INTRODUCTION

1.1 Complexity

There are

$$P(n) = \frac{2^n - 2}{2} - n = 2^{n-1} - n - 1 \quad (1.1)$$

independent internal momenta in a n -particle scattering amplitude [1]. This grows much slower than the number

$$F(n) = (2n - 5)!! = (2n - 5) \cdot (2n - 7) \cdot \dots \cdot 3 \cdot 1 \quad (1.2)$$

of tree Feynman diagrams in vanilla ϕ^3 (see table 1.1). There are no known corresponding expressions for theories with more than one particle type. However, empirical evidence from numerical studies [1, 2] as well as explicit counting results from O’Mega suggest

$$P^*(n) \propto 10^{n/2} \quad (1.3)$$

while the factorial growth of the number of Feynman diagrams remains unchecked, of course.

n	$P(n)$	$F(n)$
4	3	3
5	10	15
6	25	105
7	56	945
8	119	10395
9	246	135135
10	501	2027025
11	1012	34459425
12	2035	654729075
13	4082	13749310575
14	8177	316234143225
15	16368	7905853580625
16	32751	213458046676875

Table 1.1: The number of ϕ^3 Feynman diagrams $F(n)$ and independent poles $P(n)$.

The number of independent momenta in an amplitude is a better measure for the complexity of the amplitude than the number of Feynman diagrams, since there can be substantial cancellations among the latter. Therefore it should be possible to express the scattering amplitude more compactly than by a sum over Feynman diagrams.

1.2 Ancestors

Some of the ideas that O’Mega is based on can be traced back to HELAS [5]. HELAS builds Feynman amplitudes by recursively forming off-shell ‘wave functions’ from joining external lines with other external lines or off-shell ‘wave functions’.

The program Madgraph [6] automatically generates Feynman diagrams and writes a Fortran program corresponding to their sum. The amplitudes are calculated by calls to HELAS [5]. Madgraph uses one straightforward optimization: no statement is written more than once. Since each statement corresponds to a collection of trees, this optimization is very effective for up to four particles in the final state. However, since the amplitudes are given as a sum of Feynman diagrams, this optimization can, by design, *not* remove the factorial growth and is substantially weaker than the algorithms of [1, 2] and the algorithm of O’Mega for more particles in the final state.

Then ALPHA [1] (see also the slightly modified variant [2]) provided a numerical algorithm for calculating scattering amplitudes and it could be shown empirically, that the calculational costs are rising with a power instead of factorially.

1.3 Architecture

1.3.1 General purpose libraries

Functions that are not specific to O’Mega and could be part of the O’Caml standard library

ThoList : (mostly) simple convenience functions for lists that are missing from the standard library module *List* (section G, p. 643)

Product : efficient tensor products for lists and sets (section L, p. 676)

Combinatorics : combinatorical formulae, sets of subsets, etc. (section O, p. 687)

1.3.2 O’Mega

The non-trivial algorithms that constitute O’Mega:

DAG : Directed Acyclical Graphs (section 4, p. 37)

Topology : unusual enumerations of unflavored tree diagrams (section 3, p. 20)

Momentum : finite sums of external momenta (section 5, p. 52)

Figure 1.1: Module dependencies in O’Mega.

Fusion : off shell wave functions (section 8, p. 90)

Omega : functor constructing an application from a model and a target
(section 18, p. 614)

1.3.3 Abstract interfaces

The domains and co-domains of functors (section 9, p. 135)

Coupling : all possible couplings (not comprehensive yet)

Model : physical models

Target : target programming languages

1.3.4 Models

(section 13, p. 216)

Modellib_SM.QED : Quantum Electrodynamics

Modellib_SM.QCD : Quantum Chromodynamics (not complete yet)

Modellib_SM.SM : Minimal Standard Model (not complete yet)

etc.

1.3.5 Targets

Any programming language that supports arithmetic and a textual representation of programs can be targeted by O’Caml. The implementations translate the abstract expressions derived by *Fusion* to expressions in the target (section 15, p. 516).

Targets.Fortran : Fortran95 language implementation, calling subroutines

Other targets could come in the future: C, C++, O’Caml itself, symbolic manipulation languages, etc.

1.3.6 Applications

(section 18, p. 614)

1.4 The Big To Do Lists

1.4.1 Required

All features required for leading order physics applications are in place.

1.4.2 Useful

1. select allowed helicity combinations for massless fermions
2. Weyl-Van der Waerden spinors
3. speed up helicity sums by using discrete symmetries
4. general triple and quartic vector couplings
5. diagnostics: count corresponding Feynman diagrams more efficiently for more than ten external lines
6. recognize potential cascade decays (τ , b , etc.)
 - warn the user to add additional
 - kill fusions (at runtime), that contribute to a cascade
7. complete standard model in R_ξ -gauge
8. groves (the simple method of cloned generations works)

1.4.3 Future Features

1. investigate if unpolarized squared matrix elements can be calculated faster as traces of density matrices. Unfortunately, the answer appears to be *no* for fermions and *up to a constant factor* for massive vectors. Since the number of fusions in the amplitude grows like $10^{n/2}$, the number of fusions in the squared matrix element grows like 10^n . On the other hand, there are $2^{\text{\#fermions} + \text{\#massless vectors}}$ terms in the helicity sum, which grows *slower* than $10^{n/2}$. The constant factor is probably also not favorable. However, there will certainly be asymptotic gains for sums over gauge (and other) multiplets, like color sums.
2. compile Feynman rules from Lagrangians
3. evaluate amplitudes in O'Caml by compiling it to three address code for a virtual machine

```

type mem = scalar array × spinor array × spinor array × vector array
type instr =
  — VSS of int × int × int
  — SVS of int × int × int
  — AVA of int × int × int
  ...

```

this could be as fast as [1] or [2].

4. a virtual machine will be useful for other target as well, because native code appears to become too large for most compilers for more than ten external particles. Bytecode might even be faster due to improved cache locality.
5. use the virtual machine in O'Giga

1.4.4 Science Fiction

1. numerical and symbolical loop calculations with O'TERA: O'MEGA TOOL
FOR EVALUATING RENORMALIZED AMPLITUDES

—2—

TUPLES AND POLYTUPLES

2.1 Interface of Tuple

The *Tuple.Poly* interface abstracts the notion of tuples with variable arity. Simple cases are binary polytuples, which are simply pairs and indefinite polytuples, which are nothing but lists. Another example is the union of pairs and triples. The interface is very similar to *List* from the O’Caml standard library, but the *Tuple.Poly* signature allows a more fine grained control of arities. The latter provides typesafe linking of models, targets and topologies.

```
module type Mono =
sig
  type  $\alpha$  t

  val arity :  $\alpha$  t  $\rightarrow$  int
  val max_arity : int

  val compare : ( $\alpha \rightarrow \alpha \rightarrow$  int)  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\alpha$  t  $\rightarrow$  int

  val for_all : ( $\alpha \rightarrow$  bool)  $\rightarrow$   $\alpha$  t  $\rightarrow$  bool

  val map : ( $\alpha \rightarrow \beta$ )  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\beta$  t
  val iter : ( $\alpha \rightarrow$  unit)  $\rightarrow$   $\alpha$  t  $\rightarrow$  unit
  val fold_left : ( $\alpha \rightarrow \beta \rightarrow \alpha$ )  $\rightarrow$   $\alpha \rightarrow \beta$  t  $\rightarrow$   $\alpha$ 
  val fold_right : ( $\alpha \rightarrow \beta \rightarrow \beta$ )  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\beta \rightarrow \beta$ 
```

We have applications, where no sensible initial value can be defined:

```
val fold_left_internal : ( $\alpha \rightarrow \alpha \rightarrow \alpha$ )  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\alpha$ 
val fold_right_internal : ( $\alpha \rightarrow \alpha \rightarrow \alpha$ )  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\alpha$ 

val map2 : ( $\alpha \rightarrow \beta \rightarrow \gamma$ )  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\beta$  t  $\rightarrow$   $\gamma$  t

val split : ( $\alpha \times \beta$ ) t  $\rightarrow$   $\alpha$  t  $\times$   $\beta$  t
```

The distributive tensor product expands a tuple of lists into list of tuples, e. g. for binary tuples:

$$\text{product}([x_1; x_2], [y_1; y_2]) = [(x_1, y_1); (x_1, y_2); (x_2, y_1); (x_2, y_2)] \quad (2.1)$$

NB: *product_fold* is usually much more memory efficient than the combination of *product* and *List.fold_right* for large sets.

```
val product :  $\alpha$  list t  $\rightarrow$   $\alpha$  t list
```

```
val product_fold : (α t → β → β) → α list t → β → β
```

For homogeneous tuples the *power* function could trivially be built from *product*, e. g.:

$$power [x_1; x_2] = product ([x_1; x_2], [x_1; x_2]) = [(x_1, x_1); (x_1, x_2); (x_2, x_1); (x_2, x_2)] \quad (2.2)$$

but it is also well defined for polytuples, e. g. for pairs and triples

$$power [x_1; x_2] = product ([x_1; x_2], [x_1; x_2]) \cup product ([x_1; x_2], [x_1; x_2], [x_1; x_2]) \quad (2.3)$$

For tuples and polytuples with bounded arity, the *power* and *power_fold* functions terminate. In polytuples with unbounded arity, the *power* function always raises *No_termination*. *power_fold* also raises *No_termination*, but could be changed to run until the argument function raises an exception. However, if we need this behaviour, we should implemente *power_iter* instead.

```
val power : α list → α t list
val power_fold : (α t → β → β) → α list → β → β
```

We can also identify all (poly)tuples with permuted elements and return only one representative, e. g.:

$$sym_power [x_1; x_2] = [(x_1, x_1); (x_1, x_2); (x_2, x_2)] \quad (2.4)$$

NB: this function has not yet been implemented, because O'Mega only needs the more efficient special case *graded_sym_power*.

If a set X is graded (i. e. there is a map $\phi : X \rightarrow \mathbf{N}$, called *rank* below), the results of *power* or *sym_power* can canonically be filtered by requiring that the sum of the ranks in each (poly)tuple has one chosen value. Implementing such a function directly is much more efficient than constructing and subsequently disregarding many (poly)tuples. The elements of rank n are at offset $(n - 1)$ in the array. The array is assumed to be *immutable*, even if O'Cam1 doesn't support immutable arrays. NB: *graded_power* has not yet been implemented, because O'Mega only needs *graded_sym_power*.

```
type α graded = α list array
val graded_sym_power : int → α graded → α t list
val graded_sym_power_fold : int → (α t → β → β) → α graded →
  β → β
```

We hope to be able to avoid the next one in the long run, because it mildly breaks typesafety for arities. Unfortunately, we're still working on it ...

```
val to_list : α t → α list
```

The next one is only used for Fermi statistics below, but can not be implemented if there are no binary tuples. It must be retired as soon as possible.

```
val of2_kludge : α → α → α t
```

```

    val rcs : RCS.t
  end

module type Poly =

2.2.1 Typesafe Combinatorics

Wrap the combinatorial functions with varying arities into typesafe functions with fixed arities. We could provide specialized implementations, but since we *know* that *Impossible* is *never* raised, the present approach is just as good (except for a tiny inefficiency).

```

exception Impossible of string
let impossible name = raise (Impossible name)

let choose2 set =
  List.map (function [x; y]  $\rightarrow (x, y) \mid - \rightarrow impossible\ "choose2"$ )
    (Combinatorics.choose 2 set)

let choose3 set =
  List.map (function [x; y; z]  $\rightarrow (x, y, z) \mid - \rightarrow impossible\ "choose3"$ )
    (Combinatorics.choose 3 set)

```

2.2.2 Pairs

```

module type Binary =
sig
  sig
    include Poly (* should become Mono! *)
    val of2 :  $\alpha \rightarrow \alpha \rightarrow \alpha\ t$ 
  end
end

module Binary =

```

```

struct
  let rcs = RCS.rename rcs_file "Tuple.Binary" ["Pairs"]

  type  $\alpha$  t =  $\alpha \times \alpha$ 

  let arity _ = 2
  let max_arity = 2

  let of2 x y = (x, y)

  let compare cmp (x1, y1) (x2, y2) =

TOPOLOGIES

3.1 Interface of Topology

module type $T =$
 sig

partition is a collection of integers, with arity one larger than the arity of α *children* below. These arities can one fixed number corresponding to homogeneous tuples or a collection of tuples or lists.

type *partition*

partitions n returns the union of all $[n_1; n_2; \dots; n_d]$ with $1 \leq n_1 \leq n_2 \leq \dots \leq n_d \leq \lfloor n/2 \rfloor$ and

$$\sum_{i=1}^d n_i = n \quad (3.1)$$

for d from 3 to d_{\max} , where d_{\max} is a fixed number for each module implementing T . In particular, if `type partition = int × int × int`, then *partitions* n returns all (n_1, n_2, n_3) with $n_1 \leq n_2 \leq n_3$ and $n_1 + n_2 + n_3 = n$.

val *partitions* : int → partition list

A (poly)tuple as implemented by the modules in *Tuple*:

type α *children*

keystones externals returns all keystones for the amplitude with external states *externals* in the vanilla scalar theory with a

$$\sum_{3 \leq k \leq d_{\max}} \lambda_k \phi^k \quad (3.2)$$

interaction. One factor of the products is factorized. In particular, if

$$\text{type } \alpha \text{ children} = \alpha \text{ Tuple.Binary.t} = \alpha \times \alpha,$$

then *keystones externals* returns all keystones for the amplitude with external states *externals* in the vanilla scalar $\lambda\phi^3$ -theory.

val *keystones* : α list → (α list × α list children list) list

The maximal depth of subtrees for a given number of external lines.

```
val max_subtree : int → int
```

Only for diagnostics:

```
val inspect_partition : partition → int list
val rcs : RCS.t
```

```
end
```

```
module Binary : T with type α children = α Tuple.Binary.t
module Ternary : T with type α children = α Tuple.Ternary.t
module Mixed23 : T with type α children = α Tuple.Mixed23.t
module Nary : functor (B : Tuple.Bound) →
  (T with type α children = α Tuple.Nary(B).t)
```

3.1.1 Diagnostics: Counting Diagrams and Factorizations for $\sum_n \lambda_n \phi^n$

The number of diagrams for many particles can easily exceed the range of native integers. Even if we can not calculate the corresponding amplitudes, we want to check combinatorial factors. Therefore we code a functor that can use arbitrary implementations of integers.

```
module type Integer =
sig
  type t
  val zero : t
  val one : t
  val ( + ) : t → t → t
  val ( - ) : t → t → t
  val ( × ) : t → t → t
  val ( / ) : t → t → t
  val pred : t → t
  val succ : t → t
  val ( = ) : t → t → bool
  val ( ≠ ) : t → t → bool
  val ( < ) : t → t → bool
  val ( ≤ ) : t → t → bool
  val ( > ) : t → t → bool
  val ( ≥ ) : t → t → bool
  val of_int : int → t
  val to_int : t → int
  val to_string : t → string
  val compare : t → t → int
  val factorial : t → t
end
```

Of course, native integers will provide the fastest implementation:

```
module Int : Integer
```

```
module type Count =
```

```
sig
```

type *integer*

diagrams f d n returns the number of tree diagrams contributing to the n -point amplitude in vanilla scalar theory with

$$\sum_{3 \leq k \leq d \wedge f(k)} \lambda_k \phi^k \quad (3.3)$$

interaction. The default value of f returns **true** for all arguments.

val *diagrams* : ? $f : (integer \rightarrow bool) \rightarrow integer \rightarrow integer \rightarrow integer$
val *diagrams_via_keystones* : $integer \rightarrow integer \rightarrow integer$

$$\frac{1}{S(n_k, n - n_k)} \frac{1}{S(n_1, n_2, \dots, n_k)} \binom{n_1 + n_2 + \dots + n_k}{n_1, n_2, \dots, n_k} \quad (3.4)$$

val *keystones* : $integer\ list \rightarrow integer$

diagrams_via_keystones d n must produce the same results as *diagrams d n*. This is shown explicitly in tables 3.2, 3.3 and 3.4 for small values of d and n . The test program in appendix S can be used to verify this relation for larger values.

val *diagrams_per_keystone* : $integer \rightarrow integer\ list \rightarrow integer$

end

module *Count* : functor ($I : Integer$) $\rightarrow Count$ with type *integer* = $I.t$

3.1.2 Emulating HELAC

We can also proceed á la [2].

module *Helac* : functor ($B : Tuple.Bound$) \rightarrow
(T with type $\alpha\ children = \alpha\ Tuple.Nary(B).t$)

The following has never been tested, but it is no rocket science and should work anyway ...

module *Helac_Binary* : T with type $\alpha\ children = \alpha\ Tuple.Binary.t$

Table 3.1: $partitions\ n$ for moderate values of n .

```

module type  $T$  =
  sig
    type  $partition$ 
    val  $partitions$  :  $int \rightarrow partition\ list$ 
    type  $\alpha\ children$ 
    val  $keystones$  :  $\alpha\ list \rightarrow (\alpha\ list \times \alpha\ list\ children\ list)\ list$ 
    val  $max\_subtree$  :  $int \rightarrow int$ 
    val  $inspect\_partition$  :  $partition \rightarrow int\ list$ 
    val  $rct$  :  $RCS.t$ 
  end

```

3.2.1 Factorizing Diagrams for ϕ^3

```

module  $Binary$  =
  struct
    let  $rct$  =  $RCS.rename\ rct\_file\ "Topology.Binary"$ 
      ["phi**3_⊔topology"]

    type  $partition$  =  $int \times int \times int$ 
    let  $inspect\_partition\ (n1,\ n2,\ n3)$  = [ $n1$ ;  $n2$ ;  $n3$ ]
  end

```

One way [1] to lift the degeneracy is to select the vertex that is closest to the center (see table 3.1):

$$partitions : n \rightarrow \{(n_1, n_2, n_3) \mid n_1 + n_2 + n_3 = n \wedge n_1 \leq n_2 \leq n_3 \leq \lfloor n/2 \rfloor\} \quad (3.5)$$

Other, less symmetric, approaches are possible. The simplest of these is: choose the vertex adjacent to a fixed external line [2]. They will be made available for comparison in the future.

An obvious consequence of $n_1 + n_2 + n_3 = n$ and $n_1 \leq n_2 \leq n_3$ is $n_1 \leq \lfloor n/3 \rfloor$:

Figure 3.1: Topologies with a blatant three-fold permutation symmetry, if the number of external lines is a multiple of three

Figure 3.2: Topologies with a blatant two-fold symmetry.

```

let rec partitions' n n1 =
  if n1 > n / 3 then
    []
  else
    List.map (fun (n2, n3) → (n1, n2, n3))
      (Partition.pairs (n - n1) n1 (n / 2)) @ partitions' n (succ n1)
let partitions n = partitions' n 1
    
```

```

type α children = α Tuple.Binary.t
    
```

There remains one peculiar case, when the number of external lines is even and $n_3 = n_1 + n_2$ (cf. figure 3.3). Unfortunately, this reflection symmetry is not respected by the equivalence classes. E. g.

$$\{1\}\{2,3\}\{4,5,6\} \mapsto \{\{4\}\{5,6\}\{1,2,3\}; \{5\}\{4,6\}\{1,2,3\}; \{6\}\{4,5\}\{1,2,3\}\} \quad (3.6)$$

Figure 3.3: If $n_3 = n_1 + n_2$, the apparently asymmetric topologies on the left hand side have a non obvious two-fold symmetry, that exchanges the two halves. Therefore, the topologies on the right hand side have a four fold symmetry.

n	$(2n - 5)!!$	$\sum N(n_1, n_2, n_3)$
4	3	$3 \cdot (1, 1, 2)$
5	15	$15 \cdot (1, 2, 2)$
6	105	$90 \cdot (1, 2, 3) + 15 \cdot (2, 2, 2)$
7	945	$630 \cdot (1, 3, 3) + 315 \cdot (2, 2, 3)$
8	10395	$6300 \cdot (1, 3, 4) + 1575 \cdot (2, 2, 4) + 2520 \cdot (2, 3, 3)$
9	135135	$70875 \cdot (1, 4, 4) + 56700 \cdot (2, 3, 4) + 7560 \cdot (3, 3, 3)$
10	2027025	$992250 \cdot (1, 4, 5) + 396900 \cdot (2, 3, 5)$ $+ 354375 \cdot (2, 4, 4) + 283500 \cdot (3, 3, 4)$
11	34459425	$15280650 \cdot (1, 5, 5) + 10914750 \cdot (2, 4, 5)$ $+ 4365900 \cdot (3, 3, 5) + 3898125 \cdot (3, 4, 4)$
12	654729075	$275051700 \cdot (1, 5, 6) + 98232750 \cdot (2, 4, 6)$ $+ 91683900 \cdot (2, 5, 5) + 39293100 \cdot (3, 3, 6)$ $+ 130977000 \cdot (3, 4, 5) + 19490625 \cdot (4, 4, 4)$

Table 3.2: Equation (3.9) for small values of n .

However, these reflections will always exchange the two halves and a representative can be chosen by requiring that one fixed momentum remains in one half. We choose to filter out the half of the partitions where the element p appears in the second half, i.e. the list of length $n\beta$.

Finally, a closed expression for the number of Feynman diagrams in the equivalence class (n_1, n_2, n_3) is

$$N(n_1, n_2, n_3) = \frac{(n_1 + n_2 + n_3)!}{S(n_1, n_2, n_3)} \prod_{i=1}^3 \frac{(2n_i - 3)!!}{n_i!} \quad (3.7)$$

where the symmetry factor from the above arguments is

$$S(n_1, n_2, n_3) = \begin{cases} 3! & \text{for } n_1 = n_2 = n_3 \\ 2 \cdot 2 & \text{for } n_3 = 2n_1 = 2n_2 \\ 2 & \text{for } n_1 = n_2 \vee n_2 = n_3 \\ 2 & \text{for } n_1 + n_2 = n_3 \end{cases} \quad (3.8)$$

Indeed, the sum of all Feynman diagrams

$$\sum_{\substack{n_1+n_2+n_3=n \\ 1 \leq n_1 \leq n_2 \leq n_3 \leq \lfloor n/2 \rfloor}} N(n_1, n_2, n_3) = (2n - 5)!! \quad (3.9)$$

can be checked numerically for large values of $n = n_1 + n_2 + n_3$, verifying the symmetry factor (see table 3.2).

P. M. claims to have seen similar formulae in the context of Young tableaux. That's a good occasion to read the new edition of Howard's book ...

Return a list of all inequivalent partitions of the list l in three lists of length $n1$, $n2$ and $n3$, respectively. Common first lists are factored. This is nothing more than a typedafe wrapper around *Combinatorics.factorized_keystones*.

Figure 3.4: Degenerate (1, 1, 1, 3) and (1, 2, 3).

```

exception Impossible of string
let tuple_of_list2 = function

    | P4 (n1, n2, n3, n4) → [n1; n2; n3; n4]
type α children = α Tuple.Mixed23.t
let collect34 acc = function
    | [x; y; z] → P3 (x, y, z) :: acc
    | [x; y; z; u] → P4 (x, y, z, u) :: acc
    | _ → acc
let partitions n =
    List.fold_left collect34 [] (Nary4.partitions n)
let collect23 acc = function
    | [x; y] → Tuple.Mixed23.of2 x y :: acc
    | [x; y; z] → Tuple.Mixed23.of3 x y z :: acc
    | _ → acc
let keystones l =
    List.map (fun (bra, kets) → (bra, List.fold_left collect23 [] kets))
            (Nary4.keystones' l)
let max_subtree = Nary4.max_subtree
end

```

3.2.5 Diagnostics: Counting Diagrams and Factorizations for $\sum_n \lambda_n \phi^n$

```

module type Integer =
sig
  type t
  val zero : t
  val one : t
  val ( + ) : t → t → t
  val ( - ) : t → t → t
  val ( × ) : t → t → t
  val ( / ) : t → t → t
  val pred : t → t
  val succ : t → t
  val ( = ) : t → t → bool
  val ( ≠ ) : t → t → bool
  val ( < ) : t → t → bool
  val ( ≤ ) : t → t → bool
  val ( > ) : t → t → bool
  val ( ≥ ) : t → t → bool
  val of_int : int → t
  val to_int : t → int
  val to_string : t → string
  val compare : t → t → int
  val factorial : t → t
end

```

O’Caml’s native integers suffice for all applications, but in appendix S, we want to use big integers for numeric checks in high orders:

```

module Int : Integer =
  struct
    type t = int
    let zero = 0
    let one = 1
    let ( + ) = ( + )
    let ( - ) = ( - )
    let ( × ) = ( × )
    let ( / ) = ( / )
    let pred = pred
    let succ = succ
    let ( = ) = ( = )
    let ( ≠ ) = ( ≠ )
    let ( < ) = ( < )
    let ( ≤ ) = ( ≤ )
    let ( > ) = ( > )
    let ( ≥ ) = ( ≥ )
    let of_int n = n
    let to_int n = n
    let to_string = string_of_int
    let compare = compare
    let factorial = Combinatorics.factorial
  end

module type Count =
  sig
    type integer
    val diagrams : ?f:(integer → bool) → integer → integer → integer
    val diagrams_via_keystones : integer → integer → integer
    val keystones : integer list → integer
    val diagrams_per_keystone : integer → integer list → integer
  end

module Count (I : Integer) =
  struct
    let rcs = rcs_file
    let description = ["(still_inoperational)_phi^n_topology"]

    type integer = I.t
    open I
    let two = of_int 2
    let three = of_int 3
  end

```

If *I.t* is an abstract datatype, the polymorphic *Pervasives.min* can fail. Provide our own version using the specific comparison “(\leq)”.

```

let min x y =
  if x ≤ y then
    x
  else

```

y

Counting Diagrams for $\sum_n \lambda_n \phi^n$

Classes of diagrams are defined by the number of vertices and their degrees. We could use fixed size arrays, but we will use a map instead. For efficiency, we also maintain the number of external lines and the total number of propagators.

```
module IMap = Map.Make (struct type t = integer let compare = compare end)

type diagram_class = { ext : integer; prop : integer; v : integer IMap.t }
```

The numbers of external lines, propagators and vertices are determined by the degrees and multiplicities of vertices:

$$E(\{n_3, n_4, \dots\}) = 2 + \sum_{d=3}^{\infty} (d-2)n_d \quad (3.10a)$$

$$P(\{n_3, n_4, \dots\}) = \sum_{d=3}^{\infty} n_d - 1 = V(\{n_3, n_4, \dots\}) - 1 \quad (3.10b)$$

$$V(\{n_3, n_4, \dots\}) = \sum_{d=3}^{\infty} n_d \quad (3.10c)$$

```
let num_ext v =
  List.fold_left (fun sum (d, n) → sum + (d - two) × n) two v

let num_prop v =
  List.fold_left (fun sum (_, n) → sum + n) (zero - one) v
```

The sum of all vertex degrees must be equal to the number of propagator end points. This can be verified easily:

$$2P(\{n_3, n_4, \dots\}) + E(\{n_3, n_4, \dots\}) = \sum_{d=3}^{\infty} dn_d \quad (3.11)$$

```
let add_degree map (d, n) =
  if d < three then
    invalid_arg "add_degree: d < 3"
  else if n < zero then
    invalid_arg "add_degree: n <= 0"
  else if n = zero then
    map
  else
    IMap.add d n map

let create_class v =
  { ext = num_ext v;
    prop = num_prop v;
    v = List.fold_left add_degree IMap.empty v }

let multiplicity cl d =
```

```

if  $d \geq three$  then
  try
     $IMap.find\ d\ cl.v$ 
  with
    |  $Not\_found \rightarrow zero$ 
  else
     $invalid\_arg\ "multiplicity:\_d\<\_3"$ 

```

Remove one vertex of degree d , maintaining the invariants. Raises *Zero* if all vertices of degree d are exhausted.

```

exception Zero

let remove  $cl\ d =$ 
  let  $n = pred\ (multiplicity\ cl\ d)$  in
  if  $n < zero$  then
    raise Zero
  else
    {  $ext = cl.ext - (d - two)$ ;
       $prop = pred\ cl.prop$ ;
       $v = if\ n = zero\ then$ 
         $IMap.remove\ d\ cl.v$ 
      else
         $IMap.add\ d\ n\ cl.v$  }

```

Add one vertex of degree d , maintaining the invariants.

```

let add  $cl\ d =$ 
  {  $ext = cl.ext + (d - two)$ ;
     $prop = succ\ cl.prop$ ;
     $v = IMap.add\ d\ (succ\ (multiplicity\ cl\ d))\ cl.v$  }

```

Count the number of diagrams. Any diagram can be obtained recursively either from a diagram with one ternary vertex less by insertion of a ternary vertex in an internal or external propagator or from a diagram with a higher order vertex that has its degree reduced by one:

$$\begin{aligned}
D(\{n_3, n_4, \dots\}) = & \\
& (P(\{n_3 - 1, n_4, \dots\}) + E(\{n_3 - 1, n_4, \dots\})) D(\{n_3 - 1, n_4, \dots\}) \\
& + \sum_{d=4}^{\infty} (n_{d-1} + 1) D(\{n_3, n_4, \dots, n_{d-1} + 1, n_d - 1, \dots\}) \quad (3.12)
\end{aligned}$$

```

let rec class_size  $cl =$ 
  if  $cl.ext = two \vee cl.prop = zero$  then
    one
  else
     $IMap.fold\ (fun\ d\ _\ s \rightarrow class\_size\_n\ cl\ d + s)\ cl.v\ (class\_size\_3\ cl)$ 

```

Purely ternary vertices recurse among themselves:

```

and class_size_3  $cl =$ 
  try
    let  $d' = remove\ cl\ three$  in

```

```

      (d'.ext + d'.prop) × class_size d'
with
| Zero → zero

```

Vertices of higher degree recurse one step towards lower degrees:

```

and class_size_n cl d =
  if d > three then begin
    try
      let d' = pred d in
      let cl' = add (remove cl d) d' in
      multiplicity cl' d' × class_size cl'
    with
    | Zero → zero
  end else
    zero

```

Find all $\{n_3, n_4, \dots, n_d\}$ with

$$E(\{n_3, n_4, \dots, n_d\}) - 2 = \sum_{i=3}^c l(i-2)n_i = \text{sum} \quad (3.13)$$

The implementation is a variant of *tuples* above.

```

let rec distribute_degrees' d sum =
  if d < three then
    invalid_arg "distribute_degrees"
  else if d = three then
    [[(d, sum)]]
  else
    distribute_degrees'' d sum (sum / (d - two))
and distribute_degrees'' d sum n =
  if n < zero then
    []
  else
    List.fold_left (fun ll l → ((d, n) :: l) :: ll)
      (distribute_degrees'' d sum (pred n))
      (distribute_degrees' (pred d) (sum - (d - two) × n))

```

Actually, we need to find all $\{n_3, n_4, \dots, n_d\}$ with

$$E(\{n_3, n_4, \dots, n_d\}) = \text{sum} \quad (3.14)$$

```

let distribute_degrees d sum = distribute_degrees' d (sum - two)

```

Finally we can count all diagrams by adding all possible ways of splitting the degrees of vertices. We can also count diagrams where *all* degrees satisfy a predicate f :

```

let diagrams ?(f = fun _ → true) deg n =
  List.fold_left (fun s d →
    if List.for_all (fun (d', n') → f d' ∨ n' = zero) d then
      s + class_size (create_class d)

```

```

else
  s)
  zero (distribute_degrees deg n)

```

The next two are duplicated from *ThoList* and *Combinatorics*, in order to use the specific comparison functions.

```

let classify l =
  let rec add_to_class a = function
    | [] → [of_int 1, a]
    | (n, a') :: rest →
        if a = a' then
          (succ n, a) :: rest
        else
          (n, a') :: add_to_class a rest
  in
  let rec classify' cl = function
    | [] → cl
    | a :: rest → classify' (add_to_class a cl) rest
  in
  classify' [] l

let permutation_symmetry l =
  List.fold_left (fun s (n, _) → factorial n × s) one (classify l)

let symmetry l =
  let sum = List.fold_left (+) zero l in
  if List.exists (fun x → two × x = sum) l then
    two × permutation_symmetry l
  else
    permutation_symmetry l

```

The number of Feynman diagrams built of vertices with maximum degree d_{\max} in a partition $N_{d,n} = \{n_1, n_2, \dots, n_d\}$ with $n = n_1 + n_2 + \dots + n_d$ and

$$\tilde{F}(d_{\max}, N_{d,n}) = \frac{n!}{|\mathcal{S}(N_{d,n})|\sigma(n_d, n)} \prod_{i=1}^d \frac{F(d_{\max}, n_i + 1)}{n_i!} \quad (3.15)$$

with $|\mathcal{S}(N)|$ the size of the symmetric group of N , $\sigma(n, 2n) = 2$ and $\sigma(n, m) = 1$ otherwise.

```

let keystones p =
  let sum = List.fold_left (+) zero p in
  List.fold_left (fun acc n → acc / (factorial n)) (factorial sum) p
  / symmetry p

let diagrams_per_keystone deg p =
  List.fold_left (fun acc n → acc × diagrams deg (succ n)) one p

```

We must find

$$F(d_{\max}, n) = \sum_{d=3}^{d_{\max}} \sum_{\substack{N=\{n_1, n_2, \dots, n_d\} \\ n_1+n_2+\dots+n_d=n \\ 1 \leq n_1 \leq n_2 \leq \dots \leq n_d \leq \lfloor n/2 \rfloor}} \tilde{F}(d_{\max}, N) \quad (3.16)$$

```

let diagrams_via_keystones deg n =
  let module N = Nary (struct let max_arity = to_int (pred deg) end) in
  List.fold_left
    (fun acc p → acc + diagrams_per_keystone deg p × keystones p)
    zero (List.map (List.map of_int) (N.partitions (to_int n)))
end

```

3.2.6 Emulating HELAC

In [2], one leg is singled out:

```

module Helac (B : Tuple.Bound) =
struct
  let rcs = RCS.rename rcs_file "Topology.Helac"
    ["phi**n␣topology,␣Helac␣style"]
  module Tuple = Tuple.Nary(B)

  type partition = int list
  let inspect_partition p = p

  let partition d sum =
    Partition.tuples d sum 1 (sum - d + 1)

  let rec partitions' d sum =
    let d' = pred d in
    if d' < 2 then
      []
    else
      List.map (fun p → 1 :: p) (partition d' (pred sum)) @ partitions' d' sum

  let partitions sum = partitions' (succ B.max_arity) sum

  type α children = α Tuple.t

  let keystones' l =
    match l with
    | [] → []
    | head :: tail →
      [[head],
       ThoList.flatmap (fun p → Combinatorics.partitions (List.tl p) tail)
        (partitions (List.length l))]]

  let keystones l =
    List.map (fun (bra, kets) → (bra, List.map Tuple.of_list kets))
      (keystones' l)

  let max_subtree n = pred n
end

```

The following is not tested, but it is no rocket science either ...

```

module Helac_Binary =
struct
  let rcs = RCS.rename rcs_file "Topology.Helac_Binary"
    ["phi**3_topology, Helac_style"]

  type partition = int × int × int
  let inspect_partition (n1, n2, n3) = [n1; n2; n3]

  let partitions sum =
    List.map (fun (n2, n3) → (1, n2, n3))
      (Partition.pairs (sum - 1) 1 (sum - 2))

  type α children = α Tuple.Binary.t

  let keystones' l =
    match l with
    | [] → []
    | head :: tail →
      [[head],
        ThoList.flatmap (fun (_, p2, _) → Combinatorics.split p2 tail)
          (partitions (List.length l))]]

  let keystones l =
    List.map (fun (bra, kets) →
      (bra, List.map (fun (x, y) → Tuple.Binary.of2 x y) kets))
      (keystones' l)

  let max_subtree n = pred n
end

```

—4—

DIRECTED ACYCLICAL GRAPHS

4.1 Interface of DAG

This datastructure describes large collections of trees with many shared nodes. The sharing of nodes is semantically irrelevant, but can turn a factorial complexity to exponential complexity. Note that *DAG* implements only a very specialized subset of Directed Acyclical Graphs (DAGs).

If $T(n, D)$ denotes the set of all binary trees with root n encoded in D , while

$$O(n, D) = \{(e_1, n_1, n'_1), \dots, (e_k, n_k, n'_k)\} \quad (4.1)$$

denotes the set of all *offspring* of n in D , and $\text{tree}(e, t, t')$ denotes the binary tree formed by joining the binary trees t and t' with the label e , then

$$T(n, D) = \{\text{tree}(e_i, t_i, t'_i) \mid (e_i, t_i, t'_i) \in \{e_1\} \times T(n_1, D) \times T(n'_1, D) \cup \dots \cup \{e_k\} \times T(n_k, D) \times T(n'_k, D)\} \quad (4.2)$$

is the recursive definition of the binary trees encoded in D . It is obvious how this definitions translates to n -ary trees (including trees with mixed arity).

4.1.1 Forests

We require edges and nodes to be members of ordered sets. The semantics of *compare* are compatible with *Pervasives.compare*:

$$\text{compare}(x, y) = \begin{cases} -1 & \text{for } x < y \\ 0 & \text{for } x = y \\ 1 & \text{for } x > y \end{cases} \quad (4.3)$$

Note that this requirement does *not* exclude any trees. Even if we consider only topological equivalence classes with anonymous nodes, we can always construct a canonical labeling and order from the children of the nodes. However, if practical applications, we will often have more efficient labelings and orders at our disposal.

```
module type Ord =
  sig
    type t
```

```

    val compare : t → t → int
end

```

A forest F over a set of nodes and a set of edges is a map from the set of nodes N , to the direct product of the set of edges E and the power set 2^N of N augmented by a special element \perp (“bottom”).

$$F : N \rightarrow (E \times 2^N) \cup \{\perp\}$$

$$n \mapsto \begin{cases} (e, \{n'_1, n'_2, \dots\}) \\ \perp \end{cases} \quad (4.4)$$

The nodes are ordered so that cycles can be detected

$$\forall n \in N : F(n) = (e, x) \Rightarrow \forall n' \in x : n > n' \quad (4.5)$$

A suitable function that exists for *all* forests is the depth of the tree beneath a node.

Nodes that are mapped to \perp are called *leaf* nodes and nodes that do not appear in any $F(n)$ are called *root* nodes. There are as many trees in the forest as there are root nodes.

```

module type Forest =
sig
  module Nodes : Ord
  type node = Nodes.t
  type edge

```

A subset $X \subset 2^N$ of the powerset of the set of nodes. The members of X can be characterized by a fixed number of members (e.g. two for binary trees, as in QED). We can also have mixed arities (e.g. two and three for QCD) or even arbitrary arities. However, in most cases, the members of X will have at least two members.

```

type children

```

This type abbreviation and order allow to apply the *Set.Make* functor to $E \times X$.

```

type t = edge × children
val compare : t → t → int

```

Test a predicate for *all* children.

```

val for_all : (node → bool) → t → bool

```

fold f $(-, children)$ *acc* will calculate

$$f(x_1, f(x_2, \dots f(x_n, acc))) \quad (4.6)$$

where the *children* are $\{x_1, x_2, \dots, x_n\}$. There are slightly more efficient alternatives for fixed arity (in particular binary), but we want to be general.

```

val fold : (node → α → α) → t → α → α

```

```

end

```

```

module Forest : functor (PT : Tuple.Poly) →
functor (N : Ord) → functor (E : Ord) →
  Forest with module Nodes = N and type edge = E.t
  and type node = N.t and type children = N.t PT.t

```

4.1.2 DAGs

```

module type T =
  sig
    type node
    type edge

```

In the description of the function we assume for definiteness DAGs of binary trees with `type children = node × node`. However, we will also have implementations with `type children = node list` below.

Other possibilities include `type children = V3 of node × node | V4 of node × node × node`. There's probably never a need to use sets with logarithmic access, but it is easy to add.

```

    type children
    type t

```

The empty DAG.

```

    val empty : t

```

`add_node n dag` returns the DAG `dag` with the node `n`. If the node `n` already exists in `dag`, it is returned unchanged. Otherwise `n` is added without offspring.

```

    val add_node : node → t → t

```

`add_offspring n (e, (n1, n2)) dag` returns the DAG `dag` with the node `n` and its offspring `n1` and `n2` with edge label `e`. Each node can have an arbitrary number of offspring, but identical offspring are added only once. In order to prevent cycles, `add_offspring` requires both `n > n1` and `n > n2` in the given ordering. The nodes `n1` and `n2` are added as by `add_node`. NB: Adding all nodes `n1` and `n2`, even if they are sterile, is not strictly necessary for our applications. It even slows down the code by a few percent. But it is desirable for consistency and allows much more efficient `iter_nodes` and `fold_nodes` below.

```

    val add_offspring : node → edge × children → t → t
    exception Cycle

```

Just like `add_offspring`, but does not check for potential cycles.

```

    val add_offspring_unsafe : node → edge × children → t → t

```

`is_node n dag` returns true iff `n` is a node in `dag`.

```

    val is_node : node → t → bool

```

`is_sterile n dag` returns true iff `n` is a node in `dag` and boasts no offspring.

```

    val is_sterile : node → t → bool

```

`is_offspring n (e, (n1, n2)) dag` returns true iff `n1` and `n2` are offspring of `n` with label `e` in `dag`.

```

    val is_offspring : node → edge × children → t → bool

```

Note that the following functions can run into infinite recursion if the DAG given as argument contains cycles.

The usual functionals for processing all nodes (including sterile) ...

```

val iter_nodes : (node → unit) → t → unit
val map_nodes : (node → node) → t → t
val fold_nodes : (node → α → α) → t → α → α

```

... and all parent/offspring relations. Note that *map* requires *two* functions: one for the nodes and one for the edges and children. This is so because a change in the definition of node is *not* propagated automatically to where it is used as a child.

```

val iter : (node → edge × children → unit) → t → unit
val map : (node → node) →
  (node → edge × children → edge × children) → t → t
val fold : (node → edge × children → α → α) → t → α → α

```

Note that in its current incarnation, *fold add_offspring dag empty* copies *only* the fertile nodes, while *fold add_offspring dag (fold_nodes add_node dag empty)* includes sterile ones, as does *map (fun n → n) (fun n ec → ec) dag*.

Return the DAG as a list of lists.

```
val lists : t → (node × (edge × children) list) list
```

dependencies dag node returns a canonically sorted *Tree2.t* of all nodes reachable from *node*.

```
val dependencies : t → node → (node, edge) Tree2.t
```

harvest dag n roots returns the DAG *roots* enlarged by all nodes in *dag* reachable from *n*.

```
val harvest : t → node → t → t
```

size dag returns the number of nodes in the DAG *dag*.

```
val size : t → int
```

eval f mul_edge mul_nodes add null unit root dag

```

val eval : (node → α) → (node → edge → β → γ) →
  (α → β → β) → (γ → α → α) → α → β → node → t → α
val eval_memoized : (node → α) → (node → edge → β → γ) →
  (α → β → β) → (γ → α → α) → α → β → node → t → α

```

harvest_list dag nlist returns the part of the DAG *dag* that is reachable from the nodes in *nlist*.

```
val harvest_list : t → node list → t
```

count_trees n dag returns the number of trees with root *n* encoded in the DAG *dag*, i.e. $|T(n, D)|$. NB: the current implementation is very naive and can take a *very* long time for moderately sized DAGs that encode a large set of trees.

```
val count_trees : node → t → int
```

forest root dag

```

val forest : node → t → (node × edge option, node) Tree.t list
val forest_memoized : node → t → (node × edge option, node) Tree.t list

```

```

    val rcs : RCS.t
  end

module Make (F : Forest) :
  T with type node = F.node and type edge = F.edge
  and type children = F.children

```

4.1.3 Graded Sets, Forests & DAGs

A graded ordered¹ set is an ordered set with a map into another ordered set (often the non-negative integers). The grading does not necessarily respect the ordering.

```

module type Graded_Ord =
  sig
    include Ord
    module G : Ord
    val rank : t → G.t
  end

```

For all ordered sets, there are two canonical gradings: a *Chaotic* grading that assigns the same rank (e.g. *unit*) to all elements and the *Discrete* grading that uses the identity map as grading.

```

module type Grader = functor (O : Ord) → Graded_Ord with type t = O.t
module Chaotic : Grader
module Discrete : Grader

```

A graded forest is just a forest in which the nodes form a graded ordered set.

