The following functions return a logical value. `all` evaluates to true if the condition `en0` is true for all valid element pairs of both subevents. Invalid pairs (with common `src` entry) are ignored.

`any` and `no` are analogous.

<Eval trees: procedures>+≡

```

function all_pp (en1, en2, en0) result (lval)
  logical :: lval
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout) :: en0

            end if
        end do
    end do LOOP1
end function no_pp

```

This function evaluates an observable for a pair of particles. From the two particle lists, we take the first pair without `src` overlap. If there is no valid pair, we revert the status of the value to unknown.

```

<Eval trees: procedures>+≡
subroutine eval_pp (en1, en2, en0, rval, is_known)
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout) :: en0
  real(default), intent(out) :: rval
  logical, intent(out) :: is_known
  integer :: i, j, n1, n2
  n1 = subevt_get_length (en1%pval)
  n2 = subevt_get_length (en2%pval)
  rval = 0
  is_known = .false.
  LOOP1: do i = 1, n1
    en0%index = i
    en0%prt1 = subevt_get_prt (en1%pval, i)
    do j = 1, n2
      en0%prt2 = subevt_get_prt (en2%pval, j)
      if (are_disjoint (en0%prt1, en0%prt2)) then
        call eval_node_evaluate (en0)
        rval = en0%rval
        is_known = .true.
        exit LOOP1
      end if
    end do
  end do LOOP1
end subroutine eval_pp

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

```

<Eval trees: procedures>+≡
function user_obs_int_pp (en0, prt1, prt2) result (ival)
  integer :: ival
  type(eval_node_t), intent(inout) :: en0
  type(prt_t), intent(in) :: prt1, prt2
  type(string_t) :: name
  procedure(user_obs_int_binary), pointer :: user_obs
  call eval_node_evaluate (en0)
  if (en0%value_is_known) then
    select case (en0%result_type)
    case (V_STR); name = en0% sval
    case default
      call msg_bug ("user_obs: procedure name must be a string")
      name = ""
    end select
    call c_f_procpointer (user_code_find_proc (name), user_obs)
    ival = user_obs (c_prt (prt1), c_prt (prt2))
  else
    call eval_node_write_rec (en0)
    call msg_fatal ("User observable name is undefined")
  end if
end function user_obs_int_pp

```

```

function user_obs_real_pp (en0, prt1, prt2) result (rval)
  real(default) :: rval
  type(eval_node_t), intent(inout) :: en0
  type(prt_t), intent(in) :: prt1, prt2
  type(string_t) :: name
  procedure(user_obs_real_binary), pointer :: user_obs
  call eval_node_evaluate (en0)
  if (en0%value_is_known) then
    select case (en0%result_type)
    case (V_STR); name = en0% sval
    case default

      name = ""
    end select
    call c_f_procpointer (user_code_find_proc (name), user_obs)
    rval = user_obs (c_prt (prt1), c_prt (prt2))
  else
    call eval_node_write_rec (en0)
    call msg_fatal ("User observable name is undefined")
  end if
end function user_obs_real_pp

```

The following function returns an integer value, namely the number of valid particle-pairs from both lists for which the condition is true. Invalid pairs (with common `src` entry) are ignored. If there is no condition, it returns the number of valid particle pairs.

A function would be more natural. Making it a subroutine avoids another compiler bug (internal error in nagfor 5.2 (649)). (See the interface `binary_num`.)

(Eval trees: procedures)+≡

```

subroutine count_pp (ival, en1, en2, en0)
  integer, intent(out) :: ival
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0
  integer :: i, j, n1, n2, count
  n1 = subevt_get_length (en1%pval)
  n2 = subevt_get_length (en2%pval)
  if (present (en0)) then
    count = 0
    do i = 1, n1
      en0%index = i
      en0%prt1 = subevt_get_prt (en1%pval, i)
      do j = 1, n2
        en0%prt2 = subevt_get_prt (en2%pval, j)
        if (are_disjoint (en0%prt1, en0%prt2)) then
          call eval_node_evaluate (en0)
          if (en0%lval) count = count + 1
        end if
      end do
    end do
  else
    count = 0
    do i = 1, n1

```

```

do j = 1, n2
  if (are_disjoint (subevt_get_prt (en1%pval, i), &
                        subevt_get_prt (en2%pval, j))) then
    count = count + 1
  end if
end do
end do
end if
ival = count
end subroutine count_pp

```

This function makes up a subevent from the second argument which consists only of particles which match the PDG code array (first argument).

<Eval trees: procedures>+≡

```

subroutine select_pdg_ca (subevt, en1, en2, en0)
  type(subevt_t), intent(inout) :: subevt
  type(eval_node_t), intent(in) :: en1, en2
  type(eval_node_t), intent(inout), optional :: en0
  if (present (en0)) then
    call subevt_select_pdg_code (subevt, en1%aval, en2%pval, en0%ival)
  else
    call subevt_select_pdg_code (subevt, en1%aval, en2%pval)
  end if
end subroutine select_pdg_ca

```

Binary string functions

Currently, the only string operation is concatenation.

<Eval trees: procedures>+≡

```

subroutine concat_ss (string, en1, en2)
  type(string_t), intent(out) :: string
  type(eval_node_t), intent(in) :: en1, en2
  string = en1%sval // en2%sval
end subroutine concat_ss

```

27.3.4 Compiling the parse tree

The evaluation tree is built recursively by following a parse tree. Evaluate an expression. The requested type is given as an optional argument; default is numeric (integer or real).

<Eval trees: procedures>+≡

```

recursive subroutine eval_node_compile_genexpr &
  (en, pn, var_list, result_type)
  type(eval_node_t), pointer :: en
  type(parse_node_t), intent(in) :: pn
  type(var_list_t), intent(in), target :: var_list
  integer, intent(in), optional :: result_type
  if (debug_active (D_MODEL_F)) then
    print *, "read genexpr"; call parse_node_write (pn)
  end if

```

```

if (present (result_type)) then
  select case (result_type)
  case (V_INT, V_REAL, V_CMPLX)
    call eval_node_compile_expr (en, pn, var_list)
  case (V_LOG)
    call eval_node_compile_lexpr (en, pn, var_list)
  case (V_SEV)
    call eval_node_compile_pexpr (en, pn, var_list)
  case (V_PDG)
    call eval_node_compile_cexpr (en, pn, var_list)
  case (V_STR)
    call eval_node_compile_sexpr (en, pn, var_list)
  end select
else
  call eval_node_compile_expr (en, pn, var_list)
end if
if (debug_active (D_MODEL_F)) then
  call eval_node_write (en)
  print *, "done genexpr"
end if
end subroutine eval_node_compile_genexpr

```

Numeric expressions

This procedure compiles a numerical expression. This is a single term or a sum or difference of terms. We have to account for all combinations of integer and real arguments. If both are constant, we immediately do the calculation and allocate a constant node.

(Eval trees: procedures)+≡

```

recursive subroutine eval_node_compile_expr (en, pn, var_list)

Real, complex and integer values are numeric literals with an optional unit attached. In case of an integer, the unit actually makes it a real value in disguise. The signed version of real values is not possible in generic expressions; it is a special case for numeric constants in model files (see below). We do not introduce signed versions of complex values.

```

Compile a variable, with or without a specified type. Take the list of variables, look for the name and make a node with a pointer to the value. If no type is provided, the variable is numeric, and the stored value determines whether it is real or integer.

We explicitly demand that the variable is defined, so we do not accidentally point to variables that are declared only later in the script but have come into existence in a previous compilation pass.

Variables may actually be anonymous, these are expressions in disguise. In that case, the expression replaces the variable name in the parse tree, and we allocate an ordinary expression node in the eval tree.

Variables of type V.PDG (pdg-code array) are not treated here. They are handled by `eval_node_compile_cvariable`.

Retrieve the result of an integration. If the requested process has been integrated, the results are available as special variables. (The variables cannot be accessed in the usual way since they contain brackets in their names.)

Since this compilation step may occur before the processes have been loaded, we have to initialize the required variables before they are used.

```

This user observable behaves like a variable. We link the node to the generic user-observable entry in the variable list. The syntax element has an argument which provides the name of the user variable, this is stored as an eval-node alongside with the variable. When the variable value is used, the user-supplied external function is called and provides the (real) result value.

Variable definition

A block expression contains a variable definition (first argument) and an expression where the definition can be used (second argument). The `result-type`

decides which type of expression is expected for the second argument. For numeric variables, if there is a mismatch between real and integer type, insert an extra node for type conversion.

Conditionals

A conditional has the structure if lexpr then expr else expr. So we first evaluate the logical expression, then depending on the result the first or second expression. Note that the second expression is mandatory.

The `result_type`, if present, defines the requested type of the `then` and `else` clauses. Default is numeric (int/real). If there is a mismatch between real and integer result types, insert conversion nodes.

Comparisons

Up to the loop, this is easy. There is always at least one comparison. This is evaluated, and the result is the logical node **en**. If it is constant, we keep its second sub-node as **en2**. (Thus, at the very end **en2** has to be deleted if **en** is (still) constant.)

If there is another comparison, we first check if the first comparison was constant. In that case, there are two possibilities: (i) it was true. Then, its right-hand side is compared with the new right-hand side, and the result replaces the previous one which is deleted. (ii) it was false. In this case, the result of the whole comparison is false, and we can exit the loop without evaluating anything else.

