<Decays: procedures>+≡
  subroutine decay_root_select_chain (decay_root)
    class(decay_root_t), intent(inout) :: decay_root
    if (decay_root%selected_term > 0) then
      call decay_root%term(decay_root%selected_term)%select_chain ()
    else
      call msg_bug ("Decays: no term selected for parent process")
    end if
  end subroutine decay_root_select_chain

```

Generate a decay tree, i.e., for the selected term in the parent process, recursively generate a decay event for all unstable particles.

Factor out the trace of the connected state of the parent process. This trace should not be taken into account for unweighting the decay chain, since it was already used for unweighting the parent event, or it determines the overall event weight.

```

<Decays: decay root: TBP>+≡
  procedure :: generate => decay_root_generate

<Decays: procedures>+≡
  subroutine decay_root_generate (decay_root)
    class(decay_root_t), intent(inout) :: decay_root
    type(connected_state_t), pointer :: connected_state
    if (decay_root%selected_term > 0) then

```

```

        connected_state => decay_root%process_instance%get_connected_state_ptr &
            (decay_root%selected_term)
        call connected_state%normalize_matrix_by_trace ()
        call decay_root%term(decay_root%selected_term)%generate ()
    else
        call msg_bug ("Decays: no term selected for parent process")
    end if
end subroutine decay_root_generate

```

32.4.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

The flavor component should be identical to the flavor component of the parent particle (`unstable` object).

```

<Decays: types>+≡
type, extends (decay_root_config_t) :: decay_config_t
private
type(flavor_t) :: flv
real(default) :: weight = 0
real(default) :: integral = 0
real(default) :: abs_error = 0
real(default) :: rel_error = 0
type(selector_t) :: mci_selector
contains
<Decays: decay config: TBP>
end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
procedure :: write => decay_config_write

<Decays: procedures>+≡
recursive subroutine decay_config_write (object, unit, indent, verbose)
class(decay_config_t), intent(in) :: object
integer, intent(in), optional :: unit, indent
logical, intent(in), optional :: verbose
integer :: u, ind
u = given_output_unit (unit)
ind = 0; if (present (indent)) ind = indent
call write_indent (u, ind)
write (u, "(1x,A)") "Decay:"
call object%write_header (unit, indent)
call write_indent (u, ind)
write (u, 2) "branching ratio =", object%weight * 100
call write_indent (u, ind)
write (u, 1) "partial width  =", object%integral
call write_indent (u, ind)

```

```

        write (u, 1) "error (abs)      =", object%abs_error
        call write_indent (u, ind)
        write (u, 1) "error (rel)      =", object%rel_error
1   format (3x,A,ES19.12)
2   format (3x,A,F11.6,1x,'%')
        call object%write_terms (unit, indent, verbose)
    end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should be used instead.

```

<Decays: decay config: TBP>+≡
    procedure :: connect => decay_config_connect

<Decays: procedures>+≡
    recursive subroutine decay_config_connect &
        (decay, process, model, process_stack, process_instance)
        class(decay_config_t), intent(out) :: decay
        type(process_t), intent(in), target :: process
        class(model_data_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        type(process_instance_t), intent(in), optional, target :: process_instance
        real(default), dimension(:), allocatable :: integral_mci
        integer :: i, n_mci
        call decay%decay_root_config_t%connect (process, model, process_stack)
        decay%integral = process%get_integral ()
        decay%abs_error = process%get_error ()
        if (process%cm_frame ()) then
            call msg_fatal ("Decay process " // char (process%get_id ()) &
                // ": unusable because rest frame is fixed.")
        end if
        n_mci = process%get_n_mci ()
        allocate (integral_mci (n_mci))
        do i = 1, n_mci
            integral_mci(i) = process%get_integral_mci (i)
        end do
        call decay%mci_selector%init (integral_mci)
    end subroutine decay_config_connect

```

Set the flavor entry, which repeats the flavor of the parent unstable particle.

```

<Decays: decay config: TBP>+≡
    procedure :: set_flv => decay_config_set_flv

<Decays: procedures>+≡
    subroutine decay_config_set_flv (decay, flv)
        class(decay_config_t), intent(inout) :: decay
        type(flavor_t), intent(in) :: flv
        decay%flv = flv
    end subroutine decay_config_set_flv

```

Compute embedded branchings and the relative error. This method does not apply to the decay root.

```

<Decays: decay config: TBP>+≡
  procedure :: compute => decay_config_compute

<Decays: procedures>+≡
  recursive subroutine decay_config_compute (decay)
    class(decay_config_t), intent(inout) :: decay
    call decay%decay_root_config_t%compute ()
    if (.not. vanishes (decay%integral)) then
      decay%rel_error = decay%abs_error / decay%integral
    else
      decay%rel_error = 0
    end if
  end subroutine decay_config_compute

```

32.4.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_t
  private
    type(decay_config_t), pointer :: config => null ()
    class(rng_t), allocatable :: rng
  contains
    <Decays: decay: TBP>
  end type decay_t

```

The finalizer is recursive.

```

<Decays: decay: TBP>≡
  procedure :: final => decay_final

<Decays: procedures>+≡
  recursive subroutine decay_final (object)
    class(decay_t), intent(inout) :: object
    integer :: i
    call object%base_final ()
    do i = 1, object%config%process%get_n_mci ()
      call object%process_instance%final_simulation (i)
    end do
    call object%process_instance%final ()
    deallocate (object%process_instance)
  end subroutine decay_final

```

Output.

```

<Decays: decay: TBP>+≡
  procedure :: write => decay_write

```

```

<Decays: procedures>+≡
recursive subroutine decay_write (object, unit, indent, recursive)
  class(decay_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent, recursive
  integer :: u, ind
  u = given_output_unit (unit)
  ind = 0; if (present (indent)) ind = indent
  call object%config%write (unit, indent, verbose = .false.)
  if (allocated (object%rng)) then
    call object%rng%write (u, ind + 1)
  end if
  call write_indent (u, ind)
  if (object%selected_mci > 0) then
    write (u, "(3x,A,I0)") "Selected MCI      = ", object%selected_mci
  else
    write (u, "(3x,A)") "Selected MCI      = [undefined]"
  end if
  call write_indent (u, ind)
  if (object%selected_term > 0) then
    write (u, "(3x,A,I0)") "Selected term    = ", object%selected_term
    call object%term(object%selected_term)%write (u, ind + 1)
  else
    write (u, "(3x,A)") "Selected term    = [undefined]"
  end if
end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
procedure :: init => decay_init

<Decays: procedures>+≡
recursive subroutine decay_init (decay, config)
  class(decay_t), intent(out) :: decay
  type(decay_config_t), intent(in), target :: config
  integer :: i
  call decay%base_init (config%term_config)
  decay%config => config
  allocate (decay%process_instance)
  call decay%process_instance%init (decay%config%process)
  call decay%process_instance%setup_event_data (decay%config%model)
  do i = 1, decay%config%process%get_n_mci ()
    call decay%process_instance%init_simulation (i)
  end do
  call decay%config%process%make_rng (decay%rng)
  call decay%make_term_rng (decay%config%process)
end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process

instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
  procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
  recursive subroutine decay_link_interactions (decay, i_prt, trace)
    class(decay_t), intent(inout) :: decay
    integer, intent(in) :: i_prt
    type(interaction_t), intent(in), target :: trace
    type(interaction_t), pointer :: beam_int
    integer :: n_in, n_vir
    beam_int => decay%process_instance%get_beam_int_ptr ()
    n_in = trace%get_n_in ()
    n_vir = trace%get_n_vir ()
    call beam_int%set_source_link (1, trace, &
      n_in + n_vir + i_prt)
    call decay%link_term_interactions ()
  end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
  procedure :: select_chain => decay_select_chain

<Decays: procedures>+≡
  recursive subroutine decay_select_chain (decay)
    class(decay_t), intent(inout) :: decay
    real(default) :: x
    integer :: i
    call decay%rng%generate (x)
    decay%selected_mci = decay%config%mc_selector%select (x)
    call decay%process_instance%choose_mci (decay%selected_mci)
    decay%selected_term = decay%process_instance%select_i_term ()
    do i = 1, size (decay%term)
      call decay%term(i)%select_chain ()
    end do
  end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

<Decays: decay: TBP>+≡
  procedure :: generate => decay_generate

<Decays: procedures>+≡
  recursive subroutine decay_generate (decay)
    class(decay_t), intent(inout) :: decay

```

```

type(isolated_state_t), pointer :: isolated_state
integer :: i
call decay%process_instance%receive_beam_momenta ()
call decay%process_instance%generate_unweighted_event (decay%selected_mci)
if (signal_is_pending ()) return
call decay%process_instance%evaluate_event_data ()
isolated_state => &
    decay%process_instance%get_isolated_state_ptr (decay%selected_term)
call isolated_state%normalize_matrix_by_trace ()
do i = 1, size (decay%term)
    call decay%term(i)%generate ()
    if (signal_is_pending ()) return
end do
end subroutine decay_generate

```

32.4.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```

<Decays: types>+≡
type, extends (any_config_t) :: stable_config_t
private
type(flavor_t), dimension(:), allocatable :: flv
contains
<Decays: stable config: TBP>
end type stable_config_t

```

The finalizer is empty:

```

<Decays: stable config: TBP>≡
procedure :: final => stable_config_final

<Decays: procedures>+≡
subroutine stable_config_final (object)
class(stable_config_t), intent(inout) :: object
end subroutine stable_config_final

```

Output.

```

<Decays: stable config: TBP>+≡
procedure :: write => stable_config_write

<Decays: procedures>+≡
recursive subroutine stable_config_write (object, unit, indent, verbose)
class(stable_config_t), intent(in) :: object
integer, intent(in), optional :: unit, indent
logical, intent(in), optional :: verbose
integer :: u, i, ind
u = given_output_unit (unit)
ind = 0; if (present (indent)) ind = indent
call write_indent (u, ind)
write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"
write (u, "(1x,A)", advance = "no") char (object%flv(1)%get_name ())
do i = 2, size (object%flv)
    write (u, "(:',A)", advance = "no") &

```

```

        char (object%flv(i)%get_name ())
    end do
    write (u, *)
end subroutine stable_config_write

```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```

⟨Decays: stable config: TBP⟩+≡
    procedure :: init => stable_config_init

⟨Decays: procedures⟩+≡
    subroutine stable_config_init (config, flv)
        class(stable_config_t), intent(out) :: config
        type(flavor_t), dimension(:), intent(in) :: flv
        integer, dimension (size (flv)) :: pdg
        logical, dimension (size (flv)) :: mask
        integer :: i
        pdg = flv%get_pdg ()
        mask(1) = .true.
        forall (i = 2 : size (pdg))
            mask(i) = all (pdg(i) /= pdg(1:i-1))
        end forall
        allocate (config%flv (count (mask)))
        config%flv = pack (flv, mask)
    end subroutine stable_config_init

```

Here is the corresponding object instance. Except for the pointer to the configuration, there is no content.

```

⟨Decays: types⟩+≡
    type, extends (any_t) :: stable_t
        private
        type(stable_config_t), pointer :: config => null ()
    contains
        ⟨Decays: stable: TBP⟩
    end type stable_t

```

The finalizer does nothing.

```

⟨Decays: stable: TBP⟩≡
    procedure :: final => stable_final

⟨Decays: procedures⟩+≡
    subroutine stable_final (object)
        class(stable_t), intent(inout) :: object
    end subroutine stable_final

```

We can delegate output to the configuration object.

```

⟨Decays: stable: TBP⟩+≡
    procedure :: write => stable_write

⟨Decays: procedures⟩+≡
    subroutine stable_write (object, unit, indent)
        class(stable_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent

```

```

        call object%config%write (unit, indent)
    end subroutine stable_write

```

Initializer: just assign the configuration.

```

<Decays: stable: TBP>+≡
    procedure :: init => stable_init
<Decays: procedures>+≡
    subroutine stable_init (stable, config)
        class(stable_t), intent(out) :: stable
        type(stable_config_t), intent(in), target :: config
        stable%config => config
    end subroutine stable_init

```

32.4.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: public>+≡
    public :: unstable_config_t
<Decays: types>+≡
    type, extends (any_config_t) :: unstable_config_t
        private
        type(flavor_t) :: flv
        real(default) :: integral = 0
        real(default) :: abs_error = 0
        real(default) :: rel_error = 0
        type(selector_t) :: selector
        type(decay_config_t), dimension(:), allocatable :: decay_config
    contains
        <Decays: unstable config: TBP>
    end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
    procedure :: final => unstable_config_final
<Decays: procedures>+≡
    recursive subroutine unstable_config_final (object)
        class(unstable_config_t), intent(inout) :: object
        integer :: i
        if (allocated (object%decay_config)) then
            do i = 1, size (object%decay_config)
                call object%decay_config(i)%final ()
            end do
        end if
    end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
  procedure :: write => unstable_config_write

<Decays: procedures>+≡
  recursive subroutine unstable_config_write (object, unit, indent, verbose)
    class(unstable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    logical :: verb
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
      char (object%flv%get_name ())
    call write_indent (u, ind)
    write (u, 1) "total width =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs) =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel) =", object%rel_error
1   format (5x,A,ES19.12)
    if (verb .and. allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%write (u, ind + 1)
      end do
    end if
  end subroutine unstable_config_write

```

Initializer. For the unstable particle, the flavor is unique.

```

<Decays: unstable config: TBP>+≡
  procedure :: init => unstable_config_init

<Decays: procedures>+≡
  subroutine unstable_config_init (unstable, flv, set_decays, model)
    class(unstable_config_t), intent(out) :: unstable
    type(flavor_t), intent(in) :: flv
    logical, intent(in), optional :: set_decays
    class(model_data_t), intent(in), optional, target :: model
    type(string_t), dimension(:), allocatable :: decay
    unstable%flv = flv
    if (present (set_decays)) then
      call unstable%flv%get_decays (decay)
      call unstable%init_decays (decay, model)
    end if
  end subroutine unstable_config_init

```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```

<Decays: unstable config: TBP>+≡

```

```

    procedure :: init_decays => unstable_config_init_decays
  <Decays: procedures>+≡
    recursive subroutine unstable_config_init_decays &
      (unstable, decay_id, model, process_stack)
      class(unstable_config_t), intent(inout) :: unstable
      type(string_t), dimension(:), intent(in) :: decay_id
      class(model_data_t), intent(in), target :: model
      type(process_stack_t), intent(in), optional :: process_stack
      integer :: i
      allocate (unstable%decay_config (size (decay_id)))
      do i = 1, size (decay_id)
        associate (decay => unstable%decay_config(i))
          if (present (process_stack)) then
            call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
              model, process_stack)
          else
            call decay%init (model, decay_id(i))
          end if
          call decay%set_flv (unstable%flv)
        end associate
      end do
    end subroutine unstable_config_init_decays

```

Explicitly connect a specific decay with a process. This is used only in unit tests.

```

  <Decays: unstable config: TBP>+≡
    procedure :: connect_decay => unstable_config_connect_decay
  <Decays: procedures>+≡
    subroutine unstable_config_connect_decay (unstable, i, process, model)
      class(unstable_config_t), intent(inout) :: unstable
      integer, intent(in) :: i
      type(process_t), intent(in), target :: process
      class(model_data_t), intent(in), target :: model
      associate (decay => unstable%decay_config(i))
        call decay%connect (process, model)
      end associate
    end subroutine unstable_config_connect_decay

```

Compute the total width and branching ratios, initializing the decay selector.

