```

In the soft limit, our treatment of the divergences requires a modification of the mapping functions. Recall that there, the ratios of the d -functions must approach either 1 or 0. This means

$$\frac{d_{lm}}{d_{0m}} = \frac{(2k_l \cdot k_m) [E_l E_m / (E_l + E_m)^2]}{E_m^2 (1 - y^2)} \stackrel{k_m = E_m \hat{k}}{=} \frac{E_l E_m^2}{(E_l + E_m)^2} \frac{2k_l \cdot \hat{k}}{E_m^2 (1 - y^2)} \stackrel{E_m \rightarrow 0}{=} \frac{2}{k_l \cdot \hat{k}} (1 - y^2) E_l,$$

where we have written the gluon momentum in terms of the soft momentum \hat{k} . In the same limit

$$\frac{d_{lm}}{d_{nm}} = \frac{k_l \cdot \hat{k}}{k_n \cdot \hat{k}} \frac{E_n}{E_l}.$$

From these equations we can deduce the soft limit of d :

$$\begin{aligned} d_0^{\text{soft}} &= 1 - y^2, \\ d_1^{\text{soft}} &= 2(1 - y), \\ d_2^{\text{soft}} &= 2(1 + y), \\ d_i^{\text{soft}} &= \frac{2k_i \cdot \hat{k}}{E_i}. \end{aligned}$$

The $d_{ij,k}$ -functions for the resonance mapping are basically the same as in the default case, but the kinematical values here must be evaluated in the resonance frame of reference. The energy of parton i in a given resonance frame with momentum p_{res} is

$$E_i = \frac{p_i^0 \cdot p_{res}}{m_{res}}.$$

However, since the expressions only depend on ratios of four-momenta, we leave out the denominator because it will cancel out anyway.

The virtual subtraction terms contain Casimir operators and derived constants, listed below:

$$C(q) = C(\bar{q}) = C_F, \quad (27.2)$$

$$C(g) = C_A, \quad (27.3)$$

$$\gamma(q) = \gamma(\bar{q}) = \frac{3}{2}C_F, \quad (27.4)$$

$$\gamma(g) = \frac{11}{6}C_A - \frac{2}{3}T_F N_f, \quad (27.5)$$

$$\gamma'(q) = \gamma'(\bar{q}) = \left(\frac{13}{2} - \frac{2\pi^2}{3} \right) C_F, \quad (27.6)$$

$$\gamma'(g) = \left(\frac{67}{9} - \frac{2\pi^2}{3} \right) C_A - \frac{23}{9}T_F N_f. \quad (27.7)$$

For uncolored particles, `virtual_init_constants` sets C , γ and γ' to zero.

The virtual-subtracted matrix element is given by the equation

$$\mathcal{V} = \frac{\alpha_s}{2\pi} \left(\mathcal{Q}\mathcal{B} + \sum \mathcal{I}_{ij} \mathcal{B}_{ij} + \mathcal{V}_{fin} \right), \quad (27.8)$$

The expressions for \mathcal{Q} can be found in equations 27.9 and 27.11. The expressions for \mathcal{I}_{ij} can be found in equations (27.12), (27.13), (27.14), depending on whether the particles involved in the radiation process are massive or massless.

The collinear limit of $\tilde{\mathcal{R}}$ can be integrated over the radiation degrees of freedom, giving the collinear contribution to the virtual component. Its general structure is $\mathcal{Q} \cdot \mathcal{B}$. The initial-state contribution to \mathcal{Q} is simply given by

$$\mathcal{Q} = -\log \frac{\mu_F^2}{Q^2} (\gamma(\mathcal{I}_1) + \gamma(\mathcal{I}_2)), \quad (27.9)$$

where Q^2 is the Ellis-Sexton scale and γ is as in eqns. 27.4 and 27.5. `virtual_evaluate_initial_state` computes this quantity. The loop over the initial-state particles is only executed if we are dealing with a scattering process, because for decays there are no virtual initial-initial interactions.

```

<virtual: virtual: TBP>+=
  procedure :: evaluate_initial_state => virtual_evaluate_initial_state
<virtual: procedures>+=
  subroutine virtual_evaluate_initial_state (virt, i_flv, sqrts, reg_data, sqme, QB)
    class(virtual_t), intent(inout) :: virt

    if (virt%n_in == 2) then
      i_sqme = virt%me_index(i_flv) + 1
      do i = 1, virt%n_in
        QB(i_flv) = QB(i_flv) - virt%gamma_0(i, i_flv) * &
          log(virt%fac_scale**2 / virt%es_scale2) * sqme(i_sqme)
      end do
    end if
  end subroutine virtual_evaluate_initial_state

```

Same as above, but for final-state particles. The collinear limit for final-state particles follows from the integral

$$I_{+, \alpha_r} = \int d\Phi_{n+1} \frac{\xi_+^{-1-2\epsilon}}{\xi_-^{-1-2\epsilon}} \mathcal{R}_{\alpha_r}.$$

We can distinguish three situations:

1. α_r contains a massive emitter. In this case, no collinear subtraction terms is required and the integral above irrelevant.
2. α_r contains a massless emitter, but resonances are not taken into account in the subtraction. Here, $\xi_{max} = \frac{2E_{em}}{\sqrt{s}}$ is the upper bound on ξ .
3. α_r contains a massless emitter and resonance-aware subtraction is used. Here, $\xi_{max} = \frac{2E_{em}}{\sqrt{k_{res}^2}}$.

Before version 2.4, only situations 1 and 2 were covered. The difference between situation 2 and 3 comes from the expansion of the plus-distribution in the integral above,

$$\xi_+^{-1-2\epsilon} = \xi^{-1-2\epsilon} + \frac{1}{2\epsilon} \delta(\xi) = \xi_{max}^{-1-2\epsilon} \left[(1-z)^{-1-2\epsilon} + \frac{\xi_{max}^{2\epsilon}}{2\epsilon} \delta(1-z) \right].$$

The expression from the standard FKS literature is given by \mathcal{Q} is given by

$$\begin{aligned}
\mathcal{Q} = \sum_{k=n_{in}}^{n_L^{(B)}} & \left[\gamma'(\mathcal{I}_k) - \log \frac{s}{2Q^2} \left(\gamma(\mathcal{I}_k) - 2C(\mathcal{I}_k) \log \frac{2E_k}{\sqrt{s}} \right) \right. \\
& \left. + 2C(\mathcal{I}_k) \log^2 \frac{2E_k}{\sqrt{s}} - 2\gamma(\mathcal{I}_k) \log \frac{2E_k}{\sqrt{s}} \right].
\end{aligned} \tag{27.10}$$

$n_L^{(B)}$ is the number of legs at Born level. Here, ξ_{max} is implicitly present in the ratios in the logarithms. Using the resonance-aware ξ_{max} yields

$$\mathcal{Q} = \sum_{k=n_{in}}^{n_L^{(B)}} \left[\gamma'(\mathcal{I}_k) + \left(\log \frac{\sqrt{s}}{2E_{em}} + \log \xi_{max} \right) \left(\log \frac{\sqrt{s}}{2E_{em}} + \log \xi_{max} + \log \frac{Q^2}{s} \right) C(\mathcal{I}_k) \right. \\ \left. + 2 \log \xi_{max} \left(\log \xi_{max} - \log \frac{Q^2}{k_{res}^2} \right) C(\mathcal{I}_k) + \left(\frac{Q^2}{k_{res}^2} - 2 \log \xi_{max} \right) \gamma(\mathcal{I}_k) \right]. \quad (27.11)$$

Equation 27.11 leads to 27.10 with the substitutions $\xi_{max} \rightarrow \frac{2E_{em}}{\sqrt{s}}$ and $k_{res}^2 \rightarrow s$. `virtual_compute_collinear_contribution` only implements the second one.

The following code implements the \mathcal{I}_{ij} -function appearing in eq. blub. They are defined as follows:

Massless-Massless Case

$$\begin{aligned}\mathcal{I}_{ij} = & \frac{1}{2} \log^2 \frac{s}{Q^2} + \log \frac{s}{Q^2} \log \frac{k_i k_j}{2E_i E_j} - \text{Li}_2 \left(\frac{k_i k_j}{2E_i E_j} \right) \\ & + \frac{1}{2} \log^2 \frac{k_i k_j}{2E_i E_j} - \log \left(1 - \frac{k_i k_j}{2E_i E_j} \right) \log \frac{k_i k_j}{2E_i E_j}.\end{aligned}\quad (27.12)$$

Massive-Massive Case

$$\mathcal{I}_{ij} = -\frac{1}{2} I_0(k_i, k_j) \log \frac{Q^2}{s} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (27.13)$$

with

$$I_0(k_i, k_j) = \frac{1}{\beta} \log \frac{1+\beta}{1-\beta}, \quad \beta = \sqrt{1 - \frac{k_i^2 k_j^2}{(k_i \cdot k_j)^2}}$$

and a rather involved expression for I_ϵ :

$$\begin{aligned}I_\epsilon(k_i, k_j) = & (K(z_j) - K(z_i)) \frac{1 - \vec{\beta}_i \cdot \vec{\beta}_j}{\sqrt{a(1-b)}}, \\ \vec{\beta}_i = & \frac{\vec{k}_i}{k_i^0}, \\ a = & \beta_i^2 + \beta_j^2 - 2\vec{\beta}_i \cdot \vec{\beta}_j, \\ x_i = & \frac{\beta_i^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a}, \\ x_j = & \frac{\beta_j^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a} = 1 - x_i, \\ b = & \frac{\beta_i^2 \beta_j^2 - (\vec{\beta}_i \cdot \vec{\beta}_j)^2}{a}, \\ c = & \sqrt{\frac{b}{4a}}, \\ z_+ = & \frac{1 + \sqrt{1-b}}{\sqrt{b}}, \\ z_- = & \frac{1 - \sqrt{1-b}}{\sqrt{b}}, \\ z_i = & \frac{\sqrt{x_i^2 + 4c^2} - x_i}{2c}, \\ z_j = & \frac{\sqrt{x_j^2 + 4c^2} + x_j}{2c}, \\ K(z) = & -\frac{1}{2} \log^2 \frac{(z - z_-)(z_+ - z)}{(z_+ + z)(z_- + z)} - 2\text{Li}_2 \left(\frac{2z_-(z_+ - z)}{(z_+ - z_-)(z_- + z)} \right) \\ & - 2\text{Li}_2 \left(-\frac{2z_+(z_- + z)}{(z_+ - z_-)(z_+ - z)} \right)\end{aligned}$$

Massive-Massless Case

$$\mathcal{I}_{ij} = \frac{1}{2} \left[\log^2 \frac{Q}{s} - \frac{\pi^2}{6} \right] - \frac{1}{2} I_0(k_i, k_j) \log \frac{Q^2}{s} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (27.14)$$

with

$$I_0(p, k) = \log \frac{(\hat{p} \cdot \hat{k})^2}{\hat{k}^2},$$

$$I_\epsilon(p, k) = -2 \left[\frac{1}{4} \log^2 \frac{1-\beta}{1+\beta} + \log \frac{\hat{p} \cdot \hat{k}}{1+\beta} \log \frac{\hat{p} \cdot \hat{k}}{1-\beta} + Li_2 \left(1 - \frac{\hat{p} \cdot \hat{k}}{1+\beta} \right) + Li_2 \left(1 - \frac{\hat{p} \cdot \hat{k}}{1-\beta} \right) \right]$$

using

$$\hat{p} = \frac{p}{p^0}, \quad \hat{k} = \frac{k}{k^0}, \quad \beta = \frac{|\vec{k}|}{k_0}.$$

The treatment of the momentum k follows the discussion about the soft limit of the partition functions (ref????). The parton momentum is pulled out, $k = E\hat{k}$. In fact, we will substitute \hat{k} for k throughout the code, because the energy will factor out of the equation when the soft \mathcal{S} -function is multiplied. The soft momentum is a unit vector, because $k^2 = (k^0)^2 - (\vec{k})^2 = 0$.

The soft momentum is constructed by first creating a unit vector parallel to the emitter's Born momentum. This unit vector is then rotated about the corresponding angles y and ϕ .

The soft vector for the real mismatch is basically the same as for usual FSR, except for the scaling with the total gluon energy. Moreover, the resulting vector is rotated into the frame where the 3-axis points along the direction of the emitter. This is necessary because in the collinear limit, the approximation

$$k_i = \frac{k_i^0}{\bar{k}_j^0} \bar{k}_j = \frac{\xi \sqrt{s}}{2\bar{k}_j^0} \bar{k}_j$$

is used. The collinear limit is not included in the soft mismatch yet, but we keep the rotation for future usage here already (the performance loss is negligible).

```

```

Computation of the soft limit of R_α . Note that what we are actually integrating (in the case of final-state radiation) is the quantity $f(0, y)/\xi$, where

$$f(\xi, y) = \frac{J(\xi, y, \phi)}{\xi} \xi^2 R_\alpha.$$

J/ξ is computed by the phase space generator. The additional factor of ξ^{-1} is supplied in the `evaluate_region_fsr`-routine. Thus, we are left with a factor of ξ^2 . A look on the expression for the soft limit of R_α below reveals that we are factoring out the gluon energy E_i in the denominator. Therefore, we have a factor $\xi^2/E_i^2 = q^2/4$.

Note that the same routine is used also for the computation of the soft mismatch. There, the gluon energy is not factored out from the soft vector, so that we are left with the ξ^2 -factor, which will eventually be cancelled out again. So, we just multiply with 1. Both cases are distinguished by the flag `xi2_expanded`.

We have to multiply this with $\xi^2(1 - y)$. Further, when applying the soft \mathcal{S} -function, the energy of the radiated particle is factored out. Thus we have

$\xi^2/E_{em}^2(1-y) = 4/q_0^2(1-y)$. Computes the quantity $\mathcal{K}_{ij} = \frac{k_i \cdot k_j}{(k_i \cdot k)(k_j \cdot k)}$.

27.5.2 Collinear and soft-collinear subtraction terms

This data type deals with the calculation of the collinear and soft-collinear contribution to the cross section.

```

<real subtraction: types>+≡
  type :: coll_subtraction_t
    integer :: n_in, n_alr
    logical :: use_resonance_mappings = .false.
  contains
    <real subtraction: coll sub: TBP>
  end type coll_subtraction_t

<real subtraction: coll sub: TBP>≡
  procedure :: init => coll_subtraction_init

<real subtraction: procedures>+≡
  subroutine coll_subtraction_init (coll_sub, n_alr, n_in)
    class(coll_subtraction_t), intent(inout) :: coll_sub
    integer, intent(in) :: n_alr, n_in
    coll_sub%n_in = n_in
    coll_sub%n_alr = n_alr
  end subroutine coll_subtraction_init

```

To compute the collinear limit of \mathcal{R} , we follow the original FKS-paper. Here, the real amplitude is supposed to factorize in the collinear limit. considering a splitting $g \rightarrow g(i)g(j)$,

$$\mathcal{A}^{(n)}(h_i, h_j, \{h_l\}) \xrightarrow{i||j} g_s \sum_{d_e} \sum_{h_e} C(d_e, b, c) S_{gg}^{h_e h_i h_j}(z) \mathcal{A}_{d_e}^{(n-1)}(h_e, \{h_l\})$$

Explain quantities. Evaluating this expression leads to

$$|\mathcal{A}^{(n)}(h_i, h_j, \{h_l\})|^2 \xrightarrow{i||j} |\mathcal{N}^{(n)}(h_i, h_j, \{h_l\})|^2 + \mathcal{R}(h_i, h_j, \{h_l\})^2,$$

where \mathcal{R} contains all contributions with spin-correlated amplitudes, i.e. terms like $\mathcal{A}_{d_e}^{(n-1)}(+, \{h_l\}) \left(\mathcal{A}_{d_e}^{(n-1)}(-, \{h_l\}) \right)^*$. Explicitly,

$$\sum_{h_i, h_j, \{h_l\}} \sum_{\{d_l\}} |\mathcal{N}^{(n)}(h_i, h_j, \{h_l\})|^2 = \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{gg}(z) |\mathcal{A}^{(n-1)}|^2,$$

and

$$\begin{aligned} \sum_{h_i, h_j, \{h_l\}} \sum_{\{d_l\}} \mathcal{R}(h_i, h_j, \{h_l\}) &= 32\pi\alpha_s C_A z(1-z) \\ &\times \underbrace{Re \left\{ \frac{\langle ij \rangle}{[ij]} \sum_{\{h_l\}} \sum_{d_e, \{d_l\}} \mathcal{A}_{d_e}^{(n-1)}(+, \{h_l\}) \left(\mathcal{A}_{d_e}^{(n-1)}(-, \{h_l\}) \right)^* \right\}}_{-\tilde{\mathcal{M}}^{(n-1)}/(2k_i \cdot k_j)}. \end{aligned}$$

This yields

$$\mathcal{M}^{(n)} \xrightarrow{i||j} \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{gg}(z) \mathcal{M}^{(n-1)} - \frac{16\pi\alpha_s}{k_i \cdot k_j} C_A z(1-z) \tilde{\mathcal{M}}^{(n-1)}. \quad (27.15)$$

The equivalent expression for a $g \rightarrow qq$ -splitting is given by

$$\mathcal{M}^{(n)} \xrightarrow{i||j} \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{qg}(z) \mathcal{M}^{(n-1)} + \frac{16\pi\alpha_s}{k_i \cdot k_j} T_F z(1-z) \tilde{\mathcal{M}}^{(n-1)}. \quad (27.16)$$

The function obtains a flag to indicate whether the limit to be computed is also soft. Moreover, this consideration explains the structure of the code. In the soft limit, we find $z \rightarrow 0$ as well as $\xi \rightarrow 0$. However, the quantity z/ξ is finite, because

$$\frac{z}{\xi} = \frac{p_{rad}^0}{\bar{p}_{em}^0} \frac{q^0}{2p_{rad}^0} = \frac{q^0}{2\bar{p}_{em}^0}.$$

Thus, all expressions are written in terms of this well-behaved quantity. Recalling that there is a prefactor of $(\xi^2 z)^{-1}$, it is necessary to expand with z once.

27.5.4 The real contribution to the cross section

In each singular region α , the real contribution to σ is given by the second summand of eqn. ??,

$$\sigma_{\text{real}}^{\alpha} = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 dy \int_0^{\xi_{\text{max}}} d\xi \left(\frac{1}{\xi} \right)_+ \left(\frac{1}{1-y} \right)_+ \underbrace{\frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1-y)\xi^2 \mathcal{R}^{\alpha}(\Phi_{n+1})]}_{g^{\alpha}(\xi, y)} \quad (27.17)$$

Writing out the plus-distribution and introducing $\tilde{\xi} = \xi/\xi_{\text{max}}$ to set the upper integration limit to 1, this turns out to be equal to

$$\sigma_{\text{real}}^{\alpha} = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 \frac{dy}{1-y} \left\{ \int_0^1 d\tilde{\xi} \left[\frac{g^{\alpha}(\tilde{\xi}\xi_{\text{max}}, y)}{\tilde{\xi}} - \underbrace{\frac{g^{\alpha}(0, y)}{\tilde{\xi}}}_{\text{soft}} - \underbrace{\frac{g^{\alpha}(\tilde{\xi}\xi_{\text{max}}, 1)}{\tilde{\xi}}}_{\text{coll.}} + \underbrace{\frac{g^{\alpha}(0, 1)}{\tilde{\xi}}}_{\text{coll.+soft}} \right] \right. \\ \left. + [\log \xi_{\text{max}}(y) g^{\alpha}(0, y) - \log \xi_{\text{max}}(1) g^{\alpha}(0, 1)] \right\}. \quad (27.18)$$

This formula is implemented in `compute_sqme_real_fin`

```

This subroutine computes the finite part of the real matrix element in an individual singular region. First, the radiation variables are fetched and \mathcal{R} is

multiplied by the appropriate S_α -factors, region multiplicities and double-FSR factors. Then, it computes the soft, collinear, soft-collinear and remnant matrix elements and supplies the corresponding factor $1/\xi/(1-y)$ as well as the corresponding jacobians.

```

```

The same as above, but for the collinear subtraction terms. They are proportional to the Born matrix element so they enter the subroutine with pdfs evaluated for the Born flavor structure. Therefore, we additionally have to take the flavor of the underlying Born particle when dividing out the Born contribution.

27.7 Contribution of divergencies due to PDF Evolution

The origin of these contributions is a bit tricky to understand, because we cannot understand the initial-state real collinear contributions without also taking into account the evolution of parton density functions at $\mathcal{O}(\alpha_s)$. The NLO PDF evolution is given by

$$f(\bar{x}) = \int_0^1 \int_0^1 dx dz f(x) \Gamma(z) \delta(\bar{x} - xz), \quad (27.20)$$

where Γ are the DGLAP evolution kernels for an $a \rightarrow d$ splitting,

$$\Gamma_a^{(d)} = \delta_{ad} \delta(1-x) - \frac{\alpha_s}{2\pi} \left(\frac{1}{\epsilon} P_{ad}(x, 0) - K_{ad}(x) \right) + \mathcal{O}(\alpha_s). \quad (27.21)$$

K_{ad} is a renormalization scheme matching factor, which is exactly zero in $\bar{M}S$. Let the leading-order hadronic cross section be given by

$$d\sigma^{(0)}(s) = \int dx_{\oplus} dx_{\ominus} f_{\oplus}(x_{\oplus}) f_{\ominus}(x_{\ominus}) d\tilde{\sigma}^{(0)}(x_{\oplus} x_{\ominus} s), \quad (27.22)$$

then the NLO hadronic cross section is

$$d\sigma^{(1)}(s) = \int dx_{\oplus} dx_{\ominus} dz_{\oplus} dz_{\ominus} f_{\oplus}(x_{\oplus}) f_{\ominus}(x_{\ominus}) \underbrace{\Gamma_{\oplus}(z_{\oplus}) \Gamma_{\ominus}(z_{\ominus})}_{d\hat{\sigma}^{(1)}} d\tilde{\sigma}^{(1)}(z_{\oplus} z_{\ominus} s). \quad (27.23)$$

$d\hat{\sigma}$ is called the subtracted partonic cross section. Expanding in α_s we find

$$d\hat{\sigma}_{ab}^{(0)}(k_1, k_2) = d\tilde{\sigma}_{ab}^{(0)}(k_1, k_2), \quad (27.24)$$

$$d\hat{\sigma}_{ab}^{(1)}(k_1, k_2) = d\tilde{\sigma}_{ab}^{(1)}(k_1, k_2) \quad (27.25)$$

$$+ \frac{\alpha_s}{2\pi} \sum_d \int dx \left(\frac{1}{\epsilon} P_{da}(x, 0) - K_{da}(x) \right) d\tilde{\sigma}_{db}^{(0)}(xk_1, k_2) \quad (27.26)$$

$$+ \frac{\alpha_s}{2\pi} \sum_d \int \left(\frac{1}{\epsilon} P_{db}(x, 0) - K_{db}(x) \right) d\tilde{\sigma}_{ad}^{(0)}(k_1, xk_2). \quad (27.27)$$

$$= d\tilde{\sigma}_{ab}^{(1)} + d\tilde{\sigma}_{ab}^{(cnt,+)} + d\tilde{\sigma}_{ab}^{(cnt,-)} \quad (27.28)$$

Let us now turn the soft-subtracted real part of the cross section. For ease of notation, it is constrained to one singular region,

$$d\sigma_{\alpha}^{(in)} = \left[\left(\frac{1}{\xi} \right)_+ - 2\epsilon \left(\frac{\log \xi}{\xi} \right)_+ \right] (1-y^2) \xi^2 \mathcal{R}_{\alpha} \mathcal{S}_{\alpha} \\ \times \frac{1}{2(2\pi)^{3-2\epsilon}} \left(\frac{\sqrt{s}}{2} \right)^{2-2\epsilon} (1-y^2)^{-1-\epsilon} d\phi d\xi dy d\Omega^{2-2\epsilon},$$

where we regularize collinear divergencies using the identity

$$(1-y^2)^{-1-\epsilon} = -\frac{2^{-\epsilon}}{\epsilon} (\delta(1-y) + \delta(1+y)) + \underbrace{\frac{1}{2} \left[\left(\frac{1}{1-y} \right)_+ + \left(\frac{1}{1+y} \right)_+ \right]}_{\mathcal{P}(y)}.$$

This enables us to split the cross section into a finite and a singular part. The latter can further be separated into a contribution of the incoming and of the outgoing particles,

$$d\sigma_\alpha^{(in)} = d\sigma_\alpha^{(in,+)} + d\sigma_\alpha^{(in,-)} + d\sigma_\alpha^{(in,f)}.$$

They are given by

$$d\sigma_\alpha^{(in,f)} = \mathcal{P}(y) \left[\left(\frac{1}{\xi} \right)_+ - 2\epsilon \left(\frac{\log \xi}{\xi} \right)_+ \right] \frac{1}{2(2\pi)^{3-2\epsilon}} \left(\frac{\sqrt{s}}{2} \right)^{2-2\epsilon} \quad (27.29)$$

$$\times (1-y^2)\xi^2 \mathcal{R}_\alpha \mathcal{S}_\alpha d\phi d\xi dy d\Omega^{2-2\epsilon} \quad (27.30)$$

and

$$d\sigma_\alpha^{(in,\pm)} = -\frac{2^{-\epsilon}}{\epsilon} \delta(1 \mp y) \left[\left(\frac{1}{\xi} \right)_+ - 2\epsilon \left(\frac{\log \xi}{\xi} \right)_+ \right] \quad (27.31)$$

$$\times \frac{1}{2(2\pi)^{3-2\epsilon}} \left(\frac{\sqrt{s}}{2} \right)^{2-2\epsilon} (1-y^2)\xi^2 \mathcal{R}_\alpha \mathcal{S}_\alpha d\phi d\xi dy d\Omega^{2-2\epsilon}. \quad (27.32)$$

Equation 27.29 is the contribution to the real cross section which is computed in `evaluate_region_isr`. It is regularized both in the soft and collinear limit via the plus distributions. Equation 27.31 is a different contribution. It is only present exactly in the collinear limit, due to the delta function. The divergences present in this term do not completely cancel out divergences in the virtual matrix element, because the beam axis is distinguished. Thus, the conditions in which the KLM theorem applies are not met. To see this, we carry out the collinear limit, obtaining

$$\lim_{y \rightarrow 1} (1-y^2)\xi^2 \mathcal{R}_\alpha = 8\pi\alpha_s \mu^{2\epsilon} \left(\frac{2}{\sqrt{s}} \right)^2 \xi P^<(1-\xi, \epsilon) \mathcal{R}_\alpha,$$

with the Altarelli-Parisi splitting kernel for $z < 1$, $P^<(z, \epsilon)$. Moreover, $\lim_{\vec{k} \parallel \vec{k}_1} d\phi = d\phi_3$ violates spatial averaging. The integration over the spherical angle $d\Omega$ can be carried out easily, yielding a factor of $2\pi^{1-\epsilon}/\Gamma(1-\epsilon)$. This allows us to redefine ϵ ,

$$\frac{1}{\epsilon} - \gamma_E + \log(4\pi) \rightarrow \frac{1}{\epsilon}. \quad (27.33)$$

In order to make a connection to $d\tilde{\sigma}^{(cnt,\pm)}$, we relate $P_{ab}(z, 0)$ to $P_{ab}^<(z, 0)$ via the equation

$$P_{ab}(z, 0) = (1-z)P_{ab}^<(z, 0) \left(\frac{1}{1-z} \right)_+ + \gamma(a)\delta_{ab}\delta(1-z),$$

which yields

$$d\tilde{\sigma}^{(cnt,+)} = \frac{\alpha_s}{2\pi} \sum_d \left\{ -K_{da}(1-\xi) + \frac{1}{\epsilon} \left[\left(\frac{1}{\xi} \right)_+ \xi P_{da}^<(1-\xi, 0) + \delta_{da}\delta(\xi)\gamma(d) \right] \right\} \mathcal{R}_\alpha \mathcal{S}_\alpha. \quad (27.34)$$

This term has the same pole structure as eqn. 27.31. This makes clear that the quantity

$$d\hat{\sigma}^{(in,+)} = d\tilde{\sigma}^{(in,+)} + \frac{1}{4}d\tilde{\sigma}^{(cnt,+)} \quad (27.35)$$

has no collinear poles. Therefore, our task is to add up eqns. 27.31 and ?? in order to compute the finite remainder. This is the integrand which is evaluated in the `dglap_remnant` component.