Now assume that the first comparison results in a valid branch, its second sub-node kept as **en2**. We first need a copy of this, which becomes the new left-hand side. If **en2** is constant, we make an identical constant node **en1**. Otherwise, we make **en1** an appropriate pointer node. Next, the first branch is saved as **en0** and we evaluate the comparison between **en1** and the a right-hand side. If this turns out to be constant, there are again two possibilities: (i) true, then we revert to the previous result. (ii) false, then the wh

```

```

        call eval_node_write (en)
        print *, "done compared_expr"
    end if
end subroutine eval_node_compile_compared_expr

```

This takes two extra arguments: **en1**, the left-hand-side of the comparison, is already allocated and evaluated. **en2** (the right-hand side) and **en** (the result) are allocated by the routine. **pn** is the parse node which contains the operator and the right-hand side as subnodes.

If the result of the comparison is constant, **en1** is deleted but **en2** is kept, because it may be used in a subsequent comparison. **en** then becomes a constant. If the result is variable, **en** becomes a branch node which refers to **en1** and **en2**.

```

A particle-list value is a PDG-code array, a particle identifier, a variable, a (grouped) pexpr, a block pexpr, a conditional, or a particle-list function.

The `cexpr` node is responsible for transforming a constant PDG-code array into a subevent. It takes the code array as its first argument, the event subevent as its second argument, and the requested particle type (incoming/outgoing) as its zero-th argument. The result is the list of particles in the event that match the code array.

Particle functions

This combines the treatment of 'join', 'combine', 'collect', 'cluster', 'select', and 'extract' which all have the same syntax. The one or two argument nodes are allocated. If there is a condition, the condition node is also allocated as a logical expression, for which the variable list is augmented by the appropriate (unary/binary) observables.

(Eval trees: procedures)+≡

```

27.3.5 Auxiliary functions for the compiler

Issue an error that the current node could not be compiled because of type mismatch:

```

<Eval trees: procedures>+≡
subroutine eval_type_error (pn, string, t)
    type(parse_node_t), intent(in) :: pn
    character(*), intent(in) :: string
    integer, intent(in) :: t
    type(string_t) :: type
    select case (t)
    case (V_NONE); type = "(none)"
    case (V_LOG); type = "'logical'"
    case (V_INT); type = "'integer'"
    case (V_REAL); type = "'real'"
    case (V_CMPLX); type = "'complex'"
    case default; type = "(unknown)"
    end select
    call parse_node_write (pn)
    call msg_fatal (" The " // string // &
        " operation is not defined for the given argument type " // &
        char (type))
end subroutine eval_type_error

```

If two numerics are combined, the result is integer if both arguments are integer, if one is integer and the other real or both are real, than its argument is real, otherwise complex.

```

<Eval trees: procedures>+≡
function numeric_result_type (t1, t2) result (t)
    integer, intent(in) :: t1, t2
    integer :: t
    if (t1 == V_INT .and. t2 == V_INT) then
        t = V_INT

```

```

else if (t1 == V_INT .and. t2 == V_REAL) then
  t = V_REAL
else if (t1 == V_REAL .and. t2 == V_INT) then
  t = V_REAL
else if (t1 == V_REAL .and. t2 == V_REAL) then
  t = V_REAL
else
  t = V_CMPLX
end if
end function numeric_result_type

```

27.3.6 Evaluation

Evaluation is done recursively. For leaf nodes nothing is to be done.

Evaluating particle-list functions: First, we evaluate the particle lists. If a condition is present, we assign the particle pointers of the condition node to the allocated particle entries in the parent node, keeping in mind that the observables in the variable stack used for the evaluation of the condition also contain pointers to these entries. Then, the assigned procedure is evaluated, which sets the subevent in the parent node. If required, the procedure evaluates the condition node once for each (pair of) particles to determine the result.

```

Test method

This is called from a unit test: initialize a particular observable.

```

<Eval trees: eval node: TBP>+≡
    procedure :: test_obs => eval_node_test_obs

<Eval trees: procedures>+≡
    subroutine eval_node_test_obs (node, var_list, var_name)
        class(eval_node_t), intent(inout) :: node
        type(var_list_t), intent(in) :: var_list
        type(string_t), intent(in) :: var_name
        procedure(obs_unary_int), pointer :: obs1_iptr
        type(prt_t), pointer :: p1
        call var_list%get_obs1_iptr (var_name, obs1_iptr, p1)
        call eval_node_init_obs1_int_ptr (node, var_name, obs1_iptr, p1)
    end subroutine eval_node_test_obs

```

27.3.7 Evaluation syntax

We have two different flavors of the syntax: with and without particles.

```

<Eval trees: public>+≡
    public :: syntax_expr
    public :: syntax_pexpr

<Eval trees: variables>≡
    type(syntax_t), target, save :: syntax_expr
    type(syntax_t), target, save :: syntax_pexpr

```

These are for testing only and may be removed:

```

<Eval trees: public>+≡
    public :: syntax_expr_init
    public :: syntax_pexpr_init

```

```

<Eval trees: procedures>+≡
  subroutine syntax_expr_init ()
    type(ifile_t) :: ifile
    call define_expr_syntax (ifile, particles=.false., analysis=.false.)
    call syntax_init (syntax_expr, ifile)
    call ifile_final (ifile)
  end subroutine syntax_expr_init

  subroutine syntax_pexpr_init ()
    type(ifile_t) :: ifile
    call define_expr_syntax (ifile, particles=.true., analysis=.false.)
    call syntax_init (syntax_pexpr, ifile)
    call ifile_final (ifile)
  end subroutine syntax_pexpr_init

<Eval trees: public>+≡
  public :: syntax_expr_final
  public :: syntax_pexpr_final

<Eval trees: procedures>+≡
  subroutine syntax_expr_final ()
    call syntax_final (syntax_expr)
  end subroutine syntax_expr_final

  subroutine syntax_pexpr_final ()
    call syntax_final (syntax_pexpr)
  end subroutine syntax_pexpr_final

<Eval trees: public>+≡
  public :: syntax_pexpr_write

<Eval trees: procedures>+≡
  subroutine syntax_pexpr_write (unit)
    integer, intent(in), optional :: unit
    call syntax_write (syntax_pexpr, unit)
  end subroutine syntax_pexpr_write

<Eval trees: public>+≡
  public :: define_expr_syntax

```

Numeric expressions.

```

<Eval trees: procedures>+≡
  subroutine define_expr_syntax (ifile, particles, analysis)
    type(ifile_t), intent(inout) :: ifile
    logical, intent(in) :: particles, analysis
    type(string_t) :: numeric_pexpr

        call msg_error ("Evaluation yields an undefined result, inserting default")
    end subroutine eval_tree_unknown

```

27.3.11 Factory Type

Since `eval_tree_t` is an implementation of `expr_t`, we also need a matching factory type and build method.

```

<Eval trees: public>+≡
    public :: eval_tree_factory_t

```

```

<Eval trees: types>+≡
  type, extends (expr_factory_t) :: eval_tree_factory_t
  private
    type(parse_node_t), pointer :: pn => null ()
  contains
    <Eval trees: eval tree factory: TBP>
  end type eval_tree_factory_t

```

Output: delegate to the output of the embedded parse node.

```

<Eval trees: eval tree factory: TBP>≡
  procedure :: write => eval_tree_factory_write

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_write (expr_factory, unit)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    integer, intent(in), optional :: unit
    if (associated (expr_factory%pn)) then
      call parse_node_write_rec (expr_factory%pn, unit)
    end if
  end subroutine eval_tree_factory_write

```

Initializer: take a parse node and hide it thus from the environment.

```

<Eval trees: eval tree factory: TBP>+≡
  procedure :: init => eval_tree_factory_init

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_init (expr_factory, pn)
    class(eval_tree_factory_t), intent(out) :: expr_factory
    type(parse_node_t), intent(in), pointer :: pn
    expr_factory%pn => pn
  end subroutine eval_tree_factory_init

```

Factory method: allocate expression with correct eval tree type. If the stored parse node is not associate, don't allocate.

```

<Eval trees: eval tree factory: TBP>+≡
  procedure :: build => eval_tree_factory_build

<Eval trees: procedures>+≡
  subroutine eval_tree_factory_build (expr_factory, expr)
    class(eval_tree_factory_t), intent(in) :: expr_factory
    class(expr_t), intent(out), allocatable :: expr
    if (associated (expr_factory%pn)) then
      allocate (eval_tree_t :: expr)
      select type (expr)
        type is (eval_tree_t)
          expr%pn => expr_factory%pn
        end select
      end if
    end if
  end subroutine eval_tree_factory_build

```

27.4 Physics Models

A model object represents a physics model. It contains a table of particle data, a list of parameters, and a vertex table. The list of parameters is a variable list which includes the real parameters (which are pointers to the particle data table) and PDG array variables for the particles themselves. The vertex list is used for phase-space generation, not for calculating the matrix element.

The actual numeric model data are in the base type `model_data_t`, as part of the `qft` section. We implement the `model_t` as an extension of this, for convenient direct access to the base-type methods via inheritance. (Alternatively, we could delegate these calls explicitly.) The extension contains administrative additions, such as the methods for recalculating derived data and keeping the parameter set consistent. It thus acts as a proxy of the actual model-data object towards the WHIZARD package. There are further proxy objects, such as the `parameter_t` array which provides the interface to the actual numeric parameters.

Model definitions are read from model files. Therefore, this module contains a parser for model files. The parameter definitions (derived parameters) are Sindarin expressions.

The models, as read from file, are stored in a model library which is a simple list of model definitions. For setting up a process object we should make a copy (an instance) of a model, which gets the current parameter values from the global variable list.

⟨Models: procedures⟩

end module models

27.4.2 Physics Parameters

A parameter has a name, a value. Derived parameters also have a definition in terms of other parameters, which is stored as an **eval_tree**. External parameters are set by an external program.