```

  <Decays: unstable config: TBP>+≡
    procedure :: compute => unstable_config_compute
  <Decays: procedures>+≡
    recursive subroutine unstable_config_compute (unstable)
      class(unstable_config_t), intent(inout) :: unstable
      integer :: i
      do i = 1, size (unstable%decay_config)
        call unstable%decay_config(i)%compute ()
      end do
      unstable%integral = sum (unstable%decay_config%integral)
      if (unstable%integral <= 0) then
        call unstable%write ()
      end if
    end subroutine unstable_config_compute

```

```

        call msg_fatal ("Decay configuration: computed total width is zero")
    end if
    unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
    unstable%rel_error = unstable%abs_error / unstable%integral
    call unstable%selector%init (unstable%decay_config%integral)
    do i = 1, size (unstable%decay_config)
        unstable%decay_config(i)%weight &
            = unstable%selector%get_weight (i)
    end do
end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: public>+≡
    public :: unstable_t

<Decays: types>+≡
    type, extends (any_t) :: unstable_t
    private
        type(unstable_config_t), pointer :: config => null ()
        class(rng_t), allocatable :: rng
        integer :: selected_decay = 0
        type(decay_t), dimension(:), allocatable :: decay
    contains
        <Decays: unstable: TBP>
    end type unstable_t

```

Recursive finalizer.

```

<Decays: unstable: TBP>≡
    procedure :: final => unstable_final

<Decays: procedures>+≡
    recursive subroutine unstable_final (object)
        class(unstable_t), intent(inout) :: object

```

32.4.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state

of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+≡
  type, extends (connected_state_t) :: decay_chain_entry_t
  private
    integer :: index = 0
    type(decay_config_t), pointer :: config => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
    type(decay_chain_entry_t), pointer :: previous => null ()
  end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: public>+≡
  public :: decay_chain_t

<Decays: types>+≡
  type :: decay_chain_t
  private
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_term = 0
    type(evaluator_t) :: correlated_trace
    type(decay_chain_entry_t), pointer :: last => null ()
  contains
    <Decays: decay_chain: TBP>
  end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay_chain: TBP>≡
  procedure :: final => decay_chain_final

<Decays: procedures>+≡
  subroutine decay_chain_final (object)
    class(decay_chain_t), intent(inout) :: object
    type(decay_chain_entry_t), pointer :: entry
    do while (associated (object%last))

```

```

        entry => object%last
        object%last => entry%previous
        call entry%final ()
        deallocate (entry)
    end do
    call object%correlated_trace%final ()
end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

<Decays: decay chain: TBP>+≡
    procedure :: write => decay_chain_write

<Decays: procedures>+≡
    subroutine decay_chain_write (object, unit)
        class(decay_chain_t), intent(in) :: object

                call entry%config%term_config(entry%selected_term)%write (u, indent=1)
                call entry%write (u)
            end if
        end subroutine write_entries
    end subroutine decay_chain_write

```

Build a decay chain, recursively following the selected decays and terms in a decay tree. Before start, we finalize the chain, deleting any previous contents.

```

<Decays: decay chain: TBP>+≡
    procedure :: build => decay_chain_build

<Decays: procedures>+≡
    subroutine decay_chain_build (chain, decay_root)
        class(decay_chain_t), intent(inout), target :: chain
        type(decay_root_t), intent(in) :: decay_root
        type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
        type(interaction_t), pointer :: int_last_decay
        call chain%final ()
    end subroutine decay_chain_build

```

```

if (decay_root%selected_term > 0) then
  chain%process_instance => decay_root%process_instance
  chain%selected_term = decay_root%selected_term
  call chain%build_term_entries (decay_root%term(decay_root%selected_term))
end if
int_last_decay => chain%last%get_matrix_int_ptr ()
allocate (qn_mask (int_last_decay%get_n_tot ()))
call qn_mask%init (mask_f = .true., mask_c = .true., mask_h = .true.)
call chain%correlated_trace%init_qn_sum (int_last_decay, qn_mask)
end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable particles.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_term_entries (chain, term)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_term_t), intent(in) :: term
    integer :: i
    do i = 1, size (term%particle_out)
      select type (unstable => term%particle_out(i)%c)
        type is (unstable_t)
          if (unstable%selected_decay > 0) then
            call chain%build_decay_entries &
              (unstable%decay(unstable%selected_decay))
          end if
        end select
      end do
    end do
  end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_decay_entries => decay_chain_build_decay_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_decay_entries (chain, decay)
    class(decay_chain_t), intent(inout) :: chain

```

```

type(decay_t), intent(in) :: decay
type(decay_chain_entry_t), pointer :: entry
type(connected_state_t), pointer :: previous_state
type(isolated_state_t), pointer :: current_decay
type(helicity_t) :: hel
type(quantum_numbers_t) :: qn_filter_conn
allocate (entry)
if (associated (chain%last)) then
    entry%previous => chain%last
    entry%index = entry%previous%index + 1
    previous_state => entry%previous%connected_state_t
else
    entry%index = 1
    previous_state => &
        chain%process_instance%get_connected_state_ptr (chain%selected_term)
end if
entry%config => decay%config
entry%selected_mci = decay%selected_mci
entry%selected_term = decay%selected_term
current_decay => decay%process_instance%get_isolated_state_ptr &
    (decay%selected_term)
call entry%setup_connected_trace &
    (current_decay, previous_state%get_trace_int_ptr (), resonant=.true.)
if (entry%config%flv%has_decay_helicity ()) then
    call hel%init (entry%config%flv%get_decay_helicity ())
    call qn_filter_conn%init (hel)
    call entry%setup_connected_matrix &
        (current_decay, previous_state%get_matrix_int_ptr (), &
            resonant=.true., qn_filter_conn = qn_filter_conn)
    call entry%setup_connected_flows &
        (current_decay, previous_state%get_flows_int_ptr (), &
            resonant=.true., qn_filter_conn = qn_filter_conn)
else
    call entry%setup_connected_matrix &
        (current_decay, previous_state%get_matrix_int_ptr (), &
            resonant=.true.)
    call entry%setup_connected_flows &

            resonant=.true.)
end if
chain%last => entry
call chain%build_term_entries (decay%term(decay%selected_term))
end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

<Decays: decay chain: TBP>+≡

procedure :: evaluate => decay_chain_evaluate

<Decays: procedures>+≡

```

subroutine decay_chain_evaluate (chain)
  class(decay_chain_t), intent(inout) :: chain
  call evaluate (chain%last)
  call chain%correlated_trace%receive_momenta ()
  call chain%correlated_trace%evaluate ()
contains
  recursive subroutine evaluate (entry)
    type(decay_chain_entry_t), intent(inout), pointer :: entry
    if (associated (entry)) then
      call evaluate (entry%previous)
      call entry%receive_kinematics ()
      call entry%evaluate_trace ()
      call entry%evaluate_event_data ()
    end if
  end subroutine evaluate
end subroutine decay_chain_evaluate

```

Return the probability of a decay chain. This is given as the trace of the density matrix with intermediate helicity correlations, normalized by the product of the uncorrelated density matrix traces. This works only if an event has been evaluated and the `correlated_trace` evaluator is filled. By definition, this evaluator has only one matrix element, and this must be real.

```

<Decays: decay chain: TBP>+≡
  procedure :: get_probability => decay_chain_get_probability

<Decays: procedures>+≡
  function decay_chain_get_probability (chain) result (x)
    class(decay_chain_t), intent(in) :: chain
    real(default) :: x
    x = real (chain%correlated_trace%get_matrix_element (1))
  end function decay_chain_get_probability

```

32.4.12 Decay as Event Transform

The `evt_decay` object combines decay configuration, decay tree, and chain in a single object, as an implementation of the `evt` (event transform) abstract type.

```

<Decays: public>+≡
  public :: evt_decay_t

<Decays: types>+≡
  type, extends (evt_t) :: evt_decay_t
  private
    type(decay_root_config_t) :: decay_root_config
    type(decay_root_t) :: decay_root
    type(decay_chain_t) :: decay_chain
  contains
    <Decays: evt decay: TBP>
  end type evt_decay_t

<Decays: evt decay: TBP>≡
  procedure :: write_name => evt_decay_write_name

```

```

<Decays: procedures>+=
  subroutine evt_decay_write_name (evt, unit)

```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations is under construction. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid. This procedure directly takes the (MLM) matching into account.

32.6 Fixed Order NLO Events

This section deals with the generation of weighted event samples which take into account next-to-leading order corrections. An approach generating unweighted events is not possible here, because negative weights might occur due to subtraction. Note that the events produced this way are not physical in the sense that they will not keep NLO-accuracy when interfaced to a parton shower. They are rather useful for theoretical consistency checks and a fast estimate of NLO effects.

We generate NLO events in the following way: First, the integration is carried out using the complete divergence-subtracted NLO matrix element. In the subsequent simulation, N -particle kinematics are generated using $\mathcal{B} + \mathcal{V} + \mathcal{C}$ as weight. After that, the program loops over all singular regions and for each of them generates an event with $N + 1$ -particle kinematics. The weight for those events corresponds to the real matrix element \mathcal{R}^α evaluated at the α -region's emitter's phase space point, multiplied with S_α . This procedure is implemented using the `evt_nlo` transform.

```

This event transformation is for the generation of fixed-order NLO events. It takes an event with Born kinematics and creates $N_\alpha + 1$ modified weighted events. The first one has Born kinematics and its weight is the sum of Born, Real and subtraction matrix elements. The other N_α events have a weight which is equal to the real matrix element, evaluated with the phase space corresponding to the emitter of the α -region. All NLO event objects share the same event transformation. For this reason, we save the particle set of the current α -region in the array `particle_set_radiated`. Otherwise it would be unretrievable if the usual particle set of the event object was used. @

```

The event transform has a variable which counts the number of times it has already been called for one generation point. If `i_evaluation` is zero, this means that `evt_nlo_generate` is called for the first time, so that the generation of an N -particle event is required. In all other cases, emission events are generated. Note that for the first event, the computed weights are added to `probability`, which at this point is equal to $\mathcal{B} + \mathcal{V}$, whereas for all other runs `probability` is replaced. To keep $\langle \sum w_i \rangle = N \times \sigma$ as it is for weighted LO events, we have

to multiply by $N_{\text{phs}} + 1$ since the cross section is distributed over the real and Born subevents.

32.7.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The `safety_factor` reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The `sigma` and `n` values, if nontrivial, allow for reweighting the events according to the requested `norm_mode`.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the `event_expr_t` objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

<Events: types>≡

```

type :: event_config_t
    logical :: unweighted = .false.
    integer :: norm_mode = NORM_UNDEFINED
    integer :: factorization_mode = FM_IGNORE_HELICITY
    logical :: keep_correlations = .false.

```

```

real(default) :: sigma = 1
integer :: n = 1
real(default) :: safety_factor = 1

32.7.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event_base` module. The core manages the main (dressed) particle set pointer and the current values for weights and sqme. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

The `sqme` and `weight` values mirror corresponding values in the `expr` sub-object. The idea is that when generating or reading events, the event record is filled first, then the `expr` object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the `expr` subobject. In particular, evaluating the event-selection expression sets the `passed` flag. Furthermore, the `expr` subobject collects data that can be used in the analysis and should be written to file, including copies of `sqme` and `weight`.

32.7.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```

<Events: event: TBP>+≡
    procedure :: basic_init => event_init

<Events: procedures>+≡
    subroutine event_init (event, var_list, n_alt)
        class(event_t), intent(out) :: event
        type(var_list_t), intent(in), optional :: var_list
        integer, intent(in), optional :: n_alt
        type(string_t) :: norm_string, mode_string
        logical :: polarized_events
        if (present (n_alt)) then
            call event%base_init (n_alt)
            call event%expr%init (n_alt)
        else
            call event%base_init (0)
        end if
        if (present (var_list)) then
            event%config%unweighted = var_list%get_lval (&
                var_str ("?unweighted"))
            norm_string = var_list%get_sval (&
                var_str ("sample_normalization"))
            event%config%norm_mode = &
                event_normalization_mode (norm_string, event%config%unweighted)
            polarized_events = &
                var_list%get_lval (var_str ("?polarized_events"))
        end if
    end subroutine event_init

```

```

if (polarized_events) then
  mode_string = &
    var_list%get_sval (var_str ("polarization_mode"))
  select case (char (mode_string))
  case ("ignore")
    event%config%factorization_mode = FM_IGNORE_HELICITY
  case ("helicity")
    event%config%factorization_mode = FM_SELECT_HELICITY
  case ("factorized")
    event%config%factorization_mode = FM_FACTOR_HELICITY
  case ("correlated")
    event%config%factorization_mode = FM_CORRELATED_HELICITY
  case default
    call msg_fatal ("Polarization mode " &
      // char (mode_string) // " is undefined")
  end select
else
  event%config%factorization_mode = FM_IGNORE_HELICITY
end if
if (event%config%unweighted) then
  event%config%safety_factor = var_list%get_rval (&
    var_str ("safety_factor"))
end if
else
  event%config%norm_mode = NORM_SIGMA
end if
allocate (evt_trivial_t :: event%transform_first)
event%transform_last => event%transform_first
end subroutine event_init

```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

```

<Events: event: TBP>+≡
  procedure :: set_sigma => event_set_sigma
  procedure :: set_n => event_set_n

<Events: procedures>+≡
  elemental subroutine event_set_sigma (event, sigma)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: sigma
    event%config%sigma = sigma
  end subroutine event_set_sigma

  elemental subroutine event_set_n (event, n)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: n
    event%config%n = n
  end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
  procedure :: import_transform => event_import_transform
<Events: procedures>+≡
  subroutine event_import_transform (event, evt)
    class(event_t), intent(inout) :: event
    class(evt_t), intent(inout), pointer :: evt
    event%transform_last%next => evt
    evt%previous => event%transform_last
    event%transform_last => evt
    evt => null ()
  end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect
<Events: procedures>+≡
  subroutine event_connect (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(string_t) :: id
    integer :: num_id
    class(evt_t), pointer :: evt
    event%process => process_instance%process
    event%instance => process_instance
    id = event%process%get_id ()
    if (id /= "") call event%expr%set_process_id (id)
    num_id = event%process%get_num_id ()
    if (num_id /= 0) call event%expr%set_process_num_id (num_id)
    call event%expr%setup_vars (event%process%get_sqrts ())
    call event%expr%link_var_list (event%process%get_var_list_ptr ())
    call event%process%make_rng (event%rng)
    evt => event%transform_first
    do while (associated (evt))
      call evt%connect (process_instance, model, process_stack)
      evt => evt%next
    end do
  end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
  procedure :: set_selection => event_set_selection
  procedure :: set_reweight => event_set_reweight
  procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡
  subroutine event_set_selection (event, ef_selection)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_selection
    allocate (event%config%ef_selection, source = ef_selection)
  end subroutine event_set_selection

    class(expr_factory_t), intent(in) :: ef_analysis
    allocate (event%config%ef_analysis, source = ef_analysis)
  end subroutine event_set_analysis

```

Create evaluation trees from the parse trees. The `target` attribute is required because the expressions contain pointers to event subobjects.

