (pass)
end do
call it_list%init (n_it, n_calls, &
  adapt_grids = adapt_grids, adapt_weights = adapt_weights)
end subroutine integration_make_iterations_list

```

In NLO calculations, the individual components might scale very differently with the number of calls. This especially applies to the real-subtracted component, which usually fluctuates more than the Born and virtual component, making it a bottleneck of the calculation. Thus, the calculation is throttled twice, first by the number of calls for the real component, second by the number of surplus calls of computation-intense virtual matrix elements. Therefore, we want to set a different number of calls for each component, which is done by the subroutine `integration_apply_call_multipliers`.

*(Integrations: integration: TBP)+≡*

```

procedure :: init_iteration_multipliers => &

Return the process pointer (needed by simulate):

```

<Integrations: integration: TBP>+≡
  procedure :: get_process_ptr => integration_get_process_ptr

<Integrations: sub interfaces>+≡
  module function integration_get_process_ptr (intg) result (ptr)
  class(integration_t), intent(in) :: intg
  type(process_t), pointer :: ptr
  end function integration_get_process_ptr

<Integrations: procedures>+≡
  module function integration_get_process_ptr (intg) result (ptr)
  class(integration_t), intent(in) :: intg
  type(process_t), pointer :: ptr
  ptr => intg%process
  end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the `global` environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the process object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

### Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the  $2 \rightarrow 2$  process  $ss \rightarrow ss$  with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (33.1)$$

$c$  is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (33.2)$$

$f$  is the flux of the incoming particles with mass  $m = 125 \text{ GeV}$  and energy  $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (33.3)$$

$\Phi_2$  is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (33.4)$$

The squared matrix element  $|M|^2$  is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (33.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

### Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function  $f(x) = x$  for both beams. Together with the  $1/x_1x_2$  factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the  $m_s$  mass which we set to zero here.

```

### Integration with sign change

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`. The weight that is applied changes the sign in half of phase space. The weight is  $-3$  and  $1$ , respectively, so the total result is equal to the original, but negative sign.

The efficiency should (approximately) become the average of  $1$  and  $1/3$ , that is  $2/3$ .

```

### 33.7.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```

<Event streams: types>≡
  type :: event_stream_entry_t
  class(eio_t), allocatable :: eio
  end type event_stream_entry_t

```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```

<Event streams: public>≡
  public :: event_stream_array_t

<Event streams: types>+≡
  type :: event_stream_array_t
  type(event_stream_entry_t), dimension(:), allocatable :: entry
  integer :: i_in = 0
  contains
  <Event streams: event stream array: TBP>
  end type event_stream_array_t

```

Output.

```

<Event streams: event stream array: TBP>≡
  procedure :: write => event_stream_array_write

<Event streams: sub interfaces>≡
  module subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
  end subroutine event_stream_array_write

<Event streams: procedures>≡
  module subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event stream array:"
    if (allocated (object%entry)) then
      select case (size (object%entry))
      case (0)
        write (u, "(3x,A)") "[empty]"
      case default
        do i = 1, size (object%entry)
          if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
          call object%entry(i)%eio%write (u)
        end do
      end select
    else
      write (u, "(3x,A)") "[undefined]"
    end if
  end subroutine event_stream_array_write

```

Check if there is content.

```

<Event streams: event stream array: TBP>+≡
  procedure :: is_valid => event_stream_array_is_valid

```

```

<Event streams: sub interfaces>+≡
  module function event_stream_array_is_valid (es_array) result (flag)
    class(event_stream_array_t), intent(in) :: es_array
    logical :: flag

        call es_array%entry(i)%eio%final ()
      end do
    end if
  end subroutine event_stream_array_final

```

Initialization. We use a generic sample name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

```

<Event streams: event stream array: TBP>+≡

## 33.8 Restricted Subprocesses

This module provides an automatic means to construct restricted subprocesses of a current process object. A restricted subprocess has the same initial and final state as the current process, but a restricted set of Feynman graphs.

The actual application extracts the set of resonance histories that apply to the process and uses this to construct subprocesses that are restricted to one of those histories, respectively. The resonance histories are derived from the phase-space setup. This implies that the method is tied to the OMega matrix element generator and to the wood phase space method.

The processes are collected in a new process library that is generated on-the-fly.

The `resonant_subprocess_t` object is intended as a component of the event record, which manages all operations regarding resonance handling.

The run-time calculations are delegated to an event transform (`evt_resonance_t`), as a part of the event transform chain. The transform selects one (or none) of the resonance histories, given the momentum configuration, computes matrix elements and inserts resonances into the particle set.

### 33.8.1 Process configuration

We extend the `process_configuration_t` by another method for initialization that takes into account a resonance history.

```

<Restricted subprocesses: public>≡
  public :: restricted_process_configuration_t

<Restricted subprocesses: types>≡
  type, extends (process_configuration_t) :: restricted_process_configuration_t
  private
  contains
  <Restricted subprocesses: restricted process configuration: TBP>
  end type restricted_process_configuration_t

```

Resonance history as an argument. We use it to override the `restrictions` setting in a local variable list. Since we can construct the restricted process only by using OMega, we enforce it as the ME method. Other settings are taken from the variable list. The model will most likely be set, but we insert a safeguard just in case.

Also, the resonant subprocess should not itself spawn resonant subprocesses, so we unset `?resonance_history`.

We have to create a local copy of the model here, via pointer allocation. The reason is that the model as stored (via pointer) in the base type will be finalized and deallocated.

The current implementation will generate a LO process, the optional `nlo_process` is unset. (It is not obvious whether the construction makes sense beyond LO.)

```

<Restricted subprocesses: restricted process configuration: TBP>≡
  procedure :: init_resonant_process

```

```

### 33.8.2 Resonant-subprocess set manager

This data type enables generation of a library of resonant subprocesses for a given master process, and it allows for convenient access. The matrix elements from the subprocesses can be used as channel weights to activate a selector, which then returns a preferred channel via some random number generator.

```

<Restricted subprocesses: public>+≡

```

```

    public :: resonant_subprocess_set_t

res_history_set
res_history_set = prc_set%res_history_set
end function resonant_subprocess_set_get_resonance_history_set

```

### 33.8.4 Library for the resonance history set

The recommended library name: append `_R` to the process name.

*<Restricted subprocesses: public>+≡*

```

public :: get_libname_res

```

*<Restricted subprocesses: sub interfaces>+≡*

```

elemental module function get_libname_res (proc_id) result (libname)
type(string_t), intent(in) :: proc_id
type(string_t) :: libname
end function get_libname_res

```

*<Restricted subprocesses: procedures>+≡*

```

elemental module function get_libname_res (proc_id) result (libname)
type(string_t), intent(in) :: proc_id
type(string_t) :: libname
libname = proc_id // "_R"
end function get_libname_res

```

Here we scan the global process library whether any processes require resonant subprocesses to be constructed. If yes, create process objects with phase space and construct the process libraries as usual. Then append the library names to the array.

The temporary integration objects should carry the `phs_only` flag. We set this in the local environment.

Once a process object with resonance histories (derived from phase space) has been created, we extract the resonance histories and use them, together with the process definition, to create the new library.

Finally, compile the library.

```

<Restricted subprocesses: public>+≡
  public :: spawn_resonant_subprocess_libraries

<Restricted subprocesses: sub interfaces>+≡

### 33.8.5 Process objects and instances

Prepare process objects for all entries in the resonant-subprocesses library. The process objects are appended to the global process stack. A local environment can be used where we place temporary variable settings that affect process-object generation. We initialize the processes, such that we can evaluate matrix elements, but we do not need to integrate them.

The internal procedure `prepare_process` is an abridged version of the procedure with this name in the `simulations` module.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: prepare_process_objects &
  => resonant_subprocess_set_prepare_process_objects

```

### 33.8.6 Event transform connection

The idea is that the resonance-insertion event transform has been allocated somewhere (namely, in the standard event-transform chain), but we maintain a link such that we can inject matrix-element results event by event. The event transform holds a selector, to choose one of the resonance histories (or none), and it manages resonance insertion for the particle set.

The data that the event transform requires can be provided here. The resonance history set has already been assigned with the `dispatch` initializer. Here, we supply the set of subprocess instances that we have generated (see above). The master-process instance is set when we `connect` the transform by the standard method.

```
<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: connect_transform => &
    resonant_subprocess_set_connect_transform
```

```
<Restricted subprocesses: sub interfaces>+≡
  module subroutine resonant_subprocess_set_connect_transform (prc_set, evt)

integer, intent(in), optional :: unit
logical, intent(in), optional :: testflag
end subroutine resonant_subprocess_set_dump_instances
<Restricted subprocesses: procedures>+≡
module subroutine resonant_subprocess_set_dump_instances &
(prc_set, unit, testflag)
class(resonant_subprocess_set_t), intent(inout) :: prc_set
integer, intent(in), optional :: unit
logical, intent(in), optional :: testflag
integer :: i, n, u
u = given_output_unit (unit)
write (u, "(A)") "*** Process instances of resonant subprocesses"
write (u, *)
n = size (prc_set%subprocess)
do i = 1, n
associate (instance => prc_set%instance(i)%p)
call instance%write (u, testflag)
write (u, *)
write (u, *)
end associate
end do
end subroutine resonant_subprocess_set_dump_instances

```

Inject the current kinematics configuration, reading from the previous event transform or from the process instance.

```

<Restricted subprocesses: resonant subprocess set: TBP>+≡
  procedure :: fill_momenta => resonant_subprocess_set_fill_momenta

<Restricted subprocesses: sub interfaces>+≡
  module subroutine resonant_subprocess_set_fill_momenta (prc_set)
    class(resonant_subprocess_set_t), intent(inout) :: prc_set
  end subroutine resonant_subprocess_set_fill_momenta

## 33.9 Simulation

This module manages simulation: event generation and reading/writing of event files. The `simulation` object is intended to be used (via a pointer) outside of WHIZARD, if events are generated individually by an external driver.

```

If events have been dropped during simulation of weighted events, issue a message here. If a fraction  $n\_dropped / n\_total$  of the events fail the cuts, we keep generating new ones until we have  $n\_total$  events with `weight > 0`. Thus, the total sum of weights will be a fraction of  $n\_dropped / n\_total$  too large. However, we do not know how many events will pass or fail the cuts prior to generating them so we leave it to the user to correct for this factor.

    end if
  end subroutine counter_show_mean_and_variance

```

Count an event. The weight and event source are optional; by default we assume that the event has been generated and has positive weight.