This parameter object should be considered as a proxy object. The parameter name and value are stored in a corresponding **modelpar_data_t** object which is located in a **model_data_t** object. The latter is a component of the **model_t** handler. Methods of **parameter_t** can be delegated to the **par_data_t** component.

The **pn** component is a pointer to the parameter definition inside the model parse tree. It allows us to recreate the **eval_tree** when making copies (instances) of the parameter object.

⟨Models: parameters⟩≡

```
integer, parameter :: PAR_NONE = 0, PAR_UNUSED = -1
integer, parameter :: PAR_INDEPENDENT = 1, PAR_DERIVED = 2
integer, parameter :: PAR_EXTERNAL = 3
```

⟨Models: types⟩≡

```
type :: parameter_t
  private
  integer :: type = PAR_NONE
  class(modelpar_data_t), pointer :: data => null ()
  type(parse_node_t), pointer :: pn => null ()
  class(expr_t), allocatable :: expr
  contains
    ⟨Models: parameter: TBP⟩
  end type parameter_t
```

Initialization depends on parameter type. Independent parameters are initialized by a constant value or a constant numerical expression (which may contain a unit). Derived parameters are initialized by an arbitrary numerical expression,

which makes use of the current variable list. The expression is evaluated by the function `parameter_reset`.

This implementation supports only real parameters and real values.

```

<Models: parameter: TBP>≡
  procedure :: init_independent_value => parameter_init_independent_value

27.4.3 Model Object

A model object holds all information about parameters, particles, and vertices. For models that require an external program for parameter calculation, there is

the pointer to a function that does this calculation, given the set of independent and derived parameters.

As explained above, the type inherits from `model_data_t`, which is the actual storage for the model data.

When reading a model, we create a parse tree. Parameter definitions are available via parse nodes. Since we may need those later when making model instances, we keep the whole parse tree in the model definition (but not in the instances).

```

<Models: public>≡
    public :: model_t

<Models: types>+≡
    type, extends (model_data_t) :: model_t
        private
            character(32) :: md5sum = ""
            type(string_t), dimension(:), allocatable :: schemes
            type(string_t), allocatable :: selected_scheme
            type(parameter_t), dimension(:), allocatable :: par
            integer :: max_par_name_length = 0
            integer :: max_field_name_length = 0
            type(var_list_t) :: var_list
            type(string_t) :: dlname
            procedure(model_init_external_parameters), nopass, pointer :: &
                init_external_parameters => null ()
            type(dlaccess_t) :: dlaccess
            type(parse_tree_t) :: parse_tree
        contains
            <Models: model: TBP>
        end type model_t

```

This is the interface for a procedure that initializes the calculation of external parameters, given the array of all parameters.

```

<Models: interfaces>≡
    abstract interface
        subroutine model_init_external_parameters (par) bind (C)
            import
            real(c_default_float), dimension(*), intent(inout) :: par
        end subroutine model_init_external_parameters
    end interface

```

Initialization: Specify the number of parameters, particles, vertices and allocate memory. If an associated DL library is specified, load this library.

The model may already carry scheme information, so we have to save and restore the scheme number when actually initializing the `model_data_t` base.

```

<Models: model: TBP>≡
    generic :: init => model_init
    procedure, private :: model_init

<Models: procedures>+≡
    subroutine model_init &
        (model, name, libname, os_data, n_par, n_prt, n_vtx)
        class(model_t), intent(inout) :: model
        type(string_t), intent(in) :: name, libname

```

```

type(os_data_t), intent(in) :: os_data

      return
    end if
    call c_f_procpointer (c_fptr, model% init_external_parameters)
  end if
end if
end subroutine model_init

```

For a model instance, we do not attempt to load a DL library. This is the core of the full initializer above.

<Models: model: TBP>+≡

procedure, private :: basic_init => model_basic_init

<Models: procedures>+≡

subroutine model_basic_init (model, name, n_par, n_prt, n_vtx)

```

class(model_t), intent(inout) :: model
type(string_t), intent(in) :: name
integer, intent(in) :: n_par, n_prt, n_vtx
allocate (model%par (n_par))
call model%model_data_t%init (name, n_par, 0, n_prt, n_vtx)
end subroutine model_basic_init

```

Finalization: The variable list contains allocated pointers, also the parse tree. We also close the DL access object, if any, that enables external parameter calculation.

```

<Models: model: TBP>+≡
  procedure :: final => model_final

<Models: procedures>+≡
  subroutine model_final (model)
    class(model_t), intent(inout) :: model
    integer :: i
    if (allocated (model%par)) then
      do i = 1, size (model%par)

Make a copy of a parameter. We assume that the `model_data_t` parameter arrays have already been copied, so names and values are available in the current model, and can be used as targets. The eval tree should not be copied, since it should refer to the new variable list. The safe solution is to make use of the above initializers, which also take care of the building a new variable list.

  function model_get_var_list_ptr (model) result (var_list)
    type(var_list_t), pointer :: var_list
    class(model_t), intent(in), target :: model
    var_list => model%var_list
  end function model_get_var_list_ptr

```

27.4.5 Scheme handling

A model can specify a set of allowed schemes that steer the setup of model variables. The model file can contain scheme-specific declarations that are selected by a **select scheme** clause. Scheme support is optional.

If enabled, the model object contains a list of allowed schemes, and the model reader takes the active scheme as an argument. After the model has been read, the scheme is fixed and can no longer be modified.

The model supports schemes if the scheme array is allocated.

```

<Models: model: TBP>+≡
  procedure :: has_schemes => model_has_schemes

<Models: procedures>+≡
  function model_has_schemes (model) result (flag)
    logical :: flag
    class(model_t), intent(in) :: model
    flag = allocated (model%schemes)

```

```
end function model_has_schemes
```

Enable schemes: fix the list of allowed schemes.

```
<Models: model: TBP>+≡
  procedure :: enable_schemes => model_enable_schemes

<Models: procedures>+≡
  subroutine model_enable_schemes (model, scheme)
    class(model_t), intent(inout) :: model
    type(string_t), dimension(:), intent(in) :: scheme
    allocate (model%schemes (size (scheme)), source = scheme)
  end subroutine model_enable_schemes
```

Find the scheme. Check if the scheme is allowed. The numeric index of the selected scheme is stored in the `model_data_t` base object.

If no argument is given, select the first scheme. The numeric scheme ID will then be 1, while a model without schemes retains 0.

```
<Models: model: TBP>+≡
  procedure :: set_scheme => model_set_scheme

<Models: procedures>+≡
  subroutine model_set_scheme (model, scheme)
    class(model_t), intent(inout) :: model
    type(string_t), intent(in), optional :: scheme
    logical :: ok
    integer :: i
    if (model%has_schemes ()) then
      if (present (scheme)) then
        ok = .false.
        CHECK_SCHEME: do i = 1, size (model%schemes)
          if (scheme == model%schemes(i)) then
            allocate (model%selected_scheme, source = scheme)
            call model%set_scheme_num (i)
            ok = .true.
            exit CHECK_SCHEME
          end if
        end do CHECK_SCHEME
        if (.not. ok) then
          call msg_fatal &
            ("Model '" // char (model%get_name ()) &
              // "': scheme '" // char (scheme) // "' not supported")
        end if
      else

            end do
        end if
    end subroutine model_list_write
```

Link this list to another one.

```
<Models: model list: TBP>+≡
    procedure :: link => model_list_link
```

```

<Models: procedures>+≡
  subroutine model_list_link (model_list, context)
    class(model_list_t), intent(inout) :: model_list
    type(model_list_t), intent(in), target :: context
    model_list%context => context
  end subroutine model_list_link

```

(Private, used below:) Append an existing model, for which we have allocated a pointer entry, to the model list. The original pointer becomes disassociated, and the model should now be considered as part of the list. We assume that this model is not yet part of the list.

If we provide a model argument, this returns a pointer to the new entry.

```

<Models: model list: TBP>+≡
  procedure, private :: import => model_list_import

<Models: procedures>+≡
  subroutine model_list_import (model_list, current, model)
    class(model_list_t), intent(inout) :: model_list
    type(model_entry_t), pointer, intent(inout) :: current
    type(model_t), optional, pointer, intent(out) :: model
    if (associated (current)) then
      if (associated (model_list%first)) then
        model_list%last%next => current
      else
        model_list%first => current
      end if
      model_list%last => current
      if (present (model)) model => current%model_t
      current => null ()
    end if
  end subroutine model_list_import

```

Currently test only:

Add a new model with given name to the list, if it does not yet exist. If successful, return a pointer to the new model.

```

<Models: model list: TBP>+≡
  procedure :: add => model_list_add

<Models: procedures>+≡
  subroutine model_list_add (model_list, &
    name, os_data, n_par, n_prt, n_vtx, model)
    class(model_list_t), intent(inout) :: model_list
    type(string_t), intent(in) :: name
    type(os_data_t), intent(in) :: os_data

      model => null ()
    else
      allocate (current)
      call current%init (name, var_str (""), os_data, &
        n_par, n_prt, n_vtx)
    end if
  end subroutine model_list_add

```

```

        call model_list%import (current, model)
    end if
end subroutine model_list_add

```

Read a new model from file and add to the list, if it does not yet exist. Finalize the model by allocating the vertex table. Return a pointer to the new model. If unsuccessful, return the original pointer.

The model is always inserted in the last link of a chain of model lists. This way, we avoid loading models twice from different contexts. When a model is modified, we should first allocate a local copy.

```

27.4.9 Model instances

A model instance is a copy of a model object. The parameters are true copies. The particle data and the variable list pointers should point to the copy, so modifying the parameters has only a local effect. Hence, we build them up explicitly. The vertex array is also rebuilt, it contains particle pointers. Finally, the vertex hash table can be copied directly since it contains no pointers.