```

<Events: event: TBP>+≡
  procedure :: setup_expressions => event_setup_expressions

<Events: procedures>+≡
  subroutine event_setup_expressions (event)
    class(event_t), intent(inout), target :: event
    call event%expr%setup_selection (event%config%ef_selection)
    call event%expr%setup_analysis (event%config%ef_analysis)
    call event%expr%setup_reweight (event%config%ef_reweight)
  end subroutine event_setup_expressions

```

32.7.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

Evaluate the event-related expressions, given a valid `particle_set`. If `update_sqme` is set, we use the process instance for the `sqme_prc` value. The `sqme_ref` value is always taken from the event record.

Note: without the explicit `particle_set` pointer, some gfortran 4.8 version corrupts its memory.

(Events: event: TBP)+≡

        end if
    end subroutine event_check

```

32.7.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we

accept the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
  procedure :: generate => event_generate

<Events: procedures>+≡
  subroutine event_generate (event, i_mci, r, i_nlo)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci
    real(default), dimension(:), intent(in), optional :: r
    integer, intent(in), optional :: i_nlo
    logical :: generate_new = .true.
    if (present (i_nlo)) generate_new = (i_nlo == 1)
    if (generate_new) call event%reset ()
    event%selected_i_mci = i_mci
    if (event%config%unweighted) then
      call event%instance%generate_unweighted_event (i_mci)

  end subroutine event_get_hard_particle_set

```

32.7.8 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
  procedure :: select => event_select

<Events: procedures>+≡
  subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
    if (associated (event%instance)) then
      event%selected_i_mci = i_mci
      event%selected_i_term = i_term
      event%selected_channel = channel
    else
      event%selected_i_mci = 0
      event%selected_i_term = 0
      event%selected_channel = 0
    end if
  end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. The event reader may either read in the transformed event separately, or apply all event transforms to the hard particle set to (re)generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
  procedure :: set_hard_particle_set => event_set_hard_particle_set

<Events: procedures>+≡
  subroutine event_set_hard_particle_set (event, particle_set)
    class(event_t), intent(inout) :: event
    type(particle_set_t), intent(in) :: particle_set
    class(evt_t), pointer :: evt
    evt => event%transform_first
    call evt%set_particle_set (particle_set, &
      event%selected_i_mci, event%selected_i_term)
    call event%link_particle_set (evt%particle_set)
    evt => evt%next
    do while (associated (evt))
      call evt%reset ()
      evt => evt%next
    end do
  end subroutine event_set_hard_particle_set

```

Set the α_s value that should be used in a recalculation. This should be called only if we explicitly want to override the QCD setting of the process core.

```

<Events: event: TBP>+≡
  procedure :: set_alpha_qcd_forced => event_set_alpha_qcd_forced

```

```

<Events: procedures>+≡
  subroutine event_set_alpha_qcd_forced (event, alpha_qcd)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: alpha_qcd
    if (allocated (event%alpha_qcd_forced)) then
      event%alpha_qcd_forced = alpha_qcd
    else
      allocate (event%alpha_qcd_forced, source = alpha_qcd)
    end if
  end subroutine event_set_alpha_qcd_forced

```

Analogously, for the common scale. This forces also renormalization and factorization scale.

```

<Events: event: TBP>+≡
  procedure :: set_scale_forced => event_set_scale_forced

<Events: procedures>+≡
  subroutine event_set_scale_forced (event, scale)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: scale
    if (allocated (event%scale_forced)) then
      event%scale_forced = scale
    else
      allocate (event%scale_forced, source = scale)
    end if
  end subroutine event_set_scale_forced

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

32.8 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the `events` module which provides the concrete implementation of `event_base`. The other I/O formats access only the methods that are defined in `event_base`.

```

<eio_raw.f90>≡
  <File header>

  module eio_raw

    <Use kinds>
    <Use strings>
    use io_units
    use diagnostics
    use model_data
    use particles
    use event_base
    use eio_data
    use eio_base
    use events

    <Standard module head>

    <EIO raw: public>

    <EIO raw: parameters>

    <EIO raw: types>

    contains

```

```
⟨EIO raw: procedures⟩
```

```
end module eio_raw
```

32.8.1 File Format Version

This is the current default file version.

```
⟨EIO raw: parameters⟩≡
```

```
integer, parameter :: CURRENT_FILE_VERSION = 2
```

The user may change this number; this should force some compatibility mode for reading and writing. In any case, the file version stored in a event file that we read has to match the expected file version.

History of version numbers:

1. Format for WHIZARD 2.2.0 to 2.2.3. No version number stored in the raw file.
2. Format from 2.2.4 on. File contains version number. The file contains the transformed particle set (if applicable) after the hard-process particle set.

32.8.2 Type

Note the file version number. The default may be reset during initialization, which should enforce some compatibility mode.

```
⟨EIO raw: public⟩≡
```

```
public :: eio_raw_t
```

```
⟨EIO raw: types⟩≡
```

```
type, extends (eio_t) :: eio_raw_t

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

The `passed` flag is not written. This allow us to apply different selection criteria upon rereading.

Chapter 33

Integration and Simulation

33.1 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```
<user_files.f90>≡  
  <File header>  
  
  module user_files  
  
    <Use strings>  
    use io_units  
    use diagnostics  
    use ifiles  
    use analysis  
  
    <Standard module head>  
  
    <User files: public>  
  
    <User files: types>  
  
    <User files: interfaces>  
  
    contains  
  
    <User files: procedures>  
  
  end module user_files
```

33.1.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡
```

```

type :: file_t
  private
  type(string_t) :: name
  integer :: unit = -1
  logical :: reading = .false.
  logical :: writing = .false.
  type(file_t), pointer :: prev => null ()
  type(file_t), pointer :: next => null ()
end type file_t

```

The initializer opens the file.

```

<User files: procedures>≡
subroutine file_init (file, name, action, status, position)
  type(file_t), intent(out) :: file
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position
  file%unit = free_unit ()
  file%name = name
  open (unit = file%unit, file = char (file%name), &
        action = action, status = status, position = position)
  select case (action)
  case ("read")
    file%reading = .true.
  case ("write")
    file%writing = .true.
  case ("readwrite")
    file%reading = .true.
    file%writing = .true.
  end select
end subroutine file_init

```

The finalizer closes it.

```

<User files: procedures>+≡
subroutine file_final (file)
  type(file_t), intent(inout) :: file
  close (unit = file%unit)
  file%unit = -1
end subroutine file_final

```

Check if a file is open with correct status.

```

<User files: procedures>+≡
function file_is_open (file, action) result (flag)
  logical :: flag
  type(file_t), intent(in) :: file
  character(*), intent(in) :: action
  select case (action)
  case ("read")
    flag = file%reading
  case ("write")
    flag = file%writing
  case ("readwrite")
    flag = file%reading .and. file%writing
  end select
end function file_is_open

```

```

        case default
            call msg_bug ("Checking file '" // char (file%name) &
                // "' : illegal action specifier")
        end select
    end function file_is_open

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the `advancing` option.

```

<User files: procedures>+≡
subroutine file_write_string (file, string, advancing)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: string
    logical, intent(in), optional :: advancing
    if (file%writing) then
        if (present (string)) then
            if (present (advancing)) then
                if (advancing) then
                    write (file%unit, "(A)") char (string)
                else
                    write (file%unit, "(A)", advance="no") char (string)
                end if
            else
                write (file%unit, "(A)") char (string)
            end if
        else
            write (file%unit, *)
        end if
    else
        call msg_error ("Writing to file: File '" // char (file%name) &
            // "' is not open for writing.")
    end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
subroutine file_write_ifile (file, ifile)
    type(file_t), intent(in) :: file
    type(ifile_t), intent(in) :: ifile
    type(line_p) :: line
    call line_init (line, ifile)
    do while (line_is_associated (line))
        call file_write_string (file, line_get_string_advance (line))
    end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
subroutine file_write_analysis (file, tag)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: tag
    if (file%writing) then
        if (present (tag)) then

```

```

        call analysis_write (tag, unit = file%unit)
    else
        call analysis_write (unit = file%unit)
    end if
else
    call msg_error ("Writing analysis to file: File '" // char (file%name) &
        // "' is not open for writing.")
    end if
end subroutine file_write_analysis

```

33.1.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
    public :: file_list_t

<User files: types>+≡
    type :: file_list_t
        type(file_t), pointer :: first => null ()
        type(file_t), pointer :: last => null ()
    end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
    public :: file_list_final

<User files: procedures>+≡
    subroutine file_list_final (file_list)
        type(file_list_t), intent(inout) :: file_list
        type(file_t), pointer :: current
        do while (associated (file_list%first))
            current => file_list%first
            file_list%first => current%next
            call file_final (current)
            deallocate (current)
        end do
        file_list%last => null ()
    end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```

<User files: procedures>+≡
    function file_list_get_file_ptr (file_list, name) result (current)
        type(file_t), pointer :: current
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        current => file_list%first
        do while (associated (current))
            if (current%name == name) return
            current => current%next
        end do
    end function file_list_get_file_ptr

```

Check if a file is open, public version:

```
<User files: public>+≡
    public :: file_list_is_open

<User files: procedures>+≡
    function file_list_is_open (file_list, name, action) result (flag)
        logical :: flag
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            flag = file_is_open (current, action)
        else
            flag = .false.
        end if
    end function file_list_is_open
```

Append a new file entry, i.e., open this file. Error if it is already open.

```
<User files: public>+≡
    public :: file_list_open

<User files: procedures>+≡
    subroutine file_list_open (file_list, name, action, status, position)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action, status, position
        type(file_t), pointer :: current
        if (.not. associated (file_list_get_file_ptr (file_list, name))) then
            allocate (current)
            call msg_message ("Opening file '" // char (name) // "' for output")
            call file_init (current, name, action, status, position)
            if (associated (file_list%last)) then
                file_list%last%next => current
                current%prev => file_list%last
            else
                file_list%first => current
            end if
            file_list%last => current
        else
            call msg_error ("Opening file: File '" // char (name) &
                // "' is already open.")
        end if
    end subroutine file_list_open
```

Delete a file entry, i.e., close this file. Error if it is not open.

```
<User files: public>+≡
    public :: file_list_close

<User files: procedures>+≡
    subroutine file_list_close (file_list, name)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
```

```

type(file_t), pointer :: current
current => file_list_get_file_ptr (file_list, name)
if (associated (current)) then
    if (associated (current%prev)) then
        current%prev%next => current%next
    else
        file_list%first => current%next
    end if
    if (associated (current%next)) then
        current%next%prev => current%prev
    else
        file_list%last => current%prev
    end if
    call msg_message ("Closing file '" // char (name) // "' for output")
    call file_final (current)
    deallocate (current)
else
    call msg_error ("Closing file: File '" // char (name) &
        // "' is not open.")
end if
end subroutine file_list_close

```

Write a string to file. Error if it is not open.

```

<User files: public>+≡
    public :: file_list_write

    use beam_structures  
    use event_base, only: event_callback_t  
    use user_files  
    use process_stacks  
    use iterations  
  
    <Standard module head>  
  
    <RT data: public>  
  
    <RT data: types>  
  
    contains  
  
    <RT data: procedures>  
  
  end module rt_data
```

33.2.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn, is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

33.2.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()
    type(parse_node_t), pointer :: fac_scale_expr => null ()
    type(parse_node_t), pointer :: ren_scale_expr => null ()
    type(parse_node_t), pointer :: weight_expr => null ()
    type(parse_node_t), pointer :: selection_lexpr => null ()
    type(parse_node_t), pointer :: reweight_expr => null ()
    type(parse_node_t), pointer :: analysis_lexpr => null ()
    type(parse_node_p), dimension(:), allocatable :: alt_setup
  contains
    <RT data: rt parse nodes: TBP>
  end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

```

```

<RT data: procedures>≡
subroutine rt_parse_nodes_clear (rt_pn, name)
  class(rt_parse_nodes_t), intent(inout) :: rt_pn
  type(string_t), intent(in) :: name
  select case (char (name))
  case ("cuts")
    rt_pn%cuts_lexpr => null ()
  case ("scale")
    rt_pn%scale_expr => null ()
  case ("factorization_scale")
    rt_pn%fac_scale_expr => null ()
  case ("renormalization_scale")
    rt_pn%ren_scale_expr => null ()
  case ("weight")
    rt_pn%weight_expr => null ()
  case ("selection")
    rt_pn%selection_lexpr => null ()
  case ("reweight")
    rt_pn%reweight_expr => null ()
  case ("analysis")

  end subroutine rt_data_write_process_stack
```

33.2.5 Clear

The `clear` command can remove the contents of various subobjects. The objects themselves should stay.

```
<RT data: rt data: TBP>+≡  
  procedure :: clear_beams => rt_data_clear_beams  
  
<RT data: procedures>+≡  
  subroutine rt_data_clear_beams (global)  
    class(rt_data_t), intent(inout) :: global  
    call global%beam_structure%final_sf ()  
    call global%beam_structure%final_pol ()
```

```

    call global%beam_structure%final_mom ()
end subroutine rt_data_clear_beams

```

33.2.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

```

<RT data: rt data: TBP>+≡
  procedure :: global_init => rt_data_global_init

<RT data: procedures>+≡
  subroutine rt_data_global_init (global, paths, logfile)
    class(rt_data_t), intent(out), target :: global
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
    integer :: seed
    call os_data_init (global%os_data, paths)
    if (present (logfile)) then
      global%logfile = logfile
    else
      global%logfile = ""
    end if
    allocate (global%out_files)
    call system_clock (seed)
    call global%var_list%init_defaults (seed, paths)
    call global%init_pointer_variables ()
    call global%process_stack%init_var_list (global%var_list)
  end subroutine rt_data_global_init

```

33.2.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
  procedure :: local_init => rt_data_local_init

<RT data: procedures>+≡
  subroutine rt_data_local_init (local, global, env)
    class(rt_data_t), intent(inout), target :: local
    type(rt_data_t), intent(in), target :: global
    integer, intent(in), optional :: env
    local%context => global
    call local%process_stack%link (global%process_stack)
    call local%process_stack%init_var_list (local%var_list)
    call local%process_stack%link_var_list (global%var_list)
  end subroutine rt_data_local_init

```

```

call local%var_list%append_string (var_str ("model_name"), &
    var_str (""), intrinsic=.true.)
call local%init_pointer_variables ()
local%fallback_model => global%fallback_model
local%os_data = global%os_data
local%logfile = global%logfile
call local%model_list%link (global%model_list)
local%model => global%model
if (associated (local%model)) then
    call local%model%link_var_list (local%var_list)
end if
if (allocated (global%event_callback)) then
    allocate (local%event_callback, source = global%event_callback)
end if
end subroutine rt_data_local_init

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
    procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: procedures>+≡
    subroutine rt_data_init_pointer_variables (local)
        class(rt_data_t), intent(inout), target :: local
        logical, target, save :: known = .true.
        call local%var_list%append_string_ptr (var_str ("%fc"), &
            local%os_data%fc, known, intrinsic=.true.)
        call local%var_list%append_string_ptr (var_str ("%fcflags"), &
            local%os_data%fcflags, known, intrinsic=.true.)
    end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has intent(inout) because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+≡
    procedure :: activate => rt_data_activate

<RT data: procedures>+≡
    subroutine rt_data_activate (local)
        class(rt_data_t), intent(inout), target :: local
        class(rt_data_t), pointer :: global
        global => local%context
        if (associated (global)) then
            local%lexer => global%lexer
            call global%copy_globals (local)

```

```

local%os_data = global%os_data
local%logfile = global%logfile
if (associated (global%prclib)) then
  local%prclib => &
    local%prclib_stack%get_library_ptr (global%prclib%get_name ())
end if
call local%import_values ()
call local%process_stack%link (global%process_stack)
local%it_list = global%it_list
local%beam_structure = global%beam_structure
local%pn = global%pn
if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
if (allocated (global%sample_fmt)) then
  allocate (local%sample_fmt (size (global%sample_fmt)), &
    source = global%sample_fmt)
end if
local%out_files => global%out_files
local%model => global%model
local%model_is_copy = .false.
else if (.not. associated (local%model)) then
  local%model => local%preload_model
  local%model_is_copy = .false.
end if
if (associated (local%model)) then
  call local%model%link_var_list (local%var_list)
  call local%var_list%set_string (var_str (" $model_name"), &
    local%model%get_name (), is_known = .true.)
else
  call local%var_list%set_string (var_str (" $model_name"), &
    var_str (""), is_known = .false.)
end if
end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
  procedure :: deactivate => rt_data_deactivate

<RT data: procedures>+≡
  subroutine rt_data_deactivate (local, global, keep_local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), optional, target :: global
    logical, intent(in), optional :: keep_local
    type(string_t) :: local_model, local_scheme
    logical :: same_model, delete
    delete = .true.; if (present (keep_local)) delete = .not. keep_local
    if (present (global)) then