The optional integer `n_dropped` counts weighted events with weight zero that were encountered while generating the current event, but dropped (because of their zero weight). Accumulating this number allows for renormalizing event weight sums in histograms, after the generation step has been completed.

### 33.9.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

```

<Simulations: types>+≡
  type :: core_safe_t
  class(prc_core_t), allocatable :: core
  end type core_safe_t

```

### 33.9.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. `use_process`

implies that the process should already exist as an object in the process stack. If integration is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

```

<Simulations: procedures>+≡
  subroutine prepare_process &

```

### 33.9.5 Simulation-entry object

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares an MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocates the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

For the purpose of NLO events, `entry_t` contains a pointer list to other simulation-entries. This is due to the fact that we have to associate an event for each component of the fixed order simulation, i.e. one  $N$ -particle event and  $N_{\text{phs}}$   $N + 1$ -particle events. However, all entries share the same event transforms.

*(Simulations: types)+≡*

```

type, extends (event_t) :: entry_t
private

```

### Simulation-entry initialization

Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the `process_instance` pointer. Assign data by looking at the process object and at the environment.

If `n_alt` is set, we prepare for additional alternate sqme and weight entries.

The `compile` flag is only false if we do not need the Whizard process at all, just its definition. In that case, we skip process initialization.

Otherwise, and if the process object is not found initially: if `integrate` is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If `generate` is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

If `resonance_history` is set, we create a separate process library which contains all possible restricted subprocesses with distinct resonance histories. These processes will not be integrated, but their matrix element codes are used for determining probabilities of resonance histories. Note that this can work only if the process method is OMega, and the phase-space method is 'wood'.

When done, we assign the `instance` and `process` pointers of the base type by the `connect` method, so we can reference them later.

TODO: In case of NLO event generation, copying the configuration from the master process is rather intransparent. For instance, we override the process var list by the global var list.

### Event-transform initialization

Part of simulation-entry initialization: dispatch event transforms (decay, shower) as requested. If a transform is not applicable or switched off via some variable, it will be skipped.

Regarding resonances/decays: these two transforms are currently mutually exclusive. Resonance insertion will not be applied if there is an unstable particle in the game.

The initial particle set is the output of the trivial transform; this has already been applied when the transforms listed here are encountered. Each transform takes a particle set and produces a new one, with one exception: the decay module takes its input from the process object, ignoring the trivial transform. (Reason: spin correlations.) Therefore, the decay module must be first in line.

Settings that we don't or can't support (yet) are rejected by the embedded call to `event_transforms_check`.

```

Update and restore the process core that this entry accesses, when parameters change. If explicit arguments `model`, `qcd`, or `helicity_selection` are provided, use those. Otherwise use the parameters stored in the process object.

These two procedures come with a caching mechanism which guarantees that the current core object is saved when calling `update_process`, and restored by calling `restore_process`. If the flag `saved` is unset, saving is skipped, and the `restore` procedure should not be called.

### 33.9.6 Handling resonant subprocesses

Resonant subprocesses are required if we want to determine resonance histories when generating events. The feature is optional, to be switched on by the user.

This procedure initializes a new, separate process library that contains copies of the current process, restricted to the relevant resonance histories. (If this library exists already, it is just kept.) The histories can be extracted from the process object.

The code has to match the assignments in `create_resonant_subprocess_library`. The library may already exist – in that case, here it will be recovered without recompilation.

```

<Simulations: entry: TBP>+≡
procedure :: setup_resonant_subprocesses &
=> entry_setup_resonant_subprocesses

```

```

<Simulations: sub interfaces>+=
module subroutine entry_setup_resonant_subprocesses (entry, global, process)
class(entry_t), intent(inout) :: entry
type(rt_data_t), intent(inout), target :: global
type(process_t), intent(in), target :: process
end subroutine entry_setup_resonant_subprocesses

```

```

<Simulations: procedures>+=

end if
end subroutine entry_setup_resonant_subprocesses

```

Compile the resonant-subprocesses library. The library is assumed to be the current library in the global object. This is a simple wrapper.

```

<Simulations: entry: TBP>+=
procedure :: compile_resonant_subprocesses &
=> entry_compile_resonant_subprocesses

```

```

<Simulations: sub interfaces>+=

```

```

module subroutine entry_compile_resonant_subprocesses (entry, global)
class(entry_t), intent(inout) :: entry
type(rt_data_t), intent(inout), target :: global
end subroutine entry_compile_resonant_subprocesses

```

*<Simulations: procedures>+≡*

```

module subroutine entry_compile_resonant_subprocesses (entry, global)
class(entry_t), intent(inout) :: entry
type(rt_data_t), intent(inout), target :: global
call entry%resonant_subprocess_set%compile_library (global)
end subroutine entry_compile_resonant_subprocesses

```

Prepare process objects for the resonant-subprocesses library. The process objects are appended to the global process stack. We initialize the processes, such that we can evaluate matrix elements, but we do not need to integrate them.

*<Simulations: entry: TBP>+≡*

```

procedure :: prepare_resonant_subprocesses &
=> entry_prepare_resonant_subprocesses

```

*<Simulations: sub interfaces>+≡*

```

module subroutine entry_prepare_resonant_subprocesses (entry, local, global)
class(entry_t), intent(inout) :: entry
type(rt_data_t), intent(inout), target :: local
type(rt_data_t), intent(inout), optional, target :: global
end subroutine entry_prepare_resonant_subprocesses

```

*<Simulations: procedures>+≡*

```

module subroutine entry_prepare_resonant_subprocesses (entry, local, global)
class(entry_t), intent(inout) :: entry
type(rt_data_t), intent(inout), target :: local
type(rt_data_t), intent(inout), optional, target :: global
call entry%resonant_subprocess_set%prepare_process_objects (local, global)
end subroutine entry_prepare_resonant_subprocesses

```

Prepare process instances. They are linked to their corresponding process objects. Both, process and instance objects, are allocated as anonymous targets inside the `resonant_subprocess_set` component.

NOTE: those anonymous object are likely forgotten during finalization of the parent `event_t` (extended as `entry_t`) object. This should be checked! The memory leak is probably harmless as long as the event object is created once per run, not once per event.

*<Simulations: entry: TBP>+≡*

```

procedure :: prepare_resonant_subprocess_instances &

### 33.9.7 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
type, extends (entry_t) :: alt_entry_t
contains
<Simulations: alt entry: TBP>
end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

<Simulations: alt entry: TBP>≡
  procedure :: init_alt => alt_entry_init

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

### Simulation-object initialization

We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we do not need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

```

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the luminosity setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the luminosity, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

    n = simulation%n_evt_requested

  end function simulation_get_n_events_requested

```

Generate the number of events that has been set by `simulation_set_n_events_requested`. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

The `begin_it` and `end_it` limits are equal to 1 and the number of events, respectively, in serial mode, but differ for MPI mode.

TODO: When reading from file, event transforms cannot be applied because the process instance will not be complete. (?)

```

<Simulations: simulation: TBP>+≡
  procedure :: generate => simulation_generate

<Simulations: sub interfaces>+≡
  module subroutine simulation_generate (simulation, es_array)
    class(simulation_t), intent(inout), target :: simulation
    type(event_stream_array_t), intent(inout), optional :: es_array
  end subroutine simulation_generate

<Simulations: procedures>+≡

    end do
    call simulation%after_last_event (begin_it, end_it)

```

```
end subroutine simulation_generate
```

The header of the event loop: with all necessary information present in the `simulation` and `es_array` objects, and given a number of events `n` to generate, we prepare for actually generating/reading/writing events.

The procedure returns the real iteration bounds `begin_it` and `end_it` for the event loop. This is nontrivial only for MPI; in serial mode those are equal to 1 and to `n_events`, respectively.

## Alternate environments

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set,

then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

```

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

```

## Rescan-Events Loop

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

## Event index

Here we handle the event index that is kept in the simulation record. The event index is valid for the current sample. When generating or reading events, we initialize the index with the offset that the user provides (if any) and increment it for each event that is generated or read from file. The event index is stored in the event-entry that is current for the event. If an event on file comes with its own index, that index overwrites the predefined one and also resets the index within the simulation record.

The event index is not connected to the `counter` object. The counter is supposed to collect statistical information. The event index is a user-level object that is visible in event records and analysis expressions.

```
<Simulations: simulation: TBP>+≡
  procedure :: init_event_index => simulation_init_event_index
  procedure :: increment_event_index => simulation_increment_event_index
  procedure :: set_event_index => simulation_set_event_index

if (simulation%event_index_set) then
  i = simulation%event_index
else
  i = 0
end if
end function simulation_get_event_index

```

### 33.9.9 Direct event access

If we want to retrieve event information, we should expose the currently selected event **entry** within the simulation object. We recall that this is an extension of the (generic) **event** type. Assuming that we will restrict this to read access, we return a pointer.

```

<Simulations: simulation: TBP>+≡
  procedure :: get_process_index => simulation_get_process_index
  procedure :: get_event_ptr => simulation_get_event_ptr

<Simulations: sub interfaces>+≡
  module function simulation_get_process_index (simulation) result (i_prc)
    class(simulation_t), intent(in), target :: simulation
    integer :: i_prc
  end function simulation_get_process_index
  module function simulation_get_event_ptr (simulation) result (event)
    class(simulation_t), intent(in), target :: simulation
    class(event_t), pointer :: event
  end function simulation_get_event_ptr

<Simulations: procedures>+≡
  module function simulation_get_process_index (simulation) result (i_prc)
    class(simulation_t), intent(in), target :: simulation
    integer :: i_prc

    i_prc = simulation%i_prc

  end function simulation_get_process_index

  module function simulation_get_event_ptr (simulation) result (event)
    class(simulation_t), intent(in), target :: simulation
    class(event_t), pointer :: event

    event => simulation%entry(simulation%i_prc)

  end function simulation_get_event_ptr

```

### 33.9.10 Event Stream I/O

Write an event to a generic **eio** event stream. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+≡

```

```

generic :: write_event => write_event_eio
procedure :: write_event_eio => simulation_write_event_eio

<Simulations: sub interfaces>+≡
module subroutine simulation_write_event_eio (object, eio, i_prc)
class(simulation_t), intent(in) :: object
class(eio_t), intent(inout) :: eio
integer, intent(in), optional :: i_prc
end subroutine simulation_write_event_eio