There doesn't appear to be a nice syntax for avoiding the repetition here. Fortunately, the signature is short ...

```

module type Graded_Forest =
  sig
    module Nodes : Graded_Ord
    type node = Nodes.t
    type edge
    type children
    type t = edge × children
    val compare : t → t → int
    val for_all : (node → bool) → t → bool
    val fold : (node → α → α) → t → α → α
  end

module type Forest_Grader = functor (G : Grader) → functor (F : Forest) →

  Graded_Forest with type Nodes.t = F.node
  and type node = F.node
  and type edge = F.edge

```

¹We don't appear to have use for graded unordered sets.

```

and type children = F.children
and type t = F.t

```

```

module Grade_Forest : Forest_Grader

```

Finally, a graded DAG is a DAG in which the nodes form a graded ordered set and the subsets with a given rank can be accessed cheaply.

```

module type Graded =
sig
  include T
  type rank
  val rank : node → rank
  val ranks : t → rank list
  val min_max_rank : t → rank × rank
  val ranked : rank → t → node list
end

module Graded (F : Graded_Forest) :
  Graded with type node = F.node and type edge = F.edge
  and type children = F.children and type rank = F.Nodes.G.t

```

4.2 Implementation of DAG

```

let rcs_file = RCS.parse "DAG" ["Directed_Acyclical_Graph"]

  type children = node PT.t
  type t = edge × children

  let compare (e1, n1) (e2, n2) =
    let c = PT.compare N.compare n1 n2 in
    if c ≠ 0 then
      c
    else
      E.compare e1 e2

  let for_all f (_, nodes) = PT.for_all f nodes
  let fold f (_, nodes) acc = PT.fold_right f nodes acc
end

```

4.2.2 Gradings

```

module Chaotic (O : Ord) =
struct
  include O
  module G =
    struct
      type t = unit
      let compare _ _ = 0
    end
  let rank _ = ()
end

module Discrete (O : Ord) =
struct

```

```

    include O
    module G = O
    let rank x = x
  end

module Fake_Grading (O : Ord) =
  struct
    include O
    exception Impossible of string
    module G =
      struct
        type t = unit
        let compare _ _ = raise (Impossible "G.compare")
      end
    let rank _ = raise (Impossible "G.compare")
  end

    M2.mem key (try M1.find (O.rank key) map with Not_found → M2.empty)
  let iter f map1 = M1.iter (fun rank → M2.iter f) map1
  let fold f map1 acc1 = M1.fold (fun rank → M2.fold f) map1 acc1

```

The set of ranks and its minimum and maximum should be maintained explicitly!

```

module S1 = Set.Make(O.G)
let ranks map = M1.fold (fun key data acc → key :: acc) map []
let rank_set map = M1.fold (fun key data → S1.add key) map S1.empty
let min_max_rank map =
  let s = rank_set map in
  (S1.min_elt s, S1.max_elt s)

module S2 = Set.Make(O)
let keys map = M2.fold (fun key data acc → key :: acc) map []
let sorted_keys map =
  S2.elements (M2.fold (fun key data → S2.add key) map S2.empty)
let ranked_rank map =
  keys (try M1.find rank map with Not_found → M2.empty)
end

```

4.2.3 The DAG Functor

```

module Maybe_Graded (GMM : Graded_Map_Maker) (F : Graded_Forest) =
struct
  let rcs = RCS.rename rcs_file "DAG.Graded()"
  ["Graded_directed_Acyclical_Graph";
   "representing_binary_or_n-ary_trees"]

  module G = F.Nodes.G

```

```

type node = F.node
type rank = G.t
type edge = F.edge
type children = F.children

```

If we get tired of graded DAGs, we just have to replace *Graded_Map* by *Map* here and remove *ranked* below and gain a tiny amount of simplicity and efficiency.

```

module Parents = GMM(F.Nodes)
module Offspring = Set.Make(F)

type t = Offspring.t Parents.t

let rank = F.Nodes.rank
let ranks = Parents.ranks
let min_max_rank = Parents.min_max_rank
let ranked = Parents.ranked

let empty = Parents.empty

let add_node node dag =
  if Parents.mem node dag then
    dag
  else
    Parents.add node Offspring.empty dag

let add_offspring_unsafe node offspring dag =
  let offsprings =
    try Parents.find node dag with Not_found → Offspring.empty in
  Parents.add node (Offspring.add offspring offsprings)
  (F.fold add_node offspring dag)

exception Cycle

let add_offspring node offspring dag =
  if F.for_all (fun n → F.Nodes.compare n node < 0) offspring then
    add_offspring_unsafe node offspring dag
  else
    raise Cycle

let is_node node dag =
  Parents.mem node dag

let is_sterile node dag =
  try
    Offspring.is_empty (Parents.find node dag)
  with
  | Not_found → false

let is_offspring node offspring dag =
  try
    Offspring.mem offspring (Parents.find node dag)
  with
  | Not_found → false

let iter_nodes f dag =
  Parents.iter (fun n _ → f n) dag

```

```

let iter f dag =
  Parents.iter (fun node → Offspring.iter (f node)) dag

let map_nodes f dag =
  Parents.fold (fun n → Parents.add (f n)) dag Parents.empty

let map fn fo dag =
  Parents.fold (fun node offspring →
    Parents.add (fn node)
    (Offspring.fold (fun o → Offspring.add (fo node o))
      offspring Offspring.empty)) dag Parents.empty

let fold_nodes f dag acc =
  Parents.fold (fun n _ → f n) dag acc

let fold f dag acc =
  Parents.fold (fun node → Offspring.fold (f node)) dag acc

```

Note that in its current incarnation, *fold add_offspring dag empty* copies *only* the fertile nodes, while *fold add_offspring dag (fold_nodes add_node dag empty)* includes sterile ones, as does *map (fun n → n) (fun n ec → ec) dag*.

```

let dependencies dag node =
  let rec dependencies' node' =
    let offspring = Parents.find node' dag in
    if Offspring.is_empty offspring then
      Tree2.leaf node'
    else
      Tree2.cons
        (Offspring.fold
          (fun o acc →
            (fst o,
             node',
             F.fold (fun wf acc' → dependencies' wf :: acc') o []) :: acc)
          offspring [])
  in
  dependencies' node

let lists dag =
  Sort.list (fun (n1, _) (n2, _) → F.Nodes.compare n1 n2 ≤ 0)
    (Parents.fold (fun node offspring l →
      (node, Offspring.elements offspring) :: l) dag [])

let size dag =
  Parents.fold (fun _ n → succ n) dag 0

let rec harvest dag node roots =
  Offspring.fold
    (fun offspring roots' →
      if is_offspring node offspring roots' then
        roots'
      else

```

```

      F.fold (harvest dag)
        offspring (add_offspring_unsafe node offspring roots')
      (Parents.find node dag) (add_node node roots)
let harvest_list dag nodes =
  List.fold_left (fun roots node → harvest dag node roots) empty nodes

```

Build a closure once, so that we can recurse faster:

```

let eval f mule muln add null unit node dag =
  let rec eval' n =
    if is_sterile n dag then
      f n
    else
      Offspring.fold
        (fun (e, _ as offspring) v0 →
          add (mule n e (F.fold muln' offspring unit)) v0)
        (Parents.find n dag) null
    and muln' n = muln (eval' n) in
  eval' node

let count_trees node dag =
  eval (fun _ → 1) (fun _ _ p → p) ( × ) (+) 0 1 node dag

let build_forest evaluator node dag =
  evaluator (fun n → [Tree.leaf (n, None) n])
    (fun n e p → List.map (fun p' → Tree.cons (n, Some e) p') p)
    (fun p1 p2 → Product.fold2 (fun n nl pl → (n :: nl) :: pl) p1 p2 [])
    (@) [] [[]] node dag

let forest = build_forest eval

```

At least for *count_trees*, the memoizing variant *eval_memoized* is considerably slower than direct recursive evaluation with *eval*.

```

let eval_offspring f mule muln add null unit dag values (node, offspring) =
  let muln' n = muln (Parents.find n values) in
  let v =
    if is_sterile node dag then
      f node
    else
      Offspring.fold
        (fun (e, _ as offspring) v0 →
          add (mule node e (F.fold muln' offspring unit)) v0)
        offspring null
  in
  (v, Parents.add node v values)

let eval_memoized' f mule muln add null unit dag =
  let result, _ =
    List.fold_left
      (fun (v, values) → eval_offspring f mule muln add null unit dag values)
      (null, Parents.empty)
      (Sort.list (fun (n1, _) (n2, _) → F.Nodes.compare n1 n2 ≤ 0)
        (Parents.fold

```

```

      (fun node offspring l → (node, offspring) :: l) dag []) in
    result
  let eval_memoized f mule muln add null unit node dag =
    eval_memoized' f mule muln add null unit
      (harvest dag node empty)
  let forest_memoized = build_forest eval_memoized
end
module type Graded =
sig
  include T
  type rank
  val rank : node → rank
  val ranks : t → rank list
  val min_max_rank : t → rank × rank
  val ranked : rank → t → node list
end
module Graded (F : Graded_Forest) = Maybe_Graded(Graded_Map)(F)

```

The following is not a graded map, obviously. But it can pass as one by the typechecker for constructing non-graded DAGs.

```

module Fake_Graded_Map (O : Graded_Ord) :
  Graded_Map with type key = O.t and type rank = O.G.t =
struct
  module M = Map.Make(O)
  type key = O.t
  type (+α) t = α M.t
  let empty = M.empty
  let add = M.add
  let find = M.find
  let mem = M.mem
  let iter = M.iter
  let fold = M.fold

```

We make sure that the remaining three are never called inside *DAG* and are not visible outside.

```

  type rank = O.G.t
  exception Impossible of string
  let ranks _ = raise (Impossible "ranks")
  let min_max_rank _ = raise (Impossible "min_max_rank")
  let ranked _ _ = raise (Impossible "ranked")
end

```

We could also have used signature projection with a chaotic or discrete grading, but the *Graded_Map* can cost some efficiency. This is probably not the case for the current simple implementation, but future embellishment can change this. Therefore, the ungraded DAG uses *Map* directly, without overhead.

```

module Make (F : Forest) =
  Maybe_Graded(Fake_Graded_Map)(Grade_Forest(Fake_Grading)(F))

```

If O'Caml had *polymorphic recursion*, we could think of even more elegant implementations unifying nodes and offspring (cf. the generalized tries in [\[4\]](#)).

—5— MOMENTA

5.1 *Interface of Momentum*

Model the finite combinations

$$p = \sum_{n=1}^k c_k \bar{p}_n, \quad (\text{with } c_k \in \{0, 1\}) \quad (5.1)$$

of n_{in} incoming and $k - n_{\text{in}}$ outgoing momenta p_n

$$\bar{p}_n = \begin{cases} -p_n & \text{for } 1 \leq n \leq n_{\text{in}} \\ p_n & \text{for } n_{\text{in}} + 1 \leq n \leq k \end{cases} \quad (5.2)$$

where momentum is conserved

$$\sum_{n=1}^k \bar{p}_n = 0 \quad (5.3)$$

below, we need the notion of ‘rank’ and ‘dimension’:

$$\dim(p) = k \quad (5.4a)$$

$$\text{rank}(p) = \sum_{n=1}^k c_k \quad (5.4b)$$

where ‘dimension’ is *not* the dimension of the underlying space-time, of course.

module type $T =$

sig
type t

Constructor: $(k, N) \rightarrow p = \sum_{n \in N} \bar{p}_n$ and $k = \dim(p)$ is the *overall* number of independent momenta, while $\text{rank}(p) = |N|$ is the number of momenta in p . It would be possible to fix \dim as a functor argument instead. This might be slightly faster and allow a few more compile time checks, but would be much more tedious to use, since the number of particles will be chosen at runtime.

val $of_ints : int \rightarrow int\ list \rightarrow t$

No two indices may be the same. Implementations of of_ints can either raise the exception *Duplicate* or ignore the duplicate, but implementations of add are required to raise *Duplicate*.

exception *Duplicate* of *int*

Raise *Range* iff $n > k$:

exception *Range* of *int*

Binary operations require that both momenta have the same dimension. *Mismatch* is raised if this condition is violated.

exception *Mismatch* of $string \times t \times t$

Negative is raised if the result of *sub* is undefined.

exception *Negative*

The inverses of the constructor (we have $rank\ p = List.length\ (to_ints\ p)$, but *rank* might be more efficient):

```
val to_ints : t → int list
val dim    : t → int
val rank   : t → int
```

Shortcuts: $singleton\ d\ p = of_ints\ d\ [p]$ and $zero\ d = of_ints\ d\ []$:

```
val singleton : int → int → t
val zero      : int → t
```

An arbitrary total order, with the condition $rank(p_1) < rank(p_2) \Rightarrow p_1 < p_2$.

```
val compare : t → t → int
```

Use momentum conservation to construct the negative momentum with positive coefficients:

```
val neg : t → t
```

Return the momentum or its negative, whichever has the lower rank. NB: the present implementation does *not* guarantee that

$$abs\ p = abs\ q \iff p = p \vee p = -q \quad (5.5)$$

for momenta with $rank = dim/2$.

```
val abs : t → t
```

Add and subtract momenta. This can fail, since the coefficients c_k must be either 0 or 1.

```
val add : t → t → t
val sub : t → t → t
```

Once more, but not raising exceptions this time:

```
val try_add : t → t → t option
val try_sub : t → t → t option
```

Not the total order provided by *compare*, but set inclusion of non-zero coefficients instead:

```
val less : t → t → bool
val lesseq : t → t → bool
```

$$p_1 + (\pm p_2) + (\pm p_3) = 0$$

$$\text{val } \text{try_fusion} : t \rightarrow t \rightarrow t \rightarrow (bool \times bool) \text{ option}$$

A textual representation for debugging:

$$\text{val } \text{to_string} : t \rightarrow \text{string}$$

split i n p splits \bar{p}_i into n momenta $\bar{p}_i \rightarrow \bar{p}_i + \bar{p}_{i+1} + \dots + \bar{p}_{i+n-1}$ and makes room via $\bar{p}_{j>i} \rightarrow \bar{p}_{j+n-1}$. This is used for implementating cascade decays, like combining

$$e^+(p_1)e^-(p_2) \rightarrow W^-(p_3)\nu_e(p_4)e^+(p_5) \quad (5.6a)$$

$$W^-(p_3) \rightarrow d(p'_3)\bar{u}(p'_4) \quad (5.6b)$$

to

$$e^+(p_1)e^-(p_2) \rightarrow d(p_3)\bar{u}(p_4)\nu_e(p_5)e^+(p_6) \quad (5.7)$$

in narrow width approximation for the W^- .

$$\text{val } \text{split} : \text{int} \rightarrow \text{int} \rightarrow t \rightarrow t$$

5.1.1 Scattering Kinematics

From here on, we assume scattering kinematics $\{1, 2\} \rightarrow \{3, 4, \dots\}$, i. e. $n_{\text{in}} = 2$.

Since functions like *timelike* can be used for decays as well (in which case they must *always* return *true*, the representation—and consequently the constructors—should be extended by a flag discriminating between the two cases!

module *Scattering* :

sig

Test if the momentum is an incoming one: $p = \bar{p}_1 \vee p = \bar{p}_2$

$$\text{val } \text{incoming} : t \rightarrow \text{bool}$$

$$p = \bar{p}_3 \vee p = \bar{p}_4 \vee \dots$$

$$\text{val } \text{outgoing} : t \rightarrow \text{bool}$$

$p^2 \geq 0$. NB: *par abus de langage*, we report the incoming individual momenta as spacelike, instead as timelike. This will be useful for phasespace constructions below.

$$\text{val } \text{timelike} : t \rightarrow \text{bool}$$

$p^2 \leq 0$. NB: the simple algebraic criterion can be violated for heavy initial state particles.

$$\text{val } \text{spacelike} : t \rightarrow \text{bool}$$

$$p = \bar{p}_1 + \bar{p}_2$$

$$\text{val } \text{s_channel_in} : t \rightarrow \text{bool}$$

$$p = \bar{p}_3 + \bar{p}_4 + \dots + \bar{p}_n$$

```

    val s_channel_out : t → bool
p =  $\bar{p}_1 + \bar{p}_2 \vee p = \bar{p}_3 + \bar{p}_4 + \dots + \bar{p}_n$ 
    val s_channel : t → bool
 $\bar{p}_1 + \bar{p}_2 \rightarrow \bar{p}_3 + \bar{p}_4 + \dots + \bar{p}_n$ 
    val flip_s_channel_in : t → t
end

```

5.1.2 Decay Kinematics

```

module Decay :
  sig
    Test if the momentum is an incoming one:  $p = \bar{p}_1$ 
    val incoming : t → bool
 $p = \bar{p}_2 \vee p = \bar{p}_3 \vee \dots$ 
    val outgoing : t → bool
 $p^2 \geq 0$ . NB: here, we report the incoming individual momenta as timelike.
    val timelike : t → bool
 $p^2 \leq 0$ .
    val spacelike : t → bool
  end
  val rcs : RCS.t
end
module Lists : T
module Bits : T
module Default : T

```

Wolfgang's funny tree codes:

$$(2^n, 2^{n-1}) \rightarrow (1, 2, 4, \dots, 2^{n-2}) \quad (5.8)$$

```

module type Whizard =
  sig
    type t
    val of_momentum : t → int
    val to_momentum : int → int → t
  end
module ListsW : Whizard with type t = Lists.t
module BitsW : Whizard with type t = Bits.t
module DefaultW : Whizard with type t = Default.t

```

  end
  val rcs : RCS.t
end

```

5.2.1 Lists of Integers

The first implementation (as part of *Fusion*) was based on sorted lists, because I did not want to preclude the use of more general indices than integers. However, there's probably not much use for this generality (the indices are typically generated automatically and integer are the most natural choice) and it is no longer supported. by the current signature. Thus one can also use the more efficient implementation based on bitvectors below.

```

module Lists =
  struct
    let rcs = RCS.rename rcs_file "Momentum.Lists()"

```

5.2.2 Bit Fiddlings

Bit vectors are popular in Fortran based implementations [1, 2, 11] and can be more efficient. In particular, when all information is packed into a single integer, much of the memory overhead is reduced.

```
module Bits =
  struct
    let rcs = RCS.rename rcs_file "Momentum.Bits()"
      (RCS.description rcs_file @
       [ "using_bitfields_as_representation." ])

    type t = int
```

Bits 1...21 are used as a bitvector, indicating whether a particular momentum is included. Bits 22...26 represent the numbers of bits set in bits 1...21 and bits 27...31 denote the maximum number of momenta.

```
let mask n = (1 lsl n) - 1
let mask2 = mask 2
let mask5 = mask 5
let mask21 = mask 21

let maskd = mask5 lsl 26
let maskr = mask5 lsl 21
let maskb = mask21

let dim0 p = p land maskd
let rank0 p = p land maskr
let bits0 p = p land maskb

let dim p = (dim0 p) lsr 26
let rank p = (rank0 p) lsr 21
let bits p = bits0 p

let drb0 d r b = d lor r lor b
let drb d r b = d lsl 26 lor r lsl 21 lor b
```

For a 64-bit architecture, the corresponding sizes could be increased to 1...51, 52...57, and 58...63. However, the combinatorical complexity will have killed us long before we can reach these values.

```

end

```

5.2.4 Suggesting a Default Implementation

Lists is better tested, but the more recent *Bits* appears to work as well and is *much* more efficient, resulting in a relative factor of better than 2. This performance ratio is larger than I had expected and we are not likely to reach its limit of 21 independent vectors anyway.

```

module Default = Bits
module DefaultW = BitsW

```

—6—

CASCADES

6.1 Interface of *Cascade_syntax*

```
type ('flavor, 'p) t =  
  | True  
  | False

  string  
  
exception Syntax_Error of string × int × int
```

6.2 Implementation of *Cascade_syntax*

Concerning the Gaussian propagators, we admit the following: In principle, they would allow for flavor sums like the off-shell lines, but for all practical purposes

they are used only for determining the significance of a specified intermediate state. So we select them in the same manner as on-shell states.

```

type ('flavor, 'p) t =
  | True
  | False
  | On_shell of 'flavor list × 'p
  | On_shell_not of 'flavor list × 'p
  | Off_shell of 'flavor list × 'p
  | Off_shell_not of 'flavor list × 'p
  | Gauss of 'flavor list × 'p
  | Gauss_not of 'flavor list × 'p
  | Any_flavor of 'p
  | Or of ('flavor, 'p) t list
  | And of ('flavor, 'p) t list

```

6.5 Interface of *Cascade*

```

module type T =
  sig
    type flavor
    type p
    type t
    val of_string_list : int → string list → t
    val to_string : t → string

```

An opaque type that describes the set of all constraints on an amplitude and how to construct it from a cascade description.

```

  type selectors
  val to_selectors : t → selectors

```

Don't throw anything away:

```

  val no_cascades : selectors

```

select_wf *s is_timelike* *f p ps* returns **true** iff either the flavor *f* and momentum *p* match or *all* combinations of the momenta in *ps* are compatible, i. e. $\pm \sum p_i \leq q$

```

  val select_wf : selectors → (p → bool) → flavor → p → p list → bool

```

select_p *s p ps* same as *select_wf s f p ps*, but ignores the flavor *f*

```
val select_p : selectors → p → p list → bool
```

on_shell *s p*

```
val on_shell : selectors → flavor → p → bool
```

is_gauss *s p*

```
val is_gauss : selectors → flavor → p → bool
```

partition *s* returns a partition of the external particles that can not be reordered without violating the cascade constraints.

```
val partition : selectors → int list list
```

Diagnostics:

```
val description : selectors → string option
```

end

```
module Make (M : Model.T) (P : Momentum.T) :  
  T with type flavor = M.flavor and type p = P.t
```

6.6 Implementation of *Cascade*

```
module type T =
```

```
sig
```

```
  type flavor
```

```
  type p
```

```
  type t
```

```
  val of_string_list : int → string list → t
```

```
  val to_string : t → string
```

```
  type selectors
```

```
  val to_selectors : t → selectors
```

```
  val no_cascades : selectors
```

```
  val select_wf : selectors → (p → bool) → flavor → p → p list → bool
```

```
  val select_p : selectors → p → p list → bool
```

```
  val on_shell : selectors → flavor → p → bool
```

```
  val is_gauss : selectors → flavor → p → bool
```

```
  val partition : selectors → int list list
```

```
  val description : selectors → string option
```

```
end
```

```
module Make (M : Model.T) (P : Momentum.T) :  
  (T with type flavor = M.flavor and type p = P.t) =  
  struct
```

```
    module CS = Cascade_syntax
```

```
    type flavor = M.flavor
```

```
type p = P.t
```

Since we have

$$p \leq q \iff (-q) \leq (-p) \quad (6.1)$$

also for \leq as set inclusion *lesseq*, only four of the eight combinations are independent

$$\begin{aligned} p \leq q &\iff (-q) \leq (-p) \\ q \leq p &\iff (-p) \leq (-q) \\ p \leq (-q) &\iff q \leq (-p) \\ (-q) \leq p &\iff (-p) \leq q \end{aligned} \quad (6.2)$$

```
let one_compatible p q =
  let neg_q = P.neg q in
  P.lesseq p q ∨
  P.lesseq q p ∨
  P.lesseq p neg_q ∨
  P.lesseq neg_q p
```

'tis wasteful ... (at least by a factor of two, because every momentum combination is generated, including the negative ones.

```
let all_compatible p p_list q =
  let l = List.length p_list in
  if l ≤ 2 then
    one_compatible p q
  else
    let tuple_lengths = ThoList.range 2 (succ l / 2) in
    let tuples = ThoList.flatmap (fun n → Combinatorics.choose n p_list) tuple_lengths in
    let momenta = List.map (List.fold_left P.add (P.zero (P.dim q))) tuples in
    List.for_all (one_compatible q) momenta
```

The following assumes that the *flavor list* is always very short. Otherwise one should use an efficient set implementation.

```
type t =
  | True
  | False
  | On_shell of flavor list × P.t
  | On_shell_not of flavor list × P.t
  | Off_shell of flavor list × P.t
  | Off_shell_not of flavor list × P.t
  | Gauss of flavor list × P.t
  | Gauss_not of flavor list × P.t
  | Any_flavor of P.t
  | And of t list

let of_string s =
  Cascade_parser.main Cascade_lexer.token (Lexing.from_string s)
```

If we knew that we're dealing with a scattering, we could apply *P.flip_s_channel_in* to all momenta, so that *1 + 2* accepts the particle and not the antiparticle. Right now, we don't have this information.

```

COLOR

7.1 Interface of Color

7.1.1 Quantum Numbers

Color is not necessarily the $SU(3)$ of QCD. Conceptually, it can be any *unbroken* symmetry (*broken* symmetries correspond to *Model.flavor*). In order to keep the group theory simple, we confine ourselves to the fundamental and adjoint representation of a single $SU(N_C)$ for the moment. Therefore, particles are either color singlets or live in the defining representation of $SU(N_C)$: $SUN(|N_C|)$, its conjugate $SUN(-|N_C|)$ or in the adjoint representation of $SU(N_C)$: $AdjSUN(N_C)$.

`type t = Singlet | SUN of int | AdjSUN of int`

Mismatch
      | Lines (c1, c1') :: rest1, Lines (c2, c2') :: rest2 →
        square2' (((c1, c1'), (c2, c2'))) :: acc) rest1 rest2 in
square2' [] (cross_out f1) (cross_out f2)

```

Surprisingly, this is missing from *Pervasives*!

```

let int_power n p =
  let rec int_power' acc i =
    if i < 0 then
      invalid_arg "int_power"
    else if i = 0 then
      acc
    else
      int_power' (n × acc) (pred i) in
  int_power' 1 p

```

Instead of implementing a full fledged algebraic evaluator, let's simply expand the binomial by hand:

$$\left(\frac{N_C^2 - 2}{N_C^2}\right)^n = \sum_{i=0}^n \binom{n}{i} (-2)^i N_C^{-2i} \quad (7.1)$$

NB: Any result of *square* other than *Mismatch* guarantees *count_ghosts f1 = count_ghosts f2*.

```

let factor f1 f2 =
  match square f1 f2, square2 f1 f2 with
  | Mismatch, _ | _, Mismatch → []
  | Square f12, Square f12' →
    let num_cycles = C.count f12
    and num_cycles2, disc = C2.contract f12'
    and num_ghosts = count_ghosts f1 in
    List.map
      (fun i →
        let parity = if num_ghosts mod 2 = 0 then 1 else -1
        and power = num_cycles - num_ghosts in
        let coeff = int_power (-2) i × Combinatorics.binomial num_cycles2 i
        and power2 = - 2 × i in
        { num = parity × coeff;
          den = 1;
          power = power + power2 })
      (ThoList.range 0 num_cycles2)
end

```

later:

```

module General_Flow =
  struct
    type color =
      | Lines of int list
      | Ghost of int
  end

```

```
type t = color list × color list
let rank_default = 2 (* Standard model *)
let rank cflow =
  try
    begin match List.hd cflow with
      | Lines lines → List.length lines
      | Ghost n_lines → n_lines
    end
  with
  | _ → rank_default
end
```

—8—

FUSIONS

8.1 *Interface of Fusion*

```
module type T =  
  sig
```

```
    val options : Options.t
```

Wavefunctions are an abstract data type, containing a momentum p and additional quantum numbers, collected in *flavor*.

```
  type wf
```

Obviously, *flavor* is not restricted to the physical notion of flavor, but can carry spin, color, etc.

```
  type flavor
```

```
  type flavor_sans_color
```

```
  val flavor : wf → flavor
```

```
  val flavor_sans_color : wf → flavor_sans_color
```

Momenta are represented by an abstract datatype (defined in *Momentum*) that is optimized for performance. They can be accessed either abstractly or as lists of indices of the external momenta. These indices are assigned sequentially by *amplitude* below.

```
  type p
```

```
  val momentum : wf → p
```

```
  val momentum_list : wf → int list
```

At tree level, the wave functions are uniquely specified by *flavor* and momentum. If loops are included, we need to distinguish among orders. Also, if we build a result from an incomplete sum of diagrams, we need to add a distinguishing mark. At the moment, we assume that a *string* that can be attached to the symbol suffices.

```
  val wf_tag : wf → string option
```

Coupling constants

```
  type constant
```

and right hand sides of assignments. The latter are formed from a sign from Fermi statistics, a coupling (constant and Lorentz structure) and wave functions.

```

type coupling
type rhs
type  $\alpha$  children
val sign : rhs  $\rightarrow$  int
val coupling : rhs  $\rightarrow$  constant Coupling.t
val coupling_tag : rhs  $\rightarrow$  string option

```

In renormalized perturbation theory, couplings come in different orders of the loop expansion. Be prepared: `val order : rhs \rightarrow int`

This is here only for the benefit of *Target* and shall become `val children : rhs \rightarrow wf children` later ...

```

val children : rhs  $\rightarrow$  wf list

```

Fusions come in two types: fusions of wave functions to off-shell wave functions:

$$\phi(p+q) = \phi(p)\phi(q)$$

```

type fusion
val lhs : fusion  $\rightarrow$  wf
val rhs : fusion  $\rightarrow$  rhs list

```

and products at the keystones:

$$\phi(-p-q) \cdot \phi(p)\phi(q)$$

```

type braket
val bra : braket  $\rightarrow$  wf
val ket : braket  $\rightarrow$  rhs list

```

amplitude goldstones incoming outgoing calculates the amplitude for scattering of *incoming* to *outgoing*. If *goldstones* is true, also non-propagating off-shell Goldstone amplitudes are included to allow the checking of Slavnov-Taylor identities.

```

type amplitude
type selectors
val amplitudes : bool  $\rightarrow$  selectors  $\rightarrow$ 
  flavor_sans_color list  $\rightarrow$  flavor_sans_color list  $\rightarrow$  amplitude list
val dependencies : amplitude  $\rightarrow$  wf  $\rightarrow$  (wf, coupling) Tree2.t

```

We should be precise regarding the semantics of the following functions, since modules implementating *Target* must not make any mistakes interpreting the return values. Instead of calculating the amplitude

$$\langle f_3, p_3, f_4, p_4, \dots | T | f_1, p_1, f_2, p_2 \rangle \quad (8.1a)$$

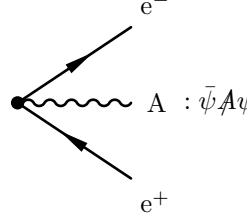

directly, O'Mega calculates the—equivalent, but more symmetrical—crossed amplitude

$$\langle \bar{f}_1, -p_1, \bar{f}_2, -p_2, f_3, p_3, f_4, p_4, \dots | T | 0 \rangle \quad (8.1b)$$

Internally, all flavors are represented by their charge conjugates

$$A(f_1, -p_1, f_2, -p_2, \bar{f}_3, p_3, \bar{f}_4, p_4, \dots) \quad (8.1c)$$

The correspondence of vertex and term in the lagrangian

$$\quad (8.2)$$

suggests to denote the *outgoing* particle by the flavor of the *antiparticle* and the *outgoing antiparticle* by the flavor of the *particle*, since this choice allows to represent the vertex by a triple

$$\bar{\psi} A \psi : (e^+, A, e^-) \quad (8.3)$$

which is more intuitive than the alternative (e^-, A, e^+) . Also, when thinking in terms of building wavefunctions from the outside in, the outgoing *antiparticle* is represented by a *particle* propagator and vice versa¹. *incoming* and *outgoing* are the physical flavors as in (8.1a)

```
val incoming : amplitude → flavor list
val outgoing : amplitude → flavor list
```

externals are flavors and momenta as in (8.1c)

```
val externals : amplitude → wf list
val variables : amplitude → wf list
val fusions : amplitude → fusion list
val brackets : amplitude → bracket list
val on_shell : amplitude → (wf → bool)
val is_gauss : amplitude → (wf → bool)
val constraints : amplitude → string option
val symmetry : amplitude → int
val allowed : amplitude → bool
```

Performance Hacks

```
val initialize_cache : string → unit
val set_cache_name : string → unit
```

¹Even if this choice will appear slightly counter-intuitive on the *Target* side, one must keep in mind that much more people are expected to prepare *Models*.

Diagnostics

```

val check_charges : unit → flavor_sans_color list list
val count_fusions : amplitude → int
val count_propagators : amplitude → int
val count_diagrams : amplitude → int

val forest : wf → amplitude → ((wf × coupling_option, wf) Tree.t) list
val poles : amplitude → wf list list
val s_channel : amplitude → wf list

val tower_to_dot : out_channel → amplitude → unit
val amplitude_to_dot : out_channel → amplitude → unit

val rcs_list : RCS.t list
end

```

There is more than one way to make fusions.

```

module type Maker =
  functor (P : Momentum.T) → functor (M : Model.T) →
    T with type p = P.t
    and type flavor = Colorize.It(M).flavor
    and type flavor_sans_color = M.flavor
    and type constant = M.constant
    and type selectors = Cascade.Make(M)(P).selectors

```

Straightforward Dirac fermions vs. slightly more complicated Majorana fermions:

```

module Binary : Maker
module Binary_Majorana : Maker

module Mixed23 : Maker
module Mixed23_Majorana : Maker

module Nary : functor (B : Tuple.Bound) → Maker
module Nary_Majorana : functor (B : Tuple.Bound) → Maker

```

We can also proceed á la [2]. Empirically, this will use slightly ($O(10\%)$) fewer fusions than the symmetric factorization. Our implementation uses significantly ($O(50\%)$) fewer fusions than reported by [2]. Our pruning of the DAG might be responsible for this.

```

module Helac : functor (B : Tuple.Bound) → Maker
module Helac_Majorana : functor (B : Tuple.Bound) → Maker

```

8.1.1 Multiple Amplitudes

```

module type Multi =
  sig
    exception Mismatch
    val options : Options.t

    type flavor

```

```

type process = flavor list × flavor list
type amplitude
type fusion
type wf
type selectors
type amplitudes

```

Construct all possible color flow amplitudes for a given process.

```

val amplitudes : bool → int option → selectors → process list →
amplitudes
val empty : amplitudes

```

Precompute the vertex table cache.

```

val initialize_cache : string → unit
val set_cache_name : string → unit

```

The list of all combinations of incoming and outgoing particles with a non-vanishing scattering amplitude.

```

val flavors : amplitudes → process list

```

The list of all combinations of incoming and outgoing particles that don't lead to any color flow with non vanishing scattering amplitude.

```

val vanishing_flavors : amplitudes → process list

```

The list of all color flows with a nonvanishing scattering amplitude.

```

val color_flows : amplitudes → Color.Flow.t list

```

The list of all valid helicity combinations.

```

val helicities : amplitudes → (int list × int list) list

```

The list of all amplitudes.

```

val processes : amplitudes → amplitude list

```

$(process_table\ a).(f).(c)$ returns the amplitude for the f th allowed flavor combination and the c th allowed color flow as an *amplitude option*.

```

val process_table : amplitudes → amplitude option array array

```

The list of all non redundant fusions together with the amplitudes they came from.

```

val fusions : amplitudes → (fusion × amplitude) list

```

If there's more than external flavor state, the wavefunctions are *not* uniquely specified by *flavor* and *Momentum.t*. This function can be used to determine how many variables must be allocated.

```

val multiplicity : amplitudes → wf → int

```

This function can be used to disambiguate wavefunctions with the same combination of *flavor* and *Momentum.t*.

```

val dictionary : amplitudes → amplitude → wf → int

```

$(color_factors\ a).(c1).(c2)$ power of N_C for the given product of color flows.

```

    val color_factors : amplitudes → Color.Flow.factor array array
    A description of optional diagram selectors.
    val constraints : amplitudes → string option
end
module type Multi_Maker = functor (Fusion_Maker : Maker) →
  functor (P : Momentum.T) →
    functor (M : Model.T) →
      Multi with type flavor = M.flavor
      and type amplitude = Fusion_Maker(P)(M).amplitude
      and type fusion = Fusion_Maker(P)(M).fusion
      and type wf = Fusion_Maker(P)(M).wf
      and type selectors = Fusion_Maker(P)(M).selectors
module Multi : Multi_Maker

```

8.1.2 Tags

It appears that there are useful applications for tagging couplings and wave functions, e. g. skeleton expansion and diagram selections. We can abstract this in a *Tags* signature:

```

module type Tags =
  sig
    type wf
    type coupling
    type α children
    val null_wf : wf
    val null_coupling : coupling
    val fuse : coupling → wf children → wf
    val wf_to_string : wf → string option
    val coupling_to_string : coupling → string option
  end
module type Tagger =
  functor (PT : Tuple.Poly) → Tags with type α children = α PT.t
module type Tagged_Maker =
  functor (Tagger : Tagger) →
    functor (P : Momentum.T) → functor (M : Model.T) →
      T with type p = P.t
      and type flavor = Colorize.It(M).flavor
      and type flavor_sans_color = M.flavor
      and type constant = M.constant
module Tagged_Binary : Tagged_Maker

```

8.2 Implementation of *Fusion*

```
let rcs_file = RCS.parse "Fusion" ["General_Fusions"]
```

```

```

8.2.4 Tagged, the *Fusion.Make* Functor

```

module Tagged (Tagger : Tagger) (PT : Tuple.Poly)
  (Stat : Stat_Maker) (T : Topology.T with type  $\alpha$  children =  $\alpha$  PT.t)
  (P : Momentum.T) (M : Model.T) =
  struct
    let rcs = RCS.rename rcs_file "Fusion.Make()"
      [ "Fusions_for_arbitrary_topologies" ]

    type cache_mode = Cache_Use | Cache_Ignore | Cache_Overwrite
    let cache_option = ref Cache_Use

    let options = Options.create
      [ "ignore-cache", Arg.Unit (fun () → cache_option := Cache_Ignore),
        "ignore_cached_model_tables";
        "overwrite-cache", Arg.Unit (fun () → cache_option := Cache_Overwrite),
        "overwrite_cached_model_tables" ]

    open Coupling

    module S = Stat(M)

    type stat = S.stat
    let stat = S.stat
    let stat_sign = S.stat_sign

```

This will do *something* for 4-, 6-, ... fermion vertices, but not necessarily the right thing ...

```

let stat_fuse s f =
  PT.fold_right_internal (fun s' acc → S.stat_fuse s' acc f) s
type constant = M.constant

```

Wave Functions

The code below is not yet functional. Too often, we assign to *Tags.null_wf* instead of calling *Tags.fuse*.

We will need two types of amplitudes: with color and without color. Since we can build them using the same types with only *flavor* replaced, it pays to use a functor to set up the scaffolding.

```
module Tags = Tagger(PT)
```

In the future, we might want to have *Coupling* among the functor arguments. However, for the moment, *Coupling* is assumed to be comprehensive.

```
module type Tagged_Coupling =
  sig
    type sign = int
    type t =
      { sign : sign;
        coupling : constant Coupling.t;
        coupling_tag : Tags.coupling }
    val sign : t → sign
    val coupling : t → constant Coupling.t
    val coupling_tag : t → string option
  end

module Tagged_Coupling : Tagged_Coupling =
  struct
    type sign = int
    type t =
      { sign : sign;
        coupling : constant Coupling.t;
        coupling_tag : Tags.coupling }
    let sign c = c.sign
    let coupling c = c.coupling
    let coupling_tag_raw c = c.coupling_tag
    let coupling_tag rhs = Tags.coupling_to_string (coupling_tag_raw rhs)
  end
```

Amplitudes: Monochrome and Colored

module A = Amplitude(PT)(P)(M)

```

Operator insertions can be fused only if they are external.

```

let is_source wf =
  match M.propagator wf.A.flavor with
  | Only_Insertion → P.rank wf.A.momentum = 1
  | _ → true

```

is_goldstone_of *g v* is *true* if and only if *g* is the Goldstone boson corresponding to the gauge particle *v*.

```

let is_goldstone_of g v =
  match M.goldstone v with
  | None → false
  | Some (g', _) → g = g'

```

In the end, *PT.to_list* should become redundant!

```
let fuse_rhs rhs = M.fuse (PT.to_list rhs)
```

Vertices

Compute the set of all vertices in the model from the allowed fusions and the set of all flavors:

One could think of using *M.vertices* instead of *M.fuse2*, *M.fuse3* and *M.fuse* ...

```
module VSet = Map.Make(struct type t = A.flavor let compare = compare end)

let add_vertices f rhs m =
  VSet.add f (try rhs :: VSet.find f m with Not_found -> [rhs]) m

let collect_vertices rhs =
  List.fold_right (fun (f1, c) -> add_vertices (M.conjugate f1) (c, rhs))
    (fuse_rhs rhs)
```

The set of all vertices with common left fields factored.

I used to think that constant initializers are a good idea to allow compile time optimizations. The down side turned out to be that the constant initializers will be evaluated *every time* the functor is applied. *Relying on the fact that the functor will be called only once is not a good idea!*

```
type vertices = (A.flavor × (constant Coupling.t × A.flavor PT.t) list) list

let vertices_nocache max_degree flavors : vertices =
  VSet.fold (fun f rhs v -> (f, rhs) :: v)
    (PT.power_fold collect_vertices flavors VSet.empty) []
```

Performance hack:

```
type vertex_table =
  ((A.flavor × A.flavor × A.flavor) × constant Coupling.vertex3 ×
   constant) list
  × ((A.flavor × A.flavor × A.flavor × A.flavor)
     × constant Coupling.vertex4 × constant) list
  × (A.flavor list × constant Coupling.vertexn × constant) list

module VCache =
  Cache.Make (struct type t = vertex_table end) (struct type t = RCS.t ×
    vertices end)

let vertices_cache = ref None
let hash = VCache.hash (M.vertices ())
```

Can we do better than the executable name provided by *Config.cache_prefix*???

We need a better way to avoid collisions among the caches for different models in the same program.

```

let cache_name =
  ref (Config.cache_prefix ^ "." ^ Config.cache_suffix)

      flush stderr;
      result
end
| Some result → result

```

Partitions

Vertices that are not crossing invariant need special treatment so that they're only generated for the correct combinations of momenta.

Using *PT.Mismatched_arity* is not really good style ...

Tho's approach doesn't work since he does not catch charge conjugated processes or crossed processes. Another very strange thing is that O'Mega seems always to run in the q2 q3 timelike case, but not in the other two. (Property of how the DAG is built?). For the ZZZZ vertex I add the same vertex again, but interchange 1 and 3 in the *crossing* vertex

```

let crossing c momenta =
  match c with
  | V4 (Vector4_K_Matrix_tho (disc, _), fusion, _)
  | V4 (Vector4_K_Matrix_jr (disc, _), fusion, _) →
    let s12, s23, s13 =
      begin match PT.to_list momenta with
      | [q1; q2; q3] → (P.Scattering.timelike (P.add q1 q2),
                       P.Scattering.timelike (P.add q2 q3),
                       P.Scattering.timelike (P.add q1 q3))
      | _ → raise PT.Mismatched_arity
      end in
    begin match disc, s12, s23, s13, fusion with
    | 0, true, false, false, (F341 | F431 | F342 | F432 | F123 | F213 |
F124 | F214)
    | 0, false, true, false, (F134 | F143 | F234 | F243 | F312 | F321 |
F412 | F421)

```

```

      | 0, false, false, true, (F314 | F413 | F324 | F423 | F132 | F231 |
F142 | F241) →
      true
      | 1, true, false, false, (F341 | F431 | F342 | F432)
      | 1, false, true, false, (F134 | F143 | F234 | F243)
      | 1, false, false, true, (F314 | F413 | F324 | F423) →
      true
      | 2, true, false, false, (F123 | F213 | F124 | F214)
      | 2, false, true, false, (F312 | F321 | F412 | F421)
      | 2, false, false, true, (F132 | F231 | F142 | F241) →
      true
      | 3, true, false, false, (F143 | F413 | F142 | F412 | F321 | F231 |
F324 | F234)
      | 3, false, true, false, (F314 | F341 | F214 | F241 | F132 | F123 |
F432 | F423)
      | 3, false, false, true, (F134 | F431 | F124 | F421 | F312 | F213 |

      true
      | _ → false
    end
  | _ → true

```

Match a set of flavors to a set of momenta. Form the direct product for the lists of momenta two and three with the list of couplings and flavors two and three.

```

let flavor_keystone select_p dim (f1, f23) (p1, p23) =
  ({ A.flavor = f1;
    A.momentum = P.of_ints dim p1;
    A.wf_tag = A.Tags.null_wf },
  Product.fold2 (fun (c, f) p acc →
    try
      if select_p
        (P.of_ints dim p1)
        (PT.to_list (PT.map (P.of_ints dim) p)) then begin
        if crossing c (PT.map (P.of_ints dim) p) then
          (c, PT.map2 (fun f' p' → { A.flavor = f';
                                   A.momentum = P.of_ints dim p';
                                   A.wf_tag = A.Tags.null_wf }) f p) :: acc
        else
          acc
        end else
          acc
      with
      | PT.Mismatched_arity → acc) f23 p23 [])

```

Produce all possible combinations of vertices (flavor keystones) and momenta by forming the direct product. The semantically equivalent *Product.list2 (flavor_keystone select_wf n) vertices k* with *subsequent* filtering would be a *very bad* idea, because a potentially huge intermediate list is built for large models. E. g. for the MSSM this would lead to non-termination by thrashing for $2 \rightarrow 4$ processes on most PCs.

```

let flavor_keystones filter select_p dim vertices keystones =

```

```

Product.fold2 (fun v k acc →
  filter (flavor_keystone select_p dim v k) acc) vertices keystones []

```

Flatten the nested lists of vertices into a list of attached lines.

```

let flatten_keystones t =
  ThoList.flatmap (fun (p1, p23) →
    p1 :: (ThoList.flatmap (fun (_, rhs) → PT.to_list rhs) p23)) t

```

Subtrees

Fuse a tuple of wavefunctions, keeping track of Fermi statistics. Record only the the sign *relative* to the children. (The type annotation is only for documentation.)

```

let fuse select_wf wfss : (A.wf × stat × A.rhs) list =
  if PT.for_all (fun (wf, _) → is_source wf) wfss then
    try
      let wfs, ss = PT.split wfss in
      let flavors = PT.map A.flavor wfs
      and momenta = PT.map A.momentum wfs

                Tagged_Coupling.coupling = c;
                Tagged_Coupling.coupling_tag = A.Tags.null_coupling }, wfs)) :: acc
          else
            acc)
        [] (fuse_rhs flavors)
    with
    | P.Duplicate _ | S.Impossible → []
  else
    []

```

Eventually, the pairs of *tower* and *dag* in *fusion_tower'* below could and should be replaced by a graded *DAG*. This will look like, but currently *tower* contains statistics information that is missing from *dag*:

Type node = flavor * p is not compatible with type wf * stat

This should be easy to fix. However, replacing `type t = wf` with `type t = wf × stat` is *not* a good idea because the variable *stat* makes it impossible to test for the existence of a particular *wf* in a *DAG*.

