Abstract

I describe parameterizations of realistic e^\pm - and γ -beam spectra at future linear e^+e^- -colliders. Emphasis is put on simplicity and reproducibility of the parameterizations, supporting reproducible physics simulations. The parameterizations are implemented in a library of distribution functions and event generators.

Program Summary:

- **Title of program:** Circe, Version 1.02 β (September 1996)
- **Program obtainable** by anonymous ftp from the host `crunch.ikp.physik.th-darmstadt.de` in the directory `pub/ohl/circe`.
- **Licensing provisions:** Free software under the GNU General Public License.
- **Programming language used:** Fortran77
- **Number of program lines in distributed program, including test data, etc.:** ≈ 1100 (excluding comments)
- **Computer/Operating System:** Any with a Fortran77 programming environment.
- **Memory required to execute with typical data:** Negligible on the scale of typical applications calling the library.
- **Typical running time:** A small fraction (typically a few percent) of the running time of applications calling the library.
- **Purpose of program:** Provide simple and reproducible, yet realistic, parameterizations of the e^{\pm} - and γ -beam spectra for linear colliders.
- **Nature of physical problem:** The intricate beam dynamics in the interaction region of a high luminosity linear collider at $\sqrt{s} = 500\text{GeV}$ result in non-trivial energy spectra of the scattering electrons, positrons and photons. Physics simulations require simple and reproducible, yet realistic, parameterizations of these spectra.
- **Method of solution:** Parameterization, curve fitting, Monte Carlo event generation.
- **Keywords:** Event generation, beamstrahlung, linear colliders.

1 Introduction

Despite the enormous quantitative success of the electro-weak standard model up to energies of 200GeV, neither the nature of electro-weak symmetry breaking (EWSB) nor the origin of mass are understood.

From theoretical considerations, we know that clues to the answer of these open questions are hidden in the energy range below $\Lambda_{\text{EWSB}} = 4\pi v \approx 3.1\text{TeV}$. Either we will discover a Higgs particle in this energy range or signatures for a strongly interacting EWSB sector will be found. Experiments at CERN's Large Hadron Collider (LHC) will shed a first light on this regime in the next decade. In the past it has been very fruitful to complement experiments at high energy hadron colliders with experiments at e^+e^- -colliders. The simpler initial state allows more precise measurements with smaller theoretical errors. Lucid expositions of the physics opportunities of high energy e^+e^- colliders with references to the literature can be found in [1].

However, the power emitted by circular storage rings in form of synchrotron radiation scales like $(E/m)^4/R^2$ with the energy and mass of the particle and the radius of the ring. This cost becomes prohibitive after LEP2 and a Linear Collider (LC) has to be built instead.

Unfortunately, the “interesting” hard cross sections scale like $1/s$ with the square of the center of mass energy and a LC will have to operate at extremely high luminosities in excess of $10^{33}\text{cm}^{-2}\text{s}^{-1}$. To achieve such luminosities, the bunches of electrons and positrons have to be very dense. Under these conditions, the electrons undergo acceleration from strong electromagnetic forces from the positron bunch (and vice versa). The resulting synchrotron radiation is called *beamstrahlung* [2] and has a strong effect on the energy spectrum $D(x_1, x_2)$ of the colliding particles. This changes the observable e^+e^- cross sections

$$\frac{d\sigma_0^{e^+e^-}}{d\Omega}(s) \rightarrow \frac{d\sigma^{e^+e^-}}{d\Omega}(s) = \int_0^1 dx_1 dx_2 D_{e^+e^-}(x_1, x_2; \sqrt{s}) J(\Omega', \Omega) \frac{d\sigma_0^{e^+e^-}}{d\Omega'}(x_1 x_2 s) \quad (1a)$$

and produces luminosity for $e^\pm\gamma$ and $\gamma\gamma$ collisions:

$$\frac{d\sigma^{e^\pm\gamma}}{d\Omega}(s) = \int_0^1 dx_1 dx_2 D_{e^\pm\gamma}(x_1, x_2; \sqrt{s}) J(\Omega', \Omega) \frac{d\sigma_0^{e^\pm\gamma}}{d\Omega'}(x_1 x_2 s) \quad (1b)$$

$$\frac{d\sigma^{\gamma\gamma}}{d\Omega}(s) = \int_0^1 dx_1 dx_2 D_{\gamma\gamma}(x_1, x_2; \sqrt{s}) J(\Omega', \Omega) \frac{d\sigma_0^{\gamma\gamma}}{d\Omega'}(x_1 x_2 s) \quad (1c)$$

Therefore, simulations of the physics expected at a LC need to know the spectra of the e^\pm and γ beams precisely.

Microscopic simulations of the beam dynamics are available (e.g. ABEL[3], CAIN[4] and Guinea-Pig[5]) and their predictions are compatible with each other. But they require too much computer time and memory for direct use in physics programs. Circe provides a fast and simple parameterization of the results from these simulations. Furthermore, even if the computational cost of the simulations would be negligible, the input parameters for microscopic simulations are not convenient for particle physics applications. Due to the highly

Table 1: Accelerator parameters for three typical designs at $\sqrt{s} = 500\text{GeV}$ and $\sqrt{s} = 1\text{TeV}$. The resulting distributions are shown in figure 1. The design efforts are currently concentrated on a 350GeV-800GeV LC. Therefore the Tesla parameters for 1TeV are slightly out of date.

non-linear beam dynamics, the optimization of LC designs is a subtle art [6], that is best practiced by the experts. Furthermore, particle physics applications need benchmarking and easily reproducible parameterizations are required for this purpose.

The parameterizations in **Circe** are not based on approximate solutions (cf. [7]) of the beamstrahlung dynamics. Instead, they provide a “phenomenological” description of the results from full simulations. The parameterizations are as simple as possible while remaining consistent with basic physical principles:

1. *positivity*: the distribution functions $D(x_1, x_2)$ *must not* be negative in the physical region $[0, 1] \times [0, 1]$.
2. *integrability*: the definite integral of the distribution functions over the physical region $[0, 1] \times [0, 1]$ *must* exist, even though the distributions can have singularities.

This paper is organized as follows: I start in section 2 with a discussion of the input for the microscopic simulations. In section 3 I describe the usage of the **Circe** library and in section 4 I discuss some technical details of the implementation. After discussing the parameterizations available in version 1.02 β in section 5, I conclude in section 8.

2 Parameters

The microscopic simulation program **Guinea-Pig** [5] used for the current version of the parameterizations in **Circe** simulates the passage of electrons through a

bunch of electrons (and vice versa). It takes the following accelerator parameters as input:

E : the energy of the particles before the beam-beam interaction.

$N_{\text{particles}}$: the number of particles per bunch.

$\epsilon_{x,y}$: the normalized horizontal and vertical emittances.

$\beta_{x,y}^*$: the horizontal and vertical beta functions.

$\sigma_{x,y,z}$: the horizontal, vertical and longitudinal beam size. A Gaussian shape is used for the charge distribution in the bunches.

f_{rep} : the repetition rate.

n_{bunch} : the number of bunches per train.

The transversal beam sizes, beta functions and normalized emittances for relativistic particles are related by

$$\beta_{x,y}^* = \frac{\sigma_{x,y}^2}{\epsilon_{x,y}} \frac{E}{m_e} \quad (2)$$

The parameters used in the most recent revision of the parameterizations are collected in tables 1 and 2. The resulting factorized electron/positron and photon distributions in version 1 of the parameterizations are depicted in figures 1 and 2.

The most important purpose of **Circe** is to map the manifold of possible beam spectra for the NLC to a *finite* number of *reproducible* parameterizations. The distributions

$$D_{p_1 p_2}^{\alpha \nu \rho}(x_1, x_2; \sqrt{s}) \quad (3)$$

provided by **Circe** are indexed by three integers

α : the *accelerator design class*: currently there are three options: S-band [9], Tesla [8], X-band [10, 11]. More variety will be added later, in particular the e^-e^- mode and the $e^-\gamma$ and $\gamma\gamma$ laser backscattering modes of these designs.

ν : the *version of the parameterization*: over the years, the form of the parameterizations can change, either because better approximations are found or because new simulation programs become available. All versions will remain available in order to be able to reproduce calculations.

ρ : the *revision date for the parameterization*: a particular parameterization can contain bugs, which will be fixed in subsequent revisions. While only the most recent revision should be used for new calculations, old revisions will remain available in order to be able to reproduce calculations.

The continuous parameter \sqrt{s} in (3) is misleading, because accelerator parameters have been optimized for discrete values of the energy. Therefore the distributions are not available for all values of \sqrt{s} .

The usage of the distributions in application programs is discussed in section 3.1. **Circe** provides for each of the distributions a non-uniform random variate generator, that generates energy fractions according to the distributions. The usage of these generators is discussed in section 3.2.

3 Usage

3.1 Distributions

A generic interface to all distributions $D_{p_1 p_2}(x_1, x_2)$ is given by the `circe` function

```
9a  <API documentation 9a>≡
      double precision circe, d, x1, x2
      integer p1, p2
      d = circe (x1, x2, p1, p2)
```

Uses `circe` 24d.

where the energy fractions are specified by $x_{1,2}$ and the particles $p_{1,2}$ are identified by their standard Monte Carlo codes:[13]

```
9b  <Particle codes 9b>≡
      integer ELECTR, POSITR, PHOTON
      parameter (ELECTR = 11)
      parameter (POSITR = -11)
      parameter (PHOTON = 22)
```

Defines:

`ELECTR`, used in chunks 18b, 24d, 63a, 67b, and 68a.