<Simulations: procedures>+≡
module subroutine simulation_write_event_eio (object, eio, i_prc)
class(simulation_t), intent(in) :: object
class(eio_t), intent(inout) :: eio
integer, intent(in), optional :: i_prc
logical :: increased
integer :: current
if (present (i_prc)) then
current = i_prc
else
current = object%i_prc
end if
if (current > 0) then
if (object%split_n_evt > 0 .and. object%counter%total > 1) then
if (mod (object%counter%total, object%split_n_evt) == 1) then
call eio%split_out ()
end if
else if (object%split_n_kbytes > 0) then
call eio%update_split_count (increased)
if (increased) call eio%split_out ()
end if
call eio%output (object%entry(current)%event_t, current, pacify = object%pacify)
else
call msg_fatal ("Simulation: write event: no process selected")
end if
end subroutine simulation_write_event_eio

```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```

<Simulations: simulation: TBP>+≡
generic :: read_event => read_event_eio
procedure :: read_event_eio => simulation_read_event_eio

<Simulations: sub interfaces>+≡
module subroutine simulation_read_event_eio (object, eio)
class(simulation_t), intent(inout) :: object
class(eio_t), intent(inout) :: eio
end subroutine simulation_read_event_eio

<Simulations: procedures>+≡
module subroutine simulation_read_event_eio (object, eio)

```

```

class(simulation_t), intent(inout) :: object
class(eio_t), intent(inout) :: eio
integer :: iostat, current
call eio%input_i_prc (current, iostat)
select case (iostat)
case (0)
object%i_prc = current
call eio%input_event (object%entry(current)%event_t, iostat)
end select
select case (iostat)
case (:-1)
object%i_prc = 0
object%i_mci = 0
case (1:)
call msg_error ("Reading events: I/O error, aborting read")
object%i_prc = 0
object%i_mci = 0
case default
object%i_mci = object%entry(current)%get_i_mci ()
end select
end subroutine simulation_read_event_eio

```

### 33.9.11 Event Stream Array

Write an event using an array of event I/O streams. The process index must be selected, or the current index must be available.

*(Simulations: simulation: TBP)*+≡

```

generic :: write_event => write_event_es_array
procedure :: write_event_es_array => simulation_write_event_es_array

```

*(Simulations: sub interfaces)*+≡

```

module subroutine simulation_write_event_es_array &
(object, es_array, passed, event_handle)
class(simulation_t), intent(in), target :: object
class(event_stream_array_t), intent(inout) :: es_array
logical, intent(in), optional :: passed
class(event_handle_t), intent(inout), optional :: event_handle
end subroutine simulation_write_event_es_array

```

*(Simulations: procedures)*+≡

```

module subroutine simulation_write_event_es_array &
(object, es_array, passed, event_handle)
class(simulation_t), intent(in), target :: object
class(event_stream_array_t), intent(inout) :: es_array
logical, intent(in), optional :: passed
class(event_handle_t), intent(inout), optional :: event_handle
integer :: i_prc, event_index
integer :: i
type(entry_t), pointer :: current_entry
i_prc = object%i_prc
if (i_prc > 0) then
event_index = object%counter%total
current_entry => object%entry(i_prc)%get_first ()

```

```

do i = 1, current_entry%count_nlo_entries ()
if (i > 1) current_entry => current_entry%get_next ()
call es_array%output (current_entry%event_t, i_prc, &
event_index, &
passed = passed, &
pacify = object%pacify, &
event_handle = event_handle)
end do
else
call msg_fatal ("Simulation: write event: no process selected")
end if
end subroutine simulation_write_event_es_array

```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

*<Simulations: simulation: TBP>+≡*

```

generic :: read_event => read_event_es_array
procedure :: read_event_es_array => simulation_read_event_es_array

end if
end subroutine simulation_read_event_es_array

```

### 33.9.12 Recover event

Recalculate the process instance contents, given an event with known particle set. The indices for MC, term, and channel must be already set. The `recalculate` method of the selected entry will import the result into `sqme_prc` and `weight_prc`.

If `recover_phs` is set (and false), do not attempt any phase-space calculation. Useful if we need only matrix elements (esp. testing); this flag is not stored in the simulation record.

```

<Simulations: simulation: TBP>+=
  procedure :: recalculate => simulation_recalculate

<Simulations: sub interfaces>+=
  module subroutine simulation_recalculate &
    (simulation, recover_phs, check_match)

```

```

  integer, intent(in) :: i
  character(32) :: md5sum
  md5sum = simulation%md5sum_alt(i)
  end function simulation_get_md5sum_alt

```

Return data that may be useful for writing event files.

Usually we can refer to a previously integrated process, for which we can fetch a process pointer. Occasionally, we do not have this because we are just rescanning an externally generated file without calculation. For that situation, we generate our local beam data object using the current environment, or, in simple cases, just fetch the necessary data from the process definition and environment.

```

<Simulations: simulation: TBP>+≡

## Resonant subprocess simulation

Prepare a process with resonances and enter resonant subprocesses in the simulation object. Simulate events with selection of resonance histories.

The process and its initialization is taken from `processes_18`, but we need a complete 0'MEGA matrix element here.

```

## Chapter 34

# More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in init/final hooks that we can set at runtime.)

### 34.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
(expr_tests_ut.f90)≡
  <File header>
  module expr_tests_ut

    use unit_tests
    use expr_tests_uti

    <Standard module head>

    <Expr tests: public test>

    contains

    <Expr tests: test driver>

  end module expr_tests_ut
(expr_tests_uti.f90)≡
  <File header>

  module expr_tests_uti

    <Use kinds>
    <Use strings>
    use format_defs, only: FMT_12
    use format_utils, only: write_separator
```

```

end subroutine dispatch_mci_empty

```

## Processes: scales and such

Initialize a process and process instance, choose a sampling point and fill the process instance, evaluating a given cut configuration.

We use the same trivial process as for the previous test. All momentum and state dependence is trivial, so we just test basic functionality.

```

## Chapter 35

# Top Level

The top level consists of

**commands** Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

**whizard** This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

**main** The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

**whizard\_c\_interface** Alternative top-level procedures, for use in the context of a C-compatible caller program.

## 35.1 Commands

This module defines the command language of the main input file.

```

### 35.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```

<Commands: types>≡
type, abstract :: command_t
type(parse_node_t), pointer :: pn => null ()
class(command_t), pointer :: next => null ()
type(parse_node_t), pointer :: pn_opt => null ()

```

```

type(command_list_t), pointer :: options => null ()
type(rt_data_t), pointer :: local => null ()
contains
  <Commands: command: TBP>
end type command_t

```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```

<Commands: command: TBP>≡
  procedure :: final => command_final

<Commands: sub interfaces>≡
  recursive module subroutine command_final (cmd)
    class(command_t), intent(inout) :: cmd
  end subroutine command_final

<Commands: procedures>≡
  recursive module subroutine command_final (cmd)
    class(command_t), intent(inout) :: cmd
    if (associated (cmd%options)) then
      call cmd%options%final ()
      deallocate (cmd%options)
      call cmd%local%local_final ()
      deallocate (cmd%local)
    else
      cmd%local => null ()
    end if
  end subroutine command_final

```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling. Gfortran 7/8/9 bug, has to remain in the main module:

```

<Commands: main procedures>≡
  subroutine dispatch_command (command, pn)
    class(command_t), intent(inout), pointer :: command
    type(parse_node_t), intent(in), target :: pn
    select case (char (parse_node_get_rule_key (pn)))

print *, char (parse_node_get_rule_key (pn))
call msg_bug ("Command not implemented")
end select
command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

⟨Commands: command: TBP⟩+≡
  procedure (command_write), deferred :: write
⟨Commands: interfaces⟩≡
  abstract interface
    subroutine command_write (cmd, unit, indent)
  import
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine command_write
  end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

⟨Commands: command: TBP⟩+≡

```

```

    procedure (command_compile), deferred :: compile
<Commands: interfaces>+≡
    abstract interface
    subroutine command_compile (cmd, global)
    import
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    end subroutine command_compile
    end interface

```

Execute a command. This will use and/or modify the runtime data set. If the `quit` flag is set, the caller should terminate command execution.

```

<Commands: command: TBP>+≡
    procedure (command_execute), deferred :: execute
<Commands: interfaces>+≡
    abstract interface
    subroutine command_execute (cmd, global)
    import
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    end subroutine command_execute
    end interface

```

### 35.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```

<Commands: command: TBP>+≡
    procedure :: write_options => command_write_options
<Commands: sub interfaces>+≡
    recursive module subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    end subroutine command_write_options
<Commands: procedures>+≡
    recursive module subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
    end subroutine command_write_options

```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```

<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

<Commands: sub interfaces>+≡
  recursive module subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine command_compile_options

<Commands: procedures>+≡
  recursive module subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call cmd%options%compile (cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
      call cmd%local%deactivate ()
    else
      cmd%local => global
    end if
  end subroutine command_compile_options

```

Execute options. First prepare the local environment, then execute the command list.

