  call eval_tree_write (eval_tree)
  call msg_error ("Evaluation yields an undefined result, inserting default")
  end subroutine eval_tree_unknown

```

### 28.3.11 Factory Type

Since `eval_tree_t` is an implementation of `expr_t`, we also need a matching factory type and build method.

```

<Eval trees: public>+≡
  public :: eval_tree_factory_t

<Eval trees: types>+≡
  type, extends (expr_factory_t) :: eval_tree_factory_t
  private
  type(parse_node_t), pointer :: pn => null ()
  contains
  <Eval trees: eval tree factory: TBP>
  end type eval_tree_factory_t

```

Output: delegate to the output of the embedded parse node.

```

<Eval trees: eval tree factory: TBP>≡
  procedure :: write => eval_tree_factory_write

<Eval trees: sub interfaces>+≡
  module subroutine eval_tree_factory_write (expr_factory, unit)
  class(eval_tree_factory_t), intent(in) :: expr_factory
  integer, intent(in), optional :: unit
  end subroutine eval_tree_factory_write

<Eval trees: procedures>+≡
  module subroutine eval_tree_factory_write (expr_factory, unit)
  class(eval_tree_factory_t), intent(in) :: expr_factory
  integer, intent(in), optional :: unit
  if (associated (expr_factory%pn)) then
  call parse_node_write_rec (expr_factory%pn, unit)
  end if
  end subroutine eval_tree_factory_write

```

Initializer: take a parse node and hide it thus from the environment.

```

<Eval trees: eval tree factory: TBP>+≡
  procedure :: init => eval_tree_factory_init

<Eval trees: sub interfaces>+≡
  module subroutine eval_tree_factory_init (expr_factory, pn)
  class(eval_tree_factory_t), intent(out) :: expr_factory
  type(parse_node_t), intent(in), pointer :: pn
  end subroutine eval_tree_factory_init

```

```

<Eval trees: procedures>+≡
  module subroutine eval_tree_factory_init (expr_factory, pn)
    class(eval_tree_factory_t), intent(out) :: expr_factory
    type(parse_node_t), intent(in), pointer :: pn
    expr_factory%pn => pn
  end subroutine eval_tree_factory_init

```

Factory method: allocate expression with correct eval tree type. If the stored parse node is not associate, don't allocate. Gfortran 7/8/9 bug, has to remain in the module.

```

<Eval trees: eval tree factory: TBP>+≡
  procedure :: build => eval_tree_factory_build

<Eval trees: main procedures>≡
  subroutine eval_tree_factory_build (expr_factory, expr)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    class(expr_t), intent(out), allocatable :: expr
    if (associated (expr_factory%pn)) then
      allocate (eval_tree_t :: expr)
      select type (expr)
        type is (eval_tree_t)
          expr%pn => expr_factory%pn
        end select
      end if
    end subroutine eval_tree_factory_build

```

## 28.4 Physics Models

A model object represents a physics model. It contains a table of particle data, a list of parameters, and a vertex table. The list of parameters is a variable list which includes the real parameters (which are pointers to the particle data table) and PDG array variables for the particles themselves. The vertex list is used for phase-space generation, not for calculating the matrix element.

The actual numeric model data are in the base type `model_data_t`, as part of the `qft` section. We implement the `model_t` as an extension of this, for convenient direct access to the base-type methods via inheritance. (Alternatively, we could delegate these calls explicitly.) The extension contains administrative additions, such as the methods for recalculating derived data and keeping the parameter set consistent. It thus acts as a proxy of the actual model-data object towards the `WHIZARD` package. There are further proxy objects, such as the `parameter_t` array which provides the interface to the actual numeric parameters.

Model definitions are read from model files. Therefore, this module contains a parser for model files. The parameter definitions (derived parameters) are Sindarin expressions.

The models, as read from file, are stored in a model library which is a simple list of model definitions. For setting up a process object we should make a copy (an instance) of a model, which gets the current parameter values from the global variable list.

### 28.4.1 Module

```
<models.f90>≡  
<File header>  
  
module models  
  
  use, intrinsic :: iso_c_binding !NODEP!

    use physics_defs, only: UNDEFINED

    use ifiles
    use lexers
    use pdg_arrays
    use ttv_formfactors, only: init_parameters

    implicit none

    contains

    <Models: procedures>

    end submodule models_s

```

## 28.4.2 Physics Parameters

A parameter has a name, a value. Derived parameters also have a definition in terms of other parameters, which is stored as an `eval_tree`. External parameters are set by an external program.

This parameter object should be considered as a proxy object. The parameter name and value are stored in a corresponding `modelpar_data_t` object which is located in a `model_data_t` object. The latter is a component of the `model_t` handler. Methods of `parameter_t` can be delegated to the `par_data_t` component.

The `block_name` and `block_index` values, if nonempty, indicate the possibility of reading this parameter from a SLHA-type input file. (Within the `parameter_t` object, this info is just used for I/O, the actual block register is located in the parent `model_t` object.)

The `pn` component is a pointer to the parameter definition inside the model parse tree. It allows us to recreate the `eval_tree` when making copies (instances) of the parameter object.

```

<Models: parameters>≡
  integer, parameter :: PAR_NONE = 0, PAR_UNUSED = -1
  integer, parameter :: PAR_INDEPENDENT = 1, PAR_DERIVED = 2
  integer, parameter :: PAR_EXTERNAL = 3

```

```

<Models: types>≡
  type :: parameter_t
  private
  integer :: type = PAR_NONE
  class(modelpar_data_t), pointer :: data => null ()
  type(string_t) :: block_name
  integer, dimension(:), allocatable :: block_index
  type(parse_node_t), pointer :: pn => null ()
  class(expr_t), allocatable :: expr
  contains
  <Models: parameter: TBP>
  end type parameter_t

```

Initialization depends on parameter type. Independent parameters are initialized by a constant value or a constant numerical expression (which may contain a unit). Derived parameters are initialized by an arbitrary numerical expression, which makes use of the current variable list. The expression is evaluated by the function `parameter_reset`.

This implementation supports only real parameters and real values.

```

<Models: parameter: TBP>≡
  procedure :: init_independent_value => parameter_init_independent_value
  procedure :: init_independent => parameter_init_independent
  procedure :: init_derived => parameter_init_derived
  procedure :: init_external => parameter_init_external
  procedure :: init_unused => parameter_init_unused

```

```

<Models: sub interfaces>≡
  module subroutine parameter_init_independent_value &
    (par, par_data, name, value)
    class(parameter_t), intent(out) :: par
    class(modelpar_data_t), intent(in), target :: par_data

end subroutine parameter_init_independent

subroutine parameter_init_derived (par, par_data, name, pn, var_list)
  class(parameter_t), intent(out) :: par
  class(modelpar_data_t), intent(in), target :: par_data
  type(string_t), intent(in) :: name
  type(parse_node_t), intent(in), target :: pn

```

```

type(var_list_t), intent(in), target :: var_list
par%type = PAR_DERIVED
par%pn => pn
allocate (eval_tree_t :: par%expr)
select type (expr => par%expr)
type is (eval_tree_t)
call expr%init_expr (pn, var_list=var_list)
end select
par%data => par_data
!      call par%expr%evaluate ()
call par%data%init (name, 0._default)
end subroutine parameter_init_derived

```

The finalizer is needed for the evaluation tree in the definition.

```

<Models: parameter: TBP>+≡
  procedure :: final => parameter_final

<Models: sub interfaces>+≡
  module subroutine parameter_final (par)
    class(parameter_t), intent(inout) :: par
  end subroutine parameter_final

<Models: procedures>+≡
  module subroutine parameter_final (par)
    class(parameter_t), intent(inout) :: par
    if (allocated (par%expr)) then
      call par%expr%final ()
    end if
  end subroutine parameter_final

```

All derived parameters should be recalculated if some independent parameters have changed:

```

<Models: parameter: TBP>+≡
  procedure :: reset_derived => parameter_reset_derived

<Models: sub interfaces>+≡
  module subroutine parameter_reset_derived (par)
    class(parameter_t), intent(inout) :: par
  end subroutine parameter_reset_derived

<Models: procedures>+≡
  module subroutine parameter_reset_derived (par)
    class(parameter_t), intent(inout) :: par
    select case (par%type)
    case (PAR_DERIVED)
      call par%expr%evaluate ()
      par%data = par%expr%get_real ()
    end select
  end subroutine parameter_reset_derived

```

Output. [We should have a formula format for the eval tree, suitable for input and output!]

```

<Models: parameter: TBP>+≡
  procedure :: write => parameter_write

```

```

```

### 28.4.3 SLHA block register

For the optional SLHA interface, the model record contains a register of SLHA-type block names together with index values, which point to a particular parameter. These are private types:

*<Models: types>+≡*

```

type :: slha_entry_t
integer, dimension(:), allocatable :: block_index
integer :: i_par = 0
end type slha_entry_t

```

*<Models: types>+≡*

```

type :: slha_block_t
type(string_t) :: name
integer :: n_entry = 0
type(slha_entry_t), dimension(:), allocatable :: entry
end type slha_block_t

```

### 28.4.4 Model Object

A model object holds all information about parameters, particles, and vertices. For models that require an external program for parameter calculation, there is the pointer to a function that does this calculation, given the set of independent and derived parameters.

As explained above, the type inherits from `model_data_t`, which is the actual storage for the model data.

When reading a model, we create a parse tree. Parameter definitions are available via parse nodes. Since we may need those later when making model instances, we keep the whole parse tree in the model definition (but not in the instances).

*<Models: public>≡*

```

public :: model_t

```

```

<Models: types>+=
  type, extends (model_data_t) :: model_t
  private
  character(32) :: md5sum = ""
  logical :: ufo_model = .false.
  type(string_t) :: ufo_path
  type(string_t), dimension(:), allocatable :: schemes
  type(string_t), allocatable :: selected_scheme
  type(parameter_t), dimension(:), allocatable :: par
  integer :: n_slha_block = 0
  type(slha_block_t), dimension(:), allocatable :: slha_block
  integer :: max_par_name_length = 0
  integer :: max_field_name_length = 0
  type(var_list_t) :: var_list
  type(string_t) :: dlname
  procedure(model_init_external_parameters), nopass, pointer :: &
  init_external_parameters => null ()
  type(dlaccess_t) :: dlaccess
  type(parse_tree_t) :: parse_tree
  contains
  <Models: model: TBP>
  end type model_t

```

This is the interface for a procedure that initializes the calculation of external parameters, given the array of all parameters.

```

<Models: interfaces>=
  abstract interface
  subroutine model_init_external_parameters (par) bind (C)
  import
  real(c_default_float), dimension(*), intent(inout) :: par
  end subroutine model_init_external_parameters
  end interface

```

Initialization: Specify the number of parameters, particles, vertices and allocate memory. If an associated DL library is specified, load this library.

The model may already carry scheme information, so we have to save and restore the scheme number when actually initializing the `model_data_t` base.

```

<Models: model: TBP>=
  generic :: init => model_init
  procedure, private :: model_init

<Models: sub interfaces>+=

Make a copy of a parameter. We assume that the `model_data_t` parameter arrays have already been copied, so names and values are available in the current model, and can be used as targets. The eval tree should not be copied, since it should refer to the new variable list. The safe solution is to make use of the above initializers, which also take care of the building a new variable list.

```

## 28.4.6 UFO models

A single flag identifies a model as a UFO model. There is no other distinction, but the flag allows us to handle built-in and UFO models with the same name in parallel.

```

<Models: model: TBP>+≡

```

```

    procedure :: is_ufo_model => model_is_ufo_model

    <Models: sub interfaces>+≡
    module function model_is_ufo_model (model) result (flag)
    class(model_t), intent(in) :: model
    logical :: flag
    end function model_is_ufo_model

    <Models: procedures>+≡
    module function model_is_ufo_model (model) result (flag)
    class(model_t), intent(in) :: model
    logical :: flag
    flag = model%ufo_model
    end function model_is_ufo_model

```

Return the UFO path used for fetching the UFO source.

```

    <Models: model: TBP>+≡
    procedure :: get_ufo_path => model_get_ufo_path

    <Models: sub interfaces>+≡
    module function model_get_ufo_path (model) result (path)
    class(model_t), intent(in) :: model
    type(string_t) :: path
    end function model_get_ufo_path

    <Models: procedures>+≡
    module function model_get_ufo_path (model) result (path)
    class(model_t), intent(in) :: model
    type(string_t) :: path
    if (model%ufo_model) then
    path = model%ufo_path
    else
    path = ""
    end if
    end function model_get_ufo_path

```

Call OMega and generate a model file from an UFO source file. We start with a file name; the model name is expected to be the base name, stripping extensions.

The path search either takes `ufo_path_requested`, or searches first in the working directory, then in a hard-coded UFO model directory.

```

    <Models: procedures>+≡
    subroutine model_generate_ufo (filename, os_data, ufo_path, &
    ufo_path_requested)
    type(string_t), intent(in) :: filename

type(string_t), intent(out) :: model_name
type(string_t) :: string
string = filename
call split (string, model_name, ".")
end subroutine get_model_name
end subroutine model_generate_ufo

```

### 28.4.7 Scheme handling

A model can specify a set of allowed schemes that steer the setup of model variables. The model file can contain scheme-specific declarations that are selected by a `select scheme` clause. Scheme support is optional.

If enabled, the model object contains a list of allowed schemes, and the model reader takes the active scheme as an argument. After the model has been read, the scheme is fixed and can no longer be modified.

The model supports schemes if the scheme array is allocated.

```
<Models: model: TBP>+≡
  procedure :: has_schemes => model_has_schemes

<Models: sub interfaces>+≡
  module function model_has_schemes (model) result (flag)
    logical :: flag
    class(model_t), intent(in) :: model
  end function model_has_schemes

<Models: procedures>+≡
  module function model_has_schemes (model) result (flag)
    logical :: flag
    class(model_t), intent(in) :: model
    flag = allocated (model%schemes)
  end function model_has_schemes
```

Enable schemes: fix the list of allowed schemes.

```
<Models: model: TBP>+≡
  procedure :: enable_schemes => model_enable_schemes

<Models: sub interfaces>+≡
  module subroutine model_enable_schemes (model, scheme)
    class(model_t), intent(inout) :: model
    type(string_t), dimension(:), intent(in) :: scheme
  end subroutine model_enable_schemes

<Models: procedures>+≡
  module subroutine model_enable_schemes (model, scheme)
    class(model_t), intent(inout) :: model
    type(string_t), dimension(:), intent(in) :: scheme
    allocate (model%schemes (size (scheme)), source = scheme)
  end subroutine model_enable_schemes
```

Find the scheme. Check if the scheme is allowed. The numeric index of the selected scheme is stored in the `model_data_t` base object.

If no argument is given, select the first scheme. The numeric scheme ID will then be 1, while a model without schemes retains 0.

```
<Models: model: TBP>+≡
  procedure :: set_scheme => model_set_scheme

<Models: sub interfaces>+≡
  module subroutine model_set_scheme (model, scheme)
    class(model_t), intent(inout) :: model
    type(string_t), intent(in), optional :: scheme
  end subroutine model_set_scheme
```

```

<Models: procedures>+≡
module subroutine model_set_scheme (model, scheme)
class(model_t), intent(inout) :: model
type(string_t), intent(in), optional :: scheme
logical :: ok
integer :: i
if (model%has_schemes ()) then
if (present (scheme)) then
ok = .false.
CHECK_SCHEME: do i = 1, size (model%schemes)
if (scheme == model%schemes(i)) then
allocate (model%selected_scheme, source = scheme)
call model%set_scheme_num (i)
ok = .true.
exit CHECK_SCHEME
end if
end do CHECK_SCHEME
if (.not. ok) then
call msg_fatal &

// "': scheme '" // char (scheme) // "' not supported")
end if
else
allocate (model%selected_scheme, source = model%schemes(1))
call model%set_scheme_num (1)
end if
else
if (present (scheme)) then
call msg_error &
("Model '" // char (model%get_name ()) &
// "' does not support schemes")
end if
end if
end subroutine model_set_scheme

```

Get the scheme. Note that the base `model_data_t` provides a `get_scheme_num` getter function.

```

<Models: model: TBP>+≡
procedure :: get_scheme => model_get_scheme

<Models: sub interfaces>+≡
module function model_get_scheme (model) result (scheme)
class(model_t), intent(in) :: model
type(string_t) :: scheme
end function model_get_scheme

<Models: procedures>+≡
module function model_get_scheme (model) result (scheme)
class(model_t), intent(in) :: model
type(string_t) :: scheme
if (allocated (model%selected_scheme)) then
scheme = model%selected_scheme
else
scheme = ""
end if

```

```
end function model_get_scheme
```

Check if a model has been set up with a specific name and (if applicable) scheme. This helps in determining whether we need a new model object.

A UFO model is considered to be distinct from a non-UFO model. We assume that if `ufo` is asked for, there is no scheme argument. Furthermore, if there is an `ufo_path` requested, it must coincide with the `ufo_path` of the model. If not, the model `ufo_path` is not checked.

*(Models: model: TBP)*+≡

```
procedure :: matches => model_matches
```

end if
else if (present (scheme)) then
flag = .false.
else
flag = .true.
end if
```

```
end function model_matches
```

### 28.4.8 SLHA-type interface

Abusing the original strict SUSY Les Houches Accord (SLHA), we support reading parameter data from some custom SLHA-type input file. To this end, the `model` object stores a list of model-specific block names together with information how to find a parameter in the model record, given a block name and index vector.

Check if the model supports custom SLHA block info. This is the case if `n_slha_block` is nonzero, i.e., after SLHA block names have been parsed and registered.

```
<Models: model: TBP>+≡
  procedure :: supports_custom_slha => model_supports_custom_slha

<Models: sub interfaces>+≡
  module function model_supports_custom_slha (model) result (flag)
    class(model_t), intent(in) :: model
    logical :: flag
  end function model_supports_custom_slha

<Models: procedures>+≡
  module function model_supports_custom_slha (model) result (flag)
    class(model_t), intent(in) :: model
    logical :: flag

    flag = model%n_slha_block > 0

  end function model_supports_custom_slha
```

Return the block names for all SLHA block references.

```
<Models: model: TBP>+≡
  procedure :: get_custom_slha_blocks => model_get_custom_slha_blocks

<Models: sub interfaces>+≡
  module subroutine model_get_custom_slha_blocks (model, block_name)

```

The lookup routine returns a pointer to the appropriate `par_data` record, if `block_name` and `block_index` are valid. The latter point to the `slha_block_t` register within the `model_t` object, if it is allocated.

This should only be needed during I/O (i.e., while reading the SLHA file), so a simple linear search for each parameter should not be a performance problem.

```

  end subroutine syntax_model_file_write

```

Read a model from file. Handle all syntax and respect the provided scheme.

The `ufo` flag just says that the model object should be tagged as being derived from an UFO model. The UFO model path may be requested by the caller. If not, we use a standard path search for UFO models. There is no difference in the contents of the file or the generated model object.

```

<Models: model: TBP>+≡

```

```

call model_list%import (current, model)
end if
end subroutine model_list_add

```

Read a new model from file and add to the list, if it does not yet exist. Finalize the model by allocating the vertex table. Return a pointer to the new model. If unsuccessful, return the original pointer.

The model is always inserted in the last link of a chain of model lists. This way, we avoid loading models twice from different contexts. When a model is modified, we should first allocate a local copy.

## 28.4.12 Model instances

A model instance is a copy of a model object. The parameters are true copies. The particle data and the variable list pointers should point to the copy, so modifying the parameters has only a local effect. Hence, we build them up explicitly. The vertex array is also rebuilt, it contains particle pointers. Finally, the vertex hash table can be copied directly since it contains no pointers.

The `multiplicity` entry depends on the association of the `mass_data` entry and therefore has to be set at the end.

The instance must carry the `target` attribute.

Parameters: the `copy_parameter` method essentially copies the parameter decorations (parse node, expression etc.). The current parameter values are part of the `model_data_t` base type and are copied afterwards via its `copy_from` method.

Note: the parameter set is initialized for real parameters only.

In order for the local model to be able to use the correct UFO model setup, UFO model information has to be transferred.

```

<Models: model: TBP>+≡
  procedure :: init_instance => model_copy

<Models: sub interfaces>+≡
  module subroutine model_copy (model, orig)
    class(model_t), intent(out), target :: model
    type(model_t), intent(in) :: orig
    end subroutine model_copy

<Models: procedures>+≡
  module subroutine model_copy (model, orig)

    contains
```

```
<SLHA: procedures>
```

```
end submodule slha_interface_s
```

### 28.5.1 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

A name clash occurs if the block name is identical to a keyword. This can happen for custom SLHA models and files. In that case, we prepend an underscore, which will be silently suppressed where needed.

```
<SLHA: parameters>≡
```

```
integer, parameter :: MODE_SKIP = 0, MODE_DATA = 1, MODE_INFO = 2
```

```
<SLHA: procedures>≡
```

```
subroutine slha_preprocess (stream, custom_block_name, ifile)
  type(stream_t), intent(inout), target :: stream
  type(string_t), dimension(:), intent(in) :: custom_block_name
  type(ifile_t), intent(out) :: ifile
  type(string_t) :: buffer, line, item
  integer :: iostat
  integer :: mode
  mode = MODE
  SCAN_FILE: do
    call stream_get_record (stream, buffer, iostat)
    select case (iostat)
    case (0)
      call split (buffer, line, "#")
      if (len_trim (line) == 0) cycle SCAN_FILE
      select case (char (extract (line, 1, 1)))
      case ("B", "b")
        call check_block_handling (line, custom_block_name, mode)
        call ifile_append (ifile, line // "$")
      case ("D", "d")
        mode = MODE_DATA
        call ifile_append (ifile, line // "$")
      case (" ")
        select case (mode)
        case (MODE_DATA)
          call ifile_append (ifile, "DATA" // line // "$")
        case (MODE_INFO)
```

```

line = adjustl (line)
call split (line, item, " ")
call ifile_append (ifile, "INFO" // " " // item // " " &
// ' "' // trim (adjustl (line)) // ' " $')
end select
case default
call msg_message (char (line))
call msg_fatal ("SLHA: Incomprehensible line")
end select
case (EOF)
exit SCAN_FILE
case default
call msg_fatal ("SLHA: I/O error occured while reading SLHA input")
end select
end do SCAN_FILE
end subroutine slha_preprocess

```

Return the mode that we should treat this block with. We add the `custom_block_name` array to the set of supported blocks, which otherwise includes only hard-coded block names. Those custom blocks are data blocks.

Unknown blocks will be skipped altogether. The standard does not specify their internal format at all, so we must not parse their content.

If the name of a (custom) block clashes with a keyword of the SLHA syntax, we append an underscore to the block name, modifying the current line string. This should be silently suppressed when actually parsing block names.

```

<SLHA: procedures> +=
subroutine check_block_handling (line, custom_block_name, mode)
type(string_t), intent(inout) :: line
type(string_t), dimension(:), intent(in) :: custom_block_name
integer, intent(out) :: mode
type(string_t) :: buffer, key, block_name
integer :: i
buffer = trim (line)
call split (buffer, key, " ")
buffer = adjustl (buffer)
call split (buffer, block_name, " ")
buffer = adjustl (buffer)
block_name = trim (adjustl (upper_case (block_name)))
select case (char (block_name))
case ("MODSEL", "MINPAR", "SMINPUTS")
mode = MODE_DATA
case ("MASS")
mode = MODE_DATA
case ("NMIX", "UMIX", "VMIX", "STOPMIX", "SBOTMIX", "STAUMIX")

case ("ALPHA", "HMX")
mode = MODE_DATA
case ("AU", "AD", "AE")
mode = MODE_DATA
case ("SPINFO", "DCINFO")
mode = MODE_INFO

```

```

case default
mode = MODE_SKIP
CHECK_CUSTOM_NAMES: do i = 1, size (custom_block_name)
if (block_name == custom_block_name(i)) then
mode = MODE_DATA
call mangle_keywords (block_name)
line = key // " " // block_name // " " // trim (buffer)
exit CHECK_CUSTOM_NAMES
end if
end do CHECK_CUSTOM_NAMES
end select
end subroutine check_block_handling

```

Append an underscore to specific block names:

```

⟨SLHA: procedures⟩+=
subroutine mangle_keywords (name)
type(string_t), intent(inout) :: name
select case (char (name))
case ("BLOCK", "DATA", "INFO", "DECAY")
name = name // "_"
end select
end subroutine mangle_keywords

```

Remove the underscore again:

```

⟨SLHA: procedures⟩+=
subroutine demangle_keywords (name)
type(string_t), intent(inout) :: name
select case (char (name))
case ("BLOCK_", "DATA_", "INFO_", "DECAY_")
name = extract (name, 1, len(name)-1)
end select
end subroutine demangle_keywords

```

call ifile_append (ifile, "SEQ decay_data = DATA decay_line '$'")
call ifile_append (ifile, "SEQ decay_line = data_item integer pdg_code+")
end subroutine define_slha_syntax

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

end subroutine lexer_init_slha

```

## 28.5.3 Interpreter

### Find blocks

From the parse tree, find the node that represents a particular block. If **required** is true, issue an error if not found. Since **block\_name** is always invoked with capital letters, we have to capitalize **pn\_block\_name**.

*<SLHA: procedures>+≡*

```

function slha_get_block_ptr &
(parse_tree, block_name, required) result (pn_block)
type(parse_node_t), pointer :: pn_block
type(parse_tree_t), intent(in) :: parse_tree

```

```

type(string_t), intent(in) :: block_name
type(string_t) :: block_def
logical, intent(in) :: required
type(parse_node_t), pointer :: pn_root, pn_block_spec, pn_block_name
pn_root => parse_tree%get_root_ptr ()
pn_block => parse_node_get_sub_ptr (pn_root)
do while (associated (pn_block))
select case (char (parse_node_get_rule_key (pn_block)))
case ("block_def")
pn_block_spec => parse_node_get_sub_ptr (pn_block, 2)
pn_block_name => parse_node_get_sub_ptr (pn_block_spec)
select case (char (pn_block_name%get_rule_key ()))
case ("block_name")
block_def = trim (adjustl (upper_case &
(pn_block_name%get_string ())))
case ("QNUMBERS")
block_def = "QNUMBERS"
end select
if (block_def == block_name) then
return
end if
end select
pn_block => parse_node_get_next_ptr (pn_block)
end do
if (required) then
call msg_fatal ("SLHA: block '" // char (block_name) // "' not found")
end if
end function slha_get_block_ptr

```

Scan the file for the first/next DECAY block.

*<SLHA: procedures>+≡*

```

function slha_get_first_decay_ptr (parse_tree) result (pn_decay)
type(parse_node_t), pointer :: pn_decay
type(parse_tree_t), intent(in) :: parse_tree
type(parse_node_t), pointer :: pn_root
pn_root => parse_tree%get_root_ptr ()
pn_decay => parse_node_get_sub_ptr (pn_root)
do while (associated (pn_decay))
select case (char (parse_node_get_rule_key (pn_decay)))
case ("decay_def")
return
end select

    type(string_t), intent(in) :: name
    type(var_list_t), intent(inout), target :: var_list
    type(parse_node_t), pointer :: pn_data, pn_item
    call slha_find_index_pair_ptr (pn_block, pn_data, pn_item, code1, code2)
    if (associated (pn_item)) then
      call var_list%set_real (name, get_real_parameter (pn_item), &
        is_known=.true., ignore=.true.)
    end if
  end subroutine set_matrix_element

```

## Transfer data from variables to SLHA

Get a real/integer parameter with index  $i$  from the variable list and write it to the current output file. In the integer case, we account for the fact that the variable is type real. If it does not exist, do nothing.

```

(SLHA: procedures)+≡
  subroutine write_integer_data_item (u, code, name, var_list, comment)
    integer, intent(in) :: u
    integer, intent(in) :: code
    type(string_t), intent(in) :: name
    type(var_list_t), intent(in) :: var_list
    character(*), intent(in) :: comment
    integer :: item
    if (var_list%contains (name)) then
      item = nint (var_list%get_rval (name))
      call write_integer_parameter (u, code, item, comment)
    end if
  end subroutine write_integer_data_item

```

```

subroutine write_real_data_item (u, code, name, var_list, comment)
integer, intent(in) :: u
integer, intent(in) :: code
type(string_t), intent(in) :: name
type(var_list_t), intent(in) :: var_list
character(*), intent(in) :: comment
real(default) :: item
if (var_list%contains (name)) then
item = var_list%get_rval (name)
call write_real_parameter (u, code, item, comment)
end if
end subroutine write_real_data_item

```

Get a real data item with two integer indices from the variable list and write it to the current output file. If it does not exist, do nothing.

*(SLHA: procedures)*+≡

```

subroutine write_matrix_element (u, code1, code2, name, var_list, comment)
integer, intent(in) :: u
integer, intent(in) :: code1, code2
type(string_t), intent(in) :: name
type(var_list_t), intent(in) :: var_list
character(*), intent(in) :: comment
real(default) :: item
if (var_list%contains (name)) then
item = var_list%get_rval (name)
call write_real_matrix_element (u, code1, code2, item, comment)
end if
end subroutine write_matrix_element

```

## 28.5.4 Auxiliary function

Write a block header.

*(SLHA: procedures)*+≡

```

subroutine write_block_header (u, name, comment)
integer, intent(in) :: u
character(*), intent(in) :: name, comment
write (u, "(A,1x,A,3x,'#',1x,A)") "BLOCK", name, comment
end subroutine write_block_header

```

Extract a real parameter that may be defined real or integer, signed or unsigned.

*(SLHA: procedures)*+≡

```

function get_real_parameter (pn_item) result (var)
real(default) :: var
type(parse_node_t), intent(in), target :: pn_item
type(parse_node_t), pointer :: pn_sign, pn_var
integer :: sign
select case (char (parse_node_get_rule_key (pn_item)))
case ("signed_number")
pn_sign => parse_node_get_sub_ptr (pn_item)
pn_var => parse_node_get_next_ptr (pn_sign)
select case (char (parse_node_get_key (pn_sign)))

```

```

case ("+"); sign = +1
case ("-"); sign = -1
end select
case default
sign = +1
pn_var => pn_item
end select
select case (char (parse_node_get_rule_key (pn_var)))
case ("integer"); var = sign * parse_node_get_integer (pn_var)
case ("real"); var = sign * parse_node_get_real (pn_var)
end select
end function get_real_parameter

```

Auxiliary: Extract an integer parameter that may be defined signed or unsigned.  
A real value is an error.

*(SLHA: procedures)*+≡

```

function get_integer_parameter (pn_item) result (var)
integer :: var
type(parse_node_t), intent(in), target :: pn_item
type(parse_node_t), pointer :: pn_sign, pn_var
integer :: sign

call msg_error ("SLHA: Integer parameter expected")
var = 0
return
end select
var = sign * parse_node_get_integer (pn_var)
end function get_integer_parameter

```

Write an integer parameter with a single index directly to file, using the required output format.

*(SLHA: procedures)*+≡

```

subroutine write_integer_parameter (u, code, item, comment)
integer, intent(in) :: u
integer, intent(in) :: code
integer, intent(in) :: item
character(*), intent(in) :: comment
1 format (1x, I9, 3x, 3x, I9, 4x, 3x, '#', 1x, A)
write (u, 1) code, item, comment
end subroutine write_integer_parameter

```

Write a real parameter with two indices directly to file, using the required output format.