In summary, it seems that $(wf \times stat) \text{ list array} \times A.D.t$ should be replaced by $(wf \rightarrow stat) \times A.D.t$.

```

module GF =
  struct
    module Nodes =
      struct
        type t = A.wf
        module G = struct type t = int let compare = compare end
        let compare = A.order_wf
        let rank wf = P.rank wf.A.momentum
      end
    module Edges = struct type t = A.coupling let compare = compare end
    module F = DAG.Forest(PT)(Nodes)(Edges)
    type node = Nodes.t
    type edge = F.edge
    type children = F.children
    type t = F.t
    let compare = F.compare
    let for_all = F.for_all
    let fold = F.fold
  end
  module D' = DAG.Graded(GF)
  let tower_of_dag dag =
    let _, max_rank = D'.min_max_rank dag in
    Array.init max_rank (fun n → D'.ranked n dag)

```

The function *fusion_tower'* recursively builds the tower of all fusions from bottom up to a chosen level. The argument *tower* is an array of lists, where the *i*-th sublist (counting from 0) represents all off shell wave functions depending on *i* + 1 momenta and their Fermistatistics.

$$\begin{aligned}
 & \left[\{ \phi_1(p_1), \phi_2(p_2), \phi_3(p_3), \dots \}, \right. \\
 & \quad \{ \phi_{12}(p_1 + p_2), \phi'_{12}(p_1 + p_2), \dots, \phi_{13}(p_1 + p_3), \dots, \phi_{23}(p_2 + p_3), \dots \}, \\
 & \quad \dots \\
 & \quad \left. \{ \phi_{1\dots n}(p_1 + \dots + p_n), \phi'_{1\dots n}(p_1 + \dots + p_n), \dots \} \right]
 \end{aligned} \tag{8.6}$$

The argument *dag* is a DAG representing all the fusions calculated so far. NB: The outer array in *tower* is always very short, so we could also have accessed a list with *List.nth*. Appending of new members at the end brings no loss of performance. NB: the array is supposed to be immutable. The towers must be sorted so that the combinatorical functions can make consistent selections.

Intuitively, this seems to be correct. However, one could have expected that no element appears twice and that this ordering is not necessary ...

```

let grow_select_wf tower =

```

Calculate the minimal tower of fusions that suffices for calculating the amplitude.

```

let minimal_fusion_tower n select_wf wfs : (A.wf → stat) × A.D.t =
  fusion_tower (T.max_subtree n) select_wf wfs

```

Calculate the complete tower of fusions. It is much larger than required, but it allows a complete set of gauge checks.

```

let complete_fusion_tower select_wf wfs : (A.wf → stat) × A.D.t =
  fusion_tower (List.length wfs - 1) select_wf wfs

```

There is a natural product of two DAGs using *fuse*. Can this be used in a replacement for *fusion_tower*? The hard part is to avoid double counting, of course. A straight forward solution could do a diagonal sum (in order to reject flipped offspring representing the same fusion) and rely on the uniqueness in *DAG* otherwise. However, this will (probably) slow down the procedure significantly, because most fusions (including Fermi signs!) will be calculated before being rejected by *DAG().add_offspring*.

Add to *dag* all Goldstone bosons defined in *tower* that correspond to gauge bosons in *dag*. This is only required for checking Slavnov-Taylor identities in unitarity gauge. Currently, it is not used, because we use the complete tower for gauge checking.

```
let harvest_goldstones tower dag =
  A.D.fold_nodes (fun wf dag' →
    match M.goldstone wf.A.flavor with
    | Some (g, _) →
      let wf' = { wf with A.flavor = g } in
      if A.D.is_node wf' tower then begin
        A.D.harvest tower wf' dag'
      end else begin
        dag'
      end
    | None → dag' ) dag dag
```

Calculate the sign from Fermi statistics that is not already included in the children.

The use of *PT.of2_kludge* is the largest skeleton on the cupboard of unified fusions. Currently, it is just another name for *PT.of2*, but the existence of the latter requires binary fusions. Of course, this is just a symptom for not fully supporting four fermion vertices ...

```
let stat_keystone stats wf1 wfs =
  let wf1' = stats wf1
  and wfs' = PT.map stats wfs in
  stat_sign
    (stat_fuse
      (PT.of2_kludge wf1' (stat_fuse wfs' (M.conjugate (A.flavor wf1))))
      (A.flavor wf1))
    × PT.fold_left (fun acc wf → acc × stat_sign wf) (stat_sign wf1') wfs'
```

Test all members of a list of wave functions are defined by the DAG simultaneously:

```
let test_rhs dag (_, wfs) =
  PT.for_all (fun wf → is_source wf ∧ A.D.is_node wf dag) wfs
```

Add the keystone (*wf1, pairs*) to *acc* only if it is present in *dag* and calculate the statistical factor depending on *stats en passant*:

```
let filter_keystone stats dag (wf1, pairs) acc =
  if is_source wf1 ∧ A.D.is_node wf1 dag then
    match List.filter (test_rhs dag) pairs with
```

Figure 8.2: The DAGs for Bhabha scattering before and after weeding out unused nodes. The blatant asymmetry of these DAGs is caused by our prescription for removing doubling counting for an even number of external lines.

```

| [] → acc
| pairs' → (wf1, List.map (fun (c, wfs) →
  ({ Tagged_Coupling.sign = stat_keystone stats wf1 wfs;
    Tagged_Coupling.coupling = c;
    Tagged_Coupling.coupling_tag = A.Tags.null_coupling },
  wfs)) pairs') :: acc
else
  acc

```

Amplitudes

```

module C = Cascade.Make(M)(P)
type selectors = C.selectors

let external_wfs n particles =
  List.map (fun (f, p) →
    ({ A.flavor = f;
      A.momentum = P.singleton n p;
      A.wf_tag = A.Tags.null_wf },
    stat f p)) particles

```

Figure 8.4: The DAGs for $e^+e^- \rightarrow u\bar{d}d\bar{u}$ before and after weeding out unused nodes.

Main Function

```

module WFMap = Map.Make (struct type t = A.wf let compare = compare end)

map_amplitude_wfs f a applies the function  $f : wf \rightarrow wf$  to all wavefunctions
appearing in the amplitude  $a$ .

let map_amplitude_wfs f a =
  let map_rhs (c, wfs) = (c, PT.map f wfs) in
  let map_braket (wf, rhs) = (f wf, List.map map_rhs rhs) in
  and map_fusion (lhs, rhs) = (f lhs, List.map map_rhs rhs) in
  let map_dag = A.D.map f (fun node rhs  $\rightarrow$  map_rhs rhs) in
  let tower = map_dag a.A.fusion_tower
  and dag = map_dag a.A.fusion_dag in
  let dependencies_map =
    A.D.fold (fun wf _  $\rightarrow$  WFMap.add wf (A.D.dependencies dag wf)) dag WFMap.empty in
  { A.fusions = List.map map_fusion a.A.fusions;
    A.brackets = List.map map_braket a.A.brackets;
    A.on_shell = a.A.on_shell;
    A.is_gauss = a.A.is_gauss;
    A.constraints = a.A.constraints;
    A.incoming = a.A.incoming;
    A.outgoing = a.A.outgoing;
    A.externals = List.map f a.A.externals;
    A.symmetry = a.A.symmetry;
    A.dependencies = (fun wf  $\rightarrow$  WFMap.find wf dependencies_map);
    A.fusion_tower = tower;
    A.fusion_dag = dag }

```

This is the main function that constructs the amplitude for sets of incoming and outgoing particles and returns the results in conveniently packaged pieces.

```

let amplitude_goldstones_selectors fin fout =

  Set up external lines and match flavors with numbered momenta.

  let f = fin @ List.map M.conjugate fout in
  let nin, nout = List.length fin, List.length fout in
  let n = nin + nout in
  let externals = List.combine f (ThoList.range 1 n) in
  let wfs = external_wfs n externals in
  let select_p = C.select_p selectors in
  let select_wf =
    match fin with
    | [-]  $\rightarrow$  C.select_wf selectors P.Decay.timelike
    | -  $\rightarrow$  C.select_wf selectors P.Scattering.timelike in

```

Build the full fusion tower (including nodes that are never needed in the amplitude).

```

let stats, tower =

```

```

if goldstones then
  complete_fusion_tower select_wf wfs
else
  minimal_fusion_tower n select_wf wfs in

```

Find all vertices for which *all* off shell wavefunctions are defined by the tower.

```

let brackets =
  flavor_keystones (filter_keystone stats tower) select_p n
  (vertices (M.max_degree ()) (M.flavors ()))
  (T.keystones (ThoList.range 1 n)) in

```

Remove the part of the DAG that is never needed in the amplitude.

```

let dag =
  if goldstones then
    tower
  else
    A.D.harvest_list tower (A.wavefunctions brackets) in

```

Remove the leaf nodes of the DAG, corresponding to external lines.

```

let fusions =
  List.filter (function (_, []) → false | _ → true) (A.D.lists dag) in

```

Calculate the symmetry factor for identical particles in the final state.

```

let symmetry =
  Combinatorics.symmetry fout in

```

```

let dependencies_map =
  A.D.fold (fun wf _ → WFMap.add wf (A.D.dependencies dag wf)) dag WFMap.empty in

```

Finally: package the results:

```

{ A.fusions = fusions;
  A.brackets = brackets;
  A.on_shell = (fun wf → C.on_shell selectors (A.flavor wf) wf.A.momentum);
  A.is_gauss = (fun wf → C.is_gauss selectors (A.flavor wf) wf.A.momentum);
  A.constraints = C.description selectors;
  A.incoming = fin;
  A.outgoing = fout;
  A.externals = List.map fst wfs;
  A.symmetry = symmetry;
  A.dependencies = (fun wf → WFMap.find wf dependencies_map);
  A.fusion_tower = tower;
  A.fusion_dag = dag }

```

Color

```

module CM = Colorize.It(M)
module CA = Amplitude(PT)(P)(CM)

```

```

let colorize_wf flavor wf =
  { CA.flavor = flavor;
    CA.momentum = wf.A.momentum;
    CA.wf_tag = wf.A.wf_tag }

let uncolorize_wf wf =
  { A.flavor = CM.flavor_sans_color wf.CA.flavor;
    A.momentum = wf.CA.momentum;
    A.wf_tag = wf.CA.wf_tag }

```

At the end of the day, I shall want to have some sort of *fibred DAG* as abstract data type, with a projection of colored nodes to their uncolored counterparts.

```

module CWFBundle = Bundle.Make
  (struct
    type elt = CA.wf
    let compare_elt = compare
    type base = A.wf
    let compare_base = compare
    let pi wf =
      { A.flavor = CM.flavor_sans_color wf.CA.flavor;
        A.momentum = wf.CA.momentum;
        A.wf_tag = wf.CA.wf_tag }
  end)

```

For now, we can live with simple aggregation:

```

type fibred_dag = { dag : CA.D.t; bundle : CWFBundle.t }

```

Not yet(?) needed: `module CS = Stat (CM)`

```

let colorize_sterile_nodes dag f wf fibred_dag =
  if A.D.is_sterile wf dag then
    let wf', wf_bundle' = f wf fibred_dag in
    { dag = CA.D.add_node wf' fibred_dag.dag;
      bundle = wf_bundle' }
  else
    fibred_dag

let colorize_nodes f wf rhs fibred_dag =
  let wf_rhs_list', wf_bundle' = f wf rhs fibred_dag in
  let dag' =
    List.fold_right
      (fun (wf', rhs') → CA.D.add_offspring wf' rhs')
      wf_rhs_list' fibred_dag.dag in
  { dag = dag';
    bundle = wf_bundle' }

```

O'Cam1 (correctly) infers the type `val colorize_dag : (D.node → D.edge × D.children → fibred_dag → (CA.D.node × (CA.D.edge × CA.D.children)) list × CWFBundle.t) →`

$(D.\text{node} \rightarrow \text{fibered_dag} \rightarrow CA.D.\text{node} \times CWFBundle.t) \rightarrow D.t \rightarrow CWFBundle.t \rightarrow \text{fibered_dag}.$

```

  end

```

JR sez' (regarding the Majorana Feynman rules): In the formalism of [7], it does not matter to distinguish spinors and conjugate spinors, it is only important to know in which direction a fermion line is calculated. So the sign is made by the calculation together with an additional one due to the permutation of the pairs of endpoints of fermion lines in the direction they are calculated. We propose a “canonical” direction from the right to the left child at a fusion point so we only have to keep in mind which external particle hangs at each side. Therefore we need not to have a list of pairs

of conjugate spinors and spinors but just a list in which the pairs are right-left-right-left and so on. Unfortunately it is unavoidable to have couplings with clashing arrows in supersymmetric theories so we need transmutations from fermions in antifermions and vice versa as well. (*JR's probably right, but I need to check myself...*)

exception *Impossible*

All wavefunctions are unique per amplitude. So we can use per-amplitude dependency trees without additional *internal* tags to identify identical wave functions.

NB: we miss potential optimizations, because we assume all coupling to be different, while in fact we have horizontal/family symmetries and non abelian gauge couplings are universal anyway.

—9—

LORENTZ REPRESENTATIONS, COUPLINGS, MODELS AND TARGETS

9.1 Interface of Coupling

The enumeration types used for communication from *Models* to *Targets*. On the physics side, the modules in *Models* must implement the Feynman rules according to the conventions set up here. On the numerics side, the modules in *Targets* must handle all cases according to the same conventions.

9.1.1 Propagators

The Lorentz representation of the particle. NB: O'Mega treats all lines as *outgoing* and particles are therefore transforming as *ConjSpinor* and antiparticles as *Spinor*.

```
type lorentz =
  | Scalar
  | Spinor (*  $\psi$  *)
  | ConjSpinor (*  $\bar{\psi}$  *)
  | Majorana (*  $\chi$  *)
  | Maj_Ghost (* SUSY ghosts *)
  | Vector
  | Massive_Vector
  | Vectorspinor (* supersymmetric currents and gravitinos *)
  | Tensor_1
  | Tensor_2 (* massive gravitons (large extra dimensions) *)
  | BRS of lorentz
```

If there were no vectors or auxiliary fields, we could deduce the propagator from the Lorentz representation. While we're at it, we can introduce “propagators” for the contact interactions of auxiliary fields as well. *Prop_Gauge* and *Prop_Feynman* are redundant as special cases of *Prop_Rxi*.

The special case *Only_Insertion* corresponds to operator insertions that do not correspond to a propagating field all. These are used for checking Slavnov-Taylor identities

$$\partial_\mu \langle \text{out} | W^\mu(x) | \text{in} \rangle = m_W \langle \text{out} | \phi(x) | \text{in} \rangle \quad (9.1)$$

	only Dirac fermions	incl. Majorana fermions
<i>Prop_Scalar</i>	$\phi(p) \leftarrow \frac{i}{p^2 - m^2 + im\Gamma} \phi(p)$	
<i>Prop_Spinor</i>	$\psi(p) \leftarrow \frac{i(-\not{p} + m)}{p^2 - m^2 + im\Gamma} \psi(p)$	$\psi(p) \leftarrow \frac{i(-\not{p} + m)}{p^2 - m^2 + im\Gamma} \psi(p)$
<i>Prop_ConjSpinor</i>	$\bar{\psi}(p) \leftarrow \bar{\psi}(p) \frac{i(\not{p} + m)}{p^2 - m^2 + im\Gamma}$	$\psi(p) \leftarrow \frac{i(-\not{p} + m)}{p^2 - m^2 + im\Gamma} \psi(p)$
<i>Prop_Majorana</i>	N/A	$\chi(p) \leftarrow \frac{i(-\not{p} + m)}{p^2 - m^2 + im\Gamma} \chi(p)$
<i>Prop_Unitarity</i>	$\epsilon_\mu(p) \leftarrow \frac{i}{p^2 - m^2 + im\Gamma} \left(-g_{\mu\nu} + \frac{p_\mu p_\nu}{m^2} \right) \epsilon^\nu(p)$	
<i>Prop_Feynman</i>	$\epsilon^\nu(p) \leftarrow \frac{-i}{p^2 - m^2 + im\Gamma} \epsilon^\nu(p)$	
<i>Prop_Gauge</i>	$\epsilon_\mu(p) \leftarrow \frac{i}{p^2} \left(-g_{\mu\nu} + (1 - \xi) \frac{p_\mu p_\nu}{p^2} \right) \epsilon^\nu(p)$	
<i>Prop_Rxi</i>	$\epsilon_\mu(p) \leftarrow \frac{i}{p^2 - m^2 + im\Gamma} \left(-g_{\mu\nu} + (1 - \xi) \frac{p_\mu p_\nu}{p^2 - \xi m^2} \right) \epsilon^\nu(p)$	

Table 9.1: Propagators. NB: The sign of the momenta in the spinor propagators comes about because O'Mega treats all momenta as *outgoing* and the charge flow for *Spinor* is therefore opposite to the momentum, while the charge flow for *ConjSpinor* is parallel to the momentum.

<i>Aux_Scalar</i>	$\phi(p) \leftarrow i\phi(p)$
<i>Aux_Spinor</i>	$\psi(p) \leftarrow i\psi(p)$
<i>Aux_ConjSpinor</i>	$\bar{\psi}(p) \leftarrow i\bar{\psi}(p)$
<i>Aux_Vector</i>	$\epsilon^\mu(p) \leftarrow i\epsilon^\mu(p)$
<i>Aux_Tensor_1</i>	$T^{\mu\nu}(p) \leftarrow iT^{\mu\nu}(p)$
<i>Only_Insertion</i>	N/A

Table 9.2: Auxiliary and non propagating fields

of gauge theories in unitarity gauge where the Goldstone bosons are not propagating. Numerically, it would suffice to use a vanishing propagator, but then superfluous fusions would be calculated in production code in which the Slavnov-Taylor identities are not tested.

```

type  $\alpha$  propagator =
  | Prop_Scalar | Prop_Ghost
  | Prop_Spinor | Prop_ConjSpinor | Prop_Majorana
  | Prop_Unitarity | Prop_Feynman | Prop_Gauge of  $\alpha$  | Prop_Rxi of  $\alpha$ 
  | Prop_Tensor_2 | Prop_Vectorspinor
  | Prop_Col_Scalar | Prop_Col_Feynman | Prop_Col_Majorana
  | Prop_Col_Unitarity
  | Aux_Scalar | Aux_Vector | Aux_Tensor_1
  | Aux_Spinor | Aux_ConjSpinor | Aux_Majorana
  | Only_Insertion

```

JR sez' (regarding the Majorana Feynman rules): We don't need different fermionic propagators as supposed by the variable names *Prop_Spinor*, *Prop_ConjSpinor* or *Prop_Majorana*. The propagator in all cases has to be multiplied on the left hand side of the spinor out of which a new one should be built. All momenta are treated as *outgoing*, so for the propagation of the different fermions the following table arises, in which the momentum direction is always downwards and the arrows show whether the momentum and the fermion line, respectively are parallel or antiparallel to the direction of calculation:

Fermion type	fermion arrow	mom.	calc.	sign
Dirac fermion	↑	↑ ↓	↑ ↑	negative
Dirac antifermion	↓	↓ ↓	↑ ↓	negative
Majorana fermion	-	↑ ↓	-	negative

So the sign of the momentum is always negative and no further distinction is needed. (*JR's probably right, but I need to check myself ...*)

```

type width =
  | Vanishing
  | Constant
  | Timelike
  | Running
  | Fudged
  | Custom of string

```

9.1.2 Vertices

The combined $S - P$ and $V - A$ couplings (see tables 9.5, 9.6, 9.8 and 9.12) are redundant, of course, but they allow some targets to create more efficient

numerical code.¹ Choosing VA2 over VA will cause the FORTRAN backend to pass the coupling as a whole array

```

type fermion = Psi | Chi | Grav
type fermionbar = Psibar | Chibar | Gravbar
type boson =
  | SP | S | P | SL | SR | SLR | VA | V | A | VL | VR | VLR
  | POT | MOM | MOM5 | MOML | MOMR | LMOM | RMOM |
  VMOM | VA2
type boson2 = S2 | P2 | S2P | S2L | S2R | S2LR
  | SV | PV | SLV | SRV | SLRV | V2 | V2LR

```

The integer is an additional coefficient that multiplies the respective coupling constant. This allows to reduce the number of required coupling constants in manifestly symmetric cases. Most of times it will be equal unity, though.

The two vertex types *PBP* and *BBB* for the couplings of two fermions or two antifermions ("clashing arrows") is unavoidable in supersymmetric theories.

... tho doesn't like the names and has promised to find a better mnemonics!

```

type α vertex3 =

```

As long as we stick to renormalizable couplings, there are only three types of quartic couplings: *Scalar4*, *Scalar2_Vector2* and *Vector4*. However, there are three inequivalent contractions for the latter and the general vertex will be a linear combination with integer coefficients:

$$\text{Scalar4 } 1 : \quad \phi_1 \phi_2 \phi_3 \phi_4 \quad (9.2a)$$

$$\text{Scalar2_Vector2 } 1 : \quad \phi_1 \phi_2 V_3^\mu V_{4,\mu} \quad (9.2b)$$

$$\text{Vector4 } [1, C_12_34] : \quad V_1^\mu V_{2,\mu} V_3^\nu V_{4,\nu} \quad (9.2c)$$

$$\text{Vector4 } [1, C_13_42] : \quad V_1^\mu V_2^\nu V_{3,\mu} V_{4,\nu} \quad (9.2d)$$

$$\text{Vector4 } [1, C_14_23] : \quad V_1^\mu V_2^\nu V_{3,\nu} V_{4,\mu} \quad (9.2e)$$

```

type contract4 = C_12_34 | C_13_42 | C_14_23

```

```

type \alpha vertex4 =
| Scalar4 of int
| Scalar2_Vector2 of int
| Vector4 of (int \times contract4) list
| DScalar4 of (int \times contract4) list
| DScalar2_Vector2 of (int \times contract4) list
| GBBG of int \times fermionbar \times boson2 \times fermion

```

In some applications, we have to allow for contributions outside of perturbation theory. The most prominent example is heavy gauge boson scattering at very high energies, where the perturbative expression violates unitarity.

One solution is the ‘*K*-matrix’ ansatz. Such unitarizations typically introduce effective propagators and/or vertices that violate crossing symmetry and vanish in the *t*-channel. This can be taken care of in *Fusion* by filtering out vertices that have the wrong momenta.

In this case the ordering of the fields in a vertex of the Feynman rules becomes significant. In particular, we assume that (V_1, V_2, V_3, V_4) implies

$$(9.3)$$

The list of pairs of parameters denotes the location and strengths of the poles in the *K*-matrix ansatz:

$$(c_1, a_1, c_2, a_2, \dots, c_n, a_n) \implies f(s) = \sum_{i=1}^n \frac{c_i}{s - a_i} \quad (9.4)$$

```

| Vector4_K_Matrix_tho of int \times (\alpha \times \alpha) list

```

| *Vector4_K_Matrix_jr* of *int* × (*int* × *contract4*) list

type α *vertexn* = *unit*

An obvious candidate for addition to *boson* is *T*, of course.

This list is sufficient for the minimal standard model, but not comprehensive enough for most of its extensions, supersymmetric or otherwise. In particular, we need a *general* parameterization for all trilinear vertices. One straightforward possibility are polynomials in the momenta for each combination of fields.

JR sez' (regarding the Majorana Feynman rules): Here we use the rules which can be found in [7] and are more properly described in *Targets* where the performing of the fusion rules in analytical expressions is encoded. (*JR's probably right, but I need to check myself ...*)

Signify which two of three fields are fused:

type *fuse2* = *F23* | *F32* | *F31* | *F13* | *F12* | *F21*

Signify which three of four fields are fused:

type *fuse3* =

	<i>F123</i>		<i>F231</i>		<i>F312</i>		<i>F132</i>		<i>F321</i>		<i>F213</i>
	<i>F124</i>		<i>F241</i>		<i>F412</i>		<i>F142</i>		<i>F421</i>		<i>F214</i>
	<i>F134</i>		<i>F341</i>		<i>F413</i>		<i>F143</i>		<i>F431</i>		<i>F314</i>
	<i>F234</i>		<i>F342</i>		<i>F423</i>		<i>F243</i>		<i>F432</i>		<i>F324</i>

Explicit enumeration types make no sense for higher degrees.

type *fusen* = *int* list

The third member of the triplet will contain the coupling constant:

type α *t* =

	<i>V3</i> of α <i>vertex3</i>	×	<i>fuse2</i>	×	α
	<i>V4</i> of α <i>vertex4</i>	×	<i>fuse3</i>	×	α
	<i>Vn</i> of α <i>vertexn</i>	×	<i>fusen</i>	×	α

9.1.3 Gauge Couplings

Dimension-4 trilinear vector boson couplings

$$\begin{aligned}
 f_{abc} \partial^\mu A^{a,\nu}_\mu A^b_\nu &\rightarrow i f_{abc} k_1^\mu A^{a,\nu}(k_1) A^b_\mu(k_2) A^c_\nu(k_3) \\
 &= -\frac{i}{3!} f_{a_1 a_2 a_3} C^{\mu_1 \mu_2 \mu_3}(k_1, k_2, k_3) A_{\mu_1}^{a_1}(k_1) A_{\mu_2}^{a_2}(k_2) A_{\mu_3}^{a_3}(k_3) \quad (9.5a)
 \end{aligned}$$

with the totally antisymmetric tensor (under simultaneous permutations of all quantum numbers μ_i and k_i) and all momenta *outgoing*

$$C^{\mu_1 \mu_2 \mu_3}(k_1, k_2, k_3) = (g^{\mu_1 \mu_2}(k_1^{\mu_3} - k_2^{\mu_3}) + g^{\mu_2 \mu_3}(k_2^{\mu_1} - k_3^{\mu_1}) + g^{\mu_3 \mu_1}(k_3^{\mu_2} - k_1^{\mu_2})) \quad (9.5b)$$

Table 9.4: Dimension-5 trilinear fermionic couplings (NB: the coefficients and signs are not fixed yet). The momenta are unambiguous, because there are no derivative couplings and all participating fields are different.

Since $f_{a_1 a_2 a_3} C^{\mu_1 \mu_2 \mu_3}(k_1, k_2, k_3)$ is totally symmetric (under simultaneous permutations of all quantum numbers a_i , μ_i and k_i), it is easy to take the partial derivative

$$A^{a,\mu}(k_2 + k_3) = -\frac{i}{2!} f_{abc} C^{\mu\rho\sigma}(-k_2 - k_3, k_2, k_3) A_\rho^b(k_2) A_\sigma^c(k_3) \quad (9.6a)$$

with

$$C^{\mu\rho\sigma}(-k_2 - k_3, k_2, k_3) = (g^{\rho\sigma}(k_2^\mu - k_3^\mu) + g^{\mu\sigma}(2k_3^\rho + k_2^\rho) - g^{\mu\rho}(2k_2^\sigma + k_3^\sigma)) \quad (9.6b)$$

i. e.

$$\begin{aligned} A^{a,\mu}(k_2 + k_3) = & -\frac{i}{2!} f_{abc} ((k_2^\mu - k_3^\mu) A^b(k_2) \cdot A^c(k_3) \\ & + (2k_3 + k_2) \cdot A^b(k_2) A^{c,\mu}(k_3) - A^{b,\mu}(k_2) A^c(k_3) \cdot (2k_2 + k_3)) \end{aligned} \quad (9.6c)$$

Investigate the rearrangements proposed in [5] for improved numerical stability.

Non-Gauge Vector Couplings

As a basis for the dimension-4 couplings of three vector bosons, we choose “transversal” and “longitudinal” (with respect to the first vector field) tensors that are odd and even under permutation of the second and third argument

$$\mathcal{L}_T(V_1, V_2, V_3) = V_1^\mu (V_{2,\nu} i \overleftrightarrow{\partial}_\mu V_3^\nu) = -\mathcal{L}_T(V_1, V_3, V_2) \quad (9.7a)$$

$$\mathcal{L}_L(V_1, V_2, V_3) = (i \partial_\mu V_1^\mu) V_{2,\nu} V_3^\nu = \mathcal{L}_L(V_1, V_3, V_2) \quad (9.7b)$$

Using partial integration in \mathcal{L}_L , we find the convenient combinations

$$\mathcal{L}_T(V_1, V_2, V_3) + \mathcal{L}_L(V_1, V_2, V_3) = -2V_1^\mu i \partial_\mu V_{2,\nu} V_3^\nu \quad (9.8a)$$

$$\mathcal{L}_T(V_1, V_2, V_3) - \mathcal{L}_L(V_1, V_2, V_3) = 2V_1^\mu V_{2,\nu} i \partial_\mu V_3^\nu \quad (9.8b)$$

Table 9.18: ...

As an important example, we can rewrite the dimension-4 “anomalous” triple gauge couplings

$$\begin{aligned} i\mathcal{L}_{\text{TGC}}(g_1, \kappa, g_4)/g_{VWW} = & g_1 V^\mu (W_{\mu\nu}^- W^{+\nu} - W_{\mu\nu}^+ W^{-\nu}) \\ & + \kappa W_\mu^+ W_\nu^- V^{\mu\nu} + g_4 W_\mu^+ W_\nu^- (\partial^\mu V^\nu + \partial^\nu V^\mu) \end{aligned} \quad (9.9)$$

as

$$\begin{aligned} \mathcal{L}_{\text{TGC}}(g_1, \kappa, g_4) = & g_1 \mathcal{L}_T(V, W^-, W^+) \\ & - \frac{\kappa + g_1 - g_4}{2} \mathcal{L}_T(W^-, V, W^+) + \frac{\kappa + g_1 + g_4}{2} \mathcal{L}_T(W^+, V, W^-) \\ & - \frac{\kappa - g_1 - g_4}{2} \mathcal{L}_L(W^-, V, W^+) + \frac{\kappa - g_1 + g_4}{2} \mathcal{L}_L(W^+, V, W^-) \end{aligned} \quad (9.10)$$

CP Violation

$$\mathcal{L}_{\tilde{T}}(V_1, V_2, V_3) = V_{1,\mu} (V_{2,\rho} i \overleftrightarrow{\partial}_\nu V_{3,\sigma}) \epsilon^{\mu\nu\rho\sigma} = +\mathcal{L}_T(V_1, V_3, V_2) \quad (9.11a)$$

$$\mathcal{L}_{\tilde{L}}(V_1, V_2, V_3) = (i\partial_\mu V_{1,\nu}) V_{2,\rho} V_{3,\sigma} \epsilon^{\mu\nu\rho\sigma} = -\mathcal{L}_L(V_1, V_3, V_2) \quad (9.11b)$$

Here the notations \tilde{T} and \tilde{L} are clearly *abuse de langage*, because $\mathcal{L}_{\tilde{L}}(V_1, V_2, V_3)$ is actually the transversal combination, due to the antisymmetry of ϵ . Using partial integration in $\mathcal{L}_{\tilde{L}}$, we could again find combinations

$$\mathcal{L}_{\tilde{T}}(V_1, V_2, V_3) + \mathcal{L}_{\tilde{L}}(V_1, V_2, V_3) = -2V_{1,\mu} V_{2,\nu} i\partial_\rho V_{3,\sigma} \epsilon^{\mu\nu\rho\sigma} \quad (9.12a)$$

$$\mathcal{L}_{\tilde{T}}(V_1, V_2, V_3) - \mathcal{L}_{\tilde{L}}(V_1, V_2, V_3) = -2V_{1,\mu} i\partial_\nu V_{2,\rho} V_{3,\sigma} \epsilon^{\mu\nu\rho\sigma} \quad (9.12b)$$

but we don't need them, since

$$\begin{aligned} i\mathcal{L}_{\text{TGC}}(g_5, \tilde{\kappa})/g_{VWW} = & g_5 \epsilon_{\mu\nu\rho\sigma} (W^{+,\mu} i \overleftrightarrow{\partial}^\rho W^{-,\nu}) V^\sigma \\ & - \frac{\tilde{\kappa}_V}{2} W_\mu^- W_\nu^+ \epsilon^{\mu\nu\rho\sigma} V_{\rho\sigma} \end{aligned} \quad (9.13)$$

is immediately recognizable as

$$\mathcal{L}_{\text{TGC}}(g_5, \tilde{\kappa})/g_{VWW} = -ig_5 \mathcal{L}_{\tilde{L}}(V, W^-, W^+) + \tilde{\kappa} \mathcal{L}_{\tilde{T}}(V, W^-, W^+) \quad (9.14)$$

9.1.4 *SU(2) Gauge Bosons*

An important special case for table 9.13 are the two usual coordinates of SU(2)

$$W_\pm = \frac{1}{\sqrt{2}} (W_1 \mp iW_2) \quad (9.15)$$

i. e.

$$W_1 = \frac{1}{\sqrt{2}} (W_+ + W_-) \quad (9.16a)$$

$$W_2 = \frac{i}{\sqrt{2}} (W_+ - W_-) \quad (9.16b)$$

Table 9.22: ...

and

$$W_1^\mu W_2^\nu - W_2^\mu W_1^\nu = i(W_-^\mu W_+^\nu - W_+^\mu W_-^\nu) \quad (9.17)$$

Thus the symmtry remains after the change of basis:

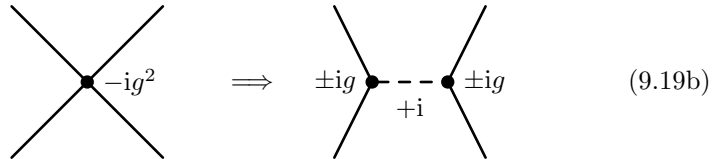

$$\begin{aligned} \epsilon^{abc} W_a^{\mu_1} W_b^{\mu_2} W_c^{\mu_3} &= i W_-^{\mu_1} (W_+^{\mu_2} W_3^{\mu_3} - W_3^{\mu_2} W_+^{\mu_3}) \\ &+ i W_+^{\mu_1} (W_3^{\mu_2} W_-^{\mu_3} - W_-^{\mu_2} W_3^{\mu_3}) + i W_3^{\mu_1} (W_-^{\mu_2} W_+^{\mu_3} - W_+^{\mu_2} W_-^{\mu_3}) \end{aligned} \quad (9.18)$$

9.1.5 Quartic Couplings and Auxiliary Fields

Quartic couplings can be replaced by cubic couplings to a non-propagating auxiliary field. The quartic term should get a negative sign so that it the energy is bounded from below for identical fields. In the language of functional integrals

$$\begin{aligned} \mathcal{L}_{\phi^4} &= -g^2 \phi_1 \phi_2 \phi_3 \phi_4 \implies \\ \mathcal{L}_{X\phi^2} &= X^* X \pm g X \phi_1 \phi_2 \pm g X^* \phi_3 \phi_4 = (X^* \pm g \phi_1 \phi_2)(X \pm g \phi_3 \phi_4) - g^2 \phi_1 \phi_2 \phi_3 \phi_4 \end{aligned} \quad (9.19a)$$

and in the language of Feynman diagrams

The other choice of signs

$$\mathcal{L}'_{X\phi^2} = -X^* X \pm g X \phi_1 \phi_2 \mp g X^* \phi_3 \phi_4 = -(X^* \pm g \phi_1 \phi_2)(X \mp g \phi_3 \phi_4) - g^2 \phi_1 \phi_2 \phi_3 \phi_4 \quad (9.20)$$

$$\begin{aligned}
& p \longrightarrow \text{vertex} \longrightarrow p' \quad \text{with gauge boson } (k, \mu, a) = +ig\gamma_\mu T_a \quad (9.22a) \\
& 2 \longrightarrow \text{vertex} \longrightarrow 1 \quad \text{with two gauge bosons } (k_1, \mu_1) \text{ and } (k_2, \mu_2) = gf_{a_1 a_2 a_3} C^{\mu_1 \mu_2 \mu_3}(k_1, k_2, k_3) \quad (9.22b) \\
& 2 \longrightarrow \text{vertex} \longrightarrow 3 \quad \text{with two gauge bosons } (k_1, \mu_1) \text{ and } (k_2, \mu_2) = \begin{aligned} & -ig^2 f_{a_1 a_2 b} f_{a_3 a_4 b} (g_{\mu_1 \mu_3} g_{\mu_4 \mu_2} - g_{\mu_1 \mu_4} g_{\mu_2 \mu_3}) \\ & -ig^2 f_{a_1 a_3 b} f_{a_4 a_2 b} (g_{\mu_1 \mu_4} g_{\mu_2 \mu_3} - g_{\mu_1 \mu_2} g_{\mu_3 \mu_4}) \\ & -ig^2 f_{a_1 a_4 b} f_{a_2 a_3 b} (g_{\mu_1 \mu_2} g_{\mu_3 \mu_4} - g_{\mu_1 \mu_3} g_{\mu_4 \mu_2}) \end{aligned} \quad (9.22c)
\end{aligned}$$

Figure 9.1: Gauge couplings. See (11.1b) for the definition of the antisymmetric tensor $C^{\mu_1 \mu_2 \mu_3}(k_1, k_2, k_3)$.

can not be extended easily to identical particles and is therefore not used. For identical particles we have

$$\begin{aligned}
\mathcal{L}_{\phi^4} &= -\frac{g^2}{4!} \phi^4 \implies \\
\mathcal{L}_{X\phi^2} &= \frac{1}{2} X^2 \pm \frac{g}{2} X \phi^2 \pm \frac{g}{2} X \phi^2 = \frac{1}{2} \left(X \pm \frac{g}{2} \phi^2 \right) \left(X \pm \frac{g}{2} \phi^2 \right) - \frac{g^2}{4!} \phi^4 \quad (9.21)
\end{aligned}$$

 Explain the factor 1/3 in the functional setting and its relation to the three diagrams in the graphical setting?

Quartic Gauge Couplings

The three crossed versions of figure 9.2 reproduces the quartic coupling in figure 9.1, because

$$\begin{aligned}
& -ig^2 f_{a_1 a_2 b} f_{a_3 a_4 b} (g_{\mu_1 \mu_3} g_{\mu_4 \mu_2} - g_{\mu_1 \mu_4} g_{\mu_2 \mu_3}) \\
& = (ig f_{a_1 a_2 b} T_{\mu_1 \mu_2, \nu_1 \nu_2}) \left(\frac{ig^{\nu_1 \nu_3} g^{\nu_2 \nu_4}}{2} \right) (ig f_{a_3 a_4 b} T_{\mu_3 \mu_4, \nu_3 \nu_4}) \quad (9.24)
\end{aligned}$$

with $T_{\mu_1 \mu_2, \mu_3 \mu_4} = g_{\mu_1 \mu_3} g_{\mu_4 \mu_2} - g_{\mu_1 \mu_4} g_{\mu_2 \mu_3}$.

$$= -ig^2 f_{a_1 a_2 b} f_{a_3 a_4 b} (g_{\mu_1 \mu_3} g_{\mu_4 \mu_2} - g_{\mu_1 \mu_4} g_{\mu_2 \mu_3}) \quad (9.23)$$

Figure 9.2: Gauge couplings.

9.1.6 Gravitinos and supersymmetric currents

In supergravity theories there is a fermionic partner of the graviton, the gravitino. Therefore we have introduced the Lorentz type *Vectorspinor*.

9.1.7 Perturbative Quantum Gravity and Kaluza-Klein Interactions

The gravitational coupling constant and the relative strength of the dilaton coupling are abbreviated as

$$\kappa = \sqrt{16\pi G_N} \quad (9.25a)$$

$$\omega = \sqrt{\frac{2}{3(n+2)}} = \sqrt{\frac{2}{3(d-2)}}, \quad (9.25b)$$

where $n = d - 4$ is the number of extra space dimensions.

In (9.27-9.34), we use the notation of [13]:

$$C_{\mu\nu,\rho\sigma} = g_{\mu\rho}g_{\nu\sigma} + g_{\mu\sigma}g_{\nu\rho} - g_{\mu\nu}g_{\rho\sigma} \quad (9.26a)$$

$$D_{\mu\nu,\rho\sigma}(k_1, k_2) = g_{\mu\nu}k_{1,\sigma}k_{2,\rho} - (g_{\mu\sigma}k_{1,\nu}k_{2,\rho} + g_{\mu\rho}k_{1,\sigma}k_{2,\nu} - g_{\rho\sigma}k_{1,\mu}k_{2,\nu} + (\mu \leftrightarrow \nu)) \quad (9.26b)$$

$$E_{\mu\nu,\rho\sigma}(k_1, k_2) = g_{\mu\nu}(k_{1,\rho}k_{1,\sigma} + k_{2,\rho}k_{2,\sigma} + k_{1,\rho}k_{2,\sigma}) - (g_{\nu\sigma}k_{1,\mu}k_{1,\rho} + g_{\nu\rho}k_{2,\mu}k_{2,\sigma} + (\mu \leftrightarrow \nu)) \quad (9.26c)$$

$$F_{\mu\nu,\rho\sigma\lambda}(k_1, k_2, k_3) = g_{\mu\rho}g_{\sigma\lambda}(k_2 - k_3)_\nu + g_{\mu\sigma}g_{\lambda\rho}(k_3 - k_1)_\nu + g_{\mu\lambda}g_{\rho\sigma}(k_1 - k_2)_\nu + (\mu \leftrightarrow \nu) \quad (9.26d)$$

$$G_{\mu\nu,\rho\sigma\lambda\delta} = g_{\mu\nu}(g_{\rho\sigma}g_{\lambda\delta} - g_{\rho\delta}g_{\lambda\sigma}) + (g_{\mu\rho}g_{\nu\delta}g_{\lambda\sigma} + g_{\mu\lambda}g_{\nu\sigma}g_{\rho\delta} - g_{\mu\rho}g_{\nu\sigma}g_{\lambda\delta} - g_{\mu\lambda}g_{\nu\delta}g_{\rho\sigma} + (\mu \leftrightarrow \nu)) \quad (9.26e)$$

Table 9.23: Combined dimension-4 trilinear fermionic couplings including a momentum. *Ferm* stands for *Psi* and *Chi*. The case of *MOMR* is identical to *MOML* if one substitutes $1 + \gamma^5$ for $1 - \gamma^5$, as well as for *LMOM* and *RMOM*. The mass term forces us to keep the chiral projector always on the left after "inverting the line" for *MOML* while on the right for *LMOM*.

Figure 9.4: Three-point dilaton couplings.