```

```

if (associated (global%model) .and. associated (local%model)) then
  local_model = local%model%get_name ()
  if (global%model%has_schemes ()) then
    local_scheme = local%model%get_scheme ()
    same_model = &
      global%model%matches (local_model, local_scheme)
  else
    same_model = global%model%matches (local_model)
  end if
else
  same_model = .false.
end if
if (delete) then
  call local%process_stack%clear ()
  call local%unselect_model ()
  call local%unset_values ()
else if (associated (local%model)) then
  call local%ensure_model_copy ()
end if
if (.not. same_model .and. associated (global%model)) then
  if (global%model%has_schemes ()) then
    call msg_message ("Restoring model '" // &
      char (global%model%get_name ()) // "', scheme '" // &
      char (global%model%get_scheme ()) // "'")
  else
    call msg_message ("Restoring model '" // &
      char (global%model%get_name ()) // "'")
  end if
end if
if (associated (global%model)) then
  call global%model%link_var_list (global%var_list)
end if
call global%restore_globals (local)
else
  call local%unselect_model ()
end if
end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
  procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
  subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
    local%prclib_stack = global%prclib_stack
  end subroutine rt_data_copy_globals

```

This restores global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡
  procedure :: restore_globals => rt_data_restore_globals

```

```

<RT data: procedures>+≡
  subroutine rt_data_restore_globals (global, local)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(in) :: local
    global%prclib_stack = local%prclib_stack
  end subroutine rt_data_restore_globals

```

33.2.8 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
  procedure :: final => rt_data_global_final

<RT data: procedures>+≡
  subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
    call global%model_list%final ()
    call global%var_list%final (follow_link=.false.)
    if (associated (global%out_files)) then
      call file_list_final (global%out_files)
      deallocate (global%out_files)
    end if
  end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: local_final => rt_data_local_final

<RT data: procedures>+≡
  subroutine rt_data_local_final (local)
    class(rt_data_t), intent(inout) :: local
    call local%process_stack%clear ()
    call local%model_list%final ()
    call local%var_list%final (follow_link=.false.)
  end subroutine rt_data_local_final

```

33.2.9 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
  procedure :: read_model => rt_data_read_model

```

```

<RT data: procedures>+≡
  subroutine rt_data_read_model (global, name, model, scheme)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(string_t), intent(in), optional :: scheme
    type(model_t), pointer, intent(out) :: model
    type(string_t) :: filename
    filename = name // ".mdl"
    call global%model_list%read_model &
      (name, filename, global%os_data, model, scheme)
  end subroutine rt_data_read_model

```

Read a UFO model. Create it on the fly if necessary.

```

<RT data: rt data: TBP>+≡
  procedure :: read_ufo_model => rt_data_read_ufo_model

```

```

<RT data: procedures>+≡
  subroutine rt_data_read_ufo_model (global, name, model)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(model_t), pointer, intent(out) :: model
    type(string_t) :: filename
    filename = name // ".ufo.mdl"
    call global%model_list%read_model &
      (name, filename, global%os_data, model, ufo=.true.)
  end subroutine rt_data_read_ufo_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
  procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: procedures>+≡
  subroutine rt_data_init_fallback_model (global, name, filename)
    class(rt_data_t), intent(inout) :: global

Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```

```

Local Model

Locally modify a model and restore the global one. We need an auxiliary function to determine the status of a model particle:

```

<RT data: test auxiliary>+≡
    function is_stable (pdg, global) result (flag)
        integer, intent(in) :: pdg
        type(rt_data_t), intent(in) :: global
        logical :: flag
        type(flavor_t) :: flv
        call flv%init (pdg, global%model)
        flag = flv%is_stable ()
    end function is_stable

    function is_polarized (pdg, global) result (flag)
        integer, intent(in) :: pdg
        type(rt_data_t), intent(in) :: global
        logical :: flag
        type(flavor_t) :: flv
        call flv%init (pdg, global%model)

```

```

        flag = flv%is_polarized ()
    end function is_polarized

<RT data: execute tests>+≡

33.3 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

We would like to put this in the `me_methods` folder but it also depends on `gosam` and `openloops`, so it is unclear where to put it.

```
<dispatch_me_methods.f90>≡  
  <File header>  
  
  module dispatch_me_methods  
  
    <Use strings>  
    use physics_defs, only: BORN  
    use diagnostics  
    use sm_qcd  
    use variables, only: var_list_t  
    use models  
    use model_data  
  
    use prc_core_def  
    use prc_core  
    use prc_test_core  
    use prc_template_me  
    use prc_test  
    use prc_omega  
    use prc_user_defined  
    use prc_gosam  
    use prc_openloops  
    use prc_recola  
    use prc_threshold  
  
    <Standard module head>  
  
    <Dispatch me methods: public>  
  
    contains  
  
    <Dispatch me methods: procedures>  
  
  end module dispatch_me_methods
```

33.3.1 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable.

Note: `core_def` has intent(inout) because gfortran 4.7.1 crashes for intent(out).

```
<Dispatch me methods: public>≡  
  public :: dispatch_core_def
```

```

(Dispatch me methods: procedures)=
subroutine dispatch_core_def (core_def, prt_in, prt_out, &

33.3.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega.t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

<Dispatch me methods: public>+≡

```
public :: dispatch_core
```

<Dispatch me methods: procedures>+≡

```

subroutine dispatch_core (core, core_def, model, &
  helicity_selection, qcd, use_color_factors)
  class(prc_core_t), allocatable, intent(inout) :: core
  class(prc_core_def_t), intent(in) :: core_def
  class(model_data_t), intent(in), target, optional :: model
  type(helicity_selection_t), intent(in), optional :: helicity_selection
  type(qcd_t), intent(in), optional :: qcd
  logical, intent(in), optional :: use_color_factors
  select type (core_def)

```

```

type is (prc_test_def_t)
  allocate (test_t :: core)
type is (template_me_def_t)
  allocate (prc_template_me_t :: core)
  select type (core)
    type is (prc_template_me_t)
      call core%set_parameters (model)
    end select
class is (omega_def_t)
  if (.not. allocated (core)) allocate (prc_omega_t :: core)
  select type (core)
    type is (prc_omega_t)
      call core%set_parameters (model, &
        helicity_selection, qcd, use_color_factors)
    end select
type is (gosam_def_t)
  if (.not. allocated (core)) allocate (prc_gosam_t :: core)
  select type (core)
    type is (prc_gosam_t)
      call core%set_parameters (qcd)
    end select
type is (openloops_def_t)
  if (.not. allocated (core)) allocate (prc_openloops_t :: core)
  select type (core)
    type is (prc_openloops_t)
      call core%set_parameters (qcd)
    end select
type is (recola_def_t)
  if (.not. allocated (core)) allocate (prc_recola_t :: core)
  select type (core)
    type is (prc_recola_t)
      call core%set_parameters (qcd, model)
    end select
type is (user_defined_test_def_t)
  if (.not. allocated (core)) allocate (prc_user_defined_test_t :: core)
  select type (core)
    type is (prc_user_defined_test_t)
      call core%set_parameters (qcd, model)
    end select
type is (threshold_def_t)

    end select
class default
  call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

33.3.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

```
<Dispatch me methods: public>+≡
  public :: dispatch_core_update
  public :: dispatch_core_restore

<Dispatch me methods: procedures>+≡
  subroutine dispatch_core_update &
    (core, model, helicity_selection, qcd, saved_core)

    class(prc_core_t), allocatable, intent(inout) :: core
    class(model_data_t), intent(in), optional, target :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    class(prc_core_t), allocatable, intent(inout), optional :: saved_core

    if (present (saved_core)) then
      allocate (saved_core, source = core)
    end if
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
      call core%set_parameters (model, helicity_selection, qcd)
      call core%activate_parameters ()
    class is (prc_user_defined_base_t)
      call msg_message ("Updating user defined cores is not implemented yet.")
    class default
      call msg_bug ("Process core update: unexpected process definition type")
    end select
  end subroutine dispatch_core_update

  subroutine dispatch_core_restore (core, saved_core)

    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_t), allocatable, intent(inout) :: saved_core

    call move_alloc (from = saved_core, to = core)
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
      call core%activate_parameters ()
    class default
      call msg_bug ("Process core restore: unexpected process definition type")
    end select
  end subroutine dispatch_core_restore
```

33.4 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

```
<process_configurations.f90>≡  
  <File header>  
  
  module process_configurations  
  
    <Use strings>  
    use diagnostics  
    use models  
    use prc_core_def  
    use particle_specifiers  
    use process_libraries  
    use rt_data  
    use variables, only: var_list_t  
  
    use dispatch_me_methods, only: dispatch_core_def  
    use prc_user_defined, only: user_defined_def_t  
  
    <Standard module head>  
  
    <Process configurations: public>  
  
    <Process configurations: types>  
  
    contains  
  
    <Process configurations: procedures>  
  
  end module process_configurations
```

33.4.1 Data Type

```
<Process configurations: public>≡  
  public :: process_configuration_t  
  
<Process configurations: types>≡  
  type :: process_configuration_t  
    type(process_def_entry_t), pointer :: entry => null ()  
    type(string_t) :: id  
    integer :: num_id = 0  
    contains  
    <Process configurations: process configuration: TBP>  
  end type process_configuration_t
```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

```
<Process configurations: process configuration: TBP>≡
```

```

procedure :: init => process_configuration_init
<Process configurations: procedures>≡
  subroutine process_configuration_init &
    (config, prc_name, n_in, n_components, global, nlo_proc)
    class(process_configuration_t), intent(out) :: config
    type(string_t), intent(in) :: prc_name
    integer, intent(in) :: n_in
    integer, intent(in) :: n_components
    type(rt_data_t), intent(in) :: global
    logical, intent(in), optional :: nlo_proc
    type(model_t), pointer :: model
    logical :: nlo_process
    model => global%model
    config%id = prc_name
    if (present (nlo_proc)) then
      nlo_process = nlo_proc
    else
      nlo_process = global%nlo_fixed_order
    end if
    allocate (config%entry)
    if (global%var_list%is_known (var_str ("process_num_id"))) then
      config%num_id = &
        global%var_list%get_ival (var_str ("process_num_id"))
      call config%entry%init (prc_name, &
        model = model, n_in = n_in, n_components = n_components, &
        num_id = config%num_id, nlo_process = nlo_process)
    else
      call config%entry%init (prc_name, &
        model = model, n_in = n_in, n_components = n_components, &
        nlo_process = nlo_process)
    end if
  end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

```

<Process configurations: process configuration: TBP>+≡
  procedure :: setup_component => process_configuration_setup_component

    <Process configurations: public test auxiliary>

    contains

    <Process configurations: test auxiliary>

    <Process configurations: tests>

  end module process_configurations_uti

```

API: driver for the unit tests below.

```
<Process configurations: public test>≡
  public :: process_configurations_test

<Process configurations: test driver>≡
  subroutine process_configurations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Process configurations: execute tests>
  end subroutine process_configurations_test
```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

This is re-exported by the UT module.

```
<Process configurations: public test auxiliary>≡
  public :: prepare_test_library

<Process configurations: test auxiliary>≡

33.5 Compilation

This module manages compilation and loading of process libraries. It is needed as a separate module because integration depends on it.

```
<compilations.f90>≡  
  <File header>  
  
  module compilations  
  
    <Use strings>  
    use io_units  
    use system_defs, only: TAB  
    use diagnostics  
    use os_interface  
    use variables, only: var_list_t  
    use model_data  
    use process_libraries  
    use prclib_stacks  
    use rt_data  
  
    <Standard module head>  
  
    <Compilations: public>  
  
    <Compilations: types>  
  
    contains  
  
    <Compilations: procedures>  
  
  end module compilations
```

33.5.1 The data type

The compilation item handles the compilation and loading of a single process library.

```
<Compilations: public>≡  
  public :: compilation_item_t  
  
<Compilations: types>≡  
  type :: compilation_item_t  
    private  
    type(string_t) :: libname  
    type(string_t) :: static_external_tag  
    type(process_library_t), pointer :: lib => null ()  
    logical :: recompile_library = .false.  
    contains  
    <Compilations: compilation item: TBP>  
  end type compilation_item_t
```

Initialize:

```
<Compilations: compilation item: TBP>≡  
  procedure :: init => compilation_item_init
```

```

<Compilations: procedures>≡
subroutine compilation_item_init (comp, libname, stack, var_list)
  class(compilation_item_t), intent(out) :: comp
  type(string_t), intent(in) :: libname
  type(prclib_stack_t), intent(inout) :: stack
  type(var_list_t), intent(in) :: var_list
  comp%libname = libname
  comp%lib => stack%get_library_ptr (comp%libname)
  if (.not. associated (comp%lib)) then
    call msg_fatal ("Process library '" // char (comp%libname) &
      // "' has not been declared.")
  end if
  comp%recompile_library = &
    var_list%get_lval (var_str ("?recompile_library"))
end subroutine compilation_item_init

```

Compile the current library. The force flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

```

<Compilations: compilation item: TBP>+≡
  procedure :: compile => compilation_item_compile

<Compilations: procedures>+≡
subroutine compilation_item_compile (comp, model, os_data, force, recompile)
  class(compilation_item_t), intent(inout) :: comp
  class(model_data_t), intent(in), target :: model
  type(os_data_t), intent(in) :: os_data
  logical, intent(in) :: force, recompile
  if (associated (comp%lib)) then
    call msg_message ("Process library '" &
      // char (comp%libname) // "': compiling ...")
    call comp%lib%configure (os_data)
    if (signal_is_pending ()) return
    call comp%lib%compute_md5sum (model)
    call comp%lib%write_makefile (os_data, force)
    if (signal_is_pending ()) return
    if (force) then
      call comp%lib%clean (os_data, distclean = .false.)
      if (signal_is_pending ()) return
    end if
    call comp%lib%write_driver (force)
    if (signal_is_pending ()) return
    if (recompile) then
      call comp%lib%load (os_data, keep_old_source = .true.)
      if (signal_is_pending ()) return
    end if
    call comp%lib%update_status (os_data)
  end if
end subroutine compilation_item_compile

```

Load the current library, just after compiling it.

```

<Compilations: compilation item: TBP>+≡
  procedure :: load => compilation_item_load

```

```

<Compilations: procedures>+≡
  subroutine compilation_item_load (comp, os_data)
    class(compilation_item_t), intent(inout) :: comp
    type(os_data_t), intent(in) :: os_data
    if (associated (comp%lib)) then
      call comp%lib%load (os_data)
    end if
  end subroutine compilation_item_load

```

Message as a separate call:

```

<Compilations: compilation item: TBP>+≡
  procedure :: success => compilation_item_success

<Compilations: procedures>+≡
  subroutine compilation_item_success (comp)
    class(compilation_item_t), intent(in) :: comp
    if (associated (comp%lib)) then
      call msg_message ("Process library '" // char (comp%libname) &
        // "' : ... success.")
    else
      call msg_fatal ("Process library '" // char (comp%libname) &
        // "' : ... failure.")
    end if
  end subroutine compilation_item_success

```

33.5.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
  public :: compile_library

<Compilations: procedures>+≡
  subroutine compile_library (libname, global)
    type(string_t), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
    type(compilation_item_t) :: comp
    logical :: force, recompile
    force = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    recompile = &
      global%var_list%get_lval (var_str ("?recompile_library"))
    if (associated (global%model)) then
      call comp%init (libname, global%prclib_stack, global%var_list)
      call comp%compile (global%model, global%os_data, force, recompile)
      if (signal_is_pending ()) return
      call comp%load (global%os_data)
      if (signal_is_pending ()) return
    else

```

```

        call msg_fatal ("Process library compilation: " &
            // " model is undefined.")
    end if
    call comp%success ()
end subroutine compile_library

```

33.5.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```

<Compilations: public>+≡
    public :: compilation_t

<Compilations: types>+≡
    type :: compilation_t
        private
        type(string_t) :: exe_name
        type(string_t), dimension(:), allocatable :: lib_name
    contains
        <Compilations: compilation: TBP>
    end type compilation_t

```

Output.

```

<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write

<Compilations: procedures>+≡
    subroutine compilation_write (object, unit)
        class(compilation_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Compilation object:"
        write (u, "(3x,3A)") "executable          = '", &
            char (object%exe_name), "'"
        write (u, "(3x,A)", advance="no") "process libraries ="
        do i = 1, size (object%lib_name)
            write (u, "(1x,3A)", advance="no") "'", char (object%lib_name(i)), "'"
        end do
        write (u, *)
    end subroutine compilation_write

```

Initialize: we know the names of the executable and of the libraries.

```

<Compilations: compilation: TBP>+≡
    procedure :: init => compilation_init

<Compilations: procedures>+≡
    subroutine compilation_init (compilation, exe_name, lib_name)
        class(compilation_t), intent(out) :: compilation
        type(string_t), intent(in) :: exe_name
        type(string_t), dimension(:), intent(in) :: lib_name
        compilation%exe_name = exe_name

```

```

        allocate (compilation%lib_name (size (lib_name)))
        compilation%lib_name = lib_name
    end subroutine compilation_init

```

Write the dispatcher subroutine for the compiled libraries. Also write a subroutine which returns the names of the compiled libraries.