`PHOTON`, used in chunks 24d, 63a, 67b, 68a, and 74.

`POSITR`, used in chunks 18c and 68a.

The distributions can have integrable singularities at the end points, therefore the calling functions *must not* evaluate them at the endpoints 0 and 1. This is usually not a problem, since standard mapping techniques (cf. (10) below) will have to be used to take care of the singularity anyway. Nevertheless, all applications should favor open quadrature formulae (i.e. formulae not involving the endpoints) over closed formulae. The distributions are guaranteed to vanish unless $0 < x_{1,2} < 1$, with two exceptions. Firstly, the value -1 allows to pick up the integral of the continuum contribution:

$$D_{p_1 p_2}(-1, x_2) = \lim_{\epsilon \rightarrow +0} \int_{\epsilon}^{1-\epsilon} dx_1 D_{p_1 p_2}(x_1, x_2) \quad (4a)$$

$$D_{p_1 p_2}(x_1, -1) = \lim_{\epsilon \rightarrow +0} \int_{\epsilon}^{1-\epsilon} dx_2 D_{p_1 p_2}(x_1, x_2) \quad (4b)$$

$$D_{p_1 p_2}(-1, -1) = \lim_{\epsilon \rightarrow +0} \int_{\epsilon}^{1-\epsilon} dx_1 dx_2 D_{p_1 p_2}(x_1, x_2) \quad (4c)$$

The other exception is that the strength of δ -function contributions at the endpoint can be picked up from the value at this endpoint:

$$D_{e^+ e^-}(x_1, x_2) = D_{e^+ e^-}(1, 1) \delta(1 - x_1) \delta(1 - x_2) + \text{smooth and single } \delta \quad (5a)$$

$$D_{e^\pm \gamma}(x_1, x_2) = D_{e^\pm \gamma}(1, x_2) \delta(1 - x_1) + \text{smooth} \quad (5b)$$

$$D_{\gamma e^\pm}(x_1, x_2) = D_{\gamma e^\pm}(x_1, 1) \delta(1 - x_2) + \text{smooth} \quad (5c)$$

The use of these special values is demonstrated in an example in section 3.1.1 below.

The distributions are normalized such that

$$\lim_{\epsilon \rightarrow +0} \int_{-\epsilon}^{1+\epsilon} dx_1 dx_2 D_{e^+e^-}(x_1, x_2) = 1. \quad (6)$$

and the nominal e^+e^- -luminosity of the currently active accelerator design can be retrieved from the database with the subroutine `circel`. The value is given in units of

$$\text{fb}^{-1} \nu^{-1} = 10^{32} \text{cm}^{-2} \text{sec}^{-1} \quad (7)$$

where $\nu = 10^7 \text{sec} \approx \text{year}/\pi$ is an “effective year” of running with about 30% up-time.

10a `<API documentation 9a>+≡`
`double precision lumi`
`call circel (lumi)`

Uses `circel` 34b.

A particular parameterization is selected by the `circes` function:

10b `<API documentation 9a>+≡`
`double precision x1m, x2m, roots`
`integer acc, ver, rev, chat`
`call circes (x1m, x2m, roots, acc, ver, rev, chat)`

Uses `circes` 25a.

The parameter `roots` corresponds to the nominal center of mass energy \sqrt{s}/GeV of the collider. Currently $\sqrt{s} = 350\text{GeV}, 500\text{GeV}, 800\text{GeV}, 1\text{TeV}$ (i.e. 350D0, 500D0, 800D0 and 1000D0) are supported. Application programs can *not* assume that energy values are interpolated. For convenience, e.g. in top threshold scans around 350GeV, a small interval around the supported values will be accepted as synonymous with the central value, but a warning will be printed. Section 5 should be consulted for the discrete values supported by a particular version of the parameterizations. Negative values of `roots` will keep the currently active value for \sqrt{s} .

The parameters `x1m` and `x2m` will set thresholds $x_{1,\min}$ and $x_{2,\min}$ for the event generation in the routines described in section 3.2.

The parameter `acc` selects the accelerator design. Currently the following accelerator codes are recognized:

10c `<Accelerator codes 10c>≡`
`integer SBAND, TESLA, XBAND`
`parameter (SBAND = 1, TESLA = 2, XBAND = 3)`
`integer JLCNLC`
`parameter (JLCNLC = 3)`
`integer SBNDEE, TESLEE, XBNDEE`
`parameter (SBNDEE = 4, TESLEE = 5, XBNDEE = 6)`
`integer NLCH`
`parameter (NLCH = 7)`
`integer NACC`
`parameter (NACC = 7)`

Defines:

`NACC`, used in chunks 28, 33, 34a, 37–39, 44b, 46c, 48c, 51c, 54c, and 58c.

`SBAND`, used in chunks 28c, 33, 36–40, 42, 78b, 91a, and 92a.

`TESLA`, used in chunks 26f, 28c, 33, 36–38, 40, 42–50, 52, 54d, 55a, 58d, 59b, 78, and 91–93.

`XBAND`, used in chunks 33, 36–40, 42, 50, 91a, and 92a.

The **ver** parameter is used to determine the version as follows:

ver > 0 : a frozen version which is documented in section 5. For example, version 1 is a family of factorized Beta distributions: $D(x_1, x_2) \propto x_1^{a_1} (1 - x_1)^{b_1} x_2^{a_2} (1 - x_2)^{b_2}$.

ver = 0 : the latest experimental version, which is usually not documented and can change at any time without announcement.

ver < 0 : keep the currently active version.

The **rev** parameter is used to determine the revision of a version as follows:

rev > 0 : a frozen revision which is documented in section 5. The integer **rev** is constructed from the date as follows: $\text{rev} = 10^4 \cdot \text{year} + 10^2 \cdot \text{month} + \text{day}$, where the year is greater than 1995. Since Fortran77 ignores whitespace, it can be written like 1996 07 11 for readability. If there is no exact match, the most recent revision before the specified date is chosen.

rev = 0 : the most recent revision.

rev < 0 : keep the currently active revision.

Finally, the parameter **chat** controls the “chattiness” of **circe**. If it is 0, only error messages are printed. If it is 1, the parameters in use are printed whenever they change. Higher values of **chat** can produce even more diagnostics.

In addition to the generic interface **circe**, there are specialized functions for particular particle distributions. Obviously

$$D_{e^\pm \gamma}^{\alpha\nu\rho}(x_1, x_2, s) = D_{\gamma e^\pm}^{\alpha\nu\rho}(x_2, x_1, s) \quad (8)$$

and there are three independent functions $D_{e^- e^+}$, $D_{e^- \gamma}$ and $D_{\gamma \gamma}$ for the $e^+ e^-$ colliders with reasonable mnemonics:

```
11 <API documentation 9a>+≡
    double precision circee, circeg, circgg
    d = circee (x1, x2)
    d = circeg (x1, x2)
    d = circgg (x1, x2)
```

Uses **circee** 34c, **circeg** 35a, and **circgg** 35c.

Calling the latter three functions is marginally faster in the current implementation, but this can change in the future.

3.1.1 Example

For clarification, let me give a simple example. Imagine we want to calculate the integrated production cross section

$$\sigma_X(s) = \int dx_1 dx_2 \sigma_{e^+ e^- \rightarrow X}(x_1 x_2 s) D_{e^+ e^-}(x_1, x_2, s) \quad (9)$$

Since the distributions are singular in the $x_{1,2} \rightarrow 1$ limit, we have to map away this singularity with

$$x \rightarrow t = (1 - x)^{1/\eta} \quad (10a)$$

Therefore

$$\int_0^1 dx f(x) = \int_0^1 dt \eta t^{\eta-1} f(1-t^\eta) \quad (10b)$$

with η sufficiently large to give the integrand a finite limit at $x \rightarrow 1$. If f diverges like a power $f(x) \propto 1/(1-x)^\beta$, this means $\eta > 1/(1-\beta)$.

As a specific example, let us “measure” a one particle s -channel exchange cross section

$$\sigma(s) \propto \frac{1}{s} \quad (11)$$

```
12a <sample.f 12a>≡
      double precision function sigma (s)
      implicit none
      double precision s
      sigma = 1d0 / s
      end
```

I will present the example code in a bottom-up fashion, which should be intuitive and is described in some more detail in appendix A. Assuming the existence of a one- and a two-dimensional Gaussian integration function **gauss1** and **gauss2**,¹ we can perform the integral as follows:

```
12b <Gauss integration 12b>≡
      s = sigma (1d0) * circee (1d0, 1d0)
      $ + gauss1 (d1, 0d0, 1d0, EPS)
      $ + gauss1 (d2, 0d0, 1d0, EPS)
      $ + gauss2 (d12, 0d0, 1d0, 0d0, 1d0, EPS)
      write (*, 1000) 'delta(sigma) (Gauss) =', (s-1d0)*100d0
      1000 format (1X, A22, 1X, F6.2, '%')
```

Uses **circee** 34c, **gauss1** 76d, and **gauss2** 77a.