```
<SLHA: procedures>+=
  subroutine write_real_parameter (u, code, item, comment)
    integer, intent(in) :: u
    integer, intent(in) :: code
    real(default), intent(in) :: item
    character(*), intent(in) :: comment
    1  format (1x, I9, 3x, 1P, E16.8, 0P, 3x, '#', 1x, A)
    write (u, 1) code, item, comment
  end subroutine write_real_parameter
```

Write a real parameter with a single index directly to file, using the required output format.

```
<SLHA: procedures>+=
  subroutine write_real_matrix_element (u, code1, code2, item, comment)
    integer, intent(in) :: u
    integer, intent(in) :: code1, code2
    real(default), intent(in) :: item
    character(*), intent(in) :: comment
    1  format (1x, I2, 1x, I2, 3x, 1P, E16.8, 0P, 3x, '#', 1x, A)
    write (u, 1) code1, code2, item, comment
  end subroutine write_real_matrix_element
```

## The concrete SLHA interpreter

SLHA codes for particular physics models

```
<SLHA: parameters>+=
  integer, parameter :: MDL_MSSM = 0
  integer, parameter :: MDL_NMSSM = 1
```

Take the parse tree and extract relevant data. Select the correct model and store all data that is present in the appropriate variable list. Finally, update the variable record.

We assume that if the model contains custom SLHA block names, we just have to scan those to get complete information. Block names could coincide with the SLHA standard block names, but we do not have to assume this. This will be the situation for an UFO-generated file. In particular, an UFO file should contain all expressions necessary for computing dependent parameters, so we can forget about the strict SLHA standard and its hard-coded conventions.

If there are no custom SLHA block names, we should assume that the model is a standard SUSY model, and the parameters and hard-coded blocks can be read as specified by the original SLHA standard. There are hard-coded block names and parameter calculations.

Public for use in unit test.

```
<SLHA: public>+=
  public :: slha_interpret_parse_tree

<SLHA: sub interfaces>+=
  module subroutine slha_interpret_parse_tree &
    (parse_tree, model, input, spectrum, decays)
```

```

type(parse_tree_t), intent(in) :: parse_tree

## SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is not defined in the block, we use the previous value from the model variable list. For the basic parameters we have to do a small recalculation, since SLHA uses the  $G_F$ - $\alpha$ - $m_Z$  scheme, while WHIZARD derives them from  $G_F$ ,  $m_W$ , and  $m_Z$ .

call set_data_item (pn_block, 5, var_str ("nmu"), var_list)
end subroutine slha_handle_NMSSMRUN

```

### 28.5.5 Parsing custom SLHA files

With the introduction of UFO models, we support custom files in generic SLHA format that reset model parameters. In contrast to strict SLHA files, the order and naming of blocks is arbitrary.

We scan the complete file (i.e., preprocessed parse tree), parsing all blocks that contain data lines. For each data line, we identify index array and associated value. Then we set the model parameter that is associated with that block name and index array, if it exists.

```

<SLHA: procedures>+=
  subroutine slha_handle_custom_file (parse_tree, model)
    type(parse_tree_t), intent(in) :: parse_tree
    type(model_t), intent(inout), target :: model

```

## 28.5.6 Parser

Read a SLHA file from stream, including preprocessing, and make up a parse tree.

```

<SLHA: procedures>+≡
subroutine slha_parse_stream (stream, custom_block_name, parse_tree)
type(stream_t), intent(inout), target :: stream
type(string_t), dimension(:), intent(in) :: custom_block_name
type(parse_tree_t), intent(out) :: parse_tree
type(ifile_t) :: ifile
type(lexer_t) :: lexer
type(stream_t), target :: stream_tmp
call slha_preprocess (stream, custom_block_name, ifile)
call stream_init (stream_tmp, ifile)
call lexer_init_slha (lexer)
call lexer_assign_stream (lexer, stream_tmp)

```

```

call parse_tree_init (parse_tree, syntax_slha, lexer)
call lexer_final (lexer)
call stream_final (stream_tmp)
call ifile_final (ifile)
end subroutine slha_parse_stream

```

Read a SLHA file chosen by name. Check first the current directory, then the directory where SUSY input files should be located.

The `default_mode` applies to unknown blocks in the SLHA file: this is either `MODE_SKIP` or `MODE_DATA`, corresponding to genuine SUSY and custom file content, respectively.

```

<SLHA: public>+≡
  public :: slha_parse_file

<SLHA: sub interfaces>+≡
  module subroutine slha_parse_file &
    (file, custom_block_name, os_data, parse_tree)
    type(string_t), intent(in) :: file
    type(string_t), dimension(:), intent(in) :: custom_block_name
    type(os_data_t), intent(in) :: os_data
    type(parse_tree_t), intent(out) :: parse_tree
  end subroutine slha_parse_file

<SLHA: procedures>+≡
  module subroutine slha_parse_file &
    (file, custom_block_name, os_data, parse_tree)
    type(string_t), intent(in) :: file
    type(string_t), dimension(:), intent(in) :: custom_block_name
    type(os_data_t), intent(in) :: os_data

c !! THIS IS NOT A PUBLIC VERSION !!
c
c - Calculation of the Green function in momentum space by solving the
c   Lippmann-Schwinger equation
c    $G(p) = G_0(p) + G_0(p) \int_0^{\text{xcutn}} V(p,q) G(q) dq$ 
c
c - Written by Thomas Teubner, Hamburg, November 1998
c   * Based on TOPPIK Version 1.1
c     from M. Jezabek and TT, Karlsruhe, June 1992
c   * Version originally for non-constant top-width
c   * Constant width supplied here
c   * No generator included
c
c - Use of double precision everywhere

```

```

c
c - All masses, momenta, energies, widths in GeV
c
c - Input parameters:
c
c   xenergy   :  $E = \sqrt{s} - 2 \cdot \text{topmass}$ 
c   xtm       : topmass (in the Pole scheme)
c   xtg       : top-width
c   xalphas   :  $\alpha_s^{\{\text{MSbar}, n_f=5\}}(\text{xscale})$ 
c   xscale    : soft scale  $\mu_{\{\text{soft}\}}$ 
c   xcutn     : numerical UV cutoff on all momenta
c               (UV cutoff of the Gauss-Legendre grid)
c   xcutv     : renormalization cutoff on the
c               delta-, the  $(p^2+q^2)/(p-q)^2$ -, and the
c                $1/r^2 - [1/|p-q|]$ -potential:
c               if  $(\max(p,q) \geq \text{xcutv})$  then the three potentials
c               are set to zero in the Lippmann-Schwinger equation
c   xc0       : 0th order coefficient for the Coulomb potential,
c               see calling example above
c   xc1       : 1st order coefficient for the Coulomb potential
c   xc2       : 2nd order coefficient for the Coulomb potential
c   xcdeltc   : constant of the delta(r)-
c               [= constant in momentum space-] potential
c   xcdeltl   : constant for the additional  $\log(q^2/\mu^2)$ -part of the
c               delta-potential:
c                $\text{xcdeltc} * 1 + \text{xcdeltl} * \log(q^2/\mu^2)$ 
c   xcfullc   : constant of the  $(p^2+q^2)/(p-q)^2$ -potential
c   xcfulll   : constant for the additional  $\log(q^2/\mu^2)$ -part of the
c                $(p^2+q^2)/(p-q)^2$ -potential
c   xcrm2     : constant of the  $1/r^2 - [1/|p-q|]$ -potential
c   xkincm    : } kinetic corrections in the 0th order Green-function:
c   xkinca    : }  $G_0(p) := 1/[E + i\Gamma_t - p^2/m_t] * (1 + xkincm) + xkinca$ 
c               !!! WATCH THE SIGN IN G_0 !!!
c   jknflg    : flag for these kinetic corrections:
c               0 : no kinetic corrections applied
c               1 : kinetic corrections applied with cutoff xcutv
c                   for xkinca only
c               2 : kinetic corrections applied with cutoff xcutv
c                   for xkinca AND xkincm
c   jgcflg    : flag for  $G_0(p)$  in the LS equation:
c               0 (standard choice) :  $G_0(p)$  as given above
c               1 (for TIPT)         :  $G_0(p) = G_c^{\{0\}}(p)$  the 0th
c                                       order Coulomb-Green-function
c                                       in analytical form; not for
c                                       momenta  $p > 1000 \cdot \text{topmass}$ 
c   xkincv    : additional kinematic vertexcorrection in  $G_0$ , see below:
c   jvflg     : flag for the additional vertexcorrection xkincv in the
c               "zeroth order"  $G_0(p)$  in the LS-equation:
c               0 : no correction, means  $G = G_0 + G_0 \text{ int } V G$ 
c                   with  $G_0 = 1/[E + i\Gamma_t - p^2/m_t] * (1 + xkincm) + xkinca$ 
c               1 : apply the correction in the LS equation as
c                    $G = G_0 + xkincv * p^2/m_t^2 / [E + i\Gamma_t - p^2/m_t] +$ 
c                    $G_0 \text{ int } V G$ 
c                   and correct the integral over  $\text{Im}[G(p)]$  to get  $\text{sigma}_{\text{tot}}$ 

```

```

c          from the optical theorem by the same factor.
c          The cutoff xcutv is applied for these corrections.
c
c - Output:
c
c   xim      : R_{ttbar} from the imaginary part of the green
c              function
c   xdi      : R_{ttbar} form the integral over the momentum
c              distribution (no cutoff but the numerical one here!!)
c   np       : number of points used for the grid; fixed in tttoppik
c   xpp      : 1-dim array (max. 900 elements) giving the momenta of
c              the Gauss-Legendre grid (pp(i) in the code)
c   xww      : 1-dim array (max. 900 elements) giving the corresponding
c              Gauss-Legendre weights for the grid
c   xdsdp    : 1-dim array (max. 900 elements) giving the
c              momentum distribution of top: d\sigma/dp,
c              normalized to R,
c              at the momenta of the Gauss-Legendre grid xpp(i)
c   zvfct    : 1-dim array (max. 900 elements) of COMPLEX*16 numbers
c              giving the vertex function K(p), G(p)=K(p)*G_0(p)
c              at the momenta of the grid

vflag=jvflg
c
alphas=xalphas
c
c Cut for divergent potential-terms for large momenta in the function vhat
c and in the integrals a(p):
dcut=xcutv
c
c Numerical Cutoff of all momenta (maximal momenta of the grid):

```

```

xpmx=xcutn
if (dcut.gt.xpmx) then
write(*,*) ' dcut > xpmx  makes no sense! Stop.'
stop
endif
c
c Not needed for the fixed order potentials:
alamb5=0.2d0
c
c      WRITE(*,*) 'INPUT TGAMMA=',TGAMMA
c Needed in subroutine GAMMAT:
GFERMI=1.16637d-5
c      CALL GAMMAT
c      WRITE(*,*) 'CALCULATED TGAMMA=',TGAMMA
c
etot=2.d0*tmass+energy
c
if ((npot.eq.1).or.(npot.eq.3).or.(npot.eq.4).or.
u      (npot.eq.5)) then
c For pure coulomb and fixed order potentials there is no delta-part:
consde = 0.d0
else if (npot.eq.2) then
c Initialize QCD-potential common-blocks and calculate constant multiplying
c the delta-part of the 'qcutted' potential in momentum-space:
call iniphc(1)
call vqdelt(consde)
else
write (*,*) ' Potential not implemented! Stop.'
stop
endif
c Delta-part of potential is absorbed by subtracting vzero from the
c original energy (shift from the potential to the free Hamiltonian):
vzero = consde / (2.d0*pi)**3
c      write (*,*) 'vzero=', vzero
c
c Find x-values pp(i) and weights w1(i) for the gaussian quadrature;
c care about large number of points in the important intervals:
c      if (energy-vzero.le.0.d0) then
cc      call gauleg(0.d0, 1.d0, pp, w1, n/3)
cc      call gauleg(1.d0, 5.d0, pp(n/3+1), w1(n/3+1), n/3)
cc      call gauleg(0.d0, 0.2d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c      call gauleg(0.d0, 5.d0, pp, w1, n/3)
c      call gauleg(5.d0, 20.d0, pp(n/3+1), w1(n/3+1), n/3)
c      call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c      else
cc Avoid numerical singular points in the inner of the intervals:
c      critp = dsqrt((energy-vzero)*tmass)
c      if (critp.le.1.d0) then
cc Gauss-Legendre is symmetric => automatically principal-value prescription:
c      call gauleg(0.d0, 2.d0*critp, pp, w1, n/3)
c      call gauleg(2.d0*critp, 20.d0, pp(n/3+1),
c      u      w1(n/3+1), n/3)
c      call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c      else

```

```

c Better behaviour at the border of the intervals:
c      call gauleg(0.d0, critp, pp, w1, n/3)
c      call gauleg(critp, 2.d0*critp, pp(n/3+1),
c      u      w1(n/3+1), n/3)
c      call gauleg(0.d0, 1.d0/(2.d0*critp), pp(2*n/3+1),
c      u      w1(2*n/3+1), n/3)
c      endif
c      endif
c
c Or different (simpler) method, good for V_JKT:
if (energy.le.0.d0) then
critp=tmass/3.d0
else
critp=max(tmass/3.d0,2.d0*dsqrt(energy*tmass))
endif
call gauleg(0.d0, critp, pp, w1, 2*n/3)
call gauleg(1.d0/xpmax, 1.d0/critp, pp(2*n/3+1),
u      w1(2*n/3+1), n/3)
c
c Do substitution  $p \Rightarrow 1/p$  for the last interval explicitly:
do 10 i=2*n/3+1,n
pp(i) = 1.d0/pp(i)
10      continue
c
c Reorder the arrays for the third interval:
do 20 i=1,n/3
xx(i) = pp(2*n/3+i)
w2(i) = w1(2*n/3+i)
20      continue
do 30 i=1,n/3
pp(n-i+1) = xx(i)
w1(n-i+1) = w2(i)
30      continue
c
c Calculate the integrals  $a(p)$  for the given momenta  $pp(i)$ 
c and store weights and momenta for the output arrays:
do 40 i=1,n
a1(i) = a(pp(i)) !!! FB: can get stuck in original Toppik!
!!! FB: abuse 'np' as a flag to communicate unstable runs
if ( abs(a1(i)) .gt. 1d10 ) then
np = -1
return
endif
xpp(i)=pp(i)
xww(i)=w1(i)
40      continue
do 41 i=n+1,nmax
xpp(i)=0.d0
xww(i)=0.d0
41      continue
c
c Solve the integral-equation by solving a system of algebraic equations:
call sae(pp, w1, bb, a1, n)
c

```

```

c (The substitution for the integration to infinity pp => 1/pp
c is done already.)
do 50 i=1,n

c Correction function for non-constant (energy and momentum dependent) width:
FUNCTION GTPCOR1(TOPP,ETOT)
c
c      TOPP - momentum of t quark = - momentum of tbar
c      ETOT - total energy of t-tbar system
c      calls: GENWDS, RAN2
c
c      Evaluates a correction factor to the width of t-tbar system.
c      in future has to be replaced by a function evaluating
c      width including radiative corrections and GTPCOR.
c      I include two factors reducing the width:
c      a - time dilatation: for decay in flight lifetime
c          increased accordingly to relativistic kinematics
c      b - overall energy-momentum conservation: I assume that
c          t and tbar decay in flight and in this decays energies
c          of Ws follow from 2-body kinematics. Then I calculate
c          effective mass squared of b-bar system (it may be
c          negative!) from en-momentum conservation.
c          If effective mass is < 2*Mb + 2 GeV configuration
c          is rejected. The weight is acceptance.

C *****

```

```

c      Version tuned to provide 0(1%) relative accuracy for Coulomb axial
c      vertex function at first and second order (search for 'cctt'):
c      - integrals A(p), Vhat, Vhhat provided analytically w/out cut-off
c      - grid range fixed to 0.1 ... 10**6 absolut
c      - and grid size enhanced to 600 points (900 foreseen in arrays).
c
c      This provides a compromise between stability and accuracy:
c      We need a relatively high momentum resolution and large maximal
c      momenta to achieve a ~1 percent accuracy, but the method of
c      direct inversion of the discretised integral equation for objects
c      whose integral is divergent induces instabilities at small
c      momenta. As the behaviour there is known, they can be cut off and
c      the vertex function fixed by hand; but limiting the grid
c      further would impact on the accuracy.
c      22.3.2017, tt
c *****
c
c      Working version with all the different original potentials
c      like (p^2+q^2)/|p-q|^2, not transformed in terms of delta and 1/r^2;
c      accuracy eps=1.d-3 possible (only), but should be save, 13.8.'98, tt.
c      cleaned up a bit, 24.2.1999, tt.

c
c      - Calculation of the Green function in momentum space by solving the
c      Lippmann-Schwinger equation
c      
$$F(p) = G_0(p) + G_0(p) \int_0^{\text{xcutn}} V(p,q) q.p/p^2 F(q) dq$$

c
c      - Written by Thomas Teubner, Hamburg, November 1998
c      * Based on TOPPIK Version 1.1
c      from M. Jezabek and TT, Karlsruhe, June 1992
c      * Version originally for non-constant top-width
c      * Constant width supplied here
c      * No generator included
c
c      - Use of double precision everywhere
c
c      - All masses, momenta, energies, widths in GeV
c
c      - Input parameters:
c

```

```

c   xenergy : E=Sqrt[s]-2*topmass
c   xtm      : topmass (in the Pole scheme)
c   xtg      : top-width
c   xalphas  : alpha_s^{MSbar,n_f=5}(xscale)
c   xscale   : soft scale mu_{soft}
c   xcutn    : numerical UV cutoff on all momenta
c              (UV cutoff of the Gauss-Legendre grid)
c   xcutv    : renormalization cutoff on the
c              delta-, the (p^2+q^2)/(p-q)^2-, and the
c              1/r^2-[1/|p-q|]-potential:
c              if (max(p,q).ge.xcutv) then the three potentials
c              are set to zero in the Lippmann-Schwinger equation
c   xc0      : 0th order coefficient for the Coulomb potential,
c              see calling example above
c   xc1      : 1st order coefficient for the Coulomb potential
c   xc2      : 2nd order coefficient for the Coulomb potential
c   xcdeltc  : constant of the delta(r)-
c              [= constant in momentum space-] potential
c   xcdeletl : constant for the additional log(q^2/mu^2)-part of the
c              delta-potential:
c              xcdeltc*1 + xcdeletl*log(q^2/mu^2)
c   xcfullc  : constant of the (p^2+q^2)/(p-q)^2-potential
c   xcfulll  : constant for the additional log(q^2/mu^2)-part of the
c              (p^2+q^2)/(p-q)^2-potential
c   xcrm2    : constant of the 1/r^2-[1/|p-q|]-potential
c   xkincm   : } kinetic corrections in the 0th order Green function:
c   xkinca   : } G_0(p):=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c              !!! WATCH THE SIGN IN G_0 !!!
c   jknflg   : flag for these kinetic corrections:
c              0 : no kinetic corrections applied
c              1 : kinetic corrections applied with cutoff xcutv
c                  for xkinca only
c              2 : kinetic corrections applied with cutoff xcutv
c                  for xkinca AND xkincm
c   jgcflg   : flag for G_0(p) in the LS equation:
c              0 (standard choice) : G_0(p) as given above
c              1 (for TIPT)         : G_0(p) = G_c^{0}(p) the 0th
c                                      order Coulomb Green function
c                                      in analytical form; not for
c                                      momenta p > 1000*topmass
c   xkincv   : additional kinematic vertexcorrection in G_0, see below:
c   jvflg    : flag for the additional vertexcorrection xkincv in the
c              "zeroth order" G_0(p) in the LS-equation:
c              0 : no correction, means G = G_0 + G_0 int V G
c                  with G_0=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c              1 : apply the correction in the LS equation as
c                  G = G_0 + xkincv*p^2/m_t^2/[E+iGamma_t-p^2/m_t] +
c                    G_0 int V G
c              and correct the integral over Im[G(p)] to get sigma_tot
c              from the optical theorem by the same factor.
c              The cutoff xcutv is applied for these corrections.
c
c - Output:
c

```

```

c      xim      :  R{P wave}{ttbar} from the imaginary part of the Green
c                  function
c      xdi      :  R{P wave}{ttbar} from the integral over the momentum
c                  distribution:  $\int_0^{x_{cutv}} dp \, p^3/m_t * |F(p,E)|^2$ 
c      np       :  number of points used for the grid; fixed in tttoppik
c      xpp      :  1-dim array (max. 900 elements) giving the momenta of
c                  the Gauss-Legendre grid (pp(i) in the code)
c      xww      :  1-dim array (max. 900 elements) giving the corresponding
c                  Gauss-Legendre weights for the grid
c      xdsdp    :  1-dim array (max. 900 elements) giving the
c                  momentum distribution of top:  $d\sigma^{P \text{ wave}}/dp$ ,
c                  normalized to R,
c                  at the momenta of the Gauss-Legendre grid xpp(i)
c      zftild   :  1-dim array (max. 900 elements) of COMPLEX*16 numbers
c                  giving the vertex function K_A for the P-wave
c                  at the momenta of the grid.
c                  Then  $F(p)=K_A(p)*G_0(p)$  corresponding to  $G=K_V*G_0$ .

## Chapter 30

# Integration and Process Objects

This is the central part of the **WHIZARD** package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

**subevt\_expr** This enables process observables as (abstract) expressions, to be evaluated for each process call.

**parton\_states** A **parton\_state\_t** object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

**process** Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: **prc\_core** for matrix-element evaluation, **prc\_core\_def** for the associated configuration and driver, **sf\_base** for beams and structure-functions, **phs\_base** for phase space, and **mci\_base** for integration and event generation.

**process\_config**

**process\_counter** Very simple object for statistics

**process\_mci**

**pcm**

**kinematics**

**instances** While the above modules set up all static information, the instances have the changing event data. There are term and process instances but no component instances.

**process\_stacks** Process stacks collect process objects.

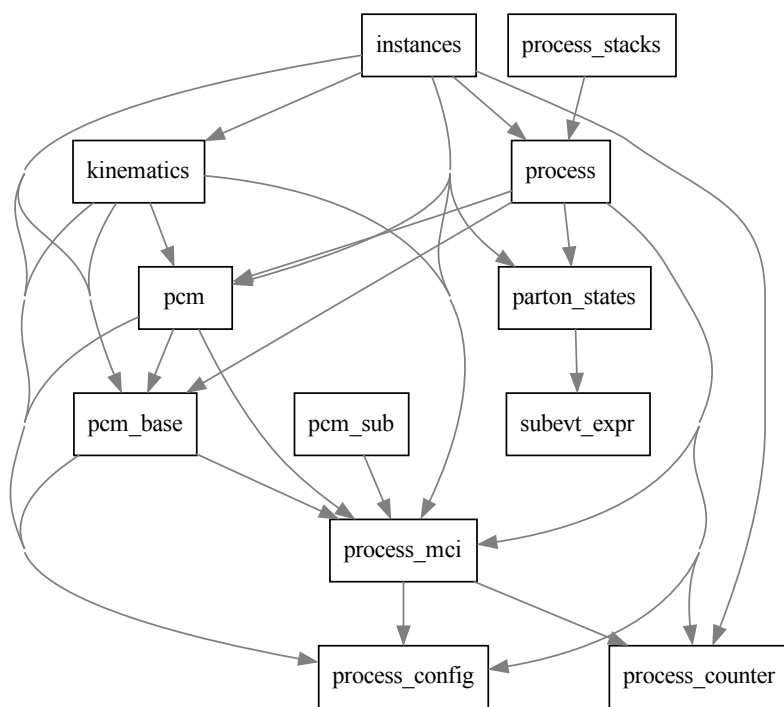

Figure 30.1: Module dependencies in `src/process_integration`.

We combine here hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the **computed** state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the **observed** state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible subsequent decay processes on the parton level, which are full-fledged process objects themselves.

## 30.1 Process observables

We define an abstract **subevt\_expr\_t** object as an extension of the **subevt\_t** type. The object contains a local variable list, variable instances (as targets for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the **subevt**.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression **selection** which determines whether the object passes user-defined cuts.

The intention is that we fill the **subevt\_t** base object and compute the variables once we have evaluated a kinematical phase space point (or a complete event). We then evaluate the expressions and can use the results in further calculations.

The **process\_expr\_t** extension contains furthermore scale and weight expressions. The **event\_expr\_t** extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the

variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

Note that there are unit tests, but they are deferred to the `expr_tests` module.

```

Append the subevent expr (its base-type core) itself to the variable list, if it is not yet present.

```
<Subevt expr: subevt expr: TBP>+≡
  procedure :: setup_var_self => subevt_expr_setup_var_self

<Subevt expr: sub interfaces>+≡
  module subroutine subevt_expr_setup_var_self (expr)
    class(subevt_expr_t), intent(inout), target :: expr
  end subroutine subevt_expr_setup_var_self

<Subevt expr: procedures>+≡
  module subroutine subevt_expr_setup_var_self (expr)
    class(subevt_expr_t), intent(inout), target :: expr
    if (.not. expr%var_list%contains (var_str ("%evt"))) then
      call expr%var_list%append_subevt_ptr &
        (var_str ("%evt"), expr%subevt_t, &
          is_known = expr%subevt_filled, &
          locked = .true., verbose = .false., intrinsic=.true.)
    end if
  end subroutine subevt_expr_setup_var_self
```

Link a variable list to the local one. This could be done event by event, but before evaluating expressions.

```
<Subevt expr: subevt expr: TBP>+≡
  procedure :: link_var_list => subevt_expr_link_var_list

<Subevt expr: sub interfaces>+≡
  module subroutine subevt_expr_link_var_list (expr, var_list)
    class(subevt_expr_t), intent(inout) :: expr
    type(var_list_t), intent(in), target :: var_list
  end subroutine subevt_expr_link_var_list

<Subevt expr: procedures>+≡
  module subroutine subevt_expr_link_var_list (expr, var_list)
    class(subevt_expr_t), intent(inout) :: expr
    type(var_list_t), intent(in), target :: var_list
    call expr%var_list%link (var_list)
  end subroutine subevt_expr_link_var_list
```

Compile the selection expression. If there is no expression, the build method will not allocate the expression object.

```
<Subevt expr: subevt expr: TBP>+≡
  procedure :: setup_selection => subevt_expr_setup_selection

<Subevt expr: sub interfaces>+≡
  module subroutine subevt_expr_setup_selection (expr, ef_cuts)
    class(subevt_expr_t), intent(inout), target :: expr
    class(expr_factory_t), intent(in) :: ef_cuts
  end subroutine subevt_expr_setup_selection
```

```

<Subvt expr: procedures>+≡
  module subroutine subvt_expr_setup_selection (expr, ef_cuts)
    class(subvt_expr_t), intent(inout), target :: expr
    class(expr_factory_t), intent(in) :: ef_cuts
    call ef_cuts%build (expr%selection)
    if (allocated (expr%selection)) then
      call expr%setup_var_self ()
      call expr%selection%setup_lexpr (expr%var_list)
      expr%has_selection = .true.
    end if
  end subroutine subvt_expr_setup_selection

```

(De)activate color storage and evaluation for the expression. The subevent particles will have color information.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: colorize => subvt_expr_colorize

<Subvt expr: sub interfaces>+≡
  module subroutine subvt_expr_colorize (expr, colorize_subvt)
    class(subvt_expr_t), intent(inout), target :: expr
    logical, intent(in) :: colorize_subvt
  end subroutine subvt_expr_colorize

<Subvt expr: procedures>+≡

    class(subvt_expr_t), intent(inout), target :: expr
    logical, intent(in) :: colorize_subvt
    expr%colorize_subvt = colorize_subvt
  end subroutine subvt_expr_colorize

```

### 30.1.3 Evaluation

Reset to initial state, i.e., mark the subvt as invalid.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: reset_contents => subvt_expr_reset_contents
  procedure :: base_reset_contents => subvt_expr_reset_contents

<Subvt expr: sub interfaces>+≡
  module subroutine subvt_expr_reset_contents (expr)
    class(subvt_expr_t), intent(inout) :: expr
  end subroutine subvt_expr_reset_contents

<Subvt expr: procedures>+≡
  module subroutine subvt_expr_reset_contents (expr)
    class(subvt_expr_t), intent(inout) :: expr
    expr%subvt_filled = .false.
  end subroutine subvt_expr_reset_contents

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: base_evaluate => subvt_expr_evaluate

```

```

⟨Subevt expr: sub interfaces⟩+≡
  module subroutine subevt_expr_evaluate (expr, passed)
  class(subevt_expr_t), intent(inout) :: expr
  logical, intent(out) :: passed
  end subroutine subevt_expr_evaluate

⟨Subevt expr: procedures⟩+≡
  module subroutine subevt_expr_evaluate (expr, passed)
  class(subevt_expr_t), intent(inout) :: expr
  logical, intent(out) :: passed
  if (expr%has_selection) then
    call expr%selection%evaluate ()
    if (expr%selection%is_known ()) then
      passed = expr%selection%get_log ()
    else

```

Filling the partonic state consists of two parts. The first routine prepares the subevt without assigning momenta. It takes the particles from an `interaction_t`. It needs the indices and flavors for the beam, incoming, and outgoing particles.

We can assume that the particle content of the subevt does not change. Therefore, we set the event variables `n_in`, `n_out`, `n_tot` already in this initialization step.