So, we have to perform an expansion of $d\hat{\sigma}^{(in,+)}$ in ϵ . Hereby, we must not neglect the implicit ϵ -dependence of $P^<$, which leads to additional terms involving the first derivative,

$$P_{ab}^<(z, \epsilon) = P_{ab}^<(z, 0) + \epsilon \frac{\partial P_{ab}^<(z, \epsilon)}{\partial \epsilon} \Big|_{\epsilon=0} + \mathcal{O}(\alpha_s^2).$$

This finally gives us the equation for the collinear remnant. Note that there is still one soft $1/\epsilon$ -pole, which cancels out with the corresponding expression in the soft-virtual terms.

$$d\hat{\sigma}^{(in,+)} = \frac{\alpha_s}{2\pi} \frac{1}{\epsilon} \gamma(a) \mathcal{R}_\alpha \mathcal{S}_\alpha \quad (27.36)$$

$$+ \frac{\alpha_s}{2\pi} \sum_d \left\{ (1-z) P_{da}^<(z, 0) \left[\left(\frac{1}{1-z} \right)_+ \log \frac{s}{\mu^2} + 2 \left(\frac{\log(1-z)}{1-z} \right)_+ \right] \right. \quad (27.37)$$

$$\left. - (1-z) \frac{\partial P_{da}^<(z, \epsilon)}{\partial \epsilon} \left(\frac{1}{1-z} \right)_+ - K_{da}(z) \right\} \mathcal{R}_\alpha \mathcal{S}_\alpha \quad (27.38)$$

Evaluates formula (...). Note that, as also is the case for the real subtraction, we have to take into account an additional term, occuring because the integral the plus distribution is evaluated over is not constrained on the interval $[0, 1]$. Explicitly, this means

$$\int_{\bar{x}_{\oplus}}^1 dz \left(\frac{1}{1-z} \right)_+ = \log(1 - \bar{x}_{\oplus}) f(1) + \int_{\bar{x}_{\oplus}}^1 \frac{f(z) - f(1)}{1-z}, \quad (27.39)$$

and

$$\int_{\bar{x}_{\oplus}}^1 dz \left(\frac{\log(1-z)}{1-z} \right)_+ f(z) = \frac{1}{2} \log^2(1-\bar{x}_{\oplus}) f(1) + \int_{\bar{x}_{\oplus}}^1 \frac{\log(1-z)[f(z) - f(1)]}{1-z}, \quad (27.40)$$

and the same of course for \bar{x}_{\ominus} . These two terms are stored in the `plus_dist_remnant` variable below.

```

Chapter 28

Model Handling and Features

These modules deal with process definitions and physics models.

These modules use the `model_data` methods to automatically generate process definitions.

auto_components Generic process-definition generator. We can specify a basic process or initial particle(s) and some rules to extend this process, given a model definition with particle names and vertex structures.

radiation_generator Applies the generic generator to the specific problem of generating NLO corrections in a restricted setup.

Model construction:

eval_trees Implementation of the generic `expr_t` type for the concrete evaluation of expressions that access user variables.

This module is actually part of the Sindarin language implementation, and should be moved elsewhere. Currently, the `models` module relies on it.

models Extends the `model_data.t` structure by user-variable objects for easy access, and provides the means to read a model definition from file.

slha_interface Read/write a SUSY model in the standardized SLHA format. The format defines fields and parameters, but no vertices.

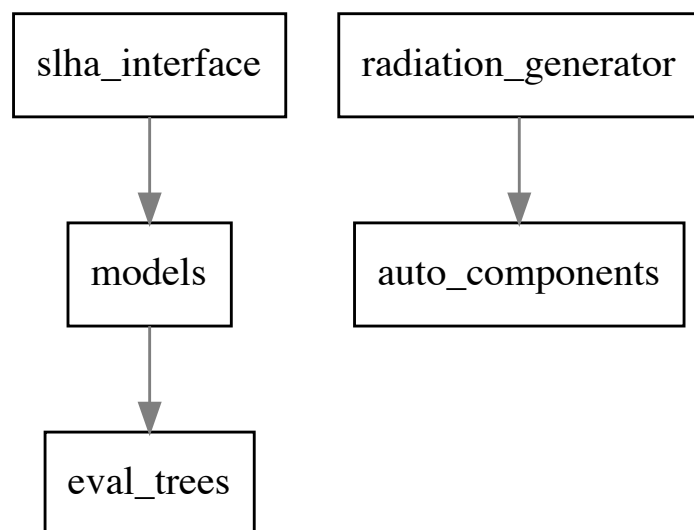

Figure 28.1: Module dependencies in `src/model_features`.

28.1 Automatic generation of process components

This module provides the functionality for automatically generating radiation corrections or decays, provided as lists of PDG codes.

```
<auto_components.f90>≡  
  <File header>  
  
  module auto_components  
  
    <Use kinds>

  end module auto_components
```

28.1.1 Constraints: Abstract types

An abstract type that denotes a constraint on the automatically generated states. The concrete objects are applied as visitor objects at certain hooks during the splitting algorithm.

```
<Auto components: types>≡  
  type, abstract :: split_constraint_t  
    contains  
    <Auto components: split constraint: TBP>  
  end type split_constraint_t
```

By default, all checks return true.

```
<Auto components: split constraint: TBP>≡  
  procedure :: check_before_split => split_constraint_check_before_split  
  procedure :: check_before_insert => split_constraint_check_before_insert  
  procedure :: check_before_record => split_constraint_check_before_record
```

```

<Auto components: procedures>≡
  subroutine split_constraint_check_before_split (c, table, pl, k, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: k
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_split

  subroutine split_constraint_check_before_insert (c, table, pa, pl, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_array_t), intent(in) :: pa
    type(pdg_list_t), intent(inout) :: pl
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_insert

  subroutine split_constraint_check_before_record (c, table, pl, n_loop, passed)
    class(split_constraint_t), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    passed = .true.
  end subroutine split_constraint_check_before_record

```

A transparent wrapper, so we can collect constraints of different type.

```

<Auto components: types>+≡
  type :: split_constraint_wrap_t
    class(split_constraint_t), allocatable :: c
  end type split_constraint_wrap_t

```

A collection of constraints.

```

<Auto components: public>≡
  public :: split_constraints_t

<Auto components: types>+≡
  type :: split_constraints_t
    class(split_constraint_wrap_t), dimension(:), allocatable :: cc
    contains
    <Auto components: split constraints: TBP>
  end type split_constraints_t

```

Initialize the constraints set with a specific number of elements.

```

<Auto components: split constraints: TBP>≡
  procedure :: init => split_constraints_init

<Auto components: procedures>+≡
  subroutine split_constraints_init (constraints, n)
    class(split_constraints_t), intent(out) :: constraints
    integer, intent(in) :: n

```

```

        allocate (constraints%cc (n))
    end subroutine split_constraints_init

```

Set a constraint.

```

<Auto components: split constraints: TBP>+≡
    procedure :: set => split_constraints_set

```

```

<Auto components: procedures>+≡
    subroutine split_constraints_set (constraints, i, c)
        class(split_constraints_t), intent(inout) :: constraints
        integer, intent(in) :: i
        class(split_constraint_t), intent(in) :: c
        allocate (constraints%cc(i)%c, source = c)
    end subroutine split_constraints_set

```

Apply checks.

`check_before_split` is applied to the particle list that we want to split.

`check_before_insert` is applied to the particle list `pl` that is to replace the particle `pa` that is split. This check may transform the particle list.

`check_before_record` is applied to the complete new particle list that results from splitting before it is recorded.

```

<Auto components: split constraints: TBP>+≡
    procedure :: check_before_split => split_constraints_check_before_split
    procedure :: check_before_insert => split_constraints_check_before_insert
    procedure :: check_before_record => split_constraints_check_before_record

```

```

<Auto components: procedures>+≡
    subroutine split_constraints_check_before_split &
        (constraints, table, pl, k, passed)
        class(split_constraints_t), intent(in) :: constraints
        class(ps_table_t), intent(in) :: table
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: k
        logical, intent(out) :: passed
        integer :: i
        passed = .true.
        do i = 1, size (constraints%cc)
            call constraints%cc(i)%c%check_before_split (table, pl, k, passed)
            if (.not. passed) return
        end do
    end subroutine split_constraints_check_before_split

    subroutine split_constraints_check_before_insert &
        (constraints, table, pa, pl, passed)
        class(split_constraints_t), intent(in) :: constraints
        class(ps_table_t), intent(in) :: table
        type(pdg_array_t), intent(in) :: pa
        type(pdg_list_t), intent(inout) :: pl
        logical, intent(out) :: passed
        integer :: i
        passed = .true.
        do i = 1, size (constraints%cc)
            call constraints%cc(i)%c%check_before_insert (table, pa, pl, passed)

```

```

        if (.not. passed) return
    end do
end subroutine split_constraints_check_before_insert

subroutine split_constraints_check_before_record &
    (constraints, table, pl, n_loop, passed)
    class(split_constraints_t), intent(in) :: constraints
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    integer :: i
    passed = .true.
    do i = 1, size (constraints%cc)
        call constraints%cc(i)%check_before_record (table, pl, n_loop, passed)
        if (.not. passed) return
    end do
end subroutine split_constraints_check_before_record

```

28.1.2 Specific constraints

Number of particles

Specific constraint: The number of particles plus the number of loops, if any, must remain less than the given limit. Note that the number of loops is defined only when we are recording the entry.

```

<Auto components: types>+≡
    type, extends (split_constraint_t) :: constraint_n_tot
    private
    integer :: n_max = 0
    contains
    procedure :: check_before_split => constraint_n_tot_check_before_split
    procedure :: check_before_record => constraint_n_tot_check_before_record
end type constraint_n_tot

<Auto components: public>+≡
    public :: constrain_n_tot

<Auto components: procedures>+≡
    function constrain_n_tot (n_max) result (c)
    integer, intent(in) :: n_max
    type(constraint_n_tot) :: c
    c%n_max = n_max
end function constrain_n_tot

subroutine constraint_n_tot_check_before_split (c, table, pl, k, passed)
    class(constraint_n_tot), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: k
    logical, intent(out) :: passed
    passed = pl%get_size () < c%n_max
end subroutine constraint_n_tot_check_before_split

```

```

subroutine constraint_n_tot_check_before_record (c, table, pl, n_loop, passed)
  class(constraint_n_tot), intent(in) :: c
  class(ps_table_t), intent(in) :: table
  type(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n_loop
  logical, intent(out) :: passed
  passed = pl%get_size () + n_loop <= c%n_max
end subroutine constraint_n_tot_check_before_record

```

Number of loops

Specific constraint: The number of loops is limited, independent of the total number of particles.

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_n_loop
  private
  integer :: n_loop_max = 0
  contains
  procedure :: check_before_record => constraint_n_loop_check_before_record
end type constraint_n_loop

<Auto components: public>+≡
  public :: constrain_n_loop

<Auto components: procedures>+≡
  function constrain_n_loop (n_loop_max) result (c)
    integer, intent(in) :: n_loop_max
    type(constraint_n_loop) :: c
    c%n_loop_max = n_loop_max
  end function constrain_n_loop

  subroutine constraint_n_loop_check_before_record &
    (c, table, pl, n_loop, passed)
    class(constraint_n_loop), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    passed = n_loop <= c%n_loop_max
  end subroutine constraint_n_loop_check_before_record

```

Particles allowed in splitting

Specific constraint: The entries in the particle list ready for insertion are matched to a given list of particle patterns. If a match occurs, the entry is replaced by the corresponding pattern. If there is no match, the check fails. If a massless gauge boson splitting is detected, the splitting partners are checked against a list of excluded particles. If a match occurs, the check fails.

```

<Auto components: types>+≡

```

```

type, extends (split_constraint_t) :: constraint_splittings

        has_massless_vector = .true.
        exit
      end if
    end do
    passed = .false.
    if (has_massless_vector .and. count (is_fermion(pl%a%get ())) == 2) then
      do i = 1, c%pl_excluded_gauge_splittings%get_size ()
        if (pl .match. c%pl_excluded_gauge_splittings%a(i)) return
      end do
      call pl%match_replace (c%pl_match, passed)
      passed = .true.
    else
      call pl%match_replace (c%pl_match, passed)
    end if
  end subroutine constraint_splittings_check_before_insert

```

Specific constraint: The entries in the particle list ready for insertion are matched to a given list of particle patterns. If a match occurs, the entry is replaced by the corresponding pattern. If there is no match, the check fails.

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_insert
  private
    type(pdg_list_t) :: pl_match

```

```

contains
  procedure :: check_before_insert => constraint_insert_check_before_insert
end type constraint_insert

<Auto components: public>+≡
  public :: constrain_insert

<Auto components: procedures>+≡
  function constrain_insert (pl_match) result (c)
    type(pdg_list_t), intent(in) :: pl_match
    type(constraint_insert) :: c
    c%pl_match = pl_match
  end function constrain_insert

  subroutine constraint_insert_check_before_insert (c, table, pa, pl, passed)
    class(constraint_insert), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_array_t), intent(in) :: pa
    type(pdg_list_t), intent(inout) :: pl
    logical, intent(out) :: passed
    call pl%match_replace (c%pl_match, passed)
  end subroutine constraint_insert_check_before_insert

```

Particles required in final state

Specific constraint: The entries in the recorded state must be a superset of the entries in the given list (for instance, the lowest-order state).

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_require
  private
  type(pdg_list_t) :: pl
  contains
  procedure :: check_before_record => constraint_require_check_before_record
end type constraint_require

```

We check the current state by matching all particle entries against the stored particle list, and crossing out the particles in the latter list when a match is found. The constraint passed if all entries have been crossed out.

For an `if_table` in particular, we check the final state only.

```

<Auto components: public>+≡
  public :: constrain_require

<Auto components: procedures>+≡
  function constrain_require (pl) result (c)

end subroutine constraint_radiation_check_before_insert

```

Mass sum

Specific constraint: The sum of masses within the particle list must be smaller than a given limit. For in/out state combinations, we check initial and final state separately.

If we specify `margin` in the initialization, the sum must be strictly less than the limit minus the given margin (which may be zero). If not, equality is allowed.

```

```

28.1.3 Tables of states

Automatically generate a list of possible process components for a given initial set (a single massive particle or a preset list of states).

The set of process components are generated by recursive splitting, applying constraints on the fly that control and limit the process. The generated states are accumulated in a table that we can read out after completion.

```

<Auto components: types>+≡
  type, extends (pdg_list_t) :: ps_entry_t
    integer :: n_loop = 0
    integer :: n_rad = 0
    type(ps_entry_t), pointer :: previous => null ()
    type(ps_entry_t), pointer :: next => null ()
  end type ps_entry_t

```

```

<Auto components: parameters>≡
  integer, parameter :: PROC_UNDEFINED = 0
  integer, parameter :: PROC_DECAY = 1
  integer, parameter :: PROC_SCATTER = 2

```

This is the wrapper type for the decay tree for the list of final states and the final array. First, an abstract base type:

```

<Auto components: public>+≡
  public :: ps_table_t

```

```

⟨Auto components: types⟩+≡
  type, abstract :: ps_table_t
    private
      class(model_data_t), pointer :: model => null ()
      logical :: loops = .false.
      type(ps_entry_t), pointer :: first => null ()
      type(ps_entry_t), pointer :: last => null ()
      integer :: proc_type
    contains
      ⟨Auto components: ps table: TBP⟩
  end type ps_table_t

```

The extensions: one for decay, one for generic final states. The decay-state table stores the initial particle. The final-state table is indifferent, and the initial/final state table treats the first two particles in its list as incoming antiparticles.

```

⟨Auto components: public⟩+≡
  public :: ds_table_t
  public :: fs_table_t
  public :: if_table_t

⟨Auto components: types⟩+≡
  type, extends (ps_table_t) :: ds_table_t
    private
      integer :: pdg_in = 0
    contains
      ⟨Auto components: ds table: TBP⟩
  end type ds_table_t

  type, extends (ps_table_t) :: fs_table_t
    contains
      ⟨Auto components: fs table: TBP⟩
  end type fs_table_t

  type, extends (fs_table_t) :: if_table_t
    contains
      ⟨Auto components: if table: TBP⟩
  end type if_table_t

```

Finalizer: we must deallocate the embedded list.

```

⟨Auto components: ps table: TBP⟩≡
  procedure :: final => ps_table_final

⟨Auto components: procedures⟩+≡
  subroutine ps_table_final (object)
    class(ps_table_t), intent(inout) :: object
    type(ps_entry_t), pointer :: current
    do while (associated (object%first))
      current => object%first
      object%first => current%next
      deallocate (current)
    end do
    nullify (object%last)
  end subroutine ps_table_final

```

Write the table. A base writer for the body and specific writers for the headers.

```

<Auto components: ps table: TBP>+=
  procedure :: base_write => ps_table_base_write
  procedure (ps_table_write), deferred :: write

<Auto components: interfaces>=

    type(split_constraints_t) :: constraints
    type(ps_entry_t), pointer :: current
    current => table%first
    do while (associated (current))
      call table%split (current, 0, constraints, record = .true.)
      current => current%next
    end do
  end subroutine fs_table_radiate

```

28.1.5 Splitting algorithm

Recursive splitting. First of all, we record the current `pdg_list` in the table, subject to `constraints`, if requested. We also record copies of the list marked as loop corrections.

When we record a particle list, we sort it first.

If there is room for splitting, We take a PDG array list and the index of an element, and split this element in all possible ways. The split entry is inserted into the list, which we split further.

The recursion terminates whenever the split array would have a length greater than n_{\max} .

```

<Auto components: ps table: TBP>+≡
  procedure :: split => ps_table_split

<Auto components: procedures>+≡
  recursive subroutine ps_table_split (table, pl, n_rad, constraints, &
    record)
    class(ps_table_t), intent(inout) :: table
    class(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_rad
    type(split_constraints_t), intent(in) :: constraints
    logical, intent(in), optional :: record
    integer :: n_loop, i
    logical :: passed, save_pdg_index
    type(vertex_iterator_t) :: vit
    integer, dimension(:), allocatable :: pdg1
    integer, dimension(:), allocatable :: pdg2
    if (present (record)) then
      if (record) then
        n_loop = 0
        INCR_LOOPS: do

```

```

        call table%record_sorted (pl, n_loop, n_rad, constraints, passed)
        if (.not. passed) exit INCR_LOOPS
        if (.not. table%loops) exit INCR_LOOPS
        n_loop = n_loop + 1
    end do INCR_LOOPS
end if
end if
select type (table)
type is (if_table_t)
    save_pdg_index = .true.
class default
    save_pdg_index = .false.
end select
do i = 1, pl%get_size ()
    call constraints%check_before_split (table, pl, i, passed)
    if (passed) then
        pdg1 = pl%get (i)
        call vit%init (table%model, pdg1, save_pdg_index)
        SCAN_VERTICES: do
            call vit%get_next_match (pdg2)
            if (allocated (pdg2)) then
                call table%insert (pl, n_rad, i, pdg2, constraints)
            else
                exit SCAN_VERTICES
            end if
        end do SCAN_VERTICES
    end if
end do
end subroutine ps_table_split

```

The worker part: insert the list of particles found by vertex matching in place of entry *i* in the PDG list. Then split/record further.

The *n_in* parameter tells the replacement routine to insert the new particles after entry *n_in*. Otherwise, they follow index *i*.

```

<Auto components: ps table: TBP>+≡
    procedure :: insert => ps_table_insert

<Auto components: procedures>+≡
    recursive subroutine ps_table_insert &
        (table, pl, n_rad, i, pdg, constraints, n_in)
        class(ps_table_t), intent(inout) :: table
        class(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: n_rad, i
        integer, dimension(:), intent(in) :: pdg
        type(split_constraints_t), intent(in) :: constraints
        integer, intent(in), optional :: n_in
        type(pdg_list_t) :: pl_insert
        logical :: passed
        integer :: k, s
        s = size (pdg)
        call pl_insert%init (s)
        do k = 1, s
            call pl_insert%set (k, pdg(k))
        end do
    end subroutine

```

```

        call constraints%check_before_insert (table, pl%get (i), pl_insert, passed)
        if (passed) call table%split (pl%replace (i, pl_insert, n_in), n_rad + s - 1, &
            constraints, record = .true.)
    end subroutine ps_table_insert

```

Special case: If we are splitting an initial particle, there is slightly more to do. We loop over the particles from the vertex match and replace the initial particle by each of them in turn. The remaining particles must be appended after the second initial particle, so they will end up in the out state. This is done by providing the `n_in` argument to the base method as an optional argument.

Note that we must call the base-method procedure explicitly, so the `table` argument keeps its dynamic type as `if_table` inside this procedure.

```

<Auto components: if table: TBP>+≡
    procedure :: insert => if_table_insert

<Auto components: procedures>+≡
    recursive subroutine if_table_insert &
        (table, pl, n_rad, i, pdg, constraints, n_in)

28.1.6 Tools

Compute the mass sum for a PDG list object, counting the entries with indices between (including) `n1` and `n2`. Rely on the requirement that if an entry is a PDG array, this array must be degenerate in mass.

(Auto components: procedures)+≡

```

function mass_sum (pl, n1, n2, model) result (m)
  type(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n1, n2
  class(model_data_t), intent(in), target :: model
  integer, dimension(:), allocatable :: pdg
  real(default) :: m
  type(field_data_t), pointer :: prt
  integer :: i
  m = 0
  do i = n1, n2
    pdg = pl%get (i)
    prt => model%get_field_ptr (pdg(1))
    m = m + prt%get_mass ()
  end do
end function mass_sum

```

Invert a PDG array, replacing particles by antiparticles. This depends on the model.

```

<Auto components: procedures>+≡
function invert_pdg_array (pa, model) result (pa_inv)
  type(pdg_array_t), intent(in) :: pa
  class(model_data_t), intent(in), target :: model
  type(pdg_array_t) :: pa_inv
  type(field_data_t), pointer :: prt
  integer :: i, pdg
  pa_inv = pa
  do i = 1, pa_inv%get_length ()
    pdg = pa_inv%get (i)
    prt => model%get_field_ptr (pdg)
    if (prt%has_antiparticle ()) call pa_inv%set (i, -pdg)
  end do
end function invert_pdg_array

```

28.1.7 Access results

Return the number of generated decays.

```

We need to reset the `reshuffle_list` in order to deal with subsequent usages of the `radiation_generator`. Below is obviously the lazy and dirty solution. Otherwise, we would have to equip this auxiliary type with additional information about `last` and `previous` pointers. Considering that at most n_{legs} integers are saved in the lists, and that the subroutine is only called during the initialization phase (more precisely: at the moment only in the `radiation_generator` unit tests), I think this quick fix is justified.

```

<radiation generator: reshuffle list: TBP>+≡
    procedure :: reset => reshuffle_list_reset

    subroutine reshuffle_list_reset (rlist)
        class(reshuffle_list_t), intent(inout) :: rlist
        rlist%next => null ()
    end subroutine reshuffle_list_reset

```

```

end subroutine reshuffle_list_reset

28.3 Sindarin Expression Implementation

This module defines expressions of all kinds, represented in a tree structure, for repeated evaluation. This provides an implementation of the `expr_base` abstract type.

We have two flavors of expressions: one with particles and one without particles. The latter version is used for defining cut/selection criteria and for online analysis.