<Compilations: compilation: TBP>+≡

```

    procedure :: write_dispatcher => compilation_write_dispatcher

```

<Compilations: procedures>+≡

33.6.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

<Integrations: public>≡
    public :: integration_t

<Integrations: types>≡
    type :: integration_t
        private
            type(string_t) :: process_id
            type(string_t) :: run_id
            type(process_t), pointer :: process => null ()
            type(var_list_t), pointer :: model_vars => null ()
            type(qcd_t) :: qcd
            logical :: rebuild_phs = .false.
            logical :: ignore_phs_mismatch = .false.
            logical :: phs_only = .false.
            logical :: process_has_me = .true.
            integer :: n_calls_test = 0
            logical :: vis_history = .true.
            type(string_t) :: history_filename
            type(string_t) :: log_filename
            logical :: combined_integration = .false.
            type(iteration_multipliers_t) :: iteration_multipliers
            type(nlo_settings_t) :: nlo_settings
        contains
            <Integrations: integration: TBP>
    end type integration_t

```

33.6.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied.

```

<Integrations: integration: TBP>≡
    procedure :: create_process => integration_create_process

```

```

<Integrations: procedures>≡
subroutine integration_create_process (intg, process_id, global)
  class(integration_t), intent(out) :: intg
  type(rt_data_t), intent(inout), optional, target :: global
  type(string_t), intent(in) :: process_id
  type(process_entry_t), pointer :: process_entry
  call msg_debug (D_CORE, "integration_create_process")
  intg%process_id = process_id
  if (present (global)) then
    allocate (process_entry)
    intg%process => process_entry%process_t
    call global%process_stack%push (process_entry)
  else
    allocate (process_t :: intg%process)
  end if
  intg%model_vars => null ()
end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the local stack directly. The intent(inout) attribute for the local data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

```

<Integrations: integration: TBP>+≡
procedure :: init_process => integration_init_process

<Integrations: procedures>+≡
subroutine integration_init_process (intg, local)
  class(integration_t), intent(inout) :: intg
  type(rt_data_t), intent(inout), target :: local
  type(string_t) :: model_name
  type(model_t), pointer :: model
  class(model_data_t), pointer :: model_instance
  class(rng_factory_t), allocatable :: rng_factory
  call msg_debug (D_CORE, "integration_init_process")
  if (.not. local%prclib%contains (intg%process_id)) then
    call msg_fatal ("Process '" // char (intg%process_id) // "' not found" &
      // " in library '" // char (local%prclib%get_name ()) // "'")
    return
  end if
  intg%run_id = &
    local%var_list%get_sval (var_str ("$_run_id"))
  call dispatch_qcd (intg%qcd, local%get_var_list_ptr (), local%os_data)

33.6.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

<Integrations: integration: TBP>+≡
    procedure :: evaluate => integration_evaluate

<Integrations: procedures>+≡
    subroutine integration_evaluate &
        (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
    integer :: n_calls, n_it
    logical :: adapt_grids, adapt_weights, final
    n_it = it_list%get_n_it (pass)
    n_calls = it_list%get_n_calls (pass)
    adapt_grids = it_list%adapt_grids (pass)
    adapt_weights = it_list%adapt_weights (pass)
    final = pass == it_list%get_n_pass ()
    call process_instance%integrate ( &
        i_mci, n_it, n_calls, adapt_grids, adapt_weights, &

```

```

        final, pacify)
    end subroutine integration_evaluate

```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

```

<Integrations: integration: TBP>+≡
    procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: procedures>+≡
    subroutine integration_make_iterations_list (intg, it_list)
        class(integration_t), intent(in) :: intg
        type(iterations_list_t), intent(out) :: it_list
        integer :: pass, n_pass
        integer, dimension(:), allocatable :: n_it, n_calls
        logical, dimension(:), allocatable :: adapt_grids, adapt_weights
        n_pass = intg%process%get_n_pass_default ()
        allocate (n_it (n_pass), n_calls (n_pass))
        allocate (adapt_grids (n_pass), adapt_weights (n_pass))
        do pass = 1, n_pass
            n_it(pass)      = intg%process%get_n_it_default (pass)
            n_calls(pass)   = intg%process%get_n_calls_default (pass)
            adapt_grids(pass) = intg%process%adapt_grids_default (pass)
            adapt_weights(pass) = intg%process%adapt_weights_default (pass)
        end do
        call it_list%init (n_it, n_calls, &
            adapt_grids = adapt_grids, adapt_weights = adapt_weights)
    end subroutine integration_make_iterations_list

```

In NLO calculations, the individual components might scale very differently with the number of calls. This especially applies to the real-subtracted component, which usually fluctuates more than the Born and virtual component, making it a bottleneck of the calculation. Thus, the calculation is throttled twice, first by the number of calls for the real component, second by the number of surplus calls of computation-intense virtual matrix elements. Therefore, we want to set a different number of calls for each component, which is done by the subroutine `integration.apply_multipliers`.

```

<Integrations: integration: TBP>+≡
    procedure :: init_iteration_multipliers => integration_init_iteration_multipliers

<Integrations: procedures>+≡
    subroutine integration_init_iteration_multipliers (intg, local)

      // "total time (wallclock): ", t_tot
    call msg_message ()
  end if
  call process_instance%final ()
end subroutine integration_sampler_test

```

Return the process pointer (needed by simulate):

<Integrations: integration: TBP>+≡

```

procedure :: get_process_ptr => integration_get_process_ptr

```

<Integrations: procedures>+≡

```

function integration_get_process_ptr (intg) result (ptr)
  class(integration_t), intent(in) :: intg
  type(process_t), pointer :: ptr
  ptr => intg%process
end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the `global` environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the `process` object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

```

Integration of test process

Compile and integrate an intrinsic test matrix element (**prc_test** type). The phase-space implementation is **phs_single** (single-particle phase space), the integrator is **mci_midpoint**.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (33.1)$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (33.2)$$

f is the flux of the incoming particles with mass $m = 125 \text{ GeV}$ and energy $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (33.3)$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (33.4)$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (33.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function $f(x) = x$ for both beams. Together with the $1/x_1 x_2$ factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the m_s mass which we set to zero here.

Integration with sign change

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`. The weight that is applied changes the sign in half of phase space. The weight is -3 and 1 , respectively, so the total result is equal to the original, but negative sign.

The efficiency should (approximately) become the average of 1 and $1/3$, that is $2/3$.

```

33.7 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
(event_streams.f90)≡  
  <File header>  
  
  module event_streams  
  
    <Use strings>  
    use io_units  
    use diagnostics  
    use events  
    use eio_data  
    use eio_base  
    use rt_data

33.7.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡  
  type :: event_stream_entry_t  
    class(eio_t), allocatable :: eio  
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```
<Event streams: public>≡  
  public :: event_stream_array_t  
  
<Event streams: types>+≡  
  type :: event_stream_array_t  
    type(event_stream_entry_t), dimension(:), allocatable :: entry  
    integer :: i_in = 0  
    contains  
    <Event streams: event stream array: TBP>  
  end type event_stream_array_t
```

Output.

```

(Event streams: event stream array: TBP)≡
  procedure :: write => event_stream_array_write

(Event streams: procedures)≡
  subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event stream array:"
    if (allocated (object%entry)) then
      select case (size (object%entry))
      case (0)
        write (u, "(3x,A)") "[empty]"
      case default
        do i = 1, size (object%entry)
          if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
          call object%entry(i)%eio%write (u)
        end do
      end select
    else
      write (u, "(3x,A)") "[undefined]"
    end if
  end subroutine event_stream_array_write

```

Finalize all streams.

```

(Event streams: event stream array: TBP)+≡
  procedure :: final => event_stream_array_final

(Event streams: procedures)+≡
  subroutine event_stream_array_final (es_array)
    class(event_stream_array_t), intent(inout) :: es_array
    integer :: i
    do i = 1, size (es_array%entry)
      call es_array%entry(i)%eio%final ()
    end do
  end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

```

33.8 Simulation

This module manages simulation: event generation and reading/writing of event files. The `simulation` object is intended to be used (via a pointer) outside of WHIZARD, if events are generated individually by an external driver.

```

33.8.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

<Simulations: types>+≡

```

    type :: core_safe_t
        class(prc_core_t), allocatable :: core
    end type core_safe_t

```

33.8.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration

is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

(Simulations: procedures)+≡

```

subroutine prepare_process &

       // char (process_id) // "' : enabled for rescan only")
    end if
end subroutine prepare_process

```

33.8.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

For the purpose of NLO events, `entry_t` contains a pointer list to other simulation-entries. This is due to the fact that we have to associate an event for each component of the fixed order simulation, i.e. one N -particle event and N_α $N + 1$ -particle events. However, all entries share the same event transforms.

(Simulations: types)+≡

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the **process_instance** pointer. Assign data by looking at the process object and at the environment.

If **n_alt** is set, we prepare for additional alternate sqme and weight entries.

The **compile** flag is only false if we don't need the Whizard process at all, just its definition. In that case, we skip process initialization.

Otherwise, and if the process object is not found initially: if **integrate** is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If **generate** is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the `instance` and `process` pointers of the base type by the `connect` method, so we can reference them later.

33.8.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

<Simulations: types>+≡

```

type, extends (entry_t) :: alt_entry_t
contains
  <Simulations: alt entry: TBP>
end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily im-

port the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the luminosity setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the luminosity, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

NB: When reading from file, event transforms can't be applied because the process instance will not be complete. This should be fixed.

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

```

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

<Simulations: simulation: TBP>+≡

    call simulation%entry(i)%restore_process ()
end do
end subroutine simulation_restore_processes

```

33.8.8 Event Stream I/O

Write an event to a generic eio event stream. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+=
generic :: write_event => write_event_eio
procedure :: write_event_eio => simulation_write_event_eio

<Simulations: procedures>+=
subroutine simulation_write_event_eio (object, eio, i_prc)
class(simulation_t), intent(in) :: object
class(eio_t), intent(inout) :: eio
integer, intent(in), optional :: i_prc
logical :: increased
integer :: current
if (present (i_prc)) then
    current = i_prc
else
    current = object%i_prc
end if
if (current > 0) then
    if (object%split_n_evt > 0 &
        .and. object%counter%total > 1 &
        .and. mod (object%counter%total, object%split_n_evt) == 1) then
        call eio%split_out ()
    else if (object%split_n_kbytes > 0) then
        call eio%update_split_count (increased)
        if (increased) call eio%split_out ()
    end if
    call eio%output (object%entry(current)%event_t, current, pacify = object%pacify)
else
    call msg_fatal ("Simulation: write event: no process selected")
end if

```

```
end subroutine simulation_write_event_eio
```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```
<Simulations: simulation: TBP>+≡
generic :: read_event => read_event_eio
procedure :: read_event_eio => simulation_read_event_eio

<Simulations: procedures>+≡
subroutine simulation_read_event_eio (object, eio)
  class(simulation_t), intent(inout) :: object
  class(eio_t), intent(inout) :: eio
  integer :: iostat, current
  call eio%input_i_prc (current, iostat)
  select case (iostat)
  case (0)
    object%i_prc = current
    call eio%input_event (object%entry(current)%event_t, iostat)
  end select
  select case (iostat)
  case (:-1)
    object%i_prc = 0
    object%i_mci = 0
  case (1:)
    call msg_error ("Reading events: I/O error, aborting read")
    object%i_prc = 0
    object%i_mci = 0
  case default
    object%i_mci = object%entry(current)%get_i_mci ()
  end select
end subroutine simulation_read_event_eio
```

33.8.9 Event Stream Array

Write an event using an array of event I/O streams. The process index must be selected, or the current index must be available.

```
<Simulations: simulation: TBP>+≡
generic :: write_event => write_event_es_array
procedure :: write_event_es_array => simulation_write_event_es_array

<Simulations: procedures>+≡
subroutine simulation_write_event_es_array (object, es_array, passed)
  class(simulation_t), intent(in), target :: object
  class(event_stream_array_t), intent(inout) :: es_array
  logical, intent(in), optional :: passed
  integer :: i_prc, event_index
  integer :: i
  type(entry_t), pointer :: current_entry
```

```

i_prc = object%i_prc
if (i_prc > 0) then
  event_index = object%counter%total
  current_entry => object%entry(i_prc)%get_first ()
  do i = 1, current_entry%count_nlo_entries ()
    if (i > 1) current_entry => current_entry%get_next ()
    call es_array%output (current_entry%event_t, i_prc, &
      event_index, passed = passed, pacify = object%pacify)
  end do
else
  call msg_fatal ("Simulation: write event: no process selected")
end if
end subroutine simulation_write_event_es_array

```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

(Simulations: simulation: TBP)+≡

    character(32) :: md5sum
    md5sum = simulation%md5sum_alt(i)
  end function simulation_get_md5sum_alt
```

Return data that may be useful for writing event files.

Usually we can refer to a previously integrated process, for which we can fetch a process pointer. Occasionally, we don't have this because we're just rescanning an externally generated file without calculation. For that situation, we generate our local beam data object using the current environment, or, in simple cases, just fetch the necessary data from the process definition and environment.

```
<Simulations: simulation: TBP>+≡
  procedure :: get_data => simulation_get_data

Chapter 34

More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in init/final hooks that we can set at runtime.)

34.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
(expr_tests_ut.f90)≡
  <File header>
  module expr_tests_ut

    use unit_tests
    use expr_tests_utili

    <Standard module head>

    <Expr tests: public test>

    contains

    <Expr tests: test driver>

  end module expr_tests_ut
(expr_tests_utili.f90)≡
  <File header>

  module expr_tests_utili

    <Use kinds>
    <Use strings>
    use format_defs, only: FMT_12
    use format_utils, only: write_separator
```

```

Chapter 35

Top Level

The top level consists of

commands Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

whizard This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

main The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

whizard_c_interface Alternative top-level procedures, for use in the context of a C-compatible caller program.