The **multiplicity** entry depends on the association of the **mass_data** entry and therefore has to be set at the end.

The instance must carry the **target** attribute.

Parameters: the **copy_parameter** method essentially copies the parameter decorations (parse node, expression etc.). The current parameter values are part of the **model_data_t** base type and are copied afterwards via its **copy_from** method.

```

<Models: model: TBP>+≡
  procedure :: init_instance => model_copy

<Models: procedures>+≡
  subroutine model_copy (model, orig)
    class(model_t), intent(out), target :: model

```

```

type(model_t), intent(in) :: orig

27.5 The SUSY Les Houches Accord

The SUSY Les Houches Accord defines a standard interfaces for storing the physics data of SUSY models. Here, we provide the means for reading, storing, and writing such data.

```
<slha_interface.f90>≡  
  <File header>  
  
  module slha_interface  
  
    <Use kinds>  
    <Use strings>  
    use io_units  
    use constants  
    use string_utils, only: upper_case  
    use unit_tests  
    use system_defs, only: VERSION_STRING  
    use system_defs, only: EOF  
    use diagnostics  
    use os_interface  
    use ifiles  
    use lexers  
    use syntax_rules  
    use parser  
    use variables  
    use models  
  
    <Standard module head>  
  
    <SLHA: public>  
  
    <SLHA: parameters>  
  
    <SLHA: variables>  
  
    save  
  
  contains  
  
    <SLHA: procedures>  
  
    <SLHA: tests>  
  
  end module slha_interface
```

27.5.1 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a

data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

<SLHA: parameters>≡

```
integer, parameter :: MODE_SKIP = 0, MODE_DATA = 1, MODE_INFO = 2
```

<SLHA: procedures>≡

```
subroutine slha_preprocess (stream, ifile)

    end subroutine define_slha_syntax

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed

somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

```

<SLHA: public>+=
    public :: lexer_init_slha

    allocate (str_array (0))
  end if
end subroutine retrieve_strings_in_block

```

Transfer data from SLHA to variables

Extract real parameter with index *i*. If it does not exist, retrieve it from the variable list, using the given name.

(SLHA: procedures)+≡

```
function get_parameter_in_block (pn_block, code, name, var_list) result (var)
  real(default) :: var
  type(parse_node_t), intent(in), target :: pn_block
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in), target :: var_list
  type(parse_node_t), pointer :: pn_data, pn_item
  call slha_find_index_ptr (pn_block, pn_data, pn_item, code)
  if (associated (pn_item)) then
    var = get_real_parameter (pn_item)
  else
    var = var_list%get_rval (name)
  end if
end function get_parameter_in_block
```

Extract a real data item with index *i*. If it does exist, set it in the variable list, using the given name. If the variable is not present in the variable list, ignore it.

(SLHA: procedures)+≡

```
subroutine set_data_item (pn_block, code, name, var_list)
  type(parse_node_t), intent(in), target :: pn_block
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(inout), target :: var_list
  type(parse_node_t), pointer :: pn_data, pn_item
  call slha_find_index_ptr (pn_block, pn_data, pn_item, code)
  if (associated (pn_item)) then
    call var_list%set_real (name, get_real_parameter (pn_item), &
      is_known=.true., ignore=.true.)
  end if
end subroutine set_data_item
```

Extract a real matrix element with index *i,j*. If it does exists, set it in the variable list, using the given name. If the variable is not present in the variable list, ignore it.

(SLHA: procedures)+≡

```
subroutine set_matrix_element (pn_block, code1, code2, name, var_list)
  type(parse_node_t), intent(in), target :: pn_block
  integer, intent(in) :: code1, code2
  type(string_t), intent(in) :: name
  type(var_list_t), intent(inout), target :: var_list
  type(parse_node_t), pointer :: pn_data, pn_item

    call var_list%set_real (name, get_real_parameter (pn_item), &
      is_known=.true., ignore=.true.)
  end if
end subroutine set_matrix_element
```

Transfer data from variables to SLHA

Get a real/integer parameter with index *i* from the variable list and write it to the current output file. In the integer case, we account for the fact that the variable is type real. If it does not exist, do nothing.

(SLHA: procedures)+≡

```
subroutine write_integer_data_item (u, code, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  integer :: item
  if (var_list%contains (name)) then
    item = nint (var_list%get_rval (name))
    call write_integer_parameter (u, code, item, comment)
  end if
end subroutine write_integer_data_item

subroutine write_real_data_item (u, code, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  real(default) :: item
  if (var_list%contains (name)) then
    item = var_list%get_rval (name)
    call write_real_parameter (u, code, item, comment)
  end if
end subroutine write_real_data_item
```

Get a real data item with two integer indices from the variable list and write it to the current output file. If it does not exist, do nothing.

(SLHA: procedures)+≡

```
subroutine write_matrix_element (u, code1, code2, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code1, code2
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  real(default) :: item
  if (var_list%contains (name)) then
    item = var_list%get_rval (name)
    call write_real_matrix_element (u, code1, code2, item, comment)
  end if
end subroutine write_matrix_element
```

27.5.4 Auxiliary function

Write a block header.

```
(SLHA: procedures)+≡
subroutine write_block_header (u, name, comment)
  integer, intent(in) :: u
  character(*), intent(in) :: name, comment
  write (u, "(A,1x,A,3x,'#',1x,A)") "BLOCK", name, comment
end subroutine write_block_header
```

Extract a real parameter that may be defined real or integer, signed or unsigned.

```
(SLHA: procedures)+≡
function get_real_parameter (pn_item) result (var)
  real(default) :: var
  type(parse_node_t), intent(in), target :: pn_item
  type(parse_node_t), pointer :: pn_sign, pn_var

    pn_decay => slha_get_next_decay_ptr (pn_decay)
end do
end subroutine slha_handle_decays

```

Mixing matrices

Read mixing matrices. We can treat all matrices by a single procedure if we just know the block name, variable prefix, and matrix dimension. The matrix dimension must be less than 10. For the pseudoscalar Higgses in NMSSM-type models we need off-diagonal matrices, so we generalize the definition.

(SLHA: procedures)+≡

```

subroutine slha_handle_matrix_block &
    (parse_tree, block_name, var_prefix, dim1, dim2, model)
type(parse_tree_t), intent(in) :: parse_tree
character(*), intent(in) :: block_name, var_prefix
integer, intent(in) :: dim1, dim2
type(model_t), intent(inout), target :: model
type(parse_node_t), pointer :: pn_block
type(var_list_t), pointer :: var_list
integer :: i, j
character(len=len(var_prefix)+2) :: var_name
var_list => model%get_var_list_ptr ()
pn_block => slha_get_block_ptr &
    (parse_tree, var_str (block_name), required=.false.)
if (.not. (associated (pn_block))) return
do i = 1, dim1
    do j = 1, dim2
        write (var_name, "(A,I1,I1)") var_prefix, i, j
        call set_matrix_element (pn_block, i, j, var_str (var_name), var_list)
    end do
end do
end subroutine slha_handle_matrix_block

```

Higgs data

Read the block ALPHA which holds just the Higgs mixing angle.

(SLHA: procedures)+≡

```

subroutine slha_handle_ALPHA (parse_tree, model)
type(parse_tree_t), intent(in) :: parse_tree
type(model_t), intent(inout), target :: model
type(parse_node_t), pointer :: pn_block, pn_line, pn_data, pn_item

```

```

type(var_list_t), pointer :: var_list

end subroutine slha_handle_NMSSMRUN

```

27.5.5 Parser

Read a SLHA file from stream, including preprocessing, and make up a parse tree.

(SLHA: procedures)+≡

```
subroutine slha_parse_stream (stream, parse_tree)
  type(stream_t), intent(inout), target :: stream
  type(parse_tree_t), intent(out) :: parse_tree
  type(ifile_t) :: ifile
  type(lexer_t) :: lexer
  type(stream_t), target :: stream_tmp
  call slha_preprocess (stream, ifile)
  call stream_init (stream_tmp, ifile)
  call lexer_init_slha (lexer)
  call lexer_assign_stream (lexer, stream_tmp)
  call parse_tree_init (parse_tree, syntax_slha, lexer)
  call lexer_final (lexer)
  call stream_final (stream_tmp)
  call ifile_final (ifile)
end subroutine slha_parse_stream
```

Read a SLHA file chosen by name. Check first the current directory, then the directory where SUSY input files should be located.