```

<Commands: command: TBP>+≡
  procedure :: execute_options => cmd_execute_options

<Commands: sub interfaces>+≡
  recursive module subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_execute_options

<Commands: procedures>+≡
  recursive module subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call cmd%local%activate ()
      call cmd%options%execute (cmd%local)
    end if
  end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

<Commands: command: TBP>+≡
  procedure :: reset_options => cmd_reset_options

```

```

<Commands: sub interfaces>+≡
  module subroutine cmd_reset_options (cmd, global)
  class(command_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_reset_options

```

```

<Commands: procedures>+≡
  module subroutine cmd_reset_options (cmd, global)
  class(command_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  if (associated (cmd%options)) then
  call cmd%local%deactivate (global)
  end if
  end subroutine cmd_reset_options

```

### 35.1.3 Specific command types

#### Model configuration

The command declares a model, looks for the specified file and loads it.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_model_t
  private
  type(string_t) :: name
  type(string_t) :: scheme
  logical :: ufo_model = .false.
  logical :: ufo_path_set = .false.
  type(string_t) :: ufo_path
  contains
  <Commands: cmd model: TBP>
  end type cmd_model_t

```

#### Output

```

<Commands: cmd model: TBP>≡
  procedure :: write => cmd_model_write

<Commands: sub interfaces>+≡
  module subroutine cmd_model_write (cmd, unit, indent)
  class(cmd_model_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  end subroutine cmd_model_write

<Commands: procedures>+≡
  module subroutine cmd_model_write (cmd, unit, indent)
  class(cmd_model_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,1x,'"',A,'"')", advance="no") "model =", char (cmd%name)
  if (cmd%ufo_model) then
  if (cmd%ufo_path_set) then

end if
end subroutine cmd_library_execute

```

## Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_process_t
private
type(string_t) :: id
integer :: n_in = 0
type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
type(parse_node_t), pointer :: pn_out => null ()
contains
⟨Commands: cmd process: TBP⟩
end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

⟨Commands: cmd process: TBP⟩≡
procedure :: write => cmd_process_write

⟨Commands: sub interfaces⟩+≡
module subroutine cmd_process_write (cmd, unit, indent)
class(cmd_process_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
end subroutine cmd_process_write

```

```

⟨Commands: procedures⟩+≡
module subroutine cmd_process_write (cmd, unit, indent)
class(cmd_process_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return

cmd%pn_pdg_in(i)%ptr => pn_codes
pn_codes => parse_node_get_next_ptr (pn_codes)
end do
end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

There are two possibilities that a process contains more than one component: by an explicit component statement by the user for inclusive processes, or by having one process at NLO level. The first option is determined in the chunk `scan components`, and determines `n_components`.

```

```

Command execution. Generate code, write driver, compile and link. Do this for all libraries in the list.

If no library names have been given and stored while compiling this command, we collect all libraries from the current stack and compile those.

As a bonus, a compiled library may be able to spawn new process libraries. For instance, a processes may ask for a set of resonant subprocesses which go into their own library, but this can be determined only after the process is available as a compiled object. Therefore, the compilation loop is implemented as a recursive internal subroutine.

We can compile static libraries (which actually just loads them). However, we can't incorporate in a generated executable.

```

call msg_error ("System command returned with nonzero status code")
end if
end if
end if
end if
end subroutine cmd_exec_execute

```

## Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_var_t
private
type(string_t) :: name
integer :: type = V_NONE

```

```

type(parse_node_t), pointer :: pn_value => null ()
logical :: is_intrinsic = .false.
logical :: is_model_var = .false.
contains
<Commands: cmd var: TBP>
end type cmd_var_t

```

Output. We know name, type, and properties, but not the value.

```

<Commands: cmd var: TBP>≡
  procedure :: write => cmd_var_write

<Commands: sub interfaces>+≡
  module subroutine cmd_var_write (cmd, unit, indent)
    class(cmd_var_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    end subroutine cmd_var_write

<Commands: procedures>+≡
  module subroutine cmd_var_write (cmd, unit, indent)
    class(cmd_var_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent

## SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_slha_t
private
type(string_t) :: file
logical :: write_mode = .false.
contains
<Commands: cmd slha: TBP>
end type cmd_slha_t

```

Output.

```

<Commands: cmd slha: TBP>≡
procedure :: write => cmd_slha_write

<Commands: sub interfaces>+≡
module subroutine cmd_slha_write (cmd, unit, indent)
class(cmd_slha_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
end subroutine cmd_slha_write

## Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

*(Commands: types)+≡*

```

type, extends (command_t) :: cmd_expect_t
private
type(parse_node_t), pointer :: pn_lexpr => null ()
contains
(Commands: cmd expect: TBP)

```

```
end type cmd_expect_t
```

Simply tell the status.

```
<Commands: cmd expect: TBP>≡
  procedure :: write => cmd_expect_write

<Commands: sub interfaces>+≡
  module subroutine cmd_expect_write (cmd, unit, indent)
    class(cmd_expect_t), intent(in) :: cmd

## Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

⟨Commands: types⟩+≡
type :: sentry_expr_t
type(parse_node_p), dimension(:), allocatable :: expr
contains
⟨Commands: sentry expr: TBP⟩
end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

⟨Commands: sentry expr: TBP⟩≡
procedure :: compile => sentry_expr_compile

⟨Commands: sub interfaces⟩+≡
module subroutine sentry_expr_compile (sentry, pn)
class(sentry_expr_t), intent(out) :: sentry
type(parse_node_t), intent(in), target :: pn
end subroutine sentry_expr_compile

```

```

<Commands: procedures>+≡
module subroutine sentry_expr_compile (sentry, pn)
class(sentry_expr_t), intent(out) :: sentry
type(parse_node_t), intent(in), target :: pn
type(parse_node_t), pointer :: pn_expr, pn_extra
integer :: n_expr, i
n_expr = parse_node_get_n_sub (pn)
allocate (sentry%expr (n_expr))
if (n_expr > 0) then
i = 0
pn_expr => parse_node_get_sub_ptr (pn)
pn_extra => parse_node_get_next_ptr (pn_expr)
do i = 1, n_expr

## Cuts

Define a cut expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the cut expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_cuts_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  ⟨Commands: cmd cuts: TBP⟩
  end type cmd_cuts_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```

⟨Commands: cmd cuts: TBP⟩≡
  procedure :: write => cmd_cuts_write

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_cuts_write (cmd, unit, indent)
  class(cmd_cuts_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  end subroutine cmd_cuts_write

⟨Commands: procedures⟩+≡
  module subroutine cmd_cuts_write (cmd, unit, indent)
  class(cmd_cuts_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A)") "cuts: [defined]"
  end subroutine cmd_cuts_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd cuts: TBP⟩+≡
  procedure :: compile => cmd_cuts_compile

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_cuts_compile (cmd, global)
  class(cmd_cuts_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_cuts_compile

```

```

<Commands: procedures>+≡
module subroutine cmd_cuts_compile (cmd, global)

global%pn%cuts_lexpr => cmd%pn_lexpr
end subroutine cmd_cuts_execute

```

## General, Factorization and Renormalization Scales

Define a scale expression for either the renormalization or the factorization scale. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_scale_t
private
type(parse_node_t), pointer :: pn_expr => null ()
contains
<Commands: cmd scale: TBP>
end type cmd_scale_t

```

```

<Commands: types>+≡
type, extends (command_t) :: cmd_fac_scale_t
private
type(parse_node_t), pointer :: pn_expr => null ()
contains
<Commands: cmd fac scale: TBP>
end type cmd_fac_scale_t

```

```

<Commands: types>+≡
type, extends (command_t) :: cmd_ren_scale_t
private
type(parse_node_t), pointer :: pn_expr => null ()
contains
<Commands: cmd ren scale: TBP>

```

```
end type cmd_ren_scale_t
```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```
<Commands: cmd scale: TBP>≡
```

```
  procedure :: write => cmd_scale_write
```

```
<Commands: sub interfaces>+≡
```

```
  module subroutine cmd_scale_write (cmd, unit, indent)
    class(cmd_scale_t), intent(in) :: cmd

    type(rt_data_t), intent(inout), target :: global
    global%pn%weight_expr => cmd%pn_expr
  end subroutine cmd_weight_execute

```

## Selection

Define a selection expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_selection_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()
  contains
  <Commands: cmd selection: TBP>
  end type cmd_selection_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd selection: TBP>≡
  procedure :: write => cmd_selection_write

<Commands: sub interfaces>+≡
  module subroutine cmd_selection_write (cmd, unit, indent)
    class(cmd_selection_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_selection_write

<Commands: procedures>+≡
  module subroutine cmd_selection_write (cmd, unit, indent)
    class(cmd_selection_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "selection expression: [defined]"
  end subroutine cmd_selection_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd selection: TBP>+≡
  procedure :: compile => cmd_selection_compile

```

```

<Commands: sub interfaces>+≡
  module subroutine cmd_selection_compile (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_selection_compile

```

```

<Commands: procedures>+≡
  module subroutine cmd_selection_compile (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_selection_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd selection: TBP>+≡
  procedure :: execute => cmd_selection_execute

<Commands: sub interfaces>+≡
  module subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_selection_execute

<Commands: procedures>+≡
  module subroutine cmd_selection_execute (cmd, global)
    class(cmd_selection_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

## Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_reweight_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()
  contains
  <Commands: cmd reweight: TBP>
  end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd reweight: TBP>≡
  procedure :: write => cmd_reweight_write

```

```

<Commands: sub interfaces>+≡
  module subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_reweight_write

<Commands: procedures>+≡
  module subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: compile => cmd_reweight_compile

<Commands: sub interfaces>+≡
  module subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_reweight_compile

<Commands: procedures>+≡
  module subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: execute => cmd_reweight_execute

<Commands: sub interfaces>+≡
  module subroutine cmd_reweight_execute (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_reweight_execute

<Commands: procedures>+≡
  module subroutine cmd_reweight_execute (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%reweight_expr => cmd%pn_expr
  end subroutine cmd_reweight_execute

```

## Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these se-

tups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_alt_setup_t
  private
  type(parse_node_p), dimension(:), allocatable :: setup
  contains
  ⟨Commands: cmd alt setup: TBP⟩
  end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

⟨Commands: cmd alt setup: TBP⟩≡
  procedure :: write => cmd_alt_setup_write

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_alt_setup_write (cmd, unit, indent)
  class(cmd_alt_setup_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  end subroutine cmd_alt_setup_write

⟨Commands: procedures⟩+≡
  module subroutine cmd_alt_setup_write (cmd, unit, indent)
  class(cmd_alt_setup_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,IO,A)") "alt_setup: ", size (cmd%setup), " entries"
  end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

⟨Commands: cmd alt setup: TBP⟩+≡
  procedure :: compile => cmd_alt_setup_compile

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_alt_setup_compile (cmd, global)
  class(cmd_alt_setup_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_alt_setup_compile

⟨Commands: procedures⟩+≡
  module subroutine cmd_alt_setup_compile (cmd, global)
  class(cmd_alt_setup_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_list, pn_setup
  integer :: i
  pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
  if (associated (pn_list)) then
    allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
    i = 1
    pn_setup => parse_node_get_sub_ptr (pn_list)
    do while (associated (pn_setup))
      cmd%setup(i)%ptr => pn_setup
      i = i + 1
      pn_setup => parse_node_get_next_ptr (pn_setup)
    end do
  end if

```

```

end do
else
allocate (cmd%setup (0))
end if
end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

<Commands: cmd alt setup: TBP>+≡
  procedure :: execute => cmd_alt_setup_execute

<Commands: sub interfaces>+≡
  module subroutine cmd_alt_setup_execute (cmd, global)
  class(cmd_alt_setup_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_alt_setup_execute

<Commands: procedures>+≡
  module subroutine cmd_alt_setup_execute (cmd, global)
  class(cmd_alt_setup_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  if (allocated (global%pn%alt_setup)) deallocate (global%pn%alt_setup)
  allocate (global%pn%alt_setup (size (cmd%setup)))
  global%pn%alt_setup = cmd%setup
  end subroutine cmd_alt_setup_execute

```

## Integration

Integrate several processes, consecutively with identical parameters.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_integrate_t
  private
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id
  contains
  <Commands: cmd integrate: TBP>
  end type cmd_integrate_t

```

Output: we know the process IDs.