Derivation of (9.27a)

$$L = \frac{1}{2}(\partial_\mu \phi)(\partial^\mu \phi) - \frac{m^2}{2}\phi^2 \quad (9.28a)$$

$$(\partial_\mu \phi) \frac{\partial L}{\partial(\partial^\nu \phi)} = (\partial_\mu \phi)(\partial_\nu \phi) \quad (9.28b)$$

$$T_{\mu\nu} = -g_{\mu\nu}L + (\partial_\mu \phi) \frac{\partial L}{\partial(\partial^\nu \phi)} + \quad (9.28c)$$

$$C_0^{\mu\nu}(k_1, k_2) = C^{\mu\nu, \mu_1\mu_2} k_{1,\mu_1} k_{2,\mu_2} \quad (9.29a)$$

$$C_1^{\mu\nu, \mu_1\mu_2}(k_1, k_2, \xi) = k_1 k_2 C^{\mu\nu, \mu_1\mu_2} + D^{\mu\nu, \mu_1\mu_2}(k_1, k_2) + \xi^{-1} E^{\mu\nu, \mu_1\mu_2}(k_1, k_2) \quad (9.29b)$$

$$C_{\frac{1}{2}, \alpha\beta}^{\mu\nu}(p, p') = \gamma_{\alpha\beta}^\mu (p + p')^\nu + \gamma_{\alpha\beta}^\nu (p + p')^\mu - 2g^{\mu\nu} (\not{p} + \not{p}')_{\alpha\beta} \quad (9.29c)$$

9.1.8 Dependent Parameters

This is a simple abstract syntax for parameter dependencies. Later, there will be a parser for a convenient concrete syntax as a part of a concrete syntax for

<i>Dilaton_Scalar_Scalar</i> : $\phi \dots k_1 k_2 \phi_1 \phi_2$
$F12 \mid F21$: $\phi_2 \leftarrow i \cdot k_1 (-k - k_1) \phi \phi_1$
$F13 \mid F31$: $\phi_1 \leftarrow i \cdot (-k - k_2) k_2 \phi \phi_2$
$F23 \mid F32$: $\phi \leftarrow i \cdot k_1 k_2 \phi_1 \phi_2$
<i>Dilaton_Vector_Vector</i> : $\phi \dots$
$F12$: $V_{2,\mu} \leftarrow i \cdot \dots$
$F21$: $V_{2,\mu} \leftarrow i \cdot \dots$
$F13$: $V_{1,\mu} \leftarrow i \cdot \dots$
$F31$: $V_{1,\mu} \leftarrow i \cdot \dots$
$F23$: $\phi \leftarrow i \cdot \dots$
$F32$: $\phi \leftarrow i \cdot \dots$
<i>Dilaton_Spinor_Spinor</i> : $\phi \dots$
$F12$: $\bar{\psi}_2 \leftarrow i \cdot \dots$
$F21$: $\bar{\psi}_2 \leftarrow i \cdot \dots$
$F13$: $\psi_1 \leftarrow i \cdot \dots$
$F31$: $\psi_1 \leftarrow i \cdot \dots$
$F23$: $\phi \leftarrow i \cdot \dots$
$F32$: $\phi \leftarrow i \cdot \dots$

Table 9.33: ...

$$\begin{aligned}
& \text{Diagram 1} = \text{Diagram 2} \quad ??? \quad (9.31a) \\
& \text{Diagram 3} = -ig \frac{\kappa}{2} C_{\mu\nu, \mu_3 \rho} (k_1 - k_2)^\rho T_{n_2 n_1}^{a_3} \quad (9.31b) \\
& \text{Diagram 4} = \text{Diagram 5} \quad ??? \quad (9.31c) \\
& \text{Diagram 6} = -g \frac{\kappa}{2} f^{a_1 a_2 a_3} (C_{\mu\nu, \mu_1 \mu_2} (k_1 - k_2)_{\mu_3} \\
& \quad + C_{\mu\nu, \mu_2 \mu_3} (k_2 - k_3)_{\mu_1} \quad (9.31d) \\
& \quad + C_{\mu\nu, \mu_3 \mu_1} (k_3 - k_1)_{\mu_2} \\

Table 9.39: ...

The PDG particle code for interfacing with Monte Carlos.

```
val pdg : flavor → int
```

The Lorentz representation of the particle.

```
val lorentz : flavor → Coupling.lorentz
```

The propagator for the particle, which *can* depend on a gauge parameter.

```
type gauge
val propagator : flavor → gauge Coupling.propagator
```

Not the symbol for the numerical value, but the scheme or strategy.

```
val width : flavor → Coupling.width
```

Charge conjugation, with and without color.

```
val conjugate : flavor → flavor
```

Returns 1 for fermions, -1 for anti-fermions, 2 for Majoranas and 0 otherwise.

```
val fermion : flavor → int
```

The Feynman rules. *vertices* and (*fuse2*, *fuse3*, *fusen*) are redundant, of course. However, *vertices* is required for building functors for models and *vertices* can be recovered from (*fuse2*, *fuse3*, *fusen*) only at great cost.

Nevertheless: *vertices* is a candidate for removal, b/c we can build a smarter *Colorize* functor acting on (*fuse2*, *fuse3*, *fusen*). It can support an arbitrary number of color lines. But we have to test whether it is efficient enough.

```
type constant
val max_degree : unit → int
val vertices : unit →
  (((flavor × flavor × flavor) × constant Coupling.vertex3 × constant) list)
  × (((flavor × flavor × flavor × flavor) × constant Coupling.vertex4 ×
  constant) list)
  × (((flavor list) × constant Coupling.vertexn × constant) list)
val fuse2 : flavor → flavor → (flavor × constant Coupling.t) list
```

```

val fuse3 : flavor → flavor → flavor → (flavor × constant Coupling.t) list
val fuse : flavor list → (flavor × constant Coupling.t) list

```

The list of all known flavors.

```

val flavors : unit → flavor list

```

The flavors that can appear in incoming or outgoing states, grouped in a way that is useful for user interfaces.

```

val external_flavors : unit → (string × flavor list) list

```

The Goldstone bosons corresponding to a gauge field, if any.

```

val goldstone : flavor → (flavor × constant Coupling.expr) option

```

The dependent parameters.

```

val parameters : unit → constant Coupling.parameters

```

Translate from and to convenient textual representations of flavors.

```

val flavor_of_string : string → flavor
val flavor_to_string : flavor → string

```

TeX and L^AT_EX

```

val flavor_to_TeX : flavor → string

```

The following must return unique symbols that are acceptable as symbols in all programming languages under consideration as targets. Strings of alphanumeric characters (starting with a letter) should be safe. Underscores are also usable, but would violate strict Fortran77.

```

val flavor_symbol : flavor → string
val gauge_symbol : gauge → string
val mass_symbol : flavor → string
val width_symbol : flavor → string
val constant_symbol : constant → string

```

Model specific options.

```

val options : Options.t

```

Revision control information.

```

val rcs : RCS.t

```

```

end

```

In addition to hardcoded models, we can have models that are initialized at run time.

9.2.2 Mutable Quantum Field Theories

```

module type Mutable =

```

```

  sig
    include T

```

Export only one big initialization function to discourage partial initializations. Labels make this usable.

```

val setup :
  color : (flavor → Color.t) →
  pdg : (flavor → int) →
  lorentz : (flavor → Coupling.lorentz) →
  propagator : (flavor → gauge Coupling.propagator) →
  width : (flavor → Coupling.width) →

  width_symbol : (flavor → string) →
  constant_symbol : (constant → string) →
  unit
end

```

9.2.3 Gauge Field Theories

The following signatures are used only for model building. The diagrammatics and numerics is supposed to be completely ignorant about the detail of the models and expected to rely on the interface *T* exclusively.

In the end, we might have functors $(M : T) \rightarrow \text{Gauge}$, but we will need to add the quantum numbers to *T*.

```

module type Gauge =
  sig
    include T

```

Matter field carry conserved quantum numbers and can be replicated in generations without changing the gauge sector.

```
type matter_field
```

Gauge bosons proper.

```
type gauge_boson
```

Higgses, Goldstones and all the rest:

```
type other
```

We can query the kind of field

```
type field =  
  | Matter of matter_field  
  | Gauge of gauge_boson  
  | Other of other  
val field : flavor → field
```

and we can build new fields of a given kind:

```
val matter_field : matter_field → flavor  
val gauge_boson : gauge_boson → flavor  
val other : other → flavor  
end
```

9.2.4 Gauge Field Theories with Broken Gauge Symmetries

Both are carefully crafted as subtypes of *Gauge* so that they can be used in place of *Gauge* and *T* everywhere:

```
module type Broken_Gauge =  
  sig  
    include Gauge  
  
    type massless  
    type massive  
    type goldstone  
  
    type kind =  
      | Massless of massless  
      | Massive of massive  
      | Goldstone of goldstone  
    val kind : gauge_boson → kind  
  
    val massless : massive → gauge_boson  
    val massive : massive → gauge_boson  
    val goldstone : goldstone → gauge_boson  
  
  end  
  
module type Unitarity_Gauge =  
  sig  
    include Gauge
```

```

type massless
type massive

type kind =
  | Massless of massless
  | Massive of massive
val kind : gauge_boson → kind

val massless : massive → gauge_boson
val massive : massive → gauge_boson

end

module type Colorized =
sig
  include T

  type flavor_sans_color
  val flavor_sans_color : flavor → flavor_sans_color
  val conjugate_sans_color : flavor_sans_color → flavor_sans_color

  val nc : unit → int
  val amplitude : flavor_sans_color list → flavor_sans_color list →
    (flavor list × flavor list) list
  val flow : flavor list → flavor list → Color.Flow.t

end

module type Colorized_Gauge =
sig
  include Gauge

  type flavor_sans_color
  val flavor_sans_color : flavor → flavor_sans_color
  val conjugate_sans_color : flavor_sans_color → flavor_sans_color

  val nc : unit → int
  val amplitude : flavor_sans_color list → flavor_sans_color list →
    (flavor list × flavor list) list
  val flow : flavor list → flavor list → Color.Flow.t

end

```

CONSERVED QUANTUM NUMBERS

10.1 Interface of Charges

10.1.1 Abstract Type

```
module type T =  
  sig
```

The abstract type of the set of conserved charges or additive quantum numbers.

```
  type t
```

Add the quantum numbers of a pair or a list of particles.

```
  val add : t → t → t
```

```
  val sum : t list → t
```

Test the charge conservation.

```
  val is_null : t → bool
```

```
end
```

10.1.2 Trivial Realisation

```
module Null : T with type t = unit
```

10.1.3 Nontrivial Realisations

Z

```
module Z : T with type t = int
```

$$\mathbf{Z} \times \mathbf{Z} \times \cdots \times \mathbf{Z}$$

```
module ZZ : T with type t = int list
```

$$\mathbf{Q}$$

```
module Q : T with type t = Algebra.Small_Rational.t
```

$$\mathbf{Q} \times \mathbf{Q} \times \cdots \times \mathbf{Q}$$

```
module QQ : T with type t = Algebra.Small_Rational.t list
```

10.2 Implementation of *Charges*

```
module type T =
sig
  type t
  val add : t → t → t
  val sum : t list → t
  val is_null : t → bool
end

module Null : T with type t = unit =

$$= g f_{a_1 a_2 a_3} C^{\mu_1 \mu_2 \mu_3}(k_1, k_2, k_3) \quad (11.1a)$$

with

$$C^{\mu_1 \mu_2 \mu_3}(k_1, k_2, k_3) = (g^{\mu_1 \mu_2}(k_1^{\mu_3} - k_2^{\mu_3}) + g^{\mu_2 \mu_3}(k_2^{\mu_1} - k_3^{\mu_1}) + g^{\mu_3 \mu_1}(k_3^{\mu_2} - k_1^{\mu_2})) \quad (11.1b)$$

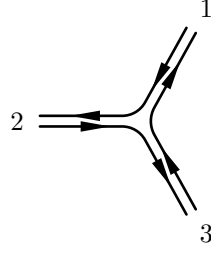

while in the color flow basis find from

$$if_{a_1 a_2 a_3} = \text{tr}(T_{a_1} [T_{a_2}, T_{a_3}]) = \text{tr}(T_{a_1} T_{a_2} T_{a_3}) - \text{tr}(T_{a_1} T_{a_3} T_{a_2}) \quad (11.2)$$

the decomposition

$$if_{a_1 a_2 a_3} T_{a_1}^{i_1 j_1} T_{a_2}^{i_2 j_2} T_{a_3}^{i_3 j_3} = \delta^{i_1 j_2} \delta^{i_2 j_3} \delta^{i_3 j_1} - \delta^{i_1 j_3} \delta^{i_3 j_2} \delta^{i_2 j_1} . \quad (11.3)$$

The resulting Feynman rule is

$$= ig (\delta^{i_1 j_3} \delta^{i_2 j_1} \delta^{i_3 j_2} - \delta^{i_1 j_2} \delta^{i_2 j_3} \delta^{i_3 j_1}) C^{\mu_1 \mu_2 \mu_3} (k_1, k_2, k_3) \quad (11.4)$$

We have to generalize this for cases of three particles in the adjoint that are not all gluons (gluinos, scalar octets):

- scalar-scalar-scalar
- scalar-scalar-vector
- scalar-vector-vector
- scalar-fermion-fermion
- vector-fermion-fermion

We could use a better understanding of the signs for the gaugino-gaugino-gaugeboson couplings!!!

```

| CF_io (f1, c1, c1'), CF_io (f2, c2, c2') →

$$\begin{aligned}
 &= -ig^2 f_{a_1 a_2 b} f_{a_3 a_4 b} (g_{\mu_1 \mu_3} g_{\mu_4 \mu_2} - g_{\mu_1 \mu_4} g_{\mu_2 \mu_3}) \\
 &\quad -ig^2 f_{a_1 a_3 b} f_{a_4 a_2 b} (g_{\mu_1 \mu_4} g_{\mu_2 \mu_3} - g_{\mu_1 \mu_2} g_{\mu_3 \mu_4}) \\
 &\quad -ig^2 f_{a_1 a_4 b} f_{a_2 a_3 b} (g_{\mu_1 \mu_2} g_{\mu_3 \mu_4} - g_{\mu_1 \mu_3} g_{\mu_4 \mu_2})
 \end{aligned} \tag{11.5}$$

Using

$$\mathcal{P}_4 = \{\{1, 2, 3, 4\}, \{1, 3, 4, 2\}, \{1, 4, 2, 3\}, \{1, 2, 4, 3\}, \{1, 4, 3, 2\}, \{1, 3, 2, 4\}\} \tag{11.6}$$

as the set of permutations of $\{1, 2, 3, 4\}$ with the cyclic permutations factored out, we have:

$$\begin{aligned}
 &= ig^2 \sum_{\{\alpha_k\}_{k=1,2,3,4} \in \mathcal{P}_4} \delta^{i_{\alpha_1} j_{\alpha_2}} \delta^{i_{\alpha_2} j_{\alpha_3}} \delta^{i_{\alpha_3} j_{\alpha_4}} \delta^{i_{\alpha_4} j_{\alpha_1}} \\
 &\quad (2g_{\mu_{\alpha_1} \mu_{\alpha_3}} g_{\mu_{\alpha_4} \mu_{\alpha_2}} - g_{\mu_{\alpha_1} \mu_{\alpha_4}} g_{\mu_{\alpha_2} \mu_{\alpha_3}} - g_{\mu_{\alpha_1} \mu_{\alpha_2}} g_{\mu_{\alpha_3} \mu_{\alpha_4}})
 \end{aligned} \tag{11.7}$$

The different color connections correspond to permutations of the particles entering the fusion and have to be matched by a corresponding permutation of the Lorentz structure:

We have to generalize this for cases of four particles in the adjoint that are not all gluons:

- scalar-scalar-scalar-scalar
- scalar-scalar-vector-vector

and even ones including fermions (gluinos) if higher dimensional operators are involved.

PROCESSES

12.1 Interface of Process

```

module type T =
  sig
    type flavor
  end

```

Eventually this should become an abstract type:

```

type t = flavor list × flavor list
val incoming : t → flavor list
val outgoing : t → flavor list

```

parse_decay *s* decodes a decay description "*a*_□->_□*b*_□*c*_□...", where each word is split into a bag of flavors separated by ':'s.

```

type decay
val parse_decay : string → decay
val expand_decays : decay list → t list

```

parse_scattering *s* decodes a scattering description "*a*_□*b*_□->_□*c*_□*d*_□...", where each word is split into a bag of flavors separated by ':'s.

```

type scattering
val parse_scattering : string → scattering
val expand_scatterings : scattering list → t list

```

parse_process *s* decodes process descriptions

$$\text{"a b c d"} \Rightarrow \text{Any } [a; b; c; d] \quad (12.1a)$$

$$\text{"a -> b c d"} \Rightarrow \text{Decay } (a, [b; c; d]) \quad (12.1b)$$

$$\text{"a b -> c d"} \Rightarrow \text{Scattering } (a, b, [c; d]) \quad (12.1c)$$

where each word is split into a bag of flavors separated by ':'s.

```

type any
type process = Any of any | Decay of decay | Scattering of scattering
val parse_process : string → process

```

remove_duplicate_final_states partition processes removes duplicates from *processes*, which differ only by a permutation of final state particles. The permutation must respect the partitioning given by the offset 1 integers in *partition*.

```
val remove_duplicate_final_states : int list list → t list → t list
```

diff set1 set2 returns the processes in *set1* with the processes in *set2* removed. *set2* does not need to be a subset of *set1*.

```
val diff : t list → t list → t list
```

Not functional yet. Interface subject to change. Should be moved to *Fusion.Multi*, because we will want to cross *colored* matrix elements.

Factor amplitudes that are related by crossing symmetry.

```
val crossing : t list → (flavor list × int list × t) list
```

```
end
```

```
module Make (M : Model.T) : T with type flavor = M.flavor
```

12.2 Implementation of *Process*

```
module type T =
```

```

```

```
  val outgoing : t → flavor list
```

```
  type decay
```

```
  val parse_decay : string → decay
```

```
  val expand_decays : decay list → t list
```

```
  type scattering
```

```
  val parse_scattering : string → scattering
```

```
  val expand_scatterings : scattering list → t list
```

```
  type any
```

```
  type process = Any of any | Decay of decay | Scattering of scattering
```

```
  val parse_process : string → process
```

```
  val remove_duplicate_final_states : int list list → t list → t list
```

```
  val diff : t list → t list → t list
```

```
  val crossing : t list → (flavor list × int list × t) list
```

```
end
```

```
module Make (M : Model.T) =
```

```

        c1
      else
        let c2 = F.compare f2 f2' in
        if c2 ≠ 0 then
          c2
        else
          F.compare f3 f3'
    let equal f f' = compare f f' = 0
  end
module Fn =
  struct
    type t = f list
    let hash = Hashtbl.hash
    let compare f f' = ThoList.compare ~cmp : F.compare f f'
    let equal f f' = compare f f' = 0
  end
module H2 = Hashtbl.Make (F2)
module H3 = Hashtbl.Make (F3)
module Hn = Hashtbl.Make (Fn)
type t =
  { v3 : (f × c Coupling.t) list H2.t;
    v4 : (f × c Coupling.t) list H3.t;
    vn : (f × c Coupling.t) list Hn.t }
let fuse2 table f1 f2 =
  try
    H2.find table.v3 (f1, f2)
  with
  | Not_found → []
let fuse3 table f1 f2 f3 =
  try
    H3.find table.v4 (f1, f2, f3)
  with
  | Not_found → []
let fusen table f =
  try

```

```

      Hn.find table.vn f
    with
    | Not_found → []
  let fuse table = function
    | [] | [-] → invalid_arg "Fusions().fuse"
    | [f1; f2] → fuse2 table f1 f2
    | [f1; f2; f3] → fuse3 table f1 f2 f3
    | f → fusen table f

```

Note that a pair or a triplet can appear more than once (e.g. $e^+e^- \rightarrow \gamma$ and $e^+e^- \rightarrow Z$). Therefore don't replace the entry, but augment it instead.

```

  let add_fusion2 table f1 f2 fusions =
    H2.add table.v3 (f1, f2) (fusions :: fuse2 table f1 f2)

  let add_fusion3 table f1 f2 f3 fusions =
    H3.add table.v4 (f1, f2, f3) (fusions :: fuse3 table f1 f2 f3)

  let add_fusionn table f fusions =
    Hn.add table.vn f (fusions :: fusen table f)

```

Do we need to take into account the charge conjugation of the coupling constants here?

If some flavors are identical, we must not introduce the same vertex more than once:

```

open Coupling

let permute3 (f1, f2, f3) =
  [ (f1, f2), F.conjugate f3, F12;
    (f2, f1), F.conjugate f3, F21;
    (f2, f3), F.conjugate f1, F23;
    (f3, f2), F.conjugate f1, F32;
    (f3, f1), F.conjugate f2, F31;
    (f1, f3), F.conjugate f2, F13 ]

```

Here we add identical permutations of pairs only once:

```

module F2' = Set.Make (F2)

let add_permute3 table v c set ((f1, f2 as f12), f, p) =
  if F2'.mem f12 set then
    set
  else begin
    add_fusion2 table f1 f2 (f, V3 (v, p, c));
    F2'.add f12 set
  end

let add_vertex3 table (f123, v, c) =
  ignore (List.fold_left (fun set f → add_permute3 table v c set f)
    F2'.empty (permute3 f123))

```

Handling all the cases explicitly is OK for cubic vertices, but starts to become questionable already for quartic couplings. The advantage remains that we can check completeness in *Targets*.

```
let permute4 (f1, f2, f3, f4) =
  [ (f1, f2, f3), F.conjugate f4, F123;
    (f2, f3, f1), F.conjugate f4, F231;
    (f3, f1, f2), F.conjugate f4, F312;
    (f2, f1, f3), F.conjugate f4, F213;
    (f3, f2, f1), F.conjugate f4, F321;
    (f1, f3, f2), F.conjugate f4, F132;
    (f1, f2, f4), F.conjugate f3, F124;
    (f2, f4, f1), F.conjugate f3, F241;
    (f4, f1, f2), F.conjugate f3, F412;
    (f2, f1, f4), F.conjugate f3, F214;
    (f4, f2, f1), F.conjugate f3, F421;
    (f1, f4, f2), F.conjugate f3, F142;
    (f1, f3, f4), F.conjugate f2, F134;
    (f3, f4, f1), F.conjugate f2, F341;
    (f4, f1, f3), F.conjugate f2, F413;
    (f3, f1, f4), F.conjugate f2, F314;
    (f4, f3, f1), F.conjugate f2, F431;
    (f1, f4, f3), F.conjugate f2, F143;
    (f2, f3, f4), F.conjugate f1, F234;
    (f3, f4, f2), F.conjugate f1, F342;
    (f4, f2, f3), F.conjugate f1, F423;
    (f3, f2, f4), F.conjugate f1, F324;
    (f4, f3, f2), F.conjugate f1, F432;
    (f2, f4, f3), F.conjugate f1, F243 ]
```

Add identical permutations of triplets only once:

```
module F3' = Set.Make (F3)

let add_permute4 table v c set ((f1, f2, f3 as f123), f, p) =
  if F3'.mem f123 set then
    set
  else begin
    add_fusion3 table f1 f2 f3 (f, V4 (v, p, c));
    F3'.add f123 set
  end

let add_vertex4 table (f1234, v, c) =
  ignore (List.fold_left (fun set f → add_permute4 table v c set f)
    F3'.empty (permute4 f1234))

let of_vertices (vlist3, vlist4, vlistn) =
  match vlistn with
  | [] →
    let table =
      { v3 = H2.create 37; v4 = H3.create 37; vn = Hn.create 37 } in
    List.iter (add_vertex3 table) vlist3;
```

```

      List.iter (add_vertex4 table) vlist4;
      table
    | _ → failwith "Models.Fusions.of_vertices:␣incomplete"
end

```

13.2.2 Mutable Models

```

module Mutable (FGC : sig type f and g and c end) =

The current abstract syntax for parameter dependencies is admittedly tedious. Later, there will be a parser for a convenient concrete syntax as a part of a concrete syntax for models. But as these examples show, it should include simple functions.

$$\alpha_{\text{QED}} = \frac{1}{137.0359895} \quad (13.1a)$$

$$\sin^2 \theta_w = 0.23124 \quad (13.1b)$$

```
let input_parameters =

$$\begin{aligned} \mathcal{L}_{\text{TGC}}(g_1, \kappa) &= g_1 \mathcal{L}_T(V, W^+, W^-) \\ &+ \frac{\kappa + g_1}{2} \left(\mathcal{L}_T(W^-, V, W^+) - \mathcal{L}_T(W^+, V, W^-) \right) \\ &+ \frac{\kappa - g_1}{2} \left(\mathcal{L}_L(W^-, V, W^+) - \mathcal{L}_T(W^+, V, W^-) \right) \end{aligned} \quad (13.10)$$

The whole thing in the LEP2 workshop notation:

$$\begin{aligned} & i\mathcal{L}_{\text{TGC},V}/g_{WWV} = \\ & g_1^V V^\mu (W_{\mu\nu}^- W^{+\nu} - W_{\mu\nu}^+ W^{-,\nu}) + \kappa_V W_\mu^+ W_\nu^- V^{\mu\nu} + \frac{\lambda_V}{m_W^2} V_{\mu\nu} W_{\rho\mu}^- W^{+,\nu\rho} \\ & + ig_5^V \epsilon_{\mu\nu\rho\sigma} ((\partial^\rho W^{-,\mu}) W^{+,\nu} - W^{-,\mu} (\partial^\rho W^{+,\nu})) V^\sigma \\ & + ig_4^V W_\mu^- W_\nu^+ (\partial^\mu V^\nu + \partial^\nu V^\mu) - \frac{\tilde{\kappa}_V}{2} W_\mu^- W_\nu^+ \epsilon^{\mu\nu\rho\sigma} V_{\rho\sigma} - \frac{\tilde{\lambda}_V}{2m_W^2} W_{\rho\mu}^- W^{+,\mu}_\nu \epsilon^{\nu\rho\alpha\beta} V_{\alpha\beta} \end{aligned} \quad (13.11)$$

using the conventions of Itzykson and Zuber with $\epsilon^{0123} = +1$.

This is equivalent to the notation of Hagiwara et al. [?], if we remember that they have opposite signs for g_{WWV} :

$$\begin{aligned}
\mathcal{L}_{WWV}/(-g_{WWV}) = & \\
& ig_1^V (W_{\mu\nu}^\dagger W^\mu - W_\mu^\dagger W_\nu^\mu) V^\nu + i\kappa_V W_\mu^\dagger W_\nu V^{\mu\nu} + i\frac{\lambda_V}{m_W^2} W_{\lambda\mu}^\dagger W_\nu^\mu V^{\nu\lambda} \\
& - g_4^V W_\mu^\dagger W_\nu (\partial^\mu V^\nu + \partial^\nu V^\mu) + g_5^V \epsilon^{\mu\nu\lambda\sigma} \left(W_\mu^\dagger \overset{\leftrightarrow}{\partial}_\lambda W_\nu \right) V_\sigma \\
& + i\tilde{\kappa}_V W_\mu^\dagger W_\nu \tilde{V}^{\mu\nu} + i\frac{\tilde{\lambda}_V}{m_W^2} W_{\lambda\mu}^\dagger W_\nu^\mu \tilde{V}^{\nu\lambda} \quad (13.12)
\end{aligned}$$

Here V^μ stands for either the photon or the Z field, W^μ is the W^- field, $W_{\mu\nu} = \partial_\mu W_\nu - \partial_\nu W_\mu$, $V_{\mu\nu} = \partial_\mu V_\nu - \partial_\nu V_\mu$, and $\tilde{V}_{\mu\nu} = \frac{1}{2}\epsilon_{\mu\nu\lambda\sigma} V^{\lambda\sigma}$.

$$\mathcal{L}_{\text{QGC}} = -g^2 W_{+,\mu} W_{-,\nu} W_+^\mu W_-^\nu + \dots \quad (13.13)$$

Actually, quartic gauge couplings are a little bit more straightforward using auxiliary fields. Here we have to impose the antisymmetry manually:

$$\begin{aligned} & (W_1^{+,\mu} W_2^{-,\nu} - W_1^{+,\nu} W_2^{-,\mu})(W_{3,\mu}^+ W_{4,\nu}^- - W_{3,\nu}^+ W_{4,\mu}^-) \\ & = 2(W_1^+ W_3^+)(W_2^- W_4^-) - 2(W_1^+ W_4^-)(W_2^- W_3^+) \end{aligned} \quad (13.14a)$$

also (V can be A or Z)

$$\begin{aligned} & (W_1^{+,\mu} V_2^\nu - W_1^{+,\nu} V_2^\mu)(W_{3,\mu}^- V_{4,\nu} - W_{3,\nu}^- V_{4,\mu}) \\ & = 2(W_1^+ W_3^-)(V_2 V_4) - 2(W_1^+ V_4)(V_2 W_3^-) \end{aligned} \quad (13.14b)$$

$$W_1^{+,\mu} W_2^{-,\nu} W_\mu^+ W_\nu^- \quad (13.15a)$$

```

In any diagonal channel χ , the scattering amplitude $a_\chi(s)$ is unitary iff¹

$$\text{Im} \left(\frac{1}{a_\chi(s)} \right) = -1 \quad (13.20)$$

For a real perturbative scattering amplitude $r_\chi(s)$ this can be enforced easily—and arbitrarily—by

$$\frac{1}{a_\chi(s)} = \frac{1}{r_\chi(s)} - i \quad (13.21)$$

let *k_matrix-quartic-gauge* =

¹Trivial proof:

$$-1 = \text{Im} \left(\frac{1}{a_\chi(s)} \right) = \frac{\text{Im}(a_\chi^*(s))}{|a_\chi(s)|^2} = -\frac{\text{Im}(a_\chi(s))}{|a_\chi(s)|^2} \quad (13.19)$$

i. e. $\text{Im}(a_\chi(s)) = |a_\chi(s)|^2$.

13.4.7 Incomplete Standard Model in R_ξ Gauge

At the end of the day, we want a functor mapping from gauge models in unitarity gauge to R_ξ gauge and vice versa. For this, we will need a more abstract implementation of (spontaneously broken) gauge theories.

```

module SM_Rxi =
struct
  let rcs = RCS.rename rcs_file "Modellib.SM_Rxi"
    [ "minimal_electroweak_standard_model_in_R-xi_gauge";
      "NB: very incomplete still!, no CKM matrix" ]

  open Coupling

  module SM = SM(SM_no_anomalous)
  let options = SM.options
  type flavor = SM.flavor
  let flavors = SM.flavors
  let external_flavors = SM.external_flavors
  type constant = SM.constant
  let lorentz = SM.lorentz
  let color = SM.color
  let goldstone = SM.goldstone
  let conjugate = SM.conjugate
  let fermion = SM.fermion

```

Check if it makes sense to have separate gauge fixing parameters for each vector boson. There's probably only one independent parameter for each group factor.

```

type gauge =
  | XiA | XiZ | XiW

let gauge_symbol = function
  | XiA → "xia" | XiZ → "xi0" | XiW → "xipm"

```

Change the gauge boson propagators and make the Goldstone bosons propagating.

```

let propagator = function
  | SM.G SM.Ga → Prop_Gauge XiA
  | SM.G SM.Z → Prop_Rxi XiZ
  | SM.G SM.Wp | SM.G SM.Wm → Prop_Rxi XiW
  | SM.O SM.Phip | SM.O SM.Phim | SM.O SM.Phi0 → Prop_Scalar
  | f → SM.propagator f

let width = SM.width

module Ch = Charges.QQ
let charges = SM.charges

module F = Modeltools.Fusions (struct
  type f = flavor
  type c = constant
  let compare = compare
  let conjugate = conjugate
end)

let vertices = SM.vertices

```

```

let table = F.of_vertices (vertices ())
let fuse2 = F.fuse2 table
let fuse3 = F.fuse3 table
let fuse = F.fuse table
let max_degree () = 3

let parameters = SM.parameters
let flavor_of_string = SM.flavor_of_string
let flavor_to_string = SM.flavor_to_string
let flavor_to_TeX = SM.flavor_to_TeX
let flavor_symbol = SM.flavor_symbol
let pdg = SM.pdg
let mass_symbol = SM.mass_symbol
let width_symbol = SM.width_symbol
let constant_symbol = SM.constant_symbol

end

```

13.4.8 Groves

```

There are PDG numbers for Z' , Z'' , W' , 32-34, respectively. We just introduce a number 38 for $Y0$ as a Z'' . As well, there is the number 8 for a t' . But we cheat a little bit and take the number 35 which is reserved for a heavy scalar Higgs for the Eta scalar. For the heavy Higgs states we take 35 and 36 for the neutral ones, 37 for the charged and 38 for the doubly-charged. The pseudoscalar gets the 39.

There are PDG numbers for Z', Z'', W', 32-34, respectively. We just introduce a number 38 for Y0 as a Z''. As well, there is the number 8 for a t'. But we cheat a little bit and take the number 35 which is reserved for a heavy scalar Higgs for the Eta scalar. For the heavy Higgs states we take 35 and 36 for the neutral ones, 37 for the charged and 38 for the doubly-charged. The pseudoscalar gets the 39. For the odd fermions we add 40 to the values for the SM particles.

```

The current abstract syntax for parameter dependencies is admittedly tedious. Later, there will be a parser for a convenient concrete syntax as a part of a concrete syntax for models. But as these examples show, it should include simple functions.

```

There are PDG numbers for Z' , Z'' , W' , 32-34, respectively. We just introduce a number 38 for $Y0$ as a Z''' . As well, there is the number 8 for a t' . But we

cheat a little bit and take the number 35 which is reserved for a heavy scalar Higgs for the Eta scalar.

We abuse notation for the heavy quarks and take the PDG code for their SUSY partners!!! (What about an update of the PDG numbering scheme?) Thereby we take only those for up-type (s)quarks. The heavy neutrinos get the numbers of the sneutrinos.

```
let pdg = function
| L n when n > 0 → 9 + 2 × n
| L n → - 9 + 2 × n
| N n when n > 0 → 10 + 2 × n
| N n → - 10 + 2 × n
| U n when n > 0 → 2 × n
| U n → 2 × n
| D n when n > 0 → - 1 + 2 × n
| D n → 1 + 2 × n
| NH n when n > 0 → 1000010 + 2 × n
| NH n → - 1000010 + 2 × n
| QH 3 → 1000006
| QH (-3) → - 1000006
| QH n when n > 0 → if Flags.anom_ferm_ass then
    1000000 + 2 × n else 999999 + 2 × n
| QH n → if Flags.anom_ferm_ass then
    - 1000000 + 2 × n else - 999999 + 2 × n
| Gl → 21
| Ga → 22 | Z → 23
| Wp → 24 | Wm → (-24)
| Xp → 34 | Xm → (-34) | ZH → 32 | X0 → 33 | Y0 → 38
| Phip | Phim → 27 | Phi0 → 26
| H → 25 | Eta → 36
```

As in the case of SUSY we introduce an internal dummy pdf code in order to have manageable arrays. Heavy neutrinos get numbers 41,43,45, while the heavy quarks have the numbers 40,42,44. I take them all as up type here.

```

        ",reduced_set_of_couplings:" ^ (renderbool Module_options.diet)
      ]
  end

```

Shamelessly stolen from *Modellib.SM3*, but with no support for fudged width yet

```

    let default_width = ref Timelike

```

If this flag is set true, all gauge bosons are assumed to be massless and are assigned feynman gauge propagators. This in conjunction with the unbroken three site model is intended for checking gauge invariance via the ward identities.

```
let all_feynman = ref false

let options = Options.create [
  "constant_width", Arg.Unit (fun _ → default_width := Constant),
    "use_constant_width(also_in_t-channel)";
  "custom_width", Arg.String (fun x → default_width := Custom x),
    "use_custom_width";
  "cancel_widths", Arg.Unit (fun _ → default_width := Vanishing),
    "use_vanishing_width";
  "all_feynman", Arg.Unit (fun _ → all_feynman := true),
    "assign_feynman_gauge_propagators_to_all_gauge_bosons\n"
    ^ "\t(for checking the ward identities); use only if you *really* know\n"
    ^ "\twhat you are doing"]
```

The quantum numbers that are carried by the particles. *csign* is *not* the charge carried by the particle, but differentiates between particles (*Pos*) and antiparticles (*Neg*)

```
type kkmode = Light | Heavy
type generation = Gen0 | Gen1 | Gen2
type csign = Pos | Neg
type isospin = Iso_up | Iso_down
```

Necessary to represent the indices of the couplings defined in FORTRAN

```
type kk2 = Light2 | Heavy2 | Light_Heavy
```

Map the different types to the constants used in the FORTRAN module

```
let fspec_of_kkmode = function Light → "l_mode" | Heavy →
  "h_mode"
let fspec_of_kk2 = function
  Light2 → "l_mode" | Heavy2 → "h_mode" | Light_Heavy →
  "lh_mode"
let fspec_of_gen = function Gen0 → "gen_0" | Gen1 → "gen_1" |
  Gen2 → "gen_2"
let fspec_of_iso = function Iso_up → "iso_up" | Iso_down →
  "iso_down"
```

Covert the “charge sign” into a numeric sign (used e.g. in the determination of the MCID codes)

```
let int_of_csign = function Pos → 1 | Neg → -1
```

Convert the generation into an integer (dito)

```
let int_of_gen = function Gen0 → 1 | Gen1 → 2 | Gen2 → 3
```

The type *flavor* is implemented as a variant. Fermions are implemented as a variant differentiating between leptons and quarks (seemed the most natural way as this is also the way in which the FORTRAN code is structured). Bosons are implemented as a variant the differentiates between *W*, *Z* and *A*. All other

quantum numbers that are required for identifying the particles are carried by the variant constructors.

```

type fermion =
  | Lepton of (kkmode × csign × generation × isospin)
  | Quark of (kkmode × csign × generation × isospin)

type boson =
  | W of (kkmode × csign)
  | Z of kkmode
  | A
  | G

type flavor = Fermion of fermion | Boson of boson

```

Helpers to construct particles from quantum numbers

```

let lepton kk cs gen iso = Lepton (kk, cs, gen, iso)
let quark kk cs gen iso = Quark (kk, cs, gen, iso)
let w kk cs = W (kk, cs)
let z kk = Z kk
let flavor_of_f x = Fermion x
let flavor_of_b x = Boson x

```

Map a list of functions to the list (partially) applied to a value

```
let revmap funs v = List.map (fun x → x v) funs
```

The same for a list of values; the result is flattened

```
let revmap2 funs vals = ThoList.flatmap (revmap funs) vals
```

Functions to loop the constructors over quantum numbers for list creation purposes

```

let loop_kk flist = revmap2 flist [Light; Heavy]
let loop_cs flist = revmap2 flist [Pos; Neg]
let loop_gen flist = revmap2 flist [Gen0; Gen1; Gen2]
let loop_iso flist = revmap2 flist [Iso_up; Iso_down]
let loop_kk2 flist = revmap2 flist [Light2; Heavy2; Light_Heavy]

```

Conditional looping over kk modes depending on whether to include heavy fermions

```

let cloop_kk flist = match Module_options.include_hf with
  | true → loop_kk flist
  | false → revmap flist Light
let cloop_kk2 flist = match Module_options.include_hf with
  | true → loop_kk2 flist
  | false → revmap flist Light2

```

Having defined the necessary helpers, the magic of currying makes building lists of particles as easy as nesting the loop functions in the correct order...

```

let all_leptons = loop_iso (loop_gen (loop_cs (cloop_kk [lepton] )))
let all_quarks = loop_iso (loop_gen (loop_cs (cloop_kk [quark] )))
let all_bosons = (loop_cs (loop_kk [w] )) @ [Z Light; Z Heavy; A; G]

```

Converts a flavor spec to the BCD identifier defined in the FORTRAN module. Splitting the function into two parts **prefix** and **rump** removes a lot of redundancy.

```

let bcdi_of_flavor =
let prefix = function
  | Fermion (Lepton (Heavy, -, -, -)) | Fermion (Quark (Heavy, -, -, -))
  | Boson (W (Heavy, -)) | Boson (Z Heavy) → "h"
  | _ → ""
in let rump = function
  | Fermion (Lepton spec) → (match spec with
    | (_, -, Gen0, Iso_up) → "nue"
    | (_, -, Gen0, Iso_down) → "e"
    | (_, -, Gen1, Iso_up) → "numu"
    | (_, -, Gen1, Iso_down) → "mu"
    | (_, -, Gen2, Iso_up) → "nutau"
    | (_, -, Gen2, Iso_down) → "tau")
  | Fermion (Quark spec) → (match spec with
    | (_, -, Gen0, Iso_up) → "u"
    | (_, -, Gen0, Iso_down) → "d"
    | (_, -, Gen1, Iso_up) → "c"
    | (_, -, Gen1, Iso_down) → "s"
    | (_, -, Gen2, Iso_up) → "t"
    | (_, -, Gen2, Iso_down) → "b")
  | Boson (W _) → "w" | Boson (Z _) → "z"
  | Boson A → invalid_arg (modname ^ ".bcd_of_flavor:_no_bcd_for_photon!")
  | Boson G → invalid_arg (modname ^ ".bcd_of_flavor:_no_bcd_for_gluon!")
in function x → (prefix x) ^ (rump x) ^ "_bcd"

```

The function defined in the model signature which returns the colour representation of a particle

```

let color =
let quarkrep = function
  | (_, Pos, -, -) → Color.SUN 3
  | (_, Neg, -, -) → Color.SUN (-3)
in function
  | Fermion (Quark x) → quarkrep x
  | Boson G → Color.AdjSUN 3
  | _ → Color.Singlet

```

Function for calculating the MCID code of a particle. Conventions have been choosen such that the heavy modes are identified by the same numbers as the light ones, prefixed with 99. This is supposedly in accord with the conventions for adding new particles to the list of MCID codes. This function is required by the signature.

```

let pdg =
let iso_delta = function Iso_down → 0 | Iso_up → 1
in let gen_delta = function Gen0 → 0 | Gen1 → 2 | Gen2 → 4
in let kk_delta = function Light → 0 | Heavy → 9900
in function
  | Fermion ( Lepton (kk, cs, gen, iso)) →

```

```

      (int_of_csign cs) × (11 + (gen_delta gen) + (iso_delta iso) + (kk_delta kk))
| Fermion (Quark (kk, cs, gen, iso)) →
      (int_of_csign cs) × (1 + (gen_delta gen) + (iso_delta iso) + (kk_delta kk))
| Boson (W (kk, cs)) → (int_of_csign cs) × (24 + (kk_delta kk))
| Boson (Z kk) → 23 + (kk_delta kk)
| Boson A → 22
| Boson G → 21

```

Returns the lorentz representation of a particle; required by the signature.

```

let lorentz =
let spinor = function
  | (_, Pos, _, _) → Spinor
  | (_, Neg, _, _) → ConjSpinor
in function
  | Fermion (Lepton x) | Fermion (Quark x) → spinor x
  | Boson (W _) | Boson (Z _) → Massive_Vector
  | Boson A → Vector
  | Boson G → Vector

```

O'Mega supports models that allow different gauges; however, we only implement unitary gauge and therefore stub this (SM3 does the same thing). The `gauge` type as well as `gauge_symbol` are required by the signature.

```

type gauge = unit
let gauge_symbol () =
  failwith (modname ^ ".gauge_symbol: internal error")

```

Returns the propagator for a given particle type. Required by signature.

```

let propagator =
let spinorprop = function
  | (_, Pos, _, _) → Prop_Spinor
  | (_, Neg, _, _) → Prop_ConjSpinor
in function
  | Fermion (Lepton x) | Fermion (Quark x) → spinorprop x
  | Boson (W _) | Boson (Z _) →
    (match !all_feynman with false → Prop_Unitarity | true →
     Prop_Feynman)
  | Boson A → Prop_Feynman
  | Boson G → Prop_Feynman

```

Return the width of a particle, required by signature.

TODO: Refine such that stable particles always are treated via vanishing width, as this might speed up the generated code a bit.

```

let width _ = !default_width

```

Returns the conjugate particle; required by signature.

```

let conjugate =
let conj_csign = function
  | Pos → Neg
  | Neg → Pos
in function

```

```

| Fermion (Lepton (kk, cs, gen, iso)) → Fermion (Lepton (kk, conj_csign cs, gen, iso))
| Fermion (Quark (kk, cs, gen, iso)) → Fermion (Quark (kk, conj_csign cs, gen, iso))
| Boson (W (kk, cs)) → Boson (W (kk, conj_csign cs))
| x → x

```

Tells the diagram generator whether a particle is a fermion, a conjugate fermion or a boson. Required by signature

```

let fermion = function
| Fermion (Lepton (_, cs, _, _)) | Fermion (Quark (_, cs, _, _)) →
int_of_csign cs
| Boson _ → 0

```

Charges are: charge, lepton number, baryon number, generation. Required by signature

```

module Ch = Charges.QQ
let ( // ) = Algebra.Small_Rational.make

let qn_charge = function
| Boson b → (match b with
| W (_, c) → (int_of_csign (c)) // 1
| _ → 0//1)
| Fermion f → (match f with
| Lepton (_, c, _, Iso_up) → 0//1
| Lepton (_, c, _, Iso_down) → (-1 × int_of_csign (c)) // 1
| Quark (_, c, _, Iso_up) → (2 × int_of_csign (c)) // 3
| Quark (_, c, _, Iso_down) → (-1 × int_of_csign (c)) // 3)

let qn_lepton = function
| Fermion (Lepton (_, c, _, _)) → int_of_csign (c) // 1
| _ → 0//1

let qn_baryon = function
| Fermion (Quark (_, c, _, _)) → int_of_csign (c) // 1
| _ → 0//1

```

Generation is conditional: if we enable the nontrivial CKM matrix, all particles carry generation 0; 0; 0

```

let qn_generation x =
let qn cs gen =
let c = int_of_csign (cs) in
match gen with
| Gen0 → [c//1; 0//1; 0//1]
| Gen1 → [0//1; c//1; 0//1]

  (loop_kk (loop_kk2 [g_wwz] )) @ (loop_kk2 (loop_kk2 [g_wwzz] )) @
  (loop_kk (loop_kk2 [g_wwza] )) @ (List.map g_wwww [0; 1; 2; 3; 4])
```

Maximum number of lines meeting at a vertex, required by signature.

```
let max_degree () = 4
```

Transform a pair of kk identifiers into a kk2 identifier

```
let get_kk2 = function (Light, Light) → Light2 | (Heavy, Heavy) →
Heavy2
  | (Light, Heavy) | (Heavy, Light) → Light_Heavy
```

Flip isospin

```
let conj_iso = function Iso_up → Iso_down | Iso_down → Iso_up
```

Below, lists of couplings are generated which ultimately are joined into a list of all couplings in the model. The generated lists can be viewed using the `dump.ml` script in the O'Mega toplevel directory.