Note how the four combinations of continuum and δ -peak are integrated separately, where you have to use three auxiliary functions **d1**, **d2** and **d12**. The continuum contribution, including the Jacobian:

```
12c <sample.f 12a>+≡
      double precision function d12 (t1, t2)
      implicit none
      double precision t1, t2, x1, x2, sigma, circee
      <EPS & PWR 13b>
      x1 = 1d0 - t1**PWR
      x2 = 1d0 - t2**PWR
      d12 = PWR*PWR * (t1*t2)**(PWR-1d0)
      $      * sigma (x1*x2) * circee (x1, x2)
      end
```

Uses **circee** 34c.

the first product of continuum and δ -peak:

```
12d <sample.f 12a>+≡
      double precision function d1 (t1)
      implicit none
```

¹They are provided in the example program **sample.f**.

```

double precision t1, x1, sigma, circee
(EPS & PWR 13b)
x1 = 1d0 - t1**PWR
d1 = PWR * t1**(PWR-1d0) * sigma (x1) * circee (x1, 1d0)
end

```

Uses circee 34c.

and the second one:

```

13a (sample.f 12a)+≡
double precision function d2 (t2)
implicit none
double precision t2, x2, sigma, circee
(EPS & PWR 13b)
x2 = 1d0 - t2**PWR
d2 = PWR * t2**(PWR-1d0) * sigma (x2) * circee (1d0, x2)
end

```

Uses circee 34c.

Below you will see that the power of the singularity of the e^+e^- distributions at $x \rightarrow 1$ is $\approx -2/3$. To be on the safe side, we choose the power η in (10) as 5. It is kept in the parameter PWR, while EPS is the desired accuracy of the Gaussian integration:

```

13b (EPS & PWR 13b)≡
double precision EPS, PWR
parameter (EPS = 1d-6, PWR = 5d0)

```

The Gauss integration of the non-singular version converges to the cotrrect value only if the final bin is integrated separately:

```

13c (Second Gauss integration 13c)≡
s = gauss2 (d12a, 0d0, 1d0-KIREPS, 0d0, 1d0-KIREPS, EPS)
$ + gauss2 (d12a, 0d0, 1d0-KIREPS, 1d0-KIREPS, 1d0, EPS)
$ + gauss2 (d12a, 1d0-KIREPS, 1d0, 0d0, 1d0-KIREPS, EPS)
$ + gauss2 (d12a, 1d0-KIREPS, 1d0, 1d0-KIREPS, 1d0, EPS)
write (*, 1000) 'delta(sigma) (Gauss) =', (s-1d0)*100d0

```

Uses gauss2 77a.

```

13d (EPS & PWR 13b)+≡
double precision KIREPS
parameter (KIREPS = 1D-6)

```

```

13e (sample.f 12a)+≡
double precision function d12a (x1, x2)
implicit none
double precision x1, x2, sigma, kirkee
d12a = sigma (x1*x2) * kirkee (x1, x2)
end

```

Uses kirkee 63b.

These code fragments can now be used in a main program that loops over energies and accelerator designs

```

13f (sample.f 12a)+≡
program sample
implicit none

```

```

    <Accelerator codes 10c>
    <EPS & PWR 13b>
    <Other variables in sample 15>
    integer acc, ver, i
    double precision roots(9)
    data roots / 90D0, 170D0, 250D0, 350D0, 500D0,
$           800D0, 1000D0, 1200D0, 1500D0 /
    do 10 acc = JLCNLC, NLCH, NLCH-JLCNLC
        do 11 ver = 9, 9
            do 12 i = 1, 9
                call circes (0d0, 0d0, roots(i), acc, ver, 20020328, 1)
                <Gauss integration 12b>
                <Second Gauss integration 13c>
                <Monte Carlo integration 16d>
14            continue
12        continue
13    continue
11    continue
10    continue
    end

```

Uses circes 25a.

with the following result

```

                    +/- 0.33%

```

Uses circe 24d.

We almost forgot to declare the variables in the main program

```

15  <Other variables in sample 15>≡
      double precision s
      double precision gauss1, gauss2, circee, sigma, d1, d2, d12, d12a
      external d1, d2, d12, d12a

```

Uses `circee` 34c, `gauss1` 76d, and `gauss2` 77a.

This concludes the integration example. It should have made it obvious how to proceed in a realistic application.

In section 3.2.1 below, I will describe a Monte Carlo method for calculating such integrals efficiently.

3.2 Generators

The function `circe` and its companions are opaque to the user. Since they will in general contain singularities, applications will *not* be able to generate corresponding samples of random numbers efficiently. To fill this gap, four random number generators are provided. The subroutine `girce` will generate particle types $p_{1,2}$ and energy fractions $x_{1,2}$ in one step, according to the selected distribution.² Particle p_1 will be either a positron or a photon and p_2 will be either an electron or a photon. The energy fractions are guaranteed to be above the currently active thresholds: $x_i \geq x_{i,\min}$. This can be used to cut on soft events—the photon distributions are rather soft—which might not be interesting in most simulations.

16a $\langle \text{API documentation 9a} \rangle + \equiv$
`call girce (x1, x2, p1, p2, rng)`

Uses `girce` 67b.

The output parameters of `girce` are identical to the input parameters of `circe`, with the exception of `rng`. The latter is a subroutine with a single double precision argument, which will be assigned a uniform deviate from the interval $[0, 1]$ after each call:

16b $\langle \text{API documentation 9a} \rangle + \equiv$
`subroutine rng (r)`
`double precision r`
`r = $\langle \text{uniform deviate on } [0, 1] \text{ (never defined)} \rangle$`
`end`

Typically, it will be just a wrapper around the standard random number generator of the application program. For studies with a definite initial state, three generator functions are available.

16c $\langle \text{API documentation 9a} \rangle + \equiv$
`call gircee (x1, x2, rng)`
`call girceg (x1, x2, rng)`
`call gircgg (x1, x2, rng)`

Uses `gircee` 69b, `girceg` 69d, and `gircgg` 70c.

3.2.1 Example

Returning to the example from section 3.2.1, I present a concise Monte Carlo algorithm for calculating the same integral:

16d $\langle \text{Monte Carlo integration 16d} \rangle \equiv$
`s = 0d0`
`s2 = 0d0`

²The implementation of the flavor selection with non-vanishing thresholds $x_{1,\min}$ and $x_{2,\min}$ is moderately inefficient at the moment. It can be improved by a factor of two.

```

do 100 n = 1, NEVENT
  call gircee (x1, x2, random)
  w = sigma (x1*x2)
  s = s + w
  s2 = s2 + w*w
100 continue
s = s / dble(NEVENT)
s2 = s2 / dble(NEVENT)
write (*, 1000) 'delta(sigma) (MC)      =', (s-1d0)*100d0
write (*, 1000) '                        +/-',
$              sqrt((s2-s*s)/dble(NEVENT))*100d0

```

Uses gircee 69b.

17a *<Other variables in sample 15>+≡*

```

double precision w, s2, x1, x2
external random
integer NEVENT, n
parameter (NEVENT = 10000)

```

Here is a simple linear congruential random number generator for the sample program. Real applications will use their more sophisticated generators instead.

17b *<sample.f 12a>+≡*

```

subroutine random (r)
implicit none
double precision r
integer m, a, c
parameter (M = 259200, A = 7141, C = 54773)
integer n
save n
data n /0/
n = mod(n*a+c,m)
r = dble (n) / dble (m)
end

```

If the cross section is slowly varying on the range where the $x_{1,2}$ distributions are non-zero, this algorithm is very efficient.

However, if this condition is not met, the explicit form of the parameterizations in section 5 should be consulted and appropriate mapping techniques should be applied. The typical example for this problem is a narrow resonance just below the nominal beam energy.

3.2.2 Event Generators

For Monte Carlo event generators that use the standard `/hepevt/` common block [14], the addition of the `Circe` library is trivial. During the initialization of the event generator, the `circes` subroutine is called to set up `Circe`'s internal state. For example:

17c *<Initialize event generator 17c>≡*

```

call circes (0d0, 0d0, roots, acc, ver, 1996 07 11, 1)

```

Uses circes 25a.

Figure 5: Architecture of **Circe**: **circes()** selects energy and accelerator and loads the parameterization. The function **circe()** calculates the values of the selected distribution function at the given energy fractions. The subroutine **girce()** generates energy fractions using a specified random number generator in accordance with the selected distribution.

During event generation, before setting up the e^+e^- initial state, the **gircee** subroutine is called with the event generator's random number generator:

```
18a  <Event generation 18a>≡
      call gircee (x1, x2, random)
```

Uses **gircee** 69b.

The resulting energy fractions x_1 and x_2 are now available for defining the initial state electron

```
18b  <Event generation 18a>+≡
      isthep(1) = 101
      idhep(1) = ELECTR
      phep(1,1) = 0d0
      phep(2,1) = 0d0
      phep(3,1) = x1 * ebeam
      phep(4,1) = x1 * ebeam
      phep(5,1) = 0d0
```

Uses **ELECTR** 9b.

and positron.

```
18c  <Event generation 18a>+≡
      isthep(2) = 102
      idhep(2) = POSITR
      phep(1,2) = 0d0
      phep(2,2) = 0d0
      phep(3,2) = - x2 * ebeam
      phep(4,2) = x2 * ebeam
      phep(5,2) = 0d0
```

Uses **POSITR** 9b.

Using **Circe** with other event generators should be straightforward as well.