```

<Commands: cmd integrate: TBP>≡
  procedure :: write => cmd_integrate_write

<Commands: sub interfaces>+≡
  module subroutine cmd_integrate_write (cmd, unit, indent)
  class(cmd_integrate_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  end subroutine cmd_integrate_write

<Commands: procedures>+≡
  module subroutine cmd_integrate_write (cmd, unit, indent)
  class(cmd_integrate_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u, i
  u = given_output_unit (unit); if (u < 0) return

```

```

call write_indent (u, indent)
write (u, "(1x,A)", advance="no") "integrate ("
do i = 1, cmd%n_proc
if (i > 1) write (u, "(A,1x)", advance="no") " ,"
write (u, "(A)", advance="no") char (cmd%process_id(i))
end do
write (u, "(A)" ) " "
end subroutine cmd_integrate_write

```

Compile.

```

<Commands: cmd integrate: TBP>+≡
  procedure :: compile => cmd_integrate_compile

<Commands: sub interfaces>+≡
  module subroutine cmd_integrate_compile (cmd, global)
  class(cmd_integrate_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_integrate_compile

<Commands: procedures>+≡
  module subroutine cmd_integrate_compile (cmd, global)
  class(cmd_integrate_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_proclist, pn_proc
  integer :: i
  pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
  call cmd%compile_options (global)
  cmd%n_proc = parse_node_get_n_sub (pn_proclist)
  allocate (cmd%process_id (cmd%n_proc))
  pn_proc => parse_node_get_sub_ptr (pn_proclist)
  do i = 1, cmd%n_proc
  cmd%process_id(i) = parse_node_get_string (pn_proc)
  call global%process_stack%init_result_vars (cmd%process_id(i))
  pn_proc => parse_node_get_next_ptr (pn_proc)
  end do
  end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The **integrate** procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

<Commands: cmd integrate: TBP>+≡
  procedure :: execute => cmd_integrate_execute

<Commands: sub interfaces>+≡
  module subroutine cmd_integrate_execute (cmd, global)

```

```

class(cmd_integrate_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
end subroutine cmd_integrate_execute

<Commands: procedures>+≡
module subroutine cmd_integrate_execute (cmd, global)
class(cmd_integrate_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
integer :: i
if (debug_on) call msg_debug (D_CORE, "cmd_integrate_execute")
do i = 1, cmd%n_proc
if (debug_on) call msg_debug &
(D_CORE, "cmd%process_id(i) ", cmd%process_id(i))
call integrate_process (cmd%process_id(i), cmd%local, global)
call global%process_stack%fill_result_vars (cmd%process_id(i))
call global%process_stack%update_result_vars &
(cmd%process_id(i), global%var_list)
if (signal_is_pending ()) return
end do
end subroutine cmd_integrate_execute

```

## Observables

Declare an observable. After the declaration, it can be used to record data, and at the end one can retrieve average and error.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_observable_t
private
type(string_t) :: id
contains
<Commands: cmd observable: TBP>
end type cmd_observable_t

```

Output. We know the ID.

```

<Commands: cmd observable: TBP>≡
procedure :: write => cmd_observable_write

<Commands: sub interfaces>+≡
module subroutine cmd_observable_write (cmd, unit, indent)
class(cmd_observable_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
end subroutine cmd_observable_write

<Commands: procedures>+≡
module subroutine cmd_observable_write (cmd, unit, indent)
class(cmd_observable_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A,A)") "observable: ", char (cmd%id)
end subroutine cmd_observable_write

```

Compile. Just record the observable ID.

```

(Commands: cmd observable: TBP) +=
  procedure :: compile => cmd_observable_compile

(Commands: sub interfaces) +=
  module subroutine cmd_observable_compile (cmd, global)
    class(cmd_observable_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_observable_compile

(Commands: procedures) +=
  module subroutine cmd_observable_compile (cmd, global)
    class(cmd_observable_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_tag
    pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)

## Plots

Declare a plot. No mandatory arguments, just options.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_plot_t
  private
  type(string_t) :: id
  contains
  ⟨Commands: cmd plot: TBP⟩
  end type cmd_plot_t

```

Output. Just print the ID.

```

⟨Commands: cmd plot: TBP⟩≡
  procedure :: write => cmd_plot_write

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_plot_write (cmd, unit, indent)
  class(cmd_plot_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  end subroutine cmd_plot_write

⟨Commands: procedures⟩+≡
  module subroutine cmd_plot_write (cmd, unit, indent)
  class(cmd_plot_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent

```

```

integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A,A)" "plot: ", char (cmd%id)
end subroutine cmd_plot_write

```

Compile. Record the plot ID and initialize lower, upper bound and bin width.

```

<Commands: cmd plot: TBP>+≡
  procedure :: compile => cmd_plot_compile

<Commands: sub interfaces>+≡
  module subroutine cmd_plot_compile (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global

    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options%init ()
    call set_graph_options (graph_options, var_list)
    call drawing_options%init_plot ()
    call set_drawing_options (drawing_options, var_list)

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

## Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_graph_t
  private
  type(string_t) :: id
  integer :: n_elements = 0
  type(cmd_plot_t), dimension(:), allocatable :: el
  type(string_t), dimension(:), allocatable :: element_id
  contains
  <Commands: cmd graph: TBP>
  end type cmd_graph_t

```

Output. Just print the ID.

```

<Commands: cmd graph: TBP>≡
  procedure :: write => cmd_graph_write

<Commands: sub interfaces>+≡
  module subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_graph_write

<Commands: procedures>+≡
  module subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd

```

```

integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A,A,A,I0,A)") "graph: ", char (cmd%id), &
" (" , cmd%n_elements, " entries)"
end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

<Commands: cmd graph: TBP>+≡
procedure :: compile => cmd_graph_compile

<Commands: sub interfaces>+≡
module subroutine cmd_graph_compile (cmd, global)
class(cmd_graph_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
end subroutine cmd_graph_compile

<Commands: procedures>+≡
module subroutine cmd_graph_compile (cmd, global)
class(cmd_graph_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
integer :: i

pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
pn_tag => parse_node_get_sub_ptr (pn_term)
cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
call cmd%compile_options (global)
select case (char (parse_node_get_rule_key (pn_tag)))

pn_term => parse_node_get_sub_ptr (pn_def)
pn_tag => parse_node_get_sub_ptr (pn_term)
cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
call cmd%el(1)%init (pn_tag, global)
cmd%element_id(1) = parse_node_get_string (pn_tag)
pn_app => parse_node_get_next_ptr (pn_term)
do i = 2, cmd%n_elements
pn_term => parse_node_get_sub_ptr (pn_app, 2)
pn_tag => parse_node_get_sub_ptr (pn_term)
cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
call cmd%el(i)%init (pn_tag, global)
cmd%element_id(i) = parse_node_get_string (pn_tag)

```

```
pn_app => parse_node_get_next_ptr (pn_app)
end do
```

```
end subroutine cmd_graph_compile
```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```
<Commands: cmd graph: TBP>+≡
  procedure :: execute => cmd_graph_execute

<Commands: sub interfaces>+≡
  module subroutine cmd_graph_execute (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_graph_execute

<Commands: procedures>+≡
  module subroutine cmd_graph_execute (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options
    integer :: i, type

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options%init ()
    call set_graph_options (graph_options, var_list)
    call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

    do i = 1, cmd%n_elements
      if (associated (cmd%el(i)%options)) then
        call cmd%el(i)%options%execute (cmd%el(i)%local)
      end if

      end select
      call set_drawing_options (drawing_options, var_list)
      if (associated (cmd%el(i)%options)) then
        call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
      end if
      call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
    end do
  end subroutine cmd_graph_execute
```

## Analysis

Hold the analysis ID either as a string or as an expression:

```
<Commands: types>+≡
  type :: analysis_id_t
  type(string_t) :: tag
  type(parse_node_t), pointer :: pn_sexpr => null ()
end type analysis_id_t
```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_analysis_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  <Commands: cmd analysis: TBP>
end type cmd_analysis_t
```

Output. Print just a message that analysis has been defined.

```
<Commands: cmd analysis: TBP>≡
  procedure :: write => cmd_analysis_write

<Commands: sub interfaces>+≡
  module subroutine cmd_analysis_write (cmd, unit, indent)
    class(cmd_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_analysis_write

    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "analysis: [defined]"
  end subroutine cmd_analysis_write
```

Compile. Simply store the parse (sub)tree.

```
<Commands: cmd analysis: TBP>+≡
  procedure :: compile => cmd_analysis_compile

<Commands: sub interfaces>+≡
  module subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_analysis_compile

<Commands: procedures>+≡
  module subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
```

```
cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
end subroutine cmd_analysis_compile
```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```
<Commands: cmd analysis: TBP>+≡
  procedure :: execute => cmd_analysis_execute

<Commands: sub interfaces>+≡
  module subroutine cmd_analysis_execute (cmd, global)
  class(cmd_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_analysis_execute

<Commands: procedures>+≡
  module subroutine cmd_analysis_execute (cmd, global)
  class(cmd_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  global%pn%analysis_lexpr => cmd%pn_lexpr
  end subroutine cmd_analysis_execute
```

## Write histograms and plots

The data type encapsulating the command:

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_write_analysis_t
  private
  type(analysis_id_t), dimension(:), allocatable :: id
  type(string_t), dimension(:), allocatable :: tag
  contains
  <Commands: cmd write analysis: TBP>
  end type cmd_write_analysis_t
```