```

⟨Subevt expr: parton expr: TBP⟩+≡

### 30.1.5 Implementation for full events

This implementation contains the expressions that we can evaluate for the full event. It also contains data that pertain to the event, suitable for communication with external event formats. These data simultaneously serve as pointer targets for the variable lists hidden in the expressions (eval trees).

Squared matrix element and weight values: when reading events from file, the **ref** value is the number in the file, while the **prc** value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of **alt** values is copied from an array of alternative event records. These values should represent calculated values.

```

<Subvt expr: public>+≡
    public :: event_expr_t
<Subvt expr: types>+≡

## 30.2 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states, depending on the the beam setup allows. The result is used for integration.

The `matrix` evaluator is the counterpart of `trace` which is kept exclusive in all observable quantum numbers. The `flows` evaluator is furthermore exclusive in colors, but neglecting all color interference. The `matrix` and `flows` evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. The extra `has_XXX` flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the `processes` module below.

```

contains

<Parton states: procedures>

end submodule parton_states_s

```

### 30.2.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

<Parton states: types>≡
type, abstract :: parton_state_t
logical :: has_trace = .false.
logical :: has_matrix = .false.
logical :: has_flows = .false.
type(evaluator_t) :: trace
type(evaluator_t) :: matrix
type(evaluator_t) :: flows
contains
<Parton states: parton state: TBP>

```

```
end type parton_state_t
```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both are implemented as a pointer. The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```
<Parton states: public>≡
  public :: isolated_state_t

<Parton states: types>+≡
  type, extends (parton_state_t) :: isolated_state_t
  logical :: sf_chain_is_allocated = .false.
  type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()
  logical :: int_is_allocated = .false.
  type(interaction_t), pointer :: int_eff => null ()
  contains
  <Parton states: isolated state: TBP>
end type isolated_state_t
```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

```
<Parton states: public>+≡
  public :: connected_state_t

<Parton states: types>+≡
  type, extends (parton_state_t) :: connected_state_t
  type(state_flv_content_t) :: state_flv
  logical :: has_flows_sf = .false.
  type(evaluator_t) :: flows_sf
  logical :: has_expr = .false.
  type(parton_expr_t) :: expr
  contains
  <Parton states: connected state: TBP>
end type connected_state_t
```

Output: each evaluator is written only when it is active. The `sf_chain` is only written if it is explicitly allocated.

```

    class(isolated_state_t), intent(out) :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(interaction_t), intent(in), target :: int
    state%sf_chain_eff => sf_chain
    state%int_eff => int
  end subroutine isolated_state_init

```

### 30.2.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask_in`.

There are two options: explicitly computing the color factor table (`use_cf` false; `nc` defined), or taking the color factor table from the hard matrix element data.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_square_trace => isolated_state_setup_square_trace

(Parton states: sub interfaces)+≡
  module subroutine isolated_state_setup_square_trace (state, core, &
    qn_mask_in, col, keep_fs_flavor)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), intent(in), dimension(:) :: qn_mask_in
    integer, intent(in), dimension(:), allocatable :: col
    logical, intent(in) :: keep_fs_flavor
  end subroutine isolated_state_setup_square_trace

(Parton states: procedures)+≡
  module subroutine isolated_state_setup_square_trace (state, core, &
    qn_mask_in, col, keep_fs_flavor)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), intent(in), dimension(:) :: qn_mask_in
    !!! Actually need allocatable attribute here for once because col might
    !!! enter the subroutine non-allocated.

```

```

integer, intent(in), dimension(:), allocatable :: col
logical, intent(in) :: keep_fs_flavor
type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
associate (data => core%data)
allocate (qn_mask (data%n_in + data%n_out))
qn_mask( : data%n_in) = &
quantum_numbers_mask (.false., .true., .false.) &
.or. qn_mask_in
qn_mask(data%n_in + 1 : ) = &
quantum_numbers_mask (.not. keep_fs_flavor, .true., .true.)
if (core%use_color_factors) then
call state%trace%init_square (state%int_eff, qn_mask, &
col_flow_index = data%cf_index, &
col_factor = data%color_factors, &
col_index_hi = col, &
nc = core%nc)
else

quantum_numbers_mask (fs_flg_flag, col_flag, .true.)

```

```

end associate
call state%int_eff%set_mask (qn_mask)
call state%trace%init_identity (state%int_eff)
state%has_trace = .true.
end subroutine isolated_state_setup_identity_trace

```

Set up the evaluator for the transition matrix, exclusive in helicities where this is requested.

For all unstable final-state particles we keep polarization according to the applicable decay options. If the process is a decay itself, this applies also to the initial state.

For all polarized final-state particles, we keep polarization including off-diagonal entries. We drop helicity completely for unpolarized final-state particles.

For the initial state, if the particle has not been handled yet, we apply the provided `qn_mask_in` which communicates the beam properties.

```

### 30.2.4 Evaluator initialization: connected state

Set up a trace evaluator as a product of two evaluators (incoming state, effective interaction). In the result, all quantum numbers are summed over.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`.

The `resonant` flag applies if we want to construct a decay chain. The resonance property can propagate to the final event output.

If an extended structure function is required `requires_extended_sf`, we have to not consider `sub` as a quantum number.

```

<Parton states: connected state: TBP>≡
  procedure :: setup_connected_trace => connected_state_setup_connected_trace

<Parton states: sub interfaces>+≡
  module subroutine connected_state_setup_connected_trace &

      connections_are_resonant = resonant)
    state%has_matrix = .true.
    end subroutine connected_state_setup_connected_matrix

```

Set up a matrix evaluator as a product of two evaluators (incoming state, effective interaction). In the intermediate state, only helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`, after creating an intermediate interaction that includes a correlated color state. We assume that for a caller-provided `int`, this is not necessary.

For fixed-order NLO differential distribution, we are interested at the partonic level, no parton showering takes place as this would demand for a proper matching. So, the flows in the `connected_state` are not needed, and the color part will be masked for the interaction coming from the `sf_chain`. The squared matrix elements coming from the OLP provider at the moment do not come with flows anyhow. This needs to be revised once the matching to the shower is completed.

```

### 30.2.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

```

<Parton states: connected state: TBP>+≡

        end if
      end select
    end if
    end subroutine parton_state_receive_kinematics

```

Recover kinematics: We assume that the trace evaluator is filled with momenta. Send those momenta back to the sources, then fill the variables and subevent as above.

The incoming momenta of the connected state are not connected to the isolated state but to the beam interaction. Therefore, the incoming momenta within the isolated state do not become defined, yet. Instead, we reconstruct the beam (and ISR) momentum configuration.

```

<Parton states: parton state: TBP>+≡

## 30.3 Process component management

This module contains tools for managing and combining process components and matrix-element code and values, acting at a level below the actual process definition.

### 30.3.1 Abstract base type

The types introduced here are abstract base types.

```

⟨pcm_base.f90⟩≡
  ⟨File header⟩

  module pcm_base

    ⟨Use kinds⟩
    ⟨Use strings⟩
    use os_interface, only: os_data_t

    use process_libraries, only: process_library_t

    use prc_core_def
    use prc_core

    use variables, only: var_list_t
    use mappings, only: mapping_defaults_t
    use phs_base, only: phs_config_t
    use phs_forests, only: phs_parameters_t
    use mci_base, only: mci_t
    use model_data, only: model_data_t
    use models, only: model_t

    use blha_config, only: blha_master_t
    use blha_olp_interfaces, only: blha_template_t
    use process_config
    use process_mci, only: process_mci_entry_t

    ⟨Standard module head⟩

    ⟨PCM base: public⟩

    ⟨PCM base: parameters⟩

    ⟨PCM base: types⟩

    ⟨PCM base: interfaces⟩

    interface
    ⟨PCM base: sub interfaces⟩
    end interface

  end module pcm_base

⟨pcm_base_sub.f90⟩≡
  ⟨File header⟩

  submodule (pcm_base) pcm_base_s

    use io_units
    use diagnostics
    use format_utils, only: write_integer_array
    use format_utils, only: write_separator
    use physics_defs, only: BORN, NLO_REAL
    !!! Intel oneAPI 2022/23 regression workaround
    use process_libraries, only: process_library_t

```

```

use variables, only: var_list_t

implicit none

contains

<PCM base: procedures>

end submodule pcm_base_s

```

### 30.3.2 Core management

This object holds information about the cores used by the components and allocates the corresponding manager instance.

`i_component` is the index of the process component which this core belongs to. The pointer to the core definition is a convenient help in configuring the core itself.

We allow for a `blha_config` configuration object that covers BLHA cores. The BLHA standard is suitable generic to warrant support outside of specific type extension (i.e., applies to LO and NLO if requested). The BLHA configuration is allocated only if the core requires it.

```

<PCM base: public>≡
  public :: core_entry_t

<PCM base: types>≡
  type :: core_entry_t
  integer :: i_component = 0
  logical :: active = .false.
  class(prc_core_def_t), pointer :: core_def => null ()
  type(blha_template_t), allocatable :: blha_config
  class(prc_core_t), allocatable :: core
  contains
  <PCM base: core entry: TBP>
end type core_entry_t

<PCM base: core entry: TBP>≡
  procedure :: get_core_ptr => core_entry_get_core_ptr

<PCM base: sub interfaces>≡
  module function core_entry_get_core_ptr (core_entry) result (core)
    class(core_entry_t), intent(in), target :: core_entry
    class(prc_core_t), pointer :: core
  end function core_entry_get_core_ptr

<PCM base: procedures>≡
  module function core_entry_get_core_ptr (core_entry) result (core)
    class(core_entry_t), intent(in), target :: core_entry
    class(prc_core_t), pointer :: core
    if (allocated (core_entry%core)) then
      core => core_entry%core
    else
      core => null ()
    end if
  end function

```

```
end function core_entry_get_core_ptr
```

Configure the core object after allocation with correct type. The `core_def` object pointer and the index `i_component` of the associated process component are already there.

```
<PCM base: core entry: TBP>+≡
```

```
  procedure :: configure => core_entry_configure
```

```
<PCM base: sub interfaces>+≡
```

```
  module subroutine core_entry_configure (core_entry, lib, id)
    class(core_entry_t), intent(inout) :: core_entry
    type(process_library_t), intent(in), target :: lib
    type(string_t), intent(in) :: id
  end subroutine core_entry_configure
```

```
<PCM base: procedures>+≡
```

```
  module subroutine core_entry_configure (core_entry, lib, id)
    class(core_entry_t), intent(inout) :: core_entry
    type(process_library_t), intent(in), target :: lib
    type(string_t), intent(in) :: id
    call core_entry%core%init &
      (core_entry%core_def, lib, id, core_entry%i_component)
  end subroutine core_entry_configure
```

### 30.3.3 Process component manager

The process-component manager `pcm` is the master component of the `process_t` object. It serves two purposes:

1. It holds configuration data which allow us to centrally manage the components, terms, etc. of the process object.
2. It implements the methods that realize the algorithm for constructing the process object and computing an integral. This algorithm makes use of the data stored within `pcm`.

To this end, the object is abstract and polymorphic. The two extensions that we support, implement (a) default tree-level calculation, optionally including a sum over sub-processes with different particle content, or (b) the FKS-NLO subtraction algorithm for QCD-corrected processes. In both cases, the type extensions may hold suitable further data.

Data included in the base type:

The number of components determines the `component_selected` array.

`i_phs_config` is a lookup table that holds the PHS configuration index for a given component index.

`i_core` is a lookup table that holds the core-entry index for a given component index.

`i_mci` is a lookup table that holds the integrator (MCI) index for a given component index.

```
<PCM base: public>+≡
```

```
  public :: pcm_t
```

```

<PCM base: types>+≡
  type, abstract :: pcm_t
    logical :: initialized = .false.
    logical :: has_pdfs = .false.
    integer :: n_components = 0
    integer :: n_cores = 0
    integer :: n_mci = 0
    logical, dimension(:), allocatable :: component_selected
    logical, dimension(:), allocatable :: component_active
    integer, dimension(:), allocatable :: i_phs_config
    integer, dimension(:), allocatable :: i_core
    integer, dimension(:), allocatable :: i_mci
    type(blha_template_t) :: blha_defaults
    logical :: uses_blha = .false.
    type(os_data_t) :: os_data
  contains
    <PCM base: pcm: TBP>
  end type pcm_t

```

The factory method. We use the inout intent, so calling this again is an error.

```

<PCM base: pcm: TBP>≡
  procedure(pcm_allocate_workspace), deferred :: allocate_workspace
<PCM base: interfaces>≡
  abstract interface
    subroutine pcm_allocate_workspace (pcm, work)
  import
    class(pcm_t), intent(in) :: pcm
    class(pcm_workspace_t), intent(inout), allocatable :: work
  end subroutine pcm_allocate_workspace
  end interface

```

```

  procedure(pcm_is_nlo), deferred :: is_nlo
<PCM base: interfaces>+≡
  abstract interface
    function pcm_is_nlo (pcm) result (is_nlo)
  import
    logical :: is_nlo
    class(pcm_t), intent(in) :: pcm
  end function pcm_is_nlo
  end interface

```

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_final), deferred :: final
<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_final (pcm)
  import
    class(pcm_t), intent(inout) :: pcm
  end subroutine pcm_final
  end interface

```

### 30.3.4 Initialization methods

The PCM has the duty to coordinate and configure the process-object components.

Initialize the PCM configuration itself, using environment data.

```
<PCM base: pcm: TBP>+≡
  procedure(pcm_init), deferred :: init
<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_init (pcm, env, meta)
  import
    class(pcm_t), intent(out) :: pcm
    type(process_environment_t), intent(in) :: env
    type(process_metadata_t), intent(in) :: meta
  end subroutine pcm_init
end interface
```

Initialize the BLHA configuration block, the component-independent default settings. This is to be called by `pcm_init`. We use the provided variable list.

This block is filled regardless of whether BLHA is actually used, because why not? We use a default value for the scheme (not set in unit tests).

```
<PCM base: pcm: TBP>+≡
  procedure :: set_blha_defaults => pcm_set_blha_defaults
<PCM base: sub interfaces>+≡
  module subroutine pcm_set_blha_defaults (pcm, polarized_beams, var_list)
    class(pcm_t), intent(inout) :: pcm
    type(var_list_t), intent(in) :: var_list
    logical, intent(in) :: polarized_beams
  end subroutine pcm_set_blha_defaults
<PCM base: procedures>+≡
  module subroutine pcm_set_blha_defaults (pcm, polarized_beams, var_list)
    class(pcm_t), intent(inout) :: pcm
    type(var_list_t), intent(in) :: var_list
    logical, intent(in) :: polarized_beams
    logical :: muon_yukawa_off
    real(default) :: top_yukawa
    type(string_t) :: ew_scheme
    muon_yukawa_off = &
    var_list%get_lval (var_str ("?openloops_switch_off_muon_yukawa"))
    top_yukawa = &
    var_list%get_rval (var_str ("blha_top_yukawa"))
    ew_scheme = &
    var_list%get_sval (var_str ("blha_ew_scheme"))
    if (ew_scheme == "") ew_scheme = "Gmu"
    call pcm%blha_defaults%init &
      (polarized_beams, muon_yukawa_off, top_yukawa, ew_scheme)
  end subroutine pcm_set_blha_defaults
```

Read the method settings from the variable list and store them in the BLHA master. The details depend on the `pcm` concrete type.

```
<PCM base: pcm: TBP>+≡
  procedure(pcm_set_blha_methods), deferred :: set_blha_methods
```

*<PCM base: interfaces>+≡*

```
abstract interface
  subroutine pcm_set_blha_methods (pcm, blha_master, var_list)
  import
  class(pcm_t), intent(inout) :: pcm
  type(blha_master_t), intent(inout) :: blha_master
  type(var_list_t), intent(in) :: var_list
end subroutine pcm_set_blha_methods
end interface
```

Produce the LO and NLO flavor-state tables (as far as available), as appropriate for BLHA configuration. We may inspect either the PCM itself or the array of process cores.

*<PCM base: pcm: TBP>+≡*

```
procedure(pcm_get_blha_flv_states), deferred :: get_blha_flv_states
```

*<PCM base: interfaces>+≡*

```
abstract interface
  subroutine pcm_get_blha_flv_states (pcm, core_entry, flv_born, flv_real)
  import
  class(pcm_t), intent(in) :: pcm
  type(core_entry_t), dimension(:), intent(in) :: core_entry
  integer, dimension(:,:), allocatable, intent(out) :: flv_born
  integer, dimension(:,:), allocatable, intent(out) :: flv_real
end subroutine pcm_get_blha_flv_states
end interface
```

Allocate the right number of process components. The number is also stored in the process meta. Initially, all components are active but none are selected.

*<PCM base: pcm: TBP>+≡*

```
procedure :: allocate_components => pcm_allocate_components
```

*<PCM base: sub interfaces>+≡*

```
module subroutine pcm_allocate_components (pcm, comp, meta)
  class(pcm_t), intent(inout) :: pcm
  type(process_component_t), dimension(:), allocatable, intent(out) :: comp
  type(process_metadata_t), intent(in) :: meta
end subroutine pcm_allocate_components
```

*<PCM base: procedures>+≡*

```
module subroutine pcm_allocate_components (pcm, comp, meta)
  class(pcm_t), intent(inout) :: pcm
  type(process_component_t), dimension(:), allocatable, intent(out) :: comp
  type(process_metadata_t), intent(in) :: meta
  pcm%n_components = meta%n_components
  allocate (comp (pcm%n_components))
  allocate (pcm%component_selected (pcm%n_components), source = .false.)
  allocate (pcm%component_active (pcm%n_components), source = .true.)
end subroutine pcm_allocate_components
```

Each process component belongs to a category/type, which we identify by a universal integer constant. The categories can be taken from the process definition. For easy lookup, we store the categories in an array.

*<PCM base: pcm: TBP>+≡*

```

    procedure(pcm_categorize_components), deferred :: categorize_components
<PCM base: interfaces>+≡
    abstract interface
    subroutine pcm_categorize_components (pcm, config)
    import
    class(pcm_t), intent(inout) :: pcm
    type(process_config_data_t), intent(in) :: config
    end subroutine pcm_categorize_components
    end interface

```

Allocate the right number and type(s) of process-core objects, i.e., the interface object between the process and matrix-element code.

Within the `pcm` block, also associate cores with components and store relevant configuration data, including the `i_core` lookup table.

```

<PCM base: pcm: TBP>+≡
    procedure(pcm_allocate_cores), deferred :: allocate_cores
<PCM base: interfaces>+≡
    abstract interface
    subroutine pcm_allocate_cores (pcm, config, core_entry)
    import
    class(pcm_t), intent(inout) :: pcm
    type(process_config_data_t), intent(in) :: config
    type(core_entry_t), dimension(:), allocatable, intent(out) :: core_entry
    end subroutine pcm_allocate_cores
    end interface

```

Generate and interface external code for a single core, if this is required.

```

<PCM base: pcm: TBP>+≡
    procedure(pcm_prepare_any_external_code), deferred :: &
    prepare_any_external_code
<PCM base: interfaces>+≡
    abstract interface
    subroutine pcm_prepare_any_external_code &
    (pcm, core_entry, i_core, libname, model, var_list)
    import
    class(pcm_t), intent(in) :: pcm
    type(core_entry_t), intent(inout) :: core_entry
    integer, intent(in) :: i_core
    type(string_t), intent(in) :: libname
    type(model_data_t), intent(in), target :: model
    type(var_list_t), intent(in) :: var_list
    end subroutine pcm_prepare_any_external_code
    end interface

```

Prepare the BLHA configuration for a core object that requires it. This does not affect the core object, which may not yet be allocated.

```

<PCM base: pcm: TBP>+≡
    procedure(pcm_setup_blha), deferred :: setup_blha

```

```

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_setup_blha (pcm, core_entry)
    import
    class(pcm_t), intent(in) :: pcm
    type(core_entry_t), intent(inout) :: core_entry
  end subroutine pcm_setup_blha
end interface

```

Configure the BLHA interface for a core object that requires it. This is separate from the previous method, assuming that the pcm has to allocate the actual cores and acquire some data in-between.

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_prepare_blha_core), deferred :: prepare_blha_core

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_prepare_blha_core (pcm, core_entry, model)
    import
    class(pcm_t), intent(in) :: pcm
    type(core_entry_t), intent(inout) :: core_entry
    class(model_data_t), intent(in), target :: model
  end subroutine pcm_prepare_blha_core
end interface

```

Allocate and configure the MCI (multi-channel integrator) records and their relation to process components, appropriate for the algorithm implemented by pcm.

Create a mci\_t template: the procedure `dispatch_mci` is called as a factory method for allocating the mci\_t object with a specific concrete type. The call may depend on the concrete pcm type.

```

<PCM base: public>+≡
  public :: dispatch_mci_proc

<PCM base: interfaces>+≡
  abstract interface
    subroutine dispatch_mci_proc (mci, var_list, process_id, is_nlo)
    import
    class(mci_t), allocatable, intent(out) :: mci
    type(var_list_t), intent(in) :: var_list
    type(string_t), intent(in) :: process_id
    logical, intent(in), optional :: is_nlo
  end subroutine dispatch_mci_proc
end interface

```

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_setup_mci), deferred :: setup_mci
  procedure(pcm_call_dispatch_mci), deferred :: call_dispatch_mci

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_setup_mci (pcm, mci_entry)
    import

```

```

class(pcm_t), intent(inout) :: pcm
type(process_mci_entry_t), &
dimension(:), allocatable, intent(out) :: mci_entry
end subroutine pcm_setup_mci
end interface

abstract interface
subroutine pcm_call_dispatch_mci (pcm, &
dispatch_mci, var_list, process_id, mci_template)
import
class(pcm_t), intent(inout) :: pcm
procedure(dispatch_mci_proc) :: dispatch_mci
type(var_list_t), intent(in) :: var_list
type(string_t), intent(in) :: process_id
class(mci_t), intent(out), allocatable :: mci_template
end subroutine pcm_call_dispatch_mci
end interface

```

Proceed with PCM configuration based on the core and component configuration data. Base version is empty.

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_complete_setup), deferred :: complete_setup
<PCM base: interfaces>+≡
  abstract interface
  subroutine pcm_complete_setup (pcm, core_entry, component, model)
  import
  class(pcm_t), intent(inout) :: pcm
  type(core_entry_t), dimension(:), intent(in) :: core_entry
  type(process_component_t), dimension(:), intent(inout) :: component
  type(model_t), intent(in), target :: model
  end subroutine pcm_complete_setup
  end interface

```

## Retrieve information

Return the core index that belongs to a particular component.

```

<PCM base: pcm: TBP>+≡
  procedure :: get_i_core => pcm_get_i_core
<PCM base: sub interfaces>+≡
  module function pcm_get_i_core (pcm, i_component) result (i_core)
  class(pcm_t), intent(in) :: pcm
  integer, intent(in) :: i_component
  integer :: i_core
  end function pcm_get_i_core
<PCM base: procedures>+≡
  module function pcm_get_i_core (pcm, i_component) result (i_core)
  class(pcm_t), intent(in) :: pcm
  integer, intent(in) :: i_component
  integer :: i_core
  if (allocated (pcm%i_core)) then

```

```

i_core = pcm%i_core(i_component)
else
i_core = 0
end if
end function pcm_get_i_core

```

## Phase-space configuration

Allocate and initialize the right number and type(s) of phase-space configuration entries. The `i_phs_config` lookup table must be set accordingly.

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_init_phs_config), deferred :: init_phs_config

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_init_phs_config &
      (pcm, phs_entry, meta, env, phs_par, mapping_defs)
    import
    class(pcm_t), intent(inout) :: pcm
    type(process_phs_config_t), &
    dimension(:), allocatable, intent(out) :: phs_entry
    type(process_metadata_t), intent(in) :: meta
    type(process_environment_t), intent(in) :: env
    type(mapping_defaults_t), intent(in) :: mapping_defs
    type(phs_parameters_t), intent(in) :: phs_par
  end subroutine pcm_init_phs_config
end interface

```

Initialize a single component. We require all process-configuration blocks, and specific templates for the phase-space and integrator configuration.

We also provide the current component index `i` and the `active` flag.

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_init_component), deferred :: init_component

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_init_component &
      (pcm, component, i, active, phs_config, env, meta, config)
    import
    class(pcm_t), intent(in) :: pcm
    type(process_component_t), intent(out) :: component
    integer, intent(in) :: i
    logical, intent(in) :: active

### 30.3.5 Manager workspace

This object deals with the actual (squared) matrix element values. It holds any central data that are generated and/or used when calculating a particular phase-space point.

Since phase-space points are associated with an integrator, we expect the instances of this type to correspond to MCI instances.

```

<PCM base: public>+≡
  public :: pcm_workspace_t

### 30.4.3 The process type

NOTE: The description below represents the intended structure after refactoring and disentangling the FKS-NLO vs. LO algorithm dependencies.

A **process** object is the internal representation of integration-run methods and data, as they are controlled by the user via a Sindarin script. The process object provides access to matrix elements (the actual “process” definitions that the user has provided before), it defines the separation into individually integrable components, and it manages phase-space construction, the actual integration over phase space, and the accumulation of results.

As a workspace for individual sampling calls, we introduce an associated **process\_instance** object type elsewhere. The **process** object contains data that either define the configuration or accumulate results from a complete integration pass.

After successful phase-space integration, subsequent event generation is not actually represented by the **process** object. However, any event generation refers to an existing **process** object which represents a specific integration pass, and it uses a fresh **process\_instance** workspace for calculations.

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The **meta** object describes the process globally. All contents become fixed when the object is initialized. Similarly, the **env** component captures the (Sindarin) environment at the point where the process object is initialized.

The **config** object holds physical and technical configuration data that are collected and derived from the environment during process initialization, and which are common to all process components.

The **pcm** object (process-component manager) is polymorphic. This is an object which holds data which represent the process-object structure and breakdown, and it contains the methods that implement the algorithm of managing this structure, accumulating partial results, and finally collecting the pieces. Depending on the generic process type, the contents of **pcm** do vary. In particular, there is some base-type data content and a simple (default) extension which is designed for traditional O’MEGA matrix elements and tree-level integration, possibly with several sub-processes to sum over. The second extension is designed for the FKS phase-space and subtraction algorithm for NLO QCD, which interfaces external one-loop providers.

The **component** subobjects are, first of all, interfaces to the original process-component definitions that have been provided by the user, which the program

has already taken to produce matrix-element code and interfaces. The management of those components is deferred by `pcm`, which contains the information that defines the role of each component. In particular, in the default (LO) version, process components correspond to distinct particle combinations which have been included in the original process definition. In the FKS-NLO version, the breakdown of a NLO process into Born, real, virtual, etc. components determines the setup.

The `phs_config` subobjects hold data that allow and implement the construction of phase-space configurations. The type `process_phs_config_t` is a wrapper type around the concrete polymorphic `phs_config_t` object type, which manages phase-space construction, including some bookkeeping required for setting up multi-channel integration. In the LO case, we expect a separate entry for each independent sub-process. For the FKS-NLO algorithm, we expect several entries: a default-type entry which implements the underlying Born phase space, and additional entries which enable the construction of various real-radiation and subtraction kinematics configurations.

A `core_entry` is the interface to existing matrix-element and interaction code. Depending on the process and its components, there may be various distinct matrix elements to compute.

The `mci_entry` objects configure distinct MC input parameter sets and their associated (multi-channel) integrators.

The `rng_factory` object is a single objects which constructs individual random-number generators for various tasks, in a uniform and well-defined way.

The `beam_config` object describes the incoming particles, either the decay mother or the scattering beams. It also contains the spectrum- and structure-function setup, which has to interact with the phase-space and integrator facilities.

The `term` subobjects break down the process in its smallest parts which appear in the calculation. For LO processes, the correspondence between terms and components is one-to-one. The FKS-NLO algorithm requires not just separation of Born, real, and virtual components but also subtraction terms, and a decomposition of the real phase space into singular regions. The general idea is that the integration results of distinct sets of terms are summed over to provide the results of individual components. This is also controlled by the `pcm` subobject.

The `process_status` object is a bookkeeping device that allows us to query the status of an ongoing calculation.

The `process_results` object collects the integration results for external use, including integration history information.

```

(Process: public)≡
    public :: process_t
(Process: types)+≡

#### 30.4.4 Process pointer

Wrapper type for storing pointers to process objects in arrays.

```

<Process: public>+≡
  public :: process_ptr_t

<Process: types>+≡
  type :: process_ptr_t
  type(process_t), pointer :: p => null ()
end type process_ptr_t

```

#### 30.4.5 Output

This procedure is an important debugging and inspection tool; it is not used during normal operation. The process object is written to a file (identified by unit, which may also be standard output). Optional flags determine whether we show everything or just the interesting parts.