4 Technical Notes

The structure of **Circe** is extremely simple (cf. figure 5) and is mainly a book-keeping exercise. All that needs to be done is to maintain a database of available parameterizations and to evaluate the corresponding functions. The only non trivial algorithms are used for the efficient generation of random deviates.

I have avoided the use of initialized **common** blocks (i.e. **block data** subroutines), because the Fortran77 standard does not provide a *portable* way of ensuring that **block data** subroutines are actually executed at loading time. Instead, the **/circom/** common block is tagged by a “magic number” to check for initialization and its members are filled by the **circes** subroutine when necessary.

Table 5: Version 1, revision 1997 04 16 of the beam spectra at 500 GeV. The rows correspond to the luminosity per effective year, the integral over the continuum and the powers in the factorized Beta distributions (12).

Figure 6: Fit of the e^\pm - and γ -distributions for the S-Band design at $\sqrt{s} = 500\text{GeV}$. The open circles with error bars are the result of the **Guinea-Pig** simulation. The full line is the fit.

Figure 7: Fit of the e^\pm - and γ -distributions for the Tesla design at $\sqrt{s} = 500\text{GeV}$.

A more flexible method would be to replace the **data** statements by reading external files. This option causes portability problems, however, because I would have to make sure that the names of the external files are valid in all files systems of the target operating systems. More significantly, splitting the implementation into several parts forces the user to keep all files up to date. This can be a problem, because Fortran source files and data input files will typically be kept in different parts of the file system.

The option of implementing **Circe** statelessly, i.e. with pure function calls and without **common** blocks, has been dismissed. While it would have been more straightforward on the side of the library, it would have placed the burdon of maintaining state (accelerator, energy, etc.) on the application program, thereby complicating them considerably. Keeping an explicit state in **Circe** has the additional benefit of allowing to precompute certain internal variables, resulting in a more efficient implementation.

5 Parameterizations

Version 1.02 β of **Circe** supports just one version of the parameterizations. Future versions will provide additional parameterizations.

Table 10: *Experimental* Version 1, revision 0 of the beam spectra at 1 TeV.

5.1 Version 1

The first version of the parameterization uses a simple factorized *ansatz*

$$D_{p_1 p_2}^{\alpha 1\rho}(x_1, x_2, s) = d_{p_1}^{\alpha 1\rho}(x_1) d_{p_2}^{\alpha 1\rho}(x_2) \quad (12a)$$

where the distributions are simple Beta distributions:

$$d_{e^\pm}^{\alpha 1\rho}(x) = a_0^{\alpha\rho} \delta(1-x) + a_1^{\alpha\rho} x^{a_2^{\alpha\rho}} (1-x)^{a_3^{\alpha\rho}} \quad (12b)$$

$$d_\gamma^{\alpha 1\rho}(x) = a_4^{\alpha\rho} x^{a_5^{\alpha\rho}} (1-x)^{a_6^{\alpha\rho}} \quad (12c)$$

This form of the distributions is motivated by the observation [2] that the e^\pm distributions diverge like a power for $x \rightarrow 1$ and vanish at $x \rightarrow 0$. The behavior of the γ distributions is similar with the borders exchanged.

Table 11: *Experimental* Version 1, revision 0 of the beam spectra for TESLEE.

5.1.1 Fitting

The parameters a_i in (12) have been obtained by a least-square fit of (12) to histograms of simulation results from **Guinea-Pig**. Some care has to be taken when fitting singular distributions to histogrammed data. Obviously equidistant bins are not a good idea, because most bins will be almost empty (cf. figures 1 and 2) and consequently a lot of information will be wasted. One solution to this problem is the use of logarithmic bins. This, however, maps the compact region $[0, 1] \times [0, 1]$ to $[-\infty, 0] \times [-\infty, 0]$, which is inconvenient because of the missing lower bounds.

The more appropriate solution is to use two maps

$$\begin{aligned} \phi : [0, 1] &\rightarrow [0, 1] \\ x &\mapsto y = x^{1/\eta} \end{aligned} \tag{13}$$

where $x = x_\gamma$ or $x = 1 - x_{e^\pm}$, and to bin the result equidistantly. If η is chosen properly (cf. (10)), the bin contents will then fall off at the singularity. The fits in tables 5, 6, and 7 have been performed with $\eta = 5$ and the resulting bin contents can be read off from figures 6–9.

Using this procedure for binning the results of the simulations, the popular fitting package MINUIT [15] converges quickly in all cases considered. The resulting parameters are given in tables 5, 6, and 7. Plots of the corresponding distributions have been shown in figures 1 and 2. It is obvious that an *ansatz* like (12) is able to distinguish among the accelerator designs. Thus it can provide a solid basis for physics studies.

In figures 6–9 I give a graphical impression of the quality of the fit, which appears to be as good as one could reasonably expect for a simple *ansatz* like (12). Note that the histograms have non-equidistant bins and that the resulting Jacobians have not been removed. Therefore the bin contents falls off at the singularities, as discussed above.

The errors used for the least-square fit had to be taken from a Monte Carlo (MC) study. **Guinea-Pig** only provides the \sqrt{n} from Poissonian statistics for each bin, but the error accumulation during tracking the particles through phase space is not available. The MC studies shows that the latter error dominates the former, but appears to be reasonably Gaussian. A complete MC study

of all parameter sets is computationally expensive (more than a week of processor time on a fast SGI). From an exemplary MC study of a few parameter sets, it appears that the errors can be described reasonably well by rescaling the Poissonian error in each bin with appropriate factors for electrons/positrons and photons and for continuum and delta. This procedure has been adopted.

The $\chi^2/\text{d.o.f.}$'s of the fits are less than $\mathcal{O}(10)$. The simple *ansatz* (12) is therefore very satisfactory. In fact, trying to improve the ad-hoc factorized Beta distributions by the better motivated approximations from [7] or [16], it turns out [17] that (12) provides a significantly better fit of the results of the simulations. The price to pay is that the parameters in (12) have no direct physical interpretation.

5.1.2 Generators

For this version of the parameterizations we need a fast generator of Beta distributions:

$$\beta^{a,b}(x) \propto x^{a-1}(1-x)^{b-1} \quad (14)$$

This problem has been studied extensively and we can use a published algorithm [18] that is guaranteed to be very fast for all a, b such that $0 < a \leq 1 \leq b$, which turns out to be always the case (cf. tables 5, 6, and 7).

5.2 Future Versions

There are two ways in which the parameterizations can be improved:

more complicated functions: the factorized fits can only be improved marginally by adding more positive semi-definite factors to (12). More improvement is possible by using sums of functions, but in this case, the best fits violate the positivity requirement and have to be discarded.

correlations: the parameterization in section 5.1 is factorized. While this is a good approximation, the simulations nevertheless show correlations among x_1 and x_2 . These correlations can be included in a future version.

interpolation: the parameterization in section 5.1 is based on fitting the simulation results by simple functions. Again, this appears to be a good approximation. But such fits can not uncover any fine structure of the distributions. Therefore it will be worthwhile to study interpolations of the simulation results in the future. A proper interpolation of results with statistical errors is however far from trivial: straightforward polynomial or spline interpolations will be oscillatory and violate the positivity requirement. Smoothing algorithms have to be investigated in depth before such a parameterization can be released.

other simulations: besides [5], other simulation codes are invited to contribute their results for inclusion in the `Circe` library.

6 Implementation of circe

24a `<circe1.f 24a>≡`
 `c circe1.f -- canonical beam spectra for linear collider physics`
 `c $Id: circe.nw 67 2002-03-28 17:13:06Z ohl $`
 `<Copleft notice 24b>`
 `<Subroutines 24d>`
Uses `circe` 24d.

The following is usually not needed for scientific programs. Nobody is going to hijack such code. But let us include it anyway to spread the gospel of free software:

24b `<Copleft notice 24b>≡`
 `c Copyright (C) 1996-2002 by Thorsten Ohl <ohl@hep.tu-darmstadt.de>`
 `c`
 `c Circe is free software; you can redistribute it and/or modify it`
 `c under the terms of the GNU General Public License as published by`
 `c the Free Software Foundation; either version 2, or (at your option)`
 `c any later version.`
 `c`
 `c Circe is distributed in the hope that it will be useful, but`
 `c WITHOUT ANY WARRANTY; without even the implied warranty of`
 `c MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the`
 `c GNU General Public License for more details.`
 `c`
 `c You should have received a copy of the GNU General Public License`
 `c along with this program; if not, write to the Free Software`
 `c Foundation, Inc., 675 Mass Ave, Cambridge, MA 02139, USA.`

Now we can move on to the implementation.

6.1 Symbolic Constants

The file `circe.h` contains symbolic names for various magic constants used by `Circe`:

24c `<circe.h 24c>≡`
 `c circe.h -- canonical beam spectra for linear collider physics`
 `c $Id: circe.nw 67 2002-03-28 17:13:06Z ohl $`
 `<Copleft notice 24b>`
 `<Particle codes 9b>`
 `<Accelerator codes 10c>`
Uses `circe` 24d.

6.2 Distributions

6.2.1 Version 1

We start with a convenience function which dispatches over the valid particle types. The hardest part is of course to avoid typos in such trivial functions ...