```
<eval_trees.f90>≡  
  <File header>  
  
  module eval_trees

    contains  
  
    <Eval trees: procedures>  
  
  end module eval_trees
```

28.3.1 Tree nodes

The evaluation tree consists of branch nodes (unary and binary) and of leaf nodes, originating from a common root. The node object should be polymorphic. For the time being, polymorphism is emulated here. This means that we have to maintain all possibilities that the node may hold, including associated procedures as pointers.

The following parameter values characterize the node. Unary and binary operators have sub-nodes. The other are leaf nodes. Possible leafs are literal constants or named-parameter references.

<Eval trees: types>≡

```
integer, parameter :: EN_UNKNOWN = 0, EN_UNARY = 1, EN_BINARY = 2
integer, parameter :: EN_CONSTANT = 3, EN_VARIABLE = 4
integer, parameter :: EN_CONDITIONAL = 5, EN_BLOCK = 6
integer, parameter :: EN_RECORD_CMD = 7
integer, parameter :: EN_OBS1_INT = 11, EN_OBS2_INT = 12
integer, parameter :: EN_OBS1_REAL = 21, EN_OBS2_REAL = 22
integer, parameter :: EN_UOBS1_INT = 31, EN_UOBS2_INT = 32
integer, parameter :: EN_UOBS1_REAL = 41, EN_UOBS2_REAL = 42
integer, parameter :: EN_PRT_FUN_UNARY = 101, EN_PRT_FUN_BINARY = 102
integer, parameter :: EN_EVAL_FUN_UNARY = 111, EN_EVAL_FUN_BINARY = 112
integer, parameter :: EN_LOG_FUN_UNARY = 121, EN_LOG_FUN_BINARY = 122
integer, parameter :: EN_INT_FUN_UNARY = 131, EN_INT_FUN_BINARY = 132
integer, parameter :: EN_REAL_FUN_UNARY = 141, EN_REAL_FUN_BINARY = 142
integer, parameter :: EN_FORMAT_STR = 161
```

This is exported only for use within unit tests.

    case (V_STR); allocate (node%sval)
  end select
  allocate (node%value_is_known)
  node%value_is_known = .false.
end subroutine eval_node_allocate_value

```

Initialize a block node which contains, in addition to the expression to be evaluated, a variable definition. The result type is not yet assigned, because we can compile the enclosed expression only after the var list is set up.

Note that the node always allocates a new variable list and appends it to the current one. Thus, if the variable redefines an existing one, it only shadows it but does not reset it. Any side-effects are therefore absent and need not be undone outside the block.

If the flag **new** is set, a variable is (re)declared. This must not be done for intrinsic variables. Vice versa, if the variable is not existent, the **new** flag is required.

<Eval trees: procedures>+≡

```

subroutine eval_node_init_block (node, name, type, var_def, var_list)
  type(eval_node_t), intent(out), target :: node
  type(string_t), intent(in) :: name
  integer, intent(in) :: type

```

```

else
  node%result_type = arg%result_type
end if
call eval_node_allocate_value (node)
node%arg0 => arg
end subroutine eval_node_set_expr

```

Initialize a conditional. There are three branches: the condition (evaluates to logical) and the two alternatives (evaluate both to the same arbitrary type).

(Eval trees: procedures)+≡

```

subroutine eval_node_init_conditional (node, result_type, cond, arg1, arg2)
  type(eval_node_t), intent(out) :: node
  integer, intent(in) :: result_type
  type(eval_node_t), intent(in), target :: cond, arg1, arg2
  node%type = EN_CONDITIONAL
  node%tag = "cond"
  node%result_type = result_type
  call eval_node_allocate_value (node)
  node%arg0 => cond
  node%arg1 => arg1
  node%arg2 => arg2
end subroutine eval_node_init_conditional

```

Initialize a recording command (which evaluates to a logical constant). The first branch is the ID of the analysis object to be filled, the optional branches 1 to 4 are the values to be recorded.

If the event-weight pointer is null, we record values with unit weight. Otherwise, we use the value pointed to as event weight.

There can be up to four arguments which represent $x, y, \Delta y, \Delta x$. Therefore, this is the only node type that may fill four sub-nodes.

(Eval trees: procedures)+≡

```

subroutine eval_node_init_record_cmd &
  (node, event_weight, id, arg1, arg2, arg3, arg4)
  type(eval_node_t), intent(out) :: node
  real(default), pointer :: event_weight
  type(eval_node_t), intent(in), target :: id
  type(eval_node_t), intent(in), optional, target :: arg1, arg2, arg3, arg4
  call eval_node_init_log (node, .true.)
  node%type = EN_RECORD_CMD
  node%rval => event_weight
  node%tag = "record_cmd"

```

If particle functions depend upon a condition (or an expression is evaluated), the observables that can be evaluated for the given particles have to be thrown on the local variable stack. This is done here. Each observable is initialized with the particle pointers which have been allocated for the node.

The integer variable that is referred to by the `Index` pseudo-observable is always known when it is referred to.

(Eval trees: procedures)+≡

```

subroutine eval_node_set_observables (node, var_list)
type(eval_node_t), intent(inout) :: node
type(var_list_t), intent(in), target :: var_list
logical, save, target :: known = .true.

28.3.2 Operation types

For the operations associated to evaluation tree nodes, we define abstract interfaces for all cases.

Particles/subevents are transferred by-reference, to avoid unnecessary copying. Therefore, subroutines instead of functions. (Furthermore, the function version of `unary_prt` triggers an obscure bug in nagfor 5.2(649) [invalid C code].)

(Eval trees: interfaces)≡

```

abstract interface
  logical function unary_log (arg)

28.3.3 Specific operators

Our expression syntax contains all Fortran functions that make sense. These functions have to be provided in a form that they can be used in procedures pointers, and have the abstract interfaces above. For some intrinsic functions, we could use specific versions provided by Fortran directly. However, this has two drawbacks: (i) We should work with the values instead of the eval-nodes as argument, which complicates the interface; (ii) more importantly, the **default** real type need not be equivalent to double precision. This would, at least, introduce system dependencies. Finally, for operators there are no specific versions.

Therefore, we write wrappers for all possible functions, at the expense of some overhead.

Binary numerical functions

```

<Eval trees: procedures>+≡

        if (lval) exit
    end do
end function no_p

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

<Eval trees: procedures>+≡

```

function user_obs_int_p (en0, prt1) result (ival)

    lval = user_cut (c_prt (en1%pval), &
                    int (subevt_get_length (en1%pval), kind=c_int)) &
        /= 0
end function user_cut_p

```

The following function returns an integer value, namely the number of particles for which the condition is true. If there is no condition, it returns simply the length of the subevent.

A function would be more natural. Making it a subroutine avoids another compiler bug (internal error in nagfor 5.2 (649)). (See the interface `unary_evi`.)

(Eval trees: procedures)+≡

```
subroutine count_a (ival, en1, en0)
  integer, intent(out) :: ival
  type(eval_node_t), intent(in) :: en1
  type(eval_node_t), intent(inout), optional :: en0
  integer :: i, n, count
  n = subevt_get_length (en1%pval)
  if (present (en0)) then
    count = 0
    do i = 1, n
      en0%index = i
      en0%prt1 = subevt_get_prt (en1%pval, i)
      call eval_node_evaluate (en0)
      if (en0%lval) count = count + 1
    end do
    ival = count
  else
    ival = n
  end if
end subroutine count_a
```

This evaluates a user-defined event-shape observable for the current subevent.

(Eval trees: procedures)+≡

```
subroutine user_event_shape_a (rval, en1, en0)
  real(default), intent(out) :: rval
  type(eval_node_t), intent(in) :: en1
  type(eval_node_t), intent(inout), optional :: en0
  type(string_t) :: name
  procedure(user_event_shape_fun), pointer :: user_event_shape
  if (.not. present (en0)) call msg_bug &
    ("user_event_shape called without procedure name")
  call eval_node_evaluate (en0)
  select case (en0%result_type)
  case (V_STR); name = en0% sval
  case default
    call msg_bug ("user_event_shape: procedure name must be a string")
    name = ""
  end select
  call c_f_procpointer (user_code_find_proc (name), user_event_shape)
  rval = user_event_shape (c_prt (en1%pval), &
    int (subevt_get_length (en1%pval), kind=c_int))
end subroutine user_event_shape_a
```

Binary particle-list functions

This joins two subevents, stored in the evaluation nodes **en1** and **en2**. If **en0** is also present, it amounts to a logical test returning true or false for every pair of particles. A particle of the second list gets a mask entry only if it passes the test for all particles of the first list.

(Eval trees: procedures)+≡

```
subroutine join_pp (subevt, en1, en2, en0)
  type(subevt_t), intent(inout) :: subevt
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0
  logical, dimension(:), allocatable :: mask2
  integer :: i, j, n1, n2
  n1 = subevt_get_length (en1%pval)
  n2 = subevt_get_length (en2%pval)
  allocate (mask2 (n2))
  mask2 = .true.
  if (present (en0)) then
    do i = 1, n1
      en0%index = i

      end do
    end do
  end if
  call subevt_join (subevt, en1%pval, en2%pval, mask2)
end subroutine join_pp
```

Combine two subevents, i.e., make a list of composite particles built from all possible particle pairs from the two lists. If **en0** is present, create a mask which is true only for those pairs that pass the test.

(Eval trees: procedures)+≡

```
subroutine combine_pp (subevt, en1, en2, en0)
  type(subevt_t), intent(inout) :: subevt
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0
  logical, dimension(:,:), allocatable :: mask12
  integer :: i, j, n1, n2
  n1 = subevt_get_length (en1%pval)
  n2 = subevt_get_length (en2%pval)
  if (present (en0)) then
    allocate (mask12 (n1, n2))
    do i = 1, n1
      en0%index = i
      en0%prt1 = subevt_get_prt (en1%pval, i)
      do j = 1, n2
        en0%prt2 = subevt_get_prt (en2%pval, j)
        call eval_node_evaluate (en0)
        mask12(i,j) = en0%lval
      end do
    end do
  end if
end subroutine combine_pp
```

```

        end do
        call subevt_combine (subevt, en1%pval, en2%pval, mask12)
    else
        call subevt_combine (subevt, en1%pval, en2%pval)
    end if
end subroutine combine_pp

```

Combine all particles of the first argument. If `en0` is present, create a mask which is true only for those particles that pass the test w.r.t. all particles in the second argument. If `en0` is absent, the second argument is ignored.

(Eval trees: procedures)+≡

```

subroutine collect_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:), allocatable :: mask1
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)

  integer :: i, j, n1, n2
  n1 = subevt_get_length (en1%pval)
  n2 = subevt_get_length (en2%pval)
  rval = 0
  is_known = .false.
  LOOP1: do i = 1, n1
    en0%index = i
    en0%prt1 = subevt_get_prt (en1%pval, i)
    do j = 1, n2
      en0%prt2 = subevt_get_prt (en2%pval, j)
      if (are_disjoint (en0%prt1, en0%prt2)) then
        call eval_node_evaluate (en0)
        rval = en0%rval
        is_known = .true.
        exit LOOP1
      end if
    end do
  end do LOOP1
end subroutine eval_pp

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

<Eval trees: procedures>+≡

```

function user_obs_int_pp (en0, prt1, prt2) result (ival)
  integer :: ival
  type(eval_node_t), intent(inout) :: en0
  type(prt_t), intent(in) :: prt1, prt2
  type(string_t) :: name
  procedure(user_obs_int_binary), pointer :: user_obs

```

```

call eval_node_evaluate (en0)
if (en0%value_is_known) then
  select case (en0%result_type)
  case (V_STR); name = en0% sval
  case default
    call msg_bug ("user_obs: procedure name must be a string")
    name = ""
  end select
  call c_f_procpointer (user_code_find_proc (name), user_obs)
  ival = user_obs (c_prt (prt1), c_prt (prt2))
else

  else
    call eval_node_write_rec (en0)
    call msg_fatal ("User observable name is undefined")
  end if
end function user_obs_real_pp

```

The following function returns an integer value, namely the number of valid particle-pairs from both lists for which the condition is true. Invalid pairs (with common `src` entry) are ignored. If there is no condition, it returns the number of valid particle pairs.

A function would be more natural. Making it a subroutine avoids another compiler bug (internal error in nagfor 5.2 (649)). (See the interface `binary_num`.)

(Eval trees: procedures)+≡

```

subroutine count_pp (ival, en1, en2, en0)
  integer, intent(out) :: ival
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0

  else
    call subevt_select_pdg_code (subevt, en1%aval, en2%pval)
  end if
end subroutine select_pdg_ca

```

Binary string functions

Currently, the only string operation is concatenation.

<Eval trees: procedures>+≡

```

subroutine concat_ss (string, en1, en2)
  type(string_t), intent(out) :: string
  type(eval_node_t), intent(in) :: en1, en2
  string = en1%sval // en2%sval
end subroutine concat_ss

```

28.3.4 Compiling the parse tree

The evaluation tree is built recursively by following a parse tree. Evaluate an expression. The requested type is given as an optional argument; default is numeric (integer or real).

(Eval trees: procedures)+≡

```
recursive subroutine eval_node_compile_genexpr &
  (en, pn, var_list, result_type)
  type(eval_node_t), pointer :: en
  type(parse_node_t), intent(in) :: pn
  type(var_list_t), intent(in), target :: var_list
  integer, intent(in), optional :: result_type
  if (debug_active (D_MODEL_F)) then
    print *, "read genexpr"; call parse_node_write (pn)
  end if
  if (present (result_type)) then
    select case (result_type)
    case (V_INT, V_REAL, V_CMPLX)
      call eval_node_compile_expr (en, pn, var_list)
    case (V_LOG)
      call eval_node_compile_lexpr (en, pn, var_list)
    case (V_SEV)
      call eval_node_compile_pexpr (en, pn, var_list)
    case (V_PDG)
      call eval_node_compile_cexpr (en, pn, var_list)
    case (V_STR)
      call eval_node_compile_sexpr (en, pn, var_list)
    end select
  else
    call eval_node_compile_expr (en, pn, var_list)
  end if
  if (debug_active (D_MODEL_F)) then
    call eval_node_write (en)
    print *, "done genexpr"
  end if
end subroutine eval_node_compile_genexpr
```

Numeric expressions

This procedure compiles a numerical expression. This is a single term or a sum or difference of terms. We have to account for all combinations of integer and real arguments. If both are constant, we immediately do the calculation and allocate a constant node.

(Eval trees: procedures)+≡

```
recursive subroutine eval_node_compile_expr (en, pn, var_list)
  type(eval_node_t), pointer :: en
  type(parse_node_t), intent(in) :: pn

```

Real, complex and integer values are numeric literals with an optional unit attached. In case of an integer, the unit actually makes it a real value in disguise. The signed version of real values is not possible in generic expressions; it is a special case for numeric constants in model files (see below). We do not introduce signed versions of complex values.

```

Compile a variable, with or without a specified type. Take the list of variables, look for the name and make a node with a pointer to the value. If no type is provided, the variable is numeric, and the stored value determines whether it is real or integer.

We explicitly demand that the variable is defined, so we do not accidentally point to variables that are declared only later in the script but have come into existence in a previous compilation pass.

Variables may actually be anonymous, these are expressions in disguise. In that case, the expression replaces the variable name in the parse tree, and we allocate an ordinary expression node in the eval tree.

Variables of type V.PDG (pdg-code array) are not treated here. They are

handled by `eval_node_compile_cvariable`.

```

This user observable behaves like a variable. We link the node to the generic user-observable entry in the variable list. The syntax element has an argument which provides the name of the user variable, this is stored as an eval-node alongside with the variable. When the variable value is used, the user-supplied external function is called and provides the (real) result value.

Variable definition

A block expression contains a variable definition (first argument) and an expression where the definition can be used (second argument). The `result_type` decides which type of expression is expected for the second argument. For numeric variables, if there is a mismatch between real and integer type, insert an extra node for type conversion.

Conditionals

A conditional has the structure `if lexpr then expr else expr`. So we first evaluate the logical expression, then depending on the result the first or second expression. Note that the second expression is mandatory.

The `result_type`, if present, defines the requested type of the `then` and `else` clauses. Default is numeric (int/real). If there is a mismatch between real and integer result types, insert conversion nodes.

(Eval trees: procedures)+≡

Comparisons

Up to the loop, this is easy. There is always at least one comparison. This is evaluated, and the result is the logical node `en`. If it is constant, we keep its second sub-node as `en2`. (Thus, at the very end `en2` has to be deleted if `en` is (still) constant.)

If there is another comparison, we first check if the first comparison was constant. In that case, there are two possibilities: (i) it was true. Then, its right-hand side is compared with the new right-hand side, and the result replaces the previous one which is deleted. (ii) it was false. In this case, the result of the whole comparison is false, and we can exit the loop without evaluating anything else.

Now assume that the first comparison results in a valid branch, its second sub-node kept as `en2`. We first need a copy of this, which becomes the new

left-hand side. If `en2` is constant, we make an identical constant node `en1`. Otherwise, we make `en1` an appropriate pointer node. Next, the first branch is saved as `en0` and we evaluate the comparison between `en1` and the a right-hand side. If this turns out to be constant, there are again two possibilities: (i) true, then we revert to the previous result. (ii) false, then the wh

end subroutine eval_node_compile_compared_expr

```

This takes two extra arguments: **en1**, the left-hand-side of the comparison, is already allocated and evaluated. **en2** (the right-hand side) and **en** (the result) are allocated by the routine. **pn** is the parse node which contains the operator and the right-hand side as subnodes.

If the result of the comparison is constant, **en1** is deleted but **en2** is kept, because it may be used in a subsequent comparison. **en** then becomes a constant. If the result is variable, **en** becomes a branch node which refers to **en1** and **en2**.

A particle-list value is a PDG-code array, a particle identifier, a variable, a (grouped) pexpr, a block pexpr, a conditional, or a particle-list function.

The **cexpr** node is responsible for transforming a constant PDG-code array into a subevent. It takes the code array as its first argument, the event subevent as its second argument, and the requested particle type (incoming/outgoing) as its zero-th argument. The result is the list of particles in the event that match the code array.

Particle functions

This combines the treatment of 'join', 'combine', 'collect', 'cluster', 'select', and 'extract' which all have the same syntax. The one or two argument nodes are allocated. If there is a condition, the condition node is also allocated as a logical expression, for which the variable list is augmented by the appropriate (unary/binary) observables.

    case (V_REAL); type = "'real'"
    case (V_CMPLX); type = "'complex'"
    case default; type = "(unknown)"
  end select
  call parse_node_write (pn)
  call msg_fatal (" The " // string // &
    " operation is not defined for the given argument type " // &
    char (type))
end subroutine eval_type_error

```

If two numerics are combined, the result is integer if both arguments are integer, if one is integer and the other real or both are real, than its argument is real, otherwise complex.

```

<Eval trees: procedures>+≡
function numeric_result_type (t1, t2) result (t)
  integer, intent(in) :: t1, t2
  integer :: t
  if (t1 == V_INT .and. t2 == V_INT) then
    t = V_INT
  else if (t1 == V_INT .and. t2 == V_REAL) then
    t = V_REAL
  else if (t1 == V_REAL .and. t2 == V_INT) then
    t = V_REAL
  else if (t1 == V_REAL .and. t2 == V_REAL) then
    t = V_REAL
  else
    t = V_CMPLX
  end if
end function numeric_result_type

```

28.3.6 Evaluation

Evaluation is done recursively. For leaf nodes nothing is to be done.

Evaluating particle-list functions: First, we evaluate the particle lists. If a condition is present, we assign the particle pointers of the condition node to the allocated particle entries in the parent node, keeping in mind that the observables in the variable stack used for the evaluation of the condition also contain pointers to these entries. Then, the assigned procedure is evaluated, which sets the subevent in the parent node. If required, the procedure evaluates the condition node once for each (pair of) particles to determine the result.

```

<Eval trees: procedures>+≡

```

```

end subroutine eval_node_test_obs

```

28.3.7 Evaluation syntax

We have two different flavors of the syntax: with and without particles.

```

<Eval trees: public>+≡
  public :: syntax_expr
  public :: syntax_pexpr

<Eval trees: variables>≡
  type(syntax_t), target, save :: syntax_expr
  type(syntax_t), target, save :: syntax_pexpr

```

These are for testing only and may be removed:

```

<Eval trees: public>+≡
  public :: syntax_expr_init
  public :: syntax_pexpr_init

<Eval trees: procedures>+≡
subroutine syntax_expr_init ()
  type(ifile_t) :: ifile
  call define_expr_syntax (ifile, particles=.false., analysis=.false.)
  call syntax_init (syntax_expr, ifile)
  call ifile_final (ifile)
end subroutine syntax_expr_init

subroutine syntax_pexpr_init ()
  type(ifile_t) :: ifile
  call define_expr_syntax (ifile, particles=.true., analysis=.false.)
  call syntax_init (syntax_pexpr, ifile)
  call ifile_final (ifile)
end subroutine syntax_pexpr_init

<Eval trees: public>+≡
  public :: syntax_expr_final
  public :: syntax_pexpr_final

<Eval trees: procedures>+≡
subroutine syntax_expr_final ()
  call syntax_final (syntax_expr)
end subroutine syntax_expr_final

```

```

subroutine syntax_pexpr_final ()
  call syntax_final (syntax_pexpr)
end subroutine syntax_pexpr_final

```

<Eval trees: public>+≡

```

public :: syntax_pexpr_write

```

<Eval trees: procedures>+≡

```

subroutine syntax_pexpr_write (unit)
  integer, intent(in), optional :: unit
  call syntax_write (syntax_pexpr, unit)
end subroutine syntax_pexpr_write

```

<Eval trees: public>+≡

```

public :: define_expr_syntax

```

Numeric expressions.

<Eval trees: procedures>+≡

```

```

28.3.11 Factory Type

Since `eval_tree_t` is an implementation of `expr_t`, we also need a matching factory type and build method.

```

<Eval trees: public>+≡
  public :: eval_tree_factory_t

<Eval trees: types>+≡
  type, extends (expr_factory_t) :: eval_tree_factory_t
  private
    type(parse_node_t), pointer :: pn => null ()
  contains
    <Eval trees: eval tree factory: TBP>
  end type eval_tree_factory_t

```

Output: delegate to the output of the embedded parse node.

```

<Eval trees: eval tree factory: TBP>≡
  procedure :: write => eval_tree_factory_write

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_write (expr_factory, unit)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    integer, intent(in), optional :: unit
    if (associated (expr_factory%pn)) then
      call parse_node_write_rec (expr_factory%pn, unit)
    end if
  end subroutine eval_tree_factory_write

```

Initializer: take a parse node and hide it thus from the environment.

```
<Eval trees: eval tree factory: TBP>+≡
  procedure :: init => eval_tree_factory_init

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_init (expr_factory, pn)
    class(eval_tree_factory_t), intent(out) :: expr_factory
    type(parse_node_t), intent(in), pointer :: pn
    expr_factory%pn => pn
  end subroutine eval_tree_factory_init
```

Factory method: allocate expression with correct eval tree type. If the stored parse node is not associate, don't allocate.

```
<Eval trees: eval tree factory: TBP>+≡
  procedure :: build => eval_tree_factory_build

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_build (expr_factory, expr)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    class(expr_t), intent(out), allocatable :: expr
    if (associated (expr_factory%pn)) then
      allocate (eval_tree_t :: expr)
      select type (expr)
        type is (eval_tree_t)
          expr%pn => expr_factory%pn
        end select
      end if
    end if
  end subroutine eval_tree_factory_build
```

28.4 Physics Models

A model object represents a physics model. It contains a table of particle data, a list of parameters, and a vertex table. The list of parameters is a variable list which includes the real parameters (which are pointers to the particle data table) and PDG array variables for the particles themselves. The vertex list is used for phase-space generation, not for calculating the matrix element.

The actual numeric model data are in the base type `model_data_t`, as part of the `qft` section. We implement the `model_t` as an extension of this, for convenient direct access to the base-type methods via inheritance. (Alternatively, we could delegate these calls explicitly.) The extension contains administrative additions, such as the methods for recalculating derived data and keeping the parameter set consistent. It thus acts as a proxy of the actual model-data object towards the WHIZARD package. There are further proxy objects, such as the `parameter_t` array which provides the interface to the actual numeric parameters.

Model definitions are read from model files. Therefore, this module contains a parser for model files. The parameter definitions (derived parameters) are Sindarin expressions.

The models, as read from file, are stored in a model library which is a simple list of model definitions. For setting up a process object we should make a copy (an instance) of a model, which gets the current parameter values from the global variable list.

28.4.1 Module

```
<models.f90>≡

    <Models: procedures>

end module models

```

28.4.2 Physics Parameters

A parameter has a name, a value. Derived parameters also have a definition in terms of other parameters, which is stored as an `eval_tree`. External parameters are set by an external program.

This parameter object should be considered as a proxy object. The parameter name and value are stored in a corresponding `modelpar_data_t` object which is located in a `model_data_t` object. The latter is a component of the `model_t` handler. Methods of `parameter_t` can be delegated to the `par_data_t` component.