35.1 Commands

This module defines the command language of the main input file.

```

    <Commands: procedures>

end module commands

```

35.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```

<Commands: types>≡
    type, abstract :: command_t
        type(parse_node_t), pointer :: pn => null ()
        class(command_t), pointer :: next => null ()
        type(parse_node_t), pointer :: pn_opt => null ()
        type(command_list_t), pointer :: options => null ()
        type(rt_data_t), pointer :: local => null ()
    contains
        <Commands: command: TBP>
    end type command_t

```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```

<Commands: command: TBP>≡
    procedure :: final => command_final

<Commands: procedures>≡
    recursive subroutine command_final (cmd)
        class(command_t), intent(inout) :: cmd
        if (associated (cmd%options)) then
            call cmd%options%final ()
            deallocate (cmd%options)
            call cmd%local%local_final ()
            deallocate (cmd%local)
        else
            cmd%local => null ()
        end if
    end subroutine command_final

```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

(Commands: procedures)+≡

```

subroutine dispatch_command (command, pn)
  class(command_t), intent(inout), pointer :: command
  type(parse_node_t), intent(in), target :: pn
  select case (char (parse_node_get_rule_key (pn)))

    end select
    command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_write), deferred :: write
⟨Commands: interfaces⟩≡
    abstract interface
        subroutine command_write (cmd, unit, indent)
            import
            class(command_t), intent(in) :: cmd
            integer, intent(in), optional :: unit, indent
        end subroutine command_write
    end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_compile), deferred :: compile
⟨Commands: interfaces⟩+≡
    abstract interface
        subroutine command_compile (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_compile
    end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_execute), deferred :: execute
⟨Commands: interfaces⟩+≡
    abstract interface
        subroutine command_execute (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_execute
    end interface

```

35.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate

local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```

⟨Commands: command: TBP⟩+≡
  procedure :: write_options => command_write_options

⟨Commands: procedures⟩+≡
  recursive subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options

```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```

⟨Commands: command: TBP⟩+≡
  procedure :: compile_options => command_compile_options

⟨Commands: procedures⟩+≡
  recursive subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call cmd%options%compile (cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
      call cmd%local%deactivate ()
    else
      cmd%local => global
    end if
  end subroutine command_compile_options

```

Execute options. First prepare the local environment, then execute the command list.

```

⟨Commands: command: TBP⟩+≡
  procedure :: execute_options => cmd_execute_options

⟨Commands: procedures⟩+≡
  recursive subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call cmd%local%activate ()
      call cmd%options%execute (cmd%local)
    end if
  end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

<Commands: command: TBP>+≡
  procedure :: reset_options => cmd_reset_options

<Commands: procedures>+≡
  subroutine cmd_reset_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call cmd%local%deactivate (global)
    end if
  end subroutine cmd_reset_options

```

35.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_model_t
  private
    type(string_t) :: name
    type(string_t) :: scheme
    logical :: ufo_model = .false.
  contains
    <Commands: cmd model: TBP>
  end type cmd_model_t

```

Output

```

<Commands: cmd model: TBP>≡
  procedure :: write => cmd_model_write

<Commands: procedures>+≡
  subroutine cmd_model_write (cmd, unit, indent)
    class(cmd_model_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,1x,'"',A,'"')", advance="no") "model =", char (cmd%name)
    if (cmd%ufo_model) then
      write (u, "(1x,A)" "(ufo)"
    else if (cmd%scheme /= "") then
      write (u, "(1x,'(,A,')'") char (cmd%scheme)
    else
      write (u, *)
    end if
  end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed. If the model has a scheme argument, take this into account.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

```

(Commands: cmd model: TBP)+≡
  procedure :: compile => cmd_model_compile

(Commands: procedures)+≡

                // char (cmd%name) // "': model not found")
    end subroutine cmd_model_execute

```

Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

```
<Commands: types>+≡
    type, extends (command_t) :: cmd_library_t
        private
        type(string_t) :: name
    contains
        <Commands: cmd library: TBP>
    end type cmd_library_t
```

Output.

```
<Commands: cmd library: TBP>≡
    procedure :: write => cmd_library_write

<Commands: procedures>+≡
    subroutine cmd_library_write (cmd, unit, indent)
        class(cmd_library_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit)
        call write_indent (u, indent)
        write (u, "(1x,A,1x,'"',A,'\"')") "library =", char (cmd%name)
    end subroutine cmd_library_write
```

Compile. Get the library name.

```
<Commands: cmd library: TBP>+≡
    procedure :: compile => cmd_library_compile

<Commands: procedures>+≡
    subroutine cmd_library_compile (cmd, global)
        class(cmd_library_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_name
        pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
        cmd%name = parse_node_get_string (pn_name)
    end subroutine cmd_library_compile
```

Execute: Initialize a new library and push it on the library stack (if it does not yet exist). Insert a pointer to the library into the global data record. Then, try to load the library unless the `rebuild` flag is set.

```
<Commands: cmd library: TBP>+≡
    procedure :: execute => cmd_library_execute

<Commands: procedures>+≡
    subroutine cmd_library_execute (cmd, global)
        class(cmd_library_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(prclib_entry_t), pointer :: lib_entry
        type(process_library_t), pointer :: lib
        logical :: rebuild_library
```

```

lib => global%prclib_stack%get_library_ptr (cmd%name)

    lib => lib_entry%process_library_t
    call global%add_prclib (lib_entry)
else
    call global%update_prclib (lib)
end if
if (associated (lib) .and. .not. rebuild_library) then
    call lib%update_status (global%os_data)
end if
end subroutine cmd_library_execute

```

Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_process_t
private
type(string_t) :: id
integer :: n_in = 0
type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
type(parse_node_t), pointer :: pn_out => null ()
contains
<Commands: cmd process: TBP>
end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

<Commands: cmd process: TBP>≡
procedure :: write => cmd_process_write

<Commands: procedures>+≡
subroutine cmd_process_write (cmd, unit, indent)
class(cmd_process_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u

```

```

u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A,A,A,I0,A)" "process: ", char (cmd%id), " (", &
      size (cmd%pn_pdg_in), " -> X)"
call cmd%write_options (u, indent)
end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

⟨Commands: cmd process: TBP⟩+≡
  procedure :: compile => cmd_process_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_process_compile (cmd, global)
    class(cmd_process_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_id, pn_in, pn_codes
    integer :: i
    pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_in => parse_node_get_next_ptr (pn_id, 2)
    cmd%pn_out => parse_node_get_next_ptr (pn_in, 2)
    cmd%pn_opt => parse_node_get_next_ptr (cmd%pn_out)
    call cmd%compile_options (global)
    cmd%id = parse_node_get_string (pn_id)
    cmd%n_in = parse_node_get_n_sub (pn_in)
    pn_codes => parse_node_get_sub_ptr (pn_in)
    allocate (cmd%pn_pdg_in (cmd%n_in))
    do i = 1, cmd%n_in
      cmd%pn_pdg_in(i)%ptr => pn_codes
      pn_codes => parse_node_get_next_ptr (pn_codes)
    end do
  end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

```

Command execution. Generate code, write driver, compile and link. Do this for all libraries in the list.

If no library names have been given and stored while compiling this command, we collect all libraries from the current stack and compile those.

We can compile static libraries (which actually just loads them). However, we can't incorporate in a generated executable.

<Commands: cmd compile: TBP>+≡

```

procedure :: execute => cmd_compile_execute

```

<Commands: procedures>+≡

```

subroutine cmd_compile_execute (cmd, global)

  end subroutine cmd_exec_execute
```

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer.

After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_slha_t
private
type(string_t) :: file
logical :: write_mode = .false.
contains
<Commands: cmd slha: TBP>
end type cmd_slha_t

```

Output.

```

<Commands: cmd slha: TBP>≡
procedure :: write => cmd_slha_write

<Commands: procedures>+≡
subroutine cmd_slha_write (cmd, unit, indent)
class(cmd_slha_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return
call write_indent (u, indent)
write (u, "(1x,A,A)") "slha: file name = ", char (cmd%file)
write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
end subroutine cmd_slha_write

```

Compile. Read the filename and store it.

```

<Commands: cmd slha: TBP>+≡
procedure :: compile => cmd_slha_compile

<Commands: procedures>+≡
subroutine cmd_slha_compile (cmd, global)
class(cmd_slha_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(parse_node_t), pointer :: pn_key, pn_arg, pn_file

case default
    call parse_node_mismatch ("read_slha|write_slha", cmd%pn)
end select
cmd%file = parse_node_get_string (pn_file)
end subroutine cmd_slha_compile

```

Execute. Read or write the specified SLHA file. Behind the scenes, this will first read the WHIZARD model file, then read the SLHA file and assign the SLHA parameters as far as determined by `dispatch_slha`. Finally, the global variables are synchronized with the model. This is similar to executing `cmd_model`.

(Commands: cmd slha: TBP)+≡

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_expect_t
private
type(parse_node_t), pointer :: pn_lexpr => null ()
contains
<Commands: cmd expect: TBP>
end type cmd_expect_t

```

Simply tell the status.

```

<Commands: cmd expect: TBP>≡
procedure :: write => cmd_expect_write

<Commands: procedures>+≡
subroutine cmd_expect_write (cmd, unit, indent)
class(cmd_expect_t), intent(in) :: cmd
integer, intent(in), optional :: unit, indent
integer :: u
u = given_output_unit (unit); if (u < 0) return

Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

<Commands: types>+≡
    type :: sentry_expr_t
        type(parse_node_p), dimension(:), allocatable :: expr
        contains
        <Commands: sentry expr: TBP>
    end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

<Commands: sentry expr: TBP>≡
    procedure :: compile => sentry_expr_compile

<Commands: procedures>+≡
    subroutine sentry_expr_compile (sentry, pn)
        class(sentry_expr_t), intent(out) :: sentry
        type(parse_node_t), intent(in), target :: pn
    end subroutine

```

```

type(parse_node_t), pointer :: pn_expr, pn_extra
integer :: n_expr, i
n_expr = parse_node_get_n_sub (pn)
allocate (sentry%expr (n_expr))
if (n_expr > 0) then
  i = 0
  pn_expr => parse_node_get_sub_ptr (pn)
  pn_extra => parse_node_get_next_ptr (pn_expr)
  do i = 1, n_expr
    sentry%expr(i)%ptr => pn_expr
    if (associated (pn_extra)) then
      pn_expr => parse_node_get_sub_ptr (pn_extra, 2)
      pn_extra => parse_node_get_next_ptr (pn_extra)
    end if
  end do
end if
end subroutine sentry_expr_compile

```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

    type(rt_data_t), intent(inout), target :: global
    global%pn%selection_lexpr => cmd%pn_expr
  end subroutine cmd_selection_execute

```

Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_reweight_t
  private
  type(parse_node_t), pointer :: pn_expr => null ()
  contains
  <Commands: cmd reweight: TBP>
  end type cmd_reweight_t

```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```

<Commands: cmd reweight: TBP>≡
  procedure :: write => cmd_reweight_write

<Commands: procedures>+≡
  subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd reweight: TBP>+≡
  procedure :: compile => cmd_reweight_compile

<Commands: procedures>+≡
  subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile

```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd reweight: TBP⟩+≡
  procedure :: execute => cmd_reweight_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_reweight_execute (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%reweight_expr => cmd%pn_expr
  end subroutine cmd_reweight_execute

```

Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_alt_setup_t
  private
  type(parse_node_p), dimension(:), allocatable :: setup
  contains
  ⟨Commands: cmd alt setup: TBP⟩
  end type cmd_alt_setup_t

```

Output. Print just a message that the alternative setup list has been defined.

```

⟨Commands: cmd alt setup: TBP⟩≡
  procedure :: write => cmd_alt_setup_write

⟨Commands: procedures⟩+≡
  subroutine cmd_alt_setup_write (cmd, unit, indent)
    class(cmd_alt_setup_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
  end subroutine cmd_alt_setup_write

```

Compile. Store the parse sub-trees in an array.

```

⟨Commands: cmd alt setup: TBP⟩+≡
  procedure :: compile => cmd_alt_setup_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_alt_setup_compile (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_list, pn_setup
    integer :: i
    pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
    if (associated (pn_list)) then

```

```

        allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
        i = 1
        pn_setup => parse_node_get_sub_ptr (pn_list)
        do while (associated (pn_setup))
            cmd%setup(i)%ptr => pn_setup
            i = i + 1
            pn_setup => parse_node_get_next_ptr (pn_setup)
        end do
    else
        allocate (cmd%setup (0))
    end if
end subroutine cmd_alt_setup_compile

```

Execute. Transfer the array of command lists to the global environment.

```

<Commands: cmd alt setup: TBP>+≡
    procedure :: execute => cmd_alt_setup_execute

<Commands: procedures>+≡
    subroutine cmd_alt_setup_execute (cmd, global)
        class(cmd_alt_setup_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (allocated (global%pn%alt_setup)) deallocate (global%pn%alt_setup)
        allocate (global%pn%alt_setup (size (cmd%setup)))
        global%pn%alt_setup = cmd%setup
    end subroutine cmd_alt_setup_execute

```

Integration

Integrate several processes, consecutively with identical parameters.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_integrate_t
    private
        integer :: n_proc = 0
        type(string_t), dimension(:), allocatable :: process_id
    contains
        <Commands: cmd integrate: TBP>
    end type cmd_integrate_t

```

Output: we know the process IDs.

```

<Commands: cmd integrate: TBP>≡
    procedure :: write => cmd_integrate_write

<Commands: procedures>+≡
    subroutine cmd_integrate_write (cmd, unit, indent)
        class(cmd_integrate_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u, i
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)", advance="no") "integrate ("
        do i = 1, cmd%n_proc
            if (i > 1) write (u, "(A,1x)", advance="no") ", "

```

```

        write (u, "(A)", advance="no") char (cmd%process_id(i))
    end do
    write (u, "(A)" )"
end subroutine cmd_integrate_write

```

Compile.