Output. Just the keyword.

```
<Commands: cmd write analysis: TBP>≡
  procedure :: write => cmd_write_analysis_write

<Commands: sub interfaces>+≡
  module subroutine cmd_write_analysis_write (cmd, unit, indent)
  class(cmd_write_analysis_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  end subroutine cmd_write_analysis_write

<Commands: procedures>+≡
  module subroutine cmd_write_analysis_write (cmd, unit, indent)
  class(cmd_write_analysis_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A)") "write_analysis"
  end subroutine cmd_write_analysis_write
```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: compile => cmd_write_analysis_compile

<Commands: sub interfaces>+≡
  module subroutine cmd_write_analysis_compile (cmd, global)
    class(cmd_write_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_write_analysis_compile

<Commands: procedures>+≡
  module subroutine cmd_write_analysis_compile (cmd, global)
    class(cmd_write_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
    integer :: n, i
    pn_clause => parse_node_get_sub_ptr (cmd%pn)
    pn_args => parse_node_get_sub_ptr (pn_clause, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
    call cmd%compile_options (global)
    if (associated (pn_args)) then
      n = parse_node_get_n_sub (pn_args)
      allocate (cmd%id (n))
      do i = 1, n
        pn_id => parse_node_get_sub_ptr (pn_args, i)
        if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
          cmd%id(i)%tag = parse_node_get_string (pn_id)
        else
          cmd%id(i)%pn_sexpr => pn_id
        end if
      end do
    else
      allocate (cmd%id (0))
    end if
  end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

<Commands: parameters>+≡
  character(*), parameter, public :: &
  DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
  character(len=1), dimension(2), parameter, public :: &
  FORBIDDEN_ENDINGS1 = [ "o", "a" ]
  character(len=2), dimension(6), parameter, public :: &
  FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "pg", "lo", "la" ]
  character(len=3), dimension(20), parameter, public :: &
  FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
  "f95", "log", "ltp", "mod", "mpx", "olc", "olp", "pdf", "phs", &
  "sin", "sub", "tex", "vg2", "vgx" ]

```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: execute => cmd_write_analysis_execute

```

```

{Commands: sub interfaces}+≡
module subroutine cmd_write_analysis_execute (cmd, global)
class(cmd_write_analysis_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
end subroutine cmd_write_analysis_execute

```

```

{Commands: procedures}+≡
module subroutine cmd_write_analysis_execute (cmd, global)
class(cmd_write_analysis_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(var_list_t), pointer :: var_list
var_list => cmd%local%get_var_list_ptr ()
call write_analysis_wrap (var_list, global%out_files, &
cmd%id, tag = cmd%tag)
end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

```

{Commands: procedures}+≡
subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
type(var_list_t), intent(inout), target :: var_list
type(file_list_t), intent(inout), target :: out_files

### 35.1.4 User-controlled output to data files

#### Open file (output)

Open a file for output.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_open_out_t
private
type(parse_node_t), pointer :: file_expr => null ()
contains
<Commands: cmd open out: TBP>
end type cmd_open_out_t

```

Finalizer for the embedded eval tree.

```

<Commands: procedures>+≡
subroutine cmd_open_out_final (object)
class(cmd_open_out_t), intent(inout) :: object
end subroutine cmd_open_out_final

```

Output (trivial here).

```

<Commands: cmd open out: TBP>≡
procedure :: write => cmd_open_out_write

<Commands: sub interfaces>+≡
module subroutine cmd_open_out_write (cmd, unit, indent)
class(cmd_open_out_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent

```

```

end subroutine cmd_open_out_write

<Commands: procedures>+≡
module subroutine cmd_open_out_write (cmd, unit, indent)
class(cmd_open_out_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)", advance="no") "open_out: <filename>"
end subroutine cmd_open_out_write

```

Compile: create an eval tree for the filename expression.

```

<Commands: cmd open out: TBP>+≡
procedure :: compile => cmd_open_out_compile

<Commands: sub interfaces>+≡
module subroutine cmd_open_out_compile (cmd, global)
class(cmd_open_out_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
end subroutine cmd_open_out_compile

<Commands: procedures>+≡
module subroutine cmd_open_out_compile (cmd, global)
class(cmd_open_out_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
cmd%file_expr => parse_node_get_sub_ptr (cmd%pn, 2)
if (associated (cmd%file_expr)) then
cmd%pn_opt => parse_node_get_next_ptr (cmd%file_expr)
end if
call cmd%compile_options (global)
end subroutine cmd_open_out_compile

```

Execute: append the file to the global list of open files.

```

<Commands: cmd open out: TBP>+≡
procedure :: execute => cmd_open_out_execute

<Commands: sub interfaces>+≡
module subroutine cmd_open_out_execute (cmd, global)

```

```

call file_list_open (global%out_files, file, &
action = "write", status = "replace", position = "asis")
else
call msg_fatal ("open_out: file name argument evaluates to unknown")
end if
call file_expr%final ()
end subroutine cmd_open_out_execute

```

### Open file (output)

Close an output file. Except for the `execute` method, everything is analogous to the open command, so we can just inherit.

```

⟨Commands: types⟩+≡
  type, extends (cmd_open_out_t) :: cmd_close_out_t
  private
  contains
  ⟨Commands: cmd close out: TBP⟩
  end type cmd_close_out_t

```

Execute: remove the file from the global list of output files.

```

⟨Commands: cmd close out: TBP⟩≡
  procedure :: execute => cmd_close_out_execute

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_close_out_execute (cmd, global)
  class(cmd_close_out_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_close_out_execute

⟨Commands: procedures⟩+≡
  module subroutine cmd_close_out_execute (cmd, global)
  class(cmd_close_out_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  type(eval_tree_t) :: file_expr
  type(string_t) :: file
  var_list => cmd%local%var_list
  call file_expr%init_sexpr (cmd%file_expr, var_list)
  call file_expr%evaluate ()
  if (file_expr%is_known ()) then
  file = file_expr%get_string ()
  call file_list_close (global%out_files, file)
  else
  call msg_fatal ("close_out: file name argument evaluates to unknown")
  end if
  call file_expr%final ()
  end subroutine cmd_close_out_execute

```

### 35.1.5 Print custom-formatted values

```

⟨Commands: types⟩+≡

```

```

type, extends (command_t) :: cmd_printf_t
private
type(parse_node_t), pointer :: sexpr => null ()
type(parse_node_t), pointer :: sprintf_fun => null ()
type(parse_node_t), pointer :: sprintf_clause => null ()
type(parse_node_t), pointer :: sprintf => null ()
contains
<Commands: cmd printf: TBP>
end type cmd_printf_t

```

Finalize.

```

<Commands: cmd printf: TBP>≡
  procedure :: final => cmd_printf_final

<Commands: sub interfaces>+≡
  module subroutine cmd_printf_final (cmd)
    class(cmd_printf_t), intent(inout) :: cmd
  end subroutine cmd_printf_final

<Commands: procedures>+≡
  module subroutine cmd_printf_final (cmd)
    class(cmd_printf_t), intent(inout) :: cmd
    call parse_node_final (cmd%sexpr, recursive = .false.)
    deallocate (cmd%sexpr)
    call parse_node_final (cmd%sprintf_fun, recursive = .false.)
    deallocate (cmd%sprintf_fun)
    call parse_node_final (cmd%sprintf_clause, recursive = .false.)
    deallocate (cmd%sprintf_clause)
    call parse_node_final (cmd%sprintf, recursive = .false.)
    deallocate (cmd%sprintf)
  end subroutine cmd_printf_final

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

```

<Commands: cmd printf: TBP>+≡
  procedure :: write => cmd_printf_write

<Commands: sub interfaces>+≡
  module subroutine cmd_printf_write (cmd, unit, indent)
    class(cmd_printf_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_printf_write

<Commands: procedures>+≡
  module subroutine cmd_printf_write (cmd, unit, indent)
    class(cmd_printf_t), intent(in) :: cmd

if (len (file) == 0) then
call msg_result (char (string))
else
call file_list_write (global%out_files, file, string, advance)
end if
end if
end subroutine cmd_printf_execute

```

## Record data

The expression syntax already contains a `record` keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_record_t
private
type(parse_node_t), pointer :: pn_lexpr => null ()
contains
<Commands: cmd record: TBP>
end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

<Commands: cmd record: TBP>≡
procedure :: write => cmd_record_write

<Commands: sub interfaces>+≡
module subroutine cmd_record_write (cmd, unit, indent)
class(cmd_record_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
end subroutine cmd_record_write

<Commands: procedures>+≡
module subroutine cmd_record_write (cmd, unit, indent)

```

```

class(cmd_record_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A)") "record"
end subroutine cmd_record_write

```

Compile. This is a hack which transforms the `record` command into a `record` expression, which we handle in the `expressions` module.

```

⟨Commands: cmd record: TBP⟩+≡
  procedure :: compile => cmd_record_compile

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_record_compile (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_record_compile

⟨Commands: procedures⟩+≡
  module subroutine cmd_record_compile (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
    call parse_node_create_branch (pn_lexpr, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))
    call parse_node_create_branch (pn_lsinglet, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lsinglet")))
    call parse_node_append_sub (pn_lexpr, pn_lsinglet)
    call parse_node_create_branch (pn_lterm, &
      syntax_get_rule_ptr (syntax_cmd_list, var_str ("lterm")))
    call parse_node_append_sub (pn_lsinglet, pn_lterm)
    pn_record => parse_node_get_sub_ptr (cmd%pn)
    call parse_node_append_sub (pn_lterm, pn_record)
    cmd%pn_lexpr => pn_lexpr
  end subroutine cmd_record_compile

```

Command execution. Again, transfer this to the embedded expression and just forget the logical result.

```

⟨Commands: cmd record: TBP⟩+≡
  procedure :: execute => cmd_record_execute

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_record_execute (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_record_execute

⟨Commands: procedures⟩+≡
  module subroutine cmd_record_execute (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    logical :: lval
    var_list => global%get_var_list_ptr ()

```

```

lval = eval_log (cmd%pn_lexpr, var_list)
end subroutine cmd_record_execute

```

## Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_unstable_t
  private
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id
  type(parse_node_t), pointer :: pn_prt_in => null ()
  contains
  ⟨Commands: cmd unstable: TBP⟩
end type cmd_unstable_t

```

Output: we know the process IDs.

```

⟨Commands: cmd unstable: TBP⟩≡
  procedure :: write => cmd_unstable_write

⟨Commands: sub interfaces⟩+≡
  module subroutine cmd_unstable_write (cmd, unit, indent)
    class(cmd_unstable_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_unstable_write

⟨Commands: procedures⟩+≡
  module subroutine cmd_unstable_write (cmd, unit, indent)
    class(cmd_unstable_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u, i
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,1x,I0,1x,A)", advance="no") &
      "unstable:", 1, "("
    do i = 1, cmd%n_proc

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

```

end do
end subroutine cmd_simulate_compile

```

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

## Range expressions

We need a special type for storing and evaluating range expressions.