The `pn` component is a pointer to the parameter definition inside the model parse tree. It allows us to recreate the `eval_tree` when making copies (instances) of the parameter object.

```

<Models: parameters>≡
    integer, parameter :: PAR_NONE = 0, PAR_UNUSED = -1
    integer, parameter :: PAR_INDEPENDENT = 1, PAR_DERIVED = 2
    integer, parameter :: PAR_EXTERNAL = 3

<Models: types>≡
    type :: parameter_t
    private
    integer :: type = PAR_NONE
    class(modelpar_data_t), pointer :: data => null ()
    type(parse_node_t), pointer :: pn => null ()
    class(expr_t), allocatable :: expr
contains
    <Models: parameter: TBP>
end type parameter_t

```

Initialization depends on parameter type. Independent parameters are initialized by a constant value or a constant numerical expression (which may contain

a unit). Derived parameters are initialized by an arbitrary numerical expression, which makes use of the current variable list. The expression is evaluated by the function `parameter_reset`.

This implementation supports only real parameters and real values.

```

<Models: parameter: TBP>≡
  procedure :: init_independent_value => parameter_init_independent_value
  procedure :: init_independent => parameter_init_independent

```

28.4.3 Model Object

A model object holds all information about parameters, particles, and vertices. For models that require an external program for parameter calculation, there is

the pointer to a function that does this calculation, given the set of independent and derived parameters.

As explained above, the type inherits from `model_data_t`, which is the actual storage for the model data.

When reading a model, we create a parse tree. Parameter definitions are available via parse nodes. Since we may need those later when making model instances, we keep the whole parse tree in the model definition (but not in the instances).

```

<Models: public>≡
    public :: model_t

<Models: types>+≡
    type, extends (model_data_t) :: model_t
        private
        character(32) :: md5sum = ""
        logical :: ufo_model = .false.
        type(string_t) :: ufo_path
        type(string_t), dimension(:), allocatable :: schemes
        type(string_t), allocatable :: selected_scheme
        type(parameter_t), dimension(:), allocatable :: par
        integer :: max_par_name_length = 0
        integer :: max_field_name_length = 0
        type(var_list_t) :: var_list
        type(string_t) :: dlname
        procedure(model_init_external_parameters), nopass, pointer :: &
            init_external_parameters => null ()
        type(dlaccess_t) :: dlaccess
        type(parse_tree_t) :: parse_tree
    contains
        <Models: model: TBP>
    end type model_t

```

This is the interface for a procedure that initializes the calculation of external parameters, given the array of all parameters.

```

<Models: interfaces>≡
    abstract interface
        subroutine model_init_external_parameters (par) bind (C)
            import
            real(c_default_float), dimension(*), intent(inout) :: par
        end subroutine model_init_external_parameters
    end interface

```

Initialization: Specify the number of parameters, particles, vertices and allocate memory. If an associated DL library is specified, load this library.

The model may already carry scheme information, so we have to save and restore the scheme number when actually initializing the `model_data_t` base.

```

<Models: model: TBP>≡
    generic :: init => model_init
    procedure, private :: model_init

end subroutine model_set_parameter_unused

```

Make a copy of a parameter. We assume that the `model_data_t` parameter arrays have already been copied, so names and values are available in the current model, and can be used as targets. The eval tree should not be copied, since it should refer to the new variable list. The safe solution is to make use of the above initializers, which also take care of the building a new variable list.

end subroutine get_model_name
end subroutine model_generate_ufo

```

28.4.6 Scheme handling

A model can specify a set of allowed schemes that steer the setup of model variables. The model file can contain scheme-specific declarations that are selected by a `select scheme` clause. Scheme support is optional.

If enabled, the model object contains a list of allowed schemes, and the model reader takes the active scheme as an argument. After the model has been read, the scheme is fixed and can no longer be modified.

The model supports schemes if the scheme array is allocated.

(Models: model: TBP)+≡

```
procedure :: has_schemes => model_has_schemes
```

(Models: procedures)+≡

```
function model_has_schemes (model) result (flag)
    logical :: flag
    class(model_t), intent(in) :: model
    flag = allocated (model%schemes)
end function model_has_schemes

```

Enable schemes: fix the list of allowed schemes.

```

<Models: model: TBP>+≡
    procedure :: enable_schemes => model_enable_schemes

<Models: procedures>+≡
    subroutine model_enable_schemes (model, scheme)
        class(model_t), intent(inout) :: model
        type(string_t), dimension(:), intent(in) :: scheme
        allocate (model%schemes (size (scheme)), source = scheme)
    end subroutine model_enable_schemes

```

Find the scheme. Check if the scheme is allowed. The numeric index of the selected scheme is stored in the `model_data_t` base object.

If no argument is given, select the first scheme. The numeric scheme ID will then be 1, while a model without schemes retains 0.

```

<Models: model: TBP>+≡
    procedure :: set_scheme => model_set_scheme

<Models: procedures>+≡
    subroutine model_set_scheme (model, scheme)
        class(model_t), intent(inout) :: model
        type(string_t), intent(in), optional :: scheme
        logical :: ok
        integer :: i
        if (model%has_schemes ()) then
            if (present (scheme)) then
                ok = .false.
                CHECK_SCHEME: do i = 1, size (model%schemes)
                    if (scheme == model%schemes(i)) then
                        allocate (model%selected_scheme, source = scheme)
                        call model%set_scheme_num (i)
                        ok = .true.

call syntax_write (syntax_model_file, unit)
end subroutine syntax_model_file_write

```

Read a model from file. Handle all syntax and respect the provided scheme.

The ufo flag just says that the model object should be tagged as being derived from an UFO model. There is no difference in the contents of the file or the generated model object.

        n_par, n_prt, n_vtx)
      call model_list%import (current, model)
    end if
  end subroutine model_list_add
```

Read a new model from file and add to the list, if it does not yet exist. Finalize the model by allocating the vertex table. Return a pointer to the new model. If unsuccessful, return the original pointer.

The model is always inserted in the last link of a chain of model lists. This way, we avoid loading models twice from different contexts. When a model is modified, we should first allocate a local copy.

```

```

28.4.10 Model instances

A model instance is a copy of a model object. The parameters are true copies. The particle data and the variable list pointers should point to the copy, so modifying the parameters has only a local effect. Hence, we build them up explicitly. The vertex array is also rebuilt, it contains particle pointers. Finally, the vertex hash table can be copied directly since it contains no pointers.

The `multiplicity` entry depends on the association of the `mass_data` entry and therefore has to be set at the end.

The instance must carry the `target` attribute.

Parameters: the `copy_parameter` method essentially copies the parameter decorations (parse node, expression etc.). The current parameter values are part of the `model_data_t` base type and are copied afterwards via its `copy_from` method.

```

<Models: model: TBP>+≡
    procedure :: init_instance => model_copy

<Models: procedures>+≡
    subroutine model_copy (model, orig)
        class(model_t), intent(out), target :: model

28.5 The SUSY Les Houches Accord

The SUSY Les Houches Accord defines a standard interfaces for storing the physics data of SUSY models. Here, we provide the means for reading, storing, and writing such data.

```
(slha_interface.f90)≡  
  <File header>  
  
  module slha_interface  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use constants  
    use string_utils, only: upper_case  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF  
    use diagnostics  
    use os_interface  
    use ifiles  
    use lexers  
    use syntax_rules  
    use parser  
    use variables  
    use models  
  
    <Standard module head>  
  
    <SLHA: public>  
  
    <SLHA: parameters>  
  
    <SLHA: variables>  
  
    save  
  
  contains  
  
    <SLHA: procedures>  
  
    <SLHA: tests>  
  
  end module slha_interface
```

28.5.1 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the

parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

<SLHA: parameters>≡

```

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

```

<SLHA: public>+=

```

```

  type(var_list_t), intent(in), target :: var_list
  type(parse_node_t), pointer :: pn_data, pn_item
  call slha_find_index_ptr (pn_block, pn_data, pn_item, code)
  if (associated (pn_item)) then
    var = get_real_parameter (pn_item)
  else
    var = var_list%get_rval (name)
  end if
end function get_parameter_in_block
```

Extract a real data item with index *i*. If it does exist, set it in the variable list, using the given name. If the variable is not present in the variable list, ignore it.

(SLHA: procedures)+≡

```
subroutine set_data_item (pn_block, code, name, var_list)
  type(parse_node_t), intent(in), target :: pn_block
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(inout), target :: var_list
  type(parse_node_t), pointer :: pn_data, pn_item
  call slha_find_index_ptr (pn_block, pn_data, pn_item, code)
  if (associated (pn_item)) then
    call var_list%set_real (name, get_real_parameter (pn_item), &
      is_known=.true., ignore=.true.)
  end if
end subroutine set_data_item
```

Extract a real matrix element with index *i,j*. If it does exists, set it in the variable list, using the given name. If the variable is not present in the variable list, ignore it.

(SLHA: procedures)+≡

```
subroutine set_matrix_element (pn_block, code1, code2, name, var_list)
  type(parse_node_t), intent(in), target :: pn_block
  integer, intent(in) :: code1, code2
  type(string_t), intent(in) :: name
  type(var_list_t), intent(inout), target :: var_list
  type(parse_node_t), pointer :: pn_data, pn_item
  call slha_find_index_pair_ptr (pn_block, pn_data, pn_item, code1, code2)
  if (associated (pn_item)) then
    call var_list%set_real (name, get_real_parameter (pn_item), &
      is_known=.true., ignore=.true.)
  end if
end subroutine set_matrix_element
```

Transfer data from variables to SLHA

Get a real/integer parameter with index *i* from the variable list and write it to the current output file. In the integer case, we account for the fact that the variable is type real. If it does not exist, do nothing.

(SLHA: procedures)+≡

```
subroutine write_integer_data_item (u, code, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  integer :: item
  if (var_list%contains (name)) then
    item = nint (var_list%get_rval (name))
    call write_integer_parameter (u, code, item, comment)
  end if
end subroutine write_integer_data_item

subroutine write_real_data_item (u, code, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  real(default) :: item
  if (var_list%contains (name)) then
    item = var_list%get_rval (name)
    call write_real_parameter (u, code, item, comment)
  end if
end subroutine write_real_data_item
```

Get a real data item with two integer indices from the variable list and write it to the current output file. If it does not exist, do nothing.

(SLHA: procedures)+≡

```
subroutine write_matrix_element (u, code1, code2, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code1, code2
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  real(default) :: item
  if (var_list%contains (name)) then
    item = var_list%get_rval (name)
    call write_real_matrix_element (u, code1, code2, item, comment)
  end if
end subroutine write_matrix_element
```

28.5.4 Auxiliary function

Write a block header.

```
(SLHA: procedures)+≡
subroutine write_block_header (u, name, comment)
  integer, intent(in) :: u
  character(*), intent(in) :: name, comment
  write (u, "(A,1x,A,3x,'#',1x,A)") "BLOCK", name, comment
end subroutine write_block_header
```

Extract a real parameter that may be defined real or integer, signed or unsigned.

```
(SLHA: procedures)+≡
function get_real_parameter (pn_item) result (var)
  real(default) :: var
  type(parse_node_t), intent(in), target :: pn_item
  type(parse_node_t), pointer :: pn_sign, pn_var

integer, parameter :: MDL_NMSSM = 1
```

Take the parse tree and extract relevant data. Select the correct model and store all data that is present in the appropriate variable list. Finally, update the variable record.

Public for use in unit test.

```

SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is not defined in the block, we use the previous value from the model variable list. For the basic parameters we have to do a small recalculation, since SLHA uses the G_F - α - m_Z scheme, while WHIZARD derives them from G_F , m_W , and m_Z .

end subroutine slha_handle_NMSSMRUN

```

28.5.5 Parser

Read a SLHA file from stream, including preprocessing, and make up a parse tree.

(SLHA: procedures)+≡

```
subroutine slha_parse_stream (stream, parse_tree)
  type(stream_t), intent(inout), target :: stream
  type(parse_tree_t), intent(out) :: parse_tree
  type(ifile_t) :: ifile
  type(lexer_t) :: lexer
  type(stream_t), target :: stream_tmp
  call slha_preprocess (stream, ifile)
  call stream_init (stream_tmp, ifile)
  call lexer_init_slha (lexer)
  call lexer_assign_stream (lexer, stream_tmp)
  call parse_tree_init (parse_tree, syntax_slha, lexer)
  call lexer_final (lexer)
  call stream_final (stream_tmp)
  call ifile_final (ifile)
end subroutine slha_parse_stream
```

Read a SLHA file chosen by name. Check first the current directory, then the directory where SUSY input files should be located.

Required for test:

(SLHA: public)+≡

```
public :: slha_parse_file
```

(SLHA: procedures)+≡

```
subroutine slha_parse_file (file, os_data, parse_tree)
  type(string_t), intent(in) :: file
  type(os_data_t), intent(in) :: os_data
  type(parse_tree_t), intent(out) :: parse_tree
  logical :: exist
  type(string_t) :: filename

    end if
  end if
  call stream_init (stream, char (filename))
  call slha_parse_stream (stream, parse_tree)
  call stream_final (stream)
end subroutine slha_parse_file
```

28.5.6 API

Read the SLHA file, parse it, and interpret the parse tree. The model parameters retrieved from the file will be inserted into the appropriate model, which is loaded and modified in the background. The pointer to this model is returned as the last argument.

```

<SLHA: public>+=
    public :: slha_read_file

<SLHA: procedures>+=
    subroutine slha_read_file &
        (file, os_data, model, input, spectrum, decays)
        type(string_t), intent(in) :: file
        type(os_data_t), intent(in) :: os_data
        type(model_t), intent(inout), target :: model
        logical, intent(in) :: input, spectrum, decays
        type(parse_tree_t) :: parse_tree
        call slha_parse_file (file, os_data, parse_tree)
        if (associated (parse_tree%get_root_ptr ())) then
            call slha_interpret_parse_tree &
                (parse_tree, model, input, spectrum, decays)
            call parse_tree_final (parse_tree)
            call model%update_parameters ()
        end if
    end subroutine slha_read_file

```

Write the SLHA contents, as far as possible, to external file.

```

<SLHA: public>+=
    public :: slha_write_file

<SLHA: procedures>+=
    subroutine slha_write_file (file, model, input, spectrum, decays)
        type(string_t), intent(in) :: file

C
C -- All masses, momenta, energies, widths in GeV
C
C -- Input parameters:
C
C xenergy : E=SQRT[s]-2*topmass
C xtm      : topmass (in the Pole scheme)
C xtg      : top-width
C xalphas  :  $\alpha_s^{\{MSbar,n_f=5\}}$ (xscale)
C xscale   : soft scale  $\mu_{\{soft\}}$ 
C xcutn    : numerical UV cutoff on all momenta
C           (UV cutoff of the Gauss-Legendre grid)
C xcutv    : renormalization cutoff on the
C           delta-, the (p^2+q^2)/(p-q)^2-, and the
C           1/r^2-[1/|p-q|]-potential:
C           if (max(p,q).ge.xcutv) then the three potentials
C           are set to zero in the Lippmann-Schwinger equation

```

```

c   xc0      : 0th order coefficient for the Coulomb potential,
c               see calling example above
c   xc1      : 1st order coefficient for the Coulomb potential
c   xc2      : 2nd order coefficient for the Coulomb potential
c   xcdeltc   : constant of the delta(r)-
c               [= constant in momentum space-] potential
c   xcdeltl   : constant for the additional log(q^2/mu^2)-part of the
c               delta-potential:
c               xcdeltc*1 + xcdeltl*log(q^2/mu^2)
c   xcfullc   : constant of the (p^2+q^2)/(p-q)^2-potential
c   xcfulll   : constant for the additional log(q^2/mu^2)-part of the
c               (p^2+q^2)/(p-q)^2-potential
c   xcrm2     : constant of the 1/r^2-[1/|p-q|]-potential
c   xkincm    : } kinetic corrections in the 0th order Green-function:
c   xkinca    : } G_0(p):=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c               !!! WATCH THE SIGN IN G_0 !!!
c   jknflg    : flag for these kinetic corrections:
c               0 : no kinetic corrections applied
c               1 : kinetic corrections applied with cutoff xcutv
c                   for xkinca only
c               2 : kinetic corrections applied with cutoff xcutv
c                   for xkinca AND xkincm
c   jgcflg    : flag for G_0(p) in the LS equation:
c               0 (standard choice) : G_0(p) as given above
c               1 (for TIPT)         : G_0(p) = G_c^{0}(p) the 0th
c                                       order Coulomb-Green-function
c                                       in analytical form; not for
c                                       momenta p > 1000*topmass
c   xkincv    : additional kinematic vertexcorrection in G_0, see below:
c   jvflg     : flag for the additional vertexcorrection xkincv in the
c               'zeroth order' G_0(p) in the LS-equation:
c               0 : no correction, means G = G_0 + G_0 int V G
c                   with G_0=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c               1 : apply the correction in the LS equation as
c                   G = G_0 + xkincv*p^2/m_t^2/[E+iGamma_t-p^2/m_t] +
c                   G_0 int V G
c               and correct the integral over Im[G(p)] to get sigma_tot
c               from the optical theorem by the same factor.
c               The cutoff xcutv is applied for these corrections.
c
c -- Output:
c
c   xim      : R_{ttbar} from the imaginary part of the green
c               function
c   xdi      : R_{ttbar} form the integral over the momentum
c               distribution (no cutoff but the numerical one here!!)
c   np       : number of points used for the grid; fixed in tttoppik
c   xpp      : 1-dim array (max. 900 elements) giving the momenta of
c               the Gauss-Legendre grid (pp(i) in the code)
c   xww      : 1-dim array (max. 900 elements) giving the corresponding
c               Gauss-Legendre weights for the grid
c   xdsdp    : 1-dim array (max. 900 elements) giving the
c               momentum distribution of top: d\sigma/dp,
c               normalized to R,

```

```

c          at the momenta of the Gauss-Legendre grid xpp(i)
c  zvfct    : 1-dim array (max. 900 elements) of COMPLEX*16 numbers
c             giving the vertex function K(p), G(p)=K(p)*G_0(p)
c             at the momenta of the grid

        if ((npot.eq.1).or.(npot.eq.3).or.(npot.eq.4).or.
            (npot.eq.5)) then
    u
c For pure coulomb and fixed order potentials there is no delta-part:
        consde = 0.d0
        else if (npot.eq.2) then
c Initialize QCD-potential common-blocks and calculate constant multiplying
c the delta-part of the 'qcutted' potential in momentum-space:
            call iniphc(1)
            call vqdelt(consde)
        else
            write (*,*) ' Potential not implemented! Stop.'
            stop
        endif
c Delta-part of potential is absorbed by subtracting vzero from the
c original energy (shift from the potential to the free Hamiltonian):
        vzero = consde / (2.d0*pi)**3
c
        write (*,*) 'vzero=', vzero
c
c Find x-values pp(i) and weigths w1(i) for the gaussian quadrature;
c care about large number of points in the important intervals:
c     if (energy-vzero.le.0.d0) then
cc         call gauleg(0.d0, 1.d0, pp, w1, n/3)
cc         call gauleg(1.d0, 5.d0, pp(n/3+1), w1(n/3+1), n/3)
cc         call gauleg(0.d0, 0.2d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c         call gauleg(0.d0, 5.d0, pp, w1, n/3)
c         call gauleg(5.d0, 20.d0, pp(n/3+1), w1(n/3+1), n/3)
c         call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c     else
cc Avoid numerical singular points in the inner of the intervals:
c         critp = dsqrt((energy-vzero)*tmass)
c         if (critp.le.1.d0) then
cc Gauss-Legendre is symmetric => automatically principal-value prescription:
c             call gauleg(0.d0, 2.d0*critp, pp, w1, n/3)
c             call gauleg(2.d0*critp, 20.d0, pp(n/3+1),
c                 u             w1(n/3+1), n/3)
c             call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c         else
cc Better behaviour at the border of the intervals:
c             call gauleg(0.d0, critp, pp, w1, n/3)
c             call gauleg(critp, 2.d0*critp, pp(n/3+1),
c                 u             w1(n/3+1), n/3)
c             call gauleg(0.d0, 1.d0/(2.d0*critp), pp(2*n/3+1),
c                 u             w1(2*n/3+1), n/3)
c         endif
c     endif
c
c Or different (simpler) method, good for V_JKT:
        if (energy.le.0.d0) then
            critp=tmass/3.d0
        else
            critp=max(tmass/3.d0,2.d0*dsqrt(energy*tmass))
        endif
        call gauleg(0.d0, critp, pp, w1, 2*n/3)
        call gauleg(1.d0/xpmax, 1.d0/critp, pp(2*n/3+1),

```

```

      u          w1(2*n/3+1), n/3)
c
c Do substitution p => 1/p for the last interval explicitly:
      do 10 i=2*n/3+1,n
          pp(i) = 1.d0/pp(i)
10      continue
c
c Reorder the arrays for the third interval:
      do 20 i=1,n/3
          xx(i) = pp(2*n/3+i)
          w2(i) = w1(2*n/3+i)
20      continue
      do 30 i=1,n/3
          pp(n-i+1) = xx(i)
          w1(n-i+1) = w2(i)
30      continue
c
c Calculate the integrals a(p) for the given momenta pp(i)
c and store weights and momenta for the output arrays:
      do 40 i=1,n
          a1(i) = a(pp(i)) !!! FB: can get stuck in original Toppik!
          !!! FB: abuse 'np' as a flag to communicate unstable runs
          if ( abs(a1(i)) .gt. 1d10 ) then
              np = -1
              return
          endif
          xpp(i)=pp(i)
          xww(i)=w1(i)
40      continue
      do 41 i=n+1,nmax
          xpp(i)=0.d0
          xww(i)=0.d0
41      continue
c
c Solve the integral-equation by solving a system of algebraic equations:
      call sae(pp, w1, bb, a1, n)
c
c (The substitution for the integration to infinity pp => 1/pp
c is done already.)
      do 50 i=1,n
          zvfct(i)=bb(i)

c Correction function for non-constant (energy and momentum dependent) width:
      FUNCTION GTPCOR1(TOPP,ETOT)
C
C      TOPP - momentum of t quark = - momentum of tbar
C      ETOT - total energy of t-tbar system
C      calls: GENWDS, RAN2
C
C      Evaluates a correction factor to the width of t-tbar system.
C      in future has to be replaced by a function evaluating
C      width including radiative corrections and GTPCOR.
C      I include two factors reducing the width:

```

```

c      a - time dilatation: for decay in flight lifetime
c      increased accordingly to relativistic kinematics
c      b - overall energy-momentum conservation: I assume that
c      t and tbar decay in flight and in this decays energies
c      of Ws follow from 2-body kinematics. Then I calculate
c      effective mass squared of b-bar system (it may be
c      negative!) from en-momentum conservation.
c      If effective mass is < 2*Mb + 2 GeV configuration
c      is rejected. The weight is acceptance.

!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!

C *****
C      Version tuned to provide 0(1%) relative accuracy for Coulomb axial
C      vertex function at first and second order (search for 'cctt'):
C      - integrals A(p), Vhat, Vhhat provided analytically w/out cut-off
C      - grid range fixed to 0.1 ... 10**6 absolut
C      - and grid size enhanced to 600 points (900 foreseen in arrays).
C
C      This provides a compromise between stability and accuracy:
C      We need a relatively high momentum resolution and large maximal
C      momenta to achieve a ~1 percent accuracy, but the method of
C      direct inversion of the discretised integral equation for objects
C      whose integral is divergent induces instabilities at small
C      momenta. As the behaviour there is known, they can be cut off and
C      the vertex function fixed by hand; but limiting the grid
C      further would impact on the accuracy.
C      22.3.2017, tt

c      from M. Jezabek and TT, Karlsruhe, June 1992
c    * Version originally for non-constant top-width
c    * Constant width supplied here
c    * No generator included
c
c -- Use of double precision everywhere
c
c -- All masses, momenta, energies, widths in GeV
c
c -- Input parameters:
c
c    xenergy  :  $E=\text{Sqrt}[s]-2*\text{topmass}$ 
c    xtm      : topmass (in the Pole scheme)
c    xtg      : top-width
c    xalphas  :  $\alpha_s^{\{\text{MSbar},n_f=5\}}(\text{xscale})$ 
c    xscale   : soft scale  $\mu_{\{\text{soft}\}}$ 
c    xcutn    : numerical UV cutoff on all momenta
c              (UV cutoff of the Gauss-Legendre grid)
c    xcutv    : renormalization cutoff on the
c              delta-, the  $(p^2+q^2)/(p-q)^2$ -, and the
c               $1/r^2-[1/|p-q|]$ -potential:
c              if  $(\max(p,q).\text{ge.xcutv})$  then the three potentials
c              are set to zero in the Lippmann-Schwinger equation
c    xc0      : 0th order coefficient for the Coulomb potential,
c              see calling example above
c    xc1      : 1st order coefficient for the Coulomb potential
c    xc2      : 2nd order coefficient for the Coulomb potential
c    xcdeltc  : constant of the delta(r)-