Required for test:

(SLHA: public)+≡

```
public :: slha_parse_file
```

(SLHA: procedures)+≡

```
subroutine slha_parse_file (file, os_data, parse_tree)
  type(string_t), intent(in) :: file
  type(os_data_t), intent(in) :: os_data
  type(parse_tree_t), intent(out) :: parse_tree
  logical :: exist
  type(string_t) :: filename
  type(stream_t), target :: stream
  call msg_message ("Reading SLHA input file '" // char (file) // "'")
  filename = file
  inquire (file=char(filename), exist=exist)
  if (.not. exist) then
    filename = os_data%whizard_susypath // "/" // file
    inquire (file=char(filename), exist=exist)
    if (.not. exist) then
      call msg_fatal ("SLHA input file '" // char (file) // "' not found")
      return
    end if
  end if
  call stream_init (stream, char (filename))
  call slha_parse_stream (stream, parse_tree)
  call stream_final (stream)
end subroutine slha_parse_file
```

27.5.6 API

Read the SLHA file, parse it, and interpret the parse tree. The model parameters retrieved from the file will be inserted into the appropriate model, which is loaded and modified in the background. The pointer to this model is returned as the last argument.

```

<SLHA: public>+=
    public :: slha_read_file

<SLHA: procedures>+=
    subroutine slha_read_file &
        (file, os_data, model, input, spectrum, decays)
        type(string_t), intent(in) :: file
        type(os_data_t), intent(in) :: os_data
        type(model_t), intent(inout), target :: model
        logical, intent(in) :: input, spectrum, decays
        type(parse_tree_t) :: parse_tree
        call slha_parse_file (file, os_data, parse_tree)
        if (associated (parse_tree%get_root_ptr ())) then
            call slha_interpret_parse_tree &
                (parse_tree, model, input, spectrum, decays)
            call parse_tree_final (parse_tree)
            call model%update_parameters ()
        end if
    end subroutine slha_read_file

```

Write the SLHA contents, as far as possible, to external file.

```

<SLHA: public>+=
    public :: slha_write_file

<SLHA: procedures>+=
    subroutine slha_write_file (file, model, input, spectrum, decays)
        type(string_t), intent(in) :: file
        type(model_t), target, intent(in) :: model
        logical, intent(in) :: input, spectrum, decays

c
c -- Calculation of the Green function in momentum space by solving the
c   Lippmann-Schwinger equation
c   
$$G(p) = G_0(p) + G_0(p) \int_0^{xcutn} V(p,q) G(q) dq$$

c
c -- Written by Thomas Teubner, Hamburg, November 1998
c   * Based on TOPPIK Version 1.1
c     from M. Jezabek and TT, Karlsruhe, June 1992
c   * Version originally for non-constant top-width
c   * Constant width supplied here
c   * No generator included
c
c -- Use of double precision everywhere
c
c -- All masses, momenta, energies, widths in GeV
c
c -- Input parameters:
c
c   xenergy : E=Sqrt[s]-2*topmass
c   xtm      : topmass (in the Pole scheme)
c   xtg      : top-width
c   xalphas  :  $\alpha_s^{MSbar,n_f=5}(xscale)$ 
c   xscale   : soft scale  $\mu_{soft}$ 
c   xcutn    : numerical UV cutoff on all momenta
c              (UV cutoff of the Gauss-Legendre grid)
c   xcutv    : renormalization cutoff on the
c              delta-, the (p^2+q^2)/(p-q)^2-, and the
c              1/r^2-[1/|p-q|]-potential:
c              if (max(p,q).ge.xcutv) then the three potentials
c              are set to zero in the Lippmann-Schwinger equation
c   xc0      : 0th order coefficient for the Coulomb potential,
c              see calling example above
c   xc1      : 1st order coefficient for the Coulomb potential
c   xc2      : 2nd order coefficient for the Coulomb potential

```

```

c   xcdeltc  : constant of the delta(r)-
c               [= constant in momentum space-] potential
c   xcdeletl : constant for the additional log(q^2/mu^2)-part of the
c               delta-potential:
c               xcdeltc*1 + xcdeletl*log(q^2/mu^2)
c   xcfullc  : constant of the (p^2+q^2)/(p-q)^2-potential
c   xcfulll  : constant for the additional log(q^2/mu^2)-part of the
c               (p^2+q^2)/(p-q)^2-potential
c   xcrm2    : constant of the 1/r^2-[1/|p-q|]-potential
c   xkincm   : } kinetic corrections in the 0th order Green-function:
c   xkinca   : } G_0(p):=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c               !!! WATCH THE SIGN IN G_0 !!!
c   jknflg   : flag for these kinetic corrections:
c               0 : no kinetic corrections applied
c               1 : kinetic corrections applied with cutoff xcutv
c                   for xkinca only
c               2 : kinetic corrections applied with cutoff xcutv
c                   for xkinca AND xkincm
c   jgcflg   : flag for G_0(p) in the LS equation:
c               0 (standard choice) : G_0(p) as given above
c               1 (for TIPT)         : G_0(p) = G_c^{0}(p) the 0th
c                                       order Coulomb-Green-function
c                                       in analytical form; not for
c                                       momenta p > 1000*topmass
c   xkincv   : additional kinematic vertexcorrection in G_0, see below:
c   jvflg    : flag for the additional vertexcorrection xkincv in the
c               'zeroth order' G_0(p) in the LS-equation:
c               0 : no correction, means G = G_0 + G_0 int V G
c                   with G_0=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c               1 : apply the correction in the LS equation as
c                   G = G_0 + xkincv*p^2/m_t^2/[E+iGamma_t-p^2/m_t] +
c                   G_0 int V G
c               and correct the integral over Im[G(p)] to get sigma_tot
c               from the optical theorem by the same factor.
c               The cutoff xcutv is applied for these corrections.
c
c -- Output:
c
c   xim      : R_{ttbar} from the imaginary part of the green
c               function
c   xdi      : R_{ttbar} form the integral over the momentum
c               distribution (no cutoff but the numerical one here!!)
c   np       : number of points used for the grid; fixed in tttoppik
c   xpp      : 1-dim array (max. 400 elements) giving the momenta of
c               the Gauss-Legendre grid (pp(i) in the code)
c   xww      : 1-dim array (max. 400 elements) giving the corresponding
c               Gauss-Legendre weights for the grid
c   xdsdp    : 1-dim array (max. 400 elements) giving the
c               momentum distribution of top: d\sigma/dp,
c               normalized to R,
c               at the momenta of the Gauss-Legendre grid xpp(i)
c   zvfct    : 1-dim array (max. 400 elements) of COMPLEX*16 numbers
c               giving the vertex function K(p), G(p)=K(p)*G_0(p)
c               at the momenta of the grid

c
        alphas=xalphas
c
c Cut for divergent potential-terms for large momenta in the function vhat
c and in the integrals a(p):
        dcut=xcutv
c
c Numerical Cutoff of all momenta (maximal momenta of the grid):
        xpmay=xcutn
        if (dcut.gt.xpmay) then
            write(*,*) ' dcut > xpmay  makes no sense! Stop.'
            stop
        endif
c
c Not needed for the fixed order potentials:
        alamb5=0.2d0
c
c      WRITE(*,*) 'INPUT TGAMMA=',TGAMMA
c Needed in subroutine GAMMAT:
        GFERMI=1.16637d-5
c      CALL GAMMAT
c      WRITE(*,*) 'CALCULATED TGAMMA=',TGAMMA
c
        etot=2.d0*tmass+energy
c
        if ((npot.eq.1).or.(npot.eq.3).or.(npot.eq.4).or.
            u      (npot.eq.5)) then
c For pure coulomb and fixed order potentials there is no delta-part:
        consde = 0.d0

```

```

        else if (npot.eq.2) then
c Initialize QCD-potential common-blocks and calculate constant multiplying
c the delta-part of the 'qcutted' potential in momentum-space:
        call iniphc(1)
        call vqdelt(consde)
        else
        write (*,*) ' Potential not implemented! Stop.'
        stop
        endif
c Delta-part of potential is absorbed by subtracting vzero from the
c original energy (shift from the potential to the free Hamiltonian):
        vzero = consde / (2.d0*pi)**3
        write (*,*) 'vzero=', vzero
c
c Find x-values pp(i) and weigths w1(i) for the gaussian quadrature;
c care about large number of points in the important intervals:
c     if (energy-vzero.le.0.d0) then
cc     call gauleg(0.d0, 1.d0, pp, w1, n/3)
cc     call gauleg(1.d0, 5.d0, pp(n/3+1), w1(n/3+1), n/3)
cc     call gauleg(0.d0, 0.2d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c     call gauleg(0.d0, 5.d0, pp, w1, n/3)
c     call gauleg(5.d0, 20.d0, pp(n/3+1), w1(n/3+1), n/3)
c     call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c     else
cc Avoid numerical singular points in the inner of the intervals:
c     critp = dsqrt((energy-vzero)*tmass)
c     if (critp.le.1.d0) then
cc Gauss-Legendre is symmetric => automatically principal-value prescription:
c     call gauleg(0.d0, 2.d0*critp, pp, w1, n/3)
c     call gauleg(2.d0*critp, 20.d0, pp(n/3+1),
c     u     w1(n/3+1), n/3)
c     call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c     else
cc Better behaviour at the border of the intervals:
c     call gauleg(0.d0, critp, pp, w1, n/3)
c     call gauleg(critp, 2.d0*critp, pp(n/3+1),
c     u     w1(n/3+1), n/3)
c     call gauleg(0.d0, 1.d0/(2.d0*critp), pp(2*n/3+1),
c     u     w1(2*n/3+1), n/3)
c     endif
c     endif
c
c Or different (simpler) method, good for V_JKT:
        if (energy.le.0.d0) then
        critp=tmass/3.d0
        else
        critp=max(tmass/3.d0,2.d0*dsqrt(energy*tmass))
        endif
        call gauleg(0.d0, critp, pp, w1, 2*n/3)
        call gauleg(1.d0/xpmax, 1.d0/critp, pp(2*n/3+1),
c     u     w1(2*n/3+1), n/3)
c
c Do substitution p => 1/p for the last interval explicitly:
        do 10 i=2*n/3+1,n

```

```

        pp(i) = 1.d0/pp(i)
10      continue
c
c Reorder the arrays for the third interval:
      do 20 i=1,n/3
        xx(i) = pp(2*n/3+i)
        w2(i) = w1(2*n/3+i)
20      continue
      do 30 i=1,n/3
        pp(n-i+1) = xx(i)
        w1(n-i+1) = w2(i)
30      continue
c
c Calculate the integrals a(p) for the given momenta pp(i)
c and store weights and momenta for the output arrays:
      do 40 i=1,n
        a1(i) = a(pp(i)) !!! FB: can get stuck in original Toppik!

c Correction function for non-constant (energy and momentum dependent) width:
      FUNCTION GTPCOR1(TOPP,ETOT)
c
c      TOPP - momentum of t quark = - momentum of tbar
c      ETOT - total energy of t-tbar system
c      calls: GENWDS, RAN2
c
c      Evaluates a correction factor to the width of t-tbar system.
c      in future has to be replaced by a function evaluating
c      width including radiative corrections and GTPCOR.
c      I include two factors reducing the width:
c      a - time dilatation: for decay in flight lifetime