```

⟨Commands: parameters⟩+≡
integer, parameter :: STEP_NONE = 0
integer, parameter :: STEP_ADD = 1
integer, parameter :: STEP_SUB = 2
integer, parameter :: STEP_MUL = 3
integer, parameter :: STEP_DIV = 4
integer, parameter :: STEP_COMP_ADD = 11
integer, parameter :: STEP_COMP_MUL = 13

```

There is an abstract base type and two implementations: scan over integers and scan over reals.

```

⟨Commands: types⟩+≡
type, abstract :: range_t
type(parse_node_t), pointer :: pn_expr => null ()
type(parse_node_t), pointer :: pn_term => null ()
type(parse_node_t), pointer :: pn_factor => null ()
type(parse_node_t), pointer :: pn_value => null ()
type(parse_node_t), pointer :: pn_literal => null ()
type(parse_node_t), pointer :: pn_beg => null ()
type(parse_node_t), pointer :: pn_end => null ()
type(parse_node_t), pointer :: pn_step => null ()
type(eval_tree_t) :: expr_beg
type(eval_tree_t) :: expr_end
type(eval_tree_t) :: expr_step
integer :: step_mode = 0
integer :: n_step = 0
contains
⟨Commands: range: TBP⟩
end type range_t

```

These are the implementations:

```

⟨Commands: types⟩+≡
type, extends (range_t) :: range_int_t
integer :: i_beg = 0
integer :: i_end = 0
integer :: i_step = 0
contains
⟨Commands: range int: TBP⟩
end type range_int_t

type, extends (range_t) :: range_real_t
real(default) :: r_beg = 0
real(default) :: r_end = 0
real(default) :: r_step = 0
real(default) :: lr_beg = 0
real(default) :: lr_end = 0
real(default) :: lr_step = 0
contains
⟨Commands: range real: TBP⟩
end type range_real_t

```

Finalize the allocated dummy node. The other nodes are just pointers.

```

⟨Commands: range: TBP⟩≡
procedure :: final => range_final

```

```

<Commands: sub interfaces>+≡
  module subroutine range_final (object)
    class(range_t), intent(inout) :: object
    end subroutine range_final

<Commands: procedures>+≡
  module subroutine range_final (object)

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as

the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

```

## Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_scan_t
private
type(string_t) :: name
integer :: n_values = 0
type(parse_node_p), dimension(:), allocatable :: scan_cmd
class(range_t), dimension(:), allocatable :: range
contains
<Commands: cmd scan: TBP>
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

<Commands: cmd scan: TBP>≡
procedure :: final => cmd_scan_final

<Commands: sub interfaces>+≡
recursive module subroutine cmd_scan_final (cmd)
class(cmd_scan_t), intent(inout) :: cmd
end subroutine cmd_scan_final

<Commands: procedures>+≡
recursive module subroutine cmd_scan_final (cmd)

```

```

class(cmd_scan_t), intent(inout) :: cmd
type(parse_node_t), pointer :: pn_var_single, pn_decl_single
type(string_t) :: key
integer :: i
if (allocated (cmd%scan_cmd)) then
do i = 1, size (cmd%scan_cmd)
pn_var_single => parse_node_get_sub_ptr (cmd%scan_cmd(i)%ptr)
key = parse_node_get_rule_key (pn_var_single)
select case (char (key))
case ("scan_string_decl", "scan_log_decl")
pn_decl_single => parse_node_get_sub_ptr (pn_var_single, 2)
call parse_node_final (pn_decl_single, recursive=.false.)
deallocate (pn_decl_single)
end select
call parse_node_final (pn_var_single, recursive=.false.)
deallocate (pn_var_single)
end do
deallocate (cmd%scan_cmd)
end if
if (allocated (cmd%range)) then
do i = 1, size (cmd%range)
call cmd%range(i)%final ()
end do
end if
end subroutine cmd_scan_final

```

Output.

```

<Commands: cmd scan: TBP>+≡
  procedure :: write => cmd_scan_write

<Commands: sub interfaces>+≡
  module subroutine cmd_scan_write (cmd, unit, indent)
    class(cmd_scan_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_scan_write

<Commands: procedures>+≡
  module subroutine cmd_scan_write (cmd, unit, indent)
    class(cmd_scan_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,1x,A,1x,'(',I0,')')") "scan:", char (cmd%name), &
      cmd%n_values
  end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node. Gfortran 7/8/9 bug, has to remain in

the main module:

```

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

```

## Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of `else if` constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_if_t
  private
  type(parse_node_t), pointer :: pn_if_lexpr => null ()

  end if
  end subroutine cmd_include_execute

```

## Export values

This command exports the current values of variables or other objects to the surrounding scope. By default, a scope enclosed by braces keeps all objects local to it. The **export** command exports the values that are generated within the scope to the corresponding object in the outer scope.

The allowed set of exportable objects is, in principle, the same as the set of objects that the **show** command supports. This includes some convenience abbreviations.

TODO: The initial implementation inherits syntax from **show**, but supports only the **results** pseudo-object. The results (i.e., the process stack) is appended to the outer process stack instead of being discarded. The behavior of

the `export` command for other object kinds is to be defined on a case-by-case basis. It may involve replacing the outer value or, instead, doing some sort of appending or reduction.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_export_t
  private
  type(string_t), dimension(:), allocatable :: name
  contains
  <Commands: cmd export: TBP>
  end type cmd_export_t

```

Output: list the object names, not values.

```

<Commands: cmd export: TBP>≡
  procedure :: write => cmd_export_write

<Commands: sub interfaces>+≡
  module subroutine cmd_export_write (cmd, unit, indent)

  class(cmd_export_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  call global%append_exports (cmd%name)
  end subroutine cmd_export_execute

```

## Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_quit_t
  private
  logical :: has_code = .false.
  type(parse_node_t), pointer :: pn_code_expr => null ()
  contains
  <Commands: cmd quit: TBP>
  end type cmd_quit_t

```

Output.

```
<Commands: cmd quit: TBP>≡
  procedure :: write => cmd_quit_write

<Commands: sub interfaces>+≡
  module subroutine cmd_quit_write (cmd, unit, indent)
    class(cmd_quit_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
  end subroutine cmd_quit_write

<Commands: procedures>+≡
  module subroutine cmd_quit_write (cmd, unit, indent)
    class(cmd_quit_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,L1)") "quit: has_code = ", cmd%has_code
  end subroutine cmd_quit_write
```

Compile: allocate a quit object which serves as a placeholder.

```
<Commands: cmd quit: TBP>+≡
  procedure :: compile => cmd_quit_compile

<Commands: sub interfaces>+≡
  module subroutine cmd_quit_compile (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_quit_compile

<Commands: procedures>+≡
  module subroutine cmd_quit_compile (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_arg
    pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
    if (associated (pn_arg)) then
      cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
      cmd%has_code = .true.
    end if
  end subroutine cmd_quit_compile
```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```
<Commands: cmd quit: TBP>+≡
  procedure :: execute => cmd_quit_execute

<Commands: sub interfaces>+≡
  module subroutine cmd_quit_execute (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
  end subroutine cmd_quit_execute
```

```

<Commands: procedures>+≡
module subroutine cmd_quit_execute (cmd, global)
class(cmd_quit_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(var_list_t), pointer :: var_list
logical :: is_known
var_list => global%get_var_list_ptr ()
if (cmd%has_code) then
global%quit_code = eval_int (cmd%pn_code_expr, var_list, &
is_known=is_known)
if (.not. is_known) then
call msg_error ("Undefined return code of quit/exit command")
end if
end if
global%quit = .true.
end subroutine cmd_quit_execute

```

### 35.1.6 The command list

The command list holds a list of commands and relevant global data.

```

<Commands: public>+≡
public :: command_list_t

<Commands: types>+≡
type :: command_list_t
! not private anymore as required by the whizard-c-interface
class(command_t), pointer :: first => null ()
class(command_t), pointer :: last => null ()
contains
<Commands: command list: TBP>
end type command_list_t

```

Output.

```

<Commands: command list: TBP>≡
procedure :: write => command_list_write

<Commands: sub interfaces>+≡
recursive module subroutine command_list_write (cmd_list, unit, indent)
class(command_list_t), intent(in) :: cmd_list
integer, intent(in), optional :: unit, indent
end subroutine command_list_write

<Commands: procedures>+≡
recursive module subroutine command_list_write (cmd_list, unit, indent)
class(command_list_t), intent(in) :: cmd_list
integer, intent(in), optional :: unit, indent
class(command_t), pointer :: cmd
cmd => cmd_list%first
do while (associated (cmd))
call cmd%write (unit, indent)
cmd => cmd%next
end do
end subroutine command_list_write

```

Append a new command to the list and free the original pointer.

```

<Commands: command list: TBP>+≡
  procedure :: append => command_list_append

<Commands: sub interfaces>+≡
  module subroutine command_list_append (cmd_list, command)
    class(command_list_t), intent(inout) :: cmd_list
    class(command_t), intent(inout), pointer :: command
  end subroutine command_list_append

<Commands: procedures>+≡
  module subroutine command_list_append (cmd_list, command)
    class(command_list_t), intent(inout) :: cmd_list
    class(command_t), intent(inout), pointer :: command
    if (associated (cmd_list%last)) then
      cmd_list%last%next => command
    else
      cmd_list%first => command
    end if
    cmd_list%last => command
    command => null ()
  end subroutine command_list_append

```

Finalize.