```

```

c          [= constant in momentum space-] potential
c  xcdeltl : constant for the additional  $\log(q^2/\mu^2)$ -part of the
c            delta-potential:
c             $xcdeltc*1 + xcdeltl*\log(q^2/\mu^2)$ 
c  xcfullc : constant of the  $(p^2+q^2)/(p-q)^2$ -potential
c  xcfulll : constant for the additional  $\log(q^2/\mu^2)$ -part of the
c             $(p^2+q^2)/(p-q)^2$ -potential
c  xcrm2    : constant of the  $1/r^2-[1/|p-q|]$ -potential
c  xkincm   : } kinetic corrections in the 0th order Green function:
c  xkinca   : }  $G_0(p) := 1/[E+i\Gamma_t-p^2/m_t]*(1+xkincm)+xkinca$ 
c            !!! WATCH THE SIGN IN  $G_0$  !!!
c  jknflg   : flag for these kinetic corrections:
c              0 : no kinetic corrections applied
c              1 : kinetic corrections applied with cutoff xcutv
c                  for xkinca only
c              2 : kinetic corrections applied with cutoff xcutv
c                  for xkinca AND xkincm
c  jgcflg   : flag for  $G_0(p)$  in the LS equation:
c              0 (standard choice) :  $G_0(p)$  as given above
c              1 (for TIPT)         :  $G_0(p) = G_c^{\{0\}}(p)$  the 0th
c                                      order Coulomb Green function
c                                      in analytical form; not for
c                                      momenta  $p > 1000*topmass$ 
c  xkincv   : additional kinematic vertexcorrection in  $G_0$ , see below:
c  jvflg    : flag for the additional vertexcorrection xkincv in the
c              'zeroth order'  $G_0(p)$  in the LS-equation:
c              0 : no correction, means  $G = G_0 + G_0 \int V G$ 
c                  with  $G_0 = 1/[E+i\Gamma_t-p^2/m_t]*(1+xkincm)+xkinca$ 
c              1 : apply the correction in the LS equation as
c                   $G = G_0 + xkincv*p^2/m_t^2/[E+i\Gamma_t-p^2/m_t] +$ 
c                   $G_0 \int V G$ 
c                  and correct the integral over  $\text{Im}[G(p)]$  to get  $\sigma_{tot}$ 
c                  from the optical theorem by the same factor.
c                  The cutoff xcutv is applied for these corrections.
c
c -- Output:
c
c  xim      :  $R^{\{P \text{ wave}\}}_{\{ttbar\}}$  from the imaginary part of the Green
c              function
c  xdi      :  $R^{\{P \text{ wave}\}}_{\{ttbar\}}$  from the integral over the momentum
c              distribution:  $\int_0^{xcutv} dp p^3/m_t * |F(p,E)|^2$ 
c  np       : number of points used for the grid; fixed in tttoppik
c  xpp      : 1-dim array (max. 900 elements) giving the momenta of
c              the Gauss-Legendre grid (pp(i) in the code)
c  xww      : 1-dim array (max. 900 elements) giving the corresponding
c              Gauss-Legendre weights for the grid
c  xdsdp    : 1-dim array (max. 900 elements) giving the
c              momentum distribution of top:  $d\sigma^{\{P \text{ wave}\}}/dp$ ,
c              normalized to R,
c              at the momenta of the Gauss-Legendre grid xpp(i)
c  zftild   : 1-dim array (max. 900 elements) of COMPLEX*16 numbers
c              giving the vertex function  $K_A$  for the P-wave
c              at the momenta of the grid.
c              Then  $F(p) = K_A(p) * G_0(p)$  corresponding to  $G = K_V * G_0$ .

cc Gauss-Legendre is symmetric => automatically principal-value prescription:
c         call gauleg(0.d0, 2.d0*critp, pp, w1, n/3)
c         call gauleg(2.d0*critp, 20.d0, pp(n/3+1),
c         u         w1(n/3+1), n/3)
c         call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c         else
cc Better behaviour at the border of the intervals:
c         call gauleg(0.d0, critp, pp, w1, n/3)
c         call gauleg(critp, 2.d0*critp, pp(n/3+1),
c         u         w1(n/3+1), n/3)
c         call gauleg(0.d0, 1.d0/(2.d0*critp), pp(2*n/3+1),
c         u         w1(2*n/3+1), n/3)
c         endif
c         endif
c
c Or different (simpler) method, good for V_JKT:
c         if (energy.le.0.d0) then
c         critp=tmass/3.d0
c         else
c         critp=max(tmass/3.d0,2.d0*sqrt(energy*tmass))
c         endif
c         call gauleg(0.d0, critp, pp, w1, 2*n/3)
c         call gauleg(1.d0/xpmax, 1.d0/critp, pp(2*n/3+1),
c         u         w1(2*n/3+1), n/3)
cctt Tuned March 2017 for best possible numerical behaviour of P-wave

```

```

        call gauleg(0.1d0, 2.d0, pp, w1, 10)
        call gauleg(2.d0, critp, pp(11), w1(11), 2*n/3-10)
        call gauleg(1.d-6, 1.d0/critp, pp(2*n/3+1),
u           w1(2*n/3+1), n/3)
c
c Do substitution  $p \Rightarrow 1/p$  for the last interval explicitly:
        do 10 i=2*n/3+1,n
            pp(i) = 1.d0/pp(i)
10         continue
c
c Reorder the arrays for the third interval:
        do 20 i=1,n/3
            xx(i) = pp(2*n/3+i)
            w2(i) = w1(2*n/3+i)
20         continue
        do 30 i=1,n/3
            pp(n-i+1) = xx(i)
            w1(n-i+1) = w2(i)
30         continue
c
c Calculate the integrals aax(p) for the given momenta pp(i)
c and store weights and momenta for the output arrays:
        do 40 i=1,n
            a1(i) = aax(pp(i)) !!! FB: can get stuck in original Toppik!
            !!! FB: abuse 'np' as a flag to communicate unstable runs
            if ( abs(a1(i)) .gt. 1d10 ) then
                np = -1
                return
            endif
            xpp(i)=pp(i)
            xww(i)=w1(i)
40         continue
        do 41 i=n+1,nmax
            xpp(i)=0.d0
            xww(i)=0.d0
41         continue
c
c Solve the integral-equation by solving a system of algebraic equations:
        call saeax(pp, w1, bb, vec, a1, n)
c
c (The substitution for the integration to infinity  $pp \Rightarrow 1/pp$ 
c is done already.)
        do 50 i=1,n
            zvfct(i)=bb(i)
            zftild(i)=vec(i)
            gg(i) = bb(i)*g0c(pp(i))
cc         gg(i) = (1.d0 + bb(i))*g0c(pp(i))
cc Urspruenglich anderes (Minus) VZ hier, dafuer kein Minus mehr bei der
cc Definition des Wqs ueber Im G, 2.6.1998, tt.
cc         gg(i) = - (1.d0 + bb(i))*g0c(pp(i))
50         continue
c
c Normalisation on R:
        const = 8.d0*pi/tmass**2

```

Chapter 30

Integration and Process Objects

This is the central part of the WHIZARD package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

subevt_expr This enables process observables as (abstract) expressions, to be evaluated for each process call.

parton_states A `parton_state_t` object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

process Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: `prc_core` for matrix-element evaluation, `prc_core_def` for the associated configuration and driver, `sf_base` for beams and structure-functions, `phs_base` for phase space, and `mci_base` for integration and event generation.

process_config

kinematics

instances While the above modules set up all static information, the instances have the changing event data. There are term and process instances but no component instances.

process_stacks Process stacks collect process objects.

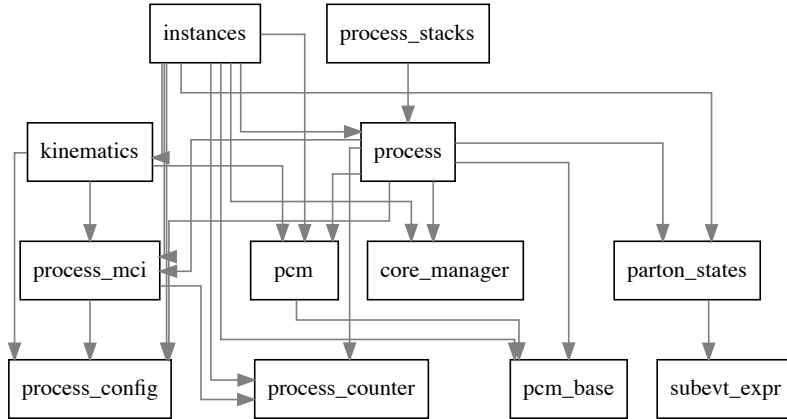

Figure 30.1: Module dependencies in `src/process_integration`.

We combine here hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the **computed** state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the **observed** state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible

subsequent decay processes on the parton level, which are full-fledged process objects themselves.

30.1 Process observables

We define an abstract `subevt_expr_t` object as an extension of the `subevt_t` type. The object contains a local variable list, variable instances (as targets for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the `subevt`.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression `selection` which determines whether the object passes user-defined cuts.

The intention is that we fill the `subevt_t` base object and compute the variables once we have evaluated a kinematical phase space point (or a complete event). We then evaluate the expressions and can use the results in further calculations.

The `process_expr_t` extension contains furthermore scale and weight expressions. The `event_expr_t` extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

Note that there are unit tests, but they are deferred to the `expr_tests` module.

```

      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_out"), expr%n_out, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
    call var_list_append_int_ptr (expr%var_list, &
      var_str ("n_tot"), expr%n_tot, &
      is_known = expr%subevt_filled, &
      locked = .true., verbose = .false., intrinsic = .true.)
  end subroutine subevt_expr_setup_vars

```

Append the subevent `expr` (its base-type core) itself to the variable list, if it is not yet present.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure :: setup_var_self => subevt_expr_setup_var_self

<Subevt expr: procedures>+≡
  subroutine subevt_expr_setup_var_self (expr)
    class(subevt_expr_t), intent(inout), target :: expr
    if (.not. expr%var_list%contains (var_str ("@evt"))) then
      call var_list_append_subevt_ptr &
        (expr%var_list, &
         var_str ("@evt"), expr%subevt_t, &
         is_known = expr%subevt_filled, &
         locked = .true., verbose = .false., intrinsic=.true.)
    end if
  end subroutine subevt_expr_setup_var_self

```

Link a variable list to the local one. This could be done event by event, but before evaluating expressions.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure :: link_var_list => subevt_expr_link_var_list

<Subevt expr: procedures>+≡
  subroutine subevt_expr_link_var_list (expr, var_list)
    class(subevt_expr_t), intent(inout) :: expr
    type(var_list_t), intent(in), target :: var_list
    call expr%var_list%link (var_list)
  end subroutine subevt_expr_link_var_list

```

Compile the selection expression. If there is no expression, the build method won't allocate the expression object.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure :: setup_selection => subevt_expr_setup_selection

<Subevt expr: procedures>+≡
  subroutine subevt_expr_setup_selection (expr, ef_cuts)
    class(subevt_expr_t), intent(inout), target :: expr
    class(expr_factory_t), intent(in) :: ef_cuts
    call ef_cuts%build (expr%selection)
    if (allocated (expr%selection)) then
      call expr%setup_var_self ()
      call expr%selection%setup_lexpr (expr%var_list)
      expr%has_selection = .true.
    end if
  end subroutine subevt_expr_setup_selection

```

30.1.3 Evaluation

Reset to initial state, i.e., mark the subevt as invalid.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure :: reset => subevt_expr_reset
  procedure :: base_reset => subevt_expr_reset

```

```

<Subvt expr: procedures>+≡
  subroutine subvt_expr_reset (expr)
    class(subvt_expr_t), intent(inout) :: expr
    expr%subvt_filled = .false.
  end subroutine subvt_expr_reset

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

<Subvt expr: subvt expr: TBP>+≡
  procedure :: base_evaluate => subvt_expr_evaluate

<Subvt expr: procedures>+≡
  subroutine subvt_expr_evaluate (expr, passed)
    class(subvt_expr_t), intent(inout) :: expr
    logical, intent(out) :: passed
    if (expr%has_selection) then
      call expr%selection%evaluate ()
      if (expr%selection%is_known ()) then
        passed = expr%selection%get_log ()
      else
        call msg_error ("Evaluate selection expression: result undefined")
        passed = .false.
      end if
    else
      passed = .true.
    end if
  end subroutine subvt_expr_evaluate

```

30.1.4 Implementation for partonic events

This implementation contains the expressions that we can evaluate for the partonic process during integration.

```

<Subvt expr: public>≡
  public :: parton_expr_t

<Subvt expr: types>+≡
  type, extends (subvt_expr_t) :: parton_expr_t
    integer, dimension(:), allocatable :: i_beam
    integer, dimension(:), allocatable :: i_in
    integer, dimension(:), allocatable :: i_out
    logical :: has_scale = .false.
    logical :: has_fac_scale = .false.
    logical :: has_ren_scale = .false.
    logical :: has_weight = .false.
    class(expr_t), allocatable :: scale
    class(expr_t), allocatable :: fac_scale
    class(expr_t), allocatable :: ren_scale
    class(expr_t), allocatable :: weight
  contains
    <Subvt expr: parton expr: TBP>
  end type parton_expr_t

```

Finalizer.

```

<Subevt expr: parton expr: TBP>≡
  procedure :: final => parton_expr_final

<Subevt expr: procedures>+≡
  subroutine parton_expr_final (object)
    class(parton_expr_t), intent(inout) :: object
    call object%base_final ()
    if (object%has_scale) then
      call object%scale%final ()
    end if
    if (object%has_fac_scale) then
      call object%fac_scale%final ()
    end if
    if (object%has_ren_scale) then
      call object%ren_scale%final ()
    end if
    if (object%has_weight) then
      call object%weight%final ()
    end if
  end subroutine parton_expr_final

```

Output: continue writing the active expressions, after the common selection expression.

Note: the `prefix` argument is declared in the `write` method of the `subevt_t` base type. Here, it is unused.

```

<Subevt expr: parton expr: TBP>+≡

            expr%has_weight = .true.
        end if
    end subroutine parton_expr_setup_weight

```

Filling the partonic state consists of two parts. The first routine prepares the subevt without assigning momenta. It takes the particles from an `interaction_t`. It needs the indices and flavors for the beam, incoming, and outgoing particles.

We can assume that the particle content of the subevt does not change. Therefore, we set the event variables `n_in`, `n_out`, `n_tot` already in this initialization step.

```

<Subevt expr: parton expr: TBP>+≡
    procedure :: setup_subevt => parton_expr_setup_subevt

<Subevt expr: procedures>+≡
    subroutine parton_expr_setup_subevt (expr, int, &
        i_beam, i_in, i_out, f_beam, f_in, f_out)
        class(parton_expr_t), intent(inout) :: expr

30.1.5 Implementation for full events

This implementation contains the expressions that we can evaluate for the full event. It also contains data that pertain to the event, suitable for communication with external event formats. These data simultaneously serve as pointer targets for the variable lists hidden in the expressions (eval trees).

Squared matrix element and weight values: when reading events from file, the **ref** value is the number in the file, while the **prc** value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of **alt** values is copied from an array of alternative event records. These values should represent calculated values.

```

30.2 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states,

depending on the the beam setup allows. The result is used for integration.

The **matrix** evaluator is the counterpart of **trace** which is kept exclusive in all observable quantum numbers. The **flows** evaluator is furthermore exclusive in colors, but neglecting all color interference. The **matrix** and **flows** evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. However, this causes memory corruption in gfortran 4.6.3. The extra **has_XXX** flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the **processes** module below.

```

<parton_states.f90>≡
  <File header>
  module parton_states

    <Use kinds>
    use io_units
    use format_utils, only: write_separator
    use diagnostics
    use lorentz
    use subevents
    use variables

    <Standard module head>

    <Parton states: public>

    <Parton states: types>

    contains

    <Parton states: procedures>

  end module parton_states

```

30.2.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

⟨Parton states: types⟩≡
  type, abstract :: parton_state_t
    logical :: has_trace = .false.
    logical :: has_matrix = .false.
    logical :: has_flows = .false.
    type(evaluator_t) :: trace
    type(evaluator_t) :: matrix
    type(evaluator_t) :: flows
  contains
    ⟨Parton states: parton state: TBP⟩
  end type parton_state_t

```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both implemented as a pointer. The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```

⟨Parton states: public⟩≡
  public :: isolated_state_t

⟨Parton states: types⟩+≡
  type, extends (parton_state_t) :: isolated_state_t
    logical :: sf_chain_is_allocated = .false.
    type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()
    logical :: int_is_allocated = .false.
    type(interaction_t), pointer :: int_eff => null ()
  contains
    ⟨Parton states: isolated state: TBP⟩
  end type isolated_state_t

```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

```

⟨Parton states: public⟩+≡
  public :: connected_state_t

⟨Parton states: types⟩+≡
  type, extends (parton_state_t) :: connected_state_t
    type(state_flv_content_t) :: state_flv
    logical :: has_flows_sf = .false.
    type(evaluator_t) :: flows_sf

```

```

    logical :: has_expr = .false.
    type(parton_expr_t) :: expr
contains
  <Parton states: connected state: TBP>
end type connected_state_t

```

Output: each evaluator is written only when it is active. The `sf_chain` is only written if it is explicitly allocated.

30.2.2 Common Initialization

Initialize the isolated parton state. In this version, the effective structure-function chain `sf_chain_eff` and the effective interaction `int_eff` both are trivial pointers to the seed structure-function chain and to the hard interaction, respectively.

```
(Parton states: isolated state: TBP)≡
  procedure :: init => isolated_state_init

(Parton states: procedures)+≡
  subroutine isolated_state_init (state, sf_chain, int)
    class(isolated_state_t), intent(out) :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(interaction_t), intent(in), target :: int
    state%sf_chain_eff => sf_chain
    state%int_eff => int
  end subroutine isolated_state_init
```

30.2.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask_in`.

There are two options: explicitly computing the color factor table (`use_cf` false; `nc` defined), or taking the color factor table from the hard matrix element data.

```
(Parton states: isolated state: TBP)+≡
  procedure :: setup_square_trace => isolated_state_setup_square_trace

(Parton states: procedures)+≡
  subroutine isolated_state_setup_square_trace (state, core, &
    qn_mask_in, col, keep_fs_flavor)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), intent(in), dimension(:) :: qn_mask_in
    !!! Actually need allocatable attribute here fore once because col might
    !!! enter the subroutine non-allocated.
    integer, intent(in), dimension(:), allocatable :: col
    logical, intent(in) :: keep_fs_flavor
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    associate (data => core%data)
      allocate (qn_mask (data%n_in + data%n_out))
      qn_mask( : data%n_in) = &
        quantum_numbers_mask (.false., .true., .false.) &
        .or. qn_mask_in
      qn_mask(data%n_in + 1 : ) = &
        quantum_numbers_mask (.not. keep_fs_flavor, .true., .true.)
      if (core%use_color_factors) then
        call state%trace%init_square (state%int_eff, qn_mask, &
          col_flow_index = data%cf_index, &
```

```

        col_factor = data%color_factors, &
        col_index_hi = col, &
        nc = core%nc)
    else
        call state%trace%init_square (state%int_eff, qn_mask, nc = core%nc)
    end if
end associate
state%has_trace = .true.
end subroutine isolated_state_setup_square_trace

```

Setup an identity-evaluator for the trace. This implies that `me` is considered to be a squared amplitude, as for example for BLHA matrix elements.

```

<Parton states: isolated state: TBP>+≡
    procedure :: setup_identity_trace => isolated_state_setup_identity_trace

<Parton states: procedures>+≡
    subroutine isolated_state_setup_identity_trace (state, core, qn_mask_in, &
        keep_fs_flavors, keep_colors)
        class(isolated_state_t), intent(inout), target :: state
        class(prc_core_t), intent(in) :: core

            qn_mask( : data%n_in) = &
                quantum_numbers_mask (.false., col_flag, .false.) .or. qn_mask_in
            qn_mask(data%n_in + 1 : ) = &
                quantum_numbers_mask (fs_flg_flag, col_flag, .true.)
        end associate
        call state%int_eff%set_mask (qn_mask)
        call state%trace%init_identity (state%int_eff)
        state%has_trace = .true.
    end subroutine isolated_state_setup_identity_trace

```

Setup the evaluator for the transition matrix, exclusive in helicities where this is requested.

For all unstable final-state particles we keep polarization according to the applicable decay options. If the process is a decay itself, this applies also to the initial state.

For all polarized final-state particles, we keep polarization including off-diagonal entries. We drop helicity completely for unpolarized final-state particles.

For the initial state, if the particle has not been handled yet, we apply the provided `qn_mask_in` which communicates the beam properties.

```

30.2.4 Evaluator initialization: connected state

Setup a trace evaluator as a product of two evaluators (incoming state, effective interaction). In the result, all quantum numbers are summed over.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`.

The `resonant` flag applies if we want to construct a decay chain. The resonance property can propagate to the final event output.

30.2.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

```

  class(expr_factory_t), intent(in) :: ef_weight
  call state%expr%setup_weight (ef_weight)
end subroutine connected_state_setup_weight

```

Reset the expression object: invalidate the subevt.

```

(Parton states: connected state: TBP)+≡
  procedure :: reset_expressions => connected_state_reset_expressions
(Parton states: procedures)+≡
  subroutine connected_state_reset_expressions (state)
    class(connected_state_t), intent(inout) :: state
    if (state%has_expr) call state%expr%reset ()
  end subroutine connected_state_reset_expressions

```

30.2.6 Evaluation

Transfer momenta to the trace evaluator and fill the subevt with this effective kinematics, if applicable.

Note: we may want to apply a boost for the subevt.

```

(Parton states: parton state: TBP)+≡
  procedure :: receive_kinematics => parton_state_receive_kinematics
(Parton states: procedures)+≡
  subroutine parton_state_receive_kinematics (state)
    class(parton_state_t), intent(inout), target :: state
    if (state%has_trace) then
      call state%trace%receive_momenta ()
      select type (state)
      class is (connected_state_t)
        if (state%has_expr) then
          call state%expr%fill_subevt (state%trace%interaction_t)
        end if
      end select
    end if
  end subroutine parton_state_receive_kinematics

```

Recover kinematics: We assume that the trace evaluator is filled with momenta. Send those momenta back to the sources, then fill the variables and subevent as above.

The incoming momenta of the connected state are not connected to the isolated state but to the beam interaction. Therefore, the incoming momenta within the isolated state do not become defined, yet. Instead, we reconstruct the beam (and ISR) momentum configuration.

```

(Parton states: parton state: TBP)+≡

```

```

    procedure :: send_kinematics => parton_state_send_kinematics
  <Parton states: procedures>+≡
    subroutine parton_state_send_kinematics (state)
      class(parton_state_t), intent(inout), target :: state
      if (state%has_trace) then
        call interaction_send_momenta (state%trace%interaction_t)
        select type (state)
          class is (connected_state_t)
            call state%expr%fill_subevt (state%trace%interaction_t)
          end select
        end if
      end subroutine parton_state_send_kinematics

```

Evaluate the expressions. The routine evaluates first the cut expression. If the event passes, it evaluates the other expressions. Where no expressions are defined, default values are inserted.

```

  <Parton states: connected state: TBP>+≡
    procedure :: evaluate_expressions => connected_state_evaluate_expressions
  <Parton states: procedures>+≡
    subroutine connected_state_evaluate_expressions (state, passed, &
      scale, fac_scale, ren_scale, weight, scale_forced, force_evaluation)
      class(connected_state_t), intent(inout) :: state

30.3 Process component management

This module contains tools for managing and combining process components and matrix-element code and values, acting at a level below the actual process definition.

30.3.1 Abstract base type

The types introduced here are abstract base types.

```

⟨pcm_base.f90⟩≡
  ⟨File header⟩

```

```

module pcm_base

  use diagnostics

```

```

    use prc_core_def
    use prc_core

    <Standard module head>

    <PCM base: public>

    <PCM base: types>

    <PCM base: interfaces>

    contains

    <PCM base: procedures>

```

```

end module pcm_base

```

This object may hold process and method-specific data, and it should allocate the corresponding manager instance.

```

<PCM base: public>≡
    public :: pcm_t
<PCM base: types>≡
    type, abstract :: pcm_t
        logical :: initialized = .false.
    contains
    <PCM base: pcm: TBP>
end type pcm_t

```

The factory method. We use the `inout` intent, so calling this again is an error.

```

<PCM base: pcm: TBP>≡
    procedure(pcm_allocate_instance), deferred :: allocate_instance
<PCM base: interfaces>≡
    abstract interface
        subroutine pcm_allocate_instance (pcm, instance)
            import
            class(pcm_t), intent(in) :: pcm
            class(pcm_instance_t), intent(inout), allocatable :: instance
        end subroutine pcm_allocate_instance
    end interface

    <PCM base: pcm: TBP>+≡
        procedure(pcm_is_nlo), deferred :: is_nlo
    <PCM base: interfaces>+≡
        abstract interface
            function pcm_is_nlo (pcm) result (is_nlo)
                import
                logical :: is_nlo
                class(pcm_t), intent(in) :: pcm
            end function pcm_is_nlo
        end interface

```

```

<PCM base: pcm: TBP>+≡
  procedure(pcm_final), deferred :: final
<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_final (pcm)
      import
      class(pcm_t), intent(inout) :: pcm
    end subroutine pcm_final
  end interface

```

30.3.2 Manager instance

This object deals with the actual (squared) matrix element values.

```

<PCM base: public>+≡
  public :: pcm_instance_t
<PCM base: types>+≡
  type, abstract :: pcm_instance_t
    class(pcm_t), pointer :: config => null ()
  contains
    <PCM base: pcm instance: TBP>
  end type pcm_instance_t

<PCM base: pcm instance: TBP>≡
  procedure(pcm_instance_final), deferred :: final
<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_instance_final (pcm_instance)
      import
      class(pcm_instance_t), intent(inout) :: pcm_instance
    end subroutine pcm_instance_final
  end interface

<PCM base: pcm instance: TBP>+≡
  procedure(pcm_instance_is_valid), deferred :: is_valid
<PCM base: interfaces>+≡
  abstract interface
    function pcm_instance_is_valid (pcm_instance) result (valid)
      import
      logical :: valid
      class(pcm_instance_t), intent(in) :: pcm_instance
    end function pcm_instance_is_valid
  end interface

<PCM base: pcm instance: TBP>+≡
  procedure :: link_config => pcm_instance_link_config

```

```

<PCM base: procedures>≡
  subroutine pcm_instance_link_config (pcm_instance, config)
    class(pcm_instance_t), intent(inout) :: pcm_instance
    class(pcm_t), intent(in), target :: config
    pcm_instance%config => config
  end subroutine pcm_instance_link_config

```

30.4 Manager configuration

This object holds information about the cores used by the components and allocates the corresponding manager instance.

```

<core_manager.f90>≡
  <File header>

  module core_manager

    use format_utils, only: write_integer_array, write_separator
    use physics_defs, only: BORN, NLO_REAL
    use io_units
    use prc_core

```

A process object is the workspace for the process instance. After initialization, its contents are filled by integration passes which shape the integration grids and compute cross sections. Processes are set up initially from user-level configuration data. After calculating integrals and thus developing integration grid data, the program may use a process object or a copy of it for the purpose of generating events.

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The **type** determines whether we are considering a decay or a scattering process.

The **meta** object describes the process and its environment. All contents become fixed when the object is initialized.

The **config** object holds physical and technical configuration data that have been obtained during process initialization, and which are common to all process components.

The individual process components are configured in the **component** objects. These objects contain more configuration parameters and workspace, as needed for the specific process variant.

The **term** objects describe parton configurations which are technically used as phase-space points. Each process component may split into several terms with distinct kinematics and particle content. Furthermore, each term may project on a different physical state, e.g., by particle recombination. The **term** object provides the framework for this projection, for applying cuts, weight, and thus completing the process calculation.

The **beam_config** object describes the incoming particles, either the decay mother or the scattering beams. It also contains the structure-function information.

The **mci_entry** objects configure a MC input parameter set and integrator, each. The number of parameters depends on the process component and on the beam and structure-function setup.

The **pcm** component is the process-component manager. This polymorphic object manages and hides the details of dealing with NLO processes where several components have to be combined in a non-trivial way. It also acts as an

abstract factory for the corresponding object in `process_instance`, which does the actual work for this matter.

This procedure is an important debugging and inspection tool; it is not used during normal operation. The process object is written to a file (identified by unit, which may also be standard output). Optional flags determine whether we show everything or just the interesting parts.

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam_data_t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by extending the code in the `beams` module.

```

For some structure functions we need to get the list of initial state flavors. This is a two-dimensional array. The first index is the beam index, the second index is the component index. Each array element is itself a PDG array object, which consists of the list of incoming PDG values for this beam and component.

```

We complete the kinematics configuration after the beam setup, but before we configure the chain of structure functions. The reason is that we need the total energy `sqrts` for the kinematics, but the structure-function setup requires the number of channels, which depends on the kinematics configuration. For instance, the kinematics module may return the need for parameterizing an s-channel resonance.

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI

object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

```

30.5.1 Default iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

(Process: process: TBP)+≡

30.5.3 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```

30.6.1 Generic configuration data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the variable list.

The number **n.in** is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number **n.components** is the number of components that constitute the current process.

The number **n.terms** is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number `n_mci` is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The `model` pointer identifies the physics model and its parameters. This is a pointer to an external object.

The `rng_factory` component spawns independent random-number generators for use in integration, event generation, and event postprocessing.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the `effective_state` subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The `md5sum` is taken and used to verify the process configuration when re-reading data from file.

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

The model that we import here should be an instance of the global model. If we create the instance outside, we can make it an extension of the basic `model_data_t`. This will allow us to synchronize the variable list with the model. Using a pointer instead of an allocatable, we can guarantee the `target` attribute.

The RNG factory object is imported by moving the allocation.

```

<Process config: process config data: TBP>+≡
    procedure :: init => process_config_data_init

<Process config: procedures>+≡
    subroutine process_config_data_init &
        (config, meta, os_data, qcd, rng_factory, model)
        class(process_config_data_t), intent(out) :: config
        type(process_metadata_t), intent(in) :: meta
        type(os_data_t), intent(in) :: os_data
        type(qcd_t), intent(in) :: qcd
        class(rng_factory_t), intent(inout), allocatable :: rng_factory
        class(model_data_t), intent(inout), pointer :: model
        config%n_in = meta%lib%get_n_in (meta%id)
        config%n_components = size (meta%component_id)
        config%os_data = os_data
        config%qcd = qcd
        call move_alloc (from = rng_factory, to = config%rng_factory)
        config%model_name = model%get_name ()
        config%model => model
        model => null ()
    end subroutine process_config_data_init

```

Since the captured model is a separate object allocated via a pointer, we need a finalizer.

```

<Process config: process config data: TBP>+≡
    procedure :: final => process_config_data_final

<Process config: procedures>+≡
    subroutine process_config_data_final (config)

```

```

class(process_config_data_t), intent(inout) :: config
if (associated (config%model)) then
  call config%model%final ()
  deallocate (config%model)
end if
end subroutine process_config_data_final

```

Compute the MD5 sum of the configuration data. This encodes, in particular, the model and the expressions for cut, scales, weight, etc. It should not contain the IDs and number of components, etc., since the MD5 sum should be useful for integrating individual components.

This is done only once. If the MD5 sum is nonempty, the calculation is skipped.

```

(Process config: process config data: TBP)+≡
  procedure :: compute_md5sum => process_config_data_compute_md5sum

(Process config: procedures)+≡
  subroutine process_config_data_compute_md5sum (config)

(Process config: procedures)+≡
  pure function process_config_data_get_md5sum (config) result (md5)
    character(32) :: md5
    class(process_config_data_t), intent(in) :: config
    md5 = config%md5sum
  end function process_config_data_get_md5sum

```

30.6.2 Metadata

This information describes the process and its environment. It is fixed upon initialization.

The `id` string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The `num_id` is meaningful if nonzero. It is used for communication with external programs or file standards which do not support string IDs.

The `run_id` string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The `var_list` is a snapshot of the variable list, taken at the point where the process was initialized.

The `lib` pointer accesses the process library where the process definition and the process driver are located.

The `lib_index` is the index of entry in the process library that corresponds to the current process.

The `component_id` array identifies the individual process components.

The `component_description` is an array of human-readable strings that characterize the process components, for instance `a, b => c, d`.

The `active` mask array marks those components which are active. The others are skipped.

30.6.3 Beam configuration

The object `data` holds all details about the initial beam configuration. The allocatable array `sf` holds the structure-function configuration blocks. There are `n_strfun` entries in the structure-function chain (not counting the initial beam object). We maintain `n_channel` independent parameterizations of this chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is `n_sfpar`.

The flag `azimuthal_dependence` tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag `lab_is_cm_frame` is obvious.

```

<Process config: public>+≡
    public :: process_beam_config_t

<Process config: types>+≡
    type :: process_beam_config_t
    type(beam_data_t) :: data
    integer :: n_strfun = 0

```

```

integer :: n_channel = 1
integer :: n_sfpar = 0
type(sf_config_t), dimension(:), allocatable :: sf
type(sf_channel_t), dimension(:), allocatable :: sf_channel
logical :: azimuthal_dependence = .false.
logical :: lab_is_cm_frame = .true.
character(32) :: md5sum = ""
logical :: sf_trace = .false.
type(string_t) :: sf_trace_file
contains
  <Process config: process beam config: TBP>
end type process_beam_config_t

```

Here we write beam data only if they are actually used.

The **verbose** flag is passed to the beam-data writer.

```

30.6.4 Process components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components can have different types. In short, `process_component_t` is a wrapper for the actual process variants.

If the `active` flag is false, we should skip this component. This happens if the associated process has vanishing matrix element.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

(Process config: public)+≡
    public :: process_component_t

(Process config: types)+≡
    type :: process_component_t
        type(process_component_def_t), pointer :: config => null ()

```

30.6.5 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`. In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`.

This is the total number of independent entries in the density matrix. For each combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

This type is public only for use in a unit test.

```

(Process config: public)+≡
    public :: process_term_t

(Process config: types)+≡
    type :: process_term_t
        integer :: i_term_global = 0
        integer :: i_component = 0
        integer :: i_term = 0
        integer :: i_sub = 0
        integer :: i_core = 0
        integer :: n_allowed = 0
        type(process_constants_t) :: data
        real(default) :: alpha_s = 0
        integer, dimension(:), allocatable :: flv, hel, col
        type(interaction_t) :: int
        type(interaction_t), pointer :: int_eff => null ()
    contains
        (Process config: process term: TBP)
    end type process_term_t

```

For the output, we skip the process constants and the tables of allowed quantum numbers. Those can also be read off from the interaction object.

```

                write (u, *)
                call it%advance ()
            end do
        end subroutine process_term_write_state_summary

```

Finalizer: the `int` and potentially `int_eff` components have a finalizer that we must call.

```

(Process config: process term: TBP)+≡
  procedure :: final => process_term_final

(Process config: procedures)+≡
  subroutine process_term_final (term)
    class(process_term_t), intent(inout) :: term
    call term%int%final ()
  end subroutine process_term_final

```

Initialize the term. We copy the process constants from the `core` object and set up the `int` hard interaction accordingly.

The `alpha_s` value is useful for writing external event records. This is the constant value which may be overridden by a event-specific running value. If the model does not contain the strong coupling, the value is zero.

The `rearrange` part is commented out; this or something equivalent could become relevant for NLO algorithms.

```

(Process config: process term: TBP)+≡
  procedure :: init => process_term_init

(Process config: procedures)+≡
  subroutine process_term_init &
    (term, i_term_global, i_component, i_term, core, model, &
     nlo_type, use_beam_pol, subtraction_method)
    class(process_term_t), intent(inout), target :: term
    integer, intent(in) :: i_term_global
    integer, intent(in) :: i_component
    integer, intent(in) :: i_term
    class(prc_core_t), intent(inout) :: core
    class(model_data_t), intent(in), target :: model

      pol_beams = use_beam_pol, use_internal_color = use_internal_color)
  end subroutine process_term_init

```

We fetch the process constants which determine the quantum numbers and use those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

```

30.7 Process call statistics

Very simple object for statistics. Could be moved to a more basic chapter.

```

<process_counter.f90>≡
  <File header>

  module process_counter

    <Use kinds>
    use io_units

    <Standard module head>

    <Process counter: public>

    <Process counter: parameters>

    <Process counter: types>

    contains

    <Process counter: procedures>

  end module process_counter

```

This object can record process calls, categorized by evaluation status. It is a part of the `mci_entry` component below.

```

<Process counter: public>≡
  public :: process_counter_t

<Process counter: types>≡
  type :: process_counter_t
    integer :: total = 0
    integer :: failed_kinematics = 0
    integer :: failed_cuts = 0
    integer :: has_passed = 0
    integer :: evaluated = 0
    integer :: complete = 0
    contains
    <Process counter: process counter: TBP>
  end type process_counter_t

```

Here are the corresponding numeric codes:

```

<Process counter: parameters>≡
  integer, parameter, public :: STAT_UNDEFINED = 0

```

```

integer, parameter, public :: STAT_INITIAL = 1
integer, parameter, public :: STAT_ACTIVATED = 2
integer, parameter, public :: STAT_BEAM_MOMENTA = 3
integer, parameter, public :: STAT_FAILED_KINEMATICS = 4
integer, parameter, public :: STAT_SEED_KINEMATICS = 5
integer, parameter, public :: STAT_HARD_KINEMATICS = 6
integer, parameter, public :: STAT_EFF_KINEMATICS = 7
integer, parameter, public :: STAT_FAILED_CUTS = 8
integer, parameter, public :: STAT_PASSED_CUTS = 9
integer, parameter, public :: STAT_EVALUATED_TRACE = 10
integer, parameter, public :: STAT_EVENT_COMPLETE = 11

```

Output.

```

(Process counter: process counter: TBP)≡
  procedure :: write => process_counter_write

(Process counter: procedures)≡
  subroutine process_counter_write (object, unit)
    class(process_counter_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)

30.8.1 Process MCI entry

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly the values that apply to the current pass. Previous values are archived in the `results` object.

The `counter` receives the counter statistics from the associated process instance, for diagnostics.

The `results` object records results, broken down in passes and iterations.

```

Initialize. From the existing configuration, we obtain the number of channels and the number of parameters, separately for the structure-function chain and for the associated process component. We assume that the phase-space object has already been configured.

The allocation of the MCI integrator with the appropriate concrete type is the duty of the process core.

We assume that there is only one component associated with a MCI entry. This restriction should be relaxed.

  end subroutine process_mci_entry_sampler_test

```

Integrate.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

Generate an event. The instance should be initialized, otherwise event generation is directed by the mci integrator subobject. The integrator instance is contained in a `mci_work` subobject of the process instance, which simultaneously serves as the sampler object. (We avoid the anti-aliasing rules if we assume that the sampling itself does not involve the integrator instance contained in the process instance.)

Regarding weighted events, we only take events which are valid, which means that they have valid kinematics and have passed cuts. Therefore, we have a rejection loop. For unweighted events, the unweighting routine should already take care of this.

30.8.2 MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

```

<Process mci: public>+≡
    public :: mci_work_t

<Process mci: types>+≡
    type :: mci_work_t
        type(process_mci_entry_t), pointer :: config => null ()
        real(default), dimension(:), allocatable :: x

```

```

        class(mci_instance_t), pointer :: mci => null ()
        type(process_counter_t) :: counter
        logical :: keep_failed_events = .false.
contains
  <Process mci: mci work: TBP>
end type mci_work_t

```

First write configuration data, then the current values.

```

<Process mci: mci work: TBP>≡
  procedure :: write => mci_work_write

<Process mci: procedures>+≡
  subroutine mci_work_write (mci_work, unit, testflag)
    class(mci_work_t), intent(in) :: mci_work
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A,I0,A)") "Active MCI instance #", &
      mci_work%config%i_mci, " ="
    write (u, "(2x)", advance="no")
    do i = 1, mci_work%config%n_par
      write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
      if (i == mci_work%config%n_par_sf) &
        write (u, "(1x,'|')", advance="no")
    end do
    write (u, *)
    if (associated (mci_work%mci)) then
      call mci_work%mci%write (u, pacify = testflag)
      call mci_work%counter%write (u)
    end if
  end subroutine mci_work_write

```

The mci component may require finalization.

```

<Process mci: mci work: TBP>+≡

30.10 Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

sf_chain is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

p_hs is an instance of the phase space for the elementary process.

The array **f** contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either **sf_chain** or **p_hs** are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component ('owned' by the object) or as a pointer.

    end subroutine kinematics_compute_other_channels

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We

do rely on the momenta of the last evaluator in the chain, however.)

```

(Kinematics: kinematics: TBP)+≡

30.11.1 Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The `k_term` object is the instance of the kinematics setup (structure-function chain, phase space, etc.) that applies specifically to this term. In ordinary cases, it consists of straight pointers to the seed kinematics.

The `amp` array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The `int_hard` interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The `isolated` object holds the effective parton state for the elementary interaction. The amplitude entries are computed from `int_hard`.

The `connected` evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The `checked` flag is set once we have applied cuts on this term. The result of this is stored in the `passed` flag. Once the term has passed cuts, we calculate the various scale and weight expressions.

  end subroutine term_instance_final

```

For initialization, we make use of defined assignment for the `interaction_t` type. This creates a deep copy.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (`rearrange`) as effective structure-function chain and interaction, respectively.

Finally, we set up the `subevt` component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

The `rearrange` parts are still commented out; they could become relevant for a NLO algorithm.

Setup seed kinematics, starting from the MC parameter set given as argument. As a result, the `k_seed` kinematics object is evaluated (except for the structure-function matrix-element evaluation, which we postpone until we know the factorization scale), and we have a valid `p_seed` momentum array.

end subroutine term_instance_recover_mcpair
```

Compute the momenta in the hard interactions, one for each term that constitutes this process component. In simple cases this amounts to just copying momenta. In more advanced cases, we may generate distinct sets of momenta from the seed kinematics.

The interactions in the term instances are accessed individually. We may choose to calculate all terms at once together with the seed kinematics, use `component%core_state` for storage, and just fill the interactions here.

(Instances: term instance: TBP)+≡

```
procedure :: compute_hard_kinematics => &

```

```
end subroutine term_instance_compute_hard_kinematics
```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

```

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain. (If we have an algorithm that uses rearrangement, it should evaluate `k_term` explicitly.)

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

```

<Instances: term instance: TBP>+≡
  procedure :: compute_eff_kinematics => &
    term_instance_compute_eff_kinematics

<Instances: procedures>+≡
  subroutine term_instance_compute_eff_kinematics (term)
    class(term_instance_t), intent(inout) :: term
    term%checked = .false.
    term%passed = .false.
    call term%isolated%receive_kinematics ()
    call term%connected%receive_kinematics ()
  end subroutine term_instance_compute_eff_kinematics

```

Inverse. Reconstruct the connected state from the momenta in the trace evaluator (which we assume to be set), then reconstruct the isolated state as far as possible. The second part finalizes the momentum configuration, using the incoming seed momenta

```

<Instances: term instance: TBP>+≡
  procedure :: recover_hard_kinematics => &
    term_instance_recover_hard_kinematics

<Instances: procedures>+≡
  subroutine term_instance_recover_hard_kinematics (term)

      scale_forced, force_evaluation = .true.)
    term%checked = .true.
  end subroutine term_instance_evaluate_expressions

```

Evaluate the trace: first evaluate the hard interaction, then the trace evaluator. We use the `evaluate_interaction` method of the process component which generated this term. The `subevt` and cut expressions are not yet filled.

The `component` argument is `intent(inout)` because the `compute_amplitude` method may modify the `core_state` workspace object.

30.11.2 The process instance

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `count` object records process evaluations, broken down according to status.

The `sqme` value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The `weight` value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the `sqme` value times Jacobian weights from the integration, or unity, respectively.

The `i_mci` index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The `sf_chain` subobject is a realization of the beam and structure-function configuration in the `process` object. It is not used for calculation directly but serves as the template for the sf-chain instances that are contained in the `component` objects.

The `component` subobjects determine the state of each component.

The `term` subobjects are workspace for evaluating kinematics, matrix elements, cuts etc.

The `mci_work` subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the `mci_work` array is selected by the `i_mci` index above.

```

<Instances: public>≡
  public :: process_instance_t

<Instances: types>+≡
  type, extends (mci_sampler_t) :: process_instance_t
    type(process_t), pointer :: process => null ()
    integer :: evaluation_status = STAT_UNDEFINED
    real(default) :: sqme = 0
    real(default) :: weight = 0
    real(default) :: excess = 0
    integer :: i_mci = 0
    integer :: selected_channel = 0
    type(sf_chain_t) :: sf_chain
    type(term_instance_t), dimension(:), allocatable :: term
    type(mci_work_t), dimension(:), allocatable :: mci_work
    class(pcm_instance_t), allocatable :: pcm
  contains
    <Instances: process instance: TBP>
  end type process_instance_t

```

The output routine contains a header with the most relevant information about the process, copied from `process_metadata_write`. We mark the active components by an asterisk.

The next section is the MC parameter input. The following sections are written only if the evaluation status is beyond setting the parameters, or if the `verbose` option is set.

```

    end subroutine process_instance_reset

```

Integration and event generation

The sampler test should just evaluate the squared matrix element `n_calls` times, discarding the results, and return. This can be done before integration, e.g., for timing estimates.

```
(Instances: process instance: TBP)+≡
  procedure :: sampler_test => process_instance_sampler_test

(Instances: procedures)+≡
  subroutine process_instance_sampler_test (instance, i_mci, n_calls)
    class(process_instance_t), intent(inout), target :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_calls
    integer :: i_mci_work
    i_mci_work = instance%process%get_i_mci_work (i_mci)
    call instance%choose_mci (i_mci_work)
    call instance%reset_counter ()
    call instance%process%sampler_test (instance, n_calls, i_mci_work)
    call instance%process%set_counter_mci_entry (i_mci_work, instance%get_counter ())
  end subroutine process_instance_sampler_test
```

Generate a weighted event. We select one of the available MCI integrators by its index `i_mci` and thus generate an event for the associated (group of) process component(s). The arguments exactly correspond to the initializer and finalizer above.

The resulting event is stored in the `process_instance` object, which also holds the workspace of the integrator.

Note: The `process` object contains the random-number state, which changes for each event. Otherwise, all volatile data are inside the `instance` object.

```
(Instances: process instance: TBP)+≡
  procedure :: generate_weighted_event => process_instance_generate_weighted_event

(Instances: procedures)+≡
  subroutine process_instance_generate_weighted_event (instance, i_mci)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    integer :: i_mci_work
    i_mci_work = instance%process%get_i_mci_work (i_mci)
    call instance%choose_mci (i_mci_work)
    associate (mci_work => instance%mci_work(i_mci_work))
      call instance%process%generate_weighted_event &
        (i_mci_work, mci_work, instance, &
         instance%keep_failed_events ())
    end associate
  end subroutine process_instance_generate_weighted_event

(Instances: process instance: TBP)+≡
  procedure :: generate_unweighted_event => process_instance_generate_unweighted_event
```

```

<Instances: procedures>+≡
subroutine process_instance_generate_unweighted_event (instance, i_mci)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_mci
  integer :: i_mci_work
  i_mci_work = instance%process%get_i_mci_work (i_mci)
  call instance%choose_mci (i_mci_work)
  associate (mci_work => instance%mci_work(i_mci_work))
    call instance%process%generate_unweighted_event &
      (i_mci_work, mci_work, instance)
  end associate
end subroutine process_instance_generate_unweighted_event

```

This replaces the event generation methods for the situation that the process instance object has been filled by other means (i.e., reading and/or recalculating its contents). We just have to fill in missing MCI data, especially the event weight.

```

    if (config%sf_trace) then
      call instance%sf_chain%setup_tracing (config%sf_trace_file)
    end if
  end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

<Instances: process instance: TBP>+≡
  procedure :: setup_event_data => process_instance_setup_event_data

<Instances: procedures>+≡
  subroutine process_instance_setup_event_data (instance, model, i_core)

    end do
  end subroutine process_instance_setup_event_data

```

```

        end if
    end associate
end do
core => null ()
end subroutine process_instance_setup_event_data

```

Choose a MC parameter set and the corresponding integrator. The choice persists beyond calls of the `reset` method above. This method is automatically called here.

```

<Instances: process instance: TBP>+≡
    procedure :: choose_mci => process_instance_choose_mci

<Instances: procedures>+≡
    subroutine process_instance_choose_mci (instance, i_mci)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci
        instance%i_mci = i_mci
        call instance%reset ()
    end subroutine process_instance_choose_mci

```

Explicitly set a MC parameter set. Works only if we are in initial state. We assume that the length of the parameter set is correct.

After setting the parameters, activate the components and terms that correspond to the chosen MC parameter set.

The `warmup_flag` is used when a dummy phase-space point is computed for the warmup of e.g. OpenLoops helicities. The setting of the `evaluation_status` has to be avoided then.

```

<Instances: process instance: TBP>+≡
    procedure :: set_mcpair => process_instance_set_mcpair

<Instances: procedures>+≡
    subroutine process_instance_set_mcpair (instance, x, warmup_flag)
        class(process_instance_t), intent(inout) :: instance
        real(default), dimension(:), intent(in) :: x
        logical, intent(in), optional :: warmup_flag
        logical :: activate
        activate = .true.; if (present (warmup_flag)) activate = .not. warmup_flag
        if (instance%evaluation_status == STAT_INITIAL) then
            associate (mci_work => instance%mci_work(instance%i_mci))
                call mci_work%set (x)
            end associate
            if (activate) call instance%activate ()
        end if
    end subroutine process_instance_set_mcpair

```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The `sf-chain` instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```

<Instances: process instance: TBP>+≡
  procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

<Instances: procedures>+≡
  subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%receive_beam_momenta ()
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_receive_beam_momenta

```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```

<Instances: process instance: TBP>+≡
  procedure :: set_beam_momenta => process_instance_set_beam_momenta

<Instances: procedures>+≡
  subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%set_beam_momenta (p)
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_set_beam_momenta

```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```

<Instances: process instance: TBP>+≡
  procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

<Instances: procedures>+≡
  subroutine process_instance_recover_beam_momenta (instance, i_term)
    class(process_instance_t), intent(inout) :: instance

        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) &
            call instance%term(i_term)%recover_seed_kinematics ()
    end subroutine process_instance_recover_seed_kinematics

```

Third step of process evaluation: compute the effective momentum configurations, for all active terms, from the hard kinematics.

```

<Instances: process instance: TBP>+≡
    procedure :: compute_eff_kinematics => &
        process_instance_compute_eff_kinematics

<Instances: procedures>+≡
    subroutine process_instance_compute_eff_kinematics (instance, skip_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in), optional :: skip_term
        integer :: i
        if (instance%evaluation_status >= STAT_HARD_KINEMATICS) then
            do i = 1, size (instance%term)
                if (present (skip_term)) then
                    if (i == skip_term) cycle
                end if
                if (instance%term(i)%active) then
                    call instance%term(i)%compute_eff_kinematics ()
                end if
            end do
            instance%evaluation_status = STAT_EFF_KINEMATICS
        end if
    end subroutine process_instance_compute_eff_kinematics

```

Inverse: recover the hard kinematics from effective kinematics for one term, then compute effective kinematics for the other terms.

```

<Instances: process instance: TBP>+≡
    procedure :: recover_hard_kinematics => &
        process_instance_recover_hard_kinematics

```

```

<Instances: procedures>+≡
subroutine process_instance_recover_hard_kinematics (instance, i_term)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_term
  integer :: i
  if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
    call instance%term(i_term)%recover_hard_kinematics ()
    do i = 1, size (instance%term)
      if (i /= i_term) then
        if (instance%term(i)%active) then
          call instance%term(i)%compute_eff_kinematics ()
        end if
      end if
    end do
    instance%evaluation_status = STAT_EFF_KINEMATICS
  end if
end subroutine process_instance_recover_hard_kinematics

```

Fourth step of process evaluation: check cuts for all terms. Where successful, compute any scales and weights. Otherwise, deactivate the term. If any of the terms has passed, set the state to STAT_PASSED_CUTS.

The argument `scale_forced`, if present, will override the scale calculation in the term expressions.

```

<Instances: process instance: TBP>+≡
procedure :: evaluate_expressions => &
  process_instance_evaluate_expressions

<Instances: procedures>+≡
subroutine process_instance_evaluate_expressions (instance, scale_forced)
  class(process_instance_t), intent(inout) :: instance
  real(default), intent(in), allocatable, optional :: scale_forced
  integer :: i
  logical :: passed_real
  if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
    do i = 1, size (instance%term)
      if (instance%term(i)%active) then
        call instance%term(i)%evaluate_expressions (scale_forced)
      end if
    end do
    call evaluate_real_scales_and_cuts ()
    if (.not. passed_real) then
      instance%evaluation_status = STAT_FAILED_CUTS
    else
      if (any (instance%term%passed)) then
        instance%evaluation_status = STAT_PASSED_CUTS
      else
        instance%evaluation_status = STAT_FAILED_CUTS
      end if
    end if
  end if
end subroutine process_instance_evaluate_expressions

contains
subroutine evaluate_real_scales_and_cuts ()
  integer :: i
  passed_real = .true.
end subroutine evaluate_real_scales_and_cuts

```

```

select type (config => instance%pcm%config)
type is (pcm_nlo_t)
do i = 1, size (instance%term)
  if (instance%term(i)%active .and. instance%term(i)%nlo_type == NLO_REAL) then
    if (config%settings%cut_all_sqmes) &
      passed_real = passed_real .and. instance%term(i)%passed
    if (config%settings%use_born_scale) &
      call replace_scales (instance%term(i))
    end if
  end do
end select
end subroutine evaluate_real_scales_and_cuts

subroutine replace_scales (this_term)
  type(term_instance_t), intent(inout) :: this_term
  integer :: i_sub
  i_sub = this_term%config%i_sub
  if (this_term%config%i_term_global /= i_sub .and. i_sub > 0) then
    this_term%ren_scale = instance%term(i_sub)%ren_scale
    this_term%fac_scale = instance%term(i_sub)%fac_scale
  end if
end subroutine replace_scales
end subroutine process_instance_evaluate_expressions

```

Fifth step of process evaluation: fill the parameters for the non-selected ,channels, that have not been used for seeding. We should do this after evaluating cuts, since we may save some expensive calculations if the phase space point fails the cuts.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Instances: process instance: TBP>+≡
  procedure :: compute_other_channels => &
    process_instance_compute_other_channels

<Instances: procedures>+≡
  subroutine process_instance_compute_other_channels (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term

    integer, dimension(:), allocatable :: i_term
    channel = instance%selected_channel
    if (channel == 0) then
      call msg_bug ("Compute other channels: undefined integration channel")
    end if
    if (present (skip_term)) then
      skip_component = instance%term(skip_term)%config%i_component
    else
      skip_component = 0
    end if
    if (instance%evaluation_status >= STAT_PASSED_CUTS) then
      do i = 1, instance%process%get_n_components ()
        if (i == skip_component) cycle

```

```

        if (instance%process%component_is_selected (i)) then
            allocate (i_term (size (instance%process%get_component_i_terms (i))))
            i_term = instance%process%get_component_i_terms (i)
            do j = 1, size (i_term)
                call instance%term(i_term(j))%compute_other_channels &
                    (instance%mc_i_work(instance%i_mci), channel)
            end do
        end if
        if (allocated (i_term)) deallocate (i_term)
    end do
end if
end subroutine process_instance_compute_other_channels

```

Sixth step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

(Instances: process instance: TBP)+≡

```

    procedure :: evaluate_trace => process_instance_evaluate_trace

```

(Instances: procedures)+≡

```

    end subroutine process_instance_normalize_weight

```

This is a convenience routine that performs the computations of the steps 1 to 5 in a single step. The arguments are the input for `set_mcpair`. After this, the evaluation status should be either `STAT_FAILED_KINEMATICS`, `STAT_FAILED_CUTS` or `STAT_EVALUATED_TRACE`.

Before calling this, we should call `choose_mci`.

```

<Instances: process instance: TBP>+≡
    procedure :: evaluate_sqme => process_instance_evaluate_sqme

<Instances: procedures>+≡
    subroutine process_instance_evaluate_sqme (instance, channel, x)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
        real(default), dimension(:), intent(in) :: x
        call instance%reset ()
        call instance%set_mcpair (x)
        call instance%select_channel (channel)
        call instance%compute_seed_kinematics ()
        call instance%compute_hard_kinematics ()
        call instance%compute_eff_kinematics ()
        call instance%evaluate_expressions ()
        call instance%compute_other_channels ()
        call instance%evaluate_trace ()
    end subroutine process_instance_evaluate_sqme

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

```

<Instances: process instance: TBP>+≡
  procedure :: recover => process_instance_recover

<Instances: procedures>+≡
  subroutine process_instance_recover &
    (instance, channel, i_term, update_sqme, scale_forced)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    integer, intent(in) :: i_term
    logical, intent(in) :: update_sqme
    real(default), intent(in), allocatable, optional :: scale_forced
    call instance%activate ()
    instance%evaluation_status = STAT_EFF_KINEMATICS
    call instance%recover_hard_kinematics (i_term)
    call instance%recover_seed_kinematics (i_term)
    call instance%select_channel (channel)
    call instance%recover_mcpair (i_term)
    call instance%recover_beam_momenta (i_term)
    call instance%compute_seed_kinematics (i_term)
    call instance%compute_hard_kinematics (i_term)
    call instance%compute_eff_kinematics (i_term)
    call instance%compute_other_channels (i_term)
    call instance%evaluate_expressions (scale_forced)
    if (update_sqme) call instance%evaluate_trace ()
  end subroutine process_instance_recover

```

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the x array, and the f Jacobian array are exposed by the `sampler_t` object.

```

<Instances: process instance: TBP>+≡
  procedure :: evaluate => process_instance_evaluate

<Instances: procedures>+≡
  subroutine process_instance_evaluate (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call sampler%evaluate_sqme (c, x_in)
    if (sampler%is_valid ()) call sampler%fetch (val, x, f)
  end subroutine process_instance_evaluate

```

```

        call sampler%record_call ()
    end subroutine process_instance_evaluate

```

The phase-space point is valid if the event has valid kinematics and has passed the cuts.

```

<Instances: process instance: TBP>+≡
    procedure :: is_valid => process_instance_is_valid

<Instances: procedures>+≡
    function process_instance_is_valid (sampler) result (valid)
        class(process_instance_t), intent(in) :: sampler
        logical :: valid
        valid = sampler%evaluation_status >= STAT_PASSED_CUTS
    end function process_instance_is_valid

```

The `rebuild` method should rebuild the kinematics section out of the `x_in` parameter set. The integrand value `val` should not be computed, but is provided as input.

```

<Instances: process instance: TBP>+≡
    procedure :: rebuild => process_instance_rebuild

<Instances: procedures>+≡
    subroutine process_instance_rebuild (sampler, c, x_in, val, x, f)
        class(process_instance_t), intent(inout) :: sampler
        integer, intent(in) :: c
        real(default), dimension(:), intent(in) :: x_in
        real(default), intent(in) :: val
        real(default), dimension(:,:), intent(out) :: x
        real(default), dimension(:), intent(out) :: f
        call msg_bug ("process_instance_rebuild not implemented yet")
        x = 0
        f = 0
    end subroutine process_instance_rebuild

```

This is another method required by the `sampler_t` base type: fetch the data that are relevant for the MCI record.

```

<Instances: process instance: TBP>+≡
    procedure :: fetch => process_instance_fetch

<Instances: procedures>+≡
    subroutine process_instance_fetch (sampler, val, x, f)
        class(process_instance_t), intent(in) :: sampler
        real(default), intent(out) :: val
        real(default), dimension(:,:), intent(out) :: x
        real(default), dimension(:), intent(out) :: f
        integer, dimension(:), allocatable :: i_terms
        integer :: i, i_term_base, cc
        integer :: n_channel

        val = 0
        associate (process => sampler%process)
            FIND_COMPONENT: do i = 1, process%get_n_components ()
                if (sampler%process%component_is_selected (i)) then

```

```

        allocate (i_terms (size (process%get_component_i_terms (i))))
        i_terms = process%get_component_i_terms (i)
        i_term_base = i_terms(1)
        associate (k => sampler%term(i_term_base)%k_term)
            n_channel = k%n_channel
            do cc = 1, n_channel
                call k%get_mcpair (cc, x(:,cc))
            end do
            f = k%f
            val = sampler%sqme * k%phs_factor
        end associate
        if (allocated (i_terms)) deallocate (i_terms)
        exit FIND_COMPONENT
    end if
end do FIND_COMPONENT
end associate
end subroutine process_instance_fetch

```

Initialize and finalize event generation for the specified MCI entry.

```

<Instances: process instance: TBP>+≡
    procedure :: init_simulation => process_instance_init_simulation
    procedure :: final_simulation => process_instance_final_simulation

<Instances: procedures>+≡
    subroutine process_instance_init_simulation (instance, i_mci, &
        safety_factor, keep_failed_events)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci

    end subroutine process_instance_init_simulation

    subroutine process_instance_final_simulation (instance, i_mci)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci
        call instance%mci_work(i_mci)%final_simulation ()
    end subroutine process_instance_final_simulation

```

Accessing the process instance

Once the seed kinematics is complete, we can retrieve the MC input parameters for all channels, not just the seed channel.

Note: We choose the first active component. This makes sense only if the seed kinematics is identical for all active components.

```

<Instances: process instance: TBP>+≡
    procedure :: get_mcpair => process_instance_get_mcpair

<Instances: procedures>+≡
    subroutine process_instance_get_mcpair (instance, channel, x)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
        real(default), dimension(:), intent(out) :: x

```

```

integer :: i
if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
  do i = 1, size (instance%term)
    if (instance%term(i)%active) then
      call instance%term(i)%k_term%get_mcpair (channel, x)
      return
    end if
  end do
  call msg_bug ("Process instance: get_mcpair: no active channels")
else
  call msg_bug ("Process instance: get_mcpair: no seed kinematics")
end if
end subroutine process_instance_get_mcpair

```

Return true if the `sqme` value is known. This also implies that the event is kinematically valid and has passed all cuts.

```

<Instances: process instance: TBP>+≡
  procedure :: has_evaluated_trace => process_instance_has_evaluated_trace

<Instances: procedures>+≡
  function process_instance_has_evaluated_trace (instance) result (flag)
    class(process_instance_t), intent(in) :: instance
    logical :: flag
    flag = instance%evaluation_status >= STAT_EVALUATED_TRACE
  end function process_instance_has_evaluated_trace

```

Return true if the event is complete. In particular, the event must be kinematically valid, passed all cuts, and the event data have been computed.

```

<Instances: process instance: TBP>+≡
  procedure :: is_complete_event => process_instance_is_complete_event

<Instances: procedures>+≡
  function process_instance_is_complete_event (instance) result (flag)
    class(process_instance_t), intent(in) :: instance
    logical :: flag
    flag = instance%evaluation_status >= STAT_EVENT_COMPLETE
  end function process_instance_is_complete_event

```

Select the term for the process instance that will provide the basic event record (used in `evt_trivial_make_particle_set`). It might be necessary to write out additional events corresponding to other terms (done in `evt_nlo`).

```

<Instances: process instance: TBP>+≡
  procedure :: select_i_term => process_instance_select_i_term

<Instances: procedures>+≡
  function process_instance_select_i_term (instance) result (i_term)

    name = instance%process%get_id ()  
  end function process_instance_get_process_name
```

Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

NB: The `recover.beams` option should be used only when the particle set originates from an external event file, and the user has asked for it. It should be switched off when reading from raw event file.

```

<Instances: process instance: TBP>+≡
  procedure :: get_trace => process_instance_get_trace
  procedure :: set_trace => process_instance_set_trace

<Instances: procedures>+≡
  subroutine process_instance_get_trace (instance, pset, i_term)
    class(process_instance_t), intent(in), target :: instance
    type(particle_set_t), intent(out) :: pset
    integer, intent(in) :: i_term
    type(interaction_t), pointer :: int
    logical :: ok
    int => instance%get_trace_int_ptr (i_term)
    call pset%init (ok, int, int, FM_IGNORE_HELICITY, &
      [0._default, 0._default], .false., .true.)
  end subroutine process_instance_get_trace

  subroutine process_instance_set_trace &
    (instance, pset, i_term, recover_beams, check_match)
    class(process_instance_t), intent(inout), target :: instance
    type(particle_set_t), intent(in) :: pset
    integer, intent(in) :: i_term
    logical, intent(in), optional :: recover_beams, check_match
    type(interaction_t), pointer :: int
    integer :: n_in
    int => instance%get_trace_int_ptr (i_term)
    n_in = instance%process%get_n_in ()
    call pset%fill_interaction (int, n_in, &
      recover_beams = recover_beams, &
      check_match = check_match, &
      state_flg = instance%get_state_flg (i_term))
  end subroutine process_instance_set_trace

```

This procedure allows us to override any QCD setting of the WHIZARD process and directly set the coupling value that comes together with a particle set.

Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```

<Processes: execute tests>+≡
  call test (processes_8, "processes_8", &
    "process evaluation with structure functions", &
    u, results)

```

Complete events

For the purpose of simplifying further tests, we implement a convenience routine that initializes a process and prepares a single event. This is a wrapup of the test `processes_10`.

The procedure is re-exported by the `processes_ut` module.

```

<Processes: public test auxiliary>≡
  public :: prepare_test_process

<Processes: test auxiliary>≡
  subroutine prepare_test_process (process, process_instance, model)
    type(process_t), intent(out), target :: process
    type(process_instance_t), intent(out), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_library_t), target :: lib
    type(string_t) :: libname
    type(string_t) :: procname
    type(string_t) :: run_id
    type(os_data_t) :: os_data
    class(model_data_t), pointer :: process_model
    type(qcd_t) :: qcd
    class(rng_factory_t), allocatable :: rng_factory
    class(mci_t), allocatable :: mci_template
    class(mci_t), pointer :: mci
    class(phs_config_t), allocatable :: phs_config_template
    real(default) :: sqrts
    libname = "processes_test"
    procname = libname
    run_id = "run_test"
    call os_data_init (os_data)
    allocate (rng_test_factory_t :: rng_factory)
    call prc_test_create_library (libname, lib)
    call reset_interaction_counter ()
    allocate (process_model)
    call process_model%init (model%get_name (), &
      model%get_n_real (), &
      model%get_n_complex (), &
      model%get_n_field (), &
      model%get_n_vtx ())
    call process_model%copy_from (model)
    call process%init (procname, run_id, &
      lib, os_data, qcd, rng_factory, process_model)
    call process%setup_test_cores ()
    allocate (mci_test_t :: mci_template)

```

```

select type (mci_template)
type is (mci_test_t); call mci_template%set_divisions (100)
end select
allocate (phs_test_config_t :: phs_config_template)

Colored interaction

This test specifically checks the transformation of process data (flavor, helicity, and color) into an interaction in a process term.

We use the `test_t` process core (which has no nontrivial particles), but call only the `is_allowed` method, which always returns true.

```

<Processes: execute tests>+≡

Resonances in Phase Space

This test demonstrates the extraction of the resonance-history set from the generated phase space. We need a nontrivial process, but no matrix element. This is provided by the `prc_template` method, using the `SM` model. We also need the `phs_wood` method, otherwise we would not have resonances in the phase space configuration.

```

<Processes: execute tests>+≡
  call test (processes_18, "processes_18", &

30.13 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib.stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

```

<process_stacks.f90>≡
  <File header>

  module process_stacks

    <Use strings>
    use io_units
    use format_utils, only: write_separator
    use diagnostics
    use os_interface
    use sm_qcd
    use model_data
    use rng_base
    use variables
    use observables
    use process_libraries
    use process

    <Standard module head>

    <Process stacks: public>

    <Process stacks: types>

    contains

    <Process stacks: procedures>

  end module process_stacks

```

30.13.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```
<Process stacks: public>≡
    public :: process_entry_t

<Process stacks: types>≡
    type, extends (process_t) :: process_entry_t
        type(process_entry_t), pointer :: next => null ()
    end type process_entry_t
```

30.13.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

The process stack can be linked to another one. This allows us to work with stacks of local scope.

```
<Process stacks: public>+≡
    public :: process_stack_t

<Process stacks: types>+≡
    type :: process_stack_t
        integer :: n = 0
        type(process_entry_t), pointer :: first => null ()
        type(var_list_t), pointer :: var_list => null ()
        type(process_stack_t), pointer :: next => null ()
    contains
        <Process stacks: process stack: TBP>
    end type process_stack_t
```

Finalize partly: deallocate the process stack and variable list entries, but keep the variable list as an empty object. This way, the variable list links are kept.

```
<Process stacks: process stack: TBP>≡
    procedure :: clear => process_stack_clear

<Process stacks: procedures>≡
    subroutine process_stack_clear (stack)
        class(process_stack_t), intent(inout) :: stack
        type(process_entry_t), pointer :: process
        if (associated (stack%var_list)) then
            call stack%var_list%final ()
        end if
        do while (associated (stack%first))
            process => stack%first
            stack%first => process%next
            call process%final ()
            deallocate (process)
        end do
```

```

        stack%n = 0
    end subroutine process_stack_clear

```

Finalizer. Clear and deallocate the variable list.

```

<Process stacks: process stack: TBP>+≡
    procedure :: final => process_stack_final

<Process stacks: procedures>+≡
    subroutine process_stack_final (object)
        class(process_stack_t), intent(inout) :: object
        call object%clear ()
        if (associated (object%var_list)) then
            deallocate (object%var_list)
        end if
    end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write => process_stack_write

<Process stacks: procedures>+≡
    recursive subroutine process_stack_write (object, unit, pacify)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: pacify
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)
        call write_separator (u, 2)
        select case (object%n)
        case (0)
            write (u, "(1x,A)") "Process stack: [empty]"
            call write_separator (u, 2)
        case default
            write (u, "(1x,A)") "Process stack:"
            process => object%first
            do while (associated (process))
                call process%write (.false., u, pacify = pacify)
                process => process%next
            end do
        end select
        if (associated (object%next)) then
            write (u, "(1x,A)") "[Processes from context environment:]"
            call object%next%write (u, pacify)
        end if
    end subroutine process_stack_write

```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```

<Process stacks: process stack: TBP>+≡
    procedure :: write_var_list => process_stack_write_var_list

```

```

<Process stacks: procedures>+≡
  subroutine process_stack_write_var_list (object, unit)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    if (associated (object%var_list)) then
      call var_list_write (object%var_list, unit)
    end if
  end subroutine process_stack_write_var_list

```

Short output.

```

<Process stacks: process stack: TBP>+≡
  procedure :: show => process_stack_show

<Process stacks: procedures>+≡
  recursive subroutine process_stack_show (object, unit)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    type(process_entry_t), pointer :: process
    integer :: u
    u = given_output_unit (unit)
    select case (object%n)
    case (0)
    case default
      process => object%first
      do while (associated (process))
        call process%show (u, verbose=.false.)
        process => process%next
      end do
    end select
    if (associated (object%next)) call object%next%show ()
  end subroutine process_stack_show

```

30.13.3 Link

Link the current process stack to a global one.

```

<Process stacks: process stack: TBP>+≡
  procedure :: link => process_stack_link

<Process stacks: procedures>+≡
  subroutine process_stack_link (local_stack, global_stack)
    class(process_stack_t), intent(inout) :: local_stack
    type(process_stack_t), intent(in), target :: global_stack
    local_stack%next => global_stack
  end subroutine process_stack_link

```

Initialize the process variable list and link the main variable list to it.

```

<Process stacks: process stack: TBP>+≡
  procedure :: init_var_list => process_stack_init_var_list

<Process stacks: procedures>+≡
  subroutine process_stack_init_var_list (stack, var_list)
    class(process_stack_t), intent(inout) :: stack

```

```

    type(var_list_t), intent(inout), optional :: var_list
    allocate (stack%var_list)
    if (present (var_list)) call var_list%link (stack%var_list)
end subroutine process_stack_init_var_list

```

Link the process variable list to a global variable list.

```

<Process stacks: process stack: TBP>+≡
    procedure :: link_var_list => process_stack_link_var_list

<Process stacks: procedures>+≡
    subroutine process_stack_link_var_list (stack, var_list)
        class(process_stack_t), intent(inout) :: stack
        type(var_list_t), intent(in), target :: var_list
        call stack%var_list%link (var_list)
    end subroutine process_stack_link_var_list

```

30.13.4 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

<Process stacks: process stack: TBP>+≡
    procedure :: push => process_stack_push

<Process stacks: procedures>+≡
    subroutine process_stack_push (stack, process)
        class(process_stack_t), intent(inout) :: stack
        type(process_entry_t), intent(inout), pointer :: process
        process%next => stack%first
        stack%first => process
        process => null ()
        stack%n = stack%n + 1
    end subroutine process_stack_push

```

Initialize process variables for a given process ID, without setting values.

```

<Process stacks: process stack: TBP>+≡
    procedure :: init_result_vars => process_stack_init_result_vars

<Process stacks: procedures>+≡
    subroutine process_stack_init_result_vars (stack, id)
        class(process_stack_t), intent(inout) :: stack
        type(string_t), intent(in) :: id
        call var_list_init_num_id (stack%var_list, id)
        call var_list_init_process_results (stack%var_list, id)
    end subroutine process_stack_init_result_vars

```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```

<Process stacks: process stack: TBP>+≡
    procedure :: fill_result_vars => process_stack_fill_result_vars

```

```

<Process stacks: procedures>+≡
subroutine process_stack_fill_result_vars (stack, id)
  class(process_stack_t), intent(inout) :: stack
  type(string_t), intent(in) :: id
  type(process_t), pointer :: process
  process => stack%get_process_ptr (id)
  if (associated (process)) then
    call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
    if (process%has_integral ()) then
      call var_list_init_process_results (stack%var_list, id, &
        integral = process%get_integral (), &
        error = process%get_error ())
    end if
  else
    call msg_bug ("process_stack_fill_result_vars: unknown process ID")
  end if
end subroutine process_stack_fill_result_vars

```

30.13.5 Data Access

Tell if a process exists.

```

<Process stacks: process stack: TBP>+≡
  procedure :: exists => process_stack_exists

<Process stacks: procedures>+≡
function process_stack_exists (stack, id) result (flag)
  class(process_stack_t), intent(in) :: stack
  type(string_t), intent(in) :: id
  logical :: flag
  type(process_t), pointer :: process
  process => stack%get_process_ptr (id)
  flag = associated (process)
end function process_stack_exists

```

Return a pointer to a process with specific ID. Look also at a linked stack, if necessary.

```

<Process stacks: process stack: TBP>+≡
  procedure :: get_process_ptr => process_stack_get_process_ptr

<Process stacks: procedures>+≡
recursive function process_stack_get_process_ptr (stack, id) result (ptr)
  class(process_stack_t), intent(in) :: stack
  type(string_t), intent(in) :: id
  type(process_t), pointer :: ptr
  type(process_entry_t), pointer :: entry
  ptr => null ()
  entry => stack%first
  do while (associated (entry))
    if (entry%get_id () == id) then
      ptr => entry%process_t
      return
    end if
    entry => entry%next
  end do
end function process_stack_get_process_ptr

```

```

        end do
        if (associated (stack%next)) ptr => stack%next%get_process_ptr (id)
    end function process_stack_get_process_ptr

```

30.13.6 Unit tests

Test module, followed by the corresponding implementation module.

```

<process_stacks_ut.f90>≡
  <File header>

  module process_stacks_ut
    use unit_tests

    <Matching base: public>  
  
    <Matching base: parameters>
```

Figure 31.1: Module dependencies in `src/matching`.

```

    <Matching base: types>

    <Matching base: interfaces>

contains

    <Matching base: procedures>

end module matching_base

```

31.1 Abstract Matching Type

A matching will need access to the `shower` as well as matrix elements that we currently get over `process_instance`. The model is intended for the backup `model_hadrons`.

```

<Matching base: public>≡
    public :: matching_t

<Matching base: types>≡
    type, abstract :: matching_t
        logical :: is_hadron_collision = .false.
        type(qcd_t), pointer :: qcd => null ()
        class(shower_base_t), pointer :: shower => null ()
        type(process_instance_t), pointer :: process_instance => null ()
        class(model_data_t), pointer :: model => null ()
        class(rng_t), allocatable :: rng
        type(string_t) :: process_name
    contains
        <Matching base: matching: TBP>
    end type matching_t

<Matching base: matching: TBP>≡
    procedure (matching_init), deferred :: init

<Matching base: interfaces>≡
    abstract interface
        subroutine matching_init (matching, var_list, process_name)
            import
            class(matching_t), intent(out) :: matching
            type(var_list_t), intent(in) :: var_list
            type(string_t), intent(in) :: process_name
        end subroutine matching_init
    end interface

<default matching_init>≡
    type(var_list_t), intent(in) :: var_list
    type(string_t), intent(in) :: process_name
    call msg_debug (D_MATCHING, "matching_init")
    call matching%settings%init (var_list)
    matching%process_name = process_name

```

If we use a polymorphic settings type, this boilerplate wouldn't be necessary but then we introduce `select type` statements all over the place.

```

31.3 CKKW matching

This module contains the CKKW matching.

The type `ckkw_pseudo_shower_weights_t` gives the (relative) weights for different clusterings of the final particles, as given in Eq. (2.7) of hep-ph/0503281v1. Each particle has a binary labelling (power of 2) (first particle = 1, second particle = 2, third particle = 4, ...). Each recombination therefore corresponds to an integer, that is not a power of 2. For multiple subsequent recombinations, no different weights for different sequences of clustering are stored. It is assumed that the weight of a multiply recombined state is a combination of the states with one fewer recombination and that these states' contributions are proportional to their weights. For a $2 - > n$ event, the weights array thus has the size $2^{(2+n)-1}$. The `weights_by_type` array gives the weights depending on the type of the particle, the first index is the same as for weights, the second index gives the type of the new mother particle:

- 0: uncolored (γ , Z , W , Higgs)
- 1: colored (quark)
- 2: gluon
- 3: squark
- 4: gluino

`alphaS` gives the value for α_s used in the generation of the matrix element. This is needed for the reweighting using the values for a running α_s at the scales of the clusterings.

31.4 POWHEG

This module generates radiation according to the POWHEG Sudakov form factor

$$\Delta^{f_b}(\Phi_n, p_T) = \prod_{\alpha_r \in \{\alpha_r | f_b\}} \Delta_{\alpha_r}^{f_b}(\Phi_n, p_T), \quad (31.1)$$

with

$$\Delta_{\alpha_r}^{f_b}(\Phi_n, p_T) = \exp \left\{ - \left[\int d\Phi_{\text{rad}} \frac{R(\Phi_{n+1})}{B^{f_b}(\Phi_n)} \theta(k_T(\Phi_{n+1}) - p_T) \right]_{\alpha_r}^{\bar{\Phi}_n^{\alpha_r} = \Phi_n} \right\} \quad (31.2)$$

We expect that an underlying Born flavor structure f_b has been generated with a probability proportional to its contribution to the \tilde{B} at the given kinematic point.

We have to solve the equation

$$\frac{\log \Delta^{(U)}(p_T)}{\log \Delta^{(U)}(p_T^{\max})} = \log \Delta^{(U)}(p_T) = \log r_1$$

iteratively for p_T . If the current emission is not accepted, in the next step it is $\log \Delta^{(U)}(p_T^{\max}) = \log r_1$, so that we have to solve the equation

$$\log \Delta^{(U)}(p_T) = \log r_1 + \log r_2$$

using the second random number r_2 .

For massive emitters, the radiation variable ξ is constructed as follows. First,

$$\xi_{\min}(k_T^2) = \frac{\sqrt{k_T^2(k_T^2 z_2^2 + 8\bar{p}^0 q(1 - z_2)) - k_T^2 z_2}}{2q^2(1 - z_2)} \quad (31.7)$$

is computed. Then ξ_1 is computed according to the same equation with $z_2 \leftrightarrow z_1$. Finally, ξ is generated according to

$$\xi = \frac{1}{q^2} \exp \left[\log(\xi_{\min} q^2 - k_T^2) + r \log \frac{\xi_m q^2 - k_T^2}{\xi_{\min} q^2 - k_T^2} + k_T^2 \right], \quad (31.8)$$

where $\xi_m = \min(\xi_{\max}, \xi_1)$.

Generation algorithm and grid initialization

`compute_sqme_real` is the projected real matrix element $R_{\alpha_r} = S_{\alpha_r} R$ whereby the current α_r is implied by the `emitter`. Furthermore, it is multiplied by the Jacobian.

For each underlying Born f_b , there is a number of radiation regions. A radiation region rr may correspond multiple α_r s. The phase space only depends upon the radiation region kinematics rr and not on the specific α_r . α_r can be picked in the set $\{\alpha_r|f_b, rr\}$ proportional to their R_{α_r} . For now, we simplify things though and just work with the α_r .

The following is valid for one underlying Born.

```

31.4.4 α_s and its reweighting

The main point to ensure here is that the simple fixed-flavor-1-loop expression α_s^{rad} is larger than the more accurate α_s such that we can use a reweighting veto and use α_s^{rad} for the generation of the emission. This can be done by setting

$$\alpha_s^{\text{rad}}(\mu_0) = \alpha_s(\mu_0) \quad (31.13)$$

whereby μ_0^2 is the `scale_to_relate2` that is taken to be $p_{T,\text{min}}^2$.

Chapter 32

Event Implementation

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

event_transforms Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

decays Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

showers Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

tau_decays (not implemented yet) Let τ leptons decay taking full spin correlations into account.

events Combine all pieces to generate full events.

eio_raw Raw I/O for complete events.

32.1 Abstract Event Transforms

<Event transforms: interfaces>

contains

<Event transforms: procedures>

end module event_transforms

```

32.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified setting that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include `previous` and `next` pointers.

```

<Event transforms: public>≡
    public :: evt_t

<Event transforms: types>≡
    type, abstract :: evt_t
        type(process_t), pointer :: process => null ()
        type(process_instance_t), pointer :: process_instance => null ()
        class(model_data_t), pointer :: model => null ()
        class(rng_t), allocatable :: rng
        integer :: rejection_count = 0
        logical :: particle_set_exists = .false.
        type(particle_set_t) :: particle_set
        class(evt_t), pointer :: previous => null ()
        class(evt_t), pointer :: next => null ()

```

```

    real(default) :: weight = 0._default
    logical :: only_weighted_events = .false.
contains
  <Event transforms: evt: TBP>
end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡
  procedure :: final => evt_final
  procedure :: base_final => evt_final

<Event transforms: procedures>≡
  subroutine evt_final (evt)
    class(evt_t), intent(inout) :: evt
    if (allocated (evt%rng)) call evt%rng%final ()
    if (evt%particle_set_exists) &
      call evt%particle_set%final ()
  end subroutine evt_final

```

Print out the type of the evt.

```

<Event transforms: evt: TBP>+≡
  procedure (evt_write_name), deferred :: write_name

<Event transforms: interfaces>≡
  abstract interface
    subroutine evt_write_name (evt, unit)
      import
      class(evt_t), intent(in) :: evt
      integer, intent(in), optional :: unit
    end subroutine evt_write_name
  end interface

```

```

<Event transforms: evt: TBP>+≡
  procedure (evt_write), deferred :: write

<Event transforms: interfaces>+≡
  abstract interface
    subroutine evt_write (evt, unit, verbose, more_verbose, testflag)
      import
      class(evt_t), intent(in) :: evt
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose, more_verbose, testflag
    end subroutine evt_write
  end interface

```

Output. We can print r.n.g. info.

```

<Event transforms: evt: TBP>+≡
  procedure :: base_write => evt_base_write

```

<Event transforms: procedures>+≡

```

subroutine evt_base_write (evt, unit, testflag, show_set)
  class(evt_t), intent(in) :: evt
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: testflag, show_set
  integer :: u
  logical :: show
  u = given_output_unit (unit)
  show = .true.; if (present (show_set)) show = show_set
  if (associated (evt%process)) then
    write (u, "(3x,A,A,A)") "Associated process: '", &
      char (evt%process%get_id ()), "'"
  end if
  if (allocated (evt%rng)) then
    call evt%rng%write (u, 1)
    write (u, "(3x,A,I0)") "Number of tries = ", evt%rejection_count
  end if
  if (show) then
    if (evt%particle_set_exists) then
      call write_separator (u)
      call evt%particle_set%write (u, testflag = testflag)
    end if
  end if
end subroutine evt_base_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

<Event transforms: evt: TBP>+≡

```

procedure :: connect => evt_connect
procedure :: base_connect => evt_connect

```

<Event transforms: procedures>+≡

```

subroutine evt_connect (evt, process_instance, model, process_stack)
  class(evt_t), intent(inout), target :: evt
  type(process_instance_t), intent(in), target :: process_instance
  class(model_data_t), intent(in), target :: model
  type(process_stack_t), intent(in), optional :: process_stack
  evt%process => process_instance%process
  evt%process_instance => process_instance
  evt%model => model
  call evt%process%make_rng (evt%rng)
end subroutine evt_connect

```

Reset internal state.

<Event transforms: evt: TBP>+≡

```

procedure :: reset => evt_reset
procedure :: base_reset => evt_reset

```

<Event transforms: procedures>+≡

```

subroutine evt_reset (evt)
  class(evt_t), intent(inout) :: evt
  evt%rejection_count = 0

```

```

    evt%particle_set_exists = .false.
end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

<Event transforms: evt: TBP>+≡
    procedure (evt_prepare_new_event), deferred :: prepare_new_event
<Event transforms: interfaces>+≡
    interface
        subroutine evt_prepare_new_event (evt, i_mci, i_term)
            import
            class(evt_t), intent(inout) :: evt
            integer, intent(in) :: i_mci, i_term
        end subroutine evt_prepare_new_event
    end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

<Event transforms: evt: TBP>+≡
    procedure (evt_generate_weighted), deferred :: generate_weighted
<Event transforms: interfaces>+≡
    abstract interface
        subroutine evt_generate_weighted (evt, probability)
            import
            class(evt_t), intent(inout) :: evt
            real(default), intent(inout) :: probability
        end subroutine evt_generate_weighted
    end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

<Event transforms: evt: TBP>+≡
    procedure :: generate_unweighted => evt_generate_unweighted
    procedure :: base_generate_unweighted => evt_generate_unweighted
<Event transforms: procedures>+≡
    subroutine evt_generate_unweighted (evt)
        class(evt_t), intent(inout) :: evt
        real(default) :: p, x
        evt%rejection_count = 0
        REJECTION: do
            evt%rejection_count = evt%rejection_count + 1
            call evt%generate_weighted (p)
            if (signal_is_pending ()) return
            call evt%rng%generate (x)
            if (x < p) exit REJECTION
        end do REJECTION
    end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set

(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_make_particle_set
end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

(Event transforms: evt: TBP)+≡
  procedure :: set_particle_set => evt_set_particle_set

(Event transforms: procedures)+≡
  subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
    class(evt_t), intent(inout) :: evt
    type(particle_set_t), intent(in) :: particle_set
    integer, intent(in) :: i_term, i_mci
    call evt%prepare_new_event (i_mci, i_term)
    evt%particle_set = particle_set
    evt%particle_set_exists = .true.
  end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. (We need two interactions, one with color summed over, and one with the probability distributed among flows.)

We use the two values from the random number generator for factorizing the state. For testing purposes, we can provide those numbers explicitly.

```

(Event transforms: evt: TBP)+≡
  procedure :: factorize_interactions => evt_factorize_interactions

(Event transforms: procedures)+≡
  subroutine evt_factorize_interactions &
    (evt, int_matrix, int_flows, factorization_mode, &

    call msg_bug ("Event factorization: event is incomplete")
end if
end subroutine make_factorized_particle_set

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we

implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

```

(Event transforms: evt: TBP)+≡
  procedure :: tag_incoming => evt_tag_incoming

(Event transforms: procedures)+≡
  subroutine evt_tag_incoming (evt)
    class(evt_t), intent(inout) :: evt
    integer :: i_term, n_in
    integer, dimension(:), allocatable :: beam_index, in_index
    n_in = evt%process%get_n_in ()
    i_term = 1
    allocate (beam_index (n_in))
    call evt%process_instance%get_beam_index (i_term, beam_index)
    call evt%particle_set%reset_status (beam_index, PRT_BEAM)
    allocate (in_index (n_in))
    call evt%process_instance%get_in_index (i_term, in_index)
    call evt%particle_set%reset_status (in_index, PRT_INCOMING)
  end subroutine evt_tag_incoming

```

32.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

(Event transforms: public)+≡
  public :: evt_trivial_t

(Event transforms: types)+≡
  type, extends (evt_t) :: evt_trivial_t
    contains
    (Event transforms: evt trivial: TBP)
  end type evt_trivial_t

(Event transforms: evt trivial: TBP)≡
  procedure :: write_name => evt_trivial_write_name

(Event transforms: procedures)+≡
  subroutine evt_trivial_write_name (evt, unit)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event transform: trivial (hard process)"
  end subroutine evt_trivial_write_name

```

The finalizer is trivial. Some output:

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: write => evt_trivial_write

```

```

(Event transforms: procedures)+≡
subroutine evt_trivial_write (evt, unit, verbose, more_verbose, testflag)
  class(evt_trivial_t), intent(in) :: evt
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: verbose, more_verbose, testflag
  integer :: u
  u = given_output_unit (unit)
  call write_separator (u, 2)
  call evt%write_name (u)
  call write_separator (u)
  call evt%base_write (u, testflag = testflag)
end subroutine evt_trivial_write

```

Nothing to do here:

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: prepare_new_event => evt_trivial_prepare_new_event

(Event transforms: procedures)+≡
subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
  class(evt_trivial_t), intent(inout) :: evt
  integer, intent(in) :: i_mci, i_term
  call evt%reset ()
end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: generate_weighted => evt_trivial_generate_weighted

(Event transforms: procedures)+≡
subroutine evt_trivial_generate_weighted (evt, probability)
  class(evt_trivial_t), intent(inout) :: evt
  real(default), intent(inout) :: probability
  probability = 1
end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is.

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: make_particle_set => evt_trivial_make_particle_set

(Event transforms: procedures)+≡
subroutine evt_trivial_make_particle_set &
  (evt, factorization_mode, keep_correlations, r)
  class(evt_trivial_t), intent(inout) :: evt
  integer, intent(in) :: factorization_mode
  logical, intent(in) :: keep_correlations
  real(default), dimension(:), intent(in), optional :: r
  call make_factorized_particle_set (evt, factorization_mode, &
    keep_correlations, r)
  evt%particle_set_exists = .true.
end subroutine evt_trivial_make_particle_set

```

        call msg_fatal ("Hadronization without shower is not supported")
    end if
end associate
evt%is_first_event = .false.
end subroutine evt_hadrons_first_event

```

Here we take the particle set from the previous event transform and apply the hadronization. The result is stored in the `evt%hadrons` object. We always return a probability of unity as we don't have the analytic weight of the hadronization. Invalid events have to be discarded by the caller which is why we mark the particle set as invalid.

<Hadrons: evt hadrons: TBP>+≡

```

procedure :: generate_weighted => evt_hadrons_generate_weighted

```

32.4.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```
<Decays: types>≡  
  type, abstract :: any_config_t  
    private  
    contains  
    <Decays: any config: TBP>  
  end type any_config_t
```

Finalizer, depends on the implementation.

```
<Decays: any config: TBP>≡  
  procedure (any_config_final), deferred :: final  
  
<Decays: interfaces>≡  
  interface  
    subroutine any_config_final (object)  
      import  
      class(any_config_t), intent(inout) :: object  
    end subroutine any_config_final  
  end interface
```

The output is also deferred:

```
<Decays: any config: TBP>+≡  
  procedure (any_config_write), deferred :: write  
  
<Decays: interfaces>+≡  
  interface  
    subroutine any_config_write (object, unit, indent, verbose)  
      import  
      class(any_config_t), intent(in) :: object  
      integer, intent(in), optional :: unit, indent  
      logical, intent(in), optional :: verbose  
    end subroutine any_config_write  
  end interface
```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```
<Decays: types>+≡  
  type :: particle_config_t  
    private  
    class(any_config_t), allocatable :: c  
  end type particle_config_t
```

32.4.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above. This also works around a compiler bug in gfortran.

```
<Decays: types>+≡
```

```

type, abstract :: any_t
  private
  contains
  <Decays: any: TBP>
end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final
<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
        class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write
<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
      import
        class(any_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
    end subroutine any_write
  end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_out_t
    private
    class(any_t), allocatable :: c
  end type particle_out_t

```

32.4.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+≡
  type :: decay_term_config_t
    private
    type(particle_config_t), dimension(:), allocatable :: prt
  contains
    <Decays: decay term config: TBP>
  end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>≡
  procedure :: final => decay_term_config_final

<Decays: procedures>≡
  recursive subroutine decay_term_config_final (object)
    class(decay_term_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%prt)) then
      do i = 1, size (object%prt)
        if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
      end do
    end if
  end subroutine decay_term_config_final

```

Output, with optional indentation

```

<Decays: decay term config: TBP>+≡
  procedure :: write => decay_term_config_write

<Decays: procedures>+≡
  recursive subroutine decay_term_config_write (object, unit, indent, verbose)

```

32.4.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```

<Decays: public>≡
  public :: decay_root_config_t

<Decays: types>+≡
  type :: decay_root_config_t
    private
    type(string_t) :: process_id
    type(process_t), pointer :: process => null ()
    class(model_data_t), pointer :: model => null ()
    type(decay_term_config_t), dimension(:), allocatable :: term_config
    contains
    <Decays: decay root config: TBP>
  end type decay_root_config_t

```

The finalizer is recursive since there may be cascade decays.

```

<Decays: decay root config: TBP>≡
  procedure :: final => decay_root_config_final

<Decays: procedures>+≡
recursive subroutine decay_root_config_final (object)
  class(decay_root_config_t), intent(inout) :: object
  integer :: i
  if (allocated (object%term_config)) then
    do i = 1, size (object%term_config)
      call object%term_config(i)%final ()
    end do
  end if
end subroutine decay_root_config_final

```

The output routine is also recursive, and it contains an adjustable indentation.

```

<Decays: decay root config: TBP>+≡
  procedure :: write => decay_root_config_write
  procedure :: write_header => decay_root_config_write_header
  procedure :: write_terms => decay_root_config_write_terms

```

<Decays: procedures>+≡

```
recursive subroutine decay_root_config_write (object, unit, indent, verbose)
  class(decay_root_config_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent
  logical, intent(in), optional :: verbose
  integer :: u, ind
  u = given_output_unit (unit)
  ind = 0; if (present (indent)) ind = indent
  call write_indent (u, ind)
  write (u, "(1x,A)") "Final-state decay tree:"
  call object%write_header (unit, indent)
  call object%write_terms (unit, indent, verbose)
end subroutine decay_root_config_write
```

```
subroutine decay_root_config_write_header (object, unit, indent)
  class(decay_root_config_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent
  integer :: u, ind
  u = given_output_unit (unit)
  ind = 0; if (present (indent)) ind = indent
  call write_indent (u, ind)
  if (associated (object%process)) then
    write (u, 3) "process ID      =", char (object%process_id), "*"
  else
    write (u, 3) "process ID      =", char (object%process_id)
  end if
3  format (3x,A,2(1x,A))
end subroutine decay_root_config_write_header
```

```
recursive subroutine decay_root_config_write_terms &
  (object, unit, indent, verbose)

```

Declare a decay term, given an array of flavors.

```

<Decays: decay root config: TBP>+≡
    procedure :: init_term => decay_root_config_init_term

<Decays: procedures>+≡
    recursive subroutine decay_root_config_init_term &
        (decay, i, flv, stable, model, process_stack)
        class(decay_root_config_t), intent(inout) :: decay
        integer, intent(in) :: i
        type(flavor_t), dimension(:, :), intent(in) :: flv
        logical, dimension(:), intent(in) :: stable
        class(model_data_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        call decay%term_config(i)%init (flv, stable, model, process_stack)
    end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

For the unstable particles, we have to check whether their masses match between the production and the decay. Fortunately, both versions are available for comparison.

```

<Decays: decay root config: TBP>+≡
    procedure :: connect => decay_root_config_connect

<Decays: procedures>+≡
    recursive subroutine decay_root_config_connect &

    end subroutine decay_root_config_compute

```

32.4.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```

<Decays: types>+≡
    type, abstract :: decay_gen_t
    private
        type(decay_term_t), dimension(:), allocatable :: term
        type(process_instance_t), pointer :: process_instance => null ()
        integer :: selected_mci = 0
        integer :: selected_term = 0
    contains
        <Decays: decay gen: TBP>
    end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

<Decays: public>+≡
    public :: decay_root_t

<Decays: types>+≡
    type, extends (decay_gen_t) :: decay_root_t
    private
        type(decay_root_config_t), pointer :: config => null ()
    contains

```

```

    <Decays: decay root: TBP>
end type decay_root_t

```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```

<Decays: decay gen: TBP>≡
    procedure :: base_final => decay_gen_final

<Decays: procedures>+≡
    recursive subroutine decay_gen_final (object)
        class(decay_gen_t), intent(inout) :: object
        integer :: i

    end subroutine decay_root_final

```

Output.

```

<Decays: decay root: TBP>+≡
    procedure :: write => decay_root_write

<Decays: procedures>+≡
    subroutine decay_root_write (object, unit)
        class(decay_root_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)
        if (associated (object%config)) then
            call object%config%write (unit, verbose = .false.)
        else
            write (u, "(1x,A)") "Final-state decay tree: [not configured]"
        end if
        if (object%selected_mci > 0) then
            write (u, "(3x,A,I0)") "Selected MCI      = ", object%selected_mci
        else
            write (u, "(3x,A)") "Selected MCI      = [undefined]"
        end if
        if (object%selected_term > 0) then
            write (u, "(3x,A,I0)") "Selected term    = ", object%selected_term
            call object%term(object%selected_term)%write (u, 1)
        else

```

```

        write (u, "(3x,A)") "Selected term  = [undefined]"
    end if
end subroutine decay_root_write

```

Write the process instances, recursively.

```

<Decays: decay gen: TBP>+≡
    procedure :: write_process_instances => decay_gen_write_process_instances

<Decays: procedures>+≡
    recursive subroutine decay_gen_write_process_instances (decay, unit, verbose)
        class(decay_gen_t), intent(in) :: decay
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: verbose
        logical :: verb
        verb = .true.; if (present (verbose)) verb = verbose
        if (associated (decay%process_instance)) then
            if (verb) then
                call decay%process_instance%write (unit)
            else
                call decay%process_instance%write_header (unit)
            end if
        end if
        if (decay%selected_term > 0) then
            call decay%term(decay%selected_term)%write_process_instances (unit, verb)
        end if
    end subroutine decay_gen_write_process_instances

```

Generic initializer. All can be done recursively.

```

<Decays: decay gen: TBP>+≡
    procedure :: base_init => decay_gen_init

<Decays: procedures>+≡
    recursive subroutine decay_gen_init (decay, term_config)
        class(decay_gen_t), intent(out) :: decay
        type(decay_term_config_t), dimension(:), intent(in), target :: term_config
        integer :: i
        allocate (decay%term (size (term_config)))
        do i = 1, size (decay%term)
            call decay%term(i)%init (term_config(i))
        end do
    end subroutine decay_gen_init

```

Specific initializer. We assign the configuration object, which should correspond to a completely initialized decay configuration tree. We also connect to an existing process instance. Then, we recursively link the child interactions to the parent process.

```

<Decays: decay root: TBP>+≡
    procedure :: init => decay_root_init

<Decays: procedures>+≡
    subroutine decay_root_init (decay_root, config, process_instance)
        class(decay_root_t), intent(out) :: decay_root
        type(decay_root_config_t), intent(in), target :: config

```

```

type(process_instance_t), intent(in), target :: process_instance
call decay_root%base_init (config%term_config)
decay_root%config => config
decay_root%process_instance => process_instance
call decay_root%make_term_rng (config%process)
call decay_root%link_term_interactions ()
end subroutine decay_root_init

```

Explicitly set/get mci and term indices. (Used in unit test.)

```

<Decays: decay gen: TBP>+≡
  procedure :: set_mci => decay_gen_set_mci
  procedure :: set_term => decay_gen_set_term
  procedure :: get_mci => decay_gen_get_mci
  procedure :: get_term => decay_gen_get_term

<Decays: procedures>+≡
  subroutine decay_gen_set_mci (decay, i)
    class(decay_gen_t), intent(inout) :: decay
    integer, intent(in) :: i
    decay%selected_mci = i
  end subroutine decay_gen_set_mci

  subroutine decay_gen_set_term (decay, i)
    class(decay_gen_t), intent(inout) :: decay
    integer, intent(in) :: i
    decay%selected_term = i
  end subroutine decay_gen_set_term

  function decay_gen_get_mci (decay) result (i)
    class(decay_gen_t), intent(inout) :: decay
    integer :: i
    i = decay%selected_mci
  end function decay_gen_get_mci

  function decay_gen_get_term (decay) result (i)
    class(decay_gen_t), intent(inout) :: decay
    integer :: i
    i = decay%selected_term
  end function decay_gen_get_term

```

Implement random-number generators for unstable decay selection in all terms.
This is not recursive.

We also make use of the fact that `process` is a pointer; the (state of the RNG factory inside the) target process will be modified by the rng-spawning method, but not the pointer.

```

<Decays: decay gen: TBP>+≡
  procedure :: make_term_rng => decay_gen_make_term_rng

<Decays: procedures>+≡
  subroutine decay_gen_make_term_rng (decay, process)
    class(decay_gen_t), intent(inout) :: decay
    type(process_t), intent(in), pointer :: process
    integer :: i

```

```

do i = 1, size (decay%term)
  call decay%term(i)%make_rng (process)
end do
end subroutine decay_gen_make_term_rng

```

Recursively link interactions of the enclosed decay terms to the corresponding terms in the current process instance.

Note: A bug in nagfor requires the extra `i_term` variable.

```

<Decays: decay gen: TBP>+≡
  procedure :: link_term_interactions => decay_gen_link_term_interactions

<Decays: procedures>+≡
  recursive subroutine decay_gen_link_term_interactions (decay)
    class(decay_gen_t), intent(inout) :: decay
    integer :: i, i_term
    type(interaction_t), pointer :: trace
    associate (instance => decay%process_instance)
      do i = 1, size (decay%term)
        i_term = i
        trace => instance%get_trace_int_ptr (i_term)
        call decay%term(i_term)%link_interactions (trace)
      end do
    end associate
  end subroutine decay_gen_link_term_interactions

```

Select a decay chain: decay modes and process components.

```

<Decays: decay root: TBP>+≡
  procedure :: select_chain => decay_root_select_chain