24d `<Subroutines 24d>≡`

```

double precision function circe (x1, x2, p1, p2)
implicit none
double precision x1, x2
integer p1, p2
double precision circee, circeg, circgg
<Particle codes 9b>
</circom/ 25b>
<Initialization check 26e>
circe = -1.0
if (abs(p1) .eq. ELECTR) then
  if (abs(p2) .eq. ELECTR) then
    circe = circee (x1, x2)
  elseif (p2 .eq. PHOTON) then
    circe = circeg (x1, x2)
  endif
elseif (p1 .eq. PHOTON) then
  if (abs(p2) .eq. ELECTR) then
    circe = circeg (x2, x1)
  elseif (p2 .eq. PHOTON) then
    circe = circgg (x1, x2)
  endif
endif
end
end

```

Defines:

`circe`, used in chunks 24d, 9a, 24, 14, 24, 26f, 74, 79a, 93c, and 98b.

Uses `ELECTR` 9b, `PHOTON` 9b, `circee` 34c, `circeg` 35a, and `circgg` 35c.

```

25a <Subroutines 24d>+≡
subroutine circes (xx1m, xx2m, xroots, xacc, xver, xrev, xchat)
implicit none
double precision xx1m, xx2m, xroots
double precision beta
integer xacc, xver, xrev, xchat
<Accelerator codes 10c>
</circom/ 25b>
<Local variables for circes 27a>
<Initializations for circes 28c>
if (magic .ne. 1904 06 16) then
  magic = 1904 06 16
  <Initialize /circom/ 26f>
endif
<Update /circom/ 26g>
<formats for circes 31d>
end

```

Defines:

`circes`, used in chunks 25a, 10b, 13f, 25a, 17c, 25, 26e, 74, and 78a.

Uses `beta` 90a.

```

25b </circom/ 25b>≡
<parameter part of /circom/ 26d>
<8-byte aligned part of /circom/ 26a>
<4-byte aligned part of /circom/ 26b>

```

```

        save /circom/
26a  <8-byte aligned part of /circom/ 26a>≡
        double precision x1m, x2m, roots
        common /circom/ x1m, x2m, roots
26b  <4-byte aligned part of /circom/ 26b>≡
        integer acc, ver, rev, chat
        common /circom/ acc, ver, rev, chat

Instead of using fragile block data subroutines, we use a magic number to tag
/circom/ as initialized:
26c  <4-byte aligned part of /circom/ 26b>+≡
        integer magic
        common /circom/ magic
26d  <parameter part of /circom/ 26d>≡
        integer MAGIC0
        parameter (MAGIC0 = 1904 06 16)

Since negative values are no updated, we can call circes with all negative
variables to ensure initialization:
26e  <Initialization check 26e>≡
        if (magic .ne. MAGIC0) then
            call circes (-1d0, -1d0, -1d0, -1, -1, -1, -1)
        endif

Uses circes 25a.
26f  <Initialize /circom/ 26f>≡
        x1m = 0d0
        x2m = 0d0
        roots = 500D0
        acc = TESLA
        ver = 0
        rev = 0
        chat = 1
        if (xchat .ne. 0) then
            call circem ('MESSAGE', 'starting up ...')
            call circem ('MESSAGE',
$              '$Id: circe.nw 67 2002-03-28 17:13:06Z ohl $')
        endif

Uses TESLA 10c and circe 24d.
26g  <Update /circom/ 26g>≡
        if ((xchat .ge. 0) .and. (xchat .ne. chat)) then

6.4 Non-Singular Distributions

63a *<Subroutines 24d>+≡*

```
double precision function kirke (x1, x2, p1, p2)
implicit none
double precision x1, x2
integer p1, p2
double precision kirkee, kirkeg, kirkgg
<Particle codes 9b>
</circom/ 25b>
<Initialization check 26e>
kirke = -1.0
if (abs(p1) .eq. ELECTR) then
  if (abs(p2) .eq. ELECTR) then
    kirke = kirkee (x1, x2)
  elseif (p2 .eq. PHOTON) then
    kirke = kirkeg (x1, x2)
  endif
elseif (p1 .eq. PHOTON) then
  if (abs(p2) .eq. ELECTR) then
    kirke = kirkeg (x2, x1)
  elseif (p2 .eq. PHOTON) then
    kirke = kirkgg (x1, x2)
  endif
endif
endif
end
```

Defines:

kirke, never used.

Uses ELECTR 9b, PHOTON 9b, kirkee 63b, kirkeg 65c, and kirkgg 66a.

63b *<Subroutines 24d>+≡*

```
double precision function kirkee (x1, x2)
implicit none
double precision x1, x2
</circom/ 25b>
double precision d1, d2
<Initialization check 26e>
kirkee = -1.0
if ((ver .eq. 1) .or. (ver .eq. 0)) then
  <Calculate version 1 of the non-singular  $e^+e^-$  distribution 64e>
<else handle invalid versions 30b>
end
```

Defines:

kirkee, used in chunks 13e, 63a, and 64e.

63c *<parameter part of /circom/ 26d>+≡*

```
double precision KIREPS
parameter (KIREPS = 1D-6)
```

64a *<8-byte aligned part of /circom/ 26a>+≡*
`double precision elect0, gamma0`
`common /circom/ elect0, gamma0`

$$\int_{1-\epsilon}^{1+} dx d_{e\pm}^{\alpha_{1\rho}}(x) = a_0^{\alpha_\rho} + a_1^{\alpha_\rho} \int_{1-\epsilon}^{1-} dx x^{a_2^{\alpha_\rho}} (1-x)^{a_3^{\alpha_\rho}} \quad (18)$$

Approximately

$$\int_{1-\epsilon}^{1+} dx d_{e\pm}^{\alpha_{1\rho}}(x) = a_0^{\alpha_\rho} + a_1^{\alpha_\rho} \int_{1-\epsilon}^{1-} dx (1-x)^{a_3^{\alpha_\rho}} = a_0^{\alpha_\rho} + a_1^{\alpha_\rho} \int_{0+}^{\epsilon} d\xi \xi^{a_3^{\alpha_\rho}} \quad (19)$$

and therefore

$$\int_{1-\epsilon}^{1+} dx d_{e\pm}^{\alpha_{1\rho}}(x) = a_0^{\alpha_\rho} + a_1^{\alpha_\rho} \frac{1 - \epsilon^{a_3^{\alpha_\rho} + 1}}{a_3^{\alpha_\rho} + 1} \quad (20)$$

This simple approximation is good enough

64b *<Update /circom/ 26g>+≡*
`elect0 = a1(0) + a1(1) * KIREPS**(a1(3)+1) / (a1(3)+1)`
`elect0 = elect0 / KIREPS`
`gamma0 = a1(4) * KIREPS**(a1(5)+1) / (a1(5)+1)`
`gamma0 = gamma0 / KIREPS`

but we can also use incomplete Beta functions for the exact result:

64c *<Alternative: Update /circom/ 64c>≡*
`elect0 = a1(0) + a1(1) * beta (a1(2)+1, a1(3)+1)`
`$ * (1d0 - betinc (a1(2)+1, a1(3)+1, 1d0 - KIREPS))`
`elect0 = elect0 / KIREPS`
`gamma0 = a1(7) + a1(4) * beta (a1(5)+1, a1(6)+1)`
`$ * betinc (a1(5)+1, a1(6)+1, KIREPS)`
`gamma0 = gamma0 / KIREPS`

Uses beta 90a.

64d *<Local variables for circes 27a>+≡*
`double precision betinc`
`external betinc`

64e *<Calculate version 1 of the non-singular e^+e^- distribution 64e>≡*
`if (x1 .gt. 1d0) then`
`d1 = 0d0`
`elseif (x1 .ge. (1d0 - KIREPS)) then`

6.5 Generators

6.5.1 Version 1

Beta distributions have the practical advantage that they have been popular among mathematicians.[?]

```

67b  <Subroutines 24d>+≡
      subroutine girce (x1, x2, p1, p2, rng)
      implicit none

```

```

double precision x1, x2
integer p1, p2
external rng
</circom/ 25b>
double precision u, w, circgg
<Particle codes 9b>
<Initialization check 26e>
<x1m, x2m kludge, part 1 68b>
<Select particles p1 and p2 68a>
if (abs(p1) .eq. ELECTR) then
  if (abs(p2) .eq. ELECTR) then
    call gircee (x1, x2, rng)
  elseif (p2 .eq. PHOTON) then
    call girceg (x1, x2, rng)
  endif
elseif (p1 .eq. PHOTON) then
  if (abs(p2) .eq. ELECTR) then
    call girceg (x2, x1, rng)
  elseif (p2 .eq. PHOTON) then
    call gircgg (x1, x2, rng)
  endif
endif
<x1m, x2m kludge, part 2 69a>
end

```

Defines:

girce, used in chunks 67b, 16a, and 67.

Uses ELECTR 9b, PHOTON 9b, circgg 35c, gircee 69b, girceg 69d, and gircgg 70c.

```

68a <Select particles p1 and p2 68a>≡
    w = 1d0 / (1d0 + circgg (-1d0, -1d0))
    call rng (u)
    if (u*u .le. w) then
      p1 = POSITR
    else
      p1 = PHOTON
    endif
    call rng (u)
    if (u*u .le. w) then
      p2 = ELECTR
    else
      p2 = PHOTON
    endif

```

Uses ELECTR 9b, PHOTON 9b, POSITR 9b, and circgg 35c.

The flavor selection is incorrect, because the relative weights depend on the minimum energy fractions. We resort to a moderately inefficient kludge, because we don't have the distribution functions available yet. We'll have to implement incomplete Beta functions and other horrible things for this. Fortunately, the efficiency can not drop below the relative contribution of e^+e^- .