```

<Commands: command list: TBP>+≡
  procedure :: final => command_list_final

<Commands: sub interfaces>+≡
  recursive module subroutine command_list_final (cmd_list)
    class(command_list_t), intent(inout) :: cmd_list
  end subroutine command_list_final

<Commands: procedures>+≡
  recursive module subroutine command_list_final (cmd_list)
    class(command_list_t), intent(inout) :: cmd_list
    class(command_t), pointer :: command
    do while (associated (cmd_list%first))
      command => cmd_list%first
      cmd_list%first => cmd_list%first%next
      call command%final ()
      deallocate (command)
    end do
    cmd_list%last => null ()
  end subroutine command_list_final

```

### 35.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint. Gfortran 7/8/9 bug: has to remain in the main module:

```

<Commands: command list: TBP>+≡
  procedure :: compile => command_list_compile

```

```

<Commands: main procedures>+≡
recursive subroutine command_list_compile (cmd_list, pn, global)
class(command_list_t), intent(inout), target :: cmd_list
type(parse_node_t), intent(in), target :: pn
type(rt_data_t), intent(inout), target :: global
type(parse_node_t), pointer :: pn_cmd
class(command_t), pointer :: command
integer :: i
pn_cmd => parse_node_get_sub_ptr (pn)
do i = 1, parse_node_get_n_sub (pn)
call dispatch_command (command, pn_cmd)
call command%compile (global)
call cmd_list%append (command)
call terminate_now_if_signal ()
pn_cmd => parse_node_get_next_ptr (pn_cmd)
end do
end subroutine command_list_compile

```

### 35.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```

<Commands: command list: TBP>+≡
procedure :: execute => command_list_execute

<Commands: sub interfaces>+≡
recursive module subroutine command_list_execute (cmd_list, global)
class(command_list_t), intent(in) :: cmd_list
type(rt_data_t), intent(inout), target :: global
end subroutine command_list_execute

<Commands: procedures>+≡
recursive module subroutine command_list_execute (cmd_list, global)
class(command_list_t), intent(in) :: cmd_list
type(rt_data_t), intent(inout), target :: global
class(command_t), pointer :: command
command => cmd_list%first
COMMAND_COND: do while (associated (command))
call command%execute_options (global)
call command%execute (global)
call command%reset_options (global)
call terminate_now_if_signal ()
if (global%quit) exit COMMAND_COND
command => command%next
end do COMMAND_COND
end subroutine command_list_execute

```

### 35.1.9 Command list syntax

```

<Commands: public>+≡
public :: syntax_cmd_list

```

```

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡
    public :: syntax_cmd_list_init

<Commands: sub interfaces>+≡
    module subroutine syntax_cmd_list_init ()

call syntax_model_file_final ()

write (u, "(A)")

```

```

write (u, "(A)")  "* Test output end: commands_34"

end subroutine commands_34

```

For this test, we invent a callback object which simply writes the analysis file, using the standard call for this. Here we rely on the fact that the analysis data are stored as a global entity, otherwise we would have to access them via the event object.

```

<Commands: test auxiliary types>≡
  type, extends (event_callback_t) :: event_callback_34_t
  private
  integer :: u = 0
  contains
  procedure :: write => event_callback_34_write
  procedure :: proc => event_callback_34
  end type event_callback_34_t

```

The output routine is unused. The actual callback should write the analysis data to the output unit that we have injected into the callback object.

```

<Commands: test auxiliary>+≡
  subroutine event_callback_34_write (event_callback, unit)
  class(event_callback_34_t), intent(in) :: event_callback
  integer, intent(in), optional :: unit
  end subroutine event_callback_34_write

  subroutine event_callback_34 (event_callback, i, event)
  class(event_callback_34_t), intent(in) :: event_callback
  integer(i64), intent(in) :: i
  class(generic_event_t), intent(in) :: event
  call analysis_write (event_callback%u)
  end subroutine event_callback_34

```

## 35.2 Toplevel module WHIZARD

```
<whizard.f90>≡  
  <File header>  
  
  module whizard  
  
    use io_units  
    <Use strings>  
    use os_interface  
    use ifiles  
    use lexers  
    use parser  
    use rt_data  
  
    <Standard module head>  
  
    <WHIZARD: public>  
  
    <WHIZARD: types>  
  
    <WHIZARD: variables>  
  
    save  
  
    interface  
    <WHIZARD: sub interfaces>  
    end interface  
  
  end module whizard  
  
<whizard_sub.f90>≡  
  <File header>  
  
  submodule (whizard) whizard_s  
  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF, BACKSLASH  
    use diagnostics  
    use eval_trees  
    use models  
    use phs_forests  
    use prclib_stacks  
    use slha_interface  
    use commands  
  
    implicit none  
  
    contains  
  
    <WHIZARD: procedures>  
  
  end submodule whizard_s
```

### 35.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```
<WHIZARD: public>≡
  public :: whizard_options_t

<WHIZARD: types>≡
  type :: whizard_options_t
  type(string_t) :: job_id
  type(string_t), dimension(:), allocatable :: pack_args
  type(string_t), dimension(:), allocatable :: unpack_args
  type(string_t) :: preload_model
  type(string_t) :: default_lib
  type(string_t) :: preload_libraries
  logical :: rebuild_library = .false.
  logical :: recompile_library = .false.
  logical :: rebuild_phs = .false.
  logical :: rebuild_grids = .false.
  logical :: rebuild_events = .false.
end type whizard_options_t
```

### 35.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```
<WHIZARD: types>+≡
  type, extends (parse_tree_t) :: pt_entry_t
  type(pt_entry_t), pointer :: previous => null ()
end type pt_entry_t
```

This is the stack. Since we always prepend, we just need the `last` pointer.

```
<WHIZARD: types>+≡
  type :: pt_stack_t
  type(pt_entry_t), pointer :: last => null ()
  contains
    <WHIZARD: pt_stack: TBP>
  end type pt_stack_t
```

The finalizer is called at the very end.

```
<WHIZARD: pt_stack: TBP>≡
  procedure :: final => pt_stack_final

<WHIZARD: sub interfaces>≡
  module subroutine pt_stack_final (pt_stack)
    class(pt_stack_t), intent(inout) :: pt_stack
  end subroutine pt_stack_final
```

```

<WHIZARD: procedures>+=
  module subroutine pt_stack_final (pt_stack)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(pt_entry_t), pointer :: current

    pt_stack%last => current
  end subroutine pt_stack_push

```

### 35.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a WHIZARD instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+=
  public :: whizard_t

```

```

<WHIZARD: types>+=
  type :: whizard_t
  type(whizard_options_t) :: options
  type(rt_data_t) :: global
  type(pt_stack_t) :: pt_stack
  contains
  <WHIZARD: whizard: TBP>
end type whizard_t

```

### 35.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>=
  procedure :: init => whizard_init

<WHIZARD: sub interfaces>+=
  module subroutine whizard_init (whizard, options, paths, logfile)
    class(whizard_t), intent(out), target :: whizard
    type(whizard_options_t), intent(in) :: options
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
  end subroutine whizard_init

<WHIZARD: procedures>+=
  module subroutine whizard_init (whizard, options, paths, logfile)
    class(whizard_t), intent(out), target :: whizard
    type(whizard_options_t), intent(in) :: options
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
    call init_syntax_tables ()
    whizard%options = options
    call whizard%global%global_init (paths, logfile)
    call whizard%init_job_id ()
    call whizard%init_rebuild_flags ()
    call whizard%unpack_files ()
    call whizard%preload_model ()
    call whizard%preload_library ()
    call whizard%global%init_fallback_model &
      (var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))
  end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+=
  procedure :: final => whizard_final

<WHIZARD: sub interfaces>+=
  module subroutine whizard_final (whizard)
    class(whizard_t), intent(inout), target :: whizard

```

### 35.2.5 Initialization and finalization: syntax tables

Initialize/finalize the syntax tables used by WHIZARD. These are effectively singleton objects. We introduce a module variable that tracks the initialization status.

Without syntax tables, essentially nothing will work. Any initializer has to call this.

```

<WHIZARD: variables>≡
  logical :: syntax_tables_exist = .false.

<WHIZARD: public>+≡
  public :: init_syntax_tables
  public :: final_syntax_tables

<WHIZARD: sub interfaces>+≡
  module subroutine init_syntax_tables ()
  end subroutine init_syntax_tables
  module subroutine final_syntax_tables ()
  end subroutine final_syntax_tables

<WHIZARD: procedures>+≡
  module subroutine init_syntax_tables ()
  if (.not. syntax_tables_exist) then
    call syntax_model_file_init ()
    call syntax_phs_forest_init ()
    call syntax_pexpr_init ()
    call syntax_slha_init ()
    call syntax_cmd_list_init ()
    syntax_tables_exist = .true.
  end if
  end subroutine init_syntax_tables

  module subroutine final_syntax_tables ()
  if (syntax_tables_exist) then
    call syntax_model_file_final ()

```

```

call syntax_phs_forest_final ()
call syntax_pexpr_final ()
call syntax_slha_final ()
call syntax_cmd_list_final ()
syntax_tables_exist = .false.
end if
end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
  public :: write_syntax_tables

<WHIZARD: sub interfaces>+≡
  module subroutine write_syntax_tables ()
  end subroutine write_syntax_tables

<WHIZARD: procedures>+≡
  module subroutine write_syntax_tables ()
  integer :: unit
  character(*), parameter :: file_model = "whizard.model_file.syntax"

## 35.3 Query Feature Support

This module accesses the various optional features (modules) that WHIZARD can support and reports on their availability.

```
<features.f90>≡
  module features

    <Standard module head>

    <Features: public>

    interface
      <Features: sub interfaces>
    end interface

  end module features

<features_sub.f90>≡
  <File header>

  submodule (features) features_s

    use string_utils, only: lower_case
    use system_dependencies, only: WHIZARD_VERSION
    <Features: dependencies>

    implicit none

    contains

    <Features: procedures>

  end submodule features_s
```

### 35.3.1 Output

```
<Features: public>≡
  public :: print_features

<Features: sub interfaces>≡
  module subroutine print_features ()
    end subroutine print_features

<Features: procedures>≡
  module subroutine print_features ()
    print "(A)", "WHIZARD " // WHIZARD_VERSION
    print "(A)", "Build configuration:"
    <Features: config>
    print "(A)", "Optional features available in this build:"
    <Features: print>
  end subroutine print_features
```

### 35.3.2 Query function

```
<Features: procedures>+≡
  subroutine check (feature, recognized, result, help)
    character(*), intent(in) :: feature
    logical, intent(out) :: recognized
    character(*), intent(out) :: result, help
    recognized = .true.
    result = "no"
    select case (lower_case (trim (feature)))
      <Features: cases>
      case default
        recognized = .false.
      end select
    end subroutine check
```

Print this result:

```
<Features: procedures>+≡
  subroutine print_check (feature)
    character(*), intent(in) :: feature
    character(16) :: f
    logical :: recognized
    character(10) :: result
    character(48) :: help
    call check (feature, recognized, result, help)