```

```

c      increased accordingly to relativistic kinematics
c      b - overall energy-momentum conservation: I assume that
c      t and tbar decay in flight and in this decays energies
c      of Ws follow from 2-body kinematics. Then I calculate
c      effective mass squared of b-bar system (it may be
c      negative!) from en-momentum conservation.
c      If effective mass is < 2*Mb + 2 GeV configuration
c      is rejected. The weight is acceptance.

c                  are set to zero in the Lippmann-Schwinger equation
c      xc0       : 0th order coefficient for the Coulomb potential,
c                  see calling example above
c      xc1       : 1st order coefficient for the Coulomb potential
c      xc2       : 2nd order coefficient for the Coulomb potential
c      xcdeltc   : constant of the delta(r)-
c                  [= constant in momentum space-] potential
c      xcdeletl  : constant for the additional  $\log(q^2/\mu^2)$ -part of the
c                  delta-potential:
c                   $xcdeltc * 1 + xcdeletl * \log(q^2/\mu^2)$ 
c      xcfullc   : constant of the  $(p^2+q^2)/(p-q)^2$ -potential
c      xcfulll   : constant for the additional  $\log(q^2/\mu^2)$ -part of the
c                   $(p^2+q^2)/(p-q)^2$ -potential
c      xcrm2     : constant of the  $1/r^2 - [1/|p-q|]$ -potential
c      xkincm    : } kinetic corrections in the 0th order Green function:
c      xkinca    : }  $G_0(p) := 1/[E + i\Gamma_t - p^2/m_t] * (1 + xkincm) + xkinca$ 
c      !!! WATCH THE SIGN IN G_0 !!!

```

```

c   jknflg   :   flag for these kinetic corrections:
c               0 : no kinetic corrections applied
c               1 : kinetic corrections applied with cutoff xcutv
c                   for xkinca only
c               2 : kinetic corrections applied with cutoff xcutv
c                   for xkinca AND xkincm
c   jgcflg   :   flag for G_0(p) in the LS equation:
c               0 (standard choice) : G_0(p) as given above
c               1 (for TIPT)         : G_0(p) = G_c^{0}(p) the 0th
c                                       order Coulomb Green function
c                                       in analytical form; not for
c                                       momenta p > 1000*topmass
c   xkincv   :   additional kinematic vertexcorrection in G_0, see below:
c   jvflg    :   flag for the additional vertexcorrection xkincv in the
c               'zeroth order' G_0(p) in the LS-equation:
c               0 : no correction, means G = G_0 + G_0 int V G
c                   with G_0=1/[E+iGamma_t-p^2/m_t]*(1+xkincm)+xkinca
c               1 : apply the correction in the LS equation as
c                   G = G_0 + xkincv*p^2/m_t^2/[E+iGamma_t-p^2/m_t] +
c                   G_0 int V G
c               and correct the integral over Im[G(p)] to get sigma_tot
c               from the optical theorem by the same factor.
c               The cutoff xcutv is applied for these corrections.
c
c -- Output:
c
c   xim      :   R^{P wave}_{ttbar} from the imaginary part of the Green
c               function
c   xdi      :   R^{P wave}_{ttbar} from the integral over the momentum
c               distribution: int_0^xcutv dp p^3/m_t*|F(p,E)|^2
c   np       :   number of points used for the grid; fixed in tttoppik
c   xpp      :   1-dim array (max. 400 elements) giving the momenta of
c               the Gauss-Legendre grid (pp(i) in the code)
c   xww      :   1-dim array (max. 400 elements) giving the corresponding
c               Gauss-Legendre weights for the grid
c   xdsdp    :   1-dim array (max. 400 elements) giving the
c               momentum distribution of top: d\sigma^{P wave}/dp,
c               normalized to R,
c               at the momenta of the Gauss-Legendre grid xpp(i)
c   zftild   :   1-dim array (max. 400 elements) of COMPLEX*16 numbers
c               giving the vertex function K_A for the P-wave
c               at the momenta of the grid.
c               Then F(p)=K_A (p)*G_0(p) corresponding to G=K_V*G_0.

        stop
    endif
endif

```

```

c Delta-part of potential is absorbed by subtracting vzero from the
c original energy (shift from the potential to the free Hamiltonian):
      vzero = consde / (2.d0*pi)**3
c      write (*,*) 'vzero=', vzero
c
c Find x-values pp(i) and weights w1(i) for the gaussian quadrature;
c care about large number of points in the important intervals:
c      if (energy-vzero.le.0.d0) then
cc      call gauleg(0.d0, 1.d0, pp, w1, n/3)
cc      call gauleg(1.d0, 5.d0, pp(n/3+1), w1(n/3+1), n/3)
cc      call gauleg(0.d0, 0.2d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c      call gauleg(0.d0, 5.d0, pp, w1, n/3)
c      call gauleg(5.d0, 20.d0, pp(n/3+1), w1(n/3+1), n/3)
c      call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c      else
cc Avoid numerical singular points in the inner of the intervals:
c      critp = sqrt((energy-vzero)*tmass)
c      if (critp.le.1.d0) then
cc Gauss-Legendre is symmetric => automatically principal-value prescription:
c      call gauleg(0.d0, 2.d0*critp, pp, w1, n/3)
c      call gauleg(2.d0*critp, 20.d0, pp(n/3+1),
c      u      w1(n/3+1), n/3)
c      call gauleg(0.d0, 0.05d0, pp(2*n/3+1), w1(2*n/3+1), n/3)
c      else
cc Better behaviour at the border of the intervals:
c      call gauleg(0.d0, critp, pp, w1, n/3)
c      call gauleg(critp, 2.d0*critp, pp(n/3+1),
c      u      w1(n/3+1), n/3)
c      call gauleg(0.d0, 1.d0/(2.d0*critp), pp(2*n/3+1),
c      u      w1(2*n/3+1), n/3)
c      endif
c      endif
c
c Or different (simpler) method, good for V_JKT:
      if (energy.le.0.d0) then
        critp=tmass/3.d0
      else
        critp=max(tmass/3.d0,2.d0*sqrt(energy*tmass))
      endif
      call gauleg(0.d0, critp, pp, w1, 2*n/3)
      call gauleg(1.d0/xpmax, 1.d0/critp, pp(2*n/3+1),
c      u      w1(2*n/3+1), n/3)
c
c Do substitution p => 1/p for the last interval explicitly:
      do 10 i=2*n/3+1,n
        pp(i) = 1.d0/pp(i)
10      continue
c
c Reorder the arrays for the third interval:
      do 20 i=1,n/3
        xx(i) = pp(2*n/3+i)
        w2(i) = w1(2*n/3+i)
20      continue
      do 30 i=1,n/3

```

```

        pp(n-i+1) = xx(i)
        w1(n-i+1) = w2(i)
30      continue
c
c Calculate the integrals aax(p) for the given momenta pp(i)
c and store weights and momenta for the output arrays:
      do 40 i=1,n
        a1(i) = aax(pp(i)) !!! FB: can get stuck in original Toppik!
        !!! FB: abuse 'np' as a flag to communicate unstable runs
        if ( abs(a1(i)) .gt. 1d10 ) then
          np = -1
          return
        endif
        xpp(i)=pp(i)
        xww(i)=w1(i)
40      continue
      do 41 i=n+1,nmax
        xpp(i)=0.d0
        xww(i)=0.d0
41      continue
c
c Solve the integral-equation by solving a system of algebraic equations:
      call saeax(pp, w1, bb, vec, a1, n)
c
c (The substitution for the integration to infinity pp => 1/pp
c is done already.)
      do 50 i=1,n

Chapter 29

Integration and Process Objects

This is the central part of the WHIZARD package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

subevt_expr This enables process observables as (abstract) expressions, to be evaluated for each process call.

parton_states A `parton_state_t` object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

process Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: `prc_core` for matrix-element evaluation, `prc_core_def` for the associated configuration and

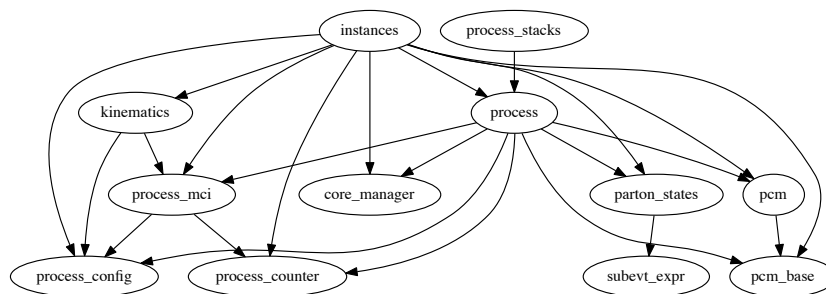

Figure 29.1: Module dependencies in `src/process_integration`.

driver, **sf_base** for beams and structure-functions, **phs_base** for phase space, and **mci_base** for integration and event generation.

process_config

process_counter Very simple object for statistics

process_mci

kinematics

instances While the above modules set up all static information, the instances have the changing event data. There are term and process instances but no component instances.

process_stacks Process stacks collect process objects.

We combine here hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the **computed** state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the **observed** state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible subsequent decay processes on the parton level, which are full-fledged process objects themselves.

29.1 Process observables

We define an abstract `subevt_expr_t` object as an extension of the `subevt_t` type. The object contains a local variable list, variable instances (as targets for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the `subevt`.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression `selection` which determines whether the object passes user-defined cuts.

The intention is that we fill the `subevt_t` base object and compute the variables once we have evaluated a kinematical phase space point (or a complete event). We then evaluate the expressions and can use the results in further calculations.

The `process_expr_t` extension contains furthermore scale and weight expressions. The `event_expr_t` extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

Note that there are unit tests, but they are deferred to the `expr_tests` module.