The shorthand as a traditional TBP.

```

<Process: process: TBP>≡
  procedure :: write => process_write

<Process: sub interfaces>≡
  module subroutine process_write (process, screen, unit, &
    show_os_data, show_var_list, show_rng, show_expressions, pacify)
    class(process_t), intent(in) :: process
    logical, intent(in) :: screen
    integer, intent(in), optional :: unit

```

```

logical, intent(in), optional :: show_os_data
logical, intent(in), optional :: show_var_list
logical, intent(in), optional :: show_rng
logical, intent(in), optional :: show_expressions
logical, intent(in), optional :: pacify
end subroutine process_write

```

*(Process: procedures)*≡

```

module subroutine process_write (process, screen, unit, &
show_os_data, show_var_list, show_rng, show_expressions, pacify)
class(process_t), intent(in) :: process
logical, intent(in) :: screen

else
call process%write_formatted (u, "DT", v_list, iostat, iomsg)
end if
end subroutine process_write

```

Standard DTIO procedure with binding.

For the particular application, the screen format is triggered by the LISTDIRECTED option for the iotype format editor string. The other options activate when the particular parameter value is found in v\_list.

NOTE: The DTIO generic binding is supported by gfortran since 7.0.

TODO wk 2018: The default could be to show everything, and we should have separate switches for all major parts. Currently, there are only a few.

Finalizer. Explicitly iterate over all subobjects that may contain allocated pointers.

TODO wk 2018 (workaround): The finalizer for the `config_data` component is not called. The reason is that this deletes model data local to the process, but these could be referenced by pointers (flavor objects) from some persistent event record. Obviously, such side effects should be avoided, but this requires refactoring the event-handling procedures.

```

```

## Process setup

Initialize a process. We need a process library `lib` and the process identifier `proc_id` (string). We will fetch the current run ID from the variable list `var_list`.

We collect all important data from the environment and store them in the appropriate places. OS data, model, and variable list are copied into `env` (true snapshot), also the process library (pointer only).

The `meta` subobject is initialized with process ID and attributes taken from the process library.

We initialize the `config` subobject with all data that are relevant for this run, using the settings from `env`. These data determine the MD5 sum for this run, which allows us to identify the setup and possibly skips in a later re-run.

We also allocate and initialize the embedded RNG factory. We take the seed from the `var_list`, and we should return the `var_list` to the caller with a new seed.

Finally, we allocate the process component manager `pcm`, which implements the chosen algorithm for process integration. The first task of the manager is to allocate the component array and to determine the component categories (e.g., Born/Virtual etc.).

TODO wk 2018: The `pcm` dispatcher should be provided by the caller, if we eventually want to eliminate dependencies on concrete `pcm_t` extensions.

Gfortran 7/8/9 bug, has to remain in the main module:

```

```

### 30.4.6 Process component manager

The `pcm` (read: process-component manager) takes the responsibility of steering the actual algorithm of configuration and integration. Depending on the concrete type, different algorithms can be implemented.

The first version of this supports just two implementations: leading-order (tree-level) integration and event generation, and NLO (QCD/FKS subtraction). We thus can start with a single logical for steering the dispatcher.

TODO wk 2018: Eventually, we may eliminate all references to the extensions of `pcm_t` from this module and therefore move this outside the module as well. Gfortran 7/8/9 bug, has to be in the main module:

```

(Process: main procedures)+≡
subroutine dispatch_pcm (pcm, is_nlo)
class(pcm_t), allocatable, intent(out) :: pcm
logical, intent(in) :: is_nlo
if (.not. is_nlo) then
allocate (pcm_default_t :: pcm)
else
allocate (pcm_nlo_t :: pcm)
end if
end subroutine dispatch_pcm

```

This step is performed after phase-space and core objects are done: collect all missing information and prepare the process component manager for the appropriate integration algorithm.

```

(Process: process: TBP)+≡
procedure :: complete_pcm_setup => process_complete_pcm_setup

(Process: sub interfaces)+≡
module subroutine process_complete_pcm_setup (process)
class(process_t), intent(inout) :: process
end subroutine process_complete_pcm_setup

(Process: procedures)+≡
module subroutine process_complete_pcm_setup (process)
class(process_t), intent(inout) :: process
call process%pcm%complete_setup &
(process%core_entry, process%component, process%env%get_model_ptr ())
end subroutine process_complete_pcm_setup

```

### 30.4.7 Core management

Allocate cores (interface objects to matrix-element code).

The `dispatch_core` procedure is taken as an argument, so we do not depend on the implementation, and thus on the specific core types.

The `helicity_selection` object collects data that the matrix-element code needs for configuring the appropriate behavior.

After the cores have been allocated, and assuming the phs initial configuration has been done before, we proceed with computing the pcm internal data.

```

(Process: process: TBP)+≡
  procedure :: setup_cores => process_setup_cores

(Process: sub interfaces)+≡
  module subroutine process_setup_cores (process, dispatch_core, &
    helicity_selection, use_color_factors, has_beam_pol)

Initialize the process components, one by one. We require templates for the mci (integrator) and phs\_config (phase-space) configuration data.

The active flag is set if the component has an associated matrix element, so we can compute it. The case of no core is a unit-test case.

The specifics depend on the algorithm and are delegated to the pcm process-component manager.

The optional `phs_config` overrides a pre-generated config array (for unit test).

```

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam_data_t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by extending the code in the `beams` module.

Set up index mapping for `region_data` for singular regions equivalent w.r.t. their amplitudes. Has to be called after `region_data` AND the `core` are fully set up. For processes with structure function, subprocesses which lead to the same amplitude for the hard interaction can differ if structure functions are applied. In this case we remap flavor structures to themselves if the equivalent hard interaction flavor structure has no identical initial state.

We complete the kinematics configuration after the beam setup, but before we configure the chain of structure functions. The reason is that we need the total energy `sqrts` for the kinematics, but the structure-function setup requires the number of channels, which depends on the kinematics configuration. For instance, the kinematics module may return the need for parameterizing an s-channel resonance.

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

## MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

### 30.4.8 Default iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

(Process: process: TBP)+≡
  procedure :: get_n_pass_default => process_get_n_pass_default

### 30.4.10 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```

<Process: process: TBP>+≡

### 30.4.11 NLO specifics

These subroutines (and the NLO specific properties they work on) could potentially be moved to `pcm_nlo_t` and used more generically in `process_t` with an appropriate interface in `pcm_t`

TODO wk 2018: This is used only by event initialization, which deals with an incomplete process object.

```

(Process: process: TBP)+≡
  procedure :: init_nlo_settings => process_init_nlo_settings

(Process: sub interfaces)+≡

end submodule process_config_s

```

Identifiers for the NLO setup.

```

<Process config: parameters>≡
  integer, parameter, public :: COMP_DEFAULT = 0
  integer, parameter, public :: COMP_REAL_FIN = 1
  integer, parameter, public :: COMP_MASTER = 2
  integer, parameter, public :: COMP_VIRT = 3
  integer, parameter, public :: COMP_REAL = 4
  integer, parameter, public :: COMP_REAL_SING = 5
  integer, parameter, public :: COMP_MISMATCH = 6
  integer, parameter, public :: COMP_PDF = 7
  integer, parameter, public :: COMP_SUB = 8
  integer, parameter, public :: COMP_RESUM = 9

```

### 30.5.1 Output selection flags

We declare a number of identifiers for write methods, so they only displays selected parts. The identifiers can be supplied to the `vlist` array argument of the standard F2008 derived-type writer call.

```

<Process config: parameters>+≡
  integer, parameter, public :: F_PACIFY = 1
  integer, parameter, public :: F_SHOW_VAR_LIST = 11
  integer, parameter, public :: F_SHOW_EXPRESSIONS = 12
  integer, parameter, public :: F_SHOW_LIB = 13
  integer, parameter, public :: F_SHOW_MODEL = 14
  integer, parameter, public :: F_SHOW_QCD = 15
  integer, parameter, public :: F_SHOW_OS_DATA = 16

```

```
integer, parameter, public :: F_SHOW_RNG = 17
integer, parameter, public :: F_SHOW_BEAMS = 18
```

This is a simple function that returns true if a flag value is present in `v_list`, but not its negative. If neither is present, it returns default.

```
<Process config: public>≡
  public :: flagged

<Process config: sub interfaces>≡
  module function flagged (v_list, id, def) result (flag)
    logical :: flag
    integer, dimension(:), intent(in) :: v_list
    integer, intent(in) :: id
    logical, intent(in), optional :: def
  end function flagged

<Process config: procedures>≡
  module function flagged (v_list, id, def) result (flag)
    logical :: flag
    integer, dimension(:), intent(in) :: v_list
    integer, intent(in) :: id
    logical, intent(in), optional :: def
    logical :: default_result
    default_result = .false.; if (present (def)) default_result = def
    if (default_result) then
      flag = all (v_list /= -id)
    else
      flag = all (v_list /= -id) .and. any (v_list == id)
    end if
  end function flagged
```

Related: if flag is set (unset), append value (its negative) to the `v_list`, respectively. `v_list` must be allocated.

```
<Process config: public>+≡
  public :: set_flag

<Process config: sub interfaces>+≡
  module subroutine set_flag (v_list, value, flag)
    integer, dimension(:), intent(inout), allocatable :: v_list
    integer, intent(in) :: value
    logical, intent(in), optional :: flag
  end subroutine set_flag

<Process config: procedures>+≡
  module subroutine set_flag (v_list, value, flag)
    integer, dimension(:), intent(inout), allocatable :: v_list
    integer, intent(in) :: value
    logical, intent(in), optional :: flag
    if (present (flag)) then
      if (flag) then
        v_list = [v_list, value]
      else
        v_list = [v_list, -value]
      end if
    end if
  end subroutine set_flag
```

### 30.5.2 Generic configuration data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the variable list.

The number **n\_in** is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number **n\_components** is the number of components that constitute the current process.

The number **n\_terms** is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number **n\_mci** is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The **model** pointer identifies the physics model and its parameters. This is a pointer to an external object.

Various **parse\_node\_t** objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the **effective\_state** subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The **md5sum** is taken and used to verify the process configuration when re-reading data from file.

```

end if
end subroutine process_config_data_write

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

The model pointer references the model data within the `env` record. That should be an instance of the global model.

We initialize the QCD object, unless the environment information is unavailable (unit tests).

The RNG factory object is imported by moving the allocation. Gfortran 7/8/9 bug: has to remain in the main module:

```

### 30.5.3 Environment

This record stores a snapshot of the process environment at the point where the process object is created.

Model and variable list are implemented as pointer, so they always have the `target` attribute.

For unit-testing purposes, setting the var list is optional. If not set, the pointer is null.

```

<Process config: public>+≡
  public :: process_environment_t

<Process config: types>+≡
  type :: process_environment_t
  private
    type(model_t), pointer :: model => null ()
    type(var_list_t), pointer :: var_list => null ()
    logical :: var_list_is_set = .false.
    type(process_library_t), pointer :: lib => null ()
    type(beam_structure_t) :: beam_structure
    type(os_data_t) :: os_data
  contains
    <Process config: process environment: TBP>
  end type process_environment_t

```

Model and local var list are snapshots and need a finalizer.

```

<Process config: process environment: TBP>≡
  procedure :: final => process_environment_final

<Process config: sub interfaces>+≡
  module subroutine process_environment_final (env)
    class(process_environment_t), intent(inout) :: env
  end subroutine process_environment_final

### 30.5.4 Metadata

This information describes the process. It is fixed upon initialization.

The `id` string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The `num_id` is meaningful if nonzero. It is used for communication with external programs or file standards which do not support string IDs.

The `run_id` string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The `lib_name` identifies the process library where the process definition and the process driver are located.

The `lib_index` is the index of entry in the process library that corresponds to the current process.

The `component_id` array identifies the individual process components.

The `component_description` is an array of human-readable strings that characterize the process components, for instance `a`, `b` => `c`, `d`.

The `active` mask array marks those components which are active. The others are skipped.

  end subroutine process_phs_config_write_formatted

```

### 30.5.6 Beam configuration

The object `data` holds all details about the initial beam configuration. The allocatable array `sf` holds the structure-function configuration blocks. There are `n_strfun` entries in the structure-function chain (not counting the initial beam object). We maintain `n_channel` independent parameterizations of this

chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is `n_sfpar`.

The flag `azimuthal_dependence` tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag `lab_is_cm` is obvious.

```

(Process config: public)+≡
  public :: process_beam_config_t

(Process config: types)+≡
  type :: process_beam_config_t
  type(beam_data_t) :: data
  integer :: n_strfun = 0
  integer :: n_channel = 1
  integer :: n_sfpar = 0

### 30.5.7 Process components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components can have different types. In short, `process_component_t` is a wrapper for the actual process variants.

If the `active` flag is false, we should skip this component. This happens if the associated process has vanishing matrix element.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

<Process config: public>+≡
  public :: process_component_t

<Process config: types>+≡
  type :: process_component_t
  type(process_component_def_t), pointer :: config => null ()
  integer :: index = 0
  logical :: active = .false.
  integer, dimension(:), allocatable :: i_term
  integer :: i_mci = 0
  class(phs_config_t), allocatable :: phs_config
  character(32) :: md5sum_phs = ""
  integer :: component_type = COMP_DEFAULT
  contains
  <Process config: process component: TBP>
  end type process_component_t

```

Finalizer. The MCI template may (potentially) need a finalizer. The process configuration finalizer may include closing an open scratch file.

```

<Process config: process component: TBP>≡

### 30.5.8 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`.

In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`. This is the total number of independent entries in the density matrix. For each combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

This type is public only for use in a unit test.

```

(Process config: public)+≡
  public :: process_term_t

(Process config: types)+≡
  type :: process_term_t
  integer :: i_term_global = 0
  integer :: i_component = 0

has_pdfs = has_pdfs, n_emitters = n_emitters)
end subroutine process_term_init

```

We fetch the process constants which determine the quantum numbers and use those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

**Why are these four subtraction entries for structure-function aware interactions?** Taking the soft or collinear limit of the real-emission matrix element, the behavior of the parton energy fractions has to be taken into account. In the pure real case,  $x_{\oplus}$  and  $x_{\ominus}$  are given by

$$x_{\oplus} = \frac{\bar{x}_{\oplus}}{\sqrt{1-\xi}} \sqrt{\frac{2-\xi(1-y)}{2-\xi(1+y)}}, \quad x_{\ominus} = \frac{\bar{x}_{\ominus}}{\sqrt{1-\xi}} \sqrt{\frac{2-\xi(1+y)}{2-\xi(1-y)}}.$$

In the soft limit,  $\xi \rightarrow 0$ , this yields  $x_{\oplus} = \bar{x}_{\oplus}$  and  $x_{\ominus} = \bar{x}_{\ominus}$ . In the collinear limit,  $y \rightarrow 1$ , it is  $x_{\oplus} = \bar{x}_{\oplus}/(1-\xi)$  and  $x_{\ominus} = \bar{x}_{\ominus}$ . Likewise, in the anti-collinear limit  $y \rightarrow -1$ , the inverse relation holds. We therefore have to distinguish four cases with the PDF assignments  $f(x_{\oplus}) \cdot f(x_{\ominus})$ ,  $f(\bar{x}_{\oplus}) \cdot f(\bar{x}_{\ominus})$ ,  $f(\bar{x}_{\oplus}/(1-\xi)) \cdot f(\bar{x}_{\ominus})$  and  $f(\bar{x}_{\oplus}) \cdot f(\bar{x}_{\ominus}/(1-\xi))$ .

The `n_emitters` optional argument is provided by the caller if this term requires spin-correlated matrix elements, and thus involves additional subtractions.

## 30.6 Process call statistics

Very simple object for statistics. Could be moved to a more basic chapter.

```

<process_counter.f90>≡
  <File header>

  module process_counter

    <Standard module head>

    <Process counter: public>

    <Process counter: parameters>

    <Process counter: types>

    interface
      <Process counter: sub interfaces>
    end interface

    end module process_counter

```

This object can record process calls, categorized by evaluation status. It is a part of the `mci_entry` component below.

```

  <Process counter: public>≡
    public :: process_counter_t

  <Process counter: types>≡
    type :: process_counter_t
    integer :: total = 0
    integer :: failed_kinematics = 0
    integer :: failed_cuts = 0
    integer :: has_passed = 0
    integer :: evaluated = 0
    integer :: complete = 0
    contains
    <Process counter: process counter: TBP>
    end type process_counter_t

```

Here are the corresponding numeric codes:

```

(Process counter: parameters)≡
  integer, parameter, public :: STAT_UNDEFINED = 0
  integer, parameter, public :: STAT_INITIAL = 1
  integer, parameter, public :: STAT_ACTIVATED = 2
  integer, parameter, public :: STAT_BEAM_MOMENTA = 3
  integer, parameter, public :: STAT_FAILED_KINEMATICS = 4
  integer, parameter, public :: STAT_SEED_KINEMATICS = 5
  integer, parameter, public :: STAT_HARD_KINEMATICS = 6
  integer, parameter, public :: STAT_EFF_KINEMATICS = 7
  integer, parameter, public :: STAT_FAILED_CUTS = 8
  integer, parameter, public :: STAT_PASSED_CUTS = 9
  integer, parameter, public :: STAT_EVALUATED_TRACE = 10
  integer, parameter, public :: STAT_EVENT_COMPLETE = 11

```

Output.

```

(Process counter: process counter: TBP)≡
  procedure :: write => process_counter_write

(Process counter: sub interfaces)≡
  module subroutine process_counter_write (object, unit)
    class(process_counter_t), intent(in) :: object
    integer, intent(in), optional :: unit
  end subroutine process_counter_write

(Process counter: procedures)≡
  module subroutine process_counter_write (object, unit)
    class(process_counter_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    if (object%total > 0) then
      write (u, "(1x,A)") "Call statistics (current run):"
      write (u, "(3x,A,I0)") "total          = ", object%total
      write (u, "(3x,A,I0)") "failed kin. = ", object%failed_kinematics
      write (u, "(3x,A,I0)") "failed cuts = ", object%failed_cuts
      write (u, "(3x,A,I0)") "passed cuts = ", object%has_passed
      write (u, "(3x,A,I0)") "evaluated   = ", object%evaluated
    else
      write (u, "(1x,A)") "Call statistics (current run): [no calls]"
    end if
  end subroutine process_counter_write

(process_counter_sub.f90)≡
  <File header>

  submodule (process_counter) process_counter_s

  use io_units

  implicit none

  contains

```

*<Process counter: procedures>*

end submodule process\_counter\_s

Reset. Just enforce default initialization.

*<Process counter: process counter: TBP>+≡*

procedure :: reset => process\_counter\_reset

*<Process counter: sub interfaces>+≡*

```
module subroutine process_counter_reset (counter)
  class(process_counter_t), intent(out) :: counter
end subroutine process_counter_reset
```

*<Process counter: procedures>+≡*

```
module subroutine process_counter_reset (counter)
  class(process_counter_t), intent(out) :: counter
  counter%total = 0
  counter%failed_kinematics = 0
  counter%failed_cuts = 0
  counter%has_passed = 0
  counter%evaluated = 0
  counter%complete = 0
end subroutine process_counter_reset
```

We record an event according to the lowest status code greater or equal to the actual status. This is actually done by the process instance; the process object just copies the instance counter.

*<Process counter: process counter: TBP>+≡*

procedure :: record => process\_counter\_record

*<Process counter: sub interfaces>+≡*

```
module subroutine process_counter_record (counter, status)
  class(process_counter_t), intent(inout) :: counter
  integer, intent(in) :: status
end subroutine process_counter_record
```

*<Process counter: procedures>+≡*

```
module subroutine process_counter_record (counter, status)
  class(process_counter_t), intent(inout) :: counter
  integer, intent(in) :: status
  if (status <= STAT_FAILED_KINEMATICS) then
    counter%failed_kinematics = counter%failed_kinematics + 1
  else if (status <= STAT_FAILED_CUTS) then
    counter%failed_cuts = counter%failed_cuts + 1
  else if (status <= STAT_PASSED_CUTS) then
    counter%has_passed = counter%has_passed + 1
  else
    counter%evaluated = counter%evaluated + 1
  end if
  counter%total = counter%total + 1
end subroutine process_counter_record
```

## 30.7 Multi-channel integration

  end submodule process_mci_s
```

### 30.7.1 Process MCI entry

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly the values that apply to the current pass. Previous values are archived in the `results` object.

The `counter` receives the counter statistics from the associated process instance, for diagnostics.

The `results` object records results, broken down in passes and iterations.

```

(Process mci: public)≡
  public :: process_mci_entry_t

```

Configure the MCI entry. This is intent(inout) since some specific settings may be done before this. The actual mci\_t object is an instance of the mci\_template argument, which determines the concrete types.

In a unit-test context, the mci\_template argument may be unallocated.

We obtain the number of channels and the number of parameters separately

for the structure-function chain and for the associated process component. We assume that the phase-space object has already been configured.

We assume that there is only one process component directly associated with an MCI entry.

Integrate.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

Generate an event. The instance should be initialized, otherwise event generation is directed by the mci integrator subobject. The integrator instance is contained in a mci\_work subobject of the process instance, which simultaneously serves as the sampler object. (We avoid the anti-aliasing rules if we assume that the sampling itself does not involve the integrator instance contained in the process instance.)

Regarding weighted events, we only take events which are valid, which means that they have valid kinematics and have passed cuts. Therefore, we have a rejection loop. For unweighted events, the unweighting routine should already take care of this.

The `keep_failed` flag determines whether events which failed cuts are nevertheless produced, to be recorded with zero weight. Alternatively, failed events are dropped, and this fact is recorded by the counter `n_dropped`.

```

### 30.8.1 Default process component manager

This is the configuration object which has the duty of allocating the corresponding instance. The default version is trivial.

```

⟨PCM: public⟩≡
  public :: pcm_default_t

⟨PCM: types⟩≡
  type, extends (pcm_t) :: pcm_default_t
  contains
  ⟨PCM: pcm default: TBP⟩
  end type pcm_default_t

Gfortran 7/8/9 bug, has to remain in the main module:

⟨PCM: pcm default: TBP⟩≡
  procedure :: allocate_workspace => pcm_default_allocate_workspace

⟨PCM: main procedures⟩≡
  subroutine pcm_default_allocate_workspace (pcm, work)
    class(pcm_default_t), intent(in) :: pcm
    class(pcm_workspace_t), intent(inout), allocatable :: work
    allocate (pcm_default_workspace_t :: work)
    end subroutine pcm_default_allocate_workspace

Finalizer: apply to core manager.

⟨PCM: pcm default: TBP⟩+≡
  procedure :: final => pcm_default_final

⟨PCM: sub interfaces⟩≡
  module subroutine pcm_default_final (pcm)
    class(pcm_default_t), intent(inout) :: pcm
    end subroutine pcm_default_final

⟨PCM: procedures⟩≡
  module subroutine pcm_default_final (pcm)
    class(pcm_default_t), intent(inout) :: pcm
    end subroutine pcm_default_final

⟨PCM: pcm default: TBP⟩+≡
  procedure :: is_nlo => pcm_default_is_nlo

⟨PCM: sub interfaces⟩+≡

    logical :: is_nlo
    class(pcm_default_workspace_t), intent(inout) :: pcm_work
    is_nlo = .false.
  end function pcm_default_workspace_is_nlo

```

### 30.8.2 Implementations for the default manager

Categorize components. Nothing to do here, all components are of Born type.

```

<PCM: pcm default: TBP>+≡
  procedure :: categorize_components => pcm_default_categorize_components

<PCM: sub interfaces>+≡
  module subroutine pcm_default_categorize_components (pcm, config)
    class(pcm_default_t), intent(inout) :: pcm
    type(process_config_data_t), intent(in) :: config
  end subroutine pcm_default_categorize_components

<PCM: procedures>+≡
  module subroutine pcm_default_categorize_components (pcm, config)
    class(pcm_default_t), intent(inout) :: pcm
    type(process_config_data_t), intent(in) :: config
  end subroutine pcm_default_categorize_components

```

### Phase-space configuration

Default setup for tree processes: a single phase-space configuration that is valid for all components.

```

<PCM: pcm default: TBP>+≡
  procedure :: init_phs_config => pcm_default_init_phs_config

<PCM: sub interfaces>+≡
  module subroutine pcm_default_init_phs_config &
    (pcm, phs_entry, meta, env, phs_par, mapping_defs)
    class(pcm_default_t), intent(inout) :: pcm
    type(process_phs_config_t), &
    dimension(:), allocatable, intent(out) :: phs_entry
    type(process_metadata_t), intent(in) :: meta
    type(process_environment_t), intent(in) :: env
    type(mapping_defaults_t), intent(in) :: mapping_defs
    type(phs_parameters_t), intent(in) :: phs_par
  end subroutine pcm_default_init_phs_config

<PCM: procedures>+≡
  module subroutine pcm_default_init_phs_config &
    (pcm, phs_entry, meta, env, phs_par, mapping_defs)
    class(pcm_default_t), intent(inout) :: pcm
    type(process_phs_config_t), &
    dimension(:), allocatable, intent(out) :: phs_entry
    type(process_metadata_t), intent(in) :: meta
    type(process_environment_t), intent(in) :: env
    type(mapping_defaults_t), intent(in) :: mapping_defs

```

```

type(phs_parameters_t), intent(in) :: phs_par
allocate (phs_entry (1))
allocate (pcm%i_phs_config (pcm%n_components), source=1)
call dispatch_phs (phs_entry(1)%phs_config, &
env%get_var_list_ptr (), &
env%get_os_data (), &
meta%id, &
mapping_defs, phs_par)
end subroutine pcm_default_init_phs_config

```

## Core management

The default component manager assigns one core per component. We allocate and configure the core objects, using the process-component configuration data.

*(PCM: pcm default: TBP)*+≡

```

procedure :: allocate_cores => pcm_default_allocate_cores

```

*(PCM: sub interfaces)*+≡

```

module subroutine pcm_default_allocate_cores (pcm, config, core_entry)
class(pcm_default_t), intent(inout) :: pcm
type(process_config_data_t), intent(in) :: config
type(core_entry_t), dimension(:), allocatable, intent(out) :: core_entry
end subroutine pcm_default_allocate_cores

```

*(PCM: procedures)*+≡

```

module subroutine pcm_default_allocate_cores (pcm, config, core_entry)
class(pcm_default_t), intent(inout) :: pcm
type(process_config_data_t), intent(in) :: config
type(core_entry_t), dimension(:), allocatable, intent(out) :: core_entry
type(process_component_def_t), pointer :: component_def
integer :: i
allocate (pcm%i_core (pcm%n_components), source = 0)
pcm%n_cores = pcm%n_components
allocate (core_entry (pcm%n_cores))
do i = 1, pcm%n_cores
pcm%i_core(i) = i
core_entry(i)%i_component = i
component_def => config%process_def%get_component_def_ptr (i)
core_entry(i)%core_def => component_def%get_core_def_ptr ()
core_entry(i)%active = component_def%can_be_integrated ()
end do
end subroutine pcm_default_allocate_cores

```

Extra code is required for certain core types (threshold) or if BLHA uses an external OLP (Born only, this case) for getting its matrix elements.

*(PCM: pcm default: TBP)*+≡

```

procedure :: prepare_any_external_code => &
pcm_default_prepare_any_external_code

```

*(PCM: sub interfaces)*+≡

```

module subroutine pcm_default_prepare_any_external_code &
(pcm, core_entry, i_core, libname, model, var_list)
class(pcm_default_t), intent(in) :: pcm

```

```

type(core_entry_t), intent(inout) :: core_entry
integer, intent(in) :: i_core
type(string_t), intent(in) :: libname
type(model_data_t), intent(in), target :: model
type(var_list_t), intent(in) :: var_list
end subroutine pcm_default_prepare_any_external_code

<PCM: procedures>+≡
module subroutine pcm_default_prepare_any_external_code &
(pcm, core_entry, i_core, libname, model, var_list)
class(pcm_default_t), intent(in) :: pcm
type(core_entry_t), intent(inout) :: core_entry
integer, intent(in) :: i_core

end subroutine pcm_default_set_blha_methods
<PCM: procedures>+≡
module subroutine pcm_default_set_blha_methods (pcm, blha_master, var_list)
class(pcm_default_t), intent(inout) :: pcm
type(blha_master_t), intent(inout) :: blha_master
type(var_list_t), intent(in) :: var_list
call blha_master%set_methods (.false., var_list)
end subroutine pcm_default_set_blha_methods

```

Produce the LO and NLO flavor-state tables (as far as available), as appropriate for BLHA configuration.

The default version looks at the first process core only, to get the Born data. (Multiple cores are thus unsupported.) The NLO flavor table is left unallocated.

```

<PCM: pcm default: TBP>+≡
procedure :: get_blha_flv_states => pcm_default_get_blha_flv_states

```

As appropriate for the NLO/FKS algorithm, the category defined by the process, is called `nlo_type`. We refine this by setting the component category `component_type` separately.

The component types `COMP_MISMATCH`, `COMP_PDF`, `COMP_SUB` are set only if the algorithm uses combined integration. Otherwise, they are set to `COMP_DEFAULT`.

The component type `COMP_REAL` is further distinguished between `COMP_REAL_SING` or `COMP_REAL_FIN`, if the algorithm uses real partitions. The former acts as a reference component for the latter, and we always assume that it is the first real component.

Each component is assigned its own core. Exceptions: the finite-real component gets the same core as the singular-real component. The mismatch component gets the same core as the subtraction component.

TODO wk 2018: this convention for real components can be improved. Check whether all component types should be assigned, not just for combined integration.

```

## Core management

Allocate the core (matrix-element interface) objects that we will need for evaluation. Every component gets an associated core, except for the real-finite and mismatch components (if any). Those components are associated with their previous corresponding real-singular and subtraction cores, respectively.