The individual couplings are defined as 5-tupels resp. 6-tupels consisting in this order of the particles meeting at the vertex, the coupling type (see `couplings.ml`) and the coupling constant.

List of llA type vertices

```

The list of couplings is transformed into the fusion lists required by the generator by the `Model.Fusions` functor.

This is copy& paste from the other models; check again with Thorsten if it is correct

```

module F = Modeltools.Fusions (struct
  type f = flavor
  type c = constant
  let compare = compare
  let conjugate = conjugate
end )

```

Not sure yet whether `F.fusex` also creates the conjugate vertices; by looking at the implementation of the other models, I assume it doesn't. Still, better ask Thorsten to be sure!!!

Update: Still didn't get to ask, but since the results are consistent, I suspect my assertion is correct.

The stuff below is required by the signature.

```

let vertices () = (vertices_all @ vertices_aqq @
  (match Module_options.diet with
    | false → vertices_wll
    | true → vertices_wll_diet) @
  (match (Module_options.include_ckm, Module_options.diet) with
    | (true, false) → vertices_wqq
    | (false, false) → vertices_wqq_no_ckm
    | (false, true) → vertices_wqq_no_ckm_diet
    | (true, true) → raise (Failure
      ("Modules4.Threesh1.vertices:_CKM_matrix_together_with_option_diet_is_not" ^
        "_implemented_yet!"))) @
  vertices_zll @ vertices_zqq @ vertices_auw @ vertices_zww @ vertices_gqq @ vertices_ggg,
  vertices_aauw @ vertices_wvzz @ vertices_wvza @ vertices_www @ vertices_gggg
  , [])
let table = F.of_vertices (vertices ())
let fuse2 = F.fuse2 table

```

```
let fuse3 = F.fuse3 table
let fuse = F.fuse table
```

A function that returns a list of a flavours known to the model, required by the signature.

```
let flavors () = (List.map flavor_of_f (all_leptons @ all_quarks)) @
  (List.map flavor_of_b all_bosons)
```

ditto, external flavours, also required.

```
let external_flavors () = [
  "light_leptons", List.map flavor_of_f (loop_iso (loop_gen (loop_cs [lepton Light])));
  "light_quarks", List.map flavor_of_f (loop_iso (loop_gen (loop_cs [quark Light])));
  "light_gauge_bosons", List.map flavor_of_b [W (Light, Pos); W (Light, Neg); Z Light; A];
  "heavy_gauge_bosons", List.map flavor_of_b [W (Heavy, Pos); W (Heavy, Neg); Z Heavy] @
  (match Module_options.include_hf with
  | true → [
    "heavy_leptons", List.map flavor_of_f (loop_iso (loop_gen (loop_cs [lepton Heavy])));
    "heavy_quarks", List.map flavor_of_f (loop_iso (loop_gen (loop_cs [quark Heavy])))]
  | false → []) @ ["gluons", [Boson G]]
```

Which of the particles are goldstones? → none. Required by the signature.

```
let goldstone x = None
```

This is wrong but handy for debugging the constant identifier generation via -params. Usually, this function would return a record consisting of the parameters as well as expression for the dependent quantities that can be used to generate FORTRAN code for calculating them. However, we have a separate module for the threeshl, so we can abuse this for debugging. Required by signature.

```
let parameters () = {input = List.map (fun x → (x, 0.)) clist;
  derived = []; derived_arrays = []}
```

Convert a flavour into a ID string with which it will be referred by the user interface of the compiled generator. Required by signature

```
let flavor_to_string =
let prefix = function
  | Fermion (Lepton (Heavy, -, -, -)) | Fermion (Quark (Heavy, -, -, -))
  | Boson (W (Heavy, -)) | Boson (Z Heavy) → "H"
  | _ → ""
in let postfix = function
  | Fermion (Lepton (-, cs, -, Iso_down)) → (match cs with Pos →
  "-" | Neg → "+")
  | Fermion (Quark (-, Neg, -, -)) | Fermion (Lepton (-, Neg, -, Iso_up)) →
  "bar"
  | Boson (W (-, cs)) → (match cs with Pos → "+" | Neg → "-")
  | _ → ""
in let rump = function
  | Fermion (Lepton desc) → (match desc with
  | (-, -, Gen0, Iso_up) → "nue"
```

```

| (-, -, Gen0, Iso_down) → "e"
| (-, -, Gen1, Iso_up) → "numu"
| (-, -, Gen1, Iso_down) → "mu"
| (-, -, Gen2, Iso_up) → "nutau"
| (-, -, Gen2, Iso_down) → "tau")
| Fermion (Quark desc) → (match desc with

| (-, -, Gen2, Iso_up) → "t"
| (-, -, Gen2, Iso_down) → "b")
| Boson (W _) → "W" | Boson (Z _) → "Z" | Boson A → "A" |
Boson G → "g1"
in function x → (prefix x) ^ (rump x) ^ (postfix x)

```

Conversion of the ID string into a particle flavor. Instead of going through all cases again, we generate a “dictionary” of flavor / ID pairs which we use to identify the correct flavor. Required by signature.

```

let flavor_of_string x =
let dict = List.map (fun x → (x, flavor_to_string x)) (flavors ())
in let get_ident = function (x, _) → x
in try
  get_ident (List.find (fun (_, y) → (x = y)) dict)
with
  Not_found → (match x with
  | "g" → Boson G
  | _ → invalid_arg (modname ^ ".flavor_of_string")
  )

```

Converts a flavor into a symbol used as identification in the generated FORTRAN code (has to comply to the conventions of valid FORTRAN identifiers therefore). We stick to the same conventions as SM3, prefixing heavy modes with a H. Required by signature.

```

let flavor_symbol =
let prefix = function
| Fermion (Lepton (Heavy, -, -, -)) | Fermion (Quark (Heavy, -, -, -))
| Boson (W (Heavy, -)) | Boson (Z Heavy) → "H"
| _ → ""
in let postfix = function
| Fermion (Lepton (_, Neg, -, -)) | Fermion (Quark (_, Neg, -, -)) →
"b"
| _ → ""
in let rump = function
| Fermion spec → (match spec with
| Lepton (_, -, gen, Iso_up) → "n" ^ (string_of_int (int_of_gen gen))
| Lepton (_, -, gen, Iso_down) → "l" ^ (string_of_int (int_of_gen gen))
| Quark (_, -, gen, Iso_up) → "u" ^ (string_of_int (int_of_gen gen))
| Quark (_, -, gen, Iso_down) → "d" ^ (string_of_int (int_of_gen gen))
| Boson spec → (match spec with

```

```

      | W (_, Pos) → "wp" | W (_, Neg) → "wm"
      | Z _ → "z" | A → "a" | G → "g1" )
in function
  x → (prefix x) ^ (rump x) ^ (postfix x)

Generate TeX for a flavor

let flavor_to_TeX =

    type gen =
      | G of int | GG of gen × gen

    let rec string_of_gen = function
      | G n when n > 0 → string_of_int n
      | G n → string_of_int (abs n) ^ "c"
      | GG (g1, g2) → string_of_gen g1 ^ "-" ^ string_of_gen g2
  end

```

With this we distinguish the flavour.

```

type sff =
  | SL | SN | SU | SD

let string_of_sff = function
  | SL → "s1" | SN → "sn" | SU → "su" | SD → "sd"

```

With this we distinguish the mass eigenstates. At the moment we have to cheat a little bit for the sneutrinos. Because we are dealing with massless neutrinos there is only one sort of sneutrino.

```

type sfm =
  | M1 | M2

let string_of_sfm = function
  | M1 → "1" | M2 → "2"

```

We also introduce special types for the charginos and neutralinos.

```

type char =
  | C1 | C2 | C1c | C2c

type neu =
  | N1 | N2 | N3 | N4

let int_of_char = function
  | C1 → 1 | C2 → 2 | C1c → -1 | C2c → -2

let string_of_char = function
  | C1 → "1" | C2 → "2" | C1c → "-1" | C2c → "-2"

let conj_char = function
  | C1 → C1c | C2 → C2c | C1c → C1 | C2c → C2

let string_of_neu = function
  | N1 → "1" | N2 → "2" | N3 → "3" | N4 → "4"

```

Also we need types to distinguish the Higgs bosons. We follow the conventions of Kuroda, which means

$$H_1 = \begin{pmatrix} \frac{1}{\sqrt{2}}(v_1 + H^0 \cos \alpha - h^0 \sin \alpha + iA^0 \sin \beta - i\phi^0 \cos \beta) \\ H^- \sin \beta - \phi^- \cos \beta \end{pmatrix}, \quad (13.34)$$

$$H_2 = \begin{pmatrix} H^+ \cos \beta + \phi^+ \sin \beta \\ \frac{1}{\sqrt{2}}(v_2 + H^0 \sin \alpha + h^0 \cos \alpha + iA^0 \cos \beta + i\phi^0 \sin \beta) \end{pmatrix} \quad (13.35)$$

This is a different sign convention compared to, e.g., Weinberg's volume iii. We will refer to it as *GS+*.

```

type higgs =
  | H1 (* the light scalar Higgs *)
  | H2 (* the heavy scalar Higgs *)
  | H3 (* the pseudoscalar Higgs *)
  | H4 (* the charged Higgs *)
  | H5 (* the neutral Goldstone boson *)
  | H6 (* the charged Goldstone boson *)
  | DH of higgs × higgs

let rec string_of_higgs = function
  | H1 → "h1" | H2 → "h2" | H3 → "h3" | H4 → "h4"
  | H5 → "p1" | H6 → "p2"
  | DH (h1, h2) → string_of_higgs h1 ^ string_of_higgs h2

type flavor =
  | L of int | N of int
  | U of int | D of int
  | Sup of sfm × int | Sdown of sfm × int
  | Ga | Wp | Wm | Z | Gl

| Grino → Only_Insertion

```

Note, that we define the gravitino only as an insertion since when using propagators we are effectively going to a higher order in the gravitational coupling. This would enforce us to also include higher-dimensional vertices with two gravitinos for a consistent power counting in $1/M_{\text{Planck}}$.

Optionally, ask for the fudge factor treatment for the widths of charged particles. Currently, this only applies to W^\pm and top.

```

let width f =
if !use_fudged_width then
  match f with
  | Wp | Wm | U 3 | U (-3) → Fudged
  | - → !default_width
else
  !default_width

```

Because the O'Caml compiler only allows 248 constructors we must divide the constants into subgroups of constants, e.g. for the Higgs couplings. In the MSSM there are a lot of angles among the parameters, the Weinberg-angle, the angle describing the Higgs vacuum structure, the mixing angle of the real parts of the Higgs dubletts, the mixing angles of the sfermions. Therefore we are going to define the trigonometric functions of those angles not as constants but as functors of the angles. Sums and differences of angles are only used as arguments for the α and β angles, so it makes no sense to define special functions for differences and sums of angles.

```

type angle =

```

```

| Thw | Al | Be | Th_SF of sff × int | Delta | CKM_12 |
CKM_13 | CKM_23

let string_of_angle = function
| Thw → "thw" | Al → "al" | Be → "be" | Delta → "d"

"ckm23"
| Th_SF (f, g) → "th" ^ string_of_sff f ^ string_of_int g

```

We introduce a Boolean type *vc* as a pseudonym for Vertex Conjugator to distinguish between vertices containing complex mixing matrices like the CKM-matrix or the sfermion or neutralino/chargino-mixing matrices, which have to become complex conjugated. The true-option stands for the conjugated vertex, the false-option for the unconjugated vertex.

```

type vc = bool

```

let ferm_of_sff = function
| SL, g → (L g) | SN, g → (N g)
| SU, g → (U g) | SD, g → (D g)

```

$$\alpha_{\text{QED}} = \frac{1}{137.0359895} \quad (13.37a)$$

$$\sin^2 \theta_w = 0.23124 \quad (13.37b)$$

Here we must perhaps allow for complex input parameters. So split them into their modulus and their phase. At first, we leave them real; the generalization to complex parameters is obvious.

For the couplings there are generally two possibilities concerning the sign of the covariant derivative.

$$CD^\pm = \partial_\mu \pm igT^a A_\mu^a \quad (13.38)$$

The particle data group defines the signs consistently to be positive. Since the convention for that signs also influence the phase definitions of the gaugino/higgsino fields via the off-diagonal entries in their mass matrices it would be the best to adopt that convention.

where the sign corresponds to CD_\pm , respectively.

** REVISED: Compatible with CD_+ . **

Remark: The definition with the other sign compared to the SM files comes from the fact that $g_{cc} = 1/(2\sqrt{2})$ is used overwhelmingly often in the SUSY Feynman rules, so that JR decided to use a different definition for g_{cc} in SM and MSSM.

The 4-slepton-vertices have the following structure: The sleptons come up in pairs of a positive and a negative slepton of the same generation; there is no vertex with e.g. two negative selectrons and two positive smuons, that of course would be a contradiction to the conservation of the separate slepton numbers of each generation which is not implemented in the MSSM. Because there is no CKM-mixing for the sleptons (in case of massless neutrinos) we maximally have two different generations of sleptons in a 4-slepton-vertex.

We must take care of the pdg numbers for the two different kinds of sfermions in the MSSM. The particle data group in its Monte Carlo particle numbering scheme takes only into account mixtures of the third generation squarks and the stau. For the other sfermions we will use the number of the lefthanded field for the lighter mixed state and the one for the righthanded for the heavier. Below are the official pdg numbers from the Particle Data Group. In order not to produce arrays with some million entries in the Fortran code for the masses and the widths we introduce our private pdg numbering scheme which only extends not too far beyond 42. Our private scheme then has the following pdf numbers (for the sparticles the subscripts L/R and $1/2$ are taken synonymously):

d	down-quark	1
u	up-quark	2
s	strange-quark	3
c	charm-quark	4
b	bottom-quark	5
t	top-quark	6
e^-	electron	11
ν_e	electron-neutrino	12
μ^-	muon	13
ν_μ	muon-neutrino	14
τ^-	tau	15
ν_τ	tau-neutrino	16
g	gluon	(9) 21
γ	photon	22
Z^0	Z-boson	23
W^+	W-boson	24
h^0	light Higgs boson	25
H^0	heavy Higgs boson	35
A^0	pseudoscalar Higgs	36
H^\pm	charged Higgs	37
$\tilde{\psi}_\mu$	gravitino	39
\tilde{d}_L	down-squark 1	41
\tilde{u}_L	up-squark 1	42
\tilde{s}_L	strange-squark 1	43
\tilde{c}_L	charm-squark 1	44
\tilde{b}_L	bottom-squark 1	45
\tilde{t}_L	top-squark 1	46
\tilde{d}_R	down-squark 2	47
\tilde{u}_R	up-squark 2	48
\tilde{s}_R	strange-squark 2	49
\tilde{c}_R	charm-squark 2	50
\tilde{b}_R	bottom-squark 2	51
\tilde{t}_R	top-squark 2	52
\tilde{e}_L	selectron 1	53
$\tilde{\nu}_{e,L}$	electron-sneutrino	54
$\tilde{\mu}_L$	smuon 1	55
$\tilde{\nu}_{\mu,L}$	muon-sneutrino	56
$\tilde{\tau}_L$	stau 1	57
$\tilde{\nu}_{\tau,L}$	tau-sneutrino	58
\tilde{e}_R	selectron 2	59
$\tilde{\mu}_R$	smuon 2	61
$\tilde{\tau}_R$	stau 2	426 63
\tilde{g}	gluino	64
$\tilde{\chi}_1^0$	neutralino 1	65
$\tilde{\chi}_2^0$	neutralino 2	66
$\tilde{\chi}_3^0$	neutralino 3	67
$\tilde{\chi}_4^0$	neutralino 4	68
$\tilde{\chi}_1^\pm$	chargino 1	69

```

13.9 Interface of *Modellib_NMSSM*

13.9.1 Extended Supersymmetric Models

We do not introduce the possibility here of using four point couplings or not. We simply add the relevant and leave the rest out. No possibility for Goldstone bosons is given. But we allow for CKM mixing.

```

module type NMSSM_flags =
  sig
    val ckm_present : bool
  end

module NMSSM : NMSSM_flags
module NMSSM_CKM : NMSSM_flags
module NMSSM_func : functor (F : NMSSM_flags) → Model.T with mod-
ule Ch = Charges.QQ

```

13.10 Implementation of *Modellib_NMSSM*

```

let rcs_file = RCS.parse "Modellib_NMSSM" ["NMSSM"]
  { RCS.revision = "$Revision: 2701$";
    RCS.date = "$Date: 2010-07-12 01:04:45 +0200 (Mon, 12 Jul 2010)$";
    RCS.author = "$Author: jr-reuter$";
    RCS.source
      = "$URL: svn+ssh://jr-reuter@login.hepforge.org/hepforge/svn/whizard/trunk/src/omeg

```

13.10.1 Next-to-Minimal Supersymmetric Standard Model

This is based on the NMSSM implementation by Felix Braam. Note that for the Higgs sector vertices the conventions of the Franke/Fraas paper have been used.

```

module type NMSSM_flags =
  sig
    val ckm_present : bool
  end

module NMSSM : NMSSM_flags =
  struct
    let ckm_present = false
  end

module NMSSM_CKM : NMSSM_flags =
  struct
    let ckm_present = true
  end

```

```

end

module NMSSM_func (Flags : NMSSM_flags) =
  struct
    let rcs = RCS.rename rcs_file "Modellib_NMSSM.NMSSM"
      [ "NMSSM" ]

    open Coupling

    let default_width = ref Timelike
    let use_fudged_width = ref false

    let options = Options.create
      [ "constant_width", Arg.Unit (fun () → default_width := Constant),
        "use_constant_width_also_in_t-channel";
        "fudged_width", Arg.Set use_fudged_width,
        "use_fudge_factor_for_charge_particle_width";
        "custom_width", Arg.String (fun f → default_width := Custom f),
        "use_custom_width";
        "cancel_widths", Arg.Unit (fun () → default_width := Vanishing),
        "use_vanishing_width" ]

```

Yields a list of tuples consistig of the off-diag combinations of the elements in "set".

```

let choose2 set =
  List.map (function [x; y] → (x, y) | _ → failwith "choose2")
    (Combinatorics.choose 2 set)

```

pairs appends the diagonal combinations to *choose2*.

```

let rec diag = function
  | [] → []
  | x1 :: rest → (x1, x1) :: diag rest

```

```
let pairs l = choose2 l @ diag l
```

```

let rec loop set i j k =
  if i > ((List.length set) - 1) then []
  else if j > i then loop set (succ i) (j - i - 1) (j - i - 1)
  else if k > j then loop set i (succ j) (k - j - 1)
  else (List.nth set i, List.nth set j, List.nth set k) :: loop set i j (succ k)

```

```
let triples set = loop set 0 0 0
```

```

let rec two_and_one' l1 z n =
  if n < 0 then []
  else
    ((fst (List.nth (pairs l1) n)), (snd (List.nth (pairs l1) n)), z) :: two_and_one' l1 z (pred n)

```

```

let two_and_one l1 l2 =
  let f z = two_and_one' l1 z ((List.length (pairs l1)) - 1)
  in
    List.flatten ( List.map f l2 )

```

```

type gen =
  | G of int | GG of gen × gen

```

```

let rec string_of_gen = function

We introduce a Boolean type `vc` as a pseudonym for Vertex Conjugator to distinguish between vertices containing complex mixing matrices like the CKM-matrix or the sfermion or neutralino/chargino-mixing matrices, which have to become complex conjugated. The `true`-option stands for the conjugated vertex, the `false`-option for the unconjugated vertex.

```

```

$$\alpha_{\text{QED}} = \frac{1}{137.0359895} \quad (13.40a)$$

$$\sin^2 \theta_w = 0.23124 \quad (13.40b)$$

Here we must perhaps allow for complex input parameters. So split them into their modulus and their phase. At first, we leave them real; the generalization to complex parameters is obvious.

```

let parameters () =
  { input = [];
    derived = [];
    derived_arrays = [] }

module F = Modeltools.Fusions (struct
  type f = flavor

```

```

type c = constant
let compare = compare
let conjugate = conjugate
end)

```

For the couplings there are generally two possibilities concerning the sign of the covariant derivative.

$$\text{CD}^\pm = \partial_\mu \pm igT^a A_\mu^a \quad (13.41)$$

The particle data group defines the signs consistently to be positive. Since the convention for that signs also influence the phase definitions of the gaugino/higgsino fields via the off-diagonal entries in their mass matrices it would be the best to adopt that convention.

where the sign corresponds to CD_\pm , respectively.

** REVISED: Compatible with CD+. **

Remark: The definition with the other sign compared to the SM files comes from the fact that $g_{cc} = 1/(2\sqrt{2})$ is used overwhelmingly often in the SUSY Feynman rules, so that JR decided to use a different definition for g_{cc} in SM and MSSM.

We must take care of the pdg numbers for the two different kinds of sfermions in the MSSM. The particle data group in its Monte Carlo particle numbering scheme takes only into account mixtures of the third generation squarks and the stau. For the other sfermions we will use the number of the lefthanded field for the lighter mixed state and the one for the righthanded for the heavier. Below are the official pdg numbers from the Particle Data Group. In order not to produce arrays with some million entries in the Fortran code for the masses and the widths we introduce our private pdg numbering scheme which only extends not too far beyond 42. Our private scheme then has the following pdf numbers (for the sparticles the subscripts L/R and $1/2$ are taken synonymously):

d	down-quark	1
u	up-quark	2
s	strange-quark	3
c	charm-quark	4
b	bottom-quark	5
t	top-quark	6
e^-	electron	11
ν_e	electron-neutrino	12
μ^-	muon	13
ν_μ	muon-neutrino	14
τ^-	tau	15
ν_τ	tau-neutrino	16
g	gluon	(9) 21
γ	photon	22
Z^0	Z-boson	23
W^+	W-boson	24
h^0	light Higgs boson	25
H^0	heavy Higgs boson	35
A^0	pseudoscalar Higgs	36
H^\pm	charged Higgs	37
\tilde{d}_L	down-squark 1	41
\tilde{u}_L	up-squark 1	42
\tilde{s}_L	strange-squark 1	43
\tilde{c}_L	charm-squark 1	44
\tilde{b}_L	bottom-squark 1	45
\tilde{t}_L	top-squark 1	46
\tilde{d}_R	down-squark 2	47
\tilde{u}_R	up-squark 2	48
\tilde{s}_R	strange-squark 2	49
\tilde{c}_R	charm-squark 2	50
\tilde{b}_R	bottom-squark 2	51
\tilde{t}_R	top-squark 2	52
\tilde{e}_L	selectron 1	53
$\tilde{\nu}_{e,L}$	electron-sneutrino	54
$\tilde{\mu}_L$	smuon 1	55
$\tilde{\nu}_{\mu,L}$	muon-sneutrino	56
$\tilde{\tau}_L$	stau 1	57
$\tilde{\nu}_{\tau,L}$	tau-sneutrino	58
\tilde{e}_R	selectron 2	59
$\tilde{\mu}_R$	smuon 2	61
$\tilde{\tau}_R$	stau 2	63
\tilde{g}	gluino 460	64
$\tilde{\chi}_1^0$	neutralino 1	65
$\tilde{\chi}_2^0$	neutralino 2	66
$\tilde{\chi}_3^0$	neutralino 3	67
$\tilde{\chi}_4^0$	neutralino 4	68
$\tilde{\chi}_5^0$	neutralino 5	69
$\tilde{\chi}_1^\pm$	chargino 1	70

13.11 Interface of *Modellib_PSSSM*

13.11.1 Extended Supersymmetric Models

We do not introduce the possibility here of using four point couplings or not. We simply add the relevant and leave the rest out. No possibility for Goldstone bosons is given. But we allow for CKM mixing.

```

module type extMSSM_flags =
  sig
    val ckm_present : bool
  end

module PSSSM : extMSSM_flags
module PSSSM_QCD : extMSSM_flags
module ExtMSSM : functor (F : extMSSM_flags) → Model.T with mod-
ule Ch = Charges.QQ

```

13.12 Implementation of *Modellib_PSSSM*

```
let rcs_file = RCS.parse "Modellib_PSSSM" ["Extended_SUSY_models"]
{ RCS.revision = "$Revision: 2701$";
  RCS.date = "$Date: 2010-07-12 01:04:45 +0200 (Mon, 12 Jul 2010)$";
  RCS.author = "$Author: jr-reuter$";
  RCS.source
    = "$URL: svn+ssh://jr-reuter@login.hepforge.org/hepforge/svn/whizard/trunk/src/omeg
```

13.12.1 Extended Supersymmetric Standard Model(s)

This is based on the NMSSM implementation by Felix Braam, and extended to the exotica – leptoquarks, leptoquarkinos, additional Higgses etc. – by Daniel Wiesler. Note that for the Higgs sector vertices the conventions of the Franke/Fraas paper have been used.

```
module type extMSSM_flags =
sig
  val ckm_present : bool
end

module PSSSM : extMSSM_flags =
struct
  let ckm_present = false
end

module PSSSM_QCD : extMSSM_flags =
struct
  let ckm_present = false
end

module ExtMSSM (Flags : extMSSM_flags) =
struct
  let rcs = RCS.rename rcs_file "Modellib_PSSSM.NMSSM"
    [ "Extended_SUSY_models" ]

  open Coupling

  let default_width = ref Timelike
  let use_fudged_width = ref false

  let options = Options.create
    [ "constant_width", Arg.Unit (fun () → default_width := Constant),
      "use_constant_width(also_in_t-channel)",
      "fudged_width", Arg.Set use_fudged_width,
      "use_fudge_factor_for_charge_particle_width",
      "custom_width", Arg.String (fun f → default_width := Custom f),
      "use_custom_width",
      "cancel_widths", Arg.Unit (fun () → default_width := Vanishing),
      "use_vanishing_width" ]

  additional_combinatorics
```

yields a list of tuples consistig of the off-diag combinations of the elements in "set"

```
let choose2 set =
  List.map (function [x;y] → (x,y) | _ → failwith "choose2")
    (Combinatorics.choose 2 set)
```

pairs

pairs appends the diagonal combinations to *choose2*

```
let rec diag = function
  | [] → []
  | x1 :: rest → (x1, x1) :: diag rest
let pairs l = choose2 l @ diag l
```

triples

rank 3 generalization of *pairs*

```
let rec cloop set i j k =
  if i > ((List.length set) - 1) then []
  else if j > i then cloop set (succ i) (j - i - 1) (j - i - 1)
  else if k > j then cloop set i (succ j) (k - j - 1)
  else (List.nth set i, List.nth set j, List.nth set k) :: cloop set i j (succ k)
let triples set = cloop set 0 0 0
(* two_and_one *)
let rec two_and_one' l1 z n =
  if n < 0 then []
  else
    ((fst (List.nth (pairs l1) n)), (snd (List.nth (pairs l1) n)), z) :: two_and_one' l1 z (pred n)
let two_and_one l1 l2 =
  let f z = two_and_one' l1 z ((List.length (pairs l1)) - 1)
  in
    List.flatten ( List.map f l2 )
type gen =
  | G of int | GG of gen × gen
let rec string_of_gen = function
  | G n when n > 0 → string_of_int n
  | G n → string_of_int (abs n) ^ "c"
  | GG (g1, g2) → string_of_gen g1 ^ "-" ^ string_of_gen g2
```

With this we distinguish the flavour.

```
type sff =
  | SL | SN | SU | SD
let string_of_sff = function
  | SL → "s1" | SN → "sn" | SU → "su" | SD → "sd"
```

With this we distinguish the mass eigenstates. At the moment we have to cheat a little bit for the sneutrinos. Because we are dealing with massless neutrinos there is only one sort of sneutrino.

```

type sfm =
  | M1 | M2

let string_of_sfm = function
  | M1 → "1" | M2 → "2"

```

We also introduce special types for the charginos and neutralinos.

```

type char =
  | C1 | C2 | C1c | C2c | C3 | C3c | C4 | C4c

 G_LQ_P of $sfm \times sfm \times int \times phiggs \times int$
 G_ZLQ of $int \times sfm \times sfm$

$$\begin{array}{ccccccc} & | & G_ZZLQLQ & | & G_ZPLQLQ & | & G_PPLQLQ & | & G_ZGLQLQ & | \\ G_PGLQLQ & | & G_NLQC & | & G_GLQLQLQ & & & & & \end{array}$$

$$\alpha_{\text{QED}} = \frac{1}{137.0359895} \quad (13.43a)$$

$$\sin^2 \theta_w = 0.23124 \quad (13.43b)$$

Here we must perhaps allow for complex input parameters. So split them into their modulus and their phase. At first, we leave them real; the generalization to complex parameters is obvious.

```
let parameters () =
  { input = [];
    derived = [];
    derived_arrays = [] }

module F = Modeltools.Fusions (struct
  type f = flavor
  type c = constant
  let compare = compare
  let conjugate = conjugate
end)
```

For the couplings there are generally two possibilities concerning the sign of the covariant derivative.

$$CD^\pm = \partial_\mu \pm igT^a A_\mu^a \quad (13.44)$$

The particle data group defines the signs consistently to be positive. Since the convention for that signs also influence the phase definitions of the gaugino/higgsino fields via the off-diagonal entries in their mass matrices it would be the best to adopt that convention.

$$\mathcal{L}_{CC} = \mp \frac{g}{2\sqrt{2}} \sum_i \bar{\psi}_i \gamma^\mu (1 - \gamma_5) (T^+ W_\mu^+ + T^- W_\mu^-) \psi_i, \quad (13.45)$$

where the sign corresponds to CD_\pm , respectively.

** REVISED: Compatible with CD_+ . **

Remark: The definition with the other sign compared to the SM files comes from the fact that $g_{cc} = 1/(2\sqrt{2})$ is used overwhelmingly often in the SUSY Feynman rules, so that JR decided to use a different definition for g_{cc} in SM and MSSM.

```

We must take care of the pdg numbers for the two different kinds of sfermions in the MSSM. The particle data group in its Monte Carlo particle numbering scheme takes only into account mixtures of the third generation squarks and the stau. For the other sfermions we will use the number of the lefthanded field for the lighter mixed state and the one for the righthanded for the heavier. Below are the official pdg numbers from the Particle Data Group. In order not to produce arrays with some million entries in the Fortran code for the masses and the widths we introduce our private pdg numbering scheme which only extends not too far beyond 42. Our private scheme then has the following pdf numbers (for the sparticles the subscripts L/R and $1/2$ are taken synonymously):

d	down-quark	1
u	up-quark	2
s	strange-quark	3
c	charm-quark	4
b	bottom-quark	5
t	top-quark	6
e^-	electron	11
ν_e	electron-neutrino	12
μ^-	muon	13
ν_μ	muon-neutrino	14
τ^-	tau	15
ν_τ	tau-neutrino	16
g	gluon	(9) 21
γ	photon	22
Z^0	Z-boson	23
W^+	W-boson	24
h^0	light Higgs boson	25
H^0	heavy Higgs boson	35
A^0	pseudoscalar Higgs	36
H^\pm	charged Higgs	37
\tilde{d}_L	down-squark 1	41
\tilde{u}_L	up-squark 1	42
\tilde{s}_L	strange-squark 1	43
\tilde{c}_L	charm-squark 1	44
\tilde{b}_L	bottom-squark 1	45
\tilde{t}_L	top-squark 1	46
\tilde{d}_R	down-squark 2	47
\tilde{u}_R	up-squark 2	48
\tilde{s}_R	strange-squark 2	49
\tilde{c}_R	charm-squark 2	50
\tilde{b}_R	bottom-squark 2	51
\tilde{t}_R	top-squark 2	52
\tilde{e}_L	selectron 1	53
$\tilde{\nu}_{e,L}$	electron-sneutrino	54
$\tilde{\mu}_L$	smuon 1	55
$\tilde{\nu}_{\mu,L}$	muon-sneutrino	56
$\tilde{\tau}_L$	stau 1	57
$\tilde{\nu}_{\tau,L}$	tau-sneutrino	58
\tilde{e}_R	selectron 2	59
$\tilde{\mu}_R$	smuon 2	61
$\tilde{\tau}_R$	stau 2	63
\tilde{g}	gluino 496	64
$\tilde{\chi}_1^0$	neutralino 1	65
$\tilde{\chi}_2^0$	neutralino 2	66
$\tilde{\chi}_3^0$	neutralino 3	67
$\tilde{\chi}_4^0$	neutralino 4	68
$\tilde{\chi}_5^0$	neutralino 5	69
$\tilde{\chi}_1^\pm$	chargino 1	70

Using a two element array for the combined vector-axial and scalar-pseudo couplings helps to support HELAS as well. Since we will probably never support general boson couplings with HELAS, it might be retired in favor of two separate variables. For this *Model.constant_symbol* has to be generalized.

NB: passing the array instead of two separate constants would be a *bad* idea, because the support for Majorana spinors below will have to flip signs!

`print_current` is the most important function that has to match the functions in `omega95` (see appendix X). It offers plentiful opportunities for making mistakes, in particular those related to signs. We start with a few auxiliary functions:

```

let children2 rhs =
  match F.children rhs with
  | [wf1; wf2] → (wf1, wf2)
  | _ → failwith "Targets.children2: can't happen"

let children3 rhs =
  match F.children rhs with
  | [wf1; wf2; wf3] → (wf1, wf2, wf3)
  | _ → invalid_arg "Targets.children3: can't happen"

```

Note that it is (marginally) faster to multiply the two scalar products with the coupling constant than the four vector components.

This could be part of `omegalib` as well ...

```

let format_coeff = function
  | 1 → ""
  | -1 → "-"
  | coeff → "(" ^ string_of_int coeff ^ ")*"

let format_coupling coeff c =
  match coeff with
  | 1 → c
  | -1 → "(-" ^ c ^ ")"
  | coeff → string_of_int coeff ^ "*" ^ c

```

The following is error prone and should be generated automatically.

```

let print_vector4 c wf1 wf2 wf3 fusion (coeff, contraction) =
  match contraction, fusion with

```

```

```

```

fusion (coeff, contraction)

let print_current amplitude dictionary rhs =
  match F.coupling rhs with
  | V3 (vertex, fusion, constant) →
    let ch1, ch2 = children2 rhs in
    let wf1 = multiple_variable amplitude dictionary ch1
    and wf2 = multiple_variable amplitude dictionary ch2
    and p1 = momentum ch1
    and p2 = momentum ch2
    and m1 = CM.mass_symbol (F.flavor ch1)
    and m2 = CM.mass_symbol (F.flavor ch2) in
    let c = CM.constant_symbol constant in
    printf "@,%s" (if (F.sign rhs) < 0 then "-" else "+");
    begin match vertex with

```

Fermionic currents $\bar{\psi}A\psi$ and $\bar{\psi}\phi\psi$ are handled by the *Fermions* module, since they depend on the choice of Feynman rules: Dirac or Majorana.

```

| FBF (coeff, fb, b, f) →
  Fermions.print_current (coeff, fb, b, f) c wf1 wf2 fusion
| PBP (coeff, f1, b, f2) →
  Fermions.print_current_p (coeff, f1, b, f2) c wf1 wf2 fusion
| BBB (coeff, fb1, b, fb2) →
  Fermions.print_current_b (coeff, fb1, b, fb2) c wf1 wf2 fusion
| GBG (coeff, fb, b, f) → let p12 =
  Printf.sprintf "(-%s-%s)" p1 p2 in
  Fermions.print_current_g (coeff, fb, b, f) c wf1 wf2 p1 p2
  p12 fusion

```

Table 9.13 is a bit misleading, since it includes totally antisymmetric structure constants. The space-time part alone is also totally antisymmetric:

```

| Gauge_Gauge_Gauge coeff →
  let c = format_coupling coeff c in
  begin match fusion with
  | (F23 | F31 | F12) →
    printf "g-gg(%s,%s,%s,%s,%s)" c wf1 p1 wf2 p2
  | (F32 | F13 | F21) →
    printf "g-gg(%s,%s,%s,%s,%s)" c wf2 p2 wf1 p1
  end

```

In *Aux_Gauge_Gauge*, we can not rely on antisymmetry alone, because of the different Lorentz representations of the auxiliary and the gauge field. Instead we have to provide the sign in

$$(V_2 \wedge V_3) \cdot T_1 = \begin{cases} V_2 \cdot (T_1 \cdot V_3) = -V_2 \cdot (V_3 \cdot T_1) \\ V_3 \cdot (V_2 \cdot T_1) = -V_3 \cdot (T_1 \cdot V_2) \end{cases} \quad (15.1)$$

ourselves. Alternatively, one could provide *g_xg* mirroring *g_gx*.

```

| Aux_Gauge_Gauge coeff →
  let c = format_coupling coeff c in
  begin match fusion with

```

```

| F23 → printf "x_gg(%s,%s,%s)" c wf1 wf2
| F32 → printf "x_gg(%s,%s,%s)" c wf2 wf1
| F12 → printf "g_gx(%s,%s,%s)" c wf2 wf1
| F21 → printf "g_gx(%s,%s,%s)" c wf1 wf2
| F13 → printf "(-1)*g_gx(%s,%s,%s)" c wf2 wf1
| F31 → printf "(-1)*g_gx(%s,%s,%s)" c wf1 wf2
end

```

These cases are symmetric and we just have to juxtapose the correct fields and provide parentheses to minimize the number of multiplications.

```

| F23 → printf "grav_ss(%s,%s,%s,%s,%s,%s)" c m1 p1 p2 wf1 wf2
| F32 → printf "grav_ss(%s,%s,%s,%s,%s,%s)" c m1 p2 p1 wf2 wf1
end

```

In producing a vector in the fusion we always contract the rightmost index with the vector wavefunction from *rhs*. So the first momentum is always the one of the vector boson produced in the fusion, while the second one is that from the *rhs*. This makes the cases *F12* and *F13* as well as *F21* and *F31* equal. In principle, we could have already done this for the *Graviton_Scalar_Scalar* case.

```

Spin, Flavor & Color Tables

The following abomination is required to keep the number of continuation lines as low as possible. FORTRAN77-style `DATA` statements are actually a bit nicer here, but they are not available for *constant* arrays.

We used to have a more elegant design with a sentinel 0 added to each initializer, but some revisions of the Compaq/Digital Compiler have a bug that causes it to reject this variant.

The actual table writing code using `reshape` should be factored, since it's the same algorithm every time.

```

Majorana Fermions

JR sez' (regarding the Majorana Feynman rules): For this function we need a different approach due to our aim of implementing the fermion vertices with the right line as ingoing (in a calculational sense) and the left line in a fusion as outgoing. In defining all external lines and the fermionic wavefunctions built out of them as ingoing we have to invert the left lines to make them outgoing. This happens by multiplying them with the inverse charge conjugation matrix in an appropriate representation and then transposing it. We must distinguish whether the direction of calculation and the physical direction of the fermion number flow are parallel or antiparallel. In the first case we can use the "normal" Feynman rules for Dirac particles, while in the second, according to the paper of Denner et al., we have to reverse the sign of the vector and antisymmetric bilinears of the Dirac spinors, cf. the *Coupling* module.

Note the subtlety for the left- and righthanded couplings: Only the vector part of these couplings changes in the appropriate cases its sign, changing the chirality to the negative of the opposite. (*JR's probably right, but I need to check myself ...*)

This function is for the vertices with three particles including two fermions but also a momentum, therefore with a dimensionful coupling constant, e.g. the gravitino vertices. One has to distinguish between the two kinds of canonical orders in the string of gamma matrices. Of course, the direction of the string of gamma matrices is reversed if one goes from the *Gravbar*, *-*, *Psi* to the *Psibar*, *-*, *Grav* vertices, and the same is true for the couplings of the gravitino to the Majorana fermions. For more details see the tables in the *coupling* implementation.

We now have to fix the directions of the momenta. For making the compiler happy and because we don't want to make constructions of infinite complexity we list the momentum including vertices without gravitinos here; the pattern matching says that's better. Perhaps we have to find a better name now.

For the cases of *MOM*, *MOM5*, *MOML* and *MOMR* which arise only in BRST transformations we take the mass as a coupling constant. For *VMOM* we don't need a mass either. These vertices are like kinetic terms and so need not have a coupling constant. By this we avoid a strange and awful construction with a new variable. But be careful with a generalization if you want to use these vertices for other purposes.

"Targets.Fortran-Majorana-Fermions: not used in the models"

```

We need support for dimension-5 vertices with two fermions and two bosons, appearing in theories of supergravity and also together with in insertions of the supersymmetric current. There is a canonical order *fermionbar*, *boson_1*, *boson_2*, *fermion*, so what one has to do is a mapping from the fusions *F123* etc. to the order of the three wave functions *wf1*, *wf2* and *wf3*.

The function *d_p* (for distinct the particle) distinguishes which particle (scalar or vector) must be fused to in the special functions.

```

PHASE SPACE

16.1 Interface of Phasespace

```

module type T =
  sig
    type momentum

    type  $\alpha$  t
    type  $\alpha$  decay
  end

```

Sort individual decays and complete phasespaces in a canonical order to determine topological equivalence classes.

```

val sort : ( $\alpha \rightarrow \alpha \rightarrow \text{int}$ )  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\alpha$  t
val sort_decay : ( $\alpha \rightarrow \alpha \rightarrow \text{int}$ )  $\rightarrow$   $\alpha$  decay  $\rightarrow$   $\alpha$  decay

```

Functionals:

```

val map : ( $\alpha \rightarrow \beta$ )  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\beta$  t
val map_decay : ( $\alpha \rightarrow \beta$ )  $\rightarrow$   $\alpha$  decay  $\rightarrow$   $\beta$  decay

val eval : ( $\alpha \rightarrow \beta$ )  $\rightarrow$  ( $\alpha \rightarrow \beta$ )  $\rightarrow$  ( $\alpha \rightarrow \beta \rightarrow \beta \rightarrow \beta$ )  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\beta$  t
val eval_decay : ( $\alpha \rightarrow \beta$ )  $\rightarrow$  ( $\alpha \rightarrow \beta \rightarrow \beta \rightarrow \beta$ )  $\rightarrow$   $\alpha$  decay  $\rightarrow$ 
 $\beta$  decay

```

of_momenta *f1 f2 plist* constructs the phasespace parameterization for a process $f_1 f_2 \rightarrow X$ with flavor decoration from pairs of outgoing momenta and flavors *plist* and initial flavors *f1* and *f2*

```

val of_momenta :  $\alpha \rightarrow \alpha \rightarrow (\text{momentum} \times \alpha)$  list  $\rightarrow$  ( $\text{momentum} \times \alpha$ ) t
val decay_of_momenta : ( $\text{momentum} \times \alpha$ ) list  $\rightarrow$  ( $\text{momentum} \times \alpha$ ) decay

exception Duplicate of momentum
exception Unordered of momentum
exception Incomplete of momentum

```

end

```

module Make (M : Momentum.T) : T with type momentum = M.t

```

16.2 Implementation of *Phasespace*

16.2.1 Tools

These are candidates for *ThoList* and not specific to phase space.

```
let rec first_match' mismatch f = function
| [] → None
| x :: rest →
  if f x then
    Some (x, List.rev_append mismatch rest)
  else
    first_match' (x :: mismatch) f rest
```

Returns $(x, X \setminus \{x\})$ if $\exists x \in X : f(x)$.

```
let first_match f l = first_match' [] f l
```

```
let rec first_pair' mismatch1 f l1 l2 =
  match l1 with
  | [] → None
  | x1 :: rest1 →
    begin match first_match (f x1) l2 with
    | None → first_pair' (x1 :: mismatch1) f rest1 l2
    | Some (x2, rest2) →
        Some ((x1, x2), (List.rev_append mismatch1 rest1, rest2))
    end
```

Returns $((x, y), (X \setminus \{x\}, Y \setminus \{y\}))$ if $\exists x \in X : \exists y \in Y : f(x, y)$.

```
let first_pair f l1 l2 = first_pair' [] f l1 l2
```

16.2.2 Phase Space Parameterization Trees

```
module type T =
sig
  type momentum
  type  $\alpha$  t
  type  $\alpha$  decay
  val sort : ( $\alpha \rightarrow \alpha \rightarrow \text{int}$ )  $\rightarrow \alpha$  t  $\rightarrow \alpha$  t
  val sort_decay : ( $\alpha \rightarrow \alpha \rightarrow \text{int}$ )  $\rightarrow \alpha$  decay  $\rightarrow \alpha$  decay
  val map : ( $\alpha \rightarrow \beta$ )  $\rightarrow \alpha$  t  $\rightarrow \beta$  t
  val map_decay : ( $\alpha \rightarrow \beta$ )  $\rightarrow \alpha$  decay  $\rightarrow \beta$  decay
  val eval : ( $\alpha \rightarrow \beta$ )  $\rightarrow (\alpha \rightarrow \beta) \rightarrow (\alpha \rightarrow \beta \rightarrow \beta \rightarrow \beta) \rightarrow \alpha$  t  $\rightarrow \beta$  t
  val eval_decay : ( $\alpha \rightarrow \beta$ )  $\rightarrow (\alpha \rightarrow \beta \rightarrow \beta \rightarrow \beta) \rightarrow \alpha$  decay  $\rightarrow \beta$  decay
  val of_momenta :  $\alpha \rightarrow \alpha \rightarrow (\text{momentum} \times \alpha)$  list  $\rightarrow (\text{momentum} \times \alpha)$  t
  val decay_of_momenta : ( $\text{momentum} \times \alpha$ ) list  $\rightarrow (\text{momentum} \times \alpha)$  decay
  exception Duplicate of momentum
  exception Unordered of momentum
  exception Incomplete of momentum
```

```

end

module Make (M : Momentum.T) =
struct
  type momentum = M.t

```

Finally, we came back to binary trees ...