```

        type(var_list_t), intent(in), target :: var_list
        call expr%var_list%link (var_list)
    end subroutine subevt_expr_link_var_list

```

Compile the selection expression. If there is no expression, the build method won't allocate the expression object.

```

<Subevt expr: subevt expr: TBP>+≡
    procedure :: setup_selection => subevt_expr_setup_selection
<Subevt expr: procedures>+≡
    subroutine subevt_expr_setup_selection (expr, ef_cuts)
        class(subevt_expr_t), intent(inout), target :: expr
        class(expr_factory_t), intent(in) :: ef_cuts
        call ef_cuts%build (expr%selection)
        if (allocated (expr%selection)) then
            call expr%setup_var_self ()
            call expr%selection%setup_lexpr (expr%var_list)
            expr%has_selection = .true.
        end if
    end subroutine subevt_expr_setup_selection

```

29.1.3 Evaluation

Reset to initial state, i.e., mark the subevt as invalid.

```

<Subevt expr: subevt expr: TBP>+≡
    procedure :: reset => subevt_expr_reset
    procedure :: base_reset => subevt_expr_reset
<Subevt expr: procedures>+≡
    subroutine subevt_expr_reset (expr)
        class(subevt_expr_t), intent(inout) :: expr
        expr%subevt_filled = .false.
    end subroutine subevt_expr_reset

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

<Subevt expr: subevt expr: TBP>+≡
    procedure :: base_evaluate => subevt_expr_evaluate

```

```

<Subvt expr: procedures>+≡
  subroutine subvt_expr_evaluate (expr, passed)
    class(subvt_expr_t), intent(inout) :: expr
    logical, intent(out) :: passed
    if (expr%has_selection) then
      call expr%selection%evaluate ()
      if (expr%selection%is_known ()) then
        passed = expr%selection%get_log ()
      else
        call msg_error ("Evaluate selection expression: result undefined")
        passed = .false.
      end if
    else
      passed = .true.
    end if
  end subroutine subvt_expr_evaluate

```

29.1.4 Implementation for partonic events

This implementation contains the expressions that we can evaluate for the partonic process during integration.

```

<Subvt expr: public>≡
  public :: parton_expr_t

<Subvt expr: types>+≡
  type, extends (subvt_expr_t) :: parton_expr_t
    integer, dimension(:), allocatable :: i_beam
    integer, dimension(:), allocatable :: i_in
    integer, dimension(:), allocatable :: i_out
    logical :: has_scale = .false.
    logical :: has_fac_scale = .false.
    logical :: has_ren_scale = .false.
    logical :: has_weight = .false.

      end if
    end subroutine parton_expr_setup_weight

```

Filling the partonic state consists of two parts. The first routine prepares the subvt without assigning momenta. It takes the particles from an `interaction_t`. It needs the indices and flavors for the beam, incoming, and outgoing particles.

We can assume that the particle content of the subvt does not change. Therefore, we set the event variables `n_in`, `n_out`, `n_tot` already in this initialization step.

```

  <Subvt expr: parton expr: TBP>+≡
    procedure :: setup_subvt => parton_expr_setup_subvt
  <Subvt expr: procedures>+≡
    subroutine parton_expr_setup_subvt (expr, int, &

29.1.5 Implementation for full events

This implementation contains the expressions that we can evaluate for the full event. It also contains data that pertain to the event, suitable for communication with external event formats. These data simultaneously serve as pointer targets for the variable lists hidden in the expressions (eval trees).

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

```

<Subvt expr: public>+≡
  public :: event_expr_t

<Subvt expr: types>+≡
  type, extends (subvt_expr_t) :: event_expr_t
    logical :: has_reweight = .false.

29.2 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states, depending on the the beam setup allows. The result is used for integration.

The `matrix` evaluator is the counterpart of `trace` which is kept exclusive in all observable quantum numbers. The `flows` evaluator is furthermore exclusive in colors, but neglecting all color interference. The `matrix` and `flows` evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. However, this causes memory corruption in gfortran 4.6.3. The extra `has_XXX` flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the `processes` module below.

```

  <Parton states: procedures>

end module parton_states

```

29.2.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

<Parton states: types>≡
  type, abstract :: parton_state_t
    logical :: has_trace = .false.
    logical :: has_matrix = .false.
    logical :: has_flows = .false.
    type(enumerator_t) :: trace
    type(enumerator_t) :: matrix
    type(enumerator_t) :: flows
  contains

```

```

    <Parton states: parton state: TBP>
end type parton_state_t

```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both implemented as a pointer. The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```

<Parton states: public>≡
    public :: isolated_state_t

<Parton states: types>+≡
    type, extends (parton_state_t) :: isolated_state_t
        logical :: sf_chain_is_allocated = .false.
        type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()
        logical :: int_is_allocated = .false.
        type(interaction_t), pointer :: int_eff => null ()
    contains
        <Parton states: isolated state: TBP>
    end type isolated_state_t

```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

```

<Parton states: types>+≡
    public :: connected_state_t

<Parton states: types>+≡
    type, extends (parton_state_t) :: connected_state_t
        type(state_flv_content_t) :: state_flv
        logical :: has_flows_sf = .false.
        type(evaluator_t) :: flows_sf
        logical :: has_expr = .false.
        type(parton_expr_t) :: expr
    contains
        <Parton states: connected state: TBP>
    end type connected_state_t

```

Output: each evaluator is written only when it is active. The `sf_chain` is only written if it is explicitly allocated.

```

29.2.2 Common Initialization

Initialize the isolated parton state. In this version, the effective structure-function chain `sf_chain_eff` and the effective interaction `int_eff` both are trivial pointers to the seed structure-function chain and to the hard interaction, respectively.

```

(Parton states: isolated state: TBP)≡
  procedure :: init => isolated_state_init

(Parton states: procedures)+≡
  subroutine isolated_state_init (state, sf_chain, int)
    class(isolated_state_t), intent(out) :: state

```

```

type(sf_chain_instance_t), intent(in), target :: sf_chain
type(interaction_t), intent(in), target :: int
state%sf_chain_eff => sf_chain
state%int_eff => int
end subroutine isolated_state_init

```

29.2.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask_in`.

There are two options: explicitly computing the color factor table (`use_cf` false; `nc` defined), or taking the color factor table from the hard matrix element data.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_square_trace => isolated_state_setup_square_trace

(Parton states: procedures)+≡
  subroutine isolated_state_setup_square_trace (state, core, &
    qn_mask_in, col)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), intent(in), dimension(:) :: qn_mask_in
    !!! Actually need allocatable attribute here fore once because col might
    !!! enter the subroutine non-allocated.
    integer, intent(in), dimension(:), allocatable :: col
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    associate (data => core%data)
      allocate (qn_mask (data%n_in + data%n_out))
      qn_mask( : data%n_in) = &
        quantum_numbers_mask (.false., .true., .false.) &
        .or. qn_mask_in
      qn_mask(data%n_in + 1 : ) = &
        quantum_numbers_mask (.true., .true., .true.)
    if (core%use_color_factors) then
      call state%trace%init_square (state%int_eff, qn_mask, &
        col_flow_index = data%cf_index, &
        col_factor = data%color_factors, &
        col_index_hi = col, &
        nc = core%nc)
    else
      call state%trace%init_square (state%int_eff, qn_mask, nc = core%nc)
    end if
    end associate
    state%has_trace = .true.
  end subroutine isolated_state_setup_square_trace

```

Setup an identity-evaluator for the trace. This implies that `me` is considered to be a squared amplitude, as for example for BLHA matrix elements.

```

(Parton states: isolated state: TBP)+≡
  procedure :: setup_identity_trace => isolated_state_setup_identity_trace

```

<Parton states: procedures>+≡

```

subroutine isolated_state_setup_identity_trace (state, core, qn_mask_in, &
    keep_fs_flavors, keep_colors)
    class(isolated_state_t), intent(inout), target :: state
    class(prc_core_t), intent(in) :: core
    type(quantum_numbers_mask_t), intent(in), dimension(:) :: qn_mask_in
    logical, intent(in), optional :: keep_fs_flavors, keep_colors
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    logical :: fs_flg_flag, col_flag
    fs_flg_flag = .true.; col_flag = .true.
    if (present(keep_fs_flavors)) fs_flg_flag = .not. keep_fs_flavors
    if (present(keep_colors)) col_flag = .not. keep_colors
    associate (data => core%data)
        allocate (qn_mask (data%n_in + data%n_out))
        qn_mask( : data%n_in) = &
            quantum_numbers_mask (.false., col_flag, .false.) .or. qn_mask_in
        qn_mask(data%n_in + 1 : ) = &
            quantum_numbers_mask (fs_flg_flag, col_flag, .true.)
    end associate
    call state%int_eff%set_mask (qn_mask)
    call state%trace%init_identity (state%int_eff)
    state%has_trace = .true.
end subroutine isolated_state_setup_identity_trace

```

Setup the evaluator for the transition matrix, exclusive in helicities where this is requested.

For all unstable final-state particles we keep polarization according to the applicable decay options. If the process is a decay itself, this applies also to the initial state.

For all polarized final-state particles, we keep polarization including off-diagonal entries. We drop helicity completely for unpolarized final-state particles.

For the initial state, if the particle has not been handled yet, we apply the provided `qn_mask_in` which communicates the beam properties.

<Parton states: isolated state: TBP>+≡

29.2.4 Evaluator initialization: connected state

Setup a trace evaluator as a product of two evaluators (incoming state, effective interaction). In the result, all quantum numbers are summed over.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`.

The `resonant` flag applies if we want to construct a decay chain. The resonance property can propagate to the final event output.