```

68b <x1m, x2m kludge, part 1 68b>≡
    99 continue

```

Crude rejection:

```

69a  <x1m, x2m kludge, part 2 69a>≡
      if ((x1 .lt. x1m) .or. (x2 .lt. x2m)) goto 99

69b  <Subroutines 24d>+≡
      subroutine gircee (x1, x2, rng)
      implicit none
      double precision x1, x2
      external rng
      </circom/ 25b>
      double precision u, girceb
      <Initialization check 26e>
      if ((ver .eq. 1) .or. (ver .eq. 0)) then
        <Generate version 1 of the e+e- distribution 69c>
      <else handle invalid versions 30b>
      end

```

Defines:

gircee, used in chunks 16, 69b, 18a, and 67b.

Uses girceb 71a.

For version 1 of the parametrizations we rely on girceb, a fast generator of β -distributions:

$$\beta_{x_{\min}, x_{\max}}^{a,b}(x) = x^{a-1}(1-x)^{b-1} \cdot \frac{\Theta(x_{\max}-x)\Theta(x-x_{\min})}{I(x_{\min}, a, b) - I(x_{\max}, a, b)} \quad (21)$$

$$I(x, a, b) = \int_x^1 d\xi \xi^{a-1}(1-\xi)^{b-1} \quad (22)$$

```

69c  <Generate version 1 of the e+e- distribution 69c>≡
      call rng (u)
      if (u .le. a1(0)) then
        x1 = 1d0
      else
        x1 = 1d0 - girceb (0d0, 1d0-x1m, a1(3)+1d0, a1(2)+1d0, rng)
      endif
      call rng (u)
      if (u .le. a1(0)) then
        x2 = 1d0
      else
        x2 = 1d0 - girceb (0d0, 1d0-x2m, a1(3)+1d0, a1(2)+1d0, rng)
      endif

```

Uses girceb 71a.

```

69d  <Subroutines 24d>+≡
      subroutine girceg (x1, x2, rng)
      implicit none
      double precision x1, x2
      external rng
      </circom/ 25b>
      double precision u, girceb
      <Initialization check 26e>
      if ((ver .eq. 1) .or. (ver .eq. 0)) then

```

```

      <Generate version 1 of the  $e^\pm\gamma$  distribution 70a>
    <else handle invalid versions 30b>
  end

```

Defines:

`gircegb`, used in chunks 16c and 67b.

Uses `girceb` 71a.

```

70a <Generate version 1 of the  $e^\pm\gamma$  distribution 70a>≡
      call rng (u)
      if (u .le. a1(0)) then
        x1 = 1d0
      else
        x1 = 1d0 - gircegb (0d0, 1d0-x1m, a1(3)+1d0, a1(2)+1d0, rng)
      endif
      x2 = gircegb (x2m, 1d0, a1(5)+1d0, a1(6)+1d0, rng)

```

Uses `girceb` 71a.

```

70b <Subroutines 24d>+≡
      subroutine gircgg (x1, x2, rng)
      implicit none
      double precision x1, x2
      external rng
      </circom/ 25b>
      double precision girceb
      <Initialization check 26e>
      if ((ver .eq. 1) .or. (ver .eq. 0)) then
        <Generate version 1 of the  $\gamma\gamma$  distribution 70c>
        <else handle invalid versions 30b>
      end

```

Uses `girceb` 71a and `gircgg` 70c.

```

70c <Generate version 1 of the  $\gamma\gamma$  distribution 70c>≡
      x1 = girceb (x1m, 1d0, a1(5)+1d0, a1(6)+1d0, rng)
      x2 = girceb (x2m, 1d0, a1(5)+1d0, a1(6)+1d0, rng)

```

Defines:

`gircgg`, used in chunks 16c, 67b, and 70b.

Uses `girceb` 71a.

6.5.2 Version 2

Retired.

6.5.3 Version 3 and 4

Identical to version 1.

6.6 Utilities

For version 1 of the parametrizations we need a fast generator of β -distributions:

$$\beta_{x_{\min}, x_{\max}}^{a,b}(x) = x^{a-1}(1-x)^{b-1} \cdot \frac{\Theta(x_{\max}-x)\Theta(x-x_{\min})}{I(x_{\min}, a, b) - I(x_{\max}, a, b)} \quad (23)$$

with the *incomplete Beta-function* I :

$$I(x, a, b) = \int_x^1 d\xi \xi^{a-1} (1 - \xi)^{b-1} \quad (24)$$

$$B(a, b) = I(0, a, b) \quad (25)$$

This problem has been studied extensively [?] and we can use an algorithm [18] that is very fast for $0 < a \leq 1 \leq b$, which turns out to be the case in our application.

```

71a  <Subroutines 24d>+≡
      double precision function girceb (xmin, xmax, a, b, rng)
      implicit none
      double precision xmin, xmax, a, b
      external rng
      double precision t, p, u, umin, umax, x, w
      <Check a and b 71b>
      <Set up girceb parameters 71c>
10   continue
      <Generate a trial x and calculate its weight w 72a>
      call rng (u)
      if (w .le. u) goto 10
      girceb = x
      end

```

Defines:

`girceb`, used in chunks 69b, 71a, 69–71, and 73b.

In fact, this algorithm works for $0 < a \leq 1 \leq b$ only:

```

71b  <Check a and b 71b>≡
      if ((a .gt. 1d0) .or. (b .lt. 1d0)) then
      girceb = -1d0
      call circem ('ERROR', 'beta-distribution expects a<=1<=b')
      return
      endif

```

Uses `girceb` 71a.

The trick is to split the interval $[0, 1]$ into two parts $[0, t]$ and $[t, 1]$. In these intervals we obviously have

$$x^{a-1}(1-x)^{b-1} \leq \begin{cases} x^{a-1} & \text{for } x \leq t \\ t^{a-1}(1-x)^{b-1} & \text{for } x \geq t \end{cases} \quad (26)$$

because we have assumed that $0 < a \leq 1 \leq b$. The integrals of the two dominating distributions are t^a/a and $t^{a-1}(1-t)^b/b$ respectively and therefore the probability for picking a random number from the first interval is

$$P(x \leq t) = \frac{bt}{bt + a(1-t)^b} \quad (27)$$

We postpone the discussion of the choice of t until later:

```

71c  <Set up girceb parameters 71c>≡
      <Set up best value for t 73c>
      p = b*t / (b*t + a * (1d0 - t)**b)

```

The dominating distributions can be generated by simple mappings

$$\phi : [0, 1] \rightarrow [0, 1] \quad (28)$$

$$u \mapsto \begin{cases} t \left(\frac{u}{p} \right)^{\frac{1}{a}} & < t \text{ for } u < p \\ t & = t \text{ for } u = p \\ 1 - (1 - t) \left(\frac{1-u}{1-p} \right)^{\frac{1}{b}} & > t \text{ for } u > p \end{cases} \quad (29)$$

The beauty of the algorithm is that we can use a single uniform deviate u for both intervals:

```
72a  <Generate a trial x and calculate its weight w 72a>≡
      call rng (u)
      u = umin + (umax - umin) * u
      if (u .le. p) then
        x = t * (u/p)**(1d0/a)
        w = (1d0 - x)**(b-1d0)
      else
        x = 1d0 - (1d0 - t) * ((1d0 - u)/(1d0 - p))**(1d0/b)
        w = (x/t)**(a-1d0)
      endif
```

The weights that are derived by dividing the distribution by the dominating distributions are already normalized correctly:

$$w : [0, 1] \rightarrow [0, 1] \quad (30)$$

$$x \mapsto \begin{cases} (1 - x)^{b-1} & \in [(1 - t)^{b-1}, 1] \text{ for } x \leq t \\ \left(\frac{x}{t} \right)^{a-1} & \in [t^{1-a}, 1] \text{ for } x \geq t \end{cases} \quad (31)$$

To derive $u_{\min, \max}$ from $x_{\min, \max}$ we can use ϕ^{-1} :

$$\phi^{-1} : [0, 1] \rightarrow [0, 1] \quad (32)$$

$$x \mapsto \begin{cases} p \left(\frac{x}{t} \right)^a & < p \text{ for } x < t \\ p & = p \text{ for } x = t \\ 1 - (1 - p) \left(\frac{1-x}{1-t} \right)^b & > p \text{ for } x > t \end{cases} \quad (33)$$

We start with u_{\min} . For efficiency, we handle the most common cases (small x_{\min}) first:

```
72b  <Set up girceb parameters 71c>+≡
      if (xmin .le. 0d0) then
        umin = 0d0
      elseif (xmin .lt. t) then
        umin = p * (xmin/t)**a
      elseif (xmin .eq. t) then
        umin = p
      elseif (xmin .lt. 1d0) then
        umin = 1d0 - (1d0 - p) * ((1d0 - xmin)/(1d0 - t))**b
      else
        umin = 1d0
      endif
```

Same procedure for u_{\max} ; again, handle the most common cases (large x_{\max}) first:

```
73a  <Set up girceb parameters 71c>+≡
      if (xmax .ge. 1d0) then
        umax = 1d0
      elseif (xmax .gt. t) then
        umax = 1d0 - (1d0 - p) * ((1d0 - xmax)/(1d0 - t))**b
      elseif (xmax .eq. t) then
        umax = p
      elseif (xmax .gt. 0d0) then
        umax = p * (xmax/t)**a
      else
        umax = 0d0
      endif
```

Check for absurd cases.