After cores are allocated, configure the region-data block that is maintained by the NLO process-component manager.

```

<PCM: pcm_nlo: TBP>+≡
  procedure :: allocate_cores => pcm_nlo_allocate_cores

end do
end subroutine pcm_nlo_allocate_cores

```

Extra code is required for certain core types (threshold) or if BLHA uses an external OLP for getting its matrix elements. Omega matrix elements, by definition, do not need extra code. NLO-virtual or subtraction matrix elements always need extra code.

More precisely: for the Born and virtual matrix element, the extra code is accessed only if the component is active. The radiation (real) and the subtraction corrections (singular and finite), extra code is accessed in any case.

The flavor state is taken from the `region_data` table in the `pcm` record. We use the Born and real flavor-state tables as appropriate.

```

After phase-space configuration data and core entries are available, we fill tables and compute the remaining NLO data that will steer the integration and subtraction algorithm.

There are three parts: recognize a threshold-type process core (if it exists), prepare the region-data tables (always), and prepare for real partitioning (if requested).

The real-component phase space acts as the source for resonance-history information, required for the region data.

```

Allocate and configure the MCI (multi-channel integrator) records. The relation depends on the `combined_integration` setting. If we integrate components separately, each component gets its own record, except for the subtraction component. If we do the combination, there is one record for the master (Born) component and a second one for the real-finite component, if present.

Each entry acquires some NLO-specific initialization. Generic configuration follows later.

Second procedure: call the MCI dispatcher with NLO-setup arguments.

```

After region data are set up, we allocate and configure the `real_partition` objects, if requested. Gfortran 7/8/9 bug, has to remain in the main module:

```

<PCM: pcm_nlo: TBP>+≡
  procedure :: setup_real_partition => pcm_nlo_setup_real_partition

<PCM: main procedures>+≡
  subroutine pcm_nlo_setup_real_partition (pcm)
  class(pcm_nlo_t), intent(inout) :: pcm
  if (pcm%use_real_partition) then
  if (.not. allocated (pcm%real_partition)) then
  allocate (real_partition_fixed_order_t :: pcm%real_partition)
  select type (partition => pcm%real_partition)
  type is (real_partition_fixed_order_t)
  call pcm%region_data%get_all_ftuples (partition%fks_pairs)
  partition%scale = pcm%real_partition_scale
  end select
  end if
  end if
  end subroutine pcm_nlo_setup_real_partition

```

Initialize a single component. We require all process-configuration blocks, and specific templates for the phase-space and integrator configuration.

We also provide the current component index `i` and the `active` flag. For a subtraction component, the `active` flag is overridden.

In the nlo mode, the component types have been determined before.

TODO wk 2018: the component type need not be stored in the component; we may remove this when everything is controlled by `pcm`.

```

<PCM: pcm_nlo: TBP>+≡

This routine modifies the kinematic factors applied to the real matrix element for use with POWHEG matching. We need to divide the real matrix element by `xi_max` to cancel a factor of `xi_max` applied in `apply_kinematic_factors_radiation`. It comes from the fact that we sample  $\tilde{\xi} \in [0,1]$  when integrating but  $\xi \in [p_T^2, \xi_{\max}]$  for POWHEG matching. Thus, we are taking into account that  $d\xi = d\tilde{\xi} \frac{\xi}{\xi_{\max}} = d\tilde{\xi} \xi_{\max}$ . Additionally, we need to cancel the Jacobian from the random number mapping. We only want the physical part of the Jacobian in our Sudakov splitting function. Furthermore, the real matrix element lacks its flux factor  $\frac{1}{2s_R}$  and the real Jacobian lacks a factor of  $\frac{1}{1-\xi}$ . Together, this is a factor of  $\frac{1}{2s_B}$ , i.e. the same as the flux factor of the Born matrix element. We do not correct any of both here, as only the ratio of both will be relevant for the Sudakov.

## 30.9 Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

**sf\_chain** is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

**phs** is an instance of the phase space for the elementary process.

The array **f** contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either **sf\_chain** or **phs** are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component ('owned' by the object) or as a pointer.

```

Configure the kinematics object. This consists of several configuration steps which correspond to individual procedures. In essence, we configure the structure-function part, the partonic phase-space part, and various NLO items.

TODO wk 19-03-01: This includes some region-data setup within `pcm`, hence `pcm` is `intent(inout)`. This should be moved elsewhere, so `pcm` can become strictly `intent(in)`.

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

```

### 30.10.1 Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics,

but whose squared transition matrices have to be added pointwise.

The **active** flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The **amp** array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The **int\_hard** interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The **isolated** object holds the effective parton state for the elementary interaction. The amplitude entries are computed from **int\_hard**.

The **connected** evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The **checked** flag is set once we have applied cuts on this term. The result of this is stored in the **passed** flag.

Although each **term\_instance** carries a **weight**, this currently always keeps the value 1 and is only used to be given to routines to fulfill their signature.

```

end if
end subroutine term_instance_configure

```

First part of term-instance configuration: initialize by assigning pointers to the overall pcm and the associated pcm\_workspace objects.

```

<Instances: term instance: TBP>+=
  procedure :: init => term_instance_init

<Instances: sub interfaces>+=
module subroutine term_instance_init &
  (term_instance, pcm, pcm_work, nlo_type)
class(term_instance_t), intent(out) :: term_instance
class(pcm_t), intent(in), target :: pcm
class(pcm_workspace_t), intent(in), target :: pcm_work
integer, intent(in) :: nlo_type
end subroutine term_instance_init

<Instances: procedures>+=
module subroutine term_instance_init (term_instance, pcm, pcm_work, nlo_type)
class(term_instance_t), intent(out) :: term_instance
class(pcm_t), intent(in), target :: pcm
class(pcm_workspace_t), intent(in), target :: pcm_work

```

```

integer, intent(in) :: nlo_type
term_instance%pcm => pcm
term_instance%pcm_work => pcm_work
term_instance%nlo_type = nlo_type
end subroutine term_instance_init

```

The second part of term-instance configuration concerns dynamics, i.e., the interface to the matrix-element (interaction), and the parton-state objects that combine all kinematics and matrix-element data for evaluation.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (**rearrange**) as effective structure-function chain and interaction, respectively.

Finally, we set up the **subevt** component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

The **rearrange** parts are still commented out; they could become relevant for a NLO algorithm.

```

Set up beam polarisation quantum numbers, if beam polarisation is required.

We retrieve the full helicity information from `term%config%data` and reduce the information only to the initial state. Afterwards, we unify the initial state polarization by applying an index (hash) table.

The helicity information is fed into an array of quantum numbers to assign flavor, helicity and subtraction indices correctly to their matrix element.

Initialization of equivalent cut expression classes.

Each flavor index `i_flv` here is assigned to the corresponding one representative for an equivalent cut expression class. This class describes the set of flavor quantum numbers for which the phase space cut expression evaluation yield the same output. The representative `i_flv` for one class correspond to the first flavor quantum numbers of that kind occuring in the state matrix.

Compute the momenta in the hard interactions, one for each term that constitutes this process component. In simple cases this amounts to just copying momenta. In more advanced cases, we may generate distinct sets of momenta from the seed kinematics.

The interactions in the term instances are accessed individually. We may choose to calculate all terms at once together with the seed kinematics, use `component%core_state` for storage, and just fill the interactions here.

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

Color-correlated matrix elements should be obtained from the external BLHA provider. According to the standard, the matrix elements output is a one-dimensional array. For FKS subtraction, we require the matrix  $B_{ij}$ . BLHA prescribes a mapping  $(i, j) \rightarrow k$ , where  $k$  is the index of the matrix element in the

output array. It focusses on the off-diagonal entries, i.e.  $i \neq j$ . The subroutine `blha_color_c_fill_offdiag` realizes this mapping. The diagonal entries can simply be obtained as the product of the Born matrix element and either  $C_A$  or  $C_F$ , which is achieved by `blha_color_c_fill_diag`. For simple processes, i.e. those with only one color line, it is  $B_{ij} = C_F \cdot B$ . For those, we keep the possibility of computing color correlations by a multiplication of the Born matrix element with  $C_F$ . It is triggered by the `use_internal_color_correlations` flag and should be used only for testing purposes. However, it is also used for the threshold computation where the process is well-defined and fixed.

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain.

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

```
(Instances: term instance: TBP)+≡
  procedure :: compute_eff_kinematics => &
    term_instance_compute_eff_kinematics

(Instances: sub interfaces)+≡
  module subroutine term_instance_compute_eff_kinematics (term)
    class(term_instance_t), intent(inout) :: term
  end subroutine term_instance_compute_eff_kinematics

(Instances: procedures)+≡
  module subroutine term_instance_compute_eff_kinematics (term)
    class(term_instance_t), intent(inout) :: term
    term%checked = .false.
    term%passed = .false.
    call term%isolated%receive_kinematics ()
    call term%connected%receive_kinematics ()
  end subroutine term_instance_compute_eff_kinematics
```

Inverse. Reconstruct the connected state from the momenta in the trace evaluator (which we assume to be set), then reconstruct the isolated state as far as possible. The second part finalizes the momentum configuration, using the incoming seed momenta

```
(Instances: term instance: TBP)+≡
  procedure :: recover_hard_kinematics => &

Evaluate the trace: first evaluate the hard interaction, then the trace evaluator.

We use the `evaluate_interaction` method of the process component which generated this term. The `subevt` and `cut` expressions are not yet filled.

The `component` argument is `intent(inout)` because the `compute_amplitude` method may modify the `core_state` workspace object.

Retrieve the matrix elements from a matrix element provider and place them into `term%amp`.

For the handling of NLO calculations, FKS applies a book keeping handling flavor and/or particle type (e.g. for QCD: quark/gluon and quark flavor) in order to calculate the subtraction terms. Therefore, we have to insert the

calculated matrix elements correctly into the state matrix where each entry corresponds to a set of quantum numbers. We apply a mapping `hard_qn_ind` from a list of quantum numbers provided by FKS to the hard process `int_hard`.

The calculated matrix elements are insert into `term%amp` in the following way. The first `n_born` particles are the matrix element of the hard process. In non-trivial beams, we store another `n_beams_rescaled` copies of these matrix elements as the first `n_beams_rescaled` subtractions. This is a remnant from times before the method `term_instance_set_sf_factors` and these entries are not used anymore. However, eliminating these entries involves deeper changes in how the connection tables for the evaluator product are set up and should therefore be part of a larger refactoring of the interactions & state matrices. The next  $n_{\text{born}} \times n_{\text{sub\_color}}$  are color-correlated Born matrix elements, with then again the next  $n_{\text{born}} \times n_{\text{emitters}} \times n_{\text{sub\_spin}}$  being spin-correlated Born matrix elements.

If two or more flavor structures would produce the same amplitude we only compute one and use the `eqv_index` determined by the `prc_core` and just copy the result to improve performance.

Same as for `term_instance_evaluate_interaction_external_tree`, but for the integrated-subtraction and finite one-loop terms. We only need color-correlated Born matrix elements, but an additional entry per flavor structure for the finite one-loop contribution. We thus have  $2 + n_{sub\_color}$  entries in the `term%amp` for each `i_flv` and `i_hel` combination.

If two or more flavor structures would produce the same amplitude we only compute one and use the `eqv_index` determined by the `prc_core` and just copy the result to improve performance.

```

Include rescaled structure functions due to NLO calculation. We rescale the structure function for the real subtraction `sf_rescale_collinear`, the collinear counter terms `sf_rescale_dglap_t` and for the case, in which we have an emitter in the initial state, we rescale the kinematics for it using `sf_rescale_real_t`. The references are arXiv:0709.2092, Eqs. (2.35)-(2.42).

Obviously, it is completely irrelevant, which beam is treated. It becomes problematic when handling *ep* collisions. Gfortran 7/8/9 bug, has to remain in the main module:

```

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

```

### 30.10.2 The process instance

NOTE: The description below represents the intended structure after refactoring and disentangling the FKS-NLO vs. LO algorithm dependencies.

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `pcm` pointer is a shortcut to the `pcm` (process-component manager) component of the associated process, which we need wherever the calculation depends on the overall algorithm.

The `pcm_work` component is the workspace for the `pcm` object referenced above.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `count` object records process evaluations, broken down according to status.

The **sqme** value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The **weight** value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the **sqme** value times Jacobian weights from the integration, or unity, respectively.

The **i\_mci** index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The **sf\_chain** subobject is a realization of the beam and structure-function configuration in the **process** object. It is not used for calculation directly but serves as the template for the sf-chain instances that are contained in the **component** objects.

The **kinematics** array contains the set of phase-space points that are associated with the current calculation. The entries may correspond to different process components and terms. (TODO wk 19-02-22: Not implemented yet.)

TODO wk 19-02-22: May include extra arrays for storing (squared) amplitude data. The **term** data set may be reduced to just results, or be removed altogether.

The **term** subobjects are workspace for evaluating kinematics, matrix elements, cuts etc. The array entries correspond to the **term** configuration entries in the associated process object.

The **mci\_work** subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the **mci\_work** array is selected by the **i\_mci** index above.

The **hook** pointer accesses a list of after evaluate objects which are evaluated after the matrix element.

```

<Instances: public>+≡
  public :: process_instance_t

<Instances: types>+≡
  type, extends (mci_sampler_t) :: process_instance_t
  type(process_t), pointer :: process => null ()
  class(pcm_t), pointer :: pcm => null ()
  class(pcm_workspace_t), allocatable :: pcm_work
  integer :: evaluation_status = STAT_UNDEFINED
  real(default) :: sqme = 0
  real(default) :: weight = 0
  real(default) :: excess = 0
  integer :: n_dropped = 0
  integer :: i_mci = 0
  integer :: selected_channel = 0
  type(sf_chain_t) :: sf_chain
  type(kinematics_t), dimension(:), allocatable :: kin
  type(term_instance_t), dimension(:), allocatable :: term
  type(mci_work_t), dimension(:), allocatable :: mci_work
  class(process_instance_hook_t), pointer :: hook => null ()
  contains
  <Instances: process instance: TBP>
end type process_instance_t

```

Wrapper type for storing pointers to process instance objects in arrays.

```

<Instances: public>+≡
  public :: process_instance_ptr_t

<Instances: types>+≡
  type :: process_instance_ptr_t
  type(process_instance_t), pointer :: p => null ()
  end type process_instance_ptr_t

```

The process hooks are first-in-last-out list of objects which are evaluated after the phase space and matrixelement are evaluated. It is possible to retrieve the sampler object and read the sampler information.

The hook object are part of the `process_instance` and therefore, share a common lifetime. A data transfer, after the usual lifetime of the `process_instance`, is not provided, as such the finalisation procedure has to take care of this! E.g. write the object to file from which later the collected information can then be retrieved.

```

<Instances: public>+≡
  public :: process_instance_hook_t

<Instances: types>+≡
  type, abstract :: process_instance_hook_t
  class(process_instance_hook_t), pointer :: next => null ()
  contains
  procedure(process_instance_hook_init), deferred :: init
  procedure(process_instance_hook_final), deferred :: final
  procedure(process_instance_hook_evaluate), deferred :: evaluate
  end type process_instance_hook_t

```

We have to provide an `init`, a `final` procedure and, for after evaluation, the `evaluate` procedure.

The `init` procedures accesses `var_list` and current `instance` object.

```

<Instances: public>+≡
  public :: process_instance_hook_final, process_instance_hook_evaluate

<Instances: interfaces>≡
  abstract interface
    subroutine process_instance_hook_init (hook, var_list, instance, pdf_data)
    import :: process_instance_hook_t, var_list_t, process_instance_t, pdf_data_t
    class(process_instance_hook_t), intent(inout), target :: hook
    type(var_list_t), intent(in) :: var_list
    class(process_instance_t), intent(in), target :: instance
    type(pdf_data_t), intent(in), optional :: pdf_data
    end subroutine process_instance_hook_init

    subroutine process_instance_hook_final (hook)
    import :: process_instance_hook_t
    class(process_instance_hook_t), intent(inout) :: hook
    end subroutine process_instance_hook_final

    subroutine process_instance_hook_evaluate (hook, instance)
    import :: process_instance_hook_t, process_instance_t
    class(process_instance_hook_t), intent(inout) :: hook

```

```

class(process_instance_t), intent(in), target :: instance
end subroutine process_instance_hook_evaluate
end interface

```

The output routine contains a header with the most relevant information about the process, copied from `process_metadata_write`. We mark the active components by an asterisk.

The next section is the MC parameter input. The following sections are written only if the evaluation status is beyond setting the parameters, or if the `verbose` option is set.

```

Initialization connects the instance with a process. All initial information is transferred from the process object. The process object contains templates for the interaction subobjects (beam and term), but no evaluators. The initialization routine creates evaluators for the matrix element trace, other evaluators are left untouched.

Before we start generating, we double-check if the process library has been

updated after the process was initialized (`check_library_sanity`). This may happen if between integration and event generation the library has been recompiled, so all links become broken.

The `instance` object must have the `target` attribute (also in any caller) since the initialization routine assigns various pointers to subobject of `instance`.

```

    end if
    instance%selected_channel = 0
    instance%evaluation_status = STAT_INITIAL
    end subroutine process_instance_reset

```

## Integration and event generation

The sampler test should just evaluate the squared matrix element `n_calls` times, discarding the results, and return. This can be done before integration, e.g., for timing estimates.

```
<Instances: process instance: TBP>+≡
  procedure :: sampler_test => process_instance_sampler_test

<Instances: sub interfaces>+≡
  module subroutine process_instance_sampler_test (instance, i_mci, n_calls)
    class(process_instance_t), intent(inout), target :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_calls
  end subroutine process_instance_sampler_test

<Instances: procedures>+≡
  module subroutine process_instance_sampler_test (instance, i_mci, n_calls)
    class(process_instance_t), intent(inout), target :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_calls
    integer :: i_mci_work
    i_mci_work = instance%process%get_i_mci_work (i_mci)
    call instance%choose_mci (i_mci_work)
    call instance%reset_counter ()
    call instance%process%sampler_test (instance, n_calls, i_mci_work)
    call instance%process%set_counter_mci_entry (i_mci_work, instance%get_counter ())
  end subroutine process_instance_sampler_test
```

Generate a weighted event. We select one of the available MCI integrators by its index `i_mci` and thus generate an event for the associated (group of) process component(s). The arguments exactly correspond to the initializer and finalizer above.

The resulting event is stored in the `process_instance` object, which also holds the workspace of the integrator.

Note: The `process` object contains the random-number state, which changes for each event. Otherwise, all volatile data are inside the `instance` object.

```
<Instances: process instance: TBP>+≡
  procedure :: generate_weighted_event => &
    process_instance_generate_weighted_event

class(process_instance_t), intent(inout) :: instance
type(process_beam_config_t), intent(in), target :: config
integer :: n_strfun

```

```

n_strfun = config%n_strfun
if (n_strfun /= 0) then
call instance%sf_chain%init (config%data, config%sf)
else
call instance%sf_chain%init (config%data)
end if
if (config%sf_trace) then
call instance%sf_chain%setup_tracing (config%sf_trace_file)
end if
end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

<Instances: process instance: TBP>+≡
  procedure :: setup_event_data => process_instance_setup_event_data

<Instances: sub interfaces>+≡
  module subroutine process_instance_setup_event_data &
    (instance, model, i_core)

        call mci_work%set (x)
      end associate
    if (activate) call instance%activate ()
  end if
  end subroutine process_instance_set_mcpair

```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The sf-chain instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```

<Instances: process instance: TBP>+≡
  procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

<Instances: sub interfaces>+≡
  module subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    end subroutine process_instance_receive_beam_momenta

<Instances: procedures>+≡
  module subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%receive_beam_momenta ()
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_receive_beam_momenta

```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```

<Instances: process instance: TBP>+≡
  procedure :: set_beam_momenta => process_instance_set_beam_momenta

<Instances: sub interfaces>+≡
  module subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    end subroutine process_instance_set_beam_momenta

<Instances: procedures>+≡
  module subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%set_beam_momenta (p)
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_set_beam_momenta

```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```

<Instances: process instance: TBP>+≡
  procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

<Instances: sub interfaces>+≡
  module subroutine process_instance_recover_beam_momenta (instance, i_term)

Calculates and then saves the ratio of the value of the (rescaled) real structure function chain of each ISR alpha region over the value of the corresponding underlying born flavor structure. In the case of emitter 0 we also need the rescaled ratio for emitter 1 and 2 in that region for the (soft-)collinear limits. If the emitter is 1 or 2 in some cases, e. g. for EW corrections where a photon in the proton is required, there can be the possibility of soft radiation off the initial state. For that purpose the unrescaled ratio is needed and as a default we always save these numbers in `sf_factors(:,0)`. Although this procedure is implying functionality for general structure functions, it should be reviewed for anything else besides PDFs, as there might be complications in the details. The general idea of getting the ratio in this way should hold up in these cases as well, however.

```

Final step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

If `weight` is provided, we already know the kinematical event weight (the MCI weight which depends on the kinematics sampling algorithm, but not on the matrix element), so we do not need to take it from the MCI record.

```

Computes the real-emission matrix element for externally supplied momenta for the term instance with index `i_term` and a phase space point set with index `i_phs`. In addition, for the real emission, each term instance corresponds to one emitter. There is the possibility to supply an external  $\alpha_s$  as well as an external scale to override the scale set in the Sindarin, e.g. for POWHEG matching.

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the  $x$  array, and the  $f$  Jacobian array are exposed by the `sampler_t` object.

We allow for the additional hook to be called, if associated, for outlying object to access information from the current state of the `sampler`.

```

<Instances: process instance: TBP>+≡
  procedure :: evaluate => process_instance_evaluate

```

Return squared matrix element and event weight, and event weight excess where applicable. `n_dropped` is a number that can be nonzero when a weighted event has been generated, dropping events with zero weight (failed cuts) on the fly. If `i_term` is provided for `get_sqme`, we take the first matrix element as we also set the first matrix element with `set_only_matrix_element` when computing the real, the dglap or the virtual contribution.

  name = instance%process%get_id ()
  end function process_instance_get_process_name

```

## Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

If `n_incoming` is provided, the status code of the first `n_incoming` particles will be reset to incoming. Otherwise, they would be classified as virtual.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

NB: The `recover_beams` option should be used only when the particle set originates from an external event file, and the user has asked for it. It should be switched off when reading from raw event file.

```

<Instances: process instance: TBP>+≡
  procedure :: get_trace => process_instance_get_trace
  procedure :: set_trace => process_instance_set_trace

<Instances: sub interfaces>+≡
  module subroutine process_instance_get_trace &
    (instance, pset, i_term, n_incoming)
  class(process_instance_t), intent(in), target :: instance
  type(particle_set_t), intent(out) :: pset
  integer, intent(in) :: i_term
  integer, intent(in), optional :: n_incoming
  end subroutine process_instance_get_trace
  module subroutine process_instance_set_trace &
    (instance, pset, i_term, recover_beams, check_match, success)
  class(process_instance_t), intent(inout), target :: instance

## Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```

## Resonances in Phase Space

This test demonstrates the extraction of the resonance-history set from the generated phase space. We need a nontrivial process, but no matrix element. This is provided by the `prc_template` method, using the `SM` model. We also need the `phs_wood` method, otherwise we would not have resonances in the phase space configuration.

```

## 30.12 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

```

<process_stacks.f90>≡
  <File header>

  module process_stacks

    <Use kinds>
    <Use strings>
    use variables
    use process

    <Standard module head>

    <Process stacks: public>

    <Process stacks: types>

    interface
    <Process stacks: sub interfaces>
    end interface

  end module process_stacks

<process_stacks_sub.f90>≡
  <File header>

  submodule (process_stacks) process_stacks_s

    use io_units
    use format_utils, only: write_separator
    use diagnostics
    use observables

    implicit none

    contains

    <Process stacks: procedures>

  end submodule process_stacks_s

```

### 30.12.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```

<Process stacks: public>≡
  public :: process_entry_t

<Process stacks: types>≡
  type, extends (process_t) :: process_entry_t
  type(process_entry_t), pointer :: next => null ()
  end type process_entry_t

```

### 30.12.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

The process stack can be linked to another one. This allows us to work with stacks of local scope.

```

<Process stacks: public>+≡
  public :: process_stack_t

<Process stacks: types>+≡
  type :: process_stack_t
  integer :: n = 0
  type(process_entry_t), pointer :: first => null ()
  type(var_list_t), pointer :: var_list => null ()
  type(process_stack_t), pointer :: next => null ()
  contains
  <Process stacks: process stack: TBP>
  end type process_stack_t

```

Finalize partly: deallocate the process stack and variable list entries, but keep the variable list as an empty object. This way, the variable list links are kept.

```

<Process stacks: process stack: TBP>≡
  procedure :: clear => process_stack_clear

<Process stacks: sub interfaces>≡
  module subroutine process_stack_clear (stack)
    class(process_stack_t), intent(inout) :: stack
  end subroutine process_stack_clear

<Process stacks: procedures>≡
  module subroutine process_stack_clear (stack)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), pointer :: process
    if (associated (stack%var_list)) then
      call stack%var_list%final ()
    end if
    do while (associated (stack%first))
      process => stack%first
      stack%first => process%next
      call process%final ()
      deallocate (process)
    end do
  end subroutine process_stack_clear

```

```

stack%n = 0
end subroutine process_stack_clear

```

Finalizer. Clear and deallocate the variable list.

```

<Process stacks: process stack: TBP>+≡
  procedure :: final => process_stack_final

<Process stacks: sub interfaces>+≡
  module subroutine process_stack_final (object)
    class(process_stack_t), intent(inout) :: object
  end subroutine process_stack_final

<Process stacks: procedures>+≡
  module subroutine process_stack_final (object)
    class(process_stack_t), intent(inout) :: object
    call object%clear ()
    if (associated (object%var_list)) then
      deallocate (object%var_list)
    end if
  end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

<Process stacks: process stack: TBP>+≡
  procedure :: write => process_stack_write

<Process stacks: sub interfaces>+≡
  recursive module subroutine process_stack_write (object, unit, pacify)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: pacify
  end subroutine process_stack_write

<Process stacks: procedures>+≡
  recursive module subroutine process_stack_write (object, unit, pacify)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: pacify
    type(process_entry_t), pointer :: process
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    select case (object%n)
    case (0)
      write (u, "(1x,A)") "Process stack: [empty]"
      call write_separator (u, 2)
    case default
      write (u, "(1x,A)") "Process stack:"
      process => object%first
      do while (associated (process))
        call process%write (.false., u, pacify = pacify)
        process => process%next
      end do
    end select
    if (associated (object%next)) then
      write (u, "(1x,A)") "[Processes from context environment:]"

```

```

    call object%next%write (u, pacify)
  end if
end subroutine process_stack_write

```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```

<Process stacks: process stack: TBP>+≡
  procedure :: write_var_list => process_stack_write_var_list

<Process stacks: sub interfaces>+≡
  module subroutine process_stack_write_var_list (object, unit)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
  end subroutine process_stack_write_var_list

<Process stacks: procedures>+≡
  module subroutine process_stack_write_var_list (object, unit)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    if (associated (object%var_list)) then
      call object%var_list%write (unit)
    end if
  end subroutine process_stack_write_var_list

```

Short output.

Since this is a stack, the default output ordering for each stack will be last-in, first-out. To enable first-in, first-out, which is more likely to be requested, there is an optional `fifo` argument.

```

<Process stacks: process stack: TBP>+≡
  procedure :: show => process_stack_show

<Process stacks: sub interfaces>+≡
  recursive module subroutine process_stack_show (object, unit, fifo)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: fifo
  end subroutine process_stack_show

<Process stacks: procedures>+≡
  recursive module subroutine process_stack_show (object, unit, fifo)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: fifo
    type(process_entry_t), pointer :: process
    logical :: reverse
    integer :: u, i, j
    u = given_output_unit (unit)
    reverse = .false.; if (present (fifo)) reverse = fifo
    select case (object%n)
    case (0)
    case default
      if (.not. reverse) then
        process => object%first
        do while (associated (process))
          call process%show (u, verbose=.false.)

```

```

process => process%next
end do
else
do i = 1, object%n
process => object%first
do j = 1, object%n - i
process => process%next
end do
call process%show (u, verbose=.false.)
end do
end if
end select
if (associated (object%next)) call object%next%show ()
end subroutine process_stack_show

```

### 30.12.3 Link

Link the current process stack to a global one.

```

(Process stacks: process stack: TBP)+≡
  procedure :: link => process_stack_link

(Process stacks: sub interfaces)+≡
  module subroutine process_stack_link (local_stack, global_stack)
    class(process_stack_t), intent(inout) :: local_stack
    type(process_stack_t), intent(in), target :: global_stack
  end subroutine process_stack_link

(Process stacks: procedures)+≡
  module subroutine process_stack_link (local_stack, global_stack)
    class(process_stack_t), intent(inout) :: local_stack
    type(process_stack_t), intent(in), target :: global_stack
    local_stack%next => global_stack
  end subroutine process_stack_link

```

Initialize the process variable list and link the main variable list to it.

```

(Process stacks: process stack: TBP)+≡
  procedure :: init_var_list => process_stack_init_var_list

(Process stacks: sub interfaces)+≡
  module subroutine process_stack_init_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(inout), optional :: var_list
  end subroutine process_stack_init_var_list

(Process stacks: procedures)+≡
  module subroutine process_stack_init_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(inout), optional :: var_list
    allocate (stack%var_list)
    if (present (var_list)) call var_list%link (stack%var_list)
  end subroutine process_stack_init_var_list

```

Link the process variable list to a global variable list.