Cascade Decays

```

type  $\alpha$  decay =
| Leaf of  $\alpha$ 
| Branch of  $\alpha \times \alpha$  decay  $\times \alpha$  decay

```

Trees of type $(\text{momentum} \times \alpha \text{ option}) \text{ decay}$ can be build easily and mapped to $(\text{momentum} \times \alpha) \text{ decay}$ later, once all the α slots are filled. A more elegant functor operating on $\beta \text{ decay}$ directly (with *Momentum* style functions defined for β) would not allow holes in the $\beta \text{ decay}$ during the construction.

```

let label = function

let rec eval_decay fl fb = function
| Leaf p → Leaf (fl p)
| Branch (p, d1, d2) →
  let d1' = eval_decay fl fb d1
  and d2' = eval_decay fl fb d2 in
  Branch (fb p (label d1') (label d2'), d1', d2')

```

Assuming that $p > p_D \vee p = p_D \vee p < p_D$, where p_D is the overall momentum of a decay tree D , we can add p to D at the top or somewhere in the middle. Note that ' $<$ ' is not a total ordering and the operation can fail (raise exceptions) if the set of momenta does not correspond to a tree. Also note that a momentum

can already be present without flavor as a complement in a branching entered earlier.

```

exception Duplicate of momentum
exception Unordered of momentum

let rec embed_in_decay (p, f as pf) = function
| Leaf (p', f' as pf') as d' →
  if M.less p' p then
    Branch ((p, Some f), d', Leaf (M.sub p p', None))
  else if M.less p p' then
    Branch (pf', Leaf (p, Some f), Leaf (M.sub p' p, None))
  else if p = p' then
    begin match f' with
    | None → Leaf (p, Some f)
    | Some _ → raise (Duplicate p)
    end
  else
    raise (Unordered p)
| Branch ((p', f' as pf'), d1, d2) as d' →
  let p1, _ = label d1
  and p2, _ = label d2 in
  if M.less p' p then
    Branch ((p, Some f), d', Leaf (M.sub p p', None))
  else if M.lesseq p p1 then
    Branch (pf', embed_in_decay pf d1, d2)
  else if M.lesseq p p2 then
    Branch (pf', d1, embed_in_decay pf d2)
  else if p = p' then
    begin match f' with
    | None → Branch ((p, Some f), d1, d2)
    | Some _ → raise (Duplicate p)
    end
  else
    raise (Unordered p)

```

Note that both *embed_in_decay* and *embed_in_decays* below do *not* commute, and should process ‘bigger’ momenta first, because disjoint sub-momenta will create disjoint subtrees in the latter and raise exceptions in the former.

```

exception Incomplete of momentum

let finalize1 = function
| p, Some f → (p, f)
| p, None → raise (Incomplete p)

let finalize_decay t = map_decay finalize1 t

```

Process the momenta starting in with the highest *M.rank*:

```

let sort_momenta plist =
  List.sort (fun (p1, _) (p2, _) → M.compare p1 p2) plist

```

Figure 16.1: Phasespace parameterization for $2 \rightarrow n$ scattering by a sequence of cascade decays.

```
let decay_of_momenta plist =
  match sort_momenta plist with
  | (p, f) :: rest →
    finalize_decay (List.fold_right embed_in_decay rest (Leaf (p, Some f)))
  | [] → invalid_arg "Phasespace.decay_of_momenta: empty"
```

$2 \rightarrow n$ Scattering

A general $2 \rightarrow n$ scattering process can be parameterized by a sequence of cascade decays. The most symmetric representation is a little bit redundant and enters each t -channel momentum twice.

```
type  $\alpha$  t = ( $\alpha \times \alpha$  decay  $\times \alpha$ ) list
```

let *topology* = *map snd* has type $(\text{momentum} \times \alpha) t \rightarrow \alpha t$ and can be used to define topological equivalence classes “up to permutations of momenta,” which are useful for calculating Whizard “groves”¹ [11].

```
let sort cmp = List.map (fun (l, d, r) → (l, sort_decay cmp d, r))
let map f = List.map (fun (l, d, r) → (f l, map_decay f d, f r))
let eval ft fl fb = List.map (fun (l, d, r) → (ft l, eval_decay fl fb d, ft r))
```

Find a tree with a defined ordering relation with respect to p or create a new one at the end of the list.

```
let rec embed_in_decays (p, f as pf) = function
| [] → [Leaf (p, Some f)]
| d' :: rest →
  let p', _ = label d' in
```

¹Not to be confused with gauge invariant classes of Feynman diagrams [12].

```

if  $M.lesseq\ p'\ p \vee M.less\ p\ p'$  then
   $embed\_in\_decay\ pf\ d' :: rest$ 
else
   $d' :: embed\_in\_decays\ pf\ rest$ 

```

Collecting Ingredients

```

type  $\alpha\ unfinished\_decays =$ 
  {  $n : int$ ;
     $t\_channel : (momentum \times \alpha\ option)\ list$ ;
     $decays : (momentum \times \alpha\ option)\ decay\ list$  }

let  $empty\ n = \{ n = n; t\_channel = []; decays = [] \}$ 

let  $insert\_in\_unfinished\_decays\ (p, f\ as\ pf)\ d =$ 
  if  $M.Scattering.spacelike\ p$  then
    {  $d\ with\ t\_channel = (p, Some\ f) :: d.t\_channel$  }
  else
    {  $d\ with\ decays = embed\_in\_decays\ pf\ d.decays$  }

let  $flip\_incoming\ plist =$ 
   $List.map\ (\fun\ (p', f') \rightarrow (M.Scattering.flip\_s\_channel\_in\ p', f'))\ plist$ 

let  $unfinished\_decays\_of\_momenta\ n\ f2\ p =$ 
   $List.fold\_right\ insert\_in\_unfinished\_decays$ 
   $(sort\_momenta\ (flip\_incoming\ ((M.of\_ints\ n\ [2], f2) :: p)))\ (empty\ n)$ 

```

Assembling Ingredients

```

let  $sort3\ compare\ x\ y\ z =$ 
  let  $a = [x; y; z]$  in
   $Array.sort\ compare\ a;$ 
   $(a.(0), a.(1), a.(2))$ 

```

Take advantage of the fact that sorting with $M.compare$ sorts with *rising* values of $M.rank$:

```

let  $allows\_momentum\_fusion\ (p, -)\ (p1, -)\ (p2, -) =$ 
  let  $p2', p1', p' = sort3\ M.compare\ p\ p1\ p2$  in
  match  $M.try\_fusion\ p'\ p1'\ p2'$  with
  |  $Some\ _ \rightarrow true$ 
  |  $None \rightarrow false$ 

let  $allows\_fusion\ p1\ p2\ d = allows\_momentum\_fusion\ (label\ d)\ p1\ p2$ 

let rec  $thread\_unfinished\_decays'\ p\ acc\ tlist\ dlist =$ 
  match  $first\_pair\ (allows\_fusion\ p)\ tlist\ dlist$  with
  |  $None \rightarrow (p, acc, tlist, dlist)$ 
  |  $Some\ ((t, -\ as\ td), (tlist', dlist')) \rightarrow$ 
     $thread\_unfinished\_decays'\ t\ (td :: acc)\ tlist'\ dlist'$ 

```

```

let thread_unfinished_decays p c =
  match thread_unfinished_decays' p [] c.t_channel c.decays with
  | -, pairs, [], [] → pairs
  | - → failwith "thread_unfinished_decays"

let rec combine_decays = function
| [] → []
| ((t, f as tf), d) :: rest →
  let p, _ = label d in
  begin match M.try_sub t p with
  | Some p' → (tf, d, (p', f)) :: combine_decays rest
  | None → (tf, d, (M.sub (M.neg t) p, f)) :: combine_decays rest
  end

let finalize t = map finalize1 t

let of_momenta f1 f2 = function
| (p, _) :: _ as l →
  let n = M.dim p in
  finalize (combine_decays
    (thread_unfinished_decays (M.of_ints n [1], Some f1)
      (unfinished_decays_of_momenta n f2 l)))
| [] → []

```

Diagnostics

```

let p_to_string p =
  String.concat "" (List.map string_of_int (M.to_ints (M.abs p)))

let rec to_string1 = function
| Leaf p → "(" ^ p_to_string p ^ ")"
| Branch (_, d1, d2) → "(" ^ to_string1 d1 ^ to_string1 d2 ^ ")"

let to_string ps =
  String.concat "/"
  (List.map (fun (p1, d, p2) →
    p_to_string p1 ^ to_string1 d ^ p_to_string p2) ps)

```

Examples

```

let try_thread_unfinished_decays p c =
  thread_unfinished_decays' p [] c.t_channel c.decays

let try_of_momenta f = function
| (p, _) :: _ as l →
  let n = M.dim p in
  try_thread_unfinished_decays
    (M.of_ints n [1], None) (unfinished_decays_of_momenta n f l)
| [] → invalid_arg "try_of_momenta"

end

```

```

17.2.1 Building Trees

A singularity is to be mapped if it is timelike and not the overall *s*-channel.

```

let timelike_map c = P.Scattering.timelike c ∧ ¬ (P.Scattering.s_channel c)

let count_maps n clist =
  List.fold_left (fun (s, t as cnt) (c, _) →
    if timelike_map c then
      (succ s, t)
    else if P.Scattering.spacelike c then
      (s, succ t)
    else
      cnt) (0, 0) clist

let poles_to_whizard n trees poles =
  let tree = List.map (fun wf →
    (P.Scattering.flip_s_channel_in (F.momentum wf), [F.flavor wf])) poles in

```

```
add_tree (count_maps n tree) tree trees
```

I must reinstate the *conjugate* eventually!

```
let trees a =
  match F.externals a with
  | in1 :: in2 :: out →
    let n = List.length out + 2 in
    { in1 = F.flavor in1;
      in2 = F.flavor in2;
      out = List.map (fun f → (* M.conjugate *) (F.flavor f)) out;
      trees = List.fold_left
        (poles_to_whizard n) Poles.empty (F.poles a) }
  | _ → invalid_arg "Whizard().trees"
```

17.2.2 Merging Homomorphic Trees

```
module Pole_Map =
  Map.Make (struct type t = P.t list let compare = compare end)
module Flavor_Set =
  Set.Make (struct type t = F.flavor let compare = compare end)

let add_flavors flist fset =
  List.fold_right Flavor_Set.add flist fset

let set_of_flavors flist =
  List.fold_right Flavor_Set.add flist Flavor_Set.empty

let pack_tree map t =
  let c, f =
    List.split (List.sort (fun (c1, _) (c2, _) →
      compare (PW.of_momentum c2) (PW.of_momentum c1))) t) in
  let f' =
    try
      List.map2 add_flavors f (Pole_Map.find c map)
    with
    | Not_found → List.map set_of_flavors f in
  Pole_Map.add c f' map

let pack_map trees = List.fold_left pack_tree Pole_Map.empty trees

let merge_sets clist flist =
  List.map2 (fun c f → (c, Flavor_Set.elements f)) clist flist

let unpack_map map =
  Pole_Map.fold (fun c f l → (merge_sets c f) :: l) map []
```

If a singularity is to be mapped (i.e. if it is timelike and not the overall *s*-channel), expand merged particles again:

```
let unfold1 (c, f) =
```

```

if timelike_map c then
  List.map (fun f' → (c, [f'])) f
else
  [(c, f)]
let unfold_tree tree = Product.list (fun x → x) (List.map unfold1 tree)
let unfold trees = ThoList.flatMap unfold_tree trees
let merge t =
  { t with trees = Poles.map
    (fun t' → unfold (unpack_map (pack_map t')) t.trees }

```

ACKNOWLEDGEMENTS

We thank Mauro Moretti for fruitful discussions of the ALPHA algorithm [1], that inspired our solution of the double counting problem.

We thank Wolfgang Kilian for providing the WHIZARD environment that turns our numbers into real events with unit weight. Thanks to the ECFA/DESY workshops and their participants for providing a showcase. Thanks to Edward Boos for discussions in Kaluza-Klein gravitons.

This research is supported by Bundesministerium für Bildung und Forschung, Germany, (05 HT9RDA) and Deutsche Forschungsgemeinschaft (MA 676/6-1).

Thanks to the Caml and Objective Caml teams from INRIA for the development and the lean and mean implementation of a programming language that does not insult the programmer's intelligence.

REVISION CONTROL

A.1 Interface of *RCS*

This is a very simple library for exporting and accessing **RCS** and **CVS** revision control information. In addition, module names and short descriptions are supported as well.

If multiple applications are constructed by functors, the functions in this module can be used to identify the concrete implementations. In the context of O’Mega, this is particularly important for physics models and target languages. One structure of type *raw* has to be initialized in each file by the raw RCS keyword strings. It can remain private to the module, because it is only used as argument to the function *parse*.

`type raw = { revision : string; date : string; author : string; source : string }`

Parsed revision control info:

`type t`

parse name description keywords initializes revision control info:

`val parse : string → string list → raw → t`

rename rcs name description changes the name and description. This is useful if more than one module is defined in a file.

`val rename : t → string → string list → t`

Access individual parts of the revision control information:

`val name : t → string`

`val description : t → string list`

`val revision : t → string`

`val date : t → string`

`val author : t → string`

This one tries **URL** (svn), **Source** (CVS) and **Id**, in that order, for the filename.

`val source : t → string`

Return the formatted revision control info as a list of strings suitable for printing to the terminal or embedding in the output:

`val summary : t → string list`

A.2 Implementation of RCS

```

type raw = { revision : string; date : string; author : string; source : string }

type t =
  { name : string;
    description : string list;
    rcs_revision : string;
    rcs_date : string;
    rcs_author : string;
    rcs_source : string }

let name r = r.name
let description r = r.description
let revision r = r.rcs_revision
let date r = r.rcs_date
let author r = r.rcs_author
let source r = r.rcs_source

module TS = ThoString

let strip_dollars s =
  TS.strip_from_last '$' (TS.strip_prefix "$" s)

let strip_keyword k s =
  TS.strip_prefix_star ' ' (TS.strip_prefix ":" (TS.strip_required_prefix k s))

let parse1 k s =
  strip_keyword k (strip_dollars s)

let strip_before_keyword k s =
  try
    let i = TS.index_string k s in
    String.sub s i (String.length s - i)
  with
  | Not_found → s

let strip_before_a_keyword k_list s =
  let rec strip_before_a_keyword' = function
    | k :: k_rest →
        begin try
          let i = TS.index_string k s in
          String.sub s i (String.length s - i)
        with
        | Not_found → strip_before_a_keyword' k_rest
        end
    | [] → s in
  strip_before_a_keyword' k_list

let parse_source s =
  let s = strip_dollars s in

```

Required for the transition from CVS to Subversion, because the latter doesn't support the `Source` keyword. `URL` is probably the way to go, but we leave in `Id` as a fallback option.

```

try strip_keyword "URL" s with Invalid_argument _ →
  try strip_keyword "Source" s with Invalid_argument _ →
    TS.strip_from_first ' ' (strip_keyword "Id" s)

```

Assume that the SVN repository follows the recommended layout and that all files can be found beneath `/trunk/`, `/branches/` or `/tags/`. Strip everything before that.

```

let strip_svn_repos s =
  strip_before_a_keyword ["/trunk/"; "/branches/"; "/tags/"] s

let parse_name_description r =
  { name = name;
    description = description;
    rcs_revision = parse1 "Revision" r.revision;
    rcs_date = parse1 "Date" r.date;
    rcs_author = parse1 "Author" r.author;
    rcs_source = strip_svn_repos (parse_source r.source) }

let rename_rcs name description =
  { rcs with name = name; description = description }

let summary_rcs =
  [ name rcs ^ ":" ] @
  List.map (fun s → "  " ^ s) (description rcs) @
  [ "  Source:" ^ source rcs;
    "  revision:" ^ revision rcs ^ "checked_in_by" ^
    author rcs ^ "at" ^ date rcs ]

```

—B—

AUTOTOOLS

B.1 Interface of Config

Cache writing is attempted in the order `[system_cache_dir]`, `[user_cache_dir]`, `["."]` and cache reading in the opposite order.

```
val system_cache_dir : string
val user_cache_dir   : string

val cache_prefix : string
val cache_suffix : string

val openmp : bool
```

B.2 Implementation of Config

```
let system_cache_dir = "/Users/reuter/Physik/progs/whizard/release_203/omega/dist/var/cache"
let user_cache_dir   = "~/.whizard/var/cache"
```

This relies on the fact that the executable names should be unique.

```
let cache_prefix =
  let basename = Filename.basename Sys.executable_name in
  try Filename.chop_extension basename with | _ -> basename

let cache_suffix = "vertices"

let openmp = false
```

—C—

TEXTUAL OPTIONS

C.1 Interface of Options

```
type t
val empty : t
val extend : t → (string × Arg.spec × string) list → t
val create : (string × Arg.spec × string) list → t
val parse : t → string × string → unit
val list : t → (string × string) list
val cmdline : string → t → (string × Arg.spec × string) list
exception Invalid of string × string
```

C.2 Implementation of Options

```
module A = Map.Make (struct type t = string let compare = compare end)

type t =
  { actions : Arg.spec A.t;
    raw : (string × Arg.spec × string) list }

let empty = { actions = A.empty; raw = [] }

let extend old options =
  { actions = List.fold_left
    (fun a (s, f, _) → A.add s f a) old.actions options;
    raw = options @ old.raw }

let create = extend empty

exception Invalid of string × string

let parse options (name, value) =
  try
    match A.find name options.actions with
    | Arg.Unit f → f ()
    | Arg.Set b → b := true
    | Arg.Clear b → b := false
    | Arg.String f → f value
    | Arg.Int f → f (int_of_string value)
```

```
| Arg.Float f → f (float_of_string value)
| _ → invalid_arg "Options.parse"
with
| Not_found → raise (Invalid (name, value))

let list options =
  List.map (fun (o, _, d) → (o, d)) options.raw

let cmdline prefix options =
  List.map (fun (o, f, d) → (prefix ^ o, f, d)) options.raw
```

```

—G—

MORE ON LISTS

G.1 Interface of ThoList

splitn $n\ l = (hdn\ l, tln\ l)$, but more efficient.

val *hdn* : $int \rightarrow \alpha\ list \rightarrow \alpha\ list$

val *tln* : $int \rightarrow \alpha\ list \rightarrow \alpha\ list$

val *splitn* : $int \rightarrow \alpha\ list \rightarrow \alpha\ list \times \alpha\ list$

chop $n\ l$ chops l into pieces of size n (except for the last one, which contains the remainder).

val *chopn* : $int \rightarrow \alpha\ list \rightarrow \alpha\ list\ list$

of_subarray $n\ m\ a$ is $[a.(n); a.(n+1); \dots; a.(m)]$. Values of n and m out of bounds are silently shifted towards these bounds.

val *of_subarray* : $int \rightarrow int \rightarrow \alpha\ array \rightarrow \alpha\ list$

range $s\ n\ m$ is $[n; n+s; n+2s; \dots; m - ((m-n) \bmod s)]$

val *range* : $?stride : int \rightarrow int \rightarrow int \rightarrow int\ list$

enumerate $s\ n\ [a1; a2; \dots]$ is $[(n, a1); (n+s, a2); \dots]$

val *enumerate* : $?stride : int \rightarrow int \rightarrow \alpha\ list \rightarrow (int \times \alpha)\ list$

Compress identical elements in a sorted list. Identity is determined using the polymorphic equality function *Pervasives*.(=).

val *uniq* : $\alpha\ list \rightarrow \alpha\ list$

Test if all members of a list are structurally identical (actually *homogeneous* l and $List.length\ (uniq\ l) \leq 1$ are equivalent, but the former is more efficient if a mismatch comes early).

val *homogeneous* : $\alpha\ list \rightarrow bool$

compare $cmp\ l1\ l2$ compare two lists $l1$ and $l2$ according to cmp . cmp defaults to the polymorphic *Pervasives*.compare.

val *compare* : $?cmp : (\alpha \rightarrow \alpha \rightarrow int) \rightarrow \alpha\ list \rightarrow \alpha\ list \rightarrow int$

Collect and count identical elements in a list. Identity is determined using the polymorphic equality function *Pervasives*.(=). *classify* does not assume that

the list is sorted. However, it is $O(n)$ for sorted lists and $O(n^2)$ in the worst case.

`val classify : α list \rightarrow ($\text{int} \times \alpha$) list`

Collect the second factors with a common first factor in lists.

`val factorize : ($\alpha \times \beta$) list \rightarrow ($\alpha \times \beta$ list) list`

`flatMap f` is equivalent to `List.flatten \circ (List.map f)`, but more efficient, because no intermediate lists are built.

`val flatmap : ($\alpha \rightarrow \beta$ list) \rightarrow α list \rightarrow β list`

`val clone : int \rightarrow $\alpha \rightarrow$ α list`

`val multiply : int \rightarrow α list \rightarrow α list`

Invent other names to avoid confusions with `List.fold_left2` and `List.fold_right2`.

`val fold_right2 : ($\alpha \rightarrow \beta \rightarrow \beta$) \rightarrow α list list \rightarrow $\beta \rightarrow \beta$`

`val fold_left2 : ($\beta \rightarrow \alpha \rightarrow \beta$) \rightarrow $\beta \rightarrow \alpha$ list list $\rightarrow \beta$`

`iteri f n [a; b; c]` evaluates `f n a`, `f (n + 1) b` and `f (n + 2) c`.

`val iteri : (int \rightarrow $\alpha \rightarrow$ unit) \rightarrow int \rightarrow α list \rightarrow unit`

`val mapi : (int \rightarrow $\alpha \rightarrow \beta$) \rightarrow int \rightarrow α list \rightarrow β list`

`iteri2 f n m [[aa; ab]; [ba; bb]]` evaluates `f n m aa`, `f n (m + 1) ab`, `f (n + 1) m ba` and `f (n + 1) (m + 1) bb`. NB: the nested lists need not be rectangular.

`val iteri2 : (int \rightarrow int \rightarrow $\alpha \rightarrow$ unit) \rightarrow int \rightarrow int \rightarrow α list list \rightarrow unit`

Transpose a *rectangular* list of lists like a matrix.

`val transpose : α list list \rightarrow α list list`

`partitioned_sort cmp index_sets list` sorts the sublists of `list` specified by the `index_sets` and the complement of their union. **NB:** the sorting follows to order in the lists in `index_sets`. **NB:** the indices are 0-based.

`val partitioned_sort : ($\alpha \rightarrow \alpha \rightarrow$ int) \rightarrow int list list \rightarrow α list \rightarrow α list`

exception `Overlapping_indices`

exception `Out_of_bounds`

`ariadne_sort cmp list` sorts `list` according to `cmp` (default `Pervasives.compare`) keeping track of the original order by a 0-based list of indices.

`val ariadne_sort : ?cmp : ($\alpha \rightarrow \alpha \rightarrow$ int) \rightarrow α list \rightarrow α list \times int list`

`ariadne_unsort (ariadne_sort cmp list)` returns `list`.

`val ariadne_unsort : α list \times int list \rightarrow α list`

G.2 Implementation of *ThoList*

let rec `hdn n l =`

if `n \leq 0` then

```

    []
  else
    match l with
    | x :: rest → x :: hdn (pred n) rest
    | [] → invalid_arg "ThoList.hdn"
let rec tln n l =
  if n ≤ 0 then
    l
  else
    match l with
    | _ :: rest → tln (pred n) rest
    | [] → invalid_arg "ThoList.tln"
let rec splitn' n l1_rev l2 =
  if n ≤ 0 then
    (List.rev l1_rev, l2)
  else
    match l2 with
    | x :: l2' → splitn' (pred n) (x :: l1_rev) l2'

MORE ON ARRAYS

H.1 Interface of ThoArray

Compressed arrays, i. e. arrays with only unique elements and an embedding that allows to recover the original array. NB: in the current implementation, compressing saves space, if *and only if* objects of type α require more storage than integers. The main use of α *compressed* is *not* for saving space, anyway, but for avoiding the repetition of hard calculations.

```
type  $\alpha$  compressed
val uniq :  $\alpha$  compressed  $\rightarrow$   $\alpha$  array
val embedding :  $\alpha$  compressed  $\rightarrow$  int array
```

These two are inverses of each other:

```
val compress :  $\alpha$  array  $\rightarrow$   $\alpha$  compressed
val uncompress :  $\alpha$  compressed  $\rightarrow$   $\alpha$  array
```

One can play the same game for matrices.

```
type  $\alpha$  compressed2
val uniq2 :  $\alpha$  compressed2  $\rightarrow$   $\alpha$  array array
val embedding1 :  $\alpha$  compressed2  $\rightarrow$  int array
val embedding2 :  $\alpha$  compressed2  $\rightarrow$  int array
```

Again, these two are inverses of each other:

```
val compress2 :  $\alpha$  array array  $\rightarrow$   $\alpha$  compressed2
val uncompress2 :  $\alpha$  compressed2  $\rightarrow$   $\alpha$  array array
```

H.2 Implementation of ThoArray

```
type  $\alpha$  compressed =
  { uniq :  $\alpha$  array;
    embedding : int array }

let uniq a = a.uniq
let embedding a = a.embedding

type  $\alpha$  compressed2 =
  { uniq2 :  $\alpha$  array array;
```

```

    embedding1 : int array;
    embedding2 : int array }

let uniq2 a = a.uniq2
let embedding1 a = a.embedding1
let embedding2 a = a.embedding2

module PMap = Pmap.Tree

let compress a =
  let last = Array.length a - 1 in
  let embedding = Array.make (succ last) (-1) in
  let rec scan num_uniq uniq elements n =
    if n > last then
      { uniq = Array.of_list (List.rev elements);
        embedding = embedding }
    else
      match PMap.find_opt compare a.(n) uniq with
      | Some n' →
        embedding.(n) ← n';
        scan num_uniq uniq elements (succ n)
      | None →
        embedding.(n) ← num_uniq;
        scan
          (succ num_uniq)
          (PMap.add compare a.(n) num_uniq uniq)
          (a.(n) :: elements)
          (succ n) in
    scan 0 PMap.empty [] 0

let uncompress a =
  Array.map (Array.get a.uniq) a.embedding

```

Using *transpose* simplifies the algorithms, but can be inefficient. If this turns out to be the case, we should add special treatments for symmetric matrices.

```

let transpose a =
  let dim1 = Array.length a
  and dim2 = Array.length a.(0) in
  let a' = Array.make_matrix dim2 dim1 a.(0).(0) in
  for i1 = 0 to pred dim1 do
    for i2 = 0 to pred dim2 do
      a'.(i2).(i1) ← a.(i1).(i2)
    done
  done;
  a'

let compress2 a =
  let c2 = compress a in
  let c12_transposed = compress (transpose c2.uniq) in
  { uniq2 = transpose c12_transposed.uniq;

```

```
    embedding1 = c12_transposed.embedding;  
    embedding2 = c2.embedding }  
let uncompress2 a =  
  let a2 = uncompress { uniq = a.uniq2; embedding = a.embedding2 } in  
  transpose (uncompress { uniq = transpose a2; embedding = a.embedding1 })
```

— I —

MORE ON STRINGS

I.1 Interface of ThoString

This is a very simple library if stroing manipulation functions missing in O'Caml's standard library.

strip_prefix prefix string returns *string* with 0 or 1 occurrences of a leading *prefix* removed.

```
val strip_prefix : string → string → string
```

strip_prefix_star prefix string returns *string* with any number of leading occurrences of *prefix* removed.

```
val strip_prefix_star : char → string → string
```

strip_prefix prefix string returns *string* with a leading *prefix* removed, raises *Invalid_argument* if there's no match.

```
val strip_required_prefix : string → string → string
```

strip_from_first c s returns *s* with everything starting from the first *c* removed.

strip_from_last c s returns *s* with everything starting from the last *c* removed.

```
val strip_from_first : char → string → string
```

```
val strip_from_last : char → string → string
```

index_string pattern string returns the index of the first occurrence of *pattern* in *string*, if any. Raises *Not_found*, if *pattern* is not in *string*.

```
val index_string : string → string → int
```

This silently fails if the argument contains both single and double quotes!

```
val quote : string → string
```

I.2 Implementation of ThoString

```
let strip_prefix p s =  
  let lp = String.length p  
  and ls = String.length s in  
  if lp > ls then  
    s
```

```

else
  let rec strip_prefix' i =
    if i ≥ lp then

TRIES

From [4], extended for [9].

K.1 Interface of Trie

K.1.1 Monomorphically

module type *T* =

sig

type *key*

type $(+\alpha)$ *t*

val *empty* : α *t*

val *is_empty* : α *t* → *bool*

Standard trie interface:

val *add* : *key* → α → α *t* → α *t*

val *find* : *key* → α *t* → α

Functionals:

val *remove* : *key* → α *t* → α *t*

val *mem* : *key* → α *t* → *bool*

val *map* : $(\alpha \rightarrow \beta) \rightarrow \alpha$ *t* → β *t*

val *mapi* : $(key \rightarrow \alpha \rightarrow \beta) \rightarrow \alpha$ *t* → β *t*

val *iter* : $(key \rightarrow \alpha \rightarrow unit) \rightarrow \alpha$ *t* → *unit*

val *fold* : $(key \rightarrow \alpha \rightarrow \beta \rightarrow \beta) \rightarrow \alpha$ *t* → $\beta \rightarrow \beta$

Try to match a longest prefix and return the unmatched rest.

val *longest* : *key* → α *t* → α *option* × *key*

Try to match a shortest prefix and return the unmatched rest.

val *shortest* : *key* → α *t* → α *option* × *key*

K.1.2 New in O’Caml 3.08

val *compare* : $(\alpha \rightarrow \alpha \rightarrow int) \rightarrow \alpha$ *t* → α *t* → *int*

```
val equal : ( $\alpha \rightarrow \alpha \rightarrow \text{bool}$ )  $\rightarrow \alpha t \rightarrow \alpha t \rightarrow \text{bool}$ 
```

K.1.3 O’Mega customization

export f_open f_close f_descend f_match trie allows us to export the trie *trie* as source code to another programming language.

```
val export : ( $\text{int} \rightarrow \text{unit}$ )  $\rightarrow (\text{int} \rightarrow \text{unit}) \rightarrow$   

  ( $\text{int} \rightarrow \text{key} \rightarrow \text{unit}$ )  $\rightarrow (\text{int} \rightarrow \text{key} \rightarrow \alpha \rightarrow \text{unit}) \rightarrow \alpha t \rightarrow \text{unit}$   

end
```

O’Caml’s *Map.S* prior to Version 3.12:

```
module type Map_S =  

sig  

  type key  

  type ( $+\alpha$ ) t  

  val empty :  $\alpha t$   

  val is_empty :  $\alpha t \rightarrow \text{bool}$   

  val add :  $\text{key} \rightarrow \alpha \rightarrow \alpha t \rightarrow \alpha t$   

  val find :  $\text{key} \rightarrow \alpha t \rightarrow \alpha$   

  val remove :  $\text{key} \rightarrow \alpha t \rightarrow \alpha t$   

  val mem :  $\text{key} \rightarrow \alpha t \rightarrow \text{bool}$   

  val iter : ( $\text{key} \rightarrow \alpha \rightarrow \text{unit}$ )  $\rightarrow \alpha t \rightarrow \text{unit}$   

  val map : ( $\alpha \rightarrow \beta$ )  $\rightarrow \alpha t \rightarrow \beta t$   

  val mapi : ( $\text{key} \rightarrow \alpha \rightarrow \beta$ )  $\rightarrow \alpha t \rightarrow \beta t$   

  val fold : ( $\text{key} \rightarrow \alpha \rightarrow \beta \rightarrow \beta$ )  $\rightarrow \alpha t \rightarrow \beta \rightarrow \beta$   

  val compare : ( $\alpha \rightarrow \alpha \rightarrow \text{int}$ )  $\rightarrow \alpha t \rightarrow \alpha t \rightarrow \text{int}$   

  val equal : ( $\alpha \rightarrow \alpha \rightarrow \text{bool}$ )  $\rightarrow \alpha t \rightarrow \alpha t \rightarrow \text{bool}$   

end  

module Make (M : Map_S) : T with type key = M.key list  

module MakeMap (M : Map_S) : Map_S with type key = M.key list
```

K.1.4 Polymorphically

```
module type Poly =  

sig  

  type ( $\alpha, \beta$ ) t  

  val empty : ( $\alpha, \beta$ ) t
```

Standard trie interface:

```
val add : ( $\alpha \rightarrow \alpha \rightarrow \text{int}$ )  $\rightarrow \alpha \text{ list} \rightarrow \beta \rightarrow (\alpha, \beta) t \rightarrow (\alpha, \beta) t$   

val find : ( $\alpha \rightarrow \alpha \rightarrow \text{int}$ )  $\rightarrow \alpha \text{ list} \rightarrow (\alpha, \beta) t \rightarrow \beta$ 
```

Functionals:

```
val remove : ( $\alpha \rightarrow \alpha \rightarrow \text{int}$ )  $\rightarrow \alpha \text{ list} \rightarrow (\alpha, \beta) t \rightarrow (\alpha, \beta) t$   

val mem : ( $\alpha \rightarrow \alpha \rightarrow \text{int}$ )  $\rightarrow \alpha \text{ list} \rightarrow (\alpha, \beta) t \rightarrow \text{bool}$ 
```

```

val map : ( $\beta \rightarrow \gamma$ )  $\rightarrow$  ( $\alpha, \beta$ )  $t \rightarrow$  ( $\alpha, \gamma$ )  $t$ 
val mapi : ( $\alpha \text{ list} \rightarrow \beta \rightarrow \gamma$ )  $\rightarrow$  ( $\alpha, \beta$ )  $t \rightarrow$  ( $\alpha, \gamma$ )  $t$ 
val iter : ( $\alpha \text{ list} \rightarrow \beta \rightarrow \text{unit}$ )  $\rightarrow$  ( $\alpha, \beta$ )  $t \rightarrow \text{unit}$ 
val fold : ( $\alpha \text{ list} \rightarrow \beta \rightarrow \gamma \rightarrow \gamma$ )  $\rightarrow$  ( $\alpha, \beta$ )  $t \rightarrow \gamma \rightarrow \gamma$ 

```

Try to match a longest prefix and return the unmatched rest.

```

val longest : ( $\alpha \rightarrow \alpha \rightarrow \text{int}$ )  $\rightarrow$   $\alpha \text{ list} \rightarrow$  ( $\alpha, \beta$ )  $t \rightarrow \beta \text{ option} \times \alpha \text{ list}$ 

```

Try to match a shortest prefix and return the unmatched rest.

```

TENSOR PRODUCTS

From [9].

L.1 Interface of Product

L.1.1 Lists

Since April 2001, we preserve lexicographic ordering.

```
val fold2 : ( $\alpha \rightarrow \beta \rightarrow \gamma \rightarrow \gamma$ )  $\rightarrow \alpha$  list  $\rightarrow \beta$  list  $\rightarrow \gamma \rightarrow \gamma$ 
val fold3 : ( $\alpha \rightarrow \beta \rightarrow \gamma \rightarrow \delta \rightarrow \delta$ )  $\rightarrow \alpha$  list  $\rightarrow \beta$  list  $\rightarrow \gamma$  list  $\rightarrow \delta \rightarrow \delta$ 
val fold : ( $\alpha$  list  $\rightarrow \beta \rightarrow \beta$ )  $\rightarrow \alpha$  list list  $\rightarrow \beta \rightarrow \beta$ 

val list2 : ( $\alpha \rightarrow \beta \rightarrow \gamma$ )  $\rightarrow \alpha$  list  $\rightarrow \beta$  list  $\rightarrow \gamma$  list
val list3 : ( $\alpha \rightarrow \beta \rightarrow \gamma \rightarrow \delta$ )  $\rightarrow \alpha$  list  $\rightarrow \beta$  list  $\rightarrow \gamma$  list  $\rightarrow \delta$  list
val list : ( $\alpha$  list  $\rightarrow \beta$ )  $\rightarrow \alpha$  list list  $\rightarrow \beta$  list

val power : int  $\rightarrow \alpha$  list  $\rightarrow \alpha$  list list
val thread :  $\alpha$  list list  $\rightarrow \alpha$  list list
```

L.1.2 Sets

'a_set is actually α set for a suitable *set*, but this relation can not be expressed polymorphically (in *set*) in O'Caml. The two sets can be of different type, but we provide a symmetric version as syntactic sugar.

type α set

```
type ( $\alpha$ , 'a_set,  $\beta$ ) fold = ( $\alpha \rightarrow \beta \rightarrow \beta$ )  $\rightarrow$  'a_set  $\rightarrow \beta \rightarrow \beta$ 
```

```
type ( $\alpha$ , 'a_set,  $\beta$ , 'b_set,  $\gamma$ ) fold2 =
  ( $\alpha \rightarrow \beta \rightarrow \gamma \rightarrow \gamma$ )  $\rightarrow$  'a_set  $\rightarrow$  'b_set  $\rightarrow \gamma \rightarrow \gamma$ 
```

```
val outer : ( $\alpha$ , 'a_set,  $\gamma$ ) fold  $\rightarrow$  ( $\beta$ , 'b_set,  $\gamma$ ) fold  $\rightarrow$ 
```

```
  ( $\alpha$ , 'a_set,  $\beta$ , 'b_set,  $\gamma$ ) fold2
```

```
val outer_self : ( $\alpha$ , 'a_set,  $\beta$ ) fold  $\rightarrow$  ( $\alpha$ , 'a_set,  $\alpha$ , 'a_set,  $\beta$ ) fold2
```

L.2 Implementation of *Product*

L.2.1 Lists

We use the tail recursive *List.fold_left* over *List.fold_right* for efficiency, but revert the argument lists in order to preserve lexicographic ordering. The argument lists are much shorter than the results, so the cost of the *List.rev* is negligible.

```
let fold2_rev f l1 l2 acc =
  List.fold_left (fun acc1 x1 →
    List.fold_left (fun acc2 x2 → f x1 x2 acc2) acc1 l2) acc l1
```

```
let fold2 f l1 l2 acc =
  fold2_rev f (List.rev l1) (List.rev l2) acc
```

```
let fold3_rev f l1 l2 l3 acc =
  List.fold_left (fun acc1 x1 → fold2 (f x1) l2 l3 acc1) acc l1
```

```
let fold3 f l1 l2 l3 acc =
  fold3_rev f (List.rev l1) (List.rev l2) (List.rev l3) acc
```

If all lists have the same type, there's also

```
let rec fold_rev f ll acc =
  match ll with
  | [] → acc
  | [l] → List.fold_left (fun acc' x → f [x] acc') acc l
  | l :: rest →
    List.fold_left (fun acc' x → fold_rev (fun xr → f (x :: xr)) rest acc') acc l
```

```
let fold f ll acc = fold_rev f (List.map List.rev ll) acc
```

```
let list2 op l1 l2 =
  fold2 (fun x1 x2 c → op x1 x2 :: c) l1 l2 []
```

```
let list3 op l1 l2 l3 =
  fold3 (fun x1 x2 x3 c → op x1 x2 x3 :: c) l1 l2 l3 []
```

```
let list op ll =
  fold (fun l c → op l :: c) ll []
```

```
let power n l =
  list (fun x → x) (ThoList.clone n l)
```

Reshuffling lists:

$$[[a_1; \dots; a_k]; [b_1; \dots; b_k]; [c_1; \dots; c_k]; \dots] \rightarrow [[a_1; b_1; c_1; \dots]; [a_2; b_2; c_2; \dots]; \dots] \quad (\text{L.1})$$

tho : Is this really an optimal implementation?

```
let thread = function
  | head :: tail →
    List.map List.rev
      (List.fold_left (fun i acc → List.map2 (fun a b → b :: a) i acc)
```

```

      (List.map (fun i → [i]) head) tail)
| [] → []

```

L.2.2 Sets

The implementation is amazingly simple:

```
type α set
```

```
type (α, 'a_set, β) fold = (α → β → β) → 'a_set → β → β
```

```
type (α, 'a_set, β, 'b_set, γ) fold2 =
  (α → β → γ → γ) → 'a_set → 'b_set → γ → γ
```

```
let outer fold1 fold2 f l1 l2 = fold1 (fun x1 → fold2 (f x1) l2) l1
```

```
let outer_self fold f l1 l2 = fold (fun x1 → fold (f x1) l2) l1
```

—M—

(FIBER) BUNDLES

M.1 Interface of Bundle

See figure [M.1](#) for the geometric intuition behind the bundle structure.

Does the current implementation support faithful projections with a forgetful comparison in the base?

```
module type Elt_Base =  
  sig  
    type elt  
    type base  
    val compare_elt : elt → elt → int
```

Figure M.1: The bundle structure implemented by *Bundle.T*

```

    val compare_base : base → base → int
  end
module type Projection =
  sig
    include Elt_Base

     $\pi : E \rightarrow B$ 

    val pi : elt → base
  end
module type T =
  sig
    type t
    type elt
    type fiber = elt list
    type base

    val add : elt → t → t
    val of_list : elt list → t

     $\pi : E \rightarrow B$ 

    val pi : elt → base

     $\pi^{-1} : B \rightarrow E$ 

    val inv_pi : base → t → fiber

    val base : t → base list

     $\pi^{-1} \circ \pi$ 

    val fiber : elt → t → fiber

    val fibers : t → (base × fiber) list
  end
module Make (P : Projection) : T with type elt = P.elt and type base = P.base

```

The same thing again, but with a projection that is not hardcoded, but passed as an argument at runtime.

```

module type Dyn =
  sig
    type t
    type elt
    type fiber = elt list
    type base

    val add : (elt → base) → elt → t → t
    val of_list : (elt → base) → elt list → t
    val inv_pi : base → t → fiber
    val base : t → base list
    val fiber : (elt → base) → elt → t → fiber
    val fibers : t → (base × fiber) list
  end
module Dyn (P : Elt_Base) : Dyn with type elt = P.elt and type base = P.base

```

M.2 Implementation of Bundle

```

module type Elt_Base =
  sig
    type elt
    type base
    val compare_elt : elt → elt → int
    val compare_base : base → base → int
  end

module type Dyn =

  val pi : elt → base
  val inv_pi : base → t → fiber
  val base : t → base list
  val fiber : elt → t → fiber
  val fibers : t → (base × fiber) list
end

module Make (P : Projection) =
struct
  module D = Dyn (P)

  type elt = D.elt
  type base = D.base
  type fiber = D.fiber
  type t = D.t

  let pi = P.pi

  let add = D.add pi
  let of_list = D.of_list pi
  let base = D.base
  let inv_pi = D.inv_pi
  let fibers = D.fibers

  let fiber elt bundle =
    inv_pi (pi elt) bundle
end

```

—N—

POWER SETS

N.1 Interface of PowSet

In the end, this should be generalized from *power set* to *lattice* with a notion of subtraction.