```

⟨Commands: cmd integrate: TBP⟩+≡
    procedure :: compile => cmd_integrate_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_integrate_compile (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_proclist, pn_proc
        integer :: i
        pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
        cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
        call cmd%compile_options (global)
        cmd%n_proc = parse_node_get_n_sub (pn_proclist)
        allocate (cmd%process_id (cmd%n_proc))
        pn_proc => parse_node_get_sub_ptr (pn_proclist)
        do i = 1, cmd%n_proc
            cmd%process_id(i) = parse_node_get_string (pn_proc)
            call global%process_stack%init_result_vars (cmd%process_id(i))
            pn_proc => parse_node_get_next_ptr (pn_proc)
        end do
    end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

⟨Commands: cmd integrate: TBP⟩+≡
    procedure :: execute => cmd_integrate_execute

⟨Commands: procedures⟩+≡
    subroutine cmd_integrate_execute (cmd, global)
        class(cmd_integrate_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global

            if (signal_is_pending ()) return
        end do
    end subroutine cmd_integrate_execute

```

```
end subroutine cmd_integrate_execute
```

Observables

Declare an observable. After the declaration, it can be used to record data, and at the end one can retrieve average and error.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_observable_t
    private
    type(string_t) :: id
    contains
    <Commands: cmd observable: TBP>
  end type cmd_observable_t
```

Output. We know the ID.

```
<Commands: cmd observable: TBP>≡
  procedure :: write => cmd_observable_write

<Commands: procedures>+≡
  subroutine cmd_observable_write (cmd, unit, indent)
    class(cmd_observable_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)" "observable: ", char (cmd%id)
  end subroutine cmd_observable_write
```

Compile. Just record the observable ID.

```
<Commands: cmd observable: TBP>+≡
  procedure :: compile => cmd_observable_compile

<Commands: procedures>+≡
  subroutine cmd_observable_compile (cmd, global)
    class(cmd_observable_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global

    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call drawing_options_init_plot (drawing_options)
    call set_drawing_options (drawing_options, var_list)

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

⟨Commands: types⟩+=
  type, extends (command_t) :: cmd_graph_t
    private
    type(string_t) :: id
    integer :: n_elements = 0
    type(cmd_plot_t), dimension(:), allocatable :: el
    type(string_t), dimension(:), allocatable :: element_id
  contains
    ⟨Commands: cmd graph: TBP⟩
  end type cmd_graph_t

```

Output. Just print the ID.

```

⟨Commands: cmd graph: TBP⟩=
  procedure :: write => cmd_graph_write

⟨Commands: procedures⟩+=
  subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u

    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)" "graph: ", char (cmd%id), &
      " (" , cmd%n_elements, " entries)"
  end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: compile => cmd_graph_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_compile (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
    integer :: i

    pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      cmd%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("graph: name expression not implemented (yet)")
    end select
    pn_def => parse_node_get_next_ptr (pn_term, 2)
    cmd%n_elements = parse_node_get_n_sub (pn_def)
    allocate (cmd%element_id (cmd%n_elements))
    allocate (cmd%el (cmd%n_elements))
    pn_term => parse_node_get_sub_ptr (pn_def)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%el(1)%init (pn_tag, global)
    cmd%element_id(1) = parse_node_get_string (pn_tag)
    pn_app => parse_node_get_next_ptr (pn_term)
    do i = 2, cmd%n_elements
      pn_term => parse_node_get_sub_ptr (pn_app, 2)
      pn_tag => parse_node_get_sub_ptr (pn_term)
      cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
      call cmd%el(i)%init (pn_tag, global)
      cmd%element_id(i) = parse_node_get_string (pn_tag)
      pn_app => parse_node_get_next_ptr (pn_app)
    end do

  end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: execute => cmd_graph_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_execute (cmd, global)

```

```

class(cmd_graph_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(var_list_t), pointer :: var_list
type(graph_options_t) :: graph_options
type(drawing_options_t) :: drawing_options
integer :: i, type

var_list => cmd%local%get_var_list_ptr ()
call graph_options_init (graph_options)
call set_graph_options (graph_options, var_list)
call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

do i = 1, cmd%n_elements
  if (associated (cmd%el(i)%options)) then
    call cmd%el(i)%options%execute (cmd%el(i)%local)
  end if
  type = analysis_store_get_object_type (cmd%element_id(i))
  select case (type)
  case (AN_HISTOGRAM)
    call drawing_options_init_histogram (drawing_options)
  case (AN_PLOT)
    call drawing_options_init_plot (drawing_options)
  end select
  call set_drawing_options (drawing_options, var_list)
  if (associated (cmd%el(i)%options)) then
    call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
  end if
  call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
end do
end subroutine cmd_graph_execute

```

Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
  type :: analysis_id_t
  type(string_t) :: tag
  type(parse_node_t), pointer :: pn_sexpr => null ()
end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_analysis_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  ⟨Commands: cmd analysis: TBP⟩
end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

<Commands: cmd analysis: TBP>≡
  procedure :: write => cmd_analysis_write

<Commands: procedures>+≡
  subroutine cmd_analysis_write (cmd, unit, indent)
    class(cmd_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "analysis: [defined]"
  end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

<Commands: cmd analysis: TBP>+≡
  procedure :: compile => cmd_analysis_compile

<Commands: procedures>+≡
  subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd analysis: TBP>+≡
  procedure :: execute => cmd_analysis_execute

<Commands: procedures>+≡
  subroutine cmd_analysis_execute (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%analysis_lexpr => cmd%pn_lexpr
  end subroutine cmd_analysis_execute

```

Write histograms and plots

The data type encapsulating the command:

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_write_analysis_t
  private
  type(analysis_id_t), dimension(:), allocatable :: id
  type(string_t), dimension(:), allocatable :: tag
  contains
  <Commands: cmd write analysis: TBP>
  end type cmd_write_analysis_t

```

Output. Just the keyword.

```

<Commands: cmd write analysis: TBP>≡
  procedure :: write => cmd_write_analysis_write

```

```

<Commands: procedures>+≡
subroutine cmd_write_analysis_write (cmd, unit, indent)
  class(cmd_write_analysis_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A)") "write_analysis"
end subroutine cmd_write_analysis_write

```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: compile => cmd_write_analysis_compile

<Commands: procedures>+≡
subroutine cmd_write_analysis_compile (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
  integer :: n, i
  pn_clause => parse_node_get_sub_ptr (cmd%pn)
  pn_args => parse_node_get_sub_ptr (pn_clause, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
  call cmd%compile_options (global)
  if (associated (pn_args)) then
    n = parse_node_get_n_sub (pn_args)
    allocate (cmd%id (n))
    do i = 1, n
      pn_id => parse_node_get_sub_ptr (pn_args, i)
      if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
        cmd%id(i)%tag = parse_node_get_string (pn_id)
      else
        cmd%id(i)%pn_sexpr => pn_id
      end if
    end do
  else
    allocate (cmd%id (0))
  end if
end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

<Commands: parameters>+≡
character(*), parameter, public :: &
  DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
  FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(5), parameter, public :: &
  FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "lo", "la" ]
character(len=3), dimension(16), parameter, public :: &
  FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
    "f95", "log", "ltp", "mpx", "olc", "olp", "pdf", "phs", "sin", "tex" ]

```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```

<Commands: cmd write analysis: TBP>+≡
    procedure :: execute => cmd_write_analysis_execute

<Commands: procedures>+≡
    subroutine cmd_write_analysis_execute (cmd, global)
        class(cmd_write_analysis_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(var_list_t), pointer :: var_list
        var_list => cmd%local%get_var_list_ptr ()
        call write_analysis_wrap (var_list, global%out_files, &
            cmd%id, tag = cmd%tag)
    end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

```

<Commands: procedures>+≡
    subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
        type(var_list_t), intent(inout), target :: var_list

        end if
    end if
end if
end subroutine cmd_printf_execute

```

Record data

The expression syntax already contains a `record` keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

(Commands: types)+≡

```

type, extends (command_t) :: cmd_record_t

```

```

    private
    type(parse_node_t), pointer :: pn_lexpr => null ()
contains
    <Commands: cmd record: TBP>
end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

<Commands: cmd record: TBP>≡
    procedure :: write => cmd_record_write

<Commands: procedures>+≡
    subroutine cmd_record_write (cmd, unit, indent)
        class(cmd_record_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)") "record"
    end subroutine cmd_record_write

```

Compile. This is a hack which transforms the record command into a record expression, which we handle in the expressions module.

```

<Commands: cmd record: TBP>+≡
    procedure :: compile => cmd_record_compile

<Commands: procedures>+≡
    subroutine cmd_record_compile (cmd, global)
        class(cmd_record_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
        call parse_node_create_branch (pn_lexpr, &
            syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))
        call parse_node_create_branch (pn_lsinglet, &
            syntax_get_rule_ptr (syntax_cmd_list, var_str ("lsinglet")))
        call parse_node_append_sub (pn_lexpr, pn_lsinglet)
        call parse_node_create_branch (pn_lterm, &
            syntax_get_rule_ptr (syntax_cmd_list, var_str ("lterm")))
        call parse_node_append_sub (pn_lsinglet, pn_lterm)
        pn_record => parse_node_get_sub_ptr (cmd%pn)
        call parse_node_append_sub (pn_lterm, pn_record)
        cmd%pn_lexpr => pn_lexpr
    end subroutine cmd_record_compile

```

Command execution. Again, transfer this to the embedded expression and just forget the logical result.

```

<Commands: cmd record: TBP>+≡
    procedure :: execute => cmd_record_execute

<Commands: procedures>+≡
    subroutine cmd_record_execute (cmd, global)
        class(cmd_record_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(var_list_t), pointer :: var_list
        logical :: lval

```

```

var_list => global%get_var_list_ptr ()
lval = eval_log (cmd%pn_lexpr, var_list)
end subroutine cmd_record_execute

```

Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

```

⟨Commands: types⟩+≡
type, extends (command_t) :: cmd_unstable_t

end subroutine err_unstable

```

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

```

```

Range expressions

We need a special type for storing and evaluating range expressions.

```

(Commands: parameters) +=
integer, parameter :: STEP_NONE = 0
integer, parameter :: STEP_ADD = 1
integer, parameter :: STEP_SUB = 2
integer, parameter :: STEP_MUL = 3
integer, parameter :: STEP_DIV = 4
integer, parameter :: STEP_COMP_ADD = 11
integer, parameter :: STEP_COMP_MUL = 13

```

There is an abstract base type and two implementations: scan over integers and scan over reals.

```

(Commands: types) +=
type, abstract :: range_t
  type(parse_node_t), pointer :: pn_expr => null ()
  type(parse_node_t), pointer :: pn_term => null ()
  type(parse_node_t), pointer :: pn_factor => null ()
  type(parse_node_t), pointer :: pn_value => null ()
  type(parse_node_t), pointer :: pn_literal => null ()
  type(parse_node_t), pointer :: pn_beg => null ()
  type(parse_node_t), pointer :: pn_end => null ()
  type(parse_node_t), pointer :: pn_step => null ()
  type(eval_tree_t) :: expr_beg
  type(eval_tree_t) :: expr_end
  type(eval_tree_t) :: expr_step
  integer :: step_mode = 0

```

```

        integer :: n_step = 0
contains
    <Commands: range: TBP>
end type range_t

```

These are the implementations:

```

<Commands: types>+≡
    type, extends (range_t) :: range_int_t
        integer :: i_beg = 0
        integer :: i_end = 0
        integer :: i_step = 0
contains
    <Commands: range int: TBP>
end type range_int_t

    type, extends (range_t) :: range_real_t
        real(default) :: r_beg = 0
        real(default) :: r_end = 0
        real(default) :: r_step = 0
        real(default) :: lr_beg = 0
        real(default) :: lr_end = 0
        real(default) :: lr_step = 0
contains
    <Commands: range real: TBP>
end type range_real_t

```

Finalize the allocated dummy node. The other nodes are just pointers.

```

<Commands: range: TBP>≡
    procedure :: final => range_final

<Commands: procedures>+≡
    subroutine range_final (object)
        class(range_t), intent(inout) :: object
        if (associated (object%pn_expr)) then
            call parse_node_final (object%pn_expr, recursive = .false.)
            call parse_node_final (object%pn_term, recursive = .false.)
            call parse_node_final (object%pn_factor, recursive = .false.)
            call parse_node_final (object%pn_value, recursive = .false.)
            call parse_node_final (object%pn_literal, recursive = .false.)
            deallocate (object%pn_expr)
            deallocate (object%pn_term)
            deallocate (object%pn_factor)
            deallocate (object%pn_value)
            deallocate (object%pn_literal)
        end if
    end subroutine range_final

```

Output.

```

<Commands: range: TBP>+≡
    procedure (range_write), deferred :: write
    procedure :: base_write => range_write

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

```

Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions

in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

Note: for the integer/real range array, the obvious implementation as a polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are apparently broken.

```

            cmd%n_values
    end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

```

```

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of `else if` constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

<Commands: types>+=
  type, extends (command_t) :: cmd_if_t
  private
  type(parse_node_t), pointer :: pn_if_lexpr => null ()
  type(command_list_t), pointer :: if_body => null ()
  type(cmd_if_t), dimension(:), pointer :: elsif_cmd => null ()

```

```

        type(command_list_t), pointer :: else_body => null ()
contains
    <Commands: cmd if: TBP>
end type cmd_if_t

```

Finalizer. There are no local options, therefore we can simply override the default finalizer.

```

<Commands: cmd if: TBP>≡
    procedure :: final => cmd_if_final
<Commands: procedures>+≡

            ("End of included '" // char (cmd%file) // "'")
    end if
end subroutine cmd_include_execute

```

Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_quit_t
    private
        logical :: has_code = .false.
        type(parse_node_t), pointer :: pn_code_expr => null ()
    contains
        ⟨Commands: cmd quit: TBP⟩
    end type cmd_quit_t

```

Output.

```

⟨Commands: cmd quit: TBP⟩≡
    procedure :: write => cmd_quit_write

⟨Commands: procedures⟩+≡
    subroutine cmd_quit_write (cmd, unit, indent)
        class(cmd_quit_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return

                is_known=is_known)
            if (.not. is_known) then
                call msg_error ("Undefined return code of quit/exit command")
            end if
        end if
        global%quit = .true.
    end subroutine cmd_quit_execute

```

35.1.6 The command list

The command list holds a list of commands and relevant global data.

```

<Commands: public>+≡
    public :: command_list_t

<Commands: types>+≡
    type :: command_list_t
        ! not private anymore as required by the whizard-c-interface
        class(command_t), pointer :: first => null ()
        class(command_t), pointer :: last => null ()
        contains
        <Commands: command list: TBP>
    end type command_list_t

```

Output.

```

<Commands: command list: TBP>≡
    procedure :: write => command_list_write

<Commands: procedures>+≡
    recursive subroutine command_list_write (cmd_list, unit, indent)
        class(command_list_t), intent(in) :: cmd_list
        integer, intent(in), optional :: unit, indent
        class(command_t), pointer :: cmd
        cmd => cmd_list%first
        do while (associated (cmd))
            call cmd%write (unit, indent)
            cmd => cmd%next
        end do
    end subroutine command_list_write

```

Append a new command to the list and free the original pointer.

```

⟨Commands: command list: TBP⟩+≡
    procedure :: append => command_list_append

⟨Commands: procedures⟩+≡
    subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
        if (associated (cmd_list%last)) then
            cmd_list%last%next => command
        else
            cmd_list%first => command
        end if
        cmd_list%last => command
        command => null ()
    end subroutine command_list_append

```

Finalize.

```

⟨Commands: command list: TBP⟩+≡
    procedure :: final => command_list_final

⟨Commands: procedures⟩+≡
    recursive subroutine command_list_final (cmd_list)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), pointer :: command
        do while (associated (cmd_list%first))
            command => cmd_list%first
            cmd_list%first => cmd_list%first%next
            call command%final ()
            deallocate (command)
        end do
        cmd_list%last => null ()
    end subroutine command_list_final

```

35.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```

⟨Commands: command list: TBP⟩+≡
    procedure :: compile => command_list_compile

⟨Commands: procedures⟩+≡
    recursive subroutine command_list_compile (cmd_list, pn, global)
        class(command_list_t), intent(inout), target :: cmd_list
        type(parse_node_t), intent(in), target :: pn
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_cmd
        class(command_t), pointer :: command
        integer :: i
        pn_cmd => parse_node_get_sub_ptr (pn)
        do i = 1, parse_node_get_n_sub (pn)
            call dispatch_command (command, pn_cmd)
        end do
    end subroutine command_list_compile

```

```

        call command%compile (global)
        call cmd_list%append (command)
        call terminate_now_if_signal ()
        pn_cmd => parse_node_get_next_ptr (pn_cmd)
    end do
end subroutine command_list_compile

```

35.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```

<Commands: command list: TBP>+≡
    procedure :: execute => command_list_execute

    recursive subroutine command_list_execute (cmd_list, global)
        class(command_list_t), intent(in) :: cmd_list
        type(rt_data_t), intent(inout), target :: global
        class(command_t), pointer :: command
        command => cmd_list%first
        COMMAND_COND: do while (associated (command))
            call command%execute_options (global)
            call command%execute (global)
            call command%reset_options (global)
            call terminate_now_if_signal ()
            if (global%quit) exit COMMAND_COND
            command => command%next
        end do COMMAND_COND
    end subroutine command_list_execute

```

35.1.9 Command list syntax

```

<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡
    public :: syntax_cmd_list_init

end subroutine commands_34

```

For this test, we invent a callback object which simply writes the analysis file, using the standard call for this. Here we rely on the fact that the analysis data are stored as a global entity, otherwise we would have to access them via the event object.

```

<Commands: test auxiliary types>≡
type, extends (event_callback_t) :: event_callback_34_t
  private
  integer :: u = 0
contains
  procedure :: write => event_callback_34_write
  procedure :: proc => event_callback_34
end type event_callback_34_t

```

The output routine is unused. The actual callback should write the analysis data to the output unit that we have injected into the callback object.

```

<Commands: test auxiliary>+≡
subroutine event_callback_34_write (event_callback, unit)
  class(event_callback_34_t), intent(in) :: event_callback
  integer, intent(in), optional :: unit
end subroutine event_callback_34_write

subroutine event_callback_34 (event_callback, i, event)
  class(event_callback_34_t), intent(in) :: event_callback
  integer(i64), intent(in) :: i
  class(generic_event_t), intent(in) :: event
  call analysis_write (event_callback%u)
end subroutine event_callback_34

```

35.2 Toplevel module WHIZARD

```
<whizard.f90>≡  
  <File header>  
  
  module whizard  
  
    use io_units  
    <Use strings>  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF, BACKSLASH  
    use diagnostics  
    use os_interface  
    use ifiles  
    use lexers  
    use parser  
    use variables, only: var_list_t  
    use eval_trees  
    use models  
    use phs_forests  
    use prclib_stacks  
    use slha_interface  
    use blha_config  
    use rt_data  
    use commands  
  
    <Standard module head>  
  
    <WHIZARD: public>  
  
    <WHIZARD: types>  
  
    save  
  
    contains  
  
    <WHIZARD: procedures>  
  
  end module whizard
```

35.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```
<WHIZARD: public>≡  
  public :: whizard_options_t  
  
<WHIZARD: types>≡  
  type :: whizard_options_t  
    type(string_t) :: preload_model  
    type(string_t) :: default_lib  
    type(string_t) :: preload_libraries  
    logical :: rebuild_library = .false.
```

```

        logical :: recompile_library = .false.
        logical :: rebuild_user
        logical :: rebuild_phs = .false.
        logical :: rebuild_grids = .false.
        logical :: rebuild_events = .false.
    end type whizard_options_t

```

35.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

<WHIZARD: types> +=
    type, extends (parse_tree_t) :: pt_entry_t
        type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the `last` pointer.