```

(Process stacks: process stack: TBP)+≡
  procedure :: link_var_list => process_stack_link_var_list

(Process stacks: sub interfaces)+≡
  module subroutine process_stack_link_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in), target :: var_list
  end subroutine process_stack_link_var_list

(Process stacks: procedures)+≡
  module subroutine process_stack_link_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in), target :: var_list
    call stack%var_list%link (var_list)
  end subroutine process_stack_link_var_list

```

### 30.12.4 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

(Process stacks: process stack: TBP)+≡
  procedure :: push => process_stack_push

(Process stacks: sub interfaces)+≡
  module subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
  end subroutine process_stack_push

(Process stacks: procedures)+≡
  module subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    process%next => stack%first
    stack%first => process
    process => null ()
    stack%n = stack%n + 1
  end subroutine process_stack_push

```

Inverse: Remove the last process pointer in the list and return it.

```

(Process stacks: process stack: TBP)+≡
  procedure :: pop_last => process_stack_pop_last

(Process stacks: sub interfaces)+≡
  module subroutine process_stack_pop_last (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
  end subroutine process_stack_pop_last

```

```

<Process stacks: procedures>+≡
module subroutine process_stack_pop_last (stack, process)
class(process_stack_t), intent(inout) :: stack
type(process_entry_t), intent(inout), pointer :: process
type(process_entry_t), pointer :: previous
integer :: i
select case (stack%n)
case (:0)
process => null ()
case (1)
process => stack%first
stack%first => null ()
stack%n = 0
case (2:)
process => stack%first
do i = 2, stack%n
previous => process
process => process%next
end do
previous%next => null ()
stack%n = stack%n - 1
end select
end subroutine process_stack_pop_last

```

Initialize process variables for a given process ID, without setting values.

```

<Process stacks: process stack: TBP>+≡
procedure :: init_result_vars => process_stack_init_result_vars

<Process stacks: sub interfaces>+≡
module subroutine process_stack_init_result_vars (stack, id)
class(process_stack_t), intent(inout) :: stack
type(string_t), intent(in) :: id
end subroutine process_stack_init_result_vars

<Process stacks: procedures>+≡
module subroutine process_stack_init_result_vars (stack, id)
class(process_stack_t), intent(inout) :: stack
type(string_t), intent(in) :: id
call var_list_init_num_id (stack%var_list, id)
call var_list_init_process_results (stack%var_list, id)
end subroutine process_stack_init_result_vars

```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```

<Process stacks: process stack: TBP>+≡
procedure :: fill_result_vars => process_stack_fill_result_vars

<Process stacks: sub interfaces>+≡
module subroutine process_stack_fill_result_vars (stack, id)
class(process_stack_t), intent(inout) :: stack
type(string_t), intent(in) :: id
end subroutine process_stack_fill_result_vars

```

```

<Process stacks: procedures>+≡
module subroutine process_stack_fill_result_vars (stack, id)
class(process_stack_t), intent(inout) :: stack
type(string_t), intent(in) :: id
type(process_t), pointer :: process
process => stack%get_process_ptr (id)
if (associated (process)) then
call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
if (process%has_integral ()) then
call var_list_init_process_results (stack%var_list, id, &
integral = process%get_integral (), &
error = process%get_error ())
end if
else
call msg_bug ("process_stack_fill_result_vars: unknown process ID")
end if
end subroutine process_stack_fill_result_vars

```

If one of the result variables has a local image in `var_list_local`, update the value there as well.

```

<Process stacks: process stack: TBP>+≡
procedure :: update_result_vars => process_stack_update_result_vars

<Process stacks: sub interfaces>+≡
module subroutine process_stack_update_result_vars &
(stack, id, var_list_local)
class(process_stack_t), intent(inout) :: stack
type(string_t), intent(in) :: id
type(var_list_t), intent(inout) :: var_list_local
end subroutine process_stack_update_result_vars

<Process stacks: procedures>+≡
module subroutine process_stack_update_result_vars (stack, id, var_list_local)
class(process_stack_t), intent(inout) :: stack
type(string_t), intent(in) :: id
type(var_list_t), intent(inout) :: var_list_local
call update ("integral(" // id // ")")
call update ("error(" // id // ")")

  module matching_base  
  
    <Use strings>  
    use sm_qcd  
    use model_data  
    use particles  
    use variables  
    use shower_base  
    use instances, only: process_instance_t  
    use rng_base  
  
    <Standard module head>  
  
    <Matching base: public>  
  
    <Matching base: parameters>
```

Figure 31.1: Module dependencies in `src/matching`.

```

    <Matching base: types>

    <Matching base: interfaces>

    interface
    <Matching base: sub interfaces>
    end interface

    end module matching_base

    <matching_base_sub.f90>≡
    <File header>

    submodule (matching_base) matching_base_s

    <Use debug>
    use diagnostics

    implicit none

    contains

    <Matching base: procedures>

    end submodule matching_base_s

```

## 31.1 Abstract Matching Type

A matching will need access to the `shower` as well as matrix elements that we currently get over `process_instace`. The `model` is intended for the backup `model_hadrons`.

```

    <Matching base: public>≡
    public :: matching_t

    <Matching base: types>≡
    type, abstract :: matching_t
    logical :: is_hadron_collision = .false.
    type(qcd_t) :: qcd
    class(shower_base_t), pointer :: shower => null ()
    type(process_instance_t), pointer :: process_instance => null ()
    class(model_data_t), pointer :: model => null ()
    class(rng_t), allocatable :: rng
    type(string_t) :: process_name
    contains
    <Matching base: matching: TBP>
    end type matching_t

    <Matching base: matching: TBP>≡
    procedure (matching_init), deferred :: init

```

```

<Matching base: interfaces>≡
  abstract interface
    subroutine matching_init (matching, var_list, process_name)
    import
    class(matching_t), intent(out) :: matching
    type(var_list_t), intent(in) :: var_list
    type(string_t), intent(in) :: process_name
    end subroutine matching_init
  end interface

```

If we use a polymorphic settings type, this boilerplate wouldn't be necessary but then we introduce `select type` statements all over the place.

```

<default matching init>≡
  type(var_list_t), intent(in) :: var_list
  type(string_t), intent(in) :: process_name
  if (debug_on) call msg_debug (D_MATCHING, "matching_init")
  call matching%settings%init (var_list)
  matching%process_name = process_name

```

```

<Matching base: matching: TBP>+≡
  procedure (matching_write), deferred :: write

```

```

### 31.3 CKKW matching

This module contains the CKKW matching.

The type `ckkw_pseudo_shower_weights_t` gives the (relative) weights for different clusterings of the final particles, as given in Eq. (2.7) of hep-ph/0503281v1. Each particle has a binary labelling (power of 2) (first particle = 1, second par-

ticle = 2, third particle = 4, ...). Each recombination therefore corresponds to an integer, that is not a power of 2. For multiple subsequent recombinations, no different weights for different sequences of clustering are stored. It is assumed that the weight of a multiply recombined state is a combination of the states with one fewer recombination and that these states' contributions are proportional to their weights. For a  $2 > n$  event, the weights array thus has the size  $2^{(2+n)-1}$ . The `weights_by_type` array gives the weights depending on the type of the particle, the first index is the same as for weights, the second index gives the type of the new mother particle:

- 0: uncolored ( $\gamma$ ,  $Z$ ,  $W$ , Higgs)
- 1: colored (quark)
- 2: gluon
- 3: squark
- 4: gluino

`alphaS` gives the value for  $\alpha_s$  used in the generation of the matrix element. This is needed for the reweighting using the values for a running  $\alpha_s$  at the scales of the clusterings.

```

## 31.4 POWHEG

This module generates radiation according to the POWHEG Sudakov form factor

$$\Delta^{f_b}(\Phi_n, p_T) = \prod_{\alpha_r \in \{\alpha_r | f_b\}} \Delta_{\alpha_r}^{f_b}(\Phi_n, p_T), \quad (31.1)$$

with

$$\Delta_{\alpha_r}^{f_b}(\Phi_n, p_T) = \exp \left\{ - \left[ \int d\Phi_{\text{rad}} \frac{R(\Phi_{n+1})}{B f_b(\Phi_n)} \theta(k_T(\Phi_{n+1}) - p_T) \right]_{\alpha_r}^{\bar{\Phi}_n^{\alpha_r} = \Phi_n} \right\} \quad (31.2)$$

We expect that an underlying Born flavor structure  $f_b$  has been generated with a probability proportional to its contribution to the  $\tilde{B}$  at the given kinematic point.

### 31.4.1 Base types for settings and data

$\lambda$  is the lowest scale  $\Lambda^{(5)}_{\overline{\text{MS}}}$  where the radiation  $\alpha_s^{\text{rad}}$  is still larger than the true  $\alpha_s$ . We relate  $\alpha_s^{\text{rad}}$  and  $\alpha_s^{\text{true}}$  at the scale  $2\Lambda^{(5)}_{\overline{\text{MS}}}$ .

```

To generate the transverse momentum, we have to solve the equation

$$\frac{\Delta^{(U)}(p_T)}{\Delta^{(U)}(p_T^{\text{max}})} = r_1$$

iteratively for  $p_T$ . In log space and with initially  $\Delta^{(U)}(p_T^{\text{max}}) = 1$ , this is

$$\log \Delta^{(U)}(p_T) = \log r_1$$

If no solution is found, we set  $p_T = p_T^{\text{min}}$  to exit the event generation loop and generate an emissionless event. If a solution is found but the current emission is not accepted, we set  $p_T = p_T^{\text{max}}$  and thus in the next step it is  $\Delta^{(U)}(p_T^{\text{max}}) = r_1$ , so that we have to solve the equation

$$\log \Delta^{(U)}(p_T) = \log r_1 + \log r_2$$

using another random number  $r_2$ . We use `sum_log_rands` to remember the sum of the logarithms of all previous random numbers used for this event.

```

Generates the FKS variables  $(\xi, y, \phi)$  and sets the emission hardness scale. In debug mode, we assert that the `pt2` saved in the `radiation_t` and the massive hardness scale are equal. This should hold as we compute `kt2` with the `y` we got from generating `pt2` so that this is a full circle. It then initiates the generation of the transverse momentum followed by a sequence of veto steps to get the correct distribution.

  u = alpha_s / (xi * (1 - y**2))
  end function sudakov_eeqq_fsr_upper_bound_func
```

The logarithmic integrated UBF in the eeqq case as explained in [0709.2092], eq. (7.98), is given by

$$\begin{aligned}
-\frac{1}{N} \log [\Delta^U(p_T)] &= 2\pi \int_0^{k_{\max}} \alpha_s(k_T) \log \left[ \frac{4k_{\max}^2}{k_T^2} \right] \theta(k_T - p_T) \frac{dk_T}{k_T} \\
&= \frac{\pi}{b_0} \left( \log \left[ \frac{4k_{\max}^2}{k_T^2} \right] \log \left[ \frac{\log(k_{\max}^2/\Lambda^2)}{\log(p_T^2/\Lambda^2)} \right] - \log \left[ \frac{k_{\max}^2}{p_T^2} \right] \right)
\end{aligned}
\tag{31.7}$$

with  $k_{\max} = \frac{q^0}{2}$ . We see that for these logarithms to be well defined, we need to set a lower bound for the transverse momentum  $p_{T,\min} > \Lambda = \text{lambda2\_gen}$ .

```
(POWHEG matching: sudakov eeqq fsr: TBP)+≡
  procedure :: log_integrated_ubf => sudakov_eeqq_fsr_log_integrated_ubf

## Massive FSR

```

<POWHEG matching: public>+≡
public :: sudakov_massive_fsr_t

<POWHEG matching: types>+≡
type, extends (sudakov_t) :: sudakov_massive_fsr_t
real(default) :: z, z1, z2 = 0._default
real(default) :: xi_1, xi_min, xi_m = 0._default
real(default) :: xi_max_extended = 1._default
contains
<POWHEG matching: sudakov massive fsr: TBP>
end type sudakov_massive_fsr_t

```

According to eq. A.42 1202.0465, during the radiation generation, an alternative expression for  $\xi_{\max}$ ,

$$\xi_{\max} = 1 - \frac{(m + m_{\text{rec}})^2}{q^2},$$

is used, which corresponds to an extended Dalitz region. Phase space points outside of the original Dalitz region will be vetoed afterwards in `sudakov_massive_fsr_reweight_xi_max`.

```

<POWHEG matching: sudakov massive fsr: TBP>≡
procedure :: compute_xi_max_extended &
=> sudakov_massive_fsr_compute_xi_max_extended

sudakov%xi_max_extended = one - (m + mrec)**2 / q0**2
end subroutine sudakov_massive_fsr_compute_xi_max_extended

```

As described in 1202.0465, App. A.5., for massive emitters, the radiation variable  $\xi$  is constructed as follows. First,

$$\xi_{\min}(K_T^2) = \frac{\sqrt{K_T^2(K_T^2 z_2^2 + 8\bar{p}^0 q(1 - z_2))} - K_T^2 z_2}{2q^2(1 - z_2)} \quad (31.12)$$

is computed where  $K_T$  is a hardness scale for the radiation that determines the upper limit of the integral for the Sudakov form factor and coincides with the usual one, i.e. the transverse momentum of the radiated particle, in the massless limit. Then  $\xi_1$  is computed according to the same equation with  $z_2 \leftrightarrow z_1$ . Finally,  $\xi$  is generated according to

$$\xi = \frac{1}{q^2} \left( \exp \left[ \log(\xi_{\min} q^2 - K_T^2) + r \log \frac{\xi_m q^2 - K_T^2}{\xi_{\min} q^2 - K_T^2} \right] + K_T^2 \right), \quad (31.13)$$

where  $\xi_m = \min(\xi_{\max}, \xi_1)$ .

```

### Auxiliary functions

Implements the function  $G(a, b, \xi)$  given in eq. (31.17) and eq. (31.16). Cannot be evaluated for  $a = 0$ .

```

<POWHEG matching: procedures>+≡
  elemental function G_FSR (a,b,xi)
  real(default) :: G_FSR
  real(default), intent(in) :: a, b, xi
  if (a > 0) then
    G_FSR = G_FSR_Plus (a,b,xi)

```

```

else if (a < 0) then
  G_FSR = G_FSR_Minus (a,b,xi)
end if
end function G_FSR

elemental function G_FSR_Minus (a,b,xi)
real(default) :: G_FSR_Minus
real(default), intent(in) :: a, b, xi
G_FSR_Minus = log(a+b*xi)*log(one - (a+b*xi)/a) + Li2((a+b*xi)/a)
end function G_FSR_Minus

elemental function G_FSR_Plus (a,b,xi)
real(default) :: G_FSR_Plus
real(default), intent(in) :: a, b, xi
G_FSR_Plus = log(abs(b*xi/a))*log(a) - Li2(-b*xi/a) + pi**2/6
end function G_FSR_Plus

```

## ISR

This is the Sudakov for ISR. This corresponds to 1002.2581, App. D. The `ubf_variant` determines which `log_integrated_ubf` is used.

```

<POWHEG matching: public>+≡
  public :: sudakov_isr_t

end if
end function sudakov_isr_log_integrated_ubf

```

In order to arrive at the log integrated Sudakov implemented in `sudakov_isr_log_integrated_ubf`, we overestimated

$$\log \left[ \frac{\sqrt{x_+ - \rho} + \sqrt{x_- - \rho}}{\sqrt{x_+ - \rho} - \sqrt{x_- - \rho}} \right] \leq \log \left[ \frac{\sqrt{x_+} + \sqrt{x_-}}{\sqrt{x_+} - \sqrt{x_-}} \right] = \frac{1}{2} \log \left[ \frac{k_T^2 + s_b}{k_T^2} \right] \leq \frac{1}{2} \log \left[ \frac{q^2}{k_T^2} \right] \quad (31.18)$$

with

$$x_{\pm} = \left( \sqrt{1 + \frac{k_T^2}{s_b}} \pm \frac{k_T}{\sqrt{s_b}} \right)^2, \quad \rho = \frac{s_b}{S} \quad \text{and} \quad q^2 = k_{T,\text{max}}^2 + s_b. \quad (31.19)$$

We correct for this in this veto step. Additionally, we correct for overestimating  $\alpha_s$ .

```

We want to generate  $x := 1 - \xi$  for the ISR UBF with probability density

$$f(x) = \frac{1}{\sqrt{(x_+ - x)(x_- - x)}}. \quad (31.21)$$

within the limits

$$\frac{s_b}{S} = x_{b,\oplus} x_{b,\ominus} = \rho \leq x \leq x_- = x_+ = \left( \sqrt{1 + \frac{k_T^2}{s_b}} - \frac{k_T}{\sqrt{s_b}} \right)^2. \quad (31.22)$$

To generate  $x$  according to the distribution

$$F(x) = \int f(x) dx = 2 \sinh^{-1} \left( \sqrt{\frac{x_- - x}{x_+ - x_-}} \right) \quad (31.23)$$

we use

$$x = x_- + (x_- - x_+) \sinh^2 \left( \frac{r_x}{2} \right) \quad (31.24)$$

with a random number  $r_x \in \text{Unif}[F(x_-), F(\rho)] = \text{Unif} \left[ 0, 2 \sinh^{-1} \left( \sqrt{\frac{x_- - \rho}{x_+ - x_-}} \right) \right]$ . Alternatively, an implementation making extended use of rejection sampling is available.

Finalization of the POWHEG matching. It creates a log file showing how many events failed at which stage of the POWHEG veto algorithm. It also issues a warning if too many POWHEG excess events occurred. If this is the case, the chosen upper-bounding function is unsuitable for the considered process.

This is the last step of the Sudakov veto algorithm removing the dependence on the normalization factor  $N(\xi_i, y_i)$  and the upper bounding function  $U(\xi, y, \alpha_s)$  from the final result.

In cases where the Born kinematic failed the cuts,  $\mathcal{B}$  was artificially set to zero, so we cannot use it in a denominator. We assume that the generator cuts applied for parton showering are weak cuts to avoid divergent phase space regions, thus  $\mathcal{B}$  would have been large and the reweighting would have failed. Here, we can compute `sqme_real` directly with scale  $p_T$  but we still need to correct `sqme_born`.

## Generation algorithm and grid initialization

`compute_sqme_real` is the projected real matrix element  $R_{\alpha_r} = S_{\alpha_r} R$  whereby the current  $\alpha_r$  is implied by the emitter. Furthermore, it is multiplied by the real and the random number Jacobian.

This routine implements the Sudakov veto algorithm as explained in [1002.2581], Sec. 7.1 and Bijans thesis, Sec. 3.3 and B.2. Here, we veto in order to correct for

1. an overestimation of parts of the upper bounding function for complicated UBFs in `reweight_ubf` as well as the usage of  $\alpha_s^{\text{rad}}$  instead of  $\alpha_s^{\text{true}}$ .
2. the usage of `xi_max_extended` instead of `xi_max` in `reweight_xi_max` which is only non-trivial for massive FSR and ISR.
3. using the maximum of the entire POWHEG normalization grid  $N_{\text{max}}$  when generating  $p_T$  instead of the correct bin value  $N(\xi_i, y_i)$  in `reweight_norm`.
4. the normalization grid and the upper bounding function in the first place in `reweight_matrix_elements` to retrieve the correct fraction  $\frac{\mathcal{R}(\xi, y) \mathcal{J}(\xi, y)}{\mathcal{B}}$ .

By looping over all ALRs and in the end choosing the ALR with the largest `pt2`, we are effectively implementing the highest bid procedure. To save some time generating equivalent phase spaces again and again, we could instead loop over all radiation regions `i_phs`, take the sum of all real matrix elements in the Sudakov and in the end pick the ALR with probability proportional to the corresponding  $\mathcal{R}_{\alpha_r}$ . We might implement this optimization in the future.

We need to compute `xi2_max` before `kt2_max` here. In the simple case, it is given by  $\xi_{\text{max}} = \frac{s - M_{\text{rec}}^2}{s}$  but we can also take the  $\xi_{\text{max}}$  from the phase space computed before; they coincide. This is possible already at this point because in the simple case,  $\xi_{\text{max}}$  only depends on the Born momentum of the emitter and not on the real kinematics. In the eeqq case,  $M_{\text{rec}} = 0$ , so  $\xi_{\text{max}} = 1$  and

in the massive case as well as in the ISR case, we compute an extended  $\xi_{\max}^{\text{ext}}$  because the actual  $\xi_{\max}$  depends on the real kinematics.

Retrieves the value of the norm for given  $\xi$  and  $y$  from the pre-computed POWHEG grid. To find the correct bin we need to map  $(\xi, y)$  in some way to  $[0, 1]^2$ . This mapping is to the most extend arbitrary. We choose  $y \mapsto |y|$  and  $\xi \mapsto \log(1 - \xi) / \log(1 - \xi_{\max})$ . It may be possible to improve these mappings to tune the performance for processes with expensive matrix elements.

#### 31.4.4 $\alpha_s$ and its reweighting

The main point to ensure here is that the simple fixed-flavor-1-loop expression  $\alpha_s^{\text{rad}}$  is larger than the more accurate  $\alpha_s$  such that we can use a reweighting veto and use  $\alpha_s^{\text{rad}}$  for the generation of the emission. This can be done by setting

$$\alpha_s^{\text{rad}}(\mu_0) = \alpha_s(\mu_0) \quad (31.25)$$

whereby  $\mu_0^2$  is the `scale_to_relate2` that is taken to be  $(2\Lambda_{\overline{MS}}^{(5)})^2$ .

```

### 31.4.5 POWHEG hook

We provide a POWHEG hook to be called by `process_instance_evaluate` to prefill the adaptation grid.

We store the actual `powheg` object, which does the computations.

```

<POWHEG matching: public>+≡
  public :: powheg_matching_hook_t

<POWHEG matching: types>+≡
  type, extends(process_instance_hook_t) :: powheg_matching_hook_t
  type(string_t) :: process_name
  type(powheg_matching_t) :: powheg
  contains

```

```

    <POWHEG matching: powheg matching hook: TBP>
    end type powheg_matching_hook_t

```

Init the hook. The init procedure will be called in `setup_process`, after everything is set up.

Additionally, we have to include `var_list` in order to retrieve the grid size in `xi` and `y`.

```

    <POWHEG matching: powheg matching hook: TBP>≡
    procedure :: init => powheg_matching_hook_init

    <POWHEG matching: sub interfaces>+≡
    module subroutine powheg_matching_hook_init (hook, var_list, &
        instance, pdf_data)
        class(powheg_matching_hook_t), intent(inout), target :: hook
        type(var_list_t), intent(in) :: var_list
        class(process_instance_t), intent(in), target :: instance
        type(pdf_data_t), intent(in), optional :: pdf_data
    end subroutine powheg_matching_hook_init

    <POWHEG matching: procedures>+≡
    module subroutine powheg_matching_hook_init (hook, var_list, &
        instance, pdf_data)
        class(powheg_matching_hook_t), intent(inout), target :: hook
        type(var_list_t), intent(in) :: var_list
        class(process_instance_t), intent(in), target :: instance
        type(pdf_data_t), intent(in), optional :: pdf_data
        if (debug_on) call msg_debug (D_MATCHING, "powheg_matching_hook_init")
        hook%process_name = instance%get_process_name ()
        call hook%powheg%init (var_list, hook%process_name)
        hook%powheg%qcd = instance%get_qcd ()
        call hook%powheg%connect (instance)
        hook%powheg%process_deps%lab_is_cm = &
        hook%powheg%process_instance%lab_is_cm (1)
        if (present(pdf_data)) then
            hook%powheg%process_deps%pdf_data = pdf_data
        end if
        call hook%powheg%prepare_for_events ()
    end subroutine powheg_matching_hook_init

```

We save the filled grid to file, such that it can be retrieved later on. The hook object will be deallocated when the instance gets deallocated.

```

    <POWHEG matching: powheg matching hook: TBP>+≡
    procedure :: final => powheg_matching_hook_final

    <POWHEG matching: sub interfaces>+≡

```

*(POWHEG matching: powheg matching hook final: reduce)≡*

Reduce all grids to a single grid by using `MPI_MAX` on each element.

*(MPI: POWHEG matching: powheg matching hook final: reduce)≡*

```

call hook%powheg%grid%mpi_reduce (MPI_MAX)

```

This routine fills each bin of the POWHEG normalization grid  $\{\tilde{\xi}, \tilde{y}\}$  such that

$$N(\{\tilde{\xi}, \tilde{y}\}) = \max_{\forall \xi, y \in \{\tilde{\xi}, \tilde{y}\}} \frac{\mathcal{R}(\xi, y) \mathcal{J}(\xi, y)}{\mathcal{B} U(\xi, y, \alpha_s^{\text{true}})} \quad (31.26)$$

where  $\mathcal{R}(\xi, y)$  is the real cross section `sqme_real`,  $\mathcal{B}$  is the Born cross section `sqme_born`,  $\mathcal{J}$  is the Jacobian and  $U$  the upper bounding function `ubf`.

For each underlying Born  $f_b$ , there is a number of radiation regions. A radiation region `rr` may correspond to multiple  $\alpha_r$ s. The phase space only depends upon the radiation region kinematics `rr` and not on the specific  $\alpha_r$ .  $\alpha_r$  can be picked in the set  $\{\alpha_r | f_b, rr\}$  proportional to their  $R_{\alpha_r}$ . For now, we simplify things though and just work with the  $\alpha_r$ .

References:

- [1002.2581], Sec. 7.1
- Bijans Thesis, Sec. 3.3 and B.2

In cases where just the Born kinematic failed the cuts,  $\mathcal{B}$  was artificially set to zero. Unfortunately, we lost information about the value of `sqme_born` in these cases but we assume that the generator cuts applied for parton showering are weak cuts to avoid divergent phase space regions, thus  $\mathcal{B}$  is large and does not influence  $N$  so we can skip these phase space points.

A more appropriate way to solve this problem of Born zeroes is given by the real partition. With real partition, there are two possible cases if  $\mathcal{B} = 0$ : if the real phase space point belongs to the real singular, the real kinematic is Born-like and very likely also fails the cuts. If the real kinematic is not Born-like, it belongs to the real finite. In both cases, it is  $\mathcal{R} = \mathcal{B} = 0$  and we can safely skip the phase space point.

In cases where just the real kinematic failed the cuts,  $\mathcal{R}$  was artificially set to zero and we have no way to recover it. We skip these phase space points too. If we apply the same cuts during integration and event generation, these points are not relevant. We also skip points where either matrix element is negative. If just one of both is negative, their ratio is negative and thus cannot possibly be relevant for the grid. If both are negative, we are in an unphysical region for the PDFs. We also need to correct all scale dependences of `sqme_born` and `sqme_real` from the process' scale to  $p_T$  as this is the scale of the entire Sudakov. This affects the PDFs and also  $\alpha_s$ .

In some phase space point, the quark PDF may vanish although the gluon PDF does not. This may lead to very large ratios  $\mathcal{R}/\mathcal{B}$  which may spoil the reweighting performance of the POWHEG grid. Excluding these values when filling the grid is a minor approximation with a huge performance gain. The PDF veto we perform is independent on the actual emitter to not artificially favor specific ALRs.

## Initialization

There are no Powheg unit tests so far.

## Compare generated emission with Sudakov form factor

This is a nontrivial test of the generation algorithm and should be independent of the used upper bounding function (as long as all singularities are included).

It runs for an extensive amount of time generating a file `sudakov.dat` containing a histogram for the Sudakov factor in bins of the radiation's transverse momentum  $p_T^2$ .

So far, it is only designed to work for lepton collisions without beam spectra and cuts. In its current state however, it fills the histogram with either 1 or NaN as the `p_hard` received in `term_instance_evaluate_interaction` is identically zero.

## Chapter 32

# Event Implementation

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

**event\_transforms** Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

**resonance\_insertion** Insert a resonance history into an event record, based on kinematical and matrix-element information.

**recoil\_kinematics** Common kinematics routines for the ISR and EPA handlers.

**isr\_photon\_handler** Transform collinear kinematics, as it results from applying ISR radiation, to non-collinear kinematics with a reasonable transverse-momentum distribution of the radiated photons, and also of the recoiling partonic event.

**epa\_beam\_handler** For photon-initiated processes where the effective photon approximation is used in integration, to add in beam-particle recoil.

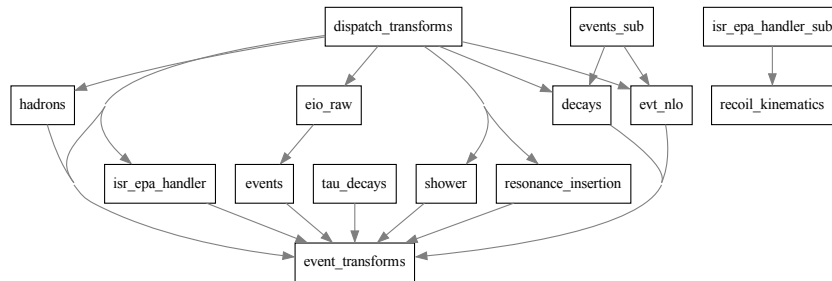

Figure 32.1: Module dependencies in `src/transforms`.

Analogous to the ISR handler.