```

module type Ordered_Type =
  sig
    type t
    val compare : t → t → int

    Debugging ...

    val to_string : t → string
  end

module type T =
  sig
    sig
      type elt
      type t

      val empty : t
      val is_empty : t → bool
      val union : t list → t

      val of_lists : elt list list → t
      val to_lists : t → elt list list

      The smallest set of disjoint subsets that generates the given subset.

      val basis : t → t

      Debugging ...

      val to_string : t → string
    end
  end

module Make (E : Ordered_Type) : T with type elt = E.t

```

N.2 Implementation of PowSet

```

module type Ordered_Type =

```

```

sig
  type t
  val compare : t → t → int
  val to_string : t → string
end

module type T =
sig
  type elt
  type t
  val empty : t
  val is_empty : t → bool
  val union : t list → t
  val of_lists : elt list list → t
  val to_lists : t → elt list list
  val basis : t → t
  val to_string : t → string
end

module Make (E : Ordered_Type) =
struct
  type elt = E.t

  module ESet = Set.Make (E)
  type set = ESet.t

  module EPowSet = Set.Make (ESet)
  type t = EPowSet.t

  let empty = EPowSet.empty
  let is_empty = EPowSet.is_empty

  let union s_list =
    List.fold_right EPowSet.union s_list EPowSet.empty

  let set_to_string set =
    "{" ^ String.concat "," (List.map E.to_string (ESet.elements set)) ^ "}"

  let to_string powset =
    "{" ^ String.concat "," (List.map set_to_string (EPowSet.elements powset)) ^ "}"

  let set_of_list list =
    List.fold_right ESet.add list ESet.empty

  let of_lists lists =
    List.fold_right
      (fun list acc → EPowSet.add (set_of_list list) acc)
      lists EPowSet.empty

  let to_lists ps =
    List.map ESet.elements (EPowSet.elements ps)

  product (s1, s2) = s1 ∘ s2 = {s1 \ s2, s1 ∩ s2, s2 \ s1} \ {∅}

  let product s1 s2 =
    List.fold_left

```

```

(fun pset set → if ESet.is_empty set then pset else EPowSet.add set pset)
EPowSet.empty [ESet.diff s1 s2; ESet.inter s1 s2; ESet.diff s2 s1]

let disjoint s1 s2 =
  ESet.is_empty (ESet.inter s1 s2)

```

In *augment_basis_overlapping* ($s, \{s_i\}_i$), we are guaranteed that

$$\forall_i : s \cap s_i \neq \emptyset \quad (\text{N.1a})$$

$$\forall_{i \neq j} : s_i \cap s_j = \emptyset. \quad (\text{N.1b})$$

Therefore from (N.1b)

$$\forall_{i \neq j} : (s \cap s_i) \cap (s \cap s_j) = s \cap (s_i \cap s_j) = s \cap \emptyset = \emptyset \quad (\text{N.2a})$$

$$\forall_{i \neq j} : (s_i \setminus s) \cap (s_j \setminus s) \subset s_i \cap s_j = \emptyset \quad (\text{N.2b})$$

$$\forall_{i \neq j} : (s \setminus s_i) \cap (s_j \setminus s) \subset s \cap \bar{s} = \emptyset \quad (\text{N.2c})$$

$$\forall_{i \neq j} : (s \cap s_i) \cap (s_j \setminus s) \subset s \cap \bar{s} = \emptyset, \quad (\text{N.2d})$$

but in general

$$\exists_{i \neq j} : (s \setminus s_i) \cap (s \setminus s_j) \neq \emptyset \quad (\text{N.3a})$$

$$\exists_{i \neq j} : (s \setminus s_i) \cap (s \cap s_j) \neq \emptyset, \quad (\text{N.3b})$$

because for $s_i = \{i\}$ and $s = \{1, 2, 3\}$

$$(s \setminus s_1) \cap (s \setminus s_2) = \{2, 3\} \cap \{1, 3\} = \{3\} \quad (\text{N.4a})$$

$$(s \setminus s_1) \cap (s \cap s_2) = \{2, 3\} \cap \{2\} = \{2\}. \quad (\text{N.4b})$$

Summarizing:

$\forall_{i \neq j} : A_i \cap A_j$	$s_j \setminus s$	$s \cap s_j$	$s \setminus s_j$
$s_i \setminus s$	\emptyset	\emptyset	\emptyset
$s \cap s_i$	\emptyset	\emptyset	$\neq \emptyset$
$s \setminus s_i$	\emptyset	$\neq \emptyset$	$\neq \emptyset$

Fortunately, we also know We also know from (N.1a) that

$$\forall_i : |s \setminus s_i| < |s| \quad (\text{N.5a})$$

$$\forall_i : |s \cap s_i| < \min(|s|, |s_i|) \quad (\text{N.5b})$$

$$\forall_i : |s_i \setminus s| < |s_i| \quad (\text{N.5c})$$

and can call *basis* recursively without risking non-termination.

```

let rec basis ps =
  EPowSet.fold augment_basis ps EPowSet.empty

and augment_basis s ps =
  if EPowSet.mem s ps then
    ps
  else
    let no_overlaps, overlaps = EPowSet.partition (disjoint s) ps in
    if EPowSet.is_empty overlaps then
      EPowSet.add s ps

```

```

    else
      EPowSet.union no_overlaps (augment_basis_overlapping s overlaps)
    and augment_basis_overlapping s ps =
      basis (EPowSet.fold (fun s' → EPowSet.union (product s s')) ps EPowSet.empty)
  end

```

—O—

COMBINATORICS

O.1 Interface of Combinatorics

This type is defined just for documentation. Below, most functions will construct a (possibly nested) *list* of partitions or permutations of a α *seq*.

`type α seq = α list`

O.1.1 Simple Combinatorial Functions

The functions

$$\text{factorial} : n \rightarrow n! \quad (\text{O.1a})$$

$$\text{binomial} : (n, k) \rightarrow \binom{n}{k} = \frac{n!}{k!(n-k)!} \quad (\text{O.1b})$$

$$\text{multinomial} : [n_1; n_2; \dots; n_k] \rightarrow \binom{n_1 + n_2 + \dots + n_k}{n_1, n_2, \dots, n_k} = \frac{(n_1 + n_2 + \dots + n_k)!}{n_1! n_2! \dots n_k!} \quad (\text{O.1c})$$

have not been optimized. They can quickly run out of the range of native integers.

`val factorial : int → int`
`val binomial : int → int → int`
`val multinomial : int list → int`

symmetry l returns the size of the symmetric group on l , i. e. the product of the factorials of the numbers of identical elements.

`val symmetry : α list → int`

O.1.2 Partitions

partitions $[n_1; n_2; \dots; n_k] [x_1; x_2; \dots; x_n]$, where $n = n_1 + n_2 + \dots + n_k$, returns all inequivalent partitions of $[x_1; x_2; \dots; x_n]$ into parts of size n_1, n_2, \dots, n_k . The order of the n_i is not respected. There are

$$\frac{1}{S(n_1, n_2, \dots, n_k)} \binom{n_1 + n_2 + \dots + n_k}{n_1, n_2, \dots, n_k} \quad (\text{O.2})$$

such partitions, where the symmetry factor $S(n_1, n_2, \dots, n_k)$ is the size of the permutation group of $[n_1; n_2; \dots; n_k]$ as determined by the function *symmetry*.

val partitions : $int\ list \rightarrow \alpha\ seq \rightarrow \alpha\ seq\ list\ list$

ordered_partitions is identical to *partitions*, except that the order of the n_i is respected. There are

$$\binom{n_1 + n_2 + \dots + n_k}{n_1, n_2, \dots, n_k} \quad (O.3)$$

such partitions.

val ordered_partitions : $int\ list \rightarrow \alpha\ seq \rightarrow \alpha\ seq\ list\ list$

keystones m l is equivalent to *partitions m l*, except for the special case when the length of l is even and m contains a part that has exactly half the length of l . In this case only the half of the partitions is created that has the head of l in the longest part.

val keystones : $int\ list \rightarrow \alpha\ seq \rightarrow \alpha\ seq\ list\ list$

It can be beneficial to factorize a common part in the partitions and keystones:

val factorized_partitions : $int\ list \rightarrow \alpha\ seq \rightarrow (\alpha\ seq \times \alpha\ seq\ list\ list)\ list$

val factorized_keystones : $int\ list \rightarrow \alpha\ seq \rightarrow (\alpha\ seq \times \alpha\ seq\ list\ list)\ list$

Special Cases

partitions is built from components that can be convenient by themselves, even though they are just special cases of *partitions*.

split k l returns the list of all inequivalent splits of the list l into one part of length k and the rest. There are

$$\frac{1}{S(|l| - k, k)} \binom{|l|}{k} \quad (O.4)$$

such splits. After replacing the pairs by two-element lists, *split k l* is equivalent to *partitions [k; length l - k] l*.

val split : $int \rightarrow \alpha\ seq \rightarrow (\alpha\ seq \times \alpha\ seq)\ list$

Create both equipartitions of lists of even length. There are

$$\binom{|l|}{k} \quad (O.5)$$

such splits. After replacing the pairs by two-element lists, the result of *ordered_split k l* is equivalent to *ordered_partitions [k; length l - k] l*.

val ordered_split : $int \rightarrow \alpha\ seq \rightarrow (\alpha\ seq \times \alpha\ seq)\ list$

multi_split n k l returns the list of all inequivalent splits of the list l into n parts of length k and the rest.

val multi_split : $int \rightarrow int \rightarrow \alpha\ seq \rightarrow (\alpha\ seq\ list \times \alpha\ seq)\ list$

val ordered_multi_split : $int \rightarrow int \rightarrow \alpha\ seq \rightarrow (\alpha\ seq\ list \times \alpha\ seq)\ list$

O.1.3 Choices

choose n $[x_1; x_2; \dots; x_n]$ returns the list of all n -element subsets of $[x_1; x_2; \dots; x_n]$.
choose n is equivalent to $(\text{map fst}) \circ (\text{ordered_split } n)$.

`val choose : int → α seq → α seq list`

multi_choose n k is equivalent to $(\text{map fst}) \circ (\text{multi_split } n \ k)$.

`val multi_choose : int → int → α seq → α seq list list`

`val ordered_multi_choose : int → int → α seq → α seq list list`

O.1.4 Permutations

`val permute : α seq → α seq list`

Graded Permutations

`val permute_signed : α seq → (int × α seq) list`

`val permute_even : α seq → α seq list`

`val permute_odd : α seq → α seq list`

Tensor Products of Permutations

In other words: permutations which respect compartmentalization.

`val permute_tensor : α seq list → α seq list list`

`val permute_tensor_signed : α seq list → (int × α seq list) list`

`val permute_tensor_even : α seq list → α seq list list`

`val permute_tensor_odd : α seq list → α seq list list`

Sorting

`val sort_signed : (α → α → int) → α list → int × α list`

O.2 Implementation of Combinatorics

`type α seq = α list`

O.2.1 Simple Combinatorial Functions

```

let rec factorial' fn n =
  if n < 1 then
    fn
  else
    factorial' (n × fn) (pred n)

let factorial n =
  if 0 ≤ n ∧ n ≤ 12 then
    factorial' 1 n
  else
    invalid_arg "Combinatorics.factorial"

```

$$\begin{aligned}
\binom{n}{k} &= \frac{n!}{k!(n-k)!} = \frac{n(n-1)\cdots(n-k+1)}{k(k-1)\cdots 1} \\
&= \frac{n(n-1)\cdots(k+1)}{(n-k)(n-k-1)\cdots 1} = \begin{cases} B_{n-k+1}(n, k) & \text{for } k \leq \lfloor n/2 \rfloor \\ B_{k+1}(n, n-k) & \text{for } k > \lfloor n/2 \rfloor \end{cases} \quad (\text{O.6})
\end{aligned}$$

where

$$B_{n_{\min}}(n, k) = \begin{cases} nB_{n_{\min}}(n-1, k) & \text{for } n \geq n_{\min} \\ \frac{1}{k}B_{n_{\min}}(n, k-1) & \text{for } k > 1 \\ 1 & \text{otherwise} \end{cases} \quad (\text{O.7})$$

```

let rec binomial' n_min n k acc =
  if n ≥ n_min then
    binomial' n_min (pred n) k (n × acc)
  else if k > 1 then
    binomial' n_min n (pred k) (acc / k)
  else
    acc

```

```

let binomial n k =
  if k > n / 2 then
    binomial' (k + 1) n (n - k) 1
  else
    binomial' (n - k + 1) n k 1

```

Overflows later, but takes much more time:

$$\binom{n}{k} = \binom{n-1}{k} + \binom{n-1}{k-1} \quad (\text{O.8})$$

```

let rec slow_binomial n k =
  if n < 0 ∨ k < 0 then
    invalid_arg "Combinatorics.binomial"
  else if k = 0 ∨ k = n then
    1
  else

```

```

slow_binomial (pred n) k + slow_binomial (pred n) (pred k)

let multinomial n_list =
  List.fold_left (fun acc n → acc / (factorial n))
    (factorial (List.fold_left (+) 0 n_list)) n_list

let symmetry l =
  List.fold_left (fun s (n, _) → s × factorial n) 1 (ThoList.classify l)

```

O.2.2 Partitions

The inner steps of the recursion (i.e. $n = 1$) are expanded as follows

$$\begin{aligned}
 \text{split}'(1, [p_k; p_{k-1}; \dots; p_1], [x_l; x_{l-1}; \dots; x_1], [x_{l+1}; x_{l+2}; \dots; x_m]) = \\
 & ([p_1; \dots; p_k; x_{l+1}], [x_1; \dots; x_l; x_{l+2}; \dots; x_m]); \\
 & ([p_1; \dots; p_k; x_{l+2}], [x_1; \dots; x_l; x_{l+1}; x_{l+3}; \dots; x_m]); \dots; \\
 & ([p_1; \dots; p_k; x_m], [x_1; \dots; x_l; x_{l+1}; \dots; x_{m-1}]) \quad (\text{O.9})
 \end{aligned}$$

while the outer steps (i.e. $n > 1$) perform the same with one element moved from the last argument to the first argument. At the n th level we have

$$\begin{aligned}
 \text{split}'(n, [p_k; p_{k-1}; \dots; p_1], [x_l; x_{l-1}; \dots; x_1], [x_{l+1}; x_{l+2}; \dots; x_m]) = \\
 & ([p_1; \dots; p_k; x_{l+1}; x_{l+2}; \dots; x_{l+n}], [x_1; \dots; x_l; x_{l+n+1}; \dots; x_m]); \dots; \\
 & ([p_1; \dots; p_k; x_{m-n+1}; x_{m-n+2}; \dots; x_m], [x_1; \dots; x_l; x_{l+1}; \dots; x_{m-n}]) \quad (\text{O.10})
 \end{aligned}$$

where the order of the $[x_1; x_2; \dots; x_m]$ is maintained in the partitions. Variations on this multiple recursion idiom are used many times below.

```

let rec split' n rev_part rev_head = function
| [] → []
| x :: tail →
  let rev_part' = x :: rev_part
  and parts = split' n rev_part (x :: rev_head) tail in
  if n < 1 then
    failwith "Combinatorics.split': can't happen"
  else if n = 1 then
    (List.rev rev_part', List.rev_append rev_head tail) :: parts
  else
    split' (pred n) rev_part' rev_head tail @ parts

```

Kick off the recursion for $0 < n < |l|$ and handle the cases $n \in \{0, |l|\}$ explicitly. Use reflection symmetry for a small optimization.

```

let ordered_split_unsafe n abs_l l =
  let abs_l = List.length l in
  if n = 0 then
    [], l
  else if n = abs_l then
    l, []
  else if n ≤ abs_l / 2 then

```

```

    split' n [] [] l
  else
    List.rev_map (fun (a, b) → (b, a)) (split' (abs_l - n) [] [] l)

```

Check the arguments and call the workhorse:

```

let ordered_split n l =
  let abs_l = List.length l in
  if n < 0 ∨ n > abs_l then
    invalid_arg "Combinatorics.ordered_split"
  else
    ordered_split_unsafe n abs_l l

```

Handle equipartitions specially:

```

let split n l =
  let abs_l = List.length l in
  if n < 0 ∨ n > abs_l then
    invalid_arg "Combinatorics.split"
  else begin
    if 2 × n = abs_l then
      match l with
      | [] → failwith "Combinatorics.split: can't happen"
      | x :: tail →
          List.map (fun (p1, p2) → (x :: p1, p2)) (split' (pred n) [] [] tail)
    else
      ordered_split_unsafe n abs_l l
  end
end

```

If we chop off parts repeatedly, we can either keep permutations or suppress them. Generically, *attach_to_fst* has type

$$(\alpha \times \beta) \text{ list} \rightarrow \alpha \text{ list} \rightarrow (\alpha \text{ list} \times \beta) \text{ list} \rightarrow (\alpha \text{ list} \times \beta) \text{ list}$$

and semantics

$$\begin{aligned} \text{attach_to_fst}([(a_1, b_1), (a_2, b_2), \dots, (a_m, b_m)], [a'_1, a'_2, \dots]) = \\ [[a_1, a'_1, \dots], b_1), ([a_2, a'_1, \dots], b_2), \dots, ([a_m, a'_1, \dots], b_m)] \quad (\text{O.11}) \end{aligned}$$

(where some of the result can be filtered out), assumed to be prepended to the final argument.

```

let rec multi_split' attach_to_fst n size splits =
  if n ≤ 0 then
    splits
  else
    multi_split' attach_to_fst (pred n) size
    (List.fold_left (fun acc (parts, tail) →
      attach_to_fst (ordered_split size tail) parts acc) [] splits)

let attach_to_fst_unsorted splits parts acc =
  List.fold_left (fun acc' (p, rest) → (p :: parts, rest) :: acc') acc splits

```

Similarly, if the second argument is a list of lists:

```

let prepend_to_fst_unsorted splits parts acc =
  List.fold_left (fun acc' (p, rest) → (p @ parts, rest) :: acc') acc splits

let attach_to_fst_sorted splits parts acc =
  match parts with
  | [] → List.fold_left (fun acc' (p, rest) → ([p], rest) :: acc') acc splits
  | p :: _ as parts →
    List.fold_left (fun acc' (p', rest) →
      if p' > p then
        (p' :: parts, rest) :: acc'
      else
        acc') acc splits

let multi_split n size l =
  multi_split' attach_to_fst_sorted n size ([], l)

let ordered_multi_split n size l =
  multi_split' attach_to_fst_unsorted n size ([], l)

let rec partitions' splits = function
  | [] → List.map (fun (h, r) → (List.rev h, r)) splits
  | (1, size) :: more →
    partitions'
    (List.fold_left (fun acc (parts, rest) →
      attach_to_fst_unsorted (split size rest) parts acc)
      [] splits) more
  | (n, size) :: more →
    partitions'
    (List.fold_left (fun acc (parts, rest) →
      prepend_to_fst_unsorted (multi_split n size rest) parts acc)
      [] splits) more

let partitions multiplicities l =
  if List.fold_left (+) 0 multiplicities ≠ List.length l then
    invalid_arg "Combinatorics.partitions"
  else
    List.map fst (partitions' ([], l)
      (ThoList.classify (List.sort compare multiplicities)))

let rec ordered_partitions' splits = function
  | [] → List.map (fun (h, r) → (List.rev h, r)) splits
  | size :: more →
    ordered_partitions'
    (List.fold_left (fun acc (parts, rest) →
      attach_to_fst_unsorted (ordered_split size rest) parts acc)
      [] splits) more

let ordered_partitions multiplicities l =
  if List.fold_left (+) 0 multiplicities ≠ List.length l then
    invalid_arg "Combinatorics.ordered_partitions"
  else
    List.map fst (ordered_partitions' ([], l) multiplicities)

let hdtl = function

```

```

| [] → invalid_arg "Combinatorics.htdl"
| h :: t → (h, t)

```

```

let factorized_partitions multiplicities l =
  ThoList.factorize (List.map hdtl (partitions multiplicities l))

```

In order to construct keystones (cf. chapter 3), we must eliminate reflections consistently. For this to work, the lengths of the parts *must not* be reordered arbitrarily. Ordering with monotonously falling lengths would be incorrect however, because then some remainders could fake a reflection symmetry and partitions would be dropped erroneously. Therefore we put the longest first and order the remaining with rising lengths:

```

let longest_first l =
  match ThoList.classify (List.sort (fun n1 n2 → compare n2 n1) l) with
  | [] → []
  | longest :: rest → longest :: List.rev rest

let keystones multiplicities l =
  if List.fold_left (+) 0 multiplicities ≠ List.length l then
    invalid_arg "Combinatorics.keystones"
  else
    List.map fst (partitions' ([], l) (longest_first multiplicities))

let factorized_keystones multiplicities l =
  ThoList.factorize (List.map hdtl (keystones multiplicities l))

```

O.2.3 Choices

The implementation is very similar to *split'*, but here we don't have to keep track of the complements of the chosen sets.

```

let rec choose' n rev_choice = function
| [] → []
| x :: tail →
  let rev_choice' = x :: rev_choice
  and choices = choose' n rev_choice tail in
  if n < 1 then
    failwith "Combinatorics.choose': can't happen"
  else if n = 1 then
    List.rev rev_choice' :: choices
  else
    choose' (pred n) rev_choice' tail @ choices

```

choose *n* is equivalent to $(List.map fst) \circ (split_ordered\ n)$, but more efficient.

```

let choose n l =
  let abs_l = List.length l in
  if n < 0 then
    invalid_arg "Combinatorics.choose"
  else if n > abs_l then
    []
  else if n = 0 then

```

```

    [[]]
  else if  $n = \text{abs\_}l$  then
    [ $l$ ]
  else
    choose'  $n$  []  $l$ 

let multi_choose  $n$  size  $l$  =
  List.map fst (multi_split  $n$  size  $l$ )

let ordered_multi_choose  $n$  size  $l$  =
  List.map fst (ordered_multi_split  $n$  size  $l$ )

```

O.2.4 Permutations

```

let rec insert  $x$  = function
| [] → [[ $x$ ]]
|  $h :: t$  as  $l$  → ( $x :: l$ ) :: List.map (fun  $l'$  →  $h :: l'$ ) (insert  $x$   $t$ )

let permute  $l$  =
  List.fold_left (fun acc  $x$  → ThoList.flatmap (insert  $x$ ) acc) [[]]  $l$ 

```

Graded Permutations

```

let rec insert_signed  $x$  = function
| ( $\text{eps}$ , []) → [( $\text{eps}$ , [ $x$ ])]
| ( $\text{eps}$ ,  $h :: t$ ) → ( $\text{eps}$ ,  $x :: h :: t$ ) ::
  (List.map (fun ( $\text{eps}'$ ,  $l'$ ) → ( $-\text{eps}'$ ,  $h :: l'$ )) (insert_signed  $x$  ( $\text{eps}$ ,  $t$ )))

let rec permute_signed' = function
| ( $\text{eps}$ , []) → [( $\text{eps}$ , [])]
| ( $\text{eps}$ ,  $h :: t$ ) → ThoList.flatmap (insert_signed  $h$ ) (permute_signed' ( $\text{eps}$ ,  $t$ ))

let permute_signed  $l$  =
  permute_signed' (1,  $l$ )

```

The following are wasting at most a factor of two and there's probably no point in improving on this ...

```

let filter_sign  $s$   $l$  =
  List.map snd (List.filter (fun ( $\text{eps}$ , _) →  $\text{eps} = s$ )  $l$ )

let permute_even  $l$  =
  filter_sign 1 (permute_signed  $l$ )

let permute_odd  $l$  =
  filter_sign (-1) (permute_signed  $l$ )

```

Tensor Products of Permutations

```

let permute_tensor ll =
  Product.list (fun l → l) (List.map permute ll)

let join_signs l =
  let el, pl = List.split l in
  (List.fold_left (fun acc x → x × acc) 1 el, pl)

let permute_tensor_signed ll =
  Product.list join_signs (List.map permute_signed ll)

let permute_tensor_even l =
  filter_sign 1 (permute_tensor_signed l)

let permute_tensor_odd l =
  filter_sign (-1) (permute_tensor_signed l)

let insert_inorder_signed order x (eps, l) =
  let rec insert eps' accu = function
    | [] → (eps × eps', List.rev_append accu [x])
    | h :: t →
        if order x h = 0 then
          invalid_arg
            "Combinatorics.insert_inorder_signed: identical elements"
        else if order x h < 0 then
          (eps × eps', List.rev_append accu (x :: h :: t))
        else
          insert (-eps') (h :: accu) t
  in
  insert 1 [] l

```

Sorting

```

let sort_signed order l =
  List.fold_left (fun acc x → insert_inorder_signed order x acc) (1, []) l

```

—P—

PARTITIONS

P.1 Interface of Partition

pairs n $n1$ $n2$ returns all (unordered) pairs of integers with the sum n in the range from $n1$ to $n2$.

`val pairs : int → int → int → (int × int) list`
`val triples : int → int → int → (int × int × int) list`

tuples d n n_{\min} n_{\max} returns all $[n_1; n_2; \dots; n_d]$ with $n_{\min} \leq n_1 \leq n_2 \leq \dots \leq n_d \leq n_{\max}$ and

$$\sum_{i=1}^d n_i = n \quad (\text{P.1})$$

`val tuples : int → int → int → int → int list list`
`val rcs : RCS.t`

P.2 Implementation of Partition

```
let rcs = RCS.parse "Partition" ["Partitions"]
  { RCS.revision = "$Revision: 759$";
    RCS.date = "$Date: 2009-06-10 11:38:07 +0200 (Wed, 10 Jun 2009)$";
    RCS.author = "$Author: ohl$";
    RCS.source
      = "$URL: svn+ssh://jr-reuter@login.hepforge.org/hepforge/svn/whizard/trunk/src/omeg
```

All unordered pairs of integers with the same sum n in a given range $\{n_1, \dots, n_2\}$:

$$\text{pairs} : (n, n_1, n_2) \rightarrow \{(i, j) \mid i + j = n \wedge n_1 \leq i \leq j \leq n_2\} \quad (\text{P.2})$$

```
let rec pairs' acc n1 n2 =
  if n1 > n2 then
    List.rev acc
  else
    pairs' ((n1, n2) :: acc) (succ n1) (pred n2)
let pairs sum min_n1 max_n2 =
  let n1 = max min_n1 (sum - max_n2) in
```

```

let n2 = sum - n1 in
if n2 ≤ max_n2 then
  pairs' [] n1 n2
else
  []

let rec tuples d sum n_min n_max =
  if d ≤ 0 then
    invalid_arg "tuples"
  else if d > 1 then
    tuples' d sum n_min n_max n_min
  else if sum ≥ n_min ∧ sum ≤ n_max then
    [[sum]]
  else
    []

and tuples' d sum n_min n_max n =
  if n > n_max then
    []
  else
    List.fold_right (fun l ll → (n :: l) :: ll)
      (tuples (pred d) (sum - n) (max n_min n) n_max)
      (tuples' d sum n_min n_max (succ n))

```

When I find a little spare time, I can provide a dedicated implementation, but we *know* that *Impossible* is *never* raised and the present approach is just as good (except for a possible tiny inefficiency).

```

exception Impossible of string
let impossible name = raise (Impossible name)

let triples sum n_min n_max =
  List.map (function [n1; n2; n3] → (n1, n2, n3) | _ → impossible "triples")
    (tuples 3 sum n_min n_max)

```

Q TREES

From [10]: Trees with one root admit a straightforward recursive definition

$$T(N, L) = L \cup N \times T(N, L) \times T(N, L) \quad (\text{Q.1})$$

that is very well adapted to mathematical reasoning. Such recursive definitions are useful because they allow us to prove properties of elements by induction

$$\begin{aligned} \forall l \in L : p(l) \wedge (\forall n \in N : \forall t_1, t_2 \in T(N, L) : p(t_1) \wedge p(t_2) \Rightarrow p(n \times t_1 \times t_2)) \\ \implies \forall t \in T(N, L) : p(t) \end{aligned} \quad (\text{Q.2})$$

i. e. establishing a property for all leaves and showing that a node automatically satisfies the property if it is true for all children proves the property for *all* trees. This induction is of course modelled after standard mathematical induction

$$p(1) \wedge (\forall n \in \mathbf{N} : p(n) \Rightarrow p(n+1)) \implies \forall n \in \mathbf{N} : p(n) \quad (\text{Q.3})$$

The recursive definition (Q.1) is mirrored by the two tree construction functions¹

$$\text{leaf} : \nu \times \lambda \rightarrow (\nu, \lambda)T \quad (\text{Q.4a})$$

$$\text{node} : \nu \times (\nu, \lambda)T \times (\nu, \lambda)T \rightarrow (\nu, \lambda)T \quad (\text{Q.4b})$$

Renaming leaves and nodes leaves the structure of the tree invariant. Therefore, morphisms $L \rightarrow L'$ and $N \rightarrow N'$ of the sets of leaves and nodes induce natural homomorphisms $T(N, L) \rightarrow T(N', L')$ of trees

$$\text{map} : (\nu \rightarrow \nu') \times (\lambda \rightarrow \lambda') \times (\nu, \lambda)T \rightarrow (\nu', \lambda')T \quad (\text{Q.5})$$

The homomorphisms constructed by *map* are trivial, but ubiquitous. More interesting are the morphisms

$$\begin{aligned} \text{fold} : (\nu \times \lambda \rightarrow \alpha) \times (\nu \times \alpha \times \alpha \rightarrow \alpha) \times (\nu, \lambda)T &\rightarrow \alpha \\ (f_1, f_2, l \in L) &\mapsto f_1(l) \\ (f_1, f_2, (n, t_1, t_2)) &\mapsto f_2(n, \text{fold}(f_1, f_2, t_1), \text{fold}(f_1, f_2, t_2)) \end{aligned} \quad (\text{Q.6})$$

¹To make the introduction more accessible to non-experts, I avoid the ‘curried’ notation for functions with multiple arguments and use tuples instead. The actual implementation takes advantage of curried functions, however. Experts can read $\alpha \rightarrow \beta \rightarrow \gamma$ for $\alpha \times \beta \rightarrow \gamma$.

and

$$\begin{aligned}
fan : (\nu \times \lambda \rightarrow \{\alpha\}) \times (\nu \times \alpha \times \alpha \rightarrow \{\alpha\}) \times (\nu, \lambda)T &\rightarrow \{\alpha\} \\
(f_1, f_2, l \in L) &\mapsto f_1(l) \\
(f_1, f_2, (n, t_1, t_2)) &\mapsto f_2(n, fold(f_1, f_2, t_1) \otimes fold(f_1, f_2, t_2))
\end{aligned} \tag{Q.7}$$

where the tensor product notation means that f_2 is applied to all combinations of list members in the argument:

$$\phi(\{x\} \otimes \{y\}) = \{\phi(x, y) | x \in \{x\} \wedge y \in \{y\}\} \tag{Q.8}$$

But note that due to the recursive nature of trees, fan is *not* a morphism from $T(N, L)$ to $T(N \otimes N, L)$.

If we identify singleton sets with their members, $fold$ could be viewed as a special case of fan , but that is probably more confusing than helpful. Also, using the special case $\alpha = (\nu', \lambda')T$, the homomorphism map can be expressed in terms of $fold$ and the constructors

$$\begin{aligned}
map : (\nu \rightarrow \nu') \times (\lambda \rightarrow \lambda') \times (\nu, \lambda)T &\rightarrow (\nu', \lambda')T \\
(f, g, t) &\mapsto fold(leaf \circ (f \times g), node \circ (f \times id \times id), t)
\end{aligned} \tag{Q.9}$$

$fold$ is much more versatile than map , because it can be used with constructors for other tree representations to translate among different representations. The target type can also be a mathematical expression. This is used extensively below for evaluating Feynman diagrams.

Using fan with $\alpha = (\nu', \lambda')T$ can be used to construct a multitude of homomorphic trees. In fact, below it will be used extensively to construct all Feynman diagrams $\{(\nu, \{p_1, \dots, p_n\})T\}$ of a given topology $t \in (\emptyset, \{1, \dots, n\})T$.

The physicist in me guesses that there is another morphism of trees that is related to fan like a Lie-algebra is related to the it's Lie-group. I have not been able to pin it down, but I guess that it is a generalization of $grow$ below.

Q.1 Interface of *Tree*

This module provides utilities for generic decorated trees, such as FeynMF output.

Q.1.1 Abstract Data Type

`type` $(\nu, \lambda) t$

`leaf` $n l$ returns a tree consisting of a single leaf of type n connected to l .

`val leaf` : $\nu \rightarrow \lambda \rightarrow (\nu, \lambda) t$

`cons` $n ch$ returns a tree node.

`val cons` : $\nu \rightarrow (\nu, \lambda) t \text{ list} \rightarrow (\nu, \lambda) t$

node *t* returns the top node of the tree *t*.

val *node* : $(\nu, \lambda) t \rightarrow \nu$

leafs *t* returns a list of all leafs *in order*.

val *leafs* : $(\nu, \lambda) t \rightarrow \lambda \text{ list}$

nodes *t* returns a list of all nodes in post-order. This guarantees that the root node can be stripped from the result by *List.tl*.

val *nodes* : $(\nu, \lambda) t \rightarrow \nu \text{ list}$

fuse conjg root contains_root trees joins the *trees*, using the leaf *root* in one of the trees as root of the new tree. *contains_root* guides the search for the subtree containing *root* as a leaf. **fun** *t* \rightarrow *List.mem* *root* (*leafs* *t*) is acceptable, but more efficient solutions could be available in special circumstances.

val *fuse* : $(\nu \rightarrow \nu) \rightarrow \lambda \rightarrow ((\nu, \lambda) t \rightarrow \text{bool}) \rightarrow (\nu, \lambda) t \text{ list} \rightarrow (\nu, \lambda) t$

sort lesseq *t* return a sorted copy of the tree *t*: node labels are ignored and nodes are according to the supremum of the leaf labels in the corresponding subtree.

val *sort* : $(\lambda \rightarrow \lambda \rightarrow \text{bool}) \rightarrow (\nu, \lambda) t \rightarrow (\nu, \lambda) t$

Q.1.2 Homomorphisms

val *map* : $('n1 \rightarrow 'n2) \rightarrow ('l1 \rightarrow 'l2) \rightarrow ('n1, 'l1) t \rightarrow ('n2, 'l2) t$

val *fold* : $(\nu \rightarrow \lambda \rightarrow \alpha) \rightarrow (\nu \rightarrow \alpha \text{ list} \rightarrow \alpha) \rightarrow (\nu, \lambda) t \rightarrow \alpha$

val *fan* : $(\nu \rightarrow \lambda \rightarrow \alpha \text{ list}) \rightarrow (\nu \rightarrow \alpha \text{ list} \rightarrow \alpha \text{ list}) \rightarrow (\nu, \lambda) t \rightarrow \alpha \text{ list}$

Q.1.3 Output

val *to_string* : $(\text{string}, \text{string}) t \rightarrow \text{string}$

Feynmf

style : $(\text{string} \times \text{string}) \text{ option}$ should be replaced by *style* : *string option*; *tex_label* : *string option*

type *feynmf* =
 { *style* : $(\text{string} \times \text{string}) \text{ option}$;
 rev : *bool*;
 label : *string option*;
 tension : *float option* }

val *vanilla* : *feynmf*

```
val sty : (string × string) × bool × string → feynmf
```

to_feynmf file to_string i2 t write the trees in the list *t* to the file named *file*. The leaf *i2* is used as the second incoming particle and *to_string* is used to convert leaf labels to L^AT_EX-strings.

```
val to_feynmf : bool ref → string → (λ → string) → λ → (feynmf, λ) t list → unit
```

Least Squares Layout

A general graph with edges of type ε , internal nodes of type ν , and external nodes of type 'ext'.

```
type (ε, ν, 'ext) graph
```

```
val graph_of_tree : (ν → ν → ε) → (ν → ν) → ν → (ν, ν) t → (ε, ν, ν) graph
```

A general graph with the layout of the external nodes fixed.

```
type (ε, ν, 'ext) ext_layout
```

```
val left_to_right : int → (ε, ν, 'ext) graph → (ε, ν, 'ext) ext_layout
```

A general graph with the layout of all nodes fixed.

```
type (ε, ν, 'ext) layout
```

```
val layout : (ε, ν, 'ext) ext_layout → (ε, ν, 'ext) layout
```

```
val dump : (ε, ν, 'ext) layout → unit
```

```
val iter_edges : (ε → float × float → float × float → unit) → (ε, ν, 'ext) layout → unit
```

```
val iter_internal : (float × float → unit) → (ε, ν, 'ext) layout → unit
```

```
val iter_incoming : ('ext × float × float → unit) → (ε, ν, 'ext) layout → unit
```

```
val iter_outgoing : ('ext × float × float → unit) → (ε, ν, 'ext) layout → unit
```

Q.2 Implementation of *Tree*

Q.2.1 Abstract Data Type

```
type (ν, λ) t =
  | Leaf of ν × λ
  | Node of ν × (ν, λ) t list
```

```
let leaf n l = Leaf (n, l)
```

```
let cons n children = Node (n, children)
```

Presenting the leaves *in order* comes naturally, but will be useful below.

```
let rec leafs = function
  | Leaf (_, l) → [l]
```

```

| Node (_, ch) → ThoList.flatmap leafs ch
let node = function
| Leaf (n, _) → n
| Node (n, _) → n

```

This guarantees that the root node can be stripped from the result by *List.tl*.

```

let rec nodes = function
| Leaf _ → []
| Node (n, ch) → n :: ThoList.flatmap nodes ch

```

first_match p list returns $(x, list')$, where x is the first element of *list* for which $p\ x = \text{true}$ and *list'* is *list* sans x .

```

let first_match p list =
  let rec first_match' no_match = function
    | [] → invalid_arg "Tree.fuse: prospective root not found"
    | t :: rest when p t → (t, List.rev_append no_match rest)
    | t :: rest → first_match' (t :: no_match) rest in
  first_match' [] list

```

One recursion step in *fuse'* rotates the topmost tree node, moving the prospective root up:

```

let fuse conjg root contains_root trees =
  let rec fuse' subtrees =
    match first_match contains_root subtrees with

```

If the prospective root is contained in a leaf, we have either found the root—in which case we're done—or have failed catastrophically:

```

| Leaf (n, l), children →
  if l = root then
    Node (conjg n, children)
  else
    invalid_arg "Tree.fuse: root predicate inconsistent"

```

Otherwise, we perform a rotation as in (Q.10) and connect all nodes that do not contain the root to a new node. For efficiency, we append the new node at the end and prevent *first_match* from searching for the root in it in vain again. Since *root_children* is probably rather short, this should be a good strategy.

```

| Node (n, root_children), other_children →
  fuse' (root_children @ [Node (conjg n, other_children)]) in
  fuse' trees

```

Sorting is also straightforward, we only have to keep track of the suprema of the subtrees:

```
type ( $\alpha$ ,  $\beta$ ) with_supremum = { sup :  $\alpha$ ; data :  $\beta$  }
```

Since the lists are rather short, *Sort.list* could be replaced by an optimized version, but we're not (yet) dealing with the most important speed bottleneck here:

```
let rec sort' lesseq = function
| Leaf (_, l) as e → { sup = l; data = e }
| Node (n, ch) →
  let ch' = Sort.list
    (fun x y → lesseq x.sup y.sup) (List.map (sort' lesseq) ch) in
  { sup = (List.hd (List.rev ch')).sup;
    data = Node (n, List.map (fun x → x.data) ch') }
```

finally, throw away the overall supremum:

```
let sort lesseq t = (sort' lesseq t).data
```

Q.2.2 Homomorphisms

Isomorphisms are simple:

```
let rec map fn fl = function
| Leaf (n, l) → Leaf (fn n, fl l)
| Node (n, ch) → Node (fn n, List.map (map fn fl) ch)
```

homomorphisms are not more complicated:

```
let rec fold leaf node = function
| Leaf (n, l) → leaf n l
| Node (n, ch) → node n (List.map (fold leaf node) ch)
```

and tensor products are fun:

```
let rec fan leaf node = function
| Leaf (n, l) → leaf n l
| Node (n, ch) → Product.fold
  (fun ch' t → node n ch' @ t) (List.map (fan leaf node) ch) []
```

Q.2.3 Output

```
let leaf_to_string n l =
  if n = "" then
    l
  else if l = "" then
    n
  else
    n ^ "(" ^ l ^ ")"
```

```

let node_to_string n ch =
  "(" ^ (if n == "" then "" else n ^ ":") ^ (String.concat "," ch) ^ ")"
let to_string t =
  fold leaf_to_string node_to_string t

```

Feynmf

Add a value that is greater than all suprema

```

type  $\alpha$  supremum_or_infinity = Infinity | Sup of  $\alpha$ 
type ( $\alpha$ ,  $\beta$ ) with_supremum_or_infinity =
  { sup :  $\alpha$  supremum_or_infinity; data :  $\beta$  }
let with_infinity lesseq x y =
  match x.sup, y.sup with
  | Infinity, _ → false
  | _, Infinity → true
  | Sup x', Sup y' → lesseq x' y'

```

Using this, we can sort the tree in another way that guarantees that a particular leaf (*i2*) is moved as far to the end as possible. We can then flip this leaf from outgoing to incoming without introducing a crossing:

```

let rec sort_2i' lesseq i2 = function
| Leaf (_, l) as e →
  { sup = if l == i2 then Infinity else Sup l; data = e }
| Node (n, ch) →
  let ch' = Sort.list (with_infinity lesseq)
    (List.map (sort_2i' lesseq i2) ch) in
  { sup = (List.hd (List.rev ch')).sup;
    data = Node (n, List.map (fun x → x.data) ch') }

```

again, throw away the overall supremum:

```

let sort_2i lesseq i2 t = (sort_2i' lesseq i2 t).data
type feynmf =
  { style : (string × string) option;
    rev : bool;
    label : string option;
    tension : float option }

```

open *Printf*

```

let style prop =
  match prop.style with
  | None → ("plain","")
  | Some s → s
let species prop = fst (style prop)
let tex_lbl prop = snd (style prop)
let leaf_label tex io leaf lab = function

```

```

| None → fprintf tex "\fmflabel{${s}${s}}{${s}${s}}\n" lab io leaf
| Some s →
    fprintf tex "\fmflabel{${s}${s}}{^{(s)}${s}}{${s}${s}}\n" s lab io leaf

```

We try to draw diagrams more symmetrically by reducing the tension on the outgoing external lines.

This is insufficient for asymmetrical cascade decays.