```
73b  <Set up girceb parameters 71c>+≡
      if (umax .lt. umin) then
        girceb = -1d0
        return
      endif
```

Uses girceb 71a.

It remains to choose the best value for t . The rejection efficiency ϵ of the algorithm is given by the ratio of the dominating distribution and the distribution

$$\frac{1}{\epsilon(t)} = \frac{B(a, b)}{ab} (bt^a + at^{a-1}(1-t)^b). \quad (34)$$

It is maximized for

$$bt - bt(1-t)^{b-1} + (a-1)(1-t)^b = 0 \quad (35)$$

This equation has a solution which can be determined numerically. While this determination is far too expensive compared to a moderate loss in efficiency, we could perform it once after fitting the coefficients a , b . Nevertheless, it has been shown,[18] that

$$t = \frac{1-a}{b+1-a} \quad (36)$$

results in non-vanishing efficiency for all values $1 < a \leq 1 \leq b$. Empirically we have found efficiencies of at least 80% for this choice, which is enough for our needs.

```
73c  <Set up best value for t 73c>≡
      t = (1d0 - a) / (b + 1d0 - a)

73d  <Subroutines 24d>+≡
      subroutine circem (errlvl, errmsg)
      implicit none
      character*(*) errlvl, errmsg
      </circom/ 25b>
      integer errcnt
      save errcnt
```

```

data errcnt /0/
if (errlvl .eq. 'MESSAGE') then
  print *, 'circe:message: ', errmsg
elseif (errlvl .eq. 'WARNING') then
  if (errcnt .lt. 100) then
    errcnt = errcnt + 1
    print *, 'circe:warning: ', errmsg
  elseif (errcnt .eq. 100) then
    errcnt = errcnt + 1
    print *, 'circe:message: more than 100 messages'
    print *, 'circe:message: turning warnings off'
  endif
elseif (errlvl .eq. 'ERROR') then
  if (errcnt .lt. 200) then
    errcnt = errcnt + 1
    print *, 'circe:error: ', errmsg
  elseif (errcnt .eq. 200) then
    errcnt = errcnt + 1
    print *, 'circe:message: more than 200 messages'
    print *, 'circe:message: turning error messages off'
  endif
elseif (errlvl .eq. 'PANIC') then
  if (errcnt .lt. 300) then
    errcnt = errcnt + 1
    print *, 'circe:panic: ', errmsg
  elseif (errcnt .eq. 300) then
    errcnt = errcnt + 1
    print *, 'circe:message: more than 300 messages'
    print *, 'circe:message: turning panic messages off'
  endif
else
  print *, 'circe:panic:   invalid error code ', errlvl
endif
end

```

6.7 Examples

6.7.1 Distributions

```

74 <cplot.f 74>≡
  program cplot
  implicit none
  <Particle codes 9b>
  double precision xmin, xmax, y, roots
  integer xory, nstep, p1, p2, acc, ver, rev
  double precision x, logx, d, circe
  read *, xory, xmin, xmax, nstep, y, p1, p2, roots, acc, ver, rev
  call circes (0d0, 0d0, roots, acc, ver, rev, 0)
  do 10 logx = log (xmin), log (xmax), log (xmax/xmin) / nstep

```

```

      x = exp (logx)
      d = 0d0
      if (xory .eq. 1) then
        if (p1 .eq. PHOTON) then
          d = circe (x, y, p1, p2)
        else
          d = circe (1d0 - x, y, p1, p2)
        endif
      elseif (xory .eq. 2) then
        if (p1 .eq. PHOTON) then
          d = circe (y, x, p1, p2)
        else
          d = circe (y, 1d0 - x, p1, p2)
        endif
      endif
      if (d .gt. 1d-4) print *, x, d
10 continue
end

```

Uses PHOTON 9b, circe 24d, and circes 25a.

6.7.2 Library functions

If Fortran77 only had first class functions, then the following cruft would not be necessary. OK, here's the outline of the adaptive Gauss integration routine from CERNLIB:

```

75a  <Part one of Gaussian integration 75a>≡
      double precision f, a, b, eps
      external f
      double precision Z1, HF, CST
      parameter (Z1 = 1, HF = Z1/2, CST = 5*Z1/1000)
      integer i
      double precision h, const, aa, bb, c1, c2, s8, s16, u
      <Gaussian weights 77b>
      h = 0
      if (b .eq. a) go to 99
      const = CST / dabs(b-a)
      bb = a
1 continue
      aa = bb
      bb = b
2 continue
      c1 = HF*(bb+aa)
      c2 = HF*(bb-aa)
      s8 = 0
      do 3 i = 1, 4
        u = c2*x(i)

```

Here are now the first two function calls that we have to fill in later in various ways:

```

75b  <Function call stub 75b>≡

```

```
s8 = s8 + w(i) * (f (c1+u) + f (c1-u))
```

Continuing

```
76a <Part two of Gaussian integration 76a>≡
      3      continue
        s16 = 0
      do 4 i = 5, 12
        u = c2*x(i)
```

And here are the other two function calls:

```
76b <Function call stub 75b>+≡
      s16 = s16 + w(i) * (f (c1+u) + f (c1-u))
```

Terminating:

```
76c <Part three of Gaussian integration 76c>≡
      4      continue
        s16 = c2*s16
      if (dabs(s16-c2*s8) .le. eps*(1+dabs(s16))) then
        h = h + s16
        if (bb .ne. b) go to 1
      else
        bb = c1
        if (1 + const*dabs(c2) .ne. 1) go to 2
        h = 0
        print *, 'gauss: too high accuracy required'
        go to 99
      end if
    99 continue
```

This one is still reasonably straightforward

$$\text{gauss1} : (f, a, b) \mapsto \int_a^b dx f(x) \quad (37)$$

```
76d <sample.f 12a>+≡
      double precision function gauss1 (f, a, b, eps)
      implicit none
      <Part one of Gaussian integration 75a>
      s8 = s8 + w(i) * (f (c1+u) + f (c1-u))
      <Part two of Gaussian integration 76a>
      s16 = s16 + w(i) * (f (c1+u) + f (c1-u))
      <Part three of Gaussian integration 76c>
      gauss1 = h
    end
```

Defines:

`gauss1`, used in chunks 76d, 12b, 15, and 76.

But this almost identical repeat

$$\text{gaussx} : (f, a, b) \mapsto \left(y \mapsto \int_a^b dx f(y, x) \right) \quad (38)$$

would not be necessary in a modern programming language with currying:

```

76e <sample.f 12a>+≡
      double precision function gaussx (f, y, a, b, eps)
      implicit none
      double precision y
      <Part one of Gaussian integration 75a>
      s8 = s8 + w(i) * (f (y, c1+u) + f (y, c1-u))
      <Part two of Gaussian integration 76a>
      s16 = s16 + w(i) * (f (y, c1+u) + f (y, c1-u))
      <Part three of Gaussian integration 76c>
      gaussx = h
      end

```

Defines:

gaussx, used in chunks 76 and 77a.

Fortunately, this is the last one we need

$$\begin{aligned}
 \text{gauss2} : (f, a, b, a_1, b_1) &\mapsto \int_a^b dx \int_{a_1}^{b_1} dy f(x, y) \\
 &= \text{gauss1}(\text{gaussx}(f, a, b), a_1, b_1) \quad (39)
 \end{aligned}$$

```

77a <sample.f 12a>+≡
      double precision function gauss2 (f, a, b, a1, b1, eps)
      implicit none
      double precision a1, b1, gaussx
      <Part one of Gaussian integration 75a>
      s8 = s8 + w(i) * (gaussx (f, c1+u, a1, b1, eps)
      $              + gaussx (f, c1-u, a1, b1, eps))
      <Part two of Gaussian integration 76a>
      s16 = s16 + w(i) * (gaussx (f, c1+u, a1, b1, eps)
      $              + gaussx (f, c1-u, a1, b1, eps))
      <Part three of Gaussian integration 76c>
      gauss2 = h
      end

```

Defines:

gauss2, used in chunks 77a, 12b, 13c, 15, and 77a.

Uses gaussx 76e.