**decays** Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

**showers** Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

**hadrons** (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

**tau\_decays** (not implemented yet) Let  $\tau$  leptons decay taking full spin correlations into account.

**evt\_nlo** Handler for fixed-order NLO events.

**events** Combine all pieces to generate full events.

**eio\_raw** Raw I/O for complete events.

## 32.1 Abstract Event Transforms

```

  <Event transforms: procedures>

  end submodule event_transforms_s

```

### 32.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified settings that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include `previous` and `next` pointers.

```

<Event transforms: public>≡
  public :: evt_t

<Event transforms: types>≡
  type, abstract :: evt_t
  type(process_t), pointer :: process => null ()
  type(process_instance_t), pointer :: process_instance => null ()
  class(model_data_t), pointer :: model => null ()
  class(rng_t), allocatable :: rng
  integer :: rejection_count = 0
  logical :: particle_set_exists = .false.
  type(particle_set_t) :: particle_set
  class(evt_t), pointer :: previous => null ()
  class(evt_t), pointer :: next => null ()
  logical :: only_weighted_events = .false.
  contains
  <Event transforms: evt: TBP>
  end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡
  procedure :: final => evt_final
  procedure :: base_final => evt_final

<Event transforms: sub interfaces>≡
  module subroutine evt_final (evt)
    class(evt_t), intent(inout) :: evt
  end subroutine evt_final

<Event transforms: procedures>≡
  module subroutine evt_final (evt)
    class(evt_t), intent(inout) :: evt
    if (allocated (evt%rng)) call evt%rng%final ()
    if (evt%particle_set_exists) &
      call evt%particle_set%final ()
  end subroutine evt_final

```

Print out the type of the evt.

```

<Event transforms: evt: TBP>+≡
  procedure (evt_write_name), deferred :: write_name

<Event transforms: interfaces>≡
  abstract interface
    subroutine evt_write_name (evt, unit)
  import
    class(evt_t), intent(in) :: evt
    integer, intent(in), optional :: unit
  end subroutine evt_write_name
  end interface

<Event transforms: evt: TBP>+≡
  procedure (evt_write), deferred :: write

<Event transforms: interfaces>+≡
  abstract interface
    subroutine evt_write (evt, unit, verbose, more_verbose, testflag)
  import
    class(evt_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, more_verbose, testflag
  end subroutine evt_write
  end interface

```

Output. We can print r.n.g. info.

```

<Event transforms: evt: TBP>+≡
  procedure :: base_write => evt_base_write

<Event transforms: sub interfaces>+≡
  module subroutine evt_base_write (evt, unit, testflag, show_set)
    class(evt_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag, show_set
  end subroutine evt_base_write

```

*<Event transforms: procedures>+≡*

```

module subroutine evt_base_write (evt, unit, testflag, show_set)
  class(evt_t), intent(in) :: evt
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: testflag, show_set
  integer :: u
  logical :: show
  u = given_output_unit (unit)
  show = .true.; if (present (show_set)) show = show_set
  if (associated (evt%process)) then
    write (u, "(3x,A,A,A)") "Associated process: '", &
      char (evt%process%get_id ()), "'"
  end if
  if (allocated (evt%rng)) then
    call evt%rng%write (u, 1)
    write (u, "(3x,A,I0)") "Number of tries = ", evt%rejection_count
  end if
  if (show) then
    if (evt%particle_set_exists) then
      call write_separator (u)
      call evt%particle_set%write (u, testflag = testflag)
    end if
  end if
end subroutine evt_base_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

*<Event transforms: evt: TBP>+≡*

```

procedure :: connect => evt_connect
procedure :: base_connect => evt_connect

```

*<Event transforms: sub interfaces>+≡*

```

module subroutine evt_connect (evt, process_instance, model, process_stack)
  class(evt_t), intent(inout), target :: evt
  type(process_instance_t), intent(in), target :: process_instance
  class(model_data_t), intent(in), target :: model
  type(process_stack_t), intent(in), optional :: process_stack
end subroutine evt_connect

```

*<Event transforms: procedures>+≡*

```

module subroutine evt_connect (evt, process_instance, model, process_stack)
  class(evt_t), intent(inout), target :: evt
  type(process_instance_t), intent(in), target :: process_instance
  class(model_data_t), intent(in), target :: model
  type(process_stack_t), intent(in), optional :: process_stack
  evt%process => process_instance%process
  evt%process_instance => process_instance
  evt%model => model
  call evt%process%make_rng (evt%rng)
end subroutine evt_connect

```

Reset internal state.

```

(Event transforms: evt: TBP)+≡
  procedure :: reset => evt_reset
  procedure :: base_reset => evt_reset
(Event transforms: sub interfaces)+≡
  module subroutine evt_reset (evt)
    class(evt_t), intent(inout) :: evt
  end subroutine evt_reset
(Event transforms: procedures)+≡
  module subroutine evt_reset (evt)
    class(evt_t), intent(inout) :: evt
    evt%rejection_count = 0
    call evt%particle_set%final ()
    evt%particle_set_exists = .false.
  end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_prepare_new_event), deferred :: prepare_new_event
(Event transforms: interfaces)+≡
  interface
    subroutine evt_prepare_new_event (evt, i_mci, i_term)
  import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
  end subroutine evt_prepare_new_event
  end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted
(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)
  import
    class(evt_t), intent(inout) :: evt
    real(default), intent(inout) :: probability
  end subroutine evt_generate_weighted
  end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted

```

```

<Event transforms: sub interfaces>+≡
  module subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    end subroutine evt_generate_unweighted

```

```

<Event transforms: procedures>+≡
  module subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

<Event transforms: evt: TBP>+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set

```

```

<Event transforms: interfaces>+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_make_particle_set
  end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

<Event transforms: evt: TBP>+≡
  procedure :: set_particle_set => evt_set_particle_set

```

```

<Event transforms: sub interfaces>+≡

call evt%prepare_new_event (i_mci, i_term)
evt%particle_set = particle_set
evt%particle_set_exists = .true.
end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. We need two interactions, one with color summed over, the `int_matrix`, and one with the probability distributed among flows, the `int_flows`.

We use the two values from the random number generator saved in `r` for factorizing the state. For testing purposes, we can provide those numbers explicitly.

The optional `qn_select` allows to limit the number of quantum numbers to choose from when factorizing. If only a single set of quantum numbers is given, it effectively dictates the quantum numbers chosen for the event.

```

(Event transforms: evt: TBP)+≡
procedure :: factorize_interactions => evt_factorize_interactions

(Event transforms: sub interfaces)+≡

end subroutine make_factorized_particle_set

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event

transforms. If this is not true for a transform (say, MPI), it should override this method.

```

<Event transforms: evt: TBP>+≡
  procedure :: tag_incoming => evt_tag_incoming

  end subroutine evt_tag_incoming

```

### 32.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

<Event transforms: public>+≡
  public :: evt_trivial_t

<Event transforms: types>+≡
  type, extends (evt_t) :: evt_trivial_t
  contains
  <Event transforms: evt trivial: TBP>
  end type evt_trivial_t

<Event transforms: evt trivial: TBP>≡
  procedure :: write_name => evt_trivial_write_name

<Event transforms: sub interfaces>+≡
  module subroutine evt_trivial_write_name (evt, unit)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
  end subroutine evt_trivial_write_name

<Event transforms: procedures>+≡
  module subroutine evt_trivial_write_name (evt, unit)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event transform: trivial (hard process)"

```

```
end subroutine evt_trivial_write_name
```

The finalizer is trivial. Some output:

*<Event transforms: evt trivial: TBP>+≡*

```
procedure :: write => evt_trivial_write
```

*<Event transforms: sub interfaces>+≡*

```
module subroutine evt_trivial_write &
  (evt, unit, verbose, more_verbose, testflag)
class(evt_trivial_t), intent(in) :: evt
integer, intent(in), optional :: unit
logical, intent(in), optional :: verbose, more_verbose, testflag
end subroutine evt_trivial_write
```

*<Event transforms: procedures>+≡*

```
module subroutine evt_trivial_write &
  (evt, unit, verbose, more_verbose, testflag)
class(evt_trivial_t), intent(in) :: evt
integer, intent(in), optional :: unit
logical, intent(in), optional :: verbose, more_verbose, testflag
integer :: u
u = given_output_unit (unit)
call write_separator (u, 2)
call evt%write_name (u)
call write_separator (u)
call evt%base_write (u, testflag = testflag)
!!! More readable but wider output; in line with evt_resonance_write
!   if (verbose .and. evt%particle_set_exists) then
!       call evt%particle_set%write &
!           (u, summary = .true., compressed = .true., testflag = testflag)
!       call write_separator (u)
!   end if
end subroutine evt_trivial_write
```

Nothing to do here:

*<Event transforms: evt trivial: TBP>+≡*

```
procedure :: prepare_new_event => evt_trivial_prepare_new_event
```

*<Event transforms: sub interfaces>+≡*

```
module subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
class(evt_trivial_t), intent(inout) :: evt
integer, intent(in) :: i_mci, i_term
end subroutine evt_trivial_prepare_new_event
```

*<Event transforms: procedures>+≡*

```
module subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
class(evt_trivial_t), intent(inout) :: evt
integer, intent(in) :: i_mci, i_term
call evt%reset ()
end subroutine evt_trivial_prepare_new_event
```

The weighted generator is, surprisingly, trivial.

*<Event transforms: evt trivial: TBP>+≡*

```
procedure :: generate_weighted => evt_trivial_generate_weighted
```

```

<Event transforms: sub interfaces>+≡
  module subroutine evt_trivial_generate_weighted (evt, probability)
  class(evt_trivial_t), intent(inout) :: evt
  real(default), intent(inout) :: probability
  end subroutine evt_trivial_generate_weighted

```

```

<Event transforms: procedures>+≡
  module subroutine evt_trivial_generate_weighted (evt, probability)
  class(evt_trivial_t), intent(inout) :: evt
  real(default), intent(inout) :: probability
  probability = 1
  end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is. Note that it is a potential risk to tolerate a non-existent particle set at this point. We should remove it once the flavors are determined correctly in all cases. It is currently necessary if we are keeping failed events `?keep_failed_events = .true.` For these events, we do not compute the matrix elements, so the factorization fails trying to determine the quantum numbers. Additionally, it is necessary for the trivial event transformation preceeding the event transformations required for POWHEG matching.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: make_particle_set => evt_trivial_make_particle_set

```

```

<Event transforms: sub interfaces>+≡
  module subroutine evt_trivial_make_particle_set &
  (evt, factorization_mode, keep_correlations, r)
  class(evt_trivial_t), intent(inout) :: evt
  integer, intent(in) :: factorization_mode
  logical, intent(in) :: keep_correlations
  real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_trivial_make_particle_set

```

```

<Event transforms: procedures>+≡
  module subroutine evt_trivial_make_particle_set &
  (evt, factorization_mode, keep_correlations, r)
  class(evt_trivial_t), intent(inout) :: evt
  integer, intent(in) :: factorization_mode
  logical, intent(in) :: keep_correlations
  real(default), dimension(:), intent(in), optional :: r
  call make_factorized_particle_set (evt, factorization_mode, &
  keep_correlations, r)
  evt%particle_set_exists = .true.
  end subroutine evt_trivial_make_particle_set

```

Here we take the particle set from the previous event transform and apply the hadronization. The result is stored in the `evt%hadrons` object. We always return a probability of unity as we don't have the analytic weight of the hadronization. Invalid events have to be discarded by the caller which is why we mark the particle set as invalid.

```

```

end if
end subroutine evt_resonance_write

```

### 32.3.2 Set contained data

Insert the resonance data, in form of a pre-generated resonance history set. Accumulate the number of histories for each set, to initialize an array of index offsets for lookup.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_resonance_data => evt_resonance_set_resonance_data

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_set_resonance_data (evt, res_history_set)
    class(evt_resonance_t), intent(inout) :: evt
    type(resonance_history_set_t), dimension(:), intent(in) :: res_history_set
  end subroutine evt_resonance_set_resonance_data

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_set_resonance_data (evt, res_history_set)
    class(evt_resonance_t), intent(inout) :: evt
    type(resonance_history_set_t), dimension(:), intent(in) :: res_history_set
    integer :: i
    evt%res_history_set = res_history_set
    allocate (evt%index_offset (size (evt%res_history_set)), source = 0)
    do i = 2, size (evt%res_history_set)
      evt%index_offset(i) = &
        evt%index_offset(i-1) + evt%res_history_set(i-1)%get_n_history ()
    end do
  end subroutine evt_resonance_set_resonance_data

```

Set the library that contains the resonant subprocesses.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_library => evt_resonance_set_library

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_set_library (evt, libname)
    class(evt_resonance_t), intent(inout) :: evt
    type(string_t), intent(in) :: libname
  end subroutine evt_resonance_set_library

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_set_library (evt, libname)
    class(evt_resonance_t), intent(inout) :: evt
    type(string_t), intent(in) :: libname
    evt%libname = libname
  end subroutine evt_resonance_set_library

```

Assign pointers to subprocess instances. Once a subprocess has been selected, the instance is used for generating the particle set with valid quantum-number assignments, ready for resonance insertion.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_subprocess_instances &
    => evt_resonance_set_subprocess_instances

```

```

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_set_subprocess_instances (evt, instance)
    class(evt_resonance_t), intent(inout) :: evt
    type(process_instance_ptr_t), dimension(:), intent(in) :: instance
  end subroutine evt_resonance_set_subprocess_instances

```

```

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_set_subprocess_instances (evt, instance)
    class(evt_resonance_t), intent(inout) :: evt
    type(process_instance_ptr_t), dimension(:), intent(in) :: instance
    evt%instance = instance
  end subroutine evt_resonance_set_subprocess_instances

```

Set the on-shell limit, the relative distance from a resonance that is still considered to be on-shell. The probability for being considered on-shell can be reduced by the turnoff parameter below. For details, see the **resonances** module.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_on_shell_limit => evt_resonance_set_on_shell_limit

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_set_on_shell_limit (evt, on_shell_limit)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_limit
  end subroutine evt_resonance_set_on_shell_limit

```

```

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_set_on_shell_limit (evt, on_shell_limit)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_limit
    evt%on_shell_limit = on_shell_limit
  end subroutine evt_resonance_set_on_shell_limit

```

Set the Gaussian on-shell turnoff parameter, the width of the weighting factor for the resonance squared matrix element. If the resonance is off shell, this factor reduces the weight of the matrix element in the selector, such that the probability for considered resonant is reduced. The factor is applied only if the offshellness is less than the **on\_shell\_limit** above. For details, see the **resonances** module.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_on_shell_turnoff => evt_resonance_set_on_shell_turnoff

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_set_on_shell_turnoff (evt, on_shell_turnoff)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_turnoff
  end subroutine evt_resonance_set_on_shell_turnoff

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_set_on_shell_turnoff (evt, on_shell_turnoff)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: on_shell_turnoff
    evt%on_shell_turnoff = on_shell_turnoff
  end subroutine evt_resonance_set_on_shell_turnoff

```

Reweight (suppress) the background contribution if there is a resonance history that applies. The event will be registered as background if there is no applicable resonance history, or if the background configuration has been selected based on (reweighted) squared matrix elements.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: set_background_factor => evt_resonance_set_background_factor

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_set_background_factor &
    (evt, background_factor)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: background_factor
    end subroutine evt_resonance_set_background_factor

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_set_background_factor (evt, background_factor)
    class(evt_resonance_t), intent(inout) :: evt
    real(default), intent(in) :: background_factor
    evt%background_factor = background_factor
    end subroutine evt_resonance_set_background_factor

```

### 32.3.3 Selector

Manually import a random-number generator object. This should be done only for testing purposes. The standard procedure is to `connect` a process to an event transform; this will create an appropriate `rng` from the RNG factory in the process object.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: import_rng => evt_resonance_import_rng

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_import_rng (evt, rng)
    class(evt_resonance_t), intent(inout) :: evt
    class(rng_t), allocatable, intent(inout) :: rng
    end subroutine evt_resonance_import_rng

<Resonance insertion: procedures>+≡
  module subroutine evt_resonance_import_rng (evt, rng)
    class(evt_resonance_t), intent(inout) :: evt
    class(rng_t), allocatable, intent(inout) :: rng
    call move_alloc (from = rng, to = evt%rng)
    end subroutine evt_resonance_import_rng

```

We use a standard selector object to choose from the available resonance histories. If the selector is inactive, we do not insert resonances.

```

<Resonance insertion: evt resonance: TBP>+≡
  procedure :: write_selector => evt_resonance_write_selector

<Resonance insertion: sub interfaces>+≡
  module subroutine evt_resonance_write_selector (evt, unit, testflag)
    class(evt_resonance_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    end subroutine evt_resonance_write_selector

```

```

<Resonance insertion: procedures>+≡
module subroutine evt_resonance_write_selector (evt, unit, testflag)
class(evt_resonance_t), intent(in) :: evt
integer, intent(in), optional :: unit
logical, intent(in), optional :: testflag
integer :: u
u = given_output_unit (unit)
if (evt%selector_active) then
call evt%selector%write (u, testflag)
else
write (u, "(1x,A)") "Selector: [inactive]"
end if
end subroutine evt_resonance_write_selector

```

The selector is initialized with relative weights of histories which need not be normalized. Channels with weight zero are ignored.

The `offset` will normally be `-1`, so we count from zero, and zero is a valid result from the selector. Selecting the zero entry implies no resonance insertion. However, this behavior is not hard-coded here (without `offset`, no resonance is not possible as a result).

```

<Resonance insertion: evt resonance: TBP>+≡
procedure :: init_selector => evt_resonance_init_selector

```

```

<Resonance insertion: sub interfaces>+≡
module subroutine evt_resonance_init_selector (evt, weight, offset)
class(evt_resonance_t), intent(inout) :: evt
real(default), dimension(:), intent(in) :: weight
integer, intent(in), optional :: offset
end subroutine evt_resonance_init_selector

```

```

<Resonance insertion: procedures>+≡
module subroutine evt_resonance_init_selector (evt, weight, offset)
class(evt_resonance_t), intent(inout) :: evt
real(default), dimension(:), intent(in) :: weight
integer, intent(in), optional :: offset
if (any (weight > 0)) then
call evt%selector%init (weight, offset = offset)
evt%selector_active = .true.
else
evt%selector_active = .false.
end if
end subroutine evt_resonance_init_selector

```

Return all selector weights, for inspection. Note that the index counts from zero.

```

<Resonance insertion: evt resonance: TBP>+≡
procedure :: get_selector_weights => evt_resonance_get_selector_weights

```

```

<Resonance insertion: sub interfaces>+≡
module subroutine evt_resonance_get_selector_weights (evt, weight)
class(evt_resonance_t), intent(in) :: evt
real(default), dimension(0:), intent(out) :: weight
end subroutine evt_resonance_get_selector_weights

```

```

<Resonance insertion: procedures>+≡
module subroutine evt_resonance_get_selector_weights (evt, weight)
class(evt_resonance_t), intent(in) :: evt
real(default), dimension(0:), intent(out) :: weight
integer :: i
do i = 0, ubound (weight,1)
weight(i) = evt%selector%get_weight (i)
end do
end subroutine evt_resonance_get_selector_weights

```

### 32.3.4 Runtime calculations

Use the associated master process instance and the subprocess instances to distribute the current momentum set, then compute the squared matrix elements weights for all subprocesses.

NOTE: Procedures in this subsection are not covered by unit tests in this module, but by unit tests of the `restricted_subprocesses` module.

Fill the particle set, so the momentum configuration can be used by the subprocess instances. The standard workflow is to copy from the previous particle set.

```

<Resonance insertion: evt resonance: TBP>+≡
procedure :: fill_momenta => evt_resonance_fill_momenta

<Resonance insertion: sub interfaces>+≡
module subroutine evt_resonance_fill_momenta (evt)
class(evt_resonance_t), intent(inout) :: evt
end subroutine evt_resonance_fill_momenta

<Resonance insertion: procedures>+≡
module subroutine evt_resonance_fill_momenta (evt)
class(evt_resonance_t), intent(inout) :: evt
integer :: i, n
if (associated (evt%previous)) then
evt%particle_set = evt%previous%particle_set
else if (associated (evt%process_instance)) then
! this branch only for unit test
call evt%process_instance%get_trace &
(evt%particle_set, i_term=1, n_incoming=evt%process%get_n_in ())
end if
end subroutine evt_resonance_fill_momenta

```

Return the indices of those subprocesses which can be considered on-shell. The result depends on the stored particle set (outgoing momenta) and on the on-shell limit value.

The index `evt%selected_component` identifies the particular history set that corresponds to the given process component. Recall that process components may have different external particles, so they have distinct history sets.

```

<Resonance insertion: evt resonance: TBP>+≡
procedure :: determine_on_shell_histories &
=> evt_resonance_determine_on_shell_histories

```

```

<Resonance insertion: sub interfaces>+≡

```

We use the calculations of resonant matrix elements to determine probabilities for all applicable resonance configurations. This method combines the steps implemented above.

First, we determine the selected process component.

TODO: the version below selects the first component which is found active. This make sense only for standard LO process components, where exactly one component corresponds to a MCI set.

For the selected process component, we query the kinematics and determine the applicable resonance histories. We collect squared matrix elements for those resonance histories and compare them to the master-process squared matrix element.

The result is the probability for each resonance history together with the probability for non-resonant background (zeroth entry). The latter is defined as the difference between the complete process result and the sum of the resonances, ignoring the possibility for interference. If the complete process result is actually undershooting the sum of resonances, we nevertheless count the background with positive probability.

When looking up the subprocess sqme, we must add the `index_offset` to the resulting array, since the indices returned by the individual history set all count from one, while the subprocess instances that belong to process components are collected in one flat array.

After determining matrix elements and background, we may reduce the weight of the matrix elements in the selector by applying a turnoff factor.

The factor `background_factor` indicates whether to include the background contribution at all, as long as there is a nonvanishing resonance contribution. Note that instead of setting background to zero, we just multiply it by a very small number. This ensures that indices are assigned correctly, and that background will eventually be selected if smooth turnoff is chosen.

```

```

### 32.3.5 Sanity check

Check the color assignment, which may be wrong for the inserted resonances. Delegated to the particle-set component. Return offending particle indices and, optionally, particles as arrays.

This is done in a unit test. The current algorithm, i.e., selecting the color assignment from the resonant-subprocess instance, should not generate invalid color assignments.

```

<Resonance insertion: evt resonance: TBP>+≡

    end if
    probability = 1
  end subroutine evt_resonance_generate_weighted

```

Here take the current particle set and insert resonance intermediate states if applicable. The resonance history has already been chosen by the generator above. If no resonance history applies, just retain the particle set.

If a resonance history applies, we factorize the exclusive interaction of the selected (resonance-process) process instance. With a temporary particle set `pvt_set` as workspace, we then insert the resonances, reinstate parent-child relations and set colors and momenta for the resonances. The temporary is then copied back.

Taking the event data from the resonant subprocess instead of the master process, guarantees that all flavor, helicity, and color assignments are valid for the selected resonance history. Note that the transform may thus choose a quantum-number combination that is different from the one chosen by the master process.

The `i_term` value for the selected subprocess instance is always 1. We support only LO process. For those, the master process may have several terms (= components) that correspond to different external states. The subprocesses are distinct, each one corresponds to a definite master component, and by itself it consists of a single component/term.

However, if the selector chooses resonance history #0, i.e., no resonance, we just copy the particle set from the previous (i.e., trivial) event transform and ignore all subprocess data.

```

### 32.4.1 $\phi$ sampler

This is trivial. Generate an azimuthal angle, given a (0,1) RNG parameter.

```

⟨Recoil kinematics: procedures⟩≡
  elemental subroutine generate_phi_recoil (r, phi)
    real(default), intent(in) :: r
    real(default), intent(out) :: phi

    phi = r * twopi

  end subroutine generate_phi_recoil

```

### 32.4.2 $Q^2$ sampler

The dynamics of factorization suggests to generate a flat  $Q^2$  distribution from a (random) number, event by event.

At the lowest momentum transfer values, the particle (electron) mass sets a smooth cutoff. The formula can produce  $Q$  values below the electron mass, down to zero, but with a power distribution that eventually evolves into the expected logarithmic distribution for  $Q^2 > m^2$ .

We are talking about the absolute value here, so all  $Q^2$  values are positive. For the actual momentum transfer,  $q^2 = -Q^2$ .

```

⟨Recoil kinematics: public⟩≡
  public :: generate_q2_recoil

⟨Recoil kinematics: sub interfaces⟩≡
  elemental module subroutine generate_q2_recoil (s, x_bar, q2_max, m2, r, q2)
    real(default), intent(in) :: s
    real(default), intent(in) :: q2_max
    real(default), intent(in) :: x_bar
    real(default), intent(in) :: m2
    real(default), intent(in) :: r
    real(default), intent(out) :: q2
  end subroutine generate_q2_recoil

```

```

⟨Recoil kinematics: procedures⟩+≡
  elemental module subroutine generate_q2_recoil (s, x_bar, q2_max, m2, r, q2)
    real(default), intent(in) :: s
    real(default), intent(in) :: q2_max
    real(default), intent(in) :: x_bar
    real(default), intent(in) :: m2
    real(default), intent(in) :: r
    real(default), intent(out) :: q2

    real(default) :: q2_max_evt

    q2_max_evt = q2_max_event (s, x_bar, q2_max)

    q2 = m2 * (exp (r * log (1 + (q2_max_evt / m2))) - 1)

  end subroutine generate_q2_recoil

```

The  $Q$  distribution is cut off from above by the kinematic limit, which depends on the energy that is available for the radiated photon, or by a user-defined cutoff – whichever is less. The kinematic limit fits the formulas for recoil momenta (see below), and it also implicitly enters the ISR collinear structure function, so the normalization of the distribution should be correct.

```

⟨Recoil kinematics: procedures⟩+≡
  elemental function q2_max_event (s, x_bar, q2_max) result (q2)
    real(default), intent(in) :: s
    real(default), intent(in) :: x_bar
    real(default), intent(in) :: q2_max
    real(default) :: q2

    q2 = min (x_bar * s, q2_max)

  end function q2_max_event

```

### 32.4.3 Kinematics functions

Given values for energies,  $Q_{1,2}^2$ , azimuthal angle, compute the matching polar angle of the radiating particle. The subroutine returns  $\sin \theta$  and  $\cos \theta$ .

```

⟨Recoil kinematics: procedures⟩+≡
  subroutine polar_angles (s, xb, rho, ee, q2, sin_th, cos_th, ok)
    real(default), intent(in) :: s
    real(default), intent(in) :: xb
    real(default), intent(in) :: rho
    real(default), dimension(2), intent(in) :: ee
    real(default), dimension(2), intent(in) :: q2
    real(default), dimension(2), intent(out) :: sin_th
    real(default), dimension(2), intent(out) :: cos_th
    logical, intent(out) :: ok

    real(default), dimension(2) :: sin2_th_2

    sin2_th_2 = q2 / (ee * rho * xb * s)

```

```

if (all (sin2_th_2 <= 1)) then
sin_th = 2 * sqrt (sin2_th_2 * (1 - sin2_th_2))
cos_th = 1 - 2 * sin2_th_2
ok = .true.
else
sin_th = 0
cos_th = 1
ok = .false.
end if

end subroutine polar_angles

```

Compute the acollinearity parameter  $\lambda$  from azimuthal and polar angles. The result is a number between 0 and 1.

```

<Recoil kinematics: procedures>+≡
function lambda_factor (sin_th, cos_th, cphi) result (lambda)
real(default), dimension(2), intent(in) :: sin_th
real(default), dimension(2), intent(in) :: cos_th
real(default), intent(in) :: cphi
real(default) :: lambda

lambda = (1 - cos_th(1) * cos_th(2) - cphi * sin_th(1) * sin_th(2)) / 2

end function lambda_factor

```

Compute the factor that rescales photon energies, such that the radiation angles match the kinematics parameters.

For small values of  $\bar{x}/\cosh\eta$ , we have to use the Taylor expansion if we do not want to lose precision. The optional argument allows for a unit test that compares exact and approximate.

```

<Recoil kinematics: procedures>+≡
function scale_factor (che, lambda, xb0, approximate) result (rho)
real(default), intent(in) :: che
real(default), intent(in) :: lambda
real(default), intent(in) :: xb0
logical, intent(in), optional :: approximate
real(default) :: rho

real(default), parameter :: &
e0 = (100 * epsilon (1._default)) ** (0.3_default)
logical :: approx

if (present (approximate)) then
approx = approximate
else
approx = (xb0/che) < e0
end if

if (approx) then
rho = 1 - lambda * (xb0/(2*che)) * (1 + (1-lambda) * (xb0/che))
else
rho = (che / ((1-lambda)*xb0)) &

```

```

* (1 - sqrt (1 - 2 * (1-lambda) * (xb0/che) &
& + (1-lambda) * (xb0 / che)**2))
end if

end function scale_factor

```

The code snippet below is not used anywhere, but may be manually inserted in a unit test to numerically verify the approximation above.

*(Recoil kinematics: extra test code)*≡

```

write (u, "(A)")
write (u, "(A)") "*** Table: scale factor calculation"
write (u, "(A)")

lambda = 0.25_default
write (u, FMT1) "lambda =", lambda

che = 4._default
write (u, FMT1) "che      =", che

write (u, "(A)") "      x0      rho(exact)   rho(approx)   rho(chosen)"

  scale_factor (che, lambda, xb0, approximate=.false.), &
  scale_factor (che, lambda, xb0, approximate=.true.), &
  scale_factor (che, lambda, xb0)
end do

```

Compute the current values for the  $x_{1,2}$  parameters, given the updated scale factor  $\rho$  and the collinear parameters.

*(Recoil kinematics: procedures)*+≡

```

subroutine scaled_x (rho, ee, xb0, x, xb)
  real(default), intent(in) :: rho
  real(default), dimension(2), intent(in) :: ee
  real(default), intent(in) :: xb0
  real(default), dimension(2), intent(out) :: x
  real(default), dimension(2), intent(out) :: xb

  xb = rho * ee * xb0
  x = 1 - xb

end subroutine scaled_x

```

#### 32.4.4 Iterative solution of kinematics constraints

Find a solution of the kinematics constraints. We know the parameters appropriate for collinear kinematics  $\sqrt{s}$ ,  $x_{1,2}^c$ . We have picked values for the momentum transfer  $Q_{1,2}$  and the azimuthal angles  $\phi_{1,2}$ . The solution consists of modified energy fractions  $x_{1,2}$  and polar angles  $\theta_{1,2}$ .

If the computation fails, which can happen for large momentum transfer, the flag ok will indicate this.

```

### 32.4.5 Generate recoil event

Combine the above kinematics calculations. First generate azimuthal angles and momentum transfer, solve kinematics and compute momenta for the radiated photons and the on-shell projected, recoiling partons.

The `mo` masses are used for the on-shell projection of the partons after radiation. They may be equal to `m`, or set to zero.

If `ok` is false, the data point has failed and we should repeat the procedure for a new set of RNG parameters `r`.

```

## 32.5 Transverse momentum for the ISR and EPA approximations

The ISR and EPA handler takes an event with a single radiated collinear particle (photon for ISR, beam particle for EPA) for each beam, respectively, and inserts transverse momentum for both. The four-particle kinematics allows us to generate  $Q^2$  and azimuthal angles independently, without violating energy-momentum conservation. The  $Q^2$  distribution is logarithmic, as required by the effective particle approximation, and reflected in the inclusive ISR/EPA structure functions. We also conserve the invariant mass of the partonic system after radiation. The total transverse-momentum kick is applied in form of a Lorentz transformation to the elementary process, both in- and out-particles. In fact, the incoming partons (beam particle for ISR, photon for EPA) which would be virtual space-like in the exact kinematics configuration, are replaced by on-shell

incoming partons, such that energy, momentum, and invariant mass  $\sqrt{\hat{s}}$  are conserved.

Regarding kinematics, we treat all particles as massless. The beam-particle mass only appears as the parameter `isr_mass` or `epa_mass`, respectively, and cuts off the logarithmic distribution. The upper cutoff is `isr_q_max` (`epa_q_max`), which defaults to the available energy  $\sqrt{s}$ .

The only differences between ISR and EPA, in this context, are the particle types, and an extra  $\bar{x}$  factor in the lower cutoff for EPA, see below.

### 32.5.1 Event transform type

Convention: **beam** are the incoming partons before ISR – not necessarily the actual beams, need not be in c.m. frame. **radiated** are the radiated particles (photon for ISR), and **parton** are the remainders which initiate the elementary process. These particles are copied verbatim from the event record, and must be collinear.

The kinematical parameters are **sqrts** = invariant mass of the **beam** particles, **q\_max** and **m** determining the  $Q^2$  distribution, and **xc/xcb** as the energy fraction (complement) of the partons, relative to the beams.

Transformations: **lti** is the Lorentz transformation that would boosts **pi** (c.m. frame) back to the original **beam** momenta (lab frame). **lto** is the recoil transformation, transforming the partons after ISR from the collinear frame to the recoiling frame. **lt** is the combination of both, which is to be applied to all particles after the hard interaction.

Momenta: **pi** are the beams transformed to their common c.m. frame. **ki** and **qi** are the photon/parton momenta in the **pi** c.m. frame. **km** and **qm** are the photon/parton momenta with the  $Q$  distribution applied, and finally **qo** are the partons **qm** projected on-shell.

### 32.5.5 Initialization

Manually import a random-number generator object. This should be done only for testing purposes. The standard procedure is to `connect` a process to an event transform; this will create an appropriate `rng` from the RNG factory in the process object.

```

<ISR/EPA handler: evt_isr: TBP>+≡
  procedure :: import_rng => evt_isr_epa_import_rng

<ISR/EPA handler: sub interfaces>+≡
  module subroutine evt_isr_epa_import_rng (evt, rng)

```

```

class(evt_isr_epa_t), intent(inout) :: evt
class(rng_t), allocatable, intent(inout) :: rng
end subroutine evt_isr_epa_import_rng
<ISR/EPA handler: procedures>+≡
module subroutine evt_isr_epa_import_rng (evt, rng)
class(evt_isr_epa_t), intent(inout) :: evt
class(rng_t), allocatable, intent(inout) :: rng
call move_alloc (from = rng, to = evt%rng)
end subroutine evt_isr_epa_import_rng

```

Set constant kinematics limits and initialize for ISR. Note that `sqrts` is used only as the fallback value for `q_max`. The actual `sqrts` value for the transform object is inferred from the incoming particles, event by event.

```

<ISR/EPA handler: evt isr: TBP>+≡
  procedure :: set_data_isr => evt_isr_epa_set_data_isr
<ISR/EPA handler: sub interfaces>+≡
module subroutine evt_isr_epa_set_data_isr (evt, sqrts, q_max, m, keep_mass)
class(evt_isr_epa_t), intent(inout) :: evt

    else
      evt%epa_q_max = q_max
    end if
    if (m > 0) then
      evt%epa_mass = m
    else
      call msg_fatal ("EPA handler: EPA_mass value must be positive")
    end if
    evt%epa_active = .true.
  end subroutine evt_isr_epa_set_data_epa

```

### 32.5.6 Fetch event data

Identify the radiated particles and the recoil momenta in the particle set. Without much sophistication, start from the end and find particles with the “remnant” status. Their parents should point to the recoiling parton. If successful, set the particle indices in the `evt` object, for further processing.

```

<ISR/EPA handler: evt isr: TBP>+≡
  procedure, private :: identify_radiated

<ISR/EPA handler: sub interfaces>+≡
  module subroutine identify_radiated (evt)
    class(evt_isr_epa_t), intent(inout) :: evt

```

### 32.5.7 Two-parton recoil

For transforming partons into recoil momenta, we make use of the routines in the `recoil_kinematics` module. In addition to the collinear momenta, we use the  $x$  energy fractions, and four numbers from the RNG.

There is one subtle difference w.r.t. ISR case: the EPA mass parameter is multiplied by the energy fraction  $x$ , separately for each beam. This is the effective lower  $Q$  cutoff.

For certain kinematics, close to the  $Q_{\max}$  endpoint, this may fail, and `ok` is set to false. In that case, we should generate new recoil momenta for the same

event. This is handled by the generic unweighting procedure.

```

<ISR/EPA handler: evt_isr: TBP>+≡
  procedure, private :: generate_recoil => evt_generate_recoil

<ISR/EPA handler: sub interfaces>+≡
  module subroutine evt_generate_recoil (evt, ok)
    class(evt_isr_epa_t), intent(inout) :: evt
    logical, intent(out) :: ok
  end subroutine evt_generate_recoil

<ISR/EPA handler: procedures>+≡
  module subroutine evt_generate_recoil (evt, ok)
    class(evt_isr_epa_t), intent(inout) :: evt
    logical, intent(out) :: ok
    real(default), dimension(4) :: r
    real(default), dimension(2) :: m, mo
    integer :: i
    call evt%rng%generate (r)
    m = 0
    mo = 0
    do i = 1, 2
      select case (evt%rad_mode(i))
      case (BEAM_RAD_ISR)
        m(i) = evt%m(i)
        if (evt%isr_keep_mass) mo(i) = m(i)
      case (BEAM_RAD_EPA)
        m(i) = evt%xc(i) * evt%m(i)
      end select
    end do
    call generate_recoil (evt%sqrts, evt%q_max, m, mo, evt%xc, evt%xcb, r, &
      evt%km, evt%qm, evt%qo, ok)
  end subroutine evt_generate_recoil

```

Replace the collinear radiated (incoming) parton momenta by the momenta that we have generated, respectively. Recall that the recoil has been applied in the c.m. system of the partons before ISR, so we apply the stored Lorentz transformation to boost them to the lab frame.

```

<ISR/EPA handler: evt_isr: TBP>+≡
  procedure, private :: replace_radiated
  procedure, private :: replace_partons

<ISR/EPA handler: sub interfaces>+≡
  module subroutine replace_radiated (evt)
    class(evt_isr_epa_t), intent(inout) :: evt

associate (prt => evt%particle_set%prt(evt%i_parton(i)))
call prt%set_momentum (evt%lti * evt%qo(i))
end associate
end do
end subroutine replace_partons

```

### 32.5.8 Transform the event

Knowing the new incoming partons for the elementary process, we can make use of another procedure in `recoil_kinematics` to determine the Lorentz transformation that transforms the collinear frame into the frame with transverse momentum. We apply this transformation, recursively, to all particles that originate from those incoming partons in the original particle set.

We have to allow for the pre-ISR partons being not in their common c.m. frame. Taking into account non-commutativity, we actually have to first transform the outgoing particles to that c.m. frame, then apply the recoil transformation, then boost back to the lab frame.

The `mask` keep track of particles that we transform, just in case the parent-child tree is multiply connected.

```

<ISR/EPA handler: evt_isr: TBP>+≡
  procedure :: transform_outgoing => evt_transform_outgoing

<ISR/EPA handler: sub interfaces>+≡
  module subroutine evt_transform_outgoing (evt)
  class(evt_isr_epa_t), intent(inout) :: evt
  end subroutine evt_transform_outgoing

  call transform_children (evt%i_parton(1))
  contains
  recursive subroutine transform_children (i)
  integer, intent(in) :: i
  integer :: j, n_child, c
  integer, dimension(:), allocatable :: child
  child = evt%particle_set%prt(i)%get_children ( )
  do j = 1, size (child)
  c = child(j)

```

```

if (.not. mask(c)) then
  associate (prt => evt%particle_set%prt(c))
  call prt%set_momentum (evt%lt * prt%get_momentum ())
  mask(c) = .true.
  call transform_children (c)
end associate
end if
end do
end subroutine transform_children
end subroutine evt_transform_outgoing

```

### 32.5.9 Implemented methods

Here we take the particle set from the previous event transform and copy it, then generate the transverse momentum for the radiated particles and for the incoming partons. If this fails (rarely, for large  $p_T$ ), return zero for the probability, to trigger another try.

NOTE: The boost for the initial partonic system, if not in the c.m. frame, has not been implemented yet.

```

<ISR/EPA handler: evt_isr: TBP>+≡

    use quantum_numbers
    !!! Intel oneAPI 2022/23 regression workaround
    use variables, only: var_list_t
    use process, only: process_t
    use instances, only: process_instance_t

    implicit none

    contains

    <Decays: procedures>

  end submodule decays_s

```

### 32.6.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

<Decays: types>≡
  type, abstract :: any_config_t
  private
  contains
  <Decays: any config: TBP>
  end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
  procedure (any_config_final), deferred :: final

```

```

<Decays: interfaces>≡
  interface
    subroutine any_config_final (object)
    import
    class(any_config_t), intent(inout) :: object
    end subroutine any_config_final
  end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
  procedure (any_config_write), deferred :: write
<Decays: interfaces>+≡
  interface
    subroutine any_config_write (object, unit, indent, verbose)
    import
    class(any_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    end subroutine any_config_write
  end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_config_t
  private
  class(any_config_t), allocatable :: c
  end type particle_config_t

```

### 32.6.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above.

```

<Decays: types>+≡
  type, abstract :: any_t
  private
  contains
  <Decays: any: TBP>
  end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final
<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
    import
    class(any_t), intent(inout) :: object

```

```

end subroutine any_final
end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
    import
    class(any_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    end subroutine any_write
  end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_out_t
  private
  class(any_t), allocatable :: c
  end type particle_out_t

```

### 32.6.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+≡
  type :: decay_term_config_t
  private
  type(particle_config_t), dimension(:), allocatable :: prt
  contains
  <Decays: decay term config: TBP>
  end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>≡
  procedure :: final => decay_term_config_final

<Decays: sub interfaces>≡
  recursive module subroutine decay_term_config_final (object)
    class(decay_term_config_t), intent(inout) :: object
    end subroutine decay_term_config_final

<Decays: procedures>≡
  recursive module subroutine decay_term_config_final (object)
    class(decay_term_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%prt)) then
      do i = 1, size (object%prt)

```

```

if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
end do
end if
end subroutine decay_term_config_final

```

Output, with optional indentation

```

<Decays: decay term config: TBP>+≡
  procedure :: write => decay_term_config_write

<Decays: sub interfaces>+≡
  recursive module subroutine decay_term_config_write &
    (object, unit, indent, verbose)
    class(decay_term_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    end subroutine decay_term_config_write

<Decays: procedures>+≡
  recursive module subroutine decay_term_config_write &
    (object, unit, indent, verbose)
    class(decay_term_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent

        call object%prt(i)%c%write (u, ind)
      end do
    end if
  end subroutine decay_term_config_write

```

Initialize, given a set of flavors. For each flavor, we must indicate whether the particle is stable. The second index of the flavor array runs over alternatives for

each decay product; alternatives are allowed only if the decay product is itself stable. Gfortran 7/8/9 bug, has to remain in the main module:

```

<Decays: decay term config: TBP>+≡

end do

```

```
end subroutine decay_term_generate
```

### 32.6.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```
<Decays: public>≡
  public :: decay_root_config_t

<Decays: types>+≡
  type :: decay_root_config_t
  private
  type(string_t) :: process_id
  type(process_t), pointer :: process => null ()
  class(model_data_t), pointer :: model => null ()
  type(decay_term_config_t), dimension(:), allocatable :: term_config
  contains
  <Decays: decay root config: TBP>
end type decay_root_config_t
```

The finalizer is recursive since there may be cascade decays.

```
<Decays: decay root config: TBP>≡
  procedure :: final => decay_root_config_final

<Decays: sub interfaces>+≡
  recursive module subroutine decay_root_config_final (object)
  class(decay_root_config_t), intent(inout) :: object
  end subroutine decay_root_config_final

<Decays: procedures>+≡
  recursive module subroutine decay_root_config_final (object)
  class(decay_root_config_t), intent(inout) :: object
  integer :: i
  if (allocated (object%term_config)) then
  do i = 1, size (object%term_config)
  call object%term_config(i)%final ()
  end do
  end if
  end subroutine decay_root_config_final
```

The output routine is also recursive, and it contains an adjustable indentation.

```
<Decays: decay root config: TBP>+≡
  procedure :: write => decay_root_config_write
  procedure :: write_header => decay_root_config_write_header

```

```

call decay%term_config(i)%init (flv, stable, model, process_stack, var_list)
end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore `intent(out)`.

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

For the unstable particles, we have to check whether their masses match between the production and the decay. Fortunately, both versions are available for comparison.

The optional `var_list` argument may override integral/error values for decay processes.

```

### 32.6.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```

⟨Decays: types⟩+≡
  type, abstract :: decay_gen_t
  private
  type(decay_term_t), dimension(:), allocatable :: term
  type(process_instance_t), pointer :: process_instance => null ()
  integer :: selected_mci = 0
  integer :: selected_term = 0
  contains
  ⟨Decays: decay gen: TBP⟩
  end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

⟨Decays: public⟩+≡
  public :: decay_root_t

⟨Decays: types⟩+≡
  type, extends (decay_gen_t) :: decay_root_t
  private
  type(decay_root_config_t), pointer :: config => null ()
  contains
  ⟨Decays: decay root: TBP⟩
  end type decay_root_t

```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```

⟨Decays: decay gen: TBP⟩≡
  procedure :: base_final => decay_gen_final

⟨Decays: sub interfaces⟩+≡
  recursive module subroutine decay_gen_final (object)
  class(decay_gen_t), intent(inout) :: object
  end subroutine decay_gen_final

⟨Decays: procedures⟩+≡

### 32.6.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

The flavor component should be identical to the flavor component of the parent particle (unstable object).

```

<Decays: types>+≡
  type, extends (decay_root_config_t) :: decay_config_t
  private
  type(flavor_t) :: flv
  real(default) :: weight = 0
  real(default) :: integral = 0
  real(default) :: abs_error = 0
  real(default) :: rel_error = 0
  type(selector_t) :: mci_selector
  contains
  <Decays: decay config: TBP>
  end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
  procedure :: write => decay_config_write

<Decays: sub interfaces>+≡
  recursive module subroutine decay_config_write &
    (object, unit, indent, verbose)
    class(decay_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    end subroutine decay_config_write

<Decays: procedures>+≡
  recursive module subroutine decay_config_write (object, unit, indent, verbose)
    class(decay_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,A)") "Decay:"
    call object%write_header (unit, indent)
  end subroutine decay_config_write

```

```

call write_indent (u, ind)
write (u, 2) "branching ratio =", object%weight * 100
call write_indent (u, ind)
write (u, 1) "partial width  =", object%integral
call write_indent (u, ind)
write (u, 1) "error (abs)    =", object%abs_error
call write_indent (u, ind)
write (u, 1) "error (rel)    =", object%rel_error
1  format (3x,A,ES19.12)
2  format (3x,A,F11.6,1x,'%')
call object%write_terms (unit, indent, verbose)
end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should be used instead.

If there is an optional `var_list`, check if the stored values for the decay partial width and error have been overridden there.

```

<Decays: decay config: TBP>+≡
  procedure :: connect => decay_config_connect

<Decays: sub interfaces>+≡
  recursive module subroutine decay_config_connect &

```

### 32.6.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

⟨Decays: types⟩+≡
  type, extends (decay_gen_t) :: decay_t
  private
  type(decay_config_t), pointer :: config => null ()
  class(rng_t), allocatable :: rng
  contains
  ⟨Decays: decay: TBP⟩
end type decay_t

```

The finalizer is recursive.

```

⟨Decays: decay: TBP⟩≡
  procedure :: final => decay_final

⟨Decays: sub interfaces⟩+≡
  recursive module subroutine decay_final (object)
  class(decay_t), intent(inout) :: object
  end subroutine decay_final

⟨Decays: procedures⟩+≡
  recursive module subroutine decay_final (object)
  class(decay_t), intent(inout) :: object
  integer :: i
  call object%base_final ()
  do i = 1, object%config%process%get_n_mci ()
  call object%process_instance%final_simulation (i)
  end do
  call object%process_instance%final ()
  deallocate (object%process_instance)
  end subroutine decay_final

```

Output.

```

⟨Decays: decay: TBP⟩+≡
  procedure :: write => decay_write

⟨Decays: sub interfaces⟩+≡
  recursive module subroutine decay_write (object, unit, indent, recursive)
  class(decay_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent, recursive
  end subroutine decay_write

```

```

<Decays: procedures>+≡
recursive module subroutine decay_write (object, unit, indent, recursive)
class(decay_t), intent(in) :: object
integer, intent(in), optional :: unit, indent, recursive
integer :: u, ind
u = given_output_unit (unit)
ind = 0; if (present (indent)) ind = indent
call object%config%write (unit, indent, verbose = .false.)
if (allocated (object%rng)) then
call object%rng%write (u, ind + 1)
end if
call write_indent (u, ind)
if (object%selected_mci > 0) then
write (u, "(3x,A,I0)") "Selected MCI      = ", object%selected_mci
else
write (u, "(3x,A)") "Selected MCI      = [undefined]"
end if
call write_indent (u, ind)
if (object%selected_term > 0) then
write (u, "(3x,A,I0)") "Selected term = ", object%selected_term
call object%term(object%selected_term)%write (u, ind + 1)
else
write (u, "(3x,A)") "Selected term = [undefined]"
end if
end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
procedure :: init => decay_init

<Decays: sub interfaces>+≡
recursive module subroutine decay_init (decay, config)
class(decay_t), intent(out) :: decay
type(decay_config_t), intent(in), target :: config
end subroutine decay_init

<Decays: procedures>+≡
recursive module subroutine decay_init (decay, config)
class(decay_t), intent(out) :: decay
type(decay_config_t), intent(in), target :: config
integer :: i
call decay%base_init (config%term_config)
decay%config => config

    type(interaction_t), pointer :: beam_int
    integer :: n_in, n_vir
    beam_int => decay%process_instance%get_beam_int_ptr ()
    n_in = trace%get_n_in ()
    n_vir = trace%get_n_vir ()
    call beam_int%set_source_link (1, trace, &
      n_in + n_vir + i_prt)
    call decay%link_term_interactions ()
  end subroutine decay_link_interactions
```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```
<Decays: decay: TBP>+≡
  procedure :: select_chain => decay_select_chain

<Decays: sub interfaces>+≡
  recursive module subroutine decay_select_chain (decay)
    class(decay_t), intent(inout) :: decay
  end subroutine decay_select_chain

<Decays: procedures>+≡
  recursive module subroutine decay_select_chain (decay)
    class(decay_t), intent(inout) :: decay
    real(default) :: x
    integer :: i
    call decay%rng%generate (x)
    decay%selected_mci = decay%config%mc_selector%select (x)
    call decay%process_instance%choose_mci (decay%selected_mci)
    decay%selected_term = decay%process_instance%select_i_term ()
    do i = 1, size (decay%term)
      call decay%term(i)%select_chain ()
    end do
  end subroutine decay_select_chain
```

```

end do
end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

<Decays: decay: TBP>+≡
  procedure :: generate => decay_generate

<Decays: sub interfaces>+≡
  recursive module subroutine decay_generate (decay)
    class(decay_t), intent(inout) :: decay
  end subroutine decay_generate

<Decays: procedures>+≡

    class(stable_t), intent(out) :: stable
    type(stable_config_t), intent(in), target :: config
    stable%config => config
  end subroutine stable_init

```

### 32.6.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: public>+≡
  public :: unstable_config_t

<Decays: types>+≡
  type, extends (any_config_t) :: unstable_config_t
  private
  type(flavor_t) :: flv
  real(default) :: integral = 0
  real(default) :: abs_error = 0
  real(default) :: rel_error = 0
  type(selector_t) :: selector
  type(decay_config_t), dimension(:), allocatable :: decay_config
  contains
  <Decays: unstable config: TBP>
  end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
  procedure :: final => unstable_config_final

<Decays: sub interfaces>+≡
  recursive module subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
  end subroutine unstable_config_final

```

```

<Decays: procedures>+≡
recursive module subroutine unstable_config_final (object)
class(unstable_config_t), intent(inout) :: object
integer :: i
if (allocated (object%decay_config)) then
do i = 1, size (object%decay_config)
call object%decay_config(i)%final ()
end do
end if
end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
procedure :: write => unstable_config_write

<Decays: sub interfaces>+≡
recursive module subroutine unstable_config_write &
(object, unit, indent, verbose)
class(unstable_config_t), intent(in) :: object
integer, intent(in), optional :: unit, indent
logical, intent(in), optional :: verbose
end subroutine unstable_config_write

<Decays: procedures>+≡
recursive module subroutine unstable_config_write &
(object, unit, indent, verbose)
class(unstable_config_t), intent(in) :: object
integer, intent(in), optional :: unit, indent
logical, intent(in), optional :: verbose

```

### 32.6.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+≡

```

```

type, extends (connected_state_t) :: decay_chain_entry_t
private
integer :: index = 0
type(decay_config_t), pointer :: config => null ()
integer :: selected_mci = 0
integer :: selected_term = 0
type(decay_chain_entry_t), pointer :: previous => null ()
end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: public>+≡
  public :: decay_chain_t

<Decays: types>+≡
  type :: decay_chain_t
  private
  type(process_instance_t), pointer :: process_instance => null ()
  integer :: selected_term = 0
  type(evaluator_t) :: correlated_trace
  type(decay_chain_entry_t), pointer :: last => null ()
  contains
  <Decays: decay chain: TBP>
  end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay chain: TBP>≡
  procedure :: final => decay_chain_final

<Decays: sub interfaces>+≡
  module subroutine decay_chain_final (object)
    class(decay_chain_t), intent(inout) :: object
  end subroutine decay_chain_final

<Decays: procedures>+≡
  module subroutine decay_chain_final (object)
    class(decay_chain_t), intent(inout) :: object
    type(decay_chain_entry_t), pointer :: entry
    do while (associated (object%last))
      entry => object%last
      object%last => entry%previous
      call entry%final ()
    deallocate (entry)
  end subroutine decay_chain_final

```

```

end do
call object%correlated_trace%final ()
end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

<Decays: decay chain: TBP>+≡
  procedure :: write => decay_chain_write

<Decays: sub interfaces>+≡
  module subroutine decay_chain_write (object, unit)
    class(decay_chain_t), intent(in) :: object
    integer, intent(in), optional :: unit
  end subroutine decay_chain_write

<Decays: procedures>+≡
  module subroutine decay_chain_write (object, unit)
    class(decay_chain_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    write (u, "(1x,A)") "Decay chain:"

    call write_separator (u)
    call object%correlated_trace%write (u)
    call write_separator (u, 2)
    contains
    recursive subroutine write_entries (entry)
      type(decay_chain_entry_t), intent(in), pointer :: entry
      if (associated (entry)) then
        call write_entries (entry%previous)
        call write_separator (u, 2)
        write (u, "(1x,A,I0)") "Decay #", entry%index
        call entry%config%write_header (u)
        write (u, "(3x,A,I0)") "Selected MCI    = ", entry%selected_mci
        write (u, "(3x,A,I0)") "Selected term  = ", entry%selected_term
        call entry%config%term_config(entry%selected_term)%write (u, indent=1)
        call entry%write (u)
      end if
    end subroutine write_entries
  end subroutine decay_chain_write

```

Build a decay chain, recursively following the selected decays and terms in a decay tree. Before start, we finalize the chain, deleting any previous contents.

```

<Decays: decay chain: TBP>+≡
  procedure :: build => decay_chain_build

<Decays: sub interfaces>+≡
  module subroutine decay_chain_build (chain, decay_root)
    class(decay_chain_t), intent(inout), target :: chain
    type(decay_root_t), intent(in) :: decay_root
  end subroutine decay_chain_build

```

```

<Decays: procedures>+≡
module subroutine decay_chain_build (chain, decay_root)
class(decay_chain_t), intent(inout), target :: chain
type(decay_root_t), intent(in) :: decay_root
type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
type(interaction_t), pointer :: int_last_decay
call chain%final ()
if (decay_root%selected_term > 0) then
chain%process_instance => decay_root%process_instance
chain%selected_term = decay_root%selected_term
call chain%build_term_entries (decay_root%term(decay_root%selected_term))
end if
int_last_decay => chain%last%get_matrix_int_ptr ()
allocate (qn_mask (int_last_decay%get_n_tot ()))
call qn_mask%init (mask_f = .true., mask_c = .true., mask_h = .true.)
call chain%correlated_trace%init_qn_sum (int_last_decay, qn_mask)
end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable particles.

```

<Decays: decay chain: TBP>+≡
procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: sub interfaces>+≡
recursive module subroutine decay_chain_build_term_entries (chain, term)
class(decay_chain_t), intent(inout) :: chain
type(decay_term_t), intent(in) :: term
end subroutine decay_chain_build_term_entries

<Decays: procedures>+≡
recursive module subroutine decay_chain_build_term_entries (chain, term)
class(decay_chain_t), intent(inout) :: chain
type(decay_term_t), intent(in) :: term
integer :: i
do i = 1, size (term%particle_out)
select type (unstable => term%particle_out(i)%c)
type is (unstable_t)
if (unstable%selected_decay > 0) then
call chain%build_decay_entries &
(unstable%decay(unstable%selected_decay))
end if
end select
end do
end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

```

<Decays: decay chain: TBP>+≡

    end subroutine evaluate
  end subroutine decay_chain_evaluate

```

Return the probability of a decay chain. This is given as the trace of the density matrix with intermediate helicity correlations, normalized by the product of the uncorrelated density matrix traces. This works only if an event has been evaluated and the `correlated_trace` evaluator is filled. By definition, this evaluator has only one matrix element, and this must be real.

```

  end function decay_chain_get_probability

```

### 32.6.12 Decay as Event Transform

The `evt_decay` object combines decay configuration, decay tree, and chain in a single object, as an implementation of the `evt` (event transform) abstract type.

The `var_list` may be a pointer to the user variable list, which could contain overridden parameters for the decay processes.

```

<Decays: public>+≡
  public :: evt_decay_t

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations is under construction. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid. This procedure directly takes the (MLM) matching into account.

## 32.9 Fixed Order NLO Events

This section deals with the generation of weighted event samples which take into account next-to-leading order corrections. An approach generating unweighted events is not possible here, because negative weights might occur due to subtraction. Note that the events produced this way are not physical in the sense that they will not keep NLO-accuracy when interfaced to a parton shower. They are rather useful for theoretical consistency checks and a fast estimate of NLO effects.

We generate NLO events in the following way: First, the integration is carried out using the complete divergence-subtracted NLO matrix element. In the subsequent simulation,  $N$ -particle kinematics are generated using  $\mathcal{B} + \mathcal{V} + \mathcal{C}$  as weight. After that, the program loops over all singular regions and for each of them generates an event with  $N + 1$ -particle kinematics. The weight for those events corresponds to the real matrix element  $\mathcal{R}^\alpha$  evaluated at the  $\alpha$ -region's emitter's phase space point, multiplied with  $S_\alpha$ . This procedure is implemented using the `evt_nlo` transform.

```

This event transformation is for the generation of fixed-order NLO events. It takes an event with Born kinematics and creates  $N_\alpha + 1$  modified weighted events. The first one has Born kinematics and its weight is the sum of Born, virtual, subtraction and, if present, also DGLAP matrix elements. The other  $N_\alpha$  events have a weight which is equal to the real matrix element, evaluated with the phase space corresponding to the emitter of the  $\alpha$ -region.

As the NLO event transforms have different kinematics, they also differ in their `particle_sets`. The NLO `event_t` object carries a single pointer to a `particle_set`. To avoid interference between the different NLO `particle_sets`, we save the `particle_set` of the current  $\alpha$ -region in the array `particle_set_nlo`. Otherwise it would be unretrievable if the usual particle set of the event object was used.

The event transform has a variable which counts the number of times it has already been called for one generation point. If this variable, `i_evaluation`, is zero, this means that `evt_nlo_generate_weighted` is called for the first time, so that the generation of an  $N$ -particle event is required. In all other cases, emission events are generated.

During a separate integration of the real component, the first event of each event group will become the counterevent. In this case, we return the sum of all subtraction matrix elements.

During a combined integration, the first event will be a combination of all Born-like events. To get the sum of their matrix elements, we subtract the sum of all real emissions from the sum of all matrix elements as the real contribution is the only non-Born contribution.

Note that the argument named `probability`, the use of the routine `generate_weighted` and the procedure we use to generate NLO events via an event transformation is an abuse of the interface which should be refactored.