```

let rec leaf_node tex to_string i2 n prop leaf =
  let io, tension, rev =
    if leaf = i2 then
      ("i", "", ¬ prop.rev)
    else
      ("o", "", tension=0.5, prop.rev) in
  leaf_label tex io (to_string leaf) (tex_lbl prop) prop.label ;
  fprintf tex "\fmfdot{v%d}\n" n;

```

Q.2.4 Least Squares Layout

$$L = \frac{1}{2} \sum_{i \neq i'} T_{ii'} (x_i - x_{i'})^2 + \frac{1}{2} \sum_{i,j} T'_{ij} (x_i - e_j)^2 \quad (\text{Q.11})$$

and thus

$$0 = \frac{\partial L}{\partial x_i} = \sum_{i' \neq i} T_{ii'} (x_i - x_{i'}) + \sum_j T'_{ij} (x_i - e_j) \quad (\text{Q.12})$$

or

$$\left(\sum_{i' \neq i} T_{ii'} + \sum_j T'_{ij} \right) x_i - \sum_{i' \neq i} T_{ii'} x_{i'} = \sum_j T'_{ij} e_j \quad (\text{Q.13})$$

where we can assume that

$$T_{ii'} = T_{i'i} \quad (\text{Q.14a})$$

$$T_{ii} = 0 \quad (\text{Q.14b})$$

```

type α node_with_tension = { node : α; tension : float }
let unit_tension t =
  map (fun n → { node = n; tension = 1.0 }) (fun l → l) t
let leaves_and_nodes i2 t =
  let t' = sort_2i (≤) i2 t in
  match nodes t' with
  | [] → failwith "Tree.nodes_and_leafs: impossible"
  | i1 :: _ as n → (i1, i2, List.filter (fun l → l ≠ i2) (leafs t'), n)

```

Not tail recursive, but they're unlikely to meet any deep trees:

```

let rec internal_edges_from n = function
| Leaf _ → []
| Node (n', ch) → (n', n) :: (ThoList.flatmap (internal_edges_from n') ch)

```

The root node of the tree represents a vertex (node) and an external line (leaf) of the Feynman diagram simultaneously. Thus it requires special treatment:

```

let internal_edges = function
| Leaf _ → []

```

```

| Node (n, ch) → ThoList.flatmap (internal_edges_from n) ch

let rec external_edges_from n = function
| Leaf (n', _) → [(n', n)]
| Node (n', ch) → ThoList.flatmap (external_edges_from n') ch

let external_edges = function
| Leaf (n, _) → [(n, n)]
| Node (n, ch) → (n, n) :: ThoList.flatmap (external_edges_from n) ch

type ('edge, 'node, 'ext) graph =

ALGEBRA

U.1 Interface of Algebra

U.1.1 Coefficients

For our algebra, we need coefficient rings.

```
module type CRing =
  sig
    type t
    val null : t
    val unit : t
    val mul : t → t → t
    val add : t → t → t
    val sub : t → t → t
    val neg : t → t
    val to_string : t → string
  end
```

And rational numbers provide a particularly important example:

```
module type Rational =
  sig
    include CRing
    val is_null : t → bool
    val is_unit : t → bool
    val make : int → int → t
    val to_ratio : t → int × int
    val to_float : t → float
  end
```

U.1.2 Naive Rational Arithmetic

This *is* dangerous and will overflow even for simple applications. The production code will have to be linked to a library for large integer arithmetic.

```
module Small_Rational : Rational
```

U.1.3 Expressions: Terms, Rings and Linear Combinations

The tensor algebra will be spanned by an abelian monoid:

module type *Term* =

```
sig
  type  $\alpha$  t
  val unit : unit  $\rightarrow$   $\alpha$  t
  val is_unit :  $\alpha$  t  $\rightarrow$  bool
  val atom :  $\alpha \rightarrow \alpha$  t
  val power : int  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\alpha$  t
  val mul :  $\alpha$  t  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\alpha$  t
  val map : ( $\alpha \rightarrow \beta$ )  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\beta$  t
  val to_string : ( $\alpha \rightarrow$  string)  $\rightarrow$   $\alpha$  t  $\rightarrow$  string
```

The derivative of a term is *not* a term, but a sum of terms instead:

$$D(f_1^{p_1} f_2^{p_2} \dots f_n^{p_n}) = \sum_i (Df_i) p_i f_1^{p_1} f_2^{p_2} \dots f_i^{p_i-1} \dots f_n^{p_n} \quad (\text{U.1})$$

The function returns the sum as a list of triples $(Df_i, p_i, f_1^{p_1} f_2^{p_2} \dots f_i^{p_i-1} \dots f_n^{p_n})$. Summing the terms is left to the calling module and the Df_i are *not* guaranteed to be different. NB: The function implementating the inner derivative, is supposed to return *Some* Df_i and *None*, iff Df_i vanishes.

```
val derive : ( $\alpha \rightarrow \beta$  option)  $\rightarrow$   $\alpha$  t  $\rightarrow$  ( $\beta \times$  int  $\times$   $\alpha$  t) list
```

convenience function

```
val product :  $\alpha$  t list  $\rightarrow$   $\alpha$  t
val atoms :  $\alpha$  t  $\rightarrow$   $\alpha$  list
```

end

module type *Ring* =

```
sig
  module C : Rational
  type  $\alpha$  t
  val null : unit  $\rightarrow$   $\alpha$  t
  val unit : unit  $\rightarrow$   $\alpha$  t
  val is_null :  $\alpha$  t  $\rightarrow$  bool
  val is_unit :  $\alpha$  t  $\rightarrow$  bool
  val atom :  $\alpha \rightarrow \alpha$  t
  val scale : C.t  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\alpha$  t
  val add :  $\alpha$  t  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\alpha$  t
  val sub :  $\alpha$  t  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\alpha$  t
  val mul :  $\alpha$  t  $\rightarrow$   $\alpha$  t  $\rightarrow$   $\alpha$  t
  val neg :  $\alpha$  t  $\rightarrow$   $\alpha$  t
```

Again

$$D(f_1^{p_1} f_2^{p_2} \dots f_n^{p_n}) = \sum_i (Df_i) p_i f_1^{p_1} f_2^{p_2} \dots f_i^{p_i-1} \dots f_n^{p_n} \quad (\text{U.2})$$

but, iff Df_i can be identified with a f' , we know how to perform the sum.

```
val derive_inner : ( $\alpha \rightarrow \alpha t$ )  $\rightarrow \alpha t \rightarrow \alpha t$  (* this? *)
val derive_inner' : ( $\alpha \rightarrow \alpha t option$ )  $\rightarrow \alpha t \rightarrow \alpha t$  (* or that? *)
```

Below, we will need partial derivatives that lead out of the ring: *derive_outer* *derive_atom* *term* returns a list of partial derivatives β with non-zero coefficients α t :

```
val derive_outer : ( $\alpha \rightarrow \beta option$ )  $\rightarrow \alpha t \rightarrow (\beta \times \alpha t) list$ 
```

convenience functions

```
val sum :  $\alpha t list \rightarrow \alpha t$ 
```

```
val product :  $\alpha t list \rightarrow \alpha t$ 
```

The list of all generators appearing in an expression:

```
val atoms :  $\alpha t \rightarrow \alpha list$ 
```

```
val to_string : ( $\alpha \rightarrow string$ )  $\rightarrow \alpha t \rightarrow string$ 
```

end

module type *Linear* =

sig

module *C* : *Ring*

type (α, γ) *t*

val *null* : *unit* $\rightarrow (\alpha, \gamma) t$

val *atom* : $\alpha \rightarrow (\alpha, \gamma) t$

val *singleton* : $\gamma C.t \rightarrow \alpha \rightarrow (\alpha, \gamma) t$

val *scale* : $\gamma C.t \rightarrow (\alpha, \gamma) t \rightarrow (\alpha, \gamma) t$

val *add* : (α, γ) *t* $\rightarrow (\alpha, \gamma) t \rightarrow (\alpha, \gamma) t$

val *sub* : (α, γ) *t* $\rightarrow (\alpha, \gamma) t \rightarrow (\alpha, \gamma) t$

A partial derivative w.r.t. a vector maps from a coefficient ring to the dual vector space.

```
val partial : ( $\gamma \rightarrow (\alpha, \gamma) t$ )  $\rightarrow \gamma C.t \rightarrow (\alpha, \gamma) t$ 
```

A linear combination of vectors

$$linear[(v_1, c_1); (v_2, c_2); \dots; (v_n, c_n)] = \sum_{i=1}^n c_i \cdot v_i \quad (\text{U.3})$$

```
val linear : (( $\alpha, \gamma$ ) t  $\times \gamma C.t$ ) list  $\rightarrow (\alpha, \gamma) t$ 
```

Some convenience functions

```
val map : ( $\alpha \rightarrow \gamma C.t \rightarrow (\beta, \delta) t$ )  $\rightarrow (\alpha, \gamma) t \rightarrow (\beta, \delta) t$ 
```

```
val sum : ( $\alpha, \gamma$ ) t list  $\rightarrow (\alpha, \gamma) t$ 
```

The list of all generators and the list of all generators of coefficients appearing in an expression:

```
val atoms : ( $\alpha, \gamma$ ) t  $\rightarrow \alpha list \times \gamma list$ 
```

```
val to_string : ( $\alpha \rightarrow string$ )  $\rightarrow (\gamma \rightarrow string) \rightarrow (\alpha, \gamma) t \rightarrow string$ 
```

end

module *Term* : *Term*

module *Make_Ring* (*C* : *Rational*) (*T* : *Term*) : *Ring*

module *Make_Linear* (*C* : *Ring*) : *Linear* with module *C* = *C*

U.2 Implementation of Algebra

The terms will be small and there's no need to be fancy and/or efficient. It's more important to have a unique representation.

```
module PM = Pmap.List
```

U.2.1 Coefficients

For our algebra, we need coefficient rings.

```
module type CRing =
sig
  type t
  val null : t
  val unit : t
  val mul : t → t → t
  val add : t → t → t
  val sub : t → t → t
  val neg : t → t
  val to_string : t → string
end
```

And rational numbers provide a particularly important example:

```
module type Rational =
sig
  include CRing
  val is_null : t → bool
  val is_unit : t → bool
  val make : int → int → t
  val to_ratio : t → int × int
  val to_float : t → float
end
```

U.2.2 Naive Rational Arithmetic

This *is* dangerous and will overflow even for simple applications. The production code will have to be linked to a library for large integer arithmetic.

Anyway, here's Euclid's algorithm:

```
let rec gcd i1 i2 =
  if i2 = 0 then
    abs i1
  else
    gcd i2 (i1 mod i2)
let lcm i1 i2 = (i1 / gcd i1 i2) × i2
```

```

module Small_Rational : Rational =
  struct
    type t = int × int
    let is_null (n, -) = (n = 0)
    let is_unit (n, d) = (n ≠ 0) ∧ (n = d)
    let null = (0, 1)
    let unit = (1, 1)
    let make n d =
      let c = gcd n d in
      (n / c, d / c)
    let mul (n1, d1) (n2, d2) = make (n1 × n2) (d1 × d2)
    let add (n1, d1) (n2, d2) = make (n1 × d2 + n2 × d1) (d1 × d2)
    let sub (n1, d1) (n2, d2) = make (n1 × d2 - n2 × d1) (d1 × d2)
    let neg (n, d) = (-n, d)
    let to_ratio (n, d) =
      if d < 0 then
        (-n, -d)
      else
        (n, d)
    let to_float (n, d) = float n /. float d
    let to_string (n, d) =
      if d = 1 then
        Printf.sprintf "%d" n
      else
        Printf.sprintf "(%d/%d)" n d
  end
end

```

U.2.3 Expressions: Terms, Rings and Linear Combinations

The tensor algebra will be spanned by an abelian monoid:

```

module type Term =
  sig
    type  $\alpha$  t
    val unit : unit →  $\alpha$  t
    val is_unit :  $\alpha$  t → bool
    val atom :  $\alpha$  →  $\alpha$  t
    val power : int →  $\alpha$  t →  $\alpha$  t
    val mul :  $\alpha$  t →  $\alpha$  t →  $\alpha$  t
    val map : ( $\alpha$  →  $\beta$ ) →  $\alpha$  t →  $\beta$  t
    val to_string : ( $\alpha$  → string) →  $\alpha$  t → string
    val derive : ( $\alpha$  →  $\beta$  option) →  $\alpha$  t → ( $\beta$  × int ×  $\alpha$  t) list
    val product :  $\alpha$  t list →  $\alpha$  t
    val atoms :  $\alpha$  t →  $\alpha$  list
  end

module type Ring =

SIMPLE LINEAR ALGEBRA

V.1 Interface of Linalg

```
exception Singular
exception Not_Square

val copy_matrix : float array array → float array array
val matmul : float array array → float array array → float array array
val matmulv : float array array → float array → float array
val lu_decompose : float array array → float array array × float array array
val solve : float array array → float array → float array
val solve_many : float array array → float array list → float array list
```

V.2 Implementation of Linalg

This is not a functional implementations, but uses imperative array in Fortran style for maximum speed.

```
exception Singular
exception Not_Square

let copy_matrix a =
  Array.init (Array.length a)
    (fun i → Array.copy a.(i))

let matmul a b =
  let ni = Array.length a
  and nj = Array.length b.(0)
  and n = Array.length b in
  let ab = Array.make_matrix ni nj 0.0 in
  for i = 0 to pred ni do
    for j = 0 to pred nj do
      for k = 0 to pred n do
        ab.(i).(j) ← ab.(i).(j) + . a.(i).(k) * . b.(k).(j)
      done
    done
  done;
  ab
```

```

let matmulv a v =
  let na = Array.length a in
  let nv = Array.length v in
  let v' = Array.make na 0.0 in
  for i = 0 to pred na do
    for j = 0 to pred nv do
      v'.(i) ← v'.(i) + . a.(i).(j) *. v.(j)
    done
  done;
  v'

let maxabsval a : float =
  let x = ref (abs_float a.(0)) in
  for i = 1 to Array.length a - 1 do
    x := max !x (abs_float a.(i))
  done;
  !x

```

V.2.1 LU Decomposition

$$A = LU \quad (\text{V.1a})$$

In more detail

$$\begin{pmatrix} a_{00} & a_{01} & \dots & a_{0(n-1)} \\ a_{10} & a_{11} & \dots & a_{1(n-1)} \\ \vdots & \vdots & \ddots & \vdots \\ a_{(n-1)0} & a_{(n-1)1} & \dots & a_{(n-1)(n-1)} \end{pmatrix} =
 \begin{pmatrix} 1 & 0 & \dots & 0 \\ l_{10} & 1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ l_{(n-1)0} & l_{(n-1)1} & \dots & 1 \end{pmatrix} \begin{pmatrix} u_{00} & u_{01} & \dots & u_{0(n-1)} \\ 0 & u_{11} & \dots & u_{1(n-1)} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & u_{(n-1)(n-1)} \end{pmatrix} \quad (\text{V.1b})$$

Rewriting (V.1) in block matrix notation

$$\begin{pmatrix} a_{00} & a_{0\cdot} \\ a_{\cdot 0} & A \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ l_{\cdot 0} & L \end{pmatrix} \begin{pmatrix} u_{00} & u_{0\cdot} \\ 0 & U \end{pmatrix} = \begin{pmatrix} u_{00} & u_{0\cdot} \\ l_{\cdot 0} u_{00} & l_{\cdot 0} \otimes u_{0\cdot} + LU \end{pmatrix} \quad (\text{V.2})$$

we can solve it easily

$$u_{00} = a_{00} \quad (\text{V.3a})$$

$$u_{0\cdot} = a_{0\cdot} \quad (\text{V.3b})$$

$$l_{\cdot 0} = \frac{a_{\cdot 0}}{a_{00}} \quad (\text{V.3c})$$

$$LU = A - \frac{a_{\cdot 0} \otimes a_{0\cdot}}{a_{00}} \quad (\text{V.3d})$$

and (V.3c) and (V.3d) define a simple iterative algorithm if we work from the outside in. It just remains to add pivoting.

```

let swap a i j =
  let a_i = a.(i) in
  a.(i) ← a.(j);
  a.(j) ← a_i

```

Here we use a phase convention for the polarization vectors compatible with the angular momentum coupling to spin 3/2 and spin 2.

$$\epsilon_1^\mu(k) = \frac{1}{|\vec{k}| \sqrt{k_x^2 + k_y^2}} (0; k_z k_x, k_y k_z, -k_x^2 - k_y^2) \quad (\text{X.12a})$$

$$\epsilon_2^\mu(k) = \frac{1}{\sqrt{k_x^2 + k_y^2}} (0; -k_y, k_x, 0) \quad (\text{X.12b})$$

$$\epsilon_3^\mu(k) = \frac{k_0}{m|\vec{k}|} \left(\vec{k}^2/k_0; k_x, k_y, k_z \right) \quad (\text{X.12c})$$

and

$$\epsilon_\pm^\mu(k) = \frac{1}{\sqrt{2}} (\epsilon_1^\mu(k) \pm i\epsilon_2^\mu(k)) \quad (\text{X.13a})$$

$$\epsilon_0^\mu(k) = \epsilon_3^\mu(k) \quad (\text{X.13b})$$

i. e.

$$\epsilon_+^\mu(k) = \frac{1}{\sqrt{2}\sqrt{k_x^2 + k_y^2}} \left(0; \frac{k_z k_x}{|\vec{k}|} - ik_y, \frac{k_y k_z}{|\vec{k}|} + ik_x, -\frac{k_x^2 + k_y^2}{|\vec{k}|} \right) \quad (\text{X.14a})$$

$$\epsilon_-^\mu(k) = \frac{1}{\sqrt{2}\sqrt{k_x^2 + k_y^2}} \left(0; \frac{k_z k_x}{|\vec{k}|} + ik_y, \frac{k_y k_z}{|\vec{k}|} - ik_x, -\frac{k_x^2 + k_y^2}{|\vec{k}|} \right) \quad (\text{X.14b})$$

$$\epsilon_0^\mu(k) = \frac{k_0}{m|\vec{k}|} \left(\vec{k}^2/k_0; k_x, k_y, k_z \right) \quad (\text{X.14c})$$

Determining the mass from the momenta is a numerically haphazardous for light particles. Therefore, we accept some redundancy and pass the mass explicitly.

X.6 Polarization vectors revisited

```

(omega_polarizations_madgraph.f90)≡
<Cotypeleft>
module omega_polarizations_madgraph
  use kinds
  use constants
  use omega_vectors
  implicit none
  private
  <Declaration of polarization vectors for madgraph>
  integer, parameter, public :: omega_pols_madgraph_2010_01_A = 0
contains
  <Implementation of polarization vectors for madgraph>
end module omega_polarizations_madgraph

```

This set of polarization vectors is compatible with HELAS [5]:

$$\epsilon_1^\mu(k) = \frac{1}{|\vec{k}|\sqrt{k_x^2 + k_y^2}} (0; k_z k_x, k_y k_z, -k_x^2 - k_y^2) \quad (\text{X.15a})$$

$$\epsilon_2^\mu(k) = \frac{1}{\sqrt{k_x^2 + k_y^2}} (0; -k_y, k_x, 0) \quad (\text{X.15b})$$

$$\epsilon_3^\mu(k) = \frac{k_0}{m|\vec{k}|} (\vec{k}^2/k_0; k_x, k_y, k_z) \quad (\text{X.15c})$$

and

$$\epsilon_\pm^\mu(k) = \frac{1}{\sqrt{2}} (\mp \epsilon_1^\mu(k) - i \epsilon_2^\mu(k)) \quad (\text{X.16a})$$

$$\epsilon_0^\mu(k) = \epsilon_3^\mu(k) \quad (\text{X.16b})$$

i. e.

$$\epsilon_+^\mu(k) = \frac{1}{\sqrt{2}\sqrt{k_x^2 + k_y^2}} \left(0; -\frac{k_z k_x}{|\vec{k}|} + i k_y, -\frac{k_y k_z}{|\vec{k}|} - i k_x, \frac{k_x^2 + k_y^2}{|\vec{k}|} \right) \quad (\text{X.17a})$$

$$\epsilon_-^\mu(k) = \frac{1}{\sqrt{2}\sqrt{k_x^2 + k_y^2}} \left(0; \frac{k_z k_x}{|\vec{k}|} + i k_y, \frac{k_y k_z}{|\vec{k}|} - i k_x, -\frac{k_x^2 + k_y^2}{|\vec{k}|} \right) \quad (\text{X.17b})$$

$$\epsilon_0^\mu(k) = \frac{k_0}{m|\vec{k}|} \left(\vec{k}^2/k_0; k_x, k_y, k_z \right) \quad (\text{X.17c})$$

Fortunately, for comparing with squared matrix generated by Madgraph we can also use the modified version, since the difference is only a phase and does *not* mix helicity states. Determining the mass from the momenta is a numerically haphazardous for light particles. Therefore, we accept some redundancy and pass the mass explicitly.

X.7 Symmetric Tensors

Spin-2 polarization tensors are symmetric, transversal and traceless

$$\epsilon_m^{\mu\nu}(k) = \epsilon_m^{\nu\mu}(k) \quad (\text{X.18a})$$

$$k_\mu \epsilon_m^{\mu\nu}(k) = k_\nu \epsilon_m^{\mu\nu}(k) = 0 \quad (\text{X.18b})$$

$$\epsilon_{m,\mu}^\mu(k) = 0 \quad (\text{X.18c})$$

with $m = 1, 2, 3, 4, 5$. Our current representation is redundant and does *not* enforce symmetry or tracelessness.

X.8 Symmetric Polarization Tensors

$$\epsilon_{+2}^{\mu\nu}(k) = \epsilon_{+}^{\mu}(k)\epsilon_{+}^{\nu}(k) \quad (\text{X.19a})$$

$$\epsilon_{+1}^{\mu\nu}(k) = \frac{1}{\sqrt{2}} (\epsilon_+^\mu(k)\epsilon_0^\nu(k) + \epsilon_0^\mu(k)\epsilon_+^\nu(k)) \quad (\text{X.19b})$$

$$\epsilon_0^{\mu\nu}(k) = \frac{1}{\sqrt{6}} (\epsilon_+^\mu(k)\epsilon_-^\nu(k) + \epsilon_-^\mu(k)\epsilon_+^\nu(k) - 2\epsilon_0^\mu(k)\epsilon_0^\nu(k)) \quad (\text{X.19c})$$

$$\epsilon_{-1}^{\mu\nu}(k) = \frac{1}{\sqrt{2}} (\epsilon_-^\mu(k)\epsilon_0^\nu(k) + \epsilon_0^\mu(k)\epsilon_-^\nu(k)) \quad (\text{X.19d})$$

$$\epsilon_{-2}^{\mu\nu}(k) = \epsilon_-^\mu(k)\epsilon_-^\nu(k) \quad (\text{X.19e})$$

Note that $\epsilon_{\pm 2, \mu}^\mu(k) = \epsilon_\pm^\mu(k)\epsilon_{\pm, \mu}(k) \propto \epsilon_\pm^\mu(k)\epsilon_{\mp, \mu}^*(k) = 0$ and that the sign in $\epsilon_0^{\mu\nu}(k)$ insures its tracelessness¹.

NB: the explicit cast to `vector` is required here, because a specific `complex_momentum` procedure for `operator (*)` would introduce ambiguities. NB: we used to use

the constructor `vector (p%t, p%x)` instead of the temporary variable, but the Intel Fortran Compiler choked on it.

```

See table X.1 for the names of Fortran functions. We could have used long names instead, but this would increase the chance of running past continuation line limits without adding much to the legibility.

X.13.1 Fermionic Vector and Axial Couplings

There's more than one chiral representation. This one is compatible with HELAS [5].

$$\gamma^0 = \begin{pmatrix} 0 & \mathbf{1} \\ \mathbf{1} & 0 \end{pmatrix}, \gamma^i = \begin{pmatrix} 0 & \sigma^i \\ -\sigma^i & 0 \end{pmatrix}, \gamma_5 = i\gamma^0\gamma^1\gamma^2\gamma^3 = \begin{pmatrix} -\mathbf{1} & 0 \\ 0 & \mathbf{1} \end{pmatrix} \quad (\text{X.49})$$

Therefore

$$g_S + g_P\gamma_5 = \begin{pmatrix} g_S - g_P & 0 & 0 & 0 \\ 0 & g_S - g_P & 0 & 0 \\ 0 & 0 & g_S + g_P & 0 \\ 0 & 0 & 0 & g_S + g_P \end{pmatrix} \quad (\text{X.50a})$$

$$g_V\gamma^0 - g_A\gamma^0\gamma_5 = \begin{pmatrix} 0 & 0 & g_V - g_A & 0 \\ 0 & 0 & 0 & g_V - g_A \\ g_V + g_A & 0 & 0 & 0 \\ 0 & g_V + g_A & 0 & 0 \end{pmatrix} \quad (\text{X.50b})$$

$$g_V\gamma^1 - g_A\gamma^1\gamma_5 = \begin{pmatrix} 0 & 0 & 0 & g_V - g_A \\ 0 & 0 & g_V - g_A & 0 \\ 0 & -g_V - g_A & 0 & 0 \\ -g_V - g_A & 0 & 0 & 0 \end{pmatrix} \quad (\text{X.50c})$$

$$g_V\gamma^2 - g_A\gamma^2\gamma_5 = \begin{pmatrix} 0 & 0 & 0 & -i(g_V - g_A) \\ 0 & 0 & i(g_V - g_A) & 0 \\ 0 & i(g_V + g_A) & 0 & 0 \\ -i(g_V + g_A) & 0 & 0 & 0 \end{pmatrix} \quad (\text{X.50d})$$

$$g_V\gamma^3 - g_A\gamma^3\gamma_5 = \begin{pmatrix} 0 & 0 & g_V - g_A & 0 \\ 0 & 0 & 0 & -g_V + g_A \\ -g_V - g_A & 0 & 0 & 0 \\ 0 & g_V + g_A & 0 & 0 \end{pmatrix} \quad (\text{X.50e})$$

Determining the mass from the momenta is a numerically haphazardous for light particles. Therefore, we accept some redundancy and pass the mass explicitly. Even if the mass is not used in the chiral representation, we do so for symmetry with polarization vectors and to be prepared for other representations.

```

X.13.4 Off Shell Wave Functions

I've just taken this over from Christian Schwinn's version.

(Declaration of spinor off shell wave functions)+≡

```

public :: brs_u, brs_ubar, brs_v, brs_vbar

```

The off-shell wave functions needed for gauge checking are obtained from the LSZ-formulas:

$$\langle \text{Out} | d^\dagger | \text{In} \rangle = i \int d^4 x \bar{v} e^{-ikx} (i \not{\partial} - m) \langle \text{Out} | \psi | \text{In} \rangle \quad (\text{X.57a})$$

$$\langle \text{Out} | b | \text{In} \rangle = -i \int d^4 x \bar{u} e^{ikx} (i \not{\partial} - m) \langle \text{Out} | \psi | \text{In} \rangle \quad (\text{X.57b})$$

$$\langle \text{Out} | d | \text{In} \rangle = i \int d^4x \langle \text{Out} | \bar{\psi} | \text{In} \rangle (-i \overleftarrow{\not{\partial}} - m) v e^{ikx} \quad (\text{X.57c})$$

$$\langle \text{Out} | b^\dagger | \text{In} \rangle = -i \int d^4x \langle \text{Out} | \bar{\psi} | \text{In} \rangle (-i \overleftarrow{\not{\partial}} - m) u e^{-ikx} \quad (\text{X.57d})$$

Since the relative sign between fermions and antifermions is ignored for on-shell amplitudes we must also ignore it here, so all wavefunctions must have a $(-i)$ factor. In momentum space we have:

$$brsu(p) = (-i)(\not{p} - m)u(p) \quad (\text{X.58})$$

(Implementation of spinor off shell wave functions) \equiv

```
pure function brs_u (m, p, s) result (dpsi)

end function brs_ubar
```

$$brs\bar{v}(p) = (i)\bar{v}(p)(\not{p} + m) \quad (X.61)$$

(Implementation of spinor off shell wave functions)+≡

```

pure function brs_vbar (m, p, s) result (dpsibar)
  type(conjspinor) :: dpsibar,psibar
  real(kind=default), intent(in) :: m
  type(momentum), intent(in) :: p
  integer, intent(in) :: s
  type(vector)::vp
  complex(kind=default), parameter :: one = (1, 0)
  vp=p
  psibar=vbar(m,p,s)
  dpsibar=cplx(0.0,1.0)*(f_fv(one,psibar,vp)+m*psibar)
end function brs_vbar

```

NB: The remarks on momentum flow in the propagators don't apply here since the incoming momenta are flipped for the wave functions.

X.13.5 Propagators

NB: the common factor of i is extracted:

(Declaration of spinor propagators)≡

```

public :: pr_psi, pr_psibar
public :: pj_psi, pj_psibar
public :: pg_psi, pg_psibar

```

$$\frac{i(-\not{p} + m)}{p^2 - m^2 + im\Gamma}\psi \quad (X.62)$$

NB: the sign of the momentum comes about because all momenta are treated as *outgoing* and the particle charge flow is therefore opposite to the momentum.

(Implementation of spinor propagators)≡

```

pure function pr_psi (p, m, w, psi) result (ppsi)
  type(spinor) :: ppsi
  type(momentum), intent(in) :: p
  real(kind=default), intent(in) :: m, w
  type(spinor), intent(in) :: psi
  type(vector) :: vp
  complex(kind=default), parameter :: one = (1, 0)
  vp = p
  ppsi = (1 / cplx (p*p - m**2, m*w, kind=default)) &
    * (- f_vf (one, vp, psi) + m * psi)
end function pr_psi

```

$$\sqrt{\frac{\pi}{M\Gamma}}(-\not{p} + m)\psi \quad (X.63)$$

(Implementation of spinor propagators)+≡

```

pure function pj_psi (p, m, w, psi) result (ppsi)
  type(spinor) :: ppsi
  type(momentum), intent(in) :: p
  real(kind=default), intent(in) :: m, w
  type(spinor), intent(in) :: psi
  type(vector) :: vp

```

```

    complex(kind=default), parameter :: one = (1, 0)
    vp = p
    ppsi = (0, -1) * sqrt (PI / m / w) * (- f_vf (one, vp, psi) + m * psi)
end function pj_psi

```

(Implementation of spinor propagators)+≡

```

pure function pg_psi (p, m, w, psi) result (ppsi)
    type(spinor) :: ppsi
    type(momentum), intent(in) :: p
    real(kind=default), intent(in) :: m, w
    type(spinor), intent(in) :: psi
    type(vector) :: vp
    complex(kind=default), parameter :: one = (1, 0)
    vp = p
    ppsi = gauss(p*p, m, w) * (- f_vf (one, vp, psi) + m * psi)
end function pg_psi

```

$$\bar{\psi} \frac{i(\not{p} + m)}{p^2 - m^2 + im\Gamma} \quad (\text{X.64})$$

NB: the sign of the momentum comes about because all momenta are treated as *outgoing* and the antiparticle charge flow is therefore parallel to the momentum.

(Implementation of spinor propagators)+≡

```

pure function pr_psibar (p, m, w, psibar) result (ppsibar)
    type(conjspinor) :: ppsibar
    type(momentum), intent(in) :: p
    real(kind=default), intent(in) :: m, w
    type(conjspinor), intent(in) :: psibar
    type(vector) :: vp
    complex(kind=default), parameter :: one = (1, 0)
    vp = p
    ppsibar = (1 / cmplx (p*p - m**2, m*w, kind=default)) &
        * (f_fv (one, psibar, vp) + m * psibar)
end function pr_psibar

```

$$\sqrt{\frac{\pi}{M\Gamma}} \bar{\psi}(\not{p} + m) \quad (\text{X.65})$$

NB: the sign of the momentum comes about because all momenta are treated as *outgoing* and the antiparticle charge flow is therefore parallel to the momentum.

(Implementation of spinor propagators)+≡

```

pure function pj_psibar (p, m, w, psibar) result (ppsibar)
    type(conjspinor) :: ppsibar
    type(momentum), intent(in) :: p
    real(kind=default), intent(in) :: m, w
    type(conjspinor), intent(in) :: psibar
    type(vector) :: vp
    complex(kind=default), parameter :: one = (1, 0)
    vp = p
    ppsibar = (0, -1) * sqrt (PI / m / w) * (f_fv (one, psibar, vp) + m * psibar)
end function pj_psibar

```

(Implementation of spinor propagators)+≡

```

pure function pg_psibar (p, m, w, psibar) result (ppsibar)
    type(conjspinor) :: ppsibar

```

```

type(momentum), intent(in) :: p
real(kind=default), intent(in) :: m, w
type(conjspinor), intent(in) :: psibar
type(vector) :: vp
complex(kind=default), parameter :: one = (1, 0)
vp = p
pppsibar = gauss (p*p, m, w) * (f_fv (one, psibar, vp) + m * psibar)
end function pg_psibar

```

$$\frac{i(-\not{p} + m)}{p^2 - m^2 + im\Gamma} \sum_n \psi_n \otimes \bar{\psi}_n \quad (\text{X.66})$$

NB: the temporary variables `psi(1:4)` are not nice, but the compilers should be able to optimize the unnecessary copies away. In any case, even if the copies are performed, they are (probably) negligible compared to the floating point multiplications anyway ...

```

```

See table X.1 for the names of Fortran functions. We could have used long names instead, but this would increase the chance of running past continuation line limits without adding much to the legibility.

X.14.1 Fermionic Vector and Axial Couplings

There's more than one chiral representation. This one is compatible with HELAS [5].

$$\gamma^0 = \begin{pmatrix} 0 & \mathbf{1} \\ \mathbf{1} & 0 \end{pmatrix}, \quad \gamma^i = \begin{pmatrix} 0 & \sigma^i \\ -\sigma^i & 0 \end{pmatrix}, \quad \gamma_5 = i\gamma^0\gamma^1\gamma^2\gamma^3 = \begin{pmatrix} -\mathbf{1} & 0 \\ 0 & \mathbf{1} \end{pmatrix}, \quad (\text{X.68a})$$

$$C = \begin{pmatrix} \epsilon & 0 \\ 0 & -\epsilon \end{pmatrix}, \quad \epsilon = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \quad (\text{X.68b})$$

Therefore

$$g_S + g_P \gamma_5 = \begin{pmatrix} g_S - g_P & 0 & 0 & 0 \\ 0 & g_S - g_P & 0 & 0 \\ 0 & 0 & g_S + g_P & 0 \\ 0 & 0 & 0 & g_S + g_P \end{pmatrix} \quad (\text{X.69a})$$

$$g_V \gamma^0 - g_A \gamma^0 \gamma_5 = \begin{pmatrix} 0 & 0 & g_V - g_A & 0 \\ 0 & 0 & 0 & g_V - g_A \\ g_V + g_A & 0 & 0 & 0 \\ 0 & g_V + g_A & 0 & 0 \end{pmatrix} \quad (\text{X.69b})$$

$$g_V \gamma^1 - g_A \gamma^1 \gamma_5 = \begin{pmatrix} 0 & 0 & 0 & g_V - g_A \\ 0 & 0 & g_V - g_A & 0 \\ 0 & -g_V - g_A & 0 & 0 \\ -g_V - g_A & 0 & 0 & 0 \end{pmatrix} \quad (\text{X.69c})$$

$$g_V \gamma^2 - g_A \gamma^2 \gamma_5 = \begin{pmatrix} 0 & 0 & 0 & -i(g_V - g_A) \\ 0 & 0 & i(g_V - g_A) & 0 \\ 0 & i(g_V + g_A) & 0 & 0 \\ -i(g_V + g_A) & 0 & 0 & 0 \end{pmatrix} \quad (\text{X.69d})$$

$$g_V \gamma^3 - g_A \gamma^3 \gamma_5 = \begin{pmatrix} 0 & 0 & g_V - g_A & 0 \\ 0 & 0 & 0 & -g_V + g_A \\ -g_V - g_A & 0 & 0 & 0 \\ 0 & g_V + g_A & 0 & 0 \end{pmatrix} \quad (\text{X.69e})$$

and

$$C(g_S + g_P \gamma_5) = \begin{pmatrix} 0 & g_S - g_P & 0 & 0 \\ -g_S + g_P & 0 & 0 & 0 \\ 0 & 0 & 0 & -g_S - g_P \\ 0 & 0 & g_S + g_P & 0 \end{pmatrix} \quad (\text{X.70a})$$

$$C(g_V \gamma^0 - g_A \gamma^0 \gamma_5) = \begin{pmatrix} 0 & 0 & 0 & g_V - g_A \\ 0 & 0 & -g_V + g_A & 0 \\ 0 & -g_V - g_A & 0 & 0 \\ g_V + g_A & 0 & 0 & 0 \end{pmatrix} \quad (\text{X.70b})$$

$$C(g_V \gamma^1 - g_A \gamma^1 \gamma_5) = \begin{pmatrix} 0 & 0 & g_V - g_A & 0 \\ 0 & 0 & 0 & -g_V + g_A \\ g_V + g_A & 0 & 0 & 0 \\ 0 & -g_V - g_A & 0 & 0 \end{pmatrix} \quad (\text{X.70c})$$

$$C(g_V \gamma^2 - g_A \gamma^2 \gamma_5) = \begin{pmatrix} 0 & 0 & i(g_V - g_A) & 0 \\ 0 & 0 & 0 & i(g_V - g_A) \\ i(g_V + g_A) & 0 & 0 & 0 \\ 0 & i(g_V + g_A) & 0 & 0 \end{pmatrix} \quad (\text{X.70d})$$

$$C(g_V \gamma^3 - g_A \gamma^3 \gamma_5) = \begin{pmatrix} 0 & 0 & 0 & -g_V + g_A \\ 0 & 0 & -g_V + g_A & 0 \\ 0 & -g_V - g_A & 0 & 0 \\ -g_V - g_A & 0 & 0 & 0 \end{pmatrix} \quad (\text{X.70e})$$

The needed construction of gamma matrices involving the commutator of two gamma matrices. For the slashed terms we use as usual the abbreviations $k_{\pm} = k_0 \pm k_3$, $k = k_1 + ik_2$, $k^* = k_1 - ik_2$ and analogous expressions for the vector v^{μ} . We remind you that \cdot^* is *not* complex conjugation for complex k_{μ} . Furthermore we introduce (in what follows the brackets around the vector in-

dices have the usual meaning of antisymmetrizing with respect to the indices inside the brackets, here without a factor two in the denominator)

$$a_+ = k_+ v_- + k v^* - k_- v_+ - k^* v = 2(k_{[3} v_{0]} + i k_{[2} v_{1]}) \quad (\text{X.77a})$$

$$a_- = k_- v_+ + k v^* - k_+ v_- - k^* v = 2(-k_{[3} v_{0]} + i k_{[2} v_{1]}) \quad (\text{X.77b})$$

$$b_+ = 2(k_+ v - k v_+) = 2(k_{[0} v_{1]} + k_{[3} v_{1]} + i k_{[0} v_{2]} + i k_{[3} v_{2]}) \quad (\text{X.77c})$$

$$b_- = 2(k_- v - k v_-) = 2(k_{[0} v_{1]} - k_{[3} v_{1]} + i k_{[0} v_{2]} - i k_{[3} v_{2]}) \quad (\text{X.77d})$$

$$b_{+*} = 2(k_+ v^* - k^* v_+) = 2(k_{[0} v_{1]} + k_{[3} v_{1]} - i k_{[0} v_{2]} - i k_{[3} v_{2]}) \quad (\text{X.77e})$$

$$b_{-*} = 2(k_- v^* - k^* v_-) = 2(k_{[0} v_{1]} - k_{[3} v_{1]} - i k_{[0} v_{2]} + i k_{[3} v_{2]}) \quad (\text{X.77f})$$

Of course, one could introduce a more advanced notation, but we don't want to become confused.

$$[k, \gamma^0] = \begin{pmatrix} -2k_3 & -2k^* & 0 & 0 \\ -2k & 2k_3 & 0 & 0 \\ 0 & 0 & 2k_3 & 2k^* \\ 0 & 0 & 2k & -2k_3 \end{pmatrix} \quad (\text{X.78a})$$

$$[k, \gamma^1] = \begin{pmatrix} -2ik_2 & -2k_- & 0 & 0 \\ -2k_+ & 2ik_2 & 0 & 0 \\ 0 & 0 & -2ik_2 & 2k_+ \\ 0 & 0 & 2k_- & 2ik_2 \end{pmatrix} \quad (\text{X.78b})$$

$$[k, \gamma^2] = \begin{pmatrix} 2ik_1 & 2ik_- & 0 & 0 \\ -2ik_+ & -2ik_1 & 0 & 0 \\ 0 & 0 & 2ik_1 & -2ik_+ \\ 0 & 0 & 2ik_- & -2ik_1 \end{pmatrix} \quad (\text{X.78c})$$

$$[k, \gamma^3] = \begin{pmatrix} -2k_0 & -2k^* & 0 & 0 \\ 2k & 2k_0 & 0 & 0 \\ 0 & 0 & 2k_0 & -2k^* \\ 0 & 0 & 2k & -2k_0 \end{pmatrix} \quad (\text{X.78d})$$

$$[k, V] = \begin{pmatrix} a_- & b_{-*} & 0 & 0 \\ b_+ & -a_- & 0 & 0 \\ 0 & 0 & a_+ & -b_{+*} \\ 0 & 0 & -b_- & -a_+ \end{pmatrix} \quad (\text{X.78e})$$

$$\gamma^5 \gamma^0 [k, V] = \begin{pmatrix} 0 & 0 & -a_+ & b_{+*} \\ 0 & 0 & b_- & a_+ \\ a_- & b_{-*} & 0 & 0 \\ b_+ & -a_- & 0 & 0 \end{pmatrix} \quad (\text{X.78f})$$

X.15 Polarization vectorspinors

Here we construct the wavefunctions for (massive) gravitinos out of the wavefunctions of (massive) vectorbosons and (massive) Majorana fermions.

$$\psi_{(u;3/2)}^\mu(k) = \epsilon_+^\mu(k) \cdot u(k, +) \quad (\text{X.91a})$$

$$\psi_{(u;1/2)}^\mu(k) = \sqrt{\frac{1}{3}} \epsilon_+^\mu(k) \cdot u(k, -) + \sqrt{\frac{2}{3}} \epsilon_0^\mu(k) \cdot u(k, +) \quad (\text{X.91b})$$

$$\psi_{(u;-1/2)}^\mu(k) = \sqrt{\frac{2}{3}} \epsilon_0^\mu(k) \cdot u(k, -) + \sqrt{\frac{1}{3}} \epsilon_-^\mu(k) \cdot u(k, +) \quad (\text{X.91c})$$

$$\psi_{(u;-3/2)}^\mu(k) = \epsilon_-^\mu(k) \cdot u(k, -) \quad (\text{X.91d})$$

and in the same manner for $\psi_{(v;s)}^\mu$ with u replaced by v and with the conjugated polarization vectors. These gravitino wavefunctions obey the Dirac equation, they are transverse and they fulfill the irreducibility condition

$$\gamma_\mu \psi_{(u/v;s)}^\mu = 0. \quad (\text{X.92})$$

```

```

Here we implement the polarization vectors for vectorbosons with trigonometric functions, without the rotating of components done in HELAS [5]. These are only used for generating the polarization vectorspinors.

$$\epsilon_+^\mu(k) = \frac{-e^{+i\phi}}{\sqrt{2}} (0; \cos\theta \cos\phi - i \sin\phi, \cos\theta \sin\phi + i \cos\phi, -\sin\theta) \quad (\text{X.93a})$$

$$\epsilon_-^\mu(k) = \frac{e^{-i\phi}}{\sqrt{2}} (0; \cos\theta \cos\phi + i \sin\phi, \cos\theta \sin\phi - i \cos\phi, -\sin\theta) \quad (\text{X.93b})$$

$$\epsilon_0^\mu(k) = \frac{1}{m} \left(|\vec{k}|; k^0 \sin\theta \cos\phi, k^0 \sin\theta \sin\phi, k^0 \cos\theta \right) \quad (\text{X.93c})$$

Determining the mass from the momenta is a numerically haphazardous for light particles. Therefore, we accept some redundancy and pass the mass explicitly. For the case that the momentum lies totally in the z -direction we take the convention $\cos\phi = 1$ and $\sin\phi = 0$.

The O'Mega amplitudes have only one particle off shell and are the sum of *all* possible diagrams with the other particles on-shell.

The problem with these gauge checks is that are numerically very small amplitudes that vanish analytically and that violate transversality. The hard part is to determine the thresholds that make these tests usable.

```

```

    !!!      ', fixed|s = ', merge (fixed, s, mask = nstates == 0)
    a = omega (p, merge (fixed, s, mask = nstates == 0))
  else
    a = omega (p, s)
  end if
  sigma = sigma + a * conjg(a)
  <Step s like a n-ary number and terminate when all (s == -1)>
end do sum_spins
sigma = sigma / num_states (2, nstates(1:2))
end function omega_sum

```

We're looping over all spins like a n -ary numbers $(-1, \dots, -1, -1)$, $(-1, \dots, -1, 0)$, $(-1, \dots, -1, 1)$, $(-1, \dots, 0, -1)$, \dots , $(1, \dots, 1, 0)$, $(1, \dots, 1, 1)$:

```

<Step s like a n-ary number and terminate when all (s == -1)>≡
do j = size (p, dim = 2), 1, -1
  select case (nstates (j))
  case (3) ! massive vectors
    s(j) = modulo (s(j) + 2, 3) - 1
  case (2) ! spinors, massless vectors
    s(j) = - s(j)
  case (1) ! scalars
    s(j) = -1
  case (0) ! fixed spin
    s(j) = -1
  case default ! ???
    s(j) = -1
  end select
  if (s(j) /= -1) then
    cycle sum_spins
  end if
end do
exit sum_spins

```

The dual operation evaluates an n -number:

Quantify the agreement of two real or complex numbers

$$\text{agreement}(x, y) = \frac{\ln \Delta(x, y)}{\ln \epsilon} \in [0, 1] \quad (\text{X.94})$$

with

$$\Delta(x, y) = \frac{|x - y|}{\max(|x|, |y|)} \quad (\text{X.95})$$

and values outside $[0, 1]$ replaced the closed value in the interval. In other words

- 1 for $x - y = \max(|x|, |y|) \cdot \mathcal{O}(\epsilon)$ and
- 0 for $x - y = \max(|x|, |y|) \cdot \mathcal{O}(1)$

with logarithmic interpolation. The cases $x = 0$ and $y = 0$ must be treated separately.

  <Cpyleft>
  module omegavm95
    use kinds
    use omega95
    ! use omega95_bispinors
    implicit none
    private
    <OVM Procedure Declarations>
    <OVM Data Declarations>
    <OVM Instructions>
  contains
    <OVM Procedure Implementations>
  end module omegavm95

```

X.21.1 Memory Layout

On one hand, we need a memory pool for all the intermediate results

```

<OVM Data Declarations>≡
  type, public :: ovm
  private
    complex(kind=default) :: amp
    type(momentum), dimension(:), pointer :: p
    complex(kind=default), dimension(:), pointer :: phi
    type(spinor), dimension(:), pointer :: psi
    type(conjspinor), dimension(:), pointer :: psibar
    ! type(bispinor), dimension(:), pointer :: chi
    type(vector), dimension(:), pointer :: v
  end type ovm

<OVM Procedure Declarations>≡
  public :: alloc

<OVM Procedure Implementations>≡
  subroutine alloc (vm, momenta, scalars, spinors, conjspinors, vectors)
    type(ovm), intent(inout) :: vm
    integer, intent(in) :: momenta, scalars, spinors, conjspinors, vectors
    allocate (vm%p(momenta))
    allocate (vm%phi(scalars))

```

```

allocate (vm%psi(spinors))
allocate (vm%psibar(conjspinors))
allocate (vm%v(vectors))
end subroutine alloc

```

and on the other hand, we need to access coupling parameters that define the environment

```

<OVM Data Declarations>+≡
type, public :: ovm_env
private
real(kind=default), dimension(:), pointer :: gr
real(kind=default), dimension(:,:), pointer :: gr2
complex(kind=default), dimension(:), pointer :: gc
complex(kind=default), dimension(:,:), pointer :: gc2
end type ovm_env

```

NB: during, execution, the type of the coupling constant is implicit in the instruction.

How to load coupling constants? Is brute force linear lookup good enough?

X.21.2 Instruction Set