```

77b <Gaussian weights 77b>≡
      double precision w(12), x(12)
      data x( 1) /9.6028985649753623d-1/, w( 1) /1.0122853629037626d-1/
      data x( 2) /7.9666647741362674d-1/, w( 2) /2.2238103445337447d-1/
      data x( 3) /5.2553240991632899d-1/, w( 3) /3.1370664587788729d-1/
      data x( 4) /1.8343464249564980d-1/, w( 4) /3.6268378337836198d-1/
      data x( 5) /9.8940093499164993d-1/, w( 5) /2.7152459411754095d-2/
      data x( 6) /9.4457502307323258d-1/, w( 6) /6.2253523938647893d-2/
      data x( 7) /8.6563120238783174d-1/, w( 7) /9.5158511682492785d-2/
      data x( 8) /7.5540440835500303d-1/, w( 8) /1.2462897125553387d-1/
      data x( 9) /6.1787624440264375d-1/, w( 9) /1.4959598881657673d-1/
      data x(10) /4.5801677765722739d-1/, w(10) /1.6915651939500254d-1/
      data x(11) /2.8160355077925891d-1/, w(11) /1.8260341504492359d-1/
      data x(12) /9.5012509837637440d-2/, w(12) /1.8945061045506850d-1/

```

6.7.3 Generators

6.8 Dumping Parameters

```
78a <params.f 78a>≡
      program params
      implicit none
      <Accelerator codes 10c>
      integer acc, ver, i
      double precision roots(7)
      data roots / 90D0, 170D0, 350D0, 500D0, 800D0, 1000D0, 1500D0 /
      do 10 ver = 7, 8
        print *, 'VERSION ', ver
        do 11 acc = TESLA, XBNDEE
          do 12 i = 1, 7
            print *, '=====
            call circes (0d0, 0d0, roots(i), acc, ver, 20020307, 0)
            call dump ()
          12      continue
        11      continue
      10      continue
      end
```

Uses TESLA 10c and circes 25a.

```
78b <params.f 78a>+≡
      subroutine dump
      implicit none
      </circom/ 25b>
      <Accelerator codes 10c>
      character*9 name
      if (acc .eq. SBAND) then
        name = 'SBAND'
      else if (acc .eq. TESLA) then
        name = 'TESLA'
      else if (acc .eq. JLCNLC) then
        name = 'JLCNLC'
      else if (acc .eq. SBNDEE) then
        name = 'SBAND/EE'
      else if (acc .eq. TESLEE) then
        name = 'TESLA/EE'
      else if (acc .eq. XBNDEE) then
        name = 'JLCNLC/EE'
      end if
      write (*, 1000) name, roots
      write (*, 1001) 'e+ e-', lumi
      write (*, 1002) 'e+/e-', a1(0)
      write (*, 1003) 'e+/e-', 1 - a1(0)

        t = t + f(ndata+1,0) + f(ndata+1,ndata+1)

```

Guinea-Pig does not provide the full error. A Monte Carlo study shows that it is a reasonable approximation to rescale the bin error by suitable factors. These factors are different for each distribution and the factors for the δ -pieces are bigger than those for the continuum parts. The follows factors are for the `slow` parameter set.

```

82c  <Fixup errors 82c>≡
        call fixerr (NDATA, dfec, 20d0, 30d0, 40d0)

      integer ndof
```

The error on the luminosity is just the (possibly rescaled) counting error:

```
87c <Write output (v1) 86a>+≡
      open (10, file = 'Errors.tex')
      write (10, 1099) tee / 1d32, dtee / 1d32, dtee / 1d32
1099 format ('$ ', F8.2, '_{- ', F4.2, '}^{+ ', F4.2, '} $')
```

After retrieving the error from MINUIT, we have to take care of the mapping of the parameters

$$a'_{1/4} = e^{a_{1/4}} B(a_{2/5} + 1, a_{3/6} + 1) N_{\text{bins}} \eta^{-1} \implies \delta a'_{1/4} = a'_{1/4} \delta a_{1/4} \quad (42)$$

ignoring the errors in the integral (i.e. the Beta function).

```
87d <Write output (v1) 86a>+≡
      call mnerrs (1, eplus, eminus, epara, corr)
      ab = a1(1) * beta(a1(2)+1d0, a1(3)+1d0)
      write (10, 1100) ab, abs (ab*eminus), abs (ab*eplus)
1100 format ('$ ', F8.4, '_{- ', F6.4, '}^{+ ', F6.4, '} $')
```

Uses beta 90a.

```
87e <Local variables for fct (v1) 81b>+≡
      double precision ab
```

The other mappings are even more trivial:

$$a'_{2/6} = a_{2/6} - 1 + \eta^{-1} \implies \delta a'_{2/6} = \delta a_{2/6} \quad a'_{3/5} = a_{3/5} - 1 + \eta^{-1} \implies \delta a'_{3/5} = \delta a_{3/5} \quad (43)$$

```
87f <Write output (v1) 86a>+≡
      do 110 i = 2, 3
        call mnerrs (i, eplus, eminus, epara, corr)
        write (10, 1100) a1(i), abs (eminus), abs (eplus)
110      continue
      call mnerrs (4, eplus, eminus, epara, corr)
      ab = a1(4) * beta(a1(5)+1d0, a1(6)+1d0)
      write (10, 1100) ab, abs (ab*eminus), abs (ab*eplus)
      do 111 i = 5, 6
        call mnerrs (i, eplus, eminus, epara, corr)
```

```

        write (10, 1100) a1(i), abs (eminus), abs (eplus)
111  continue
        close (10)
Uses beta 90a.
88a  <Local variables for fct (v1) 81b>+≡
        double precision eplus, eminus, epara, corr
        integer n
88b  <Write output (v1) 86a>+≡
        do 30 n = 1, 10
            call pslice ('ee', 'x', n, NDATA, xee, fee, dfec, phie, phie, a)

7.3 Version 2

8 Conclusions

I have presented a library of simple parameterizations of realistic e^\pm - and γ -beam spectra at future linear e^+e^- -colliders. The library can be used for integration and event generation. Emphasis is put on simplicity and reproducibility of the parameterizations for supporting reproducible physics simulations.

Acknowledgements

Daniel Schulte made his simulation code **Guinea-Pig** available and answered questions. Harald Anlauf and Torbjörn Sjöstrand have contributed useful suggestions. The Tesla group at DESY/Zeuthen made error estimates feasible by donating time on the multi-headed number cruncher **Hydra**. The 1996

ECFA/Desy Linear Collider Workshop got me started and provided support.
Thanks to all of them.

A Literate Programming

A.1 Paradigm

I have presented the sample code in this paper using the *literate programming* paradigm. This paradigm has been introduced by Donald Knuth [19] and his programs `TEX` [20] and `METAFONT` [21] provide excellent examples of the virtues of literate programming. Knuth summarized his intention as follows ([19], p. 99)

“Let us change our traditional attitude to the construction of programs. Instead of imagining that our main task is to instruct a *computer* what to do, let us concentrate rather on explaining to *human beings* what we want a computer to do.”

Usually, literate programming uses two utility programs to produce two kinds of files from the source

`tangle` produces the computer program that is acceptable to an “illiterate” (Fortran, C, etc.) compiler. This process consists of stripping documentation and reordering code. Therefore it frees the author from having to present the code in the particular order enforced by a compiler for purely technical reasons. Instead, the author can present the code in the order that is most comprehensible.

`weave` produces a documents that describes the program. Extensive cross referencing of the code sections is usually provided, which has been suppressed in this paper. If a powerful typesetting system (such a `TEX`) is used, the document can present the algorithms in clear mathematical notation alongside the code. These features improve readability and maintainability of scientific code immensely.

A.2 Practice

`Circe` uses the `noweb` [22] system. This system has the advantage to work with any traditional programming language and support the essential features described in section A.1 with minimal effort. `noweb`’s `tangle` program only reorders the code sections, but does not reformat them. Therefore its output can be used just like any other “illiterate” program.

The examples above should be almost self-explaining, but in order to avoid any ambiguities, I give another example:

107a `<Literate programming example 107a>≡`
 `<Code that has to be at the top 107c>`
 `<Other code 107b>`

I can start the presentation with the first line of the “other code”:

107b `<Other code 107b>≡`
 `line 1 of the other code`

If appropriate, the first line of the code that has to appear *before* the other code can be presented later:

107c `<Code that has to be at the top 107c>≡`
 `line 1 of the code at the top`

Now I can augment the sections:

```
108a  <Other code 107b>+≡  
      line 2 of the other code  
108b  <Code that has to be at the top 107c>+≡  
      line 2 of the code at the top
```

The complete “program” will be presented to the compiler as

```
line 1 of the code at the top  
line 2 of the code at the top  
line 1 of the other code  
line 2 of the other code
```

The examples in section 3.1.1 show that this reordering is particularly useful for declaring variables when they are first used (rather than at the beginning) and for zooming in on code inside of loops.

B Fortran Name Space

In addition to the ten procedures and one `common` block discussed in section 3

- `circe`, `circee`, `circeg`, `circgg`,
- `girce`, `gircee`, `girceg`, `gircgg`,
- `circes`, `circel`, `/circom/`,

there are two more globally visible functions which are used internally:

- `circem`: error message handler,
- `girceb`: efficient Beta distribution generator.

Even if the `/circom/` is globally visible, application programs *must not* manipulate it directly. The `circes` subroutine is provided for this purpose and updates some internal parameters as well.

With features from the current Fortran standard (Fortran90), I could have kept the last two functions and the `common` block private. But since Fortran90 has only been adopted by a small fraction of the high energy physics community, I have decided to remain in the confines of Fortran77 (except for the ubiquitous `implicit none`).

Application programs wishing to remain compatible with future versions of `Circe` must not use `common` blocks or procedures starting with `circe` or `girce`.

C Updates

Information about updates can be obtained

- on the World Wide Web:
<http://crunch.ikp.physik.th-darmstadt.de/nlc/beam.html>
- by internet FTP:

host: crunch.ikp.physik.th-darmstadt.de

user: anonymous

password: your email address

directory: pub/ohl/circe

- from mailing lists:
