## Caveat

This manual is outdated and describes the old Fortran77 interface. This interface has been replaced by a similar, but thoroughly modern Fortran 2003 interface.

Also the new smoothing feature of `circe2_tool` is not described here.

Please see the annotated template and other files in `share/examples/` for a starting point for rolling your own beam descriptions.

## Program Summary:

- **Title of program:** *Κίρκη*, Version 2.0 (June 2014)
- **Program obtainable from**  
<http://www.hepforge.org/downloads/whizard>.
- **Licensing provisions:** Free software under the GNU General Public License.
- **Programming languages used:** Fortran, OCaml[8] (available from <http://caml.inria.fr/ocaml> and <http://ocaml.org>).
- **Number of program lines in distributed program**  $\approx$  ??? lines of Fortran (excluding comments) for the library;  $\approx$  ??? lines of OCaml for the utility program
- **Computer/Operating System:** Any with a Fortran programming environment.
- **Memory required to execute with typical data:** Negligible on the scale of typical applications calling the library.
- **Typical running time:** A negligible fraction of the running time of applications calling the library.
- **Purpose of program:** Provide efficient, realistic and reproducible parameterizations of the correlated  $e^\pm$ - and  $\gamma$ -beam spectra for linear colliders and photon colliders.
- **Nature of physical problem:** The intricate beam dynamics in the interaction region of a high luminosity linear collider at  $\sqrt{s} = 500\text{GeV}$  result in non-trivial energy spectra of the scattering electrons, positrons and photons. Physics simulations require efficient, reproducible, realistic and easy-to-use parameterizations of these spectra.
- **Method of solution:** Parameterization, curve fitting, adaptive sampling, Monte Carlo event generation.
- **Keywords:** Event generation, beamstrahlung, linear colliders, photon colliders.

# 1 Introduction

The expeditious construction of a high-energy, high-luminosity  $e^+e^-$  Linear Collider (LC) to complement the Large Hadron Collider (LHC) has been identified as the next world wide project for High Energy Physics (HEP). The dynamics of the dense colliding beams providing the high luminosities required by such a facility is highly non-trivial and detailed simulations have to be performed to predict the energy spectra provided by these beams. The microscopic simulations of the beam dynamics require too much computer time and memory for direct use in physics programs. Nevertheless, the results of such simulations have to be available as input for physics studies, since these spectra affect the sensitivity of experiments for the search for deviations from the standard model and to new physics.

*Kíρκη* Version 1.x (**circe1** for short) [1] has become a de-facto standard for inclusion of realistic energy spectra of TeV-scale  $e^+e^-$  LCs in physics calculations and event generators. It is supported by the major multi purpose event generators [2, 3] and has been used in many dedicated analyses. *Kíρκη* provides a fast, concise and convenient parameterization of the results of such simulations.

**circe1** assumed strictly factorized distributions with a very restricted functional form (see [1] for details). This approach was sufficient for exploratory studies of physics at TeV-scale  $e^+e^-$  LCs. Future studies of physics at  $e^+e^-$  LCs will require a more detailed description and the estimation of non-factorized contributions. In particular, all distributions at laser backscattering  $\gamma\gamma$  colliders [4] and at multi-TeV  $e^+e^-$  LCs are correlated and can not be approximated by **circe1** at all. In addition, the proliferation of accelerator designs since the release of **circe1** has make the maintenance of parameterizations as FORTRAN77 BLOCK DATA unwieldy.

*Kíρκη* Version 2.0 (**circe2** for short) successfully addresses these shortcomings of **circe1**, as can be seen in figure 1. It should be noted that the large  $z$  region and the blown-up  $z \rightarrow 0$  region are taken from the *same* pair of datasets. In section 6.2 below, figures 3 to 9 demonstrate the interplay of **circe2**'s features. The algorithms implemented<sup>1</sup> in **circe2** should suffice for all studies until  $e^+e^-$  LCs and photon colliders come on-line and probably beyond. The implementation **circe2** bears no resemblance at all with the implementation of **circe1**.

**circe2** describes the distributions by two-dimensional grids that are optimized using an algorithm derived from VEGAS [5]. The implementation was

---

<sup>1</sup>A small number of well defined extensions that has have not been implemented yet are identified in section 3 below.

Figure 1: Comparison of a simulated realistic  $\gamma\gamma$  luminosity spectrum (helicities:  $(+, +)$ ) for a 500 GeV photon collider at TESLA [7] (filled area) with its `circe2` parameterization (solid line) using 50 bins in both directions. The  $10^4$ -fold blow-up of the  $z \rightarrow 0$  region is taken from the same pair of datasets as the plot including the large  $z$  region.

modeled on the implementation in VAMP [6], but changes were required for sampling static event sets instead of distributions given as functions. The problem solved by `circe2` is rather different from the Monte Carlo integration with importance or stratified sampling that is the focus of VEGAS and VAMP. In the case of VEGAS/VAMP the function is given as a mathematical function, either analytically or numerically. In this case, while the adapted grid is being refined, resources can be invested for studying the function more closely in problematic regions. `circe2` does not have this luxury, because it must reconstruct (“*guess*”) a function from a *fixed* and *finite* sample. Therefore it cannot avoid to introduce biases, either through a fixed global functional form (as in `circe1`) through step functions (histograms). `circe2` combines the two approaches and uses automatically adapted histograms mapped by a patchwork of functions.

## 1.1 Notes on the Implementation

The FORTRAN77 library is extremely simple (about 800 lines) and performs only two tasks: one small set of subroutines efficiently generates pairs of random numbers distributed according to two dimensional histograms with factorized non-uniform bins stored in a file. A second set of functions calculates the value of the corresponding distributions.

FORTTRAN77 has been chosen solely for practical reasons: at the time of writing, the majority of programs expected to use the `circe2` are legacy applications written in FORTRAN77. The simple functionality of the FORTRAN77 library can however be reproduced trivially in any other programming language that will be needed in the future.

The non-trivial part of constructing an optimized histogram from an arbitrary distribution is performed by a utility program `circe2_tool` written in Objective Caml [8] (or O’Caml for short). O’Caml is available as Free Software for almost all computers and operating systems currently used in high energy physics. Bootstrapping the O’Caml compiler is straightforward and quick. Furthermore, parameterizations are distributed together with `circe2`, and most users will not even need to compile `circe2_tool`. Therefore there are no practical problems in using a modern programming language like O’Caml that allows—in the author’s experience—a both more rapid and safer development than FORTRAN77 or C++.

## 1.2 Overview

The remainder of this paper is organized as follows. For the benefit of users of the library, the Application Program Interface (API) is described immediately in section 3 after defining the notation in section 2. Section 4 shows some examples using the procedures described in section 3.

A description of the inner workings of `circe2` that is more detailed than required for using the library starts in section 5. An understanding of the algorithms employed is helpful for preparing beam descriptions using the program `circe2_tool` which is described in section 6. Details of the implementation of `circe2_tool` can be found in section 7, where also the benefits provided by modern functional programming languages for program organization in the large are discussed.

## 2 Physics

The customary parametrization of polarization in beam physics [9, 10] is in terms of density matrices for the leptons

$$\rho_{e^\pm}(\zeta) = \frac{1}{2} (1 + \zeta_i \sigma_i) \quad (1)$$

and the so-called Stokes’ parameters for photons

$$\rho_\gamma(\xi) = \frac{1}{2} (1 + \xi_i \sigma_i) \quad (2)$$

where the pseudo density matrix  $2 \times 2$ -matrix  $\rho_\gamma$  for a pure polarization state  $\epsilon_\mu$  is given by

$$[\rho_\gamma]_{ij} = \langle (\epsilon e_i)(\epsilon^* e_j) \rangle \quad (3)$$

using two unit vectors  $e_{1/2}$  orthogonal to the momentum. Keeping in mind the different interpretations of  $\zeta$  and  $\xi$ , we will from now on unify the mathematical treatment and use the two interchangeably, since the correct interpretation will always be clear from the context. Using the notation  $\sigma_0 = 1$ , the joint polarization density matrix for two colliding particles can be written

$$\rho(\chi) = \sum_{a,a'=0}^3 \frac{\chi_{aa'}}{4} \sigma_a \otimes \sigma_{a'} \quad (4)$$

with  $\chi_{0,0} = \text{tr } \rho(\chi) = 1$ . Averaging density matrices will in general lead to correlated density matrices, even if the density matrices that are being averaged are factorized or correspond to pure states.

The most complete description  $B$  of a pair of colliding beams is therefore provided by a probability density and a density matrix for each pair  $(x_1, x_2)$  of energy fractions:

$$\begin{aligned} B : [0, 1] \times [0, 1] &\rightarrow \mathbf{R}^+ \times M \\ (x_1, x_2) &\mapsto (D(x_1, x_2), \rho(x_1, x_2)) \end{aligned} \quad (5)$$

where  $\rho(x_1, x_2)$  will conveniently be given using the parametrization (4). Sophisticated event generators can use  $D(x_1, x_2)$  and  $\rho(x_1, x_2)$  to account for all spin correlations with the on-shell transition matrix  $T$

$$d\sigma = \int dx_1 \wedge dx_2 D(x_1, x_2) \text{tr} (P_\Omega T(x_1 x_2 s) \rho(x_1, x_2) T^\dagger(x_1 x_2 s)) \text{ dLIPS} \quad (6)$$

## 2.1 Polarization Averaged Distributions

Physics applications that either ignore polarization (this is often not advisable, but can be a necessary compromise in some cases) or know that polarization will play no significant role can ignore the density matrix, which amounts to summing over all polarization states. If the microscopic simulations that have been used to obtain the distributions described by `circe2` do not keep track of polarization, 93% of disk space can be saved by supporting simplified interfaces that ignore polarization altogether.

## 2.2 Helicity Distributions

Between the extremes of polarization averaged distributions on one end and full correlated density matrices on the other end, there is one particularly

important case for typical applications, that deserves a dedicated implementation.

In the approximation of projecting on the subspace consisting of circular polarizations

$$\rho(\chi) = \frac{1}{4} (\chi_{0,0} \cdot 1 \otimes 1 + \chi_{0,3} \cdot 1 \otimes \sigma_3 + \chi_{3,0} \cdot \sigma_3 \otimes 1 + \chi_{3,3} \cdot \sigma_3 \otimes \sigma_3) \quad (7)$$

the density matrix can be rewritten as a convex combination of manifest projection operators build out of  $\sigma_{\pm} = (1 \pm \sigma_3)/2$ :

$$\rho(\chi) = \chi_{++} \cdot \sigma_+ \otimes \sigma_+ + \chi_{+-} \cdot \sigma_+ \otimes \sigma_- + \chi_{-+} \cdot \sigma_- \otimes \sigma_+ + \chi_{--} \cdot \sigma_- \otimes \sigma_- \quad (8)$$

The coefficients are given by

$$\chi_{++} = \frac{1}{4} (\chi_{0,0} + \chi_{0,3} + \chi_{3,0} + \chi_{3,3}) \geq 0 \quad (9a)$$

$$\chi_{+-} = \frac{1}{4} (\chi_{0,0} - \chi_{0,3} + \chi_{3,0} - \chi_{3,3}) \geq 0 \quad (9b)$$

$$\chi_{-+} = \frac{1}{4} (\chi_{0,0} + \chi_{0,3} - \chi_{3,0} - \chi_{3,3}) \geq 0 \quad (9c)$$

$$\chi_{--} = \frac{1}{4} (\chi_{0,0} - \chi_{0,3} - \chi_{3,0} + \chi_{3,3}) \geq 0 \quad (9d)$$

and satisfy

$$\chi_{++} + \chi_{+-} + \chi_{-+} + \chi_{--} = \text{tr } \rho(\chi) = 1 \quad (10)$$

Of course, the  $\chi_{\epsilon_1 \epsilon_2}$  are recognized as the probabilities for finding a particular combination of helicities for particles moving along the  $\pm \vec{e}_3$  direction and we can introduce partial probability distributions

$$D_{p_1 p_2}^{\epsilon_1 \epsilon_2}(x_1, x_2) = \chi_{\epsilon_1 \epsilon_2} \cdot D_{p_1 p_2}(x_1, x_2) \geq 0 \quad (11)$$

that are to be combined with the polarized cross sections

$$\frac{d\sigma}{d\Omega}(s) = \sum_{\epsilon_1, \epsilon_2 = \pm} \int dx_1 \wedge dx_2 D^{\epsilon_1 \epsilon_2}(x_1, x_2) \left( \frac{d\sigma}{d\Omega} \right)^{\epsilon_1 \epsilon_2}(x_1 x_2 s) \quad (12)$$

This case deserves special consideration because it is a good approximation for a majority of applications and, at the same time, it is the most general case that allows an interpretation as classical probabilities. The latter feature allows the preparation of separately tuned probability densities for all four helicity combinations. In practical applications this turns out to be useful because the power law behaviour of the extreme low energy tails turns out to have a mild polarization dependence.

### 3 API

All floating point numbers in the interfaces are declared as `double precision`. In most applications, the accuracy provided by single precision floating point numbers is likely to suffice. However most application programs will use double precision floating point numbers anyway so the most convenient choice is to use double precision in the interfaces as well.

In all interfaces, the integer particle codes follow the conventions of the Particle Data Group [11]. In particular

`p = 11`: electrons

`p = -11`: positrons

`p = 22`: photons

while other particles are unlikely to appear in the context of `circe2` before the design of  $\mu$ -colliders enters a more concrete stage. Similarly, in all interfaces, the sign of the helicities are denoted by integers

`h = 1`: helicity +1 for photons or +1/2 for leptons (electrons and positrons)

`h = -1`: helicity -1 for photons or -1/2 for leptons (electrons and positrons)

As part of tis API, we also define a few extensions, which will be available in future versions, but have not been implemented yet. This allows application programs to anticipate these extensions.

### 3.1 Initialization

Before any of the event generation routines or the functions computing probability densities can be used, beam descriptions have to be loaded. This is accomplished by the routine `cir2ld` (mnemonic: *LoaD*), which must have been called at least once before any other procedure is invoked:

```
subroutine cir2ld (file, design, roots, ierror)
```

`character*(*) file` (input): name of a `circe2` parameter file in the format described in table 2. Conventions for filenames are system dependent and the names of files will consequently be installation dependent. This can not be avoided.

`character*(*) design` (input): name of the accelerator design. The name must not be longer than 72 characters. It is expected that design names follow the following naming scheme for  $e^+e^-$  LCs

TESLA: TESLA superconducting design (DESY)

XBAND: NLC/JLC X-band design (KEK, SLAC)

CLIC: CLIC two-beam design (CERN)

Special operating modes should be designated by a qualifier

/GG: laser backscattering  $\gamma\gamma$  collider (e.g. 'TESLA/GG')

/GE: laser backscattering  $\gamma e^-$  collider

/EE:  $e^-e^-$  collider

If there is more than one matching beam description, the *last* of them is used. If `design` contains a '\*', only the characters *before* the '\*' matter in the match. E.g.:

`design = 'TESLA'` matches only 'TESLA'

`design = 'TESLA*'` matches any of 'TESLA (Higgs factory)', 'TESLA (GigaZ)', 'TESLA', etc.

`design = '*'` matches everything and is a convenient shorthand for the case that there is only a single design per file

NB: '\*' is not a real wildcard: everything after the first '\*' is ignored.

`double precision roots` (input):  $\sqrt{s}$ /GeV of the accelerator. This must match within  $\Delta\sqrt{s} = 1$  GeV. There is currently no facility for interpolation between fixed energy designs (see section 4.3, however).

`integer ierror` (input/output): if `ierror` > 0 on input, comments will be echoed to the standard output stream. On output, if no errors have been encountered `cir2ld` guarantees that `ierror` = 0. If `ierror` < 0, an error has occurred:

```

ierror = -1: file not found
ierror = -2: no match for design and  $\sqrt{s}$ 
ierror = -3: invalid format of parameter file
ierror = -4: parameter file too large

```

A typical application, assuming that a file named `photon_colliders.circe` contains beam descriptions for photon colliders (including TESLA/GG) is

```

integer ierror
...
ierror = 1
call cir2ld ('photon_colliders.circe', 'TESLA/GG', 500D0, ierror)
if (ierror .lt. 0)
  print *, 'error: cir2ld failed: ', ierror
  stop
end if
...

```

In order to allow application programs to be as independent from operating system dependent file naming conventions, the file formal has been designed so beam descriptions can be concatenated and application programs can hide file names from the user completely, as in

```

subroutine ldbeam (design, roots, ierror)
implicit none
character*(*) design
double precision roots
integer ierror
call cir2ld ('beam_descriptions.circe', design, roots, ierror)
if (ierror .eq. -1)
  print *, 'ldbeam: internal error: file not found'
  stop
end if
end

```

The other extreme uses one file per design and uses the '\*' wildcard to make the `design` argument superfluous.

```

subroutine ldfile (name, roots, ierror)
implicit none
character*(*) name
double precision roots
integer ierror
call cir2ld (name, '*', roots, ierror)
end

```

Note that while it is in principle possible to use a data file intended for helicity states for polarization averaged distributions instead, no convenience procedures for this purpose are provided.

### 3.2 Luminosities

One of the results of the simulations that provide the input for `circe2` are the partial luminosities for all combinations of flavors and helicities. The luminosities for a combination of flavors and helicities can be inspected with the function `cir2lm` (*LuMinosity*). The return value is given in the convenient units

$$\text{fb}^{-1}v^{-1} = 10^{32}\text{cm}^{-2}\text{sec}^{-1} \quad (13)$$

where  $v = 10^7 \text{ sec} \approx \text{year}/\pi$  is an “effective year” of running with about 30% up-time

```

double precision function cir2lm (p1, h1, p2, h2)

integer p1 (input): particle code for the first particle
integer h1 (input): helicity of the first particle
integer p2 (input): particle code for the second particle
integer h2 (input): helicity of the second particle

```

For the particle codes and helicities the special value 0 can be used to imply a sum over all flavors and helicities. E.g. the total luminosity is obtained with

```
lumi = cir2lm (0, 0, 0, 0)
```

and the  $\gamma\gamma$  luminosity summed over all helicities

```
lumigg = cir2lm (22, 0, 22, 0)
```

### 3.3 Sampling and Event Generation

Given a combination of flavors and helicities, the routine `cir2gn` (*GeNerate*) can be called repeatedly to obtain a sample of pairs  $(x_1, x_2)$  distributed according to the currently loaded beam description:

```
subroutine cir2gn (p1, h1, p2, h2, x1, x2, rng)

  integer p1 (input): particle code for the first particle
  integer h1 (input): helicity of the first particle
  integer p2 (input): particle code for the second particle
  integer h2 (input): helicity of the second particle
  double precision x1 (output): fraction of the beam en-
    ergy carried by the first particle
  double precision x2 (output): fraction of the beam en-
    ergy carried by the second particle
  external rng: subroutine

    subroutine rng (u)
      double precision u
      u = ...
    end

    generating a uniform deviate, i.e. a random number uni-
    formly distributed in  $[0, 1]$ .
```

If the combination of flavors and helicities has zero luminosity for the selected accelerator design parameters, *no error code* is available (`x1` and `x2` are set to a very large negative value in this case). Applications should use `cir2lm` to test that the luminosity is non vanishing.

Instead of scanning the luminosities for all possible combinations of flavors and helicities, applications can call the procedure `cir2ch` (*CHannel*) which chooses a “channel” (a combination of flavors and helicities) for the currently loaded beam description with the relative probabilities given by the luminosities:

```
subroutine cir2ch (p1, h1, p2, h2, rng)

  integer p1 (output): particle code for the first particle
  integer h1 (output): helicity of the first particle
  integer p2 (output): particle code for the second particle
```

`integer h2` (output): helicity of the second particle  
`external rng`: subroutine generating a uniform deviate (as above)

Many applications will use these two functions only in the combination

```
subroutine circe2 (p1, h1, p2, h2, x1, x2, rng)
integer p1, h1, p2, h2
double precision x1, x2
external rng
call cir2ch (p1, h1, p2, h2, rng)
call cir2gn (p1, h1, p2, h2, x1, x2, rng)
end
```

after which randomly distributed `p1`, `h1`, `p2`, `h2`, `x1`, and `x2` are available for further processing.

NB: a function like `circe2` has not been added to the default FORTRAN77 API, because `cir2gn` and `circe2` have the same number and types of arguments, differing only in the input/output direction of four of the arguments. This is a source of errors that a FORTRAN77 compiler can not help the application programmer to spot. The current design should be less error prone and is only minimally less convenient because of the additional procedure call

```
integer p1, h1, p2, h2
double precision x1, x2
integer n, nevent
external rng
...
do 10 n = 1, nevent
  call cir2ch (p1, h1, p2, h2, rng)
  call cir2gn (p1, h1, p2, h2, x1, x2, rng)
...
10 continue
...
```

Implementations in more modern programming languages (Fortran90/95, C++, Java, O'Caml, etc.) can and will provide a richer API with reduced name space pollution and danger of confusion.

### 3.3.1 Extensions: General Polarizations

Given a pair of flavors, triples  $(x_1, x_2, \rho)$  of momentum fractions together with density matrices for the polarizations distributed according to the cur-

rently loaded beam descriptions can be obtained by repeatedly calling `cir2gp` (*GeneratePolarized*):

```
subroutine cir2gp (p1, p2, x1, x2, pol, rng)

  integer p1 (input): particle code for the first particle
  integer p2 (input): particle code for the second particle
  double precision x1 (output): fraction of the beam en-
    ergy carried by the first particle
  double precision x2 (output): fraction of the beam en-
    ergy carried by the second particle
  double precision pol(0:3,0:3) (output): the joint den-
    sity matrix of the two polarizations is parametrized by a
    real  $4 \times 4$ -matrix
```

$$\rho(\chi) = \sum_{a,a'=0}^3 \frac{\chi_{aa'}}{4} \sigma_a \otimes \sigma_{a'} \quad (14)$$

using the notation  $\sigma_0 = 1$ . We have `pol(0,0) = 1` since  $\text{tr } \rho = 1$ .

```
external rng: subroutine generating a uniform deviate
```

*This procedure has not been implemented in version 2.0 and will be provided in release 2.1.*

### 3.4 Distributions

The normalized luminosity density  $D_{p_1 p_2}(x_1, x_2)$  for the given flavor and helicity combination for the currently loaded beam description satisfies

$$\int dx_1 \wedge dx_2 D_{p_1 p_2}(x_1, x_2) = 1 \quad (15)$$

and is calculated by `cir2dn` (*DistributionN*):

```
double precision function cir2dn (p1, h1, p2, h2, x1, x2)

  integer p1 (input): particle code for the first particle
  integer h1 (input): helicity of the first particle
  integer p2 (input): particle code for the second particle
  integer h2 (input): helicity of the second particle
```

double precision x1 (input): fraction of the beam energy  
carried by the first particle

double precision x2 (input): fraction of the beam energy  
carried by the second particle

If any of the helicities is 0 and the loaded beam description is not summed over polarizations, the result is *not* the polarization summed distribution and 0 is returned instead. Application programs must either sum by themselves or load a more efficient abbreviated beam description.

`circe1` users should take note that the densities are now normalized *individually* and no longer relative to a master  $e^+e^-$  distribution. Users of `circe1` should also take note that the special treatment of  $\delta$ -distributions at the endpoints has been removed. The corresponding contributions have been included in small bins close to the endpoints. For small enough bins, this approach is sufficiently accurate and avoids the pitfalls of the approach of `circe1`.

⚡ Applications that convolute the `circe2` distributions with other distributions can benefit from accessing the map employed by `circe2` internally through `cir2mp` (*MaP*):

```
subroutine cir2mp (p1, h1, p2, h2, x1, x2, m1, m2, d)
  integer p1 (input): particle code for the first particle
  integer h1 (input): helicity of the first particle
  integer p2 (input): particle code for the second particle
  integer h2 (input): helicity of the second particle
  double precision x1 (input): fraction of the beam en-
    ergy carried by the first particle
  double precision x2 (input): fraction of the beam en-
    ergy carried by the second particle
  integer m1 (output): map
  integer m2 (output): map
  double precision d (output):
```

### 3.4.1 Extensions: General Polarizations

The product of the normalized luminosity density  $D_{p_1 p_2}(x_1, x_2)$  and the joint polarization density matrix for the given flavor and helicity combination for the currently loaded beam description is calculated by `cir2dm` (*DensityMatrices*):

double precision function cir2dm (p1, p2, x1, x2, pol)

integer p1 (input): particle code for the first particle

integer p2 (input): particle code for the second particle

double precision x1 (input): fraction of the beam energy  
carried by the first particle

double precision x2 (input): fraction of the beam energy  
carried by the second particle

double precision pol(0:3,0:3) (output): the joint den-  
sity matrix multiplied by the normalized probability den-  
sity. The density matrix is parametrized by a real  $4 \times 4$ -  
matrix

$$D_{p_1 p_2}(x_1, x_2) \cdot \rho(\chi) = \sum_{a, a'=0}^3 \frac{1}{4} \chi_{p_1 p_2, aa'}(x_1, x_2) \sigma_a \otimes \sigma_{a'} \quad (16)$$

using the notation  $\sigma_0 = 1$ . We have  $\text{pol}(0,0) = D_{p_1 p_2}(x_1, x_2)$   
since  $\text{tr } \rho = 1$ .

*This procedure has not been implemented in version 2.0 and will be provided  
in release 2.1.*

### 3.5 Private Parts

The following need not concern application programmer, except that there  
must be no clash with any other global name in the application program:

common /cir2cm/: the internal data store for **circe2**, which *must not*  
be accessed by application programs.

## 4 Examples

In this section, we collect some simple yet complete examples using the API  
described in section 3. In all examples, the role of the physics application  
is played by a **write** statement, which would be replaced by an appropriate  
event generator for hard scattering physics or background events. The exam-  
ples assume the existence of either a file **default.circe** describing polarized  
 $\sqrt{s} = 500 \text{ GeV}$  beams or an abbreviated file **default\_polavg.circe** where  
the helicities are summed over.

## 4.1 Unweighted Event Generation

`circe2` has been designed for the efficient generation of unweighted events, i.e. event samples that are distributed according to the given probability density. Examples of weighted events are discussed in section 4.2 below.

### 4.1.1 Mixed Flavors and Helicities

The most straightforward application uses a stream of events with a mixture of flavors and helicities in *random* order. If the application can consume events without the need for costly reinitializations when the flavors are changed, a simple loop around `cir2ch` and `cir2gn` suffices:

```
program demo1
implicit none
integer p1, h1, p2, h2, n, nevent, ierror
double precision x1, x2
external random
nevent = 20
ierror = 1
call cir2ld ('default.circe', '*', 500D0, ierror)
if (ierror .lt. 0) stop
write (*, '(A7,4(X,A4),2(X,A10))')
$      '#', 'pdg1', 'hel1', 'pdg2', 'hel2', 'x1', 'x2'
do 10 n = 1, nevent
    call cir2ch (p1, h1, p2, h2, random)
    call cir2gn (p1, h1, p2, h2, x1, x2, random)
    write (*, '(I7,4(X,I4),2(X,F10.8))') n, p1, h1, p2, h2, x1, x2
10  continue
end
```

The following minimalistic linear congruential random number generator can be used for demonstrating the interface, but it is known to produce correlations and *must* be replaced by a more sophisticated one in real applications:

```
subroutine random (r)
implicit none
double precision r
integer M, A, C
parameter (M = 259200, A = 7141, C = 54773)
integer n
save n
data n /0/
n = mod (n*A + C, M)
```

```

r = dble (n) / dble (M)
end

```

#### 4.1.2 Separated Flavors and Helicities

If the application can not switch efficiently among flavors and helicities, another approach is more useful. It walks through the flavors and helicities sequentially and uses the partial luminosities `cir2lm` to determine the correct number of events for each combination:

```

program demo2
implicit none
integer i1, i2, pdg(3), h1, h2, i, n, nevent, nev, ierror
double precision x1, x2, lumi, cir2lm
external random, cir2lm
data pdg /22, 11, -11/
nevent = 20
ierror = 1
call cir2ld ('default.circe', '*', 500D0, ierror)
if (ierror .lt. 0) stop
lumi = cir2lm (0, 0, 0, 0)
write (*, '(A7,4(X,A4),2(X,A10))')
$      '#', 'pdg1', 'hel1', 'pdg2', 'hel2', 'x1', 'x2'
i = 0
do 10 i1 = 1, 3
  do 11 i2 = 1, 3
    do 12 h1 = -1, 1, 2
      do 13 h2 = -1, 1, 2
        nev = nevent * cir2lm (pdg(i1), h1, pdg(i2), h2) / lumi
        do 20 n = 1, nev
          call cir2gn (pdg(i1), h1, pdg(i2), h2, x1, x2, random)
          i = i + 1
          write (*, '(I7,4(X,I4),2(X,F10.8))')
$              i, pdg(i1), h1, pdg(i2), h2, x1, x2
20          continue
13          continue
12          continue
11          continue
10          continue
end

```

More care can be taken to guarantee that the total number of events is not reduced by rounding `nev` towards 0, but the error will be negligible for reasonably high statistics anyway.

### 4.1.3 Polarization Averaged

If the helicities are to be ignored, the abbreviated file `default_polavg.circe` can be read. The code remains unchanged, but the variables `h1` and `h2` will always be set to 0.

```
program demo3
implicit none
integer p1, h1, p2, h2, n, nevent, ierror
double precision x1, x2
external random
nevent = 20
ierror = 1
call cir2ld ('default_polavg.circe', '*', 500D0, ierror)
if (ierror .lt. 0) stop
write (*, '(A7,2(X,A4),2(X,A10))')
$      '#', 'pdg1', 'pdg2', 'x1', 'x2'
do 10 n = 1, nevent
    call cir2ch (p1, h1, p2, h2, random)
    call cir2gn (p1, h1, p2, h2, x1, x2, random)
    write (*, '(I7,2(X,I4),2(X,F10.8))') n, p1, p2, x1, x2
10 continue
end
```

### 4.1.4 Flavors and Helicity Projections

There are three ways to produce samples with a fixed subset of flavors or helicities. As an example, we generate a sample of two photon events with  $L = 0$ . The first approach generates the two channels  $++$  and  $--$  sequentially:

```
program demo4
implicit none
double precision x1, x2, lumipp, lumimm, cir2lm
integer n, nevent, npp, nmm, ierror
external random, cir2lm
nevent = 20
ierror = 1
call cir2ld ('default.circe', '*', 500D0, ierror)
if (ierror .lt. 0) stop
lumipp = cir2lm (22, 1, 22, 1)
lumimm = cir2lm (22, -1, 22, -1)
npp = nevent * lumipp / (lumipp + lumimm)
nmm = nevent - npp
write (*, '(A7,2(X,A10))') '#', 'x1', 'x2'
```

```

do 10 n = 1, npp
  call cir2gn (22, 1, 22, 1, x1, x2, random)
  write (*, '(I7,2(X,F10.8))') n, x1, x2
10 continue
do 20 n = 1, nmm
  call cir2gn (22, -1, 22, -1, x1, x2, random)
  write (*, '(I7,2(X,F10.8))') n, x1, x2
20 continue
end

```

a second approach alternates between the two possibilities

```

program demo5
implicit none
double precision x1, x2, u, lumipp, lumimm, cir2lm
integer n, nevent, ierror
external random, cir2lm
nevent = 20
ierror = 1
call cir2ld ('default.circe', '*', 500D0, ierror)
if (ierror .lt. 0) stop
lumipp = cir2lm (22, 1, 22, 1)
lumimm = cir2lm (22, -1, 22, -1)
write (*, '(A7,2(X,A10))') '#', 'x1', 'x2'
do 10 n = 1, nevent
  call random (u)
  if (u * (lumipp + lumimm) .lt. lumipp) then
    call cir2gn (22, 1, 22, 1, x1, x2, random)
  else
    call cir2gn (22, -1, 22, -1, x1, x2, random)
  endif
  write (*, '(I7,2(X,F10.8))') n, x1, x2
10 continue
end

```

finally, the third approach uses rejection to select the desired flavors and helicities

```

program demo6
implicit none
integer p1, h1, p2, h2, n, nevent, ierror
double precision x1, x2
external random
nevent = 20
ierror = 1

```

```

call cir2ld ('default.circe', '*', 500D0, ierror)
if (ierror .lt. 0) stop
write (*, '(A7,2(X,A10))') '#', 'x1', 'x2'
n = 0
10 continue
    call cir2ch (p1, h1, p2, h2, random)
    call cir2gn (p1, h1, p2, h2, x1, x2, random)
    if ((p1 .eq. 22) .and. (p2 .eq. 22) .and.
$      ((h1 .eq. 1) .and. (h2 .eq. 1)) .or.
$      ((h1 .eq. -1) .and. (h2 .eq. -1))) then
        n = n + 1
        write (*, '(I7,2(X,F10.8))') n, x1, x2
    end if
    if (n .lt. nevent) then
        goto 10
    end if
end

```

All generated distributions are equivalent, but the chosen subsequences of random numbers will be different. It depends on the application and the channels under consideration, which approach is the most appropriate.

## 4.2 Distributions and Weighted Event Generation

If no events are to be generated, `cir2dn` can be used to calculate the probability density  $D(x_1, x_2)$  at a given point. This can be used for numerical integration other than Monte Carlo or for importance sampling in the case that the distribution to be folded with  $D$  is more rapidly varying than  $D$  itself.

Depending on the beam descriptions, these distributions are available either for fixed helicities

```

program demo7
implicit none
integer n, nevent, ierror
double precision x1, x2, w, cir2dn
nevent = 20
ierror = 1
call cir2ld ('default.circe', '*', 500D0, ierror)
if (ierror .lt. 0) stop
write (*, '(A7,3(X,A10))') '#', 'x1', 'x2', 'weight'
do 10 n = 1, nevent
    call random (x1)

```

```

        call random (x2)
        w = cir2dn (22, 1, 22, 1, x1, x2)
        write (*, '(I7,2(X,F10.8),X,E10.4)') n, x1, x2, w
10    continue
    end

```

or summed over all helicities if the beam description is polarization averaged:

```

program demo8
implicit none
integer n, nevent, ierror
double precision x1, x2, w, cir2dn
nevent = 20
ierror = 1
call cir2ld ('default_polavg.circe', '*', 500D0, ierror)
if (ierror .lt. 0) stop
write (*, '(A7,3(X,A10))') '#', 'x1', 'x2', 'weight'
do 10 n = 1, nevent
    call random (x1)
    call random (x2)
    w = cir2dn (22, 0, 22, 0, x1, x2)
    write (*, '(I7,2(X,F10.8),X,E10.4)') n, x1, x2, w
10    continue
end

```

If the beam description is not polarization averaged, the application can perform the averaging itself (note that each distribution is normalized):

```

program demo9
implicit none
integer n, nevent, ierror
double precision x1, x2, w, cir2dn, cir2lm
double precision lumi, lumipp, lumimp, lumipm, lumimm
nevent = 20
ierror = 1
call cir2ld ('default.circe', '*', 500D0, ierror)
if (ierror .lt. 0) stop
lumipp = cir2lm (22, 1, 22, 1)
lumipm = cir2lm (22, 1, 22, -1)
lumimp = cir2lm (22, -1, 22, 1)
lumimm = cir2lm (22, -1, 22, -1)
lumi = lumipp + lumimp + lumipm + lumimm
write (*, '(A7,3(X,A10))') '#', 'x1', 'x2', 'weight'
do 10 n = 1, nevent
    call random (x1)

```

```

        call random (x2)
        w = ( lumipp * cir2dn (22, 1, 22, 1, x1, x2)
$          + lumipm * cir2dn (22, 1, 22, -1, x1, x2)
$          + lumimp * cir2dn (22, -1, 22, 1, x1, x2)
$          + lumimm * cir2dn (22, -1, 22, -1, x1, x2)) / lumi
        write (*, '(I7,2(X,F10.8),X,E10.4)') n, x1, x2, w
10    continue
    end

```

The results produced by the preceeding pair of examples will differ point-by-point, because the polarized and the polarization summed distribution will be binned differently. However, all histograms of the results with reasonable bin sizes will agree.

### 4.3 Scans and Interpolations

Currently there is no supported mechanism for interpolating among distributions for the discrete parameter sets. The most useful application of such a facility would be a scan of the energy dependence of an observable

$$\mathcal{O}(s) = \int dx_1 dx_2 d\Omega D(x_1, x_2, s) \frac{d\sigma}{d\Omega}(x_1, x_2, s, \Omega) \mathcal{O}(x_1, x_2, s, \Omega) \quad (17a)$$

which has to take into account the  $s$ -dependence of the distribution  $D(x_1, x_2, s)$ . Full simulations of the beam dynamics for each value of  $s$  are too costly and `circe1` [1] supported linear interpolation

$$\bar{D}(x_1, x_2, s) = \frac{(s - s_-)D(x_1, x_2, s_+) + (s_+ - s)D(x_1, x_2, s_-)}{s_+ - s_-} \quad (17b)$$

as an economical compromise. However, since  $\mathcal{O}$  in (17) is a strictly *linear* functional of  $D$ , it is mathematically equivalent to interpolating  $\mathcal{O}$  itself

$$\bar{\mathcal{O}}(s) = \frac{(s - s_-)\tilde{\mathcal{O}}(s, s_+) + (s_+ - s)\tilde{\mathcal{O}}(s, s_-)}{s_+ - s_-} \quad (18a)$$

where

$$\tilde{\mathcal{O}}(s, s_0) = \int dx_1 dx_2 d\Omega D(x_1, x_2, s_0) \frac{d\sigma}{d\Omega}(x_1, x_2, s, \Omega) \mathcal{O}(x_1, x_2, s, \Omega) \quad (18b)$$

Of course, evaluating the two integrals in (18) with comparable accuracy demands four times the calculational effort of the single integral in (17). Therefore, if overwhelming demand arises, support for (17) can be reinstated, but at the price of a considerably more involved API for loading distributions.

## 5 Algorithms

`circe2` attempts to recover a probability density  $w(x_1, x_2)$  from a finite set of triples  $\{(x_{1,i}, x_{2,i}, w_i)\}_{i=1, \dots, N}$  that are known to be distributed according to  $w(x_1, x_2)$ . This recovery should introduce as little bias as possible. The solution should provide a computable form of  $w(x_1, x_2)$  as well as a procedure for generating more sets of triples  $\{(x_{1,i}, x_{2,i}, w_i)\}$  with “the same” distribution.

The discrete distribution

$$\hat{w}(x_1, x_2) = \sum_i w_i \delta(x_1 - x_{1,i}) \delta(x_2 - x_{2,i}) \quad (19)$$

adds no bias, but is obviously not an adequate solution of the problem, because it depends qualitatively on the sample. While the sought after distribution may contain singularities, their number and the dimension of their support must not depend on the sample size. There is, of course, no unique solution to this problem and we must allow some prejudices to enter in order to single out the most adequate solution.

The method employed by `circe1` was to select a family of analytical distributions that are satisfy reasonable criteria suggested by physics [1] and select representatives by fitting the parameters of these distributions. This has been unreasonably successful for modelling the general properties, but must fail eventually if finer details are studied. Enlarging the families is theoretically possible but empirically it turns out that the number of free parameters grows faster than the descriptive power of the families.

Another approach is to forego functions that are defined globally by an analytical expression and to perform interpolation of binned samples, requiring continuity of the distribution and their derivatives. Again, this fails in practice, this time because such interpolations tend to create wild fluctuations for statistically distributed data and the resulting distributions will often violate basic conditions like positivity.

Any attempt to recover the distributions that uses local properties will have to bin the data

$$N_i = \int_{\Delta_i} dx w(x) \quad (20)$$

with

$$\Delta_i \cap \Delta_j = \emptyset \quad (i \neq j), \quad \bigcup_i \Delta_i = [0, 1] \times [0, 1] \quad (21)$$

Therefore it appears to be eminently reasonable to approximate  $w$  by a piecewise constant

$$\hat{w}(x) = \sum_i \frac{N_i}{|\Delta_i|} \Theta(x \in \Delta_i). \quad (22)$$

However, this procedure also introduces a bias and if the number of bins is to remain finite, this bias cannot be removed.

Nevertheless, one can tune this bias to the problem under study and obtain better approximations by making use of the well known fact that probability distributions are not invariant under coordinate transformations, as described in section ?? below.

## 5.1 Histograms

The obvious approach to histogramming is to cover the unit square  $[0, 1] \times [0, 1]$  uniformly with  $n_b^2$  squares, but this approach is not economical in its use of storage. For example, high energy physics studies at a  $\sqrt{s} = 500$  GeV LC will require an energy resolution of better than 1 GeV and we should bin each beam in steps of 500 MeV, i.e.  $n_b = 500$ . This results in a two dimensional histogram of  $500^2 = 25000$  bins for each combination of flavor and helicity. Using non-portable binary storage, this amounts to 100 KB for typical single precision floating point numbers and 200 KB for typical double precision floating point numbers.

Obviously, binary storage is not a useful exchange format and we have to use an ASCII exchange format, which in its human readable form uses 14 bytes for single precision and 22 bytes for double precision and the above estimates have to be changed to 350 KB and 550 KB respectively. We have four flavor combinations if pair creation is ignored and nine flavor combinations if it is taken into account. For each flavor combination there are four helicity combinations and we arrive at 16 or 36 combinations.

Altogether, a fixed bin histogram requires up to 20 MB of data for *each* accelerator design at *each* energy step for a mere 1% energy resolution. While this could be handled with modern hardware, we have to keep in mind that the storage requirements grow quadratically with the resolution and that several generations of designs should be kept available for comparison studies.

For background studies, low energy tails down to the pair production threshold  $m_e = 511$  KeV  $\approx 10^{-6} \cdot \sqrt{s}$  have to be described correctly. Obviously, fixed bin histograms are not an option at all in this case.

 mention 2-D Delauney triangulations here

 mention Stazsek's FOAM [14] here

 praise VEGAS/VAMP

## 5.2 Coordinate Dependence of Sampling Distributions

The contents of this section is well known to all practitioners and is repeated only for establishing notation. For any sufficiently smooth (piecewise differentiable suffices) map

$$\begin{aligned}\phi : D_x &\rightarrow D_y \\ x &\mapsto y = \phi(x)\end{aligned}\tag{23}$$

integrals of distribution functions  $w : D_y \rightarrow \mathbf{R}$  are invariant, as long as we apply the correct Jacobian factor

$$\int_{D_y} dy w(y) = \int_{D_x} dx \frac{d\phi}{dx} \cdot (w \circ \phi)(x) = \int_{D_x} dx w^\phi(x)\tag{24a}$$

where

$$w^\phi(x) = (w \circ \phi)(x) \cdot \frac{d\phi}{dx}(x) = \frac{(w \circ \phi)(x)}{\left(\frac{d\phi^{-1}}{dy} \circ \phi\right)(x)}\tag{24b}$$

The fraction can be thought of as being defined by the product, if the map  $\phi$  is not invertible. Below, we will always deal with invertible maps and the fraction is more suggestive for our purposes. Therefore,  $\phi$  induces a pull-back map  $\phi^*$  on the space of integrable functions

$$\begin{aligned}\phi^* : L_1(D_y, \mathbf{R}) &\rightarrow L_1(D_x, \mathbf{R}) \\ w &\mapsto w^\phi = \frac{w \circ \phi}{\left(\frac{d\phi^{-1}}{dy} \circ \phi\right)}\end{aligned}\tag{25}$$

If we find a map  $\phi_w$  with  $d\phi^{-1}/dy \sim w$ , then sampling the transformed weight  $w^{\phi_w}$  will be very stable, even if sampling the original weight  $w$  is not.

On the other hand, the inverse map

$$\begin{aligned}(\phi^*)^{-1} : L_1(D_x, \mathbf{R}) &\rightarrow L_1(D_y, \mathbf{R}) \\ w &\mapsto w^{(\phi^{-1})} = \left(\frac{d\phi^{-1}}{dy}\right) \cdot (w \circ \phi^{-1})\end{aligned}\tag{26}$$

with  $(\phi^{-1})^* = (\phi^*)^{-1}$  can be used to transform a uniform distribution into the potentially much more interesting  $d\phi^{-1}/dy$ .

## 5.3 Sampling Distributions With Integrable Singularities

A typical example appearing in `circle1`

$$\int_0^1 dx w(x) \approx \int_0^1 dx (1-x)^\beta\tag{27}$$

Figure 2: Distribution with both an integrable singularity  $\propto x^{-0.2}$  and a peak at finite  $x \approx 0.7$ .

converges for  $\beta > -1$ , while the variance

$$\int_0^1 dx (w(x))^2 \approx \int_0^1 dx (1-x)^{2\beta} \quad (28)$$

does not converge for  $\beta \leq -1/2$ . Indeed, this case is the typical case for realistic beamstrahlung spectra at  $e^+e^-$  LCs and has to be covered.

Attempting a naive VEGAS/VAMP adaption fails, because the *nonintegrable* variance density acts as a sink for bins, even though the density itself is integrable.

- examples show that moments of distributions are reproduced *much* better after mapping, even if histograms look indistinguishable.
- biasing doesn't appear to work as well as fences

The distributions that we want to describe can contain integrable singularities and  $\delta$ -distributions at the endpoints. Since there is always a finite resolution, both contributions can be handled by a finite binsize at the endpoints. However, we can expect to improve the convergence of the grid adaption in neighborhoods of the singularities by canceling the singularities with the Jacobian of a power map. Also the description of the distribution *inside* each bin will be improved for reasonable maps.

## 5.4 Piecewise Differentiable Maps

blah, blah, blah

Ansatz:

$$\begin{aligned}\Phi_{\{\phi\}} : [X_0, X_1] &\rightarrow [Y_0, Y_1] \\ x &\mapsto \Phi_{\{\phi\}}(x) = \sum_{i=1}^n \Theta(x_i - x) \Theta(x - x_{i-1}) \phi(x)\end{aligned}\quad (29)$$

with  $x_0 = X_0$ ,  $x_n = X_1$  and  $x_i > x_{i-1}$ . In each interval

$$\begin{aligned}\phi_i : [x_{i-1}, x_i] &\rightarrow [y_{i-1}, y_i] \\ x &\mapsto y = \phi_i(x)\end{aligned}\quad (30)$$

with  $y_0 = Y_0$ ,  $y_n = Y_1$

#### 5.4.1 Powers

 integrable singularities

$$\begin{aligned}\psi_{a_i, b_i}^{\alpha_i, \xi_i, \eta_i} : [x_{i-1}, x_i] &\rightarrow [y_{i-1}, y_i] \\ x &\mapsto \psi_{a_i, b_i}^{\alpha_i, \xi_i, \eta_i}(x) = \frac{1}{b_i} (a_i(x - \xi_i))^{\alpha_i} + \eta_i\end{aligned}\quad (31)$$

We assume  $\alpha_i \neq 0$ ,  $a_i \neq 0$  and  $b_i \neq 0$ . Note that  $\psi_{a,b}^{\alpha,\xi,\eta}$  encompasses both typical cases for integrable endpoint singularities  $x \in [0, 1]$ :

$$\psi_{1,1}^{\alpha,0,0}(x) = x^\alpha \quad (32a)$$

$$\psi_{-1,-1}^{\alpha,1,1}(x) = 1 - (1 - x)^\alpha \quad (32b)$$

The inverse maps are

$$\begin{aligned}(\psi_{a_i, b_i}^{\alpha_i, \xi_i, \eta_i})^{-1} : [y_{i-1}, y_i] &\rightarrow [x_{i-1}, x_i] \\ y &\mapsto (\psi_{a_i, b_i}^{\alpha_i, \xi_i, \eta_i})^{-1}(y) = \frac{1}{a_i} (b_i(y - \eta_i))^{1/\alpha_i} + \xi_i\end{aligned}\quad (33)$$

and incidentally:

$$(\psi_{a,b}^{\alpha,\xi,\eta})^{-1} = \psi_{b,a}^{1/\alpha,\eta,\xi} \quad (34)$$

The Jacobians are

$$\frac{dy}{dx}(x) = \frac{a\alpha}{b} (a(x - \xi))^{\alpha-1} \quad (35a)$$

$$\frac{dx}{dy}(y) = \frac{b}{a\alpha} (b(y - \eta))^{1/\alpha-1} \quad (35b)$$

and satisfy, of course,

$$\frac{dx}{dy}(y(x)) = \frac{1}{\frac{dy}{dx}(x)} \quad (36)$$

In order to get a strictly monotonous function, we require

$$\frac{a\alpha}{b} > 0 \quad (37)$$

Since we will see below that almost always in practical applications  $\alpha > 0$ , this means  $\epsilon(a) = \epsilon(b)$ .

From (25) and (35b), we see that this map is useful for handling weights<sup>2</sup>

$$w(y) \propto (y - \eta)^\beta \quad (38)$$

for  $\beta > -1$ , if we choose  $\beta - (1/\alpha - 1) \geq 0$ , i. e.  $\alpha \gtrsim 1/(1 + \beta)$ .

The five parameters  $(\alpha, \xi, \eta, a, b)$  are partially redundant. Indeed, there is a one parameter semigroup of transformations

$$(\alpha, \xi, \eta, a, b) \rightarrow (\alpha, \xi, \eta, at, bt^\alpha), \quad (t > 0) \quad (39)$$

that leaves  $\psi_{a,b}^{\alpha,\xi,\eta}$  invariant:

$$\psi_{a,b}^{\alpha,\xi,\eta} = \psi_{at,bt^\alpha}^{\alpha,\xi,\eta} \quad (40)$$

Assuming that multiplications are more efficient than sign transfers, the redundant representation is advantageous. Unless sign transfers are implemented directly in hardware, they involve a branch in the code and the assumption appears to be reasonable.

### 5.4.2 Identity

The identity map

$$\begin{aligned} \iota : [x_{i-1}, x_i] &\rightarrow [y_{i-1}, y_i] = [x_{i-1}, x_i] \\ x &\mapsto \iota(x) = x \end{aligned} \quad (41)$$

is a special case of the power map  $\iota = \psi_{1,1}^{1,0,0}$ , but, for efficiency, it is useful to provide a dedicated “implementation” anyway.

---

<sup>2</sup>The limiting case  $(y - \eta)^{-1}$  could be covered by maps  $x \mapsto e^{a(x-\xi)}/b + \eta$ , where the non-integrability of the density is reflected in the fact that the domain of the map is semi-infinite (i. e.  $x \rightarrow -\epsilon(a) \cdot \infty$ ). In physical applications, the densities are usually integrable and we do not consider this case in the following.

### 5.4.3 Resonances

- not really needed in the applications so far, because the variance remains integrable.
- no clear example for significantly reduced numbers of bins for the same quality with mapping.
- added for illustration.

$$\begin{aligned} \rho_{a_i, b_i}^{\xi_i, \eta_i} : [x_{i-1}, x_i] &\rightarrow [y_{i-1}, y_i] \\ x &\mapsto \rho_{a_i, b_i}^{\xi_i, \eta_i}(x) = a_i \tan \left( \frac{a_i}{b_i^2} (x - \xi_i) \right) + \eta_i \end{aligned} \quad (42)$$

Inverse

$$\begin{aligned} (\rho_{a_i, b_i}^{\xi_i, \eta_i})^{-1} : [y_{i-1}, y_i] &\rightarrow [x_{i-1}, x_i] \\ y &\mapsto (\rho_{a_i, b_i}^{\xi_i, \eta_i})^{-1}(y) = \frac{b_i^2}{a_i} \operatorname{atan} \left( \frac{y - \eta_i}{a_i} \right) + \xi_i \end{aligned} \quad (43)$$

is useful for mapping *known* peaks, since

$$\frac{d\phi^{-1}}{dy}(y) = \frac{dx}{dy}(y) = \frac{b^2}{(y - \eta)^2 + a^2} \quad (44)$$

### 5.4.4 Patching Up

Given a collection of intervals with associated maps, it remains to construct a combined map. Since *any* two intervals can be mapped onto each other by a map with constant Jacobian, we have a “gauge” freedom and must treat  $x_{i-1}$  and  $x_i$  as free parameters in

$$\psi_{a_i, b_i}^{\alpha_i, \xi_i, \eta_i} : [x_{i-1}, x_i] \rightarrow [y_{i-1}, y_i] \quad (45)$$

i. e.

$$x_j = (\psi_{a_i, b_i}^{\alpha_i, \xi_i, \eta_i})^{-1}(y_j) = \frac{1}{a_i} (b_i(y_j - \eta_i))^{1/\alpha_i} + \xi_i \quad \text{for } j \in \{i-1, i\} \quad (46)$$

Since  $\alpha$  and  $\eta$  denote the strength and the location of the singularity, respectively, they are the relevant input parameters and we must solve the constraints (46) for  $\xi_i$ ,  $a_i$  and  $b_i$ . Indeed a family of solutions is

$$a_i = \frac{(b_i(y_i - \eta_i))^{1/\alpha_i} - (b_i(y_{i-1} - \eta_i))^{1/\alpha_i}}{x_i - x_{i-1}} \quad (47a)$$

$$\xi_i = \frac{x_{i-1}|y_i - \eta_i|^{1/\alpha_i} - x_i|y_{i-1} - \eta_i|^{1/\alpha_i}}{|y_i - \eta_i|^{1/\alpha_i} - |y_{i-1} - \eta_i|^{1/\alpha_i}} \quad (47b)$$

which is unique up to (39). The degeneracy (39) can finally be resolved by demanding  $|b| = 1$  in (47a).

It remains to perform a ‘gauge fixing’ and choose the domains  $[x_{i-1}, x_i]$ . The minimal solution is  $x_i = y_i$  for all  $i$ , which maps the boundaries between different mappings onto themselves and we need only to store either  $\{x_0, x_1, \dots, x_n\}$  or  $\{y_0, y_1, \dots, y_n\}$ .

For the resonance map

$$x_j = (\rho_{a_i, b_i}^{\xi_i, \eta_i})^{-1}(y_j) = \frac{b_i^2}{a_i} \operatorname{atan} \left( \frac{y_j - \eta_i}{a_i} \right) + \xi_i \quad \text{for } j \in \{i-1, i\} \quad (48)$$

i. e.

$$b_i = \sqrt{a_i \frac{x_i - x_{i-1}}{\operatorname{atan} \left( \frac{y_i - \eta_i}{a_i} \right) - \operatorname{atan} \left( \frac{y_{i-1} - \eta_i}{a_i} \right)}} \quad (49a)$$

$$\xi_i = \frac{x_{i-1} \operatorname{atan} \left( \frac{y_i - \eta_i}{a_i} \right) - x_i \operatorname{atan} \left( \frac{y_{i-1} - \eta_i}{a_i} \right)}{x_i - x_{i-1}} \quad (49b)$$

as a function of the physical peak location  $\eta$  and width  $a$ .

## 6 Preparing Beam Descriptions with circe2\_tool

 rationale

### 6.1 circe2\_tool Files

 { and }

#### 6.1.1 Per File Options

**file:** a double quote delimited string denoting the name of the output file that will be read by `cir2ld` (in the format described in table 2).

#### 6.1.2 Per Design Options

**design:** a double quote delimited string denoting a name for the design. See the description of `cir2ld` on page 10 for conventions for these names.

**roots:**  $\sqrt{s}$ /GeV of the accelerator design.

**bins:** number of bins for the histograms in both directions. **bins/1** and **bins/2** apply only to  $x_1$  and  $x_2$  respectively. This number can be overwritten by channel options.

**comment:** a double quote delimited string denoting a one line comment that will be copied to the output file. This command can be repeated.

### 6.1.3 Per Channel Options

If an option can apply to either beam or both, it can be qualified by /1 or /2. For example, **bins** applies to both beams, while **bins/1** and **bins/2** apply only to  $x_1$  and  $x_2$  respectively.

**bins:** number of bins for the histograms. These overwrite the per-design option.

**pid:** particle identification: either a PDG code [11] (see page 3) or one of **gamma**, **photon**, **electron**, **positron**.

**pol:** polarization: one of  $\{-1, 0, 1\}$ , where 0 means unpolarized (see page 3).

**min:** minimum value of the coordinate(s). The default is 0.

**max:** maximum value of the coordinate(s). The default is 1.

**fix**

**free**

**map:** apply a map to a subinterval. Currently, three types of maps are supported:

**id** {  $n$  [ $x_{\min}, x_{\max}$ ] }: apply an identity map in the interval [ $x_{\min}, x_{\max}$ ] subdivided into  $n$  bins. The non-trivial effect of this map is that the endpoints  $x_{\min}$  and  $x_{\max}$  are frozen.

**power** {  $n$  [ $x_{\min}, x_{\max}$ ] **beta** =  $\beta$  **eta** =  $\eta$  }: apply a power map in the interval [ $x_{\min}, x_{\max}$ ] subdivided into  $n$  bins.  $\alpha = 1/(1 + \beta)$ , such that an integrable singularity at  $\eta$  with power  $\beta$  is mapped away. This is the most important

map in practical applications and manual fine tuning is rewarded.

**resonance** {  $n$  [ $x_{\min}, x_{\max}$ ] **center** =  $\eta$  **width** =  $a$  }: apply a resonance map in the interval [ $x_{\min}, x_{\max}$ ] subdivided into  $n$  bins. This map is hardly ever needed, since VEGAS/VAMP appears to be able to handle non-singular peaks very well.

**triangle**

**notriangle**

**lumi**: luminosity of the beam design, in units of

$$\text{fb}^{-1} \nu^{-1} = 10^{32} \text{cm}^{-2} \text{sec}^{-1} \quad (50)$$

where  $\nu = 10^7 \text{sec} \approx \text{year}/\pi$  is an “effective year” of running with about 30% up-time

**events**: a double quote delimited string denoting the name of the input file.

**ascii**: input file contains formatted ASCII numbers.

**binary**: input file is in raw binary format that can be accessed by fast memory mapped I/O. Such files are not portable and must not contain Fortran record markers.

**columns**: number of columns in a binary file.

**iterations**: maximum number of iterations of the VEGAS/VAMP refinement. It is not necessary to set this parameter, but e.g. **iterations** = 0 is useful for illustrating the effect of adaption.

## 6.2 circe2\_tool Demonstration

We can use the example of figure 1 (a simulated realistic  $\gamma\gamma$  luminosity spectrum (helicities: (+, +)) for a 500 GeV photon collider at TESLA [7]) to demonstrate the effects of different options. In order to amplify the effects, only 20 bins are used in each direction, but figure 8 will show that adequate results are achievable in this case too.

In figure 3, 20 equidistant bins in each direction

**bins** = 20 **iterations** = 0

Figure 3: Using 20 equidistant bins in each direction. In the region blown up on the right neither 20 equidistant bins nor 50 equidistant bin produce enough events to be visible. In this and all following plots, the simulated input data is shown as a filled histogram, and the `circe2` parametrization is shown as a solid line.

Figure 4: Using 20 bins, both equidistant (left) and adapted (right).

produce an acceptable description of the high energy peak but are clearly inadequate for  $z < 0.2$ . In the blown up region, neither 20 equidistant bins nor 50 equidistant bin produce more than a handful of events and remain almost invisible. The bad low energy behaviour can be understood from the convolution of the obviously coarse approximations in left figure of figure 4. Letting the grid adapt

Figure 5: 20 adapted bins. In the blow-up, the 50 bin result is shown for illustration as a thin line, while the 20 bin result remains almost invisible.

Figure 6: Using 20 equidistant bins in each direction with a power map appropriate for  $x^{-0.67}$ .

`bins = 20`

produces a much better approximation in the right figure of figure 4. And indeed, the convolution in figure 5 is significantly improved for  $x \lesssim 0.2$ , but remains completely inadequate in the very low energy region, blown up on the right hand side.

A better description of the low energy tail requires a power map and figure 6 shows that equidistant bins

Figure 7: Using 20 bins with a power map appropriate for  $x^{-0.67}$ , equidistant (left) and adapted (right).

Figure 8: Using 20 adapted bins in each direction with a power map appropriate for  $x^{-0.67}$ .

```
map = power { 20 [0,1] beta = -0.67 eta = 0 } iterations = 0
```

already produce a much improved description of the low energy region, including the blow-up on the right hand side. However, the description of the peak has gotten much worse, which is explained by the coarsening of the bins in the high energy region, as shown in figure 7. The best result is obtained by combining a power map with adaption

```
map = power { 20 [0,1] beta = -0.67 eta = 0 }
```

Figure 9: Using 4 + 16 adapted bins in each direction with a power map appropriate for  $x^{-0.67}$  in the 4 bins below  $x < 0.05$ .

with the results depicted in figure 8. Balancing the number of bins used for a neighborhood of the integrable singularity at  $x_i \rightarrow 0$  and the remainder can be improved by allocating a fixed number of bins for each

```
map = power { 4 [0,0.05] beta = -0.67 eta = 0 }
map = id { 16 [0.05,1] }
```

as shown in figure 9. If the data were not stochastic, this manual allocation would not be necessary, because the neighborhood of the singularity would not contribute to the variance and consequently use few bins. However, the stochastic variance cannot be suppressed and will pull in more bins than useful. If the power of the map were overcompensating the power of the singularity, instead of being tuned to it, the limit  $x_i \rightarrow 0$  would be suppressed automatically. But in this case, the low-energy tail could not be described accurately.

The description with 20 bins in figure 9 is not as precise as the 50 bins

```
map = power { 10 [0,0.05] beta = -0.67 eta = 0 }
map = id { 40 [0.05,1] }
```

in figure 1, but can suffice for many studies and requires less than one sixth of the storage space.

### 6.3 More circe2\_tool Examples

Here is an example that can be used to demonstrate the beneficial effects of powermaps. The simulated events in `teslagg-500.gg.++.events` are

processed once with map and once without a map. Both times 50 bins are used in each direction.

```
{ file = "test_mappings.circe"
  { design = "TESLA" roots = 500
    { pid/1 = 22 pid/2 = 11 pol/1 = 1 pol/2 = 1
      events = "teslagg_500.gg.++.events" binary lumi = 110.719
      bins/1 = 50
      map/2 = id { 49 [0,0.9999999999] }
      map/2 = id { 1 [0.9999999999,1] } } }
  { design = "TESLA (mapped)" roots = 500
    { pid/1 = 22 pid/2 = 11 pol/1 = 1 pol/2 = 1
      events = "teslagg_500.gg.++.events" binary lumi = 110.719
      map/1 = power { 50 [0,1] beta = -0.67 eta = 0 }
      map/2 = power { 49 [0,0.9999999999] beta = -0.6 eta = 1 }
      map/2 = id { 1 [0.9999999999,1] } } } }
```

In a second step, the distributions generated from both designs in `test_mappings.circe` can be compared with the original distribution.

## 7 On the Implementation of `circe2_tool`

### 7.1 Divisions

 VEGAS/VAMP, basically ...

### 7.2 Differentiable Maps

### 7.3 Polydivisions

 patched divisions ...

### 7.4 Grids

## 8 The Next Generation

Future generations can try to implement the following features:

<i>! any comment</i>	optional, repeatable
CIRCE2 FORMAT#1	mandatory start line
design, roots	
'name' $\sqrt{s}$	mandatory quotes!
#channels, pol.support	
$n_c$ 'name'	mandatory quotes!
pid1, pol1, pid2, pol2, lumi	] repeat $n_c$ times
$p_1 h_1 p_2 h_2 \int \mathcal{L}$	
#bins1, #bins2, triangle?	
$n_1 n_2 t$	
x1, map1, alpha1, xi1, eta1, a1, b1	
$x_{1,0}$	
$x_{1,1} m_{1,1} \alpha_{1,1} \xi_{1,1} \eta_{1,1} a_{1,1} b_{1,1}$	
...	
$x_{1,n_1} m_{1,n_1} \alpha_{1,n_1} \xi_{1,n_1} \eta_{1,n_1} a_{1,n_1} b_{1,n_1}$	
x2, map2, alpha2, xi2, eta2, a2, b2	
$x_{2,0}$	
$x_{2,1} m_{2,1} \alpha_{2,1} \xi_{2,1} \eta_{2,1} a_{2,1} b_{2,1}$	
...	
$x_{2,n_2} m_{2,n_2} \alpha_{2,n_2} \xi_{2,n_2} \eta_{2,n_2} a_{2,n_2} b_{2,n_2}$	
weights	
$w_1 [w_1 \chi_1^{0,1} w_1 \chi_1^{0,2} \dots w_1 \chi_1^{3,3}]$	optional $w \cdot \chi$
$w_2 [w_1 \chi_2^{0,1} w_1 \chi_2^{0,2} \dots w_1 \chi_2^{3,3}]$	
...	
$w_{n_1 n_2} [w_1 \chi_{n_1 n_2}^{0,1} w_1 \chi_{n_1 n_2}^{0,2} \dots w_1 \chi_{n_1 n_2}^{3,3}]$	] end repeat
ECRIC2	
	mandatory end line

Table 2: File format. The variable input lines (except comments) are designed to be readable by FORTRAN77 ‘list-directed’ input. The files are generated from simulation data with the program `circe2_tool` and are read transparently by the procedure `cir2ld`. The format is documented here only for completeness.

```

module type Division =
  sig
    type t
    val copy : t -> t
    val record : t -> float -> float -> unit
    val rebin : ?power:float -> t -> t
    val find : t -> float -> int
    val bins : t -> float array
    val to_channel : out_channel -> t -> unit
  end

```

Figure 10: O’Caml signature for divisions. `Division.t` is the abstract data type for division of a real interval. Note that `Division` does *not* contain a function `create : ... -> t` for constructing maps. This is provided by concrete implementations (see figures 11 and 14), that can be projected on `Diffmap`

```

module type Mono_Division =
  sig
    include Division
    val create : int -> float -> float -> t
  end

```

Figure 11: O’Caml signature for simple divisions of an interval. The `create` function returns an equidistant starting division.

## 8.1 Variable # of Bins

One can monitor the total variance in each interval of the polydivisions and move bins from smooth intervals to wildly varying intervals, keeping the total number of bins constant.

## 8.2 Adapting Maps Per-Cell

If there is enough statistics, one can adapt the mapping class and parameters per bin.

There’s a nice duality between adapting bins for a constant mapping on one side and adapting mappings for constant bins. Can one merge the two approaches.

```

module type Diffmap =
  sig
    type t
    type domain
    val x_min : t -> domain
    val x_max : t -> domain
    type codomain
    val y_min : t -> codomain
    val y_max : t -> codomain
    val phi : t -> domain -> codomain
    val ihp : t -> codomain -> domain
    val jac : t -> domain -> float
    val caj : t -> codomain -> float
  end

module type Real_Diffmap =
  T with type domain = float and type codomain = float

```

Figure 12: O’Caml signature for differentiable maps. `Diffmap.t` is the abstract data type for differentiable maps. Note that `Diffmap` does *not* contain a functions like `create : ... -> t` for constructing maps. These are provided by concrete implementations, that can be projected onto `Diffmap`.

```

module type Real_Diffmaps =
  sig
    include Real_Diffmap
    val id : float -> float -> t
  end

```

Figure 13: Collections of real differentiable maps, including at least the identity. The function `id` returns an identity map from a real interval onto itself.

### 8.3 Non-Factorized Polygrids

One could think of a non-factorized distribution of mappings.

```

module type Poly_Division =
  sig
    include Division
    module M : Real_Diffmaps
    val create :
      (int * M.t) list -> int -> float -> float -> t
  end

module Make_Poly_Division (M : Real_Diffmaps) :
  Poly_Division with module Diffmaps = M

```

Figure 14: O’Caml signature for divisions of an interval, with piecewise differentiable mappings, as specified by the first argument of `create`. The functor `Make_Poly_Division` ...

```

module type Grid =
  sig
    module D : Division
    type t
    val create : D.t -> D.t -> t
    val copy : t -> t
    val record : t -> float -> float -> float -> unit
    val rebin : ?power:float -> t -> t
    val variance : t -> float
    val to_channel : out_channel -> t -> unit
  end

module Make_Grid (D : Division) : Grid with module D = D

```

Figure 15: O’Caml signature for grids. The functor `Make_Grid` can be applied to *any* module of type `Division`, in particular both `Mono_Division` and `Poly_Division`.

## 9 Conclusions

### Acknowledgements

end type circe2\_state  
public :: circe2\_state

We store the probability distribution function as a one-dimensional array `wgt`<sup>3</sup>, since this simplifies the binary search used for inverting the distribution. `[wgt(0,ic)]` is always 0 and serves as a convenient sentinel for the binary search. It is *not* written in the file, which contains the normalized weight of the bins.

46d  $\langle$ circe2\_state members 46d $\rangle \equiv$   
type(circe2\_channel), dimension(:), allocatable :: ch

46e  $\langle$ circe2\_channel members 46e $\rangle \equiv$

46f  $\langle$ circe2\_channel members 46e $\rangle + \equiv$   
type(circe2\_division), dimension(2) :: d

Using figure 16, calculating the index of a bin from the two-dimensional coordinates is straightforward, of course:

$$i = i_1 + (i_2 - 1)n_1. \quad (51)$$

The inverse

$$i_1 = 1 + ((i - 1) \bmod n_1) \quad (52a)$$

---

<sup>3</sup>The second “dimension” is just an index for the channel.

$x_3^{\max}$					
$i_2 = n_2$	$n_1(n_2 - 1) + 1$	$n_1(n_2 - 1) + 2$	$\dots$	$n_1 n_2 - 1$	$n_1 n_2$
$\dots$	$\dots$	$\dots$	$\dots$	$\dots$	$n_1(n_2 - 1)$
3	$2n_1 + 1$	$\dots$	$\dots$	$\dots$	$\dots$
2	$n_1 + 1$	$n_1 + 2$	$\dots$	$\dots$	$2n_1$
1	1	2	3	$\dots$	$n_1$
$x_2^{\min}$					
	$x_1^{\min} \quad i_1 = 1$	2	3	$\dots$	$n_1 \quad x_1^{\max}$

Figure 16: Enumerating the bins linearly, starting from 1 (Fortran style). Probability distribution functions will have a sentinel at 0 that's always 0.

$$i_2 = 1 + \lfloor (i - 1)/n_1 \rfloor \quad (52b)$$

can also be written

$$i_2 = 1 + \lfloor (i - 1)/n_1 \rfloor \quad (53a)$$

$$i_1 = i - (i_2 - 1)n_1 \quad (53b)$$

because

$$\begin{aligned} 1 + \lfloor (i - 1)/n_1 \rfloor &= 1 + \lfloor i_2 - 1 + (i_1 - 1)/n_1 \rfloor \\ &= 1 + \lfloor (i_1 + (i_2 - 1)n_1 - 1)/n_1 \rfloor = 1 + i_2 - 1 + \underbrace{\lfloor (i_1 - 1)/n_1 \rfloor}_{=0} = i_2 \end{aligned} \quad (54a)$$

and trivially

$$i - (i_2 - 1)n_1 = i_1 + (i_2 - 1)n_1 - (i_2 - 1)n_1 = i_1 \quad (54b)$$

47a  $\langle (i_1, i_2) \leftarrow i \text{ 47a} \rangle \equiv$   
 $i_2 = 1 + (i - 1) / \text{ubound}(\text{ch\%d(1)\%x}, \text{dim}=1)$   
 $i_1 = i - (i_2 - 1) * \text{ubound}(\text{ch\%d(1)\%x}, \text{dim}=1)$

47b  $\langle i_b \leftarrow i \text{ 47b} \rangle \equiv$   
 $i_b(2) = 1 + (i - 1) / \text{ubound}(\text{ch\%d(1)\%x}, \text{dim}=1)$   
 $i_b(1) = i - (i_b(2) - 1) * \text{ubound}(\text{ch\%d(1)\%x}, \text{dim}=1)$

Figure 17: Almost factorizable distributions, like  $e^+e^-$ .

The density normalized to the bin size

$$v = \frac{w}{\Delta x_1 \Delta x_2}$$

such that

$$\int dx_1 dx_2 v = \sum w = 1$$

For mapped distributions, on the level of bins, we can either use the area of the domain and apply a jacobian or the area of the codomain directly

$$\frac{dx}{dy} \cdot \frac{1}{\Delta x} \approx \frac{1}{\Delta y} \quad (55)$$

We elect to use the former, because this reflects the distribution of the events generated by `circe2_generate` *inside* the bins as well. This quantity is more conveniently stored as a true two-dimensional array:

```

48a  <circe2_channel members 46e>+≡
      real(kind=default), dimension(:,,:), allocatable :: val

48b  <circe2_division members 48b>≡
      real(kind=default), dimension(:), allocatable :: x

48c  <circe2_channel members 46e>+≡
      logical :: triang
```

Figure 18: Symmetrical, strongly correlated distributions, e.g. with a ridge on the diagonal, like  $\gamma\gamma$  at a  $\gamma$ -collider.

## 11.1 Channels

The number of available channels  $\gamma\gamma$ ,  $e^- \gamma$ ,  $e^- e^+$ , etc. can be found with `size (circe2_state%ch)`. The particles that are described by this channel and their polarizations:

49a `<circe2_channel members 46e>+≡`  
`integer, dimension(2) :: pid, pol`

The integrated luminosity of the channel

49b `<circe2_channel members 46e>+≡`  
`real(kind=default) :: lumi`

The integrated luminosity of the channel

49c `<circe2_state members 46d>+≡`  
`real(kind=default), dimension(:), allocatable :: cwgt`

## 11.2 Maps

49d `<circe2_division members 48b>+≡`  
`integer, dimension(:), allocatable :: map`

49e `<circe2_division members 48b>+≡`  
`real(kind=default), dimension(:), allocatable :: y`

49f `<circe2_division members 48b>+≡`  
`real(kind=default), dimension(:), allocatable :: alpha, xi, eta, a, b`

## 12 Random Number Generation

We use the new WHIZARD interface.

```
50a <circe2 declarations 46a>+≡
    public :: rng_type
    type, abstract :: rng_type
    contains
        procedure(rng_generate), deferred :: generate
    end type rng_type

50b <circe2 declarations 46a>+≡
    abstract interface
        subroutine rng_generate (rng_obj, u)
            import :: rng_type, default
            class(rng_type), intent(inout) :: rng_obj
            real(kind=default), intent(out) :: u
        end subroutine rng_generate
    end interface
```

## 13 Event Generation

Generate a two-dimensional distribution for (x1,x2) according to the histogram for channel ic.

```
50c <circe2 declarations 46a>+≡
    public :: circe2_generate
    interface circe2_generate
        module procedure circe2_generate
    end interface circe2_generate

50d <circe2 implementation 50d>≡

```

call rng%generate (u)
if (2*u >= 1) then
  tmp = y(1)
  y(1) = y(2)
  y(2) = tmp
end if

```

## 14 Channel selection

We could call `circe2_generate` immediately, but then `circe2_generate` and `cir2_choose_channel` would have the same calling conventions and might have caused a lot of confusion.

54b *<circe2 declarations 46a>*+≡

```

public :: circe2_choose_channel
interface circe2_choose_channel
  module procedure circe2_choose_channel
end interface circe2_choose_channel

```

54c *<circe2 implementation 50d>*+≡

```

subroutine circe2_choose_channel (c2s, rng, p, h)
  type(circe2_state), intent(in) :: c2s
  class(rng_type), intent(inout) :: rng
  integer, dimension(:), intent(out) :: p, h
  integer :: ic, ibot, itop
  real(kind=default) :: u
  call rng%generate (u)
  ibot = 0
  itop = size (c2s%ch)
  do
    if (itop <= ibot + 1) then
      ic = ibot + 1
      p = c2s%ch(ic)%pid
      h = c2s%ch(ic)%pol
      return
    else
      ic = (ibot + itop) / 2
      if (u < c2s%cwgt(ic)) then

```

```

        itop = ic
    else
        ibot = ic
    end if
end if
end do
write (*, '(A)') 'circe2: internal error'
stop
end subroutine circe2_choose_channel

```

Below, we will always have  $h = 0$ . but we don't have to check this explicitly, because `circe2_density_matrix` will do it anyway. The procedure could be made more efficient, since most of `circe2_density_matrix` is undoing parts of `circe2_generate`.

```

55a  <circe2 declarations 46a>+≡
    public :: circe2_generate_polarized
    interface circe2_generate_polarized
        module procedure circe2_generate_polarized

        end do
    end do

```

The boundaries are guaranteed to be fixed points of the maps only if the boundaries are not allowed to float. This doesn't affect the unweighted events, because they never see the codomain grid, but distribution would be distorted significantly. In the following sums *i1* and *i2* run over the maps, while *i* runs over the boundaries.

An alternative would be to introduce sentinels `alpha(1,0,:)`, `xi(1,0,:)`, etc.

```
63a  <Calculate y 63a>≡

## 18 Tests and Examples

```

65b  <sample.f90 65b>≡
      ! sample.f90 -- testing circe2
      <Copyleft notice 45e>
      <Separator 45d>
      program sample
        <implicit none 45b>
        external circe2_distribution
        real(kind=default) :: circe2_distribution
        integer :: i, n, ierror
        integer, dimension(2) :: p, h
        character(len=256) :: file, design, mode
        real(kind=default) :: roots, x1, x2, w
        read *, file, design, roots, p(1), h(1), p(2), h(2), mode, n
        ierror = 0
        call circe2_load (file, design, roots, ierror)
        if (ierror /= 0) then
          print *, 'sample: circe2_load failed!'
          stop
        end if
        if (mode(1:1) == 'w' .or. mode(1:1) == 'W') then
          <Generate n weighted events 66a>
        else
          <Generate n unweighted events 65c>
        end if
      end program sample
      <Separator 45d>
      <Sample procedures 66c>
      <Separator 45d>

```

Generation of unweighted events is  $K\ell\rho\kappa\eta$ 's home turf

```

65c  <Generate n unweighted events 65c>≡
      do i = 1, n
        call circe2_generate (p, [x1, x2], h)
        call write3 (x1, x2, 1d0)
      end do

```

while generation of weighted events without any importance sampling is slightly abusive and only useful for checking `circe2_distribution`.

```
66a  <Generate n weighted events 66a>≡
      do i = 1, n
        call random (x1)
        call random (x2)
        w = circe2_distribution (p, [x1, x2], h)
        print *, x, y, w
      end do
```

The following bare bones random number generator produces some correlations that have been observed in testing `circe2`

```
66b  <Unused sample procedures 66b>≡
      subroutine random (r)
        real(kind=default) :: r
        integer, parameter :: M = 259200, A = 7141, C = 54773
        integer, save :: n = 0
        n = mod (n*A + C, M)
        r = dble (n) / dble (M)
      end subroutine random
```

therefore, it makes sense to call a more sophisticated one:

```
66c  <Sample procedures 66c>≡
      subroutine random (u)
        real(kind=default) :: u
        call taornu (u)
      end subroutine random
```

## 19 Listing File Contents

Here's a small utility program for listing the contents of `circe2` data files. It performs *no* verification and assumes that the file is in the correct format (cf. table 2).

```
66d  <circe2_ls.f90 66d>≡
      ! circe2_ls.f90 -- beam spectra for linear colliders and photon colliders
      <Copyleft notice 45e>

```

## B $\beta$ -distributions

We need a fast generator of  $\beta$ -distributions:

$$\beta_{x_{\min}, x_{\max}}^{a,b}(x) = x^{a-1}(1-x)^{b-1} \cdot \frac{\Theta(x_{\max} - x)\Theta(x - x_{\min})}{I(x_{\min}, a, b) - I(x_{\max}, a, b)} \quad (59)$$

with the *incomplete Beta-function*  $I$ :

$$I(x, a, b) = \int_x^1 d\xi \xi^{a-1}(1-\xi)^{b-1} \quad (60)$$

$$I(0, a, b) = B(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)} \quad (61)$$

This problem has been studied extensively [?] and we can use an algorithm [1] that is very fast for  $0 < a \leq 1 \leq b$ , which turns out to be the case in our application.

```

69b  <circe2_moments_library declarations 69b>≡
      public :: generate_beta

69c  <circe2_moments_library implementation 69c>≡
      subroutine generate_beta (rng, x, xmin, xmax, a, b)
        class(rng_type), intent(inout) :: rng
        real(kind=default), intent(out) :: x
        real(kind=default), intent(in) :: xmin, xmax, a, b
        real(kind=default) :: t, p, u, umin, umax, w
        <Check a and b 70a>
        <Set up generate_beta parameters 70b>
        do
          <Generate a trial x and calculate its weight w 70c>
          call rng%generate (u)
          if (w > u) exit
        end do
      end subroutine generate_beta

```

In fact, this algorithm works for  $0 < a \leq 1 \leq b$  only:

```
70a  <Check a and b 70a>≡
      if (a >= 1 .or. b <= 1) then
        x = -1
        print *, 'ERROR: beta-distribution expects a<1<b'
        return
      end if
```

The trick is to split the interval  $[0, 1]$  into two parts  $[0, t]$  and  $[t, 1]$ . In these intervals we obviously have

$$x^{a-1}(1-x)^{b-1} \leq \begin{cases} x^{a-1} & \text{for } x \leq t \\ t^{a-1}(1-x)^{b-1} & \text{for } x \geq t \end{cases} \quad (62)$$

because we have assumed that  $0 < a < 1 < b$ . The integrals of the two dominating distributions are  $t^a/a$  and  $t^{a-1}(1-t)^b/b$  respectively and therefore the probability for picking a random number from the first interval is

$$P(x \leq t) = \frac{bt}{bt + a(1-t)^b} \quad (63)$$

We postpone the discussion of the choice of  $t$  until later:

```
70b  <Set up generate_beta parameters 70b>≡
      <Set up best value for t 72b>
      p = b*t / (b*t + a * (1 - t)**b)
```

The dominating distributions can be generated by simple mappings

$$\phi : [0, 1] \rightarrow [0, 1] \quad (64)$$

$$u \mapsto \begin{cases} t \left(\frac{u}{p}\right)^{\frac{1}{a}} & < t \text{ for } u < p \\ t & = t \text{ for } u = p \\ 1 - (1-t) \left(\frac{1-u}{1-p}\right)^{\frac{1}{b}} & > t \text{ for } u > p \end{cases} \quad (65)$$

The beauty of the algorithm is that we can use a single uniform deviate  $u$  for both intervals:

```
70c  <Generate a trial x and calculate its weight w 70c>≡
      call rng%generate (u)
      u = umin + (umax - umin) * u
      if (u <= p) then
        x = t * (u/p)**(1/a)
        w = (1 - x)**(b-1)
      else
        x = 1 - (1 - t) * ((1 - u)/(1 - p))**(1/b)
        w = (x/t)**(a-1)
      end if
```

The weights that are derived by dividing the distribution by the dominating distributions are already normalized correctly:

$$w : [0, 1] \rightarrow [0, 1] \quad (66)$$

$$x \mapsto \begin{cases} (1-x)^{b-1} & \in [(1-t)^{b-1}, 1] \text{ for } x \leq t \\ \left(\frac{x}{t}\right)^{a-1} & \in [t^{1-a}, 1] \text{ for } x \geq t \end{cases} \quad (67)$$

To derive  $u_{\min, \max}$  from  $x_{\min, \max}$  we can use  $\phi^{-1}$ :

$$\phi^{-1} : [0, 1] \rightarrow [0, 1] \quad (68)$$

$$x \mapsto \begin{cases} p \left(\frac{x}{t}\right)^a & < p \text{ for } x < t \\ p & = p \text{ for } x = t \\ 1 - (1-p) \left(\frac{1-x}{1-t}\right)^b & > p \text{ for } x > t \end{cases} \quad (69)$$

We start with  $u_{\min}$ . For efficiency, we handle the most common cases (small  $x_{\min}$ ) first:

```
71a  <Set up generate_beta parameters 70b>+≡
      if (xmin <= 0) then
        umin = 0
      elseif (xmin < t) then
        umin = p * (xmin/t)**a
      elseif (xmin == t) then
        umin = p
      elseif (xmin < 1) then
        umin = 1 - (1 - p) * ((1 - xmin)/(1 - t))**b
      else
        umin = 1
      endif
```

Same procedure for  $u_{\max}$ ; again, handle the most common cases (large  $x_{\max}$ ) first:

```
71b  <Set up generate_beta parameters 70b>+≡
      if (xmax >= 1) then
        umax = 1
      elseif (xmax > t) then
        umax = 1 - (1 - p) * ((1 - xmax)/(1 - t))**b
      elseif (xmax == t) then
        umax = p
      elseif (xmax > 0) then
        umax = p * (xmax/t)**a
      else
        umax = 0
      endif
```

Check for absurd cases.

```
72a  <Set up generate_beta parameters 70b>+≡
      if (umax < umin) then
        x = -1
        return
      endif
```

It remains to choose the best value for  $t$ . The rejection efficiency  $\epsilon$  of the algorithm is given by the ratio of the dominating distribution and the distribution

$$\frac{1}{\epsilon(t)} = \frac{B(a, b)}{ab} (bt^a + at^{a-1}(1-t)^b). \quad (70)$$

It is maximized for

$$bt - bt(1-t)^{b-1} + (a-1)(1-t)^b = 0 \quad (71)$$

This equation has a solution which can be determined numerically. While this determination is far too expensive compared to a moderate loss in efficiency, we could perform it once after fitting the coefficients  $a$ ,  $b$ . Nevertheless, it has been shown,[1] that

$$t = \frac{1-a}{b+1-a} \quad (72)$$

results in non-vanishing efficiency for all values  $1 < a \leq 1 \leq b$ . Empirically we have found efficiencies of at least 80% for this choice, which is enough for our needs.

```
72b  <Set up best value for t 72b>≡
      t = (1 - a) / (b + 1 - a)
```

## C Sampling

```
72c  <circe2_moments.f90 68c>+≡
      module sampling
        use kinds
        implicit none
        private
        <sampling declarations 73a>
        contains
        <sampling implementation 73c>
      end module sampling
```

```

73a  <sampling declarations 73a>≡
      type sample
        integer :: n = 0
        real(kind=default) :: w = 0
        real(kind=default) :: w2 = 0
      end type sample
      public :: sample

73b  <sampling declarations 73a>+≡
      public :: reset, record

73c  <sampling implementation 73c>≡
      elemental subroutine reset (s)
        type(sample), intent(inout) :: s
        s%n = 0
        s%w = 0
        s%w2 = 0
      end subroutine reset

73d  <sampling implementation 73c>+≡
      elemental subroutine record (s, w)
        type(sample), intent(inout) :: s
        real(kind=default), intent(in), optional :: w
        s%n = s%n + 1
        if (present (w)) then
          s%w = s%w + w
          s%w2 = s%w2 + w*w
        else
          s%w = s%w + 1
          s%w2 = s%w2 + 1
        endif
      end subroutine record

73e  <sampling declarations 73a>+≡
      public :: mean, variance

73f  <sampling implementation 73c>+≡
      elemental function mean (s)
        type(sample), intent(in) :: s
        real(kind=default) :: mean
        mean = s%w / s%n
      end function mean

73g  <sampling implementation 73c>+≡
      elemental function variance (s)
        type(sample), intent(in) :: s
        real(kind=default) :: variance

```

```

    variance = (s%w2 / s%n - mean(s)**2) / s%n
    variance = max (variance, epsilon (variance))
end function variance

```

## D Moments

This would probably be a good place for inheritance

```

74a <circe2_moments_library declarations 69b>+≡
    type moment
        integer, dimension(2) :: n, m
        type(sample) :: sample = sample (0, 0.0_default, 0.0_default)
    end type moment
    public :: moment

74b <circe2_moments_library declarations 69b>+≡
    public :: init_moments

74c <circe2_moments_library implementation 69c>+≡
    subroutine init_moments (moments)
        type(moment), dimension(0:,0:,0:,0:), intent(inout) :: moments
        integer :: nx, mx, ny, my
        do nx = lbound(moments,1), ubound(moments,1)
            do mx = lbound(moments,2), ubound(moments,2)
                do ny = lbound(moments,3), ubound(moments,3)
                    do my = lbound(moments,4), ubound(moments,4)
                        moments(nx,mx,ny,my) = moment([nx,ny],[mx,my])
                    end do
                end do
            end do
        end do
        call reset_moment (moments)
    end subroutine init_moments

74d <circe2_moments_library declarations 69b>+≡
    public :: reset_moment, record_moment

74e <circe2_moments_library implementation 69c>+≡
    elemental subroutine reset_moment (m)
        type(moment), intent(inout) :: m
        call reset (m%sample)
    end subroutine reset_moment

```

If we were pressed for time, we would compute the moments by iterative multiplications instead by powers, of course. In any case, we would like to combine `x1` and `x2` into an array. Unfortunately this is not possible for

elemental procedures. NB: the NAG compiler appears to want a more careful evaluation of the powers. We enforce  $0.0**0 == 0$ .

```

75a  <circe2_moments_library implementation 69c>+≡
      elemental subroutine record_moment (m, x1, x2, w)
        type(moment), intent(inout) :: m
        real(kind=default), intent(in) :: x1, x2
        real(kind=default), intent(in), optional :: w
        real(kind=default) :: p
        p = pwr (x1, m%n(1)) * pwr (1-x1, m%m(1)) &
          * pwr (x2, m%n(2)) * pwr (1-x2, m%m(2))
        if (present (w)) p = p*w
        call record (m%sample, p)
      contains
        pure function pwr (x, n)
          real(kind=default), intent(in) :: x
          integer, intent(in) :: n
          real(kind=default) :: pwr
          if (n == 0) then
            pwr = 1
          else
            pwr = x**n
          end if
        end function pwr
      end subroutine record_moment

75b  <circe2_moments_library declarations 69b>+≡
      public :: mean_moment, variance_moment

75c  <circe2_moments_library implementation 69c>+≡
      elemental function mean_moment (m)
        type(moment), intent(in) :: m
        real(kind=default) :: mean_moment
        mean_moment = mean (m%sample)
      end function mean_moment

75d  <circe2_moments_library implementation 69c>+≡
      elemental function variance_moment (m)
        type(moment), intent(in) :: m
        real(kind=default) :: variance_moment
        variance_moment = variance (m%sample)
      end function variance_moment

```

## D.1 Moments of $\beta$ -distributions

```

75e  <circe2_moments_library declarations 69b>+≡

```

```
public :: beta_moment
```

$$\begin{aligned}
M_{n,m}(a,b) &= \int_0^1 dx x^n (1-x)^m \beta_{0,1}^{a,b}(x) = \int_0^1 dx x^n (1-x)^m \frac{x^{a-1} (1-x)^{b-1}}{B(a,b)} \\
&= \frac{1}{B(a,b)} \int_0^1 dx x^{n+a-1} (1-x)^{m+b-1} = \frac{B(n+a, m+b)}{B(a,b)} \\
&= \frac{\Gamma(n+a)\Gamma(m+b)\Gamma(a+b)}{\Gamma(n+a+m+b)\Gamma(a)\Gamma(b)} = \frac{\Gamma(n+a)}{\Gamma(a)} \frac{\Gamma(m+b)}{\Gamma(b)} \frac{\Gamma(n+m+a+b)}{\Gamma(a+b)} \\
&= \frac{(a+n)(a+n-1)\cdots(a+1)a(b+m)(b+m-1)\cdots(b+1)b}{(a+b+n+m)(a+b+n+m-1)\cdots(a+b+1)(a+b)} \quad (73)
\end{aligned}$$

```
76a  <circe2_moments_library implementation 69c>+≡
      elemental function beta_moment (n, m, a, b)
        integer, intent(in) :: n, m
        real(kind=default), intent(in) :: a, b
        real(kind=default) :: beta_moment
        beta_moment = &
          gamma_ratio (a, n) * gamma_ratio (b, m) / gamma_ratio (a+b, n+m)
      end function beta_moment
      
$$\frac{\Gamma(x+n)}{\Gamma(x)} = (x+n)(x+n-1)\cdots(x+1)x \quad (74)$$

```

```
76b  <circe2_moments_library implementation 69c>+≡
      elemental function gamma_ratio (x, n)
        real(kind=default), intent(in) :: x
        integer, intent(in) :: n
        real(kind=default) :: gamma_ratio
        integer :: i
        gamma_ratio = 1
        do i = 0, n - 1
          gamma_ratio = gamma_ratio * (x + i)
        end do
      end function gamma_ratio
```

## D.2 Channels

```
76c  <circe2_moments_library declarations 69b>+≡
      type channel
        real(kind=default) :: w = 1
        real(kind=default), dimension(2) :: a = 1, b = 1
        logical, dimension(2) :: delta = .false.
      end type channel
      public :: channel
```

```

77a  <circe2_moments_library declarations 69b>+≡
      public :: generate_beta_multi, beta_moments_multi

77b  <circe2_moments_library implementation 69c>+≡
      subroutine generate_beta_multi (rng, x, channels)
        class(rng_type), intent(inout) :: rng
        real(kind=default), dimension(:), intent(out) :: x
        type(channel), dimension(:), intent(in) :: channels
        real(kind=default) :: u, accum
        integer :: i, n
        <Select n according to the weight channels(n)%w 77c>
        do i = 1, size (x)
          if (channels(n)%delta(i)) then
            x(i) = 1
          else
            if (channels(n)%a(i) == 1 .and. channels(n)%b(i) == 1) then
              call rng%generate (x(i))
            else if (channels(n)%b(i) < channels(n)%a(i)) then
              call generate_beta (rng, x(i), 0.0_default, 1.0_default, &
                                channels(n)%b(i), channels(n)%a(i))
              x(i) = 1 - x(i)
            else
              call generate_beta (rng, x(i), 0.0_default, 1.0_default, &
                                channels(n)%a(i), channels(n)%b(i))
            end if
          end if
        end do
      end subroutine generate_beta_multi

      Subtlety: if the upper limit of the do loop where size(channels), we
      could end up with n set to size(channels)+1 when rounding errors pro-
      duce accum > sum(channels%w).

77c  <Select n according to the weight channels(n)%w 77c>≡
      call rng%generate (u)
      u = u * sum (channels%w)
      accum = 0
      scan: do n = 1, size (channels) - 1
        accum = accum + channels(n)%w
        if (accum >= u) exit scan
      end do scan

77d  <circe2_moments_library implementation 69c>+≡
      pure function beta_moments_multi (n, m, channels)
        integer, intent(in), dimension(2) :: n, m
        type(channel), dimension(:), intent(in) :: channels

```

```

real(kind=default) :: beta_moments_multi
real(kind=default) :: w
integer :: c, i
beta_moments_multi = 0
do c = 1, size (channels)
  w = channels(c)%w
  do i = 1, 2
    if (channels(c)%delta(i)) then
      if (m(i) > 0) w = 0
    else
      w = w * beta_moment (n(i), m(i), channels(c)%a(i), channels(c)%b(i))
    end if
  end do
  beta_moments_multi = beta_moments_multi + w
end do
beta_moments_multi = beta_moments_multi / sum (channels%w)
end function beta_moments_multi

```

## F Making Grids

### F.1 Interface of *Float*

module type  $T =$

```

    sig
        type  $t$ 

```

```

    (* Difference between 1.0 and the minimum float greater than 1.0 *)
    val epsilon : t
    val to_string : t → string
    val input_binary_float : in_channel → float
    val input_binary_floats : in_channel → float array → unit
end

module Double : T with type t = float

```

## F.2 Implementation of *Float*

```

open Printf

module type T =
  sig
    type t
    (* Difference between 1.0 and the minimum float greater than 1.0 *)
    val epsilon : t
    val to_string : t → string
    val input_binary_float : in_channel → float
    val input_binary_floats : in_channel → float array → unit
  end

module Double =
  struct
    type t = float

```

Difference between 1.0 and the minimum float greater than 1.0

 This is the hard coded value for double precision on Linux/Intel. We should determine this *machine dependent* value during configuration.

```

let epsilon = 2.2204460492503131 · 10-16
let little_endian = true

let to_string x =
  let s = sprintf "%.17E" x in
  for i = 0 to String.length s - 1 do
    let c = s[i] in
    if c = 'e' ∨ c = 'E' then
      s[i] ← 'D'
  done;
s

```

Identity floatingpoint numbers that are indistinguishable from integers for more concise printing.

```

  done;
  Int64.float_of_bits !n

let input_binary_float = input_float_little_endian

let input_binary_floats ic array =
  for i = 0 to Array.length array - 1 do
    array.(i) ← input_binary_float ic
  done

end

```

### F.3 Interface of *ThoArray*

exception *Out\_of\_bounds* of  $int \times int$

Interpret optional array boundaries. Assuming that  $Array.length\ a \mapsto n$ , we have

- $decode\_inf\ a \mapsto 0$
- $decode\_sup\ a \mapsto n - 1$
- $decode\_inf \sim inf : i\ a \mapsto i$  for  $0 \leq i \leq n - 1$
- $decode\_sup \sim sup : i\ a \mapsto i$  for  $0 \leq i \leq n - 1$

- $decode\_inf \sim inf : (-i) \ a \mapsto n - i$  for  $1 \leq i \leq n$
- $decode\_sup \sim sup : (-i) \ a \mapsto n - i$  for  $1 \leq i \leq n$
- $decode\_inf \sim inf : i \ a$  raises *Out\_of\_bounds* for  $i \geq n \vee i < -n$
- $decode\_sup \sim sup : i \ a$  raises *Out\_of\_bounds* for  $i \geq n \vee i < -n$

In particular

- $decode\_inf \sim inf : (-2) \ a \mapsto n - 2$ , i.e. the index of the next-to-last element.
- $decode\_sup \sim sup : (-1) \ a \mapsto n - 1$ , i.e. the index of the last element.

```
val decode_inf : ?inf:int → α array → int
val decode_sup : ?sup:int → α array → int
```

Just like the functions from *Array* of the same name, but acting only on the subarray specified by the optional  $\sim inf$  and  $\sim sup$ , interpreted as above. E.g.  $copy \sim inf : 1 \sim sup : (-2) \ a$  chops off the first and last elements.

```
val map : ?inf:int → ?sup:int → (α → β) → α array → β array
val copy : ?inf:int → ?sup:int → α array → α array
val iter : ?inf:int → ?sup:int → (α → unit) → α array → unit
val fold_left : ?inf:int → ?sup:int →
  (α → β → α) → α → β array → α
```

A convenience function.

```
val sum_float : ?inf:int → ?sup:int → float array → float
val suite : OUnit.test
```

## F.4 Implementation of *ThoArray*

## F.9 Interface of *Diffmap*

module type *T* =

sig

type *t*

An invertible differentiable map is characterized by its domain  $[x_{\min}, x_{\max}]$

type *domain*

val *x\_min* : *t* → *domain*

val *x\_max* : *t* → *domain*

and codomain  $[y_{\min}, y_{\max}]$

type *codomain*

val *y\_min* : *t* → *codomain*

val *y\_max* : *t* → *codomain*

the map proper

$$\begin{aligned} \phi : [x_{\min}, x_{\max}] &\rightarrow [y_{\min}, y_{\max}] \\ x &\mapsto y = \phi(x) \end{aligned} \tag{75}$$

val *phi* : *t* → *domain* → *codomain*

the inverse map

$$\begin{aligned} \phi^{-1} : [y_{\min}, y_{\max}] &\rightarrow [x_{\min}, x_{\max}] \\ y &\mapsto x = \phi^{-1}(y) \end{aligned} \tag{76}$$

val *ihp* : *t* → *codomain* → *domain*

the jacobian of the map

$$\begin{aligned} J : [x_{\min}, x_{\max}] &\rightarrow \mathbf{R} \\ x &\mapsto J(x) = \frac{d\phi}{dx}(x) \end{aligned} \tag{77}$$

val *jac* : *t* → *domain* → *float*

and finally the jacobian of the inverse map

$$\begin{aligned} J^* : [y_{\min}, y_{\max}] &\rightarrow \mathbf{R} \\ y &\mapsto J^*(y) = \frac{d\phi^{-1}}{dy}(y) = \left( \frac{d\phi}{dx}(\phi^{-1}(y)) \right)^{-1} \end{aligned} \tag{78}$$

```

    val cadj : t → codomain → float
    with_domain map x_min x_max takes the map map and returns the
    ‘same’ map with the new domain  $[x_{\min}, x_{\max}]$ 

```

```

    val with_domain : t → x_min : domain → x_max : domain → t

```

There is also a convention for encoding the map so that it can be read by `circe2`:

```

    val encode : t → string
end

```

For the application in `circe2`, it suffices to consider real maps. Introducing *domain* and *codomain* does not make any difference for the typechecker as long as we only use *Diffmap.Real*, but it provides documentation and keeps the door for extensions open.

```

module type Real = T with type domain = float and type codomain = float

```

## F.10 Testing Real Maps

```

module type Test =

```

```

    sig
        module M : Real
        val domain : M.t → unit
        val inverse : M.t → unit
        val jacobian : M.t → unit
        val all : M.t → unit
    end

```

```

module Make_Test (M : Real) : Test with module M = M

```

## F.11 Specific Real Maps

```

module Id :

```

```

    sig
        include Real

```

```

        create x_min x_max y_min y_max creates an identity map  $[x_{\min}, x_{\max}] \rightarrow [y_{\min}, y_{\max}]$ .

```

$$\begin{aligned}
 \iota : [x_{\min}, x_{\max}] &\rightarrow [x_{\min}, x_{\max}] \\
 x &\mapsto \iota(x) = x
 \end{aligned} \tag{79}$$

Default values for  $x\_min$  and  $x\_max$  are  $y\_min$  and  $y\_max$ , respectively. Indeed, they are the only possible values and other values raise an exception.

```

    val create :
      ?x_min : domain → ?x_max : domain → codomain →
      codomain → t
    end

```

module *Linear* :

```

sig
  include Real

```

*create x\_min x\_max y\_min y\_max* creates a linear map  $[x_{\min}, x_{\max}] \rightarrow [y_{\min}, y_{\max}]$ . The parameters  $a$  and  $b$  are determined from domain and codomain.

$$\begin{aligned} \lambda_{a,b} : [x_{\min}, x_{\max}] &\rightarrow [y_{\min}, y_{\max}] \\ x &\mapsto \lambda_{a,b}(x) = ax + b \end{aligned} \quad (80)$$

Default values for  $x\_min$  and  $x\_max$  are  $y\_min$  and  $y\_max$ , respectively.

```

    val create :
      ?x_min : domain → ?x_max : domain → codomain →
      codomain → t
    end

```

module *Power* :

```

sig
  include Real

```

*create alpha eta x\_min x\_max y\_min y\_max* creates a power map  $[x_{\min}, x_{\max}] \rightarrow [y_{\min}, y_{\max}]$ . The parameters  $\xi$ ,  $a$  and  $b$  are determined from  $\alpha$ ,  $\eta$ , domain and codomain.

$$\begin{aligned} \psi_{a,b}^{\alpha,\xi,\eta} : [x_{\min}, x_{\max}] &\rightarrow [y_{\min}, y_{\max}] \\ x &\mapsto \psi_{a,b}^{\alpha,\xi,\eta}(x) = \frac{1}{b}(a(x - \xi))^\alpha + \eta \end{aligned} \quad (81)$$

Default values for  $x\_min$  and  $x\_max$  are  $y\_min$  and  $y\_max$ , respectively.

```

    val create : alpha : float → eta : float →
      ?x_min : domain → ?x_max : domain → codomain →
      codomain → t
    end

```

module *Resonance* :

```

sig
  include Real

```

*create eta a x\_min x\_max y\_min y\_max* creates a resonance map  $[x_{\min}, x_{\max}] \rightarrow [y_{\min}, y_{\max}]$ .

$$\begin{aligned} \rho_{a,b}^{\xi,\eta} : [x_{\min}, x_{\max}] &\rightarrow [y_{\min}, y_{\max}] \\ x \mapsto \rho_{a,b}^{\xi,\eta}(x) &= a \tan\left(\frac{a}{b^2}(x - \xi)\right) + \eta \end{aligned} \quad (82)$$

The parameters  $\xi$  and  $b$  are determined from  $\eta$ ,  $a$ , domain and codomain. Default values for  $x_{\min}$  and  $x_{\max}$  are  $y_{\min}$  and  $y_{\max}$ , respectively.

```

    val create : eta : float → a : float →
      ?x_min : domain → ?x_max : domain → codomain →
codomain → t
  end

```

## F.18 Interface of *Division*

We have divisions (*Mono*) and divisions of divisions (*Poly*). Except for creation, they share the same interface (*T*), which can be used as a signature for functor arguments. In particular, both kinds of divisions can be used with the *Grid.Make* functor.

```

module type T =
  sig
    type t
    Copy a division, allocating fresh arrays with identical contents.
    val copy : t → t

    Using  $\{x_0, x_1, \dots, x_n\}$ , find  $i$ , such that  $x_i \leq x < x_{i+1}$ . We need to
    export this, if we want to maintain additional histograms in user modules.
    val find : t → float → int

    record d x f records the value  $f$  at coordinate  $x$ . NB: this function
    modifies  $d$ .
    val record : t → float → float → unit

    VEGAS style rebinning. The default values for power and both fixed_min,
    fixed_max are 1.5 and false respectively.
    val rebin : ?power:float → ?fixed_min:bool → ?fixed_max:bool →
    t → t

     $J^*(y)$ 
     Should this include the  $1/\Delta y$ ?

    val caj : t → float → float
    val n_bins : t → int
    val bins : t → float array
    val to_channel : out_channel → t → unit
  end

exception Out_of_range of float × (float × float)
exception Rebinning_failure of string

```

### F.18.1 Primary Divisions

module type *Mono* =

sig

include *T*

*create bias n x\_min x\_max* creates a division with  $n$  equidistant bins spanning  $[x_{\min}, x_{\max}]$ . The *bias* is a function that is multiplied with the weights for VEGAS/VAMP rebinning. It can be used to highlight the regions of phasespace that are expected to be most relevant in applications. The default is  $\text{fun } x \rightarrow 1.0$ , of course.

val *create* : ?*bias* : (float → float) → int → float → float → t

end

module *Mono* : *Mono*

### F.18.2 Polydivisions

module type *Poly* =

sig

module *M* : *Diffmaps.Real*

include *T*

*create n x\_min x\_max intervals* creates a polydivision of the interval from  $x_{\min}$  to  $x_{\max}$  described by the list of *intervals*, filling the gaps among intervals and between the intervals and the outer borders with an unmapped divisions with  $n$  bins each.

val *create* : ?*bias* : (float → float) →  
(int × *M.t*) list → int → float → float → t

## F.20 Interface of *Grid*

```
module type T =
```

```
sig
```

```
  module D : Division.T
```

```
  type t
```

```
  val copy : t → t
```

Create an initial grid.

```
  val create : ?triangle:bool → D.t → D.t → t
```

*record grid x1 x2 w* records the value *w* in the bin corresponding to coordinates *x1* and *x2*.

```
  val record : t → float → float → float → unit
```

VEGAS style rebinning.

```
  val rebin : ?power:float →
```

```
    ?fixed_x1_min:bool → ?fixed_x1_max:bool →
```

```
    ?fixed_x2_min:bool → ?fixed_x2_max:bool → t → t
```

The sum of all the weights shall be one.

```
  val normalize : t → t
```

Adapt an initial grid to data. The *power* controls speed vs. stability of adaption and is passed on to *Division.rebin*. *iterations* provides a hard cutoff for the number of iterations (default: 1000), while *margin* and *cutoff* control the soft cutoff of the adaption. If the variance grows to the best value multiplied by *margin* or if there are no improvements for *cutoff* steps, the adaption is stopped (defaults: 1.5 and 20). The remaining options control if the boundaries are fixed or allowed to move towards the limits of the dataset. The defaults are all **false**, meaning that the boundaries are allowed to move.

```
  val of_bigarray : ?verbose:bool → ?power:float →
```

```
    ?iterations:int → ?margin:float → ?cutoff:int →
```

```
    ?fixed_x1_min:bool → ?fixed_x1_max:bool →
```

```
    ?fixed_x2_min:bool → ?fixed_x2_max:bool →
```

```
    ?areas : Syntax.area list →
```

```
    (float, Bigarray.float64_elt,
```

```
    Bigarray.fortran_layout) Bigarray.Array2.t → t → t
```

```
  val smooth : float → Syntax.area → t → t

## F.22 Interface of *Events*

We’re dealing with Fortran style DOUBLE PRECISION arrays exclusively.

```

type t =
    (float, Bigarray.float64_elt, Bigarray.fortran_layout) Bigarray.Array2.t

```

Read an ASCII representation of a big array from a channel or a file. The array is read in pieces of *chunk* columns each; the default value for *chunk* is 100000. The number of rows is given by the integer argument, while the number of columns is determined by the number of lines in the file. If the *file* argument is present the resulting bigarray is mapped to a file.

```

val of_ascii_channel : ?file:string → ?chunk:int → int → in_channel → t
val of_ascii_file   : ?file:string → ?chunk:int → int → string → t

```

Map a file containing a binary representation of a big array. The number of rows is again given by the argument and the number of columns is determined by the size of the file. The first version does a read-only (or rather copy-on-write) map, while the second version allows modifications.

```

val of_binary_file : int → string → t
val shared_map_binary_file : int → string → t

```

Selfexplaining, hopefully ...

```

val to_ascii_channel : out_channel → t → unit
val to_ascii_file   : string → t → unit
val to_binary_file  : string → t → unit

```

Rescale the entries.

```

val rescale : float → float → t → unit

```

Utilities for reading ASCII representations.

```

val lexer : char Stream.t → Genlex.token Stream.t
val next_float : Genlex.token Stream.t → float

```

## F.23 Implementation of *Events*

### F.23.1 Reading Bigarrays

Reading big arrays efficiently is not trivial, if we don’t know the size of the arrays beforehand. Here we use the brute force approach of reading a list

of not-so-big arrays and blitting them into the resulting array later. This avoids a second reading of the file, but temporarily needs twice the memory.

```
open Bigarray
open Printf

type t = (float, float64_elt, fortran_layout) Array2.t

exception Incomplete of int × t
```

Read lines from a channel into the columns of a bigarray. If the file turns out to be short, the exception *Incomplete* (*i2*, *array*) is raised with the number of columns actually read.

```
let read_lines ic reader array i2_first i2_last =
  let i2 = ref i2_first in
  try
    while !i2 ≤ i2_last do
      let line = input_line ic in
      if line ≠ "" then begin
        reader array !i2 line;
        incr i2
      end
    done
  with
  | End_of_file → raise (Incomplete (pred !i2, array))
```

Decode a line of floating point numbers into a column of a bigarray. Fortran allows 'd' and 'D' as exponent starter, but O'Caml's *Genlex* doesn't accept it.

```
let normalize_ascii_floats orig =
  let normalized = String.copy orig in
  for i = 0 to String.length normalized - 1 do
    let c = normalized.[i] in
    if c = 'd' ∨ c = 'D' then
      normalized.[i] ← 'E'
  done;
  normalized
```

```
let lexer = Genlex.make_lexer []
```

```
let next_float s =
  match Stream.next s with
  | Genlex.Int n → float n
  | Genlex.Float x → x
  | _ → invalid_arg "Events.int_as_float"
```

```

let read_floats array i2 line =
  let tokens = lexer (Stream.of_string (normalize_ascii_floats line)) in
  for i1 = 1 to Array2.dim1 array do
    Array2.set array i1 i2 (next_float tokens)
  done

```

Try to read the columns of a bigarray from a channel. If the file turns out to be short, the exception *Incomplete* (*dim2*, *array*) is raised with the number of columns actually read.

```

let try_of_ascii_channel dim1 dim2 ic =
  let array = Array2.create float64 fortran_layout dim1 dim2 in
  read_lines ic read_floats array 1 dim2;
  (dim2, array)

```

Read a *dim1* floating point numbers per line into the columns of a reverted list of bigarrays, each with a maximum of *chunk* columns.

```

let rev_list_of_ascii_channel chunk dim1 ic =
  let rec rev_list_of_ascii_channel' acc =
    let continue =
      try
        let acc' = try_of_ascii_channel dim1 chunk ic :: acc in
        fun () → rev_list_of_ascii_channel' acc'
      with
      | Incomplete (len, a) → fun () → (len, a) :: acc in
    continue () in
  rev_list_of_ascii_channel' []

```

Concatenate a list of bigarrays  $[(l_n, a_n); \dots; (l_2, a_2); (l_1, a_1)]$  in reverse order  $a_1 a_2 \dots a_n$ . Of each array  $a_i$ , only the first  $l_i$  columns are used. If the optional *file* name is present, map the corresponding file to the bigarray. We can close the file descriptor immediately, since `close(2)` does *not* `munmap(2)`.

```

let create_array ?file dim1 dim2 =
  match file with
  | None → Array2.create float64 fortran_layout dim1 dim2
  | Some name →
    let fd =
      Unix.openfile name

    Array2.set data 2 i2 (Array2.get data 2 i2 /. scale2)
  done

```

## F.24 Interface of *Syntax*

exception *Syntax\_Error* of *string*  $\times$  *int*  $\times$  *int*

## F.25 Abstract Syntax and Default Values

val *epsilon* : *float*

A channel is uniquely specified by PDG particle ids and polarizations  $\{-1, 0, +1\}$ , which must match the ‘events’ in the given file; as should the luminosity. The options are for tuning the grid.

```

type boundary =
| Closed of float
| Open of float
| Bin of int

```

```

type point =
| Delta of float
| Box of int

type interval = boundary × boundary

type area =
| Rect of interval × interval
| Slice1 of interval × point
| Slice2 of point × interval

type channel =
{ pid1 : int;
  pol1 : int;
  pid2 : int;
  pol2 : int;
  lumi : float;
  bins1 : int;
  scale1 : float option;
  x1_min : float;
  x1_max : float;
  fixed_x1_min : bool;
  fixed_x1_max : bool;
  intervals1 : (int × Diffmaps.Default.t) list;
  bins2 : int;
  scale2 : float option;
  x2_min : float;
  x2_max : float;
  fixed_x2_min : bool;
  fixed_x2_max : bool;
  intervals2 : (int × Diffmaps.Default.t) list;
  smooth : (float × area) list;
  triangle : bool;
  iterations : int;
  events : string;
  histogram : string option;
  binary : bool;
  columns : int }

```

A parameter set is uniquely specified by PDG particle ids (*par abus de langage*), polarizations (now a floating point number for the effective polarization of the beam), and center of mass energy. This must match the ‘events’ in the files given for the channels. The other options are for tuning the grid.

```