```

<WHIZARD: types> +=
    type :: pt_stack_t
        type(pt_entry_t), pointer :: last => null ()
        contains
            <WHIZARD: pt_stack: TBP>
    end type pt_stack_t

```

The finalizer is called at the very end.

```

<WHIZARD: pt_stack: TBP> =
    procedure :: final => pt_stack_final

<WHIZARD: procedures> =
    subroutine pt_stack_final (pt_stack)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(pt_entry_t), pointer :: current
        do while (associated (pt_stack%last))
            current => pt_stack%last
            pt_stack%last => current%previous
            call parse_tree_final (current%parse_tree_t)
            deallocate (current)
        end do
    end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt_stack: TBP> +=
    procedure :: push => pt_stack_push

<WHIZARD: procedures> +=
    subroutine pt_stack_push (pt_stack, parse_tree)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(parse_tree_t), intent(out), pointer :: parse_tree
        type(pt_entry_t), pointer :: current

```

```

allocate (current)
parse_tree => current%parse_tree_t
current%previous => pt_stack%last
pt_stack%last => current
end subroutine pt_stack_push

```

35.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a `WHIZARD` instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+≡
public :: whizard_t

<WHIZARD: types>+≡
type :: whizard_t
type(whizard_options_t) :: options
type(rt_data_t) :: global
type(pt_stack_t) :: pt_stack
contains
<WHIZARD: whizard: TBP>
end type whizard_t

```

35.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>≡
procedure :: init => whizard_init

<WHIZARD: procedures>+≡
subroutine whizard_init (whizard, options, paths, logfile)
class(whizard_t), intent(out), target :: whizard
type(whizard_options_t), intent(in) :: options
type(paths_t), intent(in), optional :: paths
type(string_t), intent(in), optional :: logfile
call init_syntax_tables ()
whizard%options = options
call whizard%global%global_init (paths, logfile)
call whizard%init_rebuild_flags ()
call whizard%preload_model ()
call whizard%preload_library ()
call whizard%global%init_fallback_model &
(var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))

```

```
end subroutine whizard_init
```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```
<WHIZARD: whizard: TBP>+≡
  procedure :: final => whizard_final
<WHIZARD: procedures>+≡
  subroutine whizard_final (whizard)
    class(whizard_t), intent(inout), target :: whizard
    call whizard%global%final ()
    call whizard%pt_stack%final ()
    !!! JRR: WK please check (#529)
    !   call user_code_final ()
    call final_syntax_tables ()
  end subroutine whizard_final
```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```
<WHIZARD: whizard: TBP>+≡
  procedure :: init_rebuild_flags => whizard_init_rebuild_flags
<WHIZARD: procedures>+≡
  subroutine whizard_init_rebuild_flags (whizard)
    class(whizard_t), intent(inout), target :: whizard
    associate (var_list => whizard%global%var_list, options => whizard%options)
      call var_list%append_log (var_str ("?rebuild_library"), &
        options%rebuild_library, intrinsic=.true.)
      call var_list%append_log (var_str ("?recompile_library"), &
        options%recompile_library, intrinsic=.true.)
      call var_list%append_log (var_str ("?rebuild_phase_space"), &
        options%rebuild_phs, intrinsic=.true.)
      call var_list%append_log (var_str ("?rebuild_grids"), &
        options%rebuild_grids, intrinsic=.true.)
      call var_list%append_log (var_str ("?powheg_rebuild_grids"), &
        options%rebuild_grids, intrinsic=.true.)
      call var_list%append_log (var_str ("?rebuild_events"), &
        options%rebuild_events, intrinsic=.true.)
    end associate
  end subroutine whizard_init_rebuild_flags
```

This procedure preloads a model, if a model name is given.

```
<WHIZARD: whizard: TBP>+≡
  procedure :: preload_model => whizard_preload_model
<WHIZARD: procedures>+≡
  subroutine whizard_preload_model (whizard)
    class(whizard_t), intent(inout), target :: whizard
    type(string_t) :: model_name
    model_name = whizard%options%preload_model
    if (model_name /= "") then
      call whizard%global%read_model (model_name, whizard%global%preload_model)
      whizard%global%model => whizard%global%preload_model
    end if
  end subroutine whizard_preload_model
```

```

        if (associated (whizard%global%model)) then
            call whizard%global%model%link_var_list (whizard%global%var_list)
            call msg_message ("Preloaded model: " &
                             // char (model_name))
        else
            call msg_fatal ("Preloading model " // char (model_name) &
                           // " failed")
        end if
    else
        call msg_message ("No model preloaded")
    end if
end subroutine whizard_preload_model

```

This procedure preloads a library, if a library name is given.

Note: This version just opens a new library with that name. It does not load (yet) an existing library on file, as previous WHIZARD versions would do.

<WHIZARD: whizard: TBP>+≡

```

    procedure :: preload_library => whizard_preload_library

```

<WHIZARD: procedures>+≡

```

subroutine whizard_preload_library (whizard)
    class(whizard_t), intent(inout), target :: whizard

        call split (libs, library_name, " ")
        if (library_name /= "") then
            allocate (lib_entry)
            call lib_entry%init (library_name)
            call whizard%global%add_prclib (lib_entry)
            call msg_message ("Preloaded library: " // char (library_name))
        end if
    end do SCAN_LIBS
end subroutine whizard_preload_library

```

35.2.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

```
<WHIZARD: public>+≡
    public :: init_syntax_tables
    public :: final_syntax_tables

<WHIZARD: procedures>+≡
    subroutine init_syntax_tables ()
        call syntax_model_file_init ()
        call syntax_phs_forest_init ()
        call syntax_pexpr_init ()
        call syntax_slha_init ()
        call syntax_cmd_list_init ()
    end subroutine init_syntax_tables

    subroutine final_syntax_tables ()
        call syntax_model_file_final ()
        call syntax_phs_forest_final ()
        call syntax_pexpr_final ()
        call syntax_slha_final ()
        call syntax_cmd_list_final ()
    end subroutine final_syntax_tables
```

Write the syntax tables to external files.

```
<WHIZARD: public>+≡
    public :: write_syntax_tables

<WHIZARD: procedures>+≡
    subroutine write_syntax_tables ()
        integer :: unit
        character(*), parameter :: file_model = "whizard.model_file.syntax"
        character(*), parameter :: file_phs = "whizard.phase_space_file.syntax"
        character(*), parameter :: file_pexpr = "whizard.prt_expressions.syntax"
        character(*), parameter :: file_slha = "whizard.slha.syntax"
        character(*), parameter :: file_sindarin = "whizard.sindarin.syntax"
        unit = free_unit ()
        print *, "Writing file '" // file_model // "'"
        open (unit=unit, file=file_model, status="replace", action="write")

35.5 Driver program

The main program handles command options, initializes the environment, and runs WHIZARD in a particular mode (interactive, file, standard input).

This is also used in the C interface:

```
<Main: cmdline arg len declaration>≡  
    integer, parameter :: CMDLINE_ARG_LEN = 1000
```

The actual main program:

```
<main.f90>≡  
<File header>  
  
program main  
  
    <Use strings>  
    use system_dependencies  
    use diagnostics  
    use ifiles  
    use os_interface  
    use whizard  
  
    use cmdline_options  
    use features  
  
    implicit none  
  
    <Main: cmdline arg len declaration>  
  
    !!! (WK 02/2016) Interface for the separate external routine below  
    interface  
        subroutine print_usage ()  
        end subroutine print_usage  
    end interface

35.6.1 Self-tests

For those self-tests, we need some auxiliary routines that provide an environment. The environment depends on things that are not available at the level of the module that we want to test.

Testbed for event I/O

This subroutine prepares a test process with a single event. All objects are allocated via anonymous pointers, because we want to recover the pointers and delete the objects in a separate procedure.

```

<Main: tests>≡
subroutine prepare_eio_test (event, unweighted, n_alt)
    use variables, only: var_list_t
    use model_data
    use process, only: process_t
    use instances, only: process_instance_t
    use processes_ut, only: prepare_test_process
    use event_base
    use events

    class(generic_event_t), intent(inout), pointer :: event
    logical, intent(in), optional :: unweighted
    integer, intent(in), optional :: n_alt
    type(model_data_t), pointer :: model

```

```

type(var_list_t) :: var_list
type(process_t), pointer :: proc
type(process_instance_t), pointer :: process_instance

allocate (model)
call model%init_test ()

allocate (proc)
allocate (process_instance)

call prepare_test_process (proc, process_instance, model)
call process_instance%setup_event_data ()

call model%final ()
deallocate (model)

allocate (event_t :: event)
select type (event)
type is (event_t)
  if (present (unweighted)) then
    call var_list%append_log (&
      var_str ("?unweighted"), unweighted, &
      intrinsic = .true.)
  else
    call var_list%append_log (&
      var_str ("?unweighted"), .true., &
      intrinsic = .true.)
  end if
  call var_list%append_string (&
    var_str ("sample_normalization"), &
    var_str ("auto"), intrinsic = .true.)
  call event%basic_init (var_list, n_alt)
  call event%connect (process_instance, proc%get_model_ptr ())
  call var_list%final ()
end select

end subroutine prepare_eio_test

```

Recover those pointers, finalize the objects and deallocate.

(Main: tests)+≡

```

subroutine cleanup_eio_test (event)
  use model_data
  use process, only: process_t
  use instances, only: process_instance_t
  use processes_ut, only: cleanup_test_process
  use event_base
  use events

  class(generic_event_t), intent(inout), pointer :: event
  type(process_t), pointer :: proc
  type(process_instance_t), pointer :: process_instance

  select type (event)
  type is (event_t)

```

```

        proc => event%get_process_ptr ()
        process_instance => event%get_process_instance_ptr ()
        call cleanup_test_process (proc, process_instance)
        deallocate (process_instance)
        deallocate (proc)
        call event%final ()
    end select
    deallocate (event)

end subroutine cleanup_eio_test

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

<Main: use tests>≡
    use eio_base_ut, only: eio_prepare_test
    use eio_base_ut, only: eio_cleanup_test

<Main: prepare testbed>≡
    eio_prepare_test => prepare_eio_test
    eio_cleanup_test => cleanup_eio_test

```

Any Model

This procedure reads any model from file and, optionally, assigns a var-list pointer.

```

<Main: tests>+≡
    subroutine prepare_whizard_model (model, name, vars)
    <Use strings>
        use os_interface
        use model_data
        use var_base
        use models
        class(model_data_t), intent(inout), pointer :: model
        type(string_t), intent(in) :: name
        class(vars_t), pointer, intent(out), optional :: vars
        type(os_data_t) :: os_data
        call syntax_model_file_init ()
        call os_data_init (os_data)
        allocate (model_t :: model)
        select type (model)
        type is (model_t)
            call model%read (name // ".mdl", os_data)
            if (present (vars)) then
                vars => model%get_var_list_ptr ()
            end if
        end select
    end subroutine prepare_whizard_model

```

Cleanup after use. Includes deletion of the model-file syntax.

```

<Main: tests>+≡
    subroutine cleanup_whizard_model (model)
        use model_data
        use models

```

```

class(model_data_t), intent(inout), pointer :: model
call model%final ()
deallocate (model)
call syntax_model_file_final ()
end subroutine cleanup_whizard_model

```

Assign those procedures to appropriate pointers (module variables) in the `model_testbed` module, so they can be called as if they were module procedures.

```

(Main: prepare_testbed)+≡
prepare_model => prepare_whizard_model
cleanup_model => cleanup_whizard_model

```

Fallback model: hadrons

Some event format tests require the hadronic SM implementation, which has to be read from file. We provide the functionality here, so the tests do not depend on model I/O.

```

(Main: tests)+≡
subroutine prepare_fallback_model (model)
use model_data
class(model_data_t), intent(inout), pointer :: model
call prepare_whizard_model (model, var_str ("SM_hadrons"))
end subroutine prepare_fallback_model

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

(Main: use_tests)+≡
use eio_base_ut, only: eio_prepare_fallback_model
use eio_base_ut, only: eio_cleanup_fallback_model

(Main: prepare_testbed)+≡
eio_prepare_fallback_model => prepare_fallback_model
eio_cleanup_fallback_model => cleanup_model

```

Access to the test random-number generator

This generator is not normally available for the dispatcher. We assign an additional dispatch routine to the hook in the `dispatch` module which will be checked before the default rule.

```

(Main: use_tests)+≡
use dispatch_rng, only: dispatch_rng_factory_extra
use dispatch_rng_ut, only: dispatch_rng_factory_test

(Main: prepare_testbed)+≡
dispatch_rng_factory_extra => dispatch_rng_factory_test

```

Access to the test structure functions

These are not normally available for the dispatcher. We assign an additional dispatch routine to the hook in the `dispatch` module which will be checked before the default rule.

```

(Main: use_tests)+≡

```

```

        use dispatch_beams, only: dispatch_sf_data_extra
        use dispatch_ut, only: dispatch_sf_data_test
    <Main: prepare testbed>+≡
        dispatch_sf_data_extra => dispatch_sf_data_test

```

Procedure for Checking

This is for developers only, but needs a well-defined interface.

```

    <Main: tests>+≡
        subroutine whizard_check (check, results)
            type(string_t), intent(in) :: check
            type(test_results_t), intent(inout) :: results
            type(os_data_t) :: os_data
            integer :: u
            call os_data_init (os_data)
            u = free_unit ()
            open (u, file="whizard_check." // char (check) // ".log", &
                action="write", status="replace")
            call msg_message (repeat ('=', 76), 0)
            call msg_message ("Running self-test: " // char (check), 0)
            call msg_message (repeat ('-', 76), 0)
        <Main: prepare testbed>
            select case (char (check))
        <Main: test cases>
            case ("all")
                <Main: all tests>
            case default