```

29.2.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

```

<Parton states: connected state: TBP>+≡
  procedure :: setup_subevt => connected_state_setup_subevt

<Parton states: procedures>+≡
  subroutine connected_state_setup_subevt (state, sf_chain, f_beam, f_in, f_out)
    class(connected_state_t), intent(inout), target :: state

  class(expr_factory_t), intent(in) :: ef_ren_scale
  call state%expr%setup_ren_scale (ef_ren_scale)
end subroutine connected_state_setup_ren_scale

subroutine connected_state_setup_weight (state, ef_weight)
  class(connected_state_t), intent(inout), target :: state
  class(expr_factory_t), intent(in) :: ef_weight
  call state%expr%setup_weight (ef_weight)
end subroutine connected_state_setup_weight
```

Reset the expression object: invalidate the subvt.

<Parton states: connected state: TBP>+≡

```
procedure :: reset_expressions => connected_state_reset_expressions
```

<Parton states: procedures>+≡

```
subroutine connected_state_reset_expressions (state)
```

```

class (connected_state_t), intent (inout) :: state
if (state%has_expr) call state%expr%reset ()
end subroutine connected_state_reset_expressions

```

29.2.6 Evaluation

Transfer momenta to the trace evaluator and fill the `subevt` with this effective kinematics, if applicable.

Note: we may want to apply a boost for the `subevt`.

```

(Parton states: parton state: TBP)+≡
  procedure :: receive_kinematics => parton_state_receive_kinematics
(Parton states: procedures)+≡
  subroutine parton_state_receive_kinematics (state)
    class (parton_state_t), intent (inout), target :: state
    if (state%has_trace) then
      call state%trace%receive_momenta ()
      select type (state)
      class is (connected_state_t)
        if (state%has_expr) then
          call state%expr%fill_subevt (state%trace%interaction_t)
        end if
      end select
    end if
  end subroutine parton_state_receive_kinematics

```

Recover kinematics: We assume that the trace evaluator is filled with momenta. Send those momenta back to the sources, then fill the variables and subevent as above.

The incoming momenta of the connected state are not connected to the isolated state but to the beam interaction. Therefore, the incoming momenta within the isolated state do not become defined, yet. Instead, we reconstruct the beam (and ISR) momentum configuration.

```

(Parton states: parton state: TBP)+≡
  procedure :: send_kinematics => parton_state_send_kinematics
(Parton states: procedures)+≡
  subroutine parton_state_send_kinematics (state)
    class (parton_state_t), intent (inout), target :: state

29.3 Process component management

This module contains tools for managing and combining process components and matrix-element code and values, acting at a level below the actual process definition.

29.3.1 Abstract base type

The types introduced here are abstract base types.

$\langle \text{pcm_base.f90} \rangle \equiv$
 $\langle \text{File header} \rangle$

```

module pcm_base

    use diagnostics

    use prc_core_def
    use prc_core

     $\langle \text{Standard module head} \rangle$ 

     $\langle \text{PCM base: public} \rangle$ 

     $\langle \text{PCM base: types} \rangle$ 

     $\langle \text{PCM base: interfaces} \rangle$ 

    contains

     $\langle \text{PCM base: procedures} \rangle$ 

end module pcm_base

```

This object may hold process and method-specific data, and it should allocate the corresponding manager instance.

$\langle \text{PCM base: public} \rangle \equiv$
`public :: pcm_t`
 $\langle \text{PCM base: types} \rangle \equiv$
`type, abstract :: pcm_t`
`logical :: initialized = .false.`
`contains`
 $\langle \text{PCM base: pcm: TBP} \rangle$
`end type pcm_t`

The factory method. We use the `inout` intent, so calling this again is an error.

$\langle \text{PCM base: pcm: TBP} \rangle \equiv$
`procedure(pcm_allocate_instance), deferred :: allocate_instance`

```

<PCM base: interfaces>≡
  abstract interface
    subroutine pcm_allocate_instance (pcm, instance)
      import
      class(pcm_t), intent(in) :: pcm
      class(pcm_instance_t), intent(inout), allocatable :: instance
    end subroutine pcm_allocate_instance
  end interface

<PCM base: pcm: TBP>+≡
  procedure(pcm_is_nlo), deferred :: is_nlo

<PCM base: interfaces>+≡
  abstract interface
    function pcm_is_nlo (pcm) result (is_nlo)
      import
      logical :: is_nlo
      class(pcm_t), intent(in) :: pcm
    end function pcm_is_nlo
  end interface

<PCM base: pcm: TBP>+≡
  procedure(pcm_final), deferred :: final

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_final (pcm)
      import
      class(pcm_t), intent(inout) :: pcm
    end subroutine pcm_final
  end interface

```

29.3.2 Manager instance

This object deals with the actual (squared) matrix element values.

```

<PCM base: public>+≡
  public :: pcm_instance_t

<PCM base: types>+≡
  type, abstract :: pcm_instance_t
    class(pcm_t), pointer :: config => null ()
  contains
    <PCM base: pcm instance: TBP>
  end type pcm_instance_t

<PCM base: pcm instance: TBP>≡
  procedure(pcm_instance_final), deferred :: final

```

```

<PCM base: interfaces>+≡
  abstract interface
    subroutine pcm_instance_final (pcm_instance)
      import
      class(pcm_instance_t), intent(inout) :: pcm_instance
    end subroutine pcm_instance_final
  end interface

<PCM base: pcm instance: TBP>+≡
  procedure(pcm_instance_is_valid), deferred :: is_valid

<PCM base: interfaces>+≡
  abstract interface
    function pcm_instance_is_valid (pcm_instance) result (valid)
      import
      logical :: valid
      class(pcm_instance_t), intent(in) :: pcm_instance
    end function pcm_instance_is_valid
  end interface

<PCM base: pcm instance: TBP>+≡
  procedure :: link_config => pcm_instance_link_config

<PCM base: procedures>≡
  subroutine pcm_instance_link_config (pcm_instance, config)
    class(pcm_instance_t), intent(inout) :: pcm_instance
    class(pcm_t), intent(in), target :: config
    pcm_instance%config => config
  end subroutine pcm_instance_link_config

```

29.4 Manager configuration

This object holds information about the cores used by the components and allocates the corresponding manager instance.

```

<core_manager.f90>≡
  <File header>

  module core_manager

    use format_utils, only: write_integer_array, write_separator

```

⟨Process: procedures⟩

```
end module process
```

A process object is the workspace for the process instance. After initialization, its contents are filled by integration passes which shape the integration grids and compute cross sections. Processes are set up initially from user-level configuration data. After calculating integrals and thus developing integration grid data, the program may use a process object or a copy of it for the purpose of generating events.

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The **type** determines whether we are considering a decay or a scattering process.

The **meta** object describes the process and its environment. All contents become fixed when the object is initialized.

The **config** object holds physical and technical configuration data that have been obtained during process initialization, and which are common to all process components.

The individual process components are configured in the **component** objects. These objects contain more configuration parameters and workspace, as needed for the specific process variant.

The **term** objects describe parton configurations which are technically used as phase-space points. Each process component may split into several terms with distinct kinematics and particle content. Furthermore, each term may project on a different physical state, e.g., by particle recombination. The **term** object provides the framework for this projection, for applying cuts, weight, and thus completing the process calculation.

The **beam_config** object describes the incoming particles, either the decay mother or the scattering beams. It also contains the structure-function information.

The **mci_entry** objects configure a MC input parameter set and integrator, each. The number of parameters depends on the process component and on the beam and structure-function setup.

The **pcm** component is the process-component manager. This polymorphic object manages and hides the details of dealing with NLO processes where several components have to be combined in a non-trivial way. It also acts as an abstract factory for the corresponding object in **process_instance**, which does the actual work for this matter.

```

contains
<Process: process: TBP>
end type process_t

```

This procedure is an important debugging and inspection tool; it is not used during normal operation. The process object is written to a file (identified by unit, which may also be standard output). Optional flags determine whether we show everything or just the interesting parts.

```

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam.data.t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by

extending the code in the beams module.

We complete the kinematics configuration after the beam setup, but before we configure the chain of structure functions. The reason is that we need the total energy `sqrts` for the kinematics, but the structure-function setup requires the number of channels, which depends on the kinematics configuration. For

instance, the kinematics module may return the need for parameterizing an s-channel resonance.

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

```

MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

Let us call the ratio of the LO and the NLO result $\iota = I_{LO}/I_{NLO}$. Then usual error propagation gives

$$\sigma_{\iota}^2 = \left(\frac{\partial \iota}{\partial I_{LO}} \right)^2 \sigma_{I_{LO}}^2 + \left(\frac{\partial \iota}{\partial I_{NLO}} \right)^2 \sigma_{I_{NLO}}^2 = \frac{I_{NLO}^2 \sigma_{I_{LO}}^2}{I_{LO}^4} + \frac{\sigma_{I_{NLO}}^2}{I_{LO}^2}.$$

```

29.5.1 Default iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

(Process: process: TBP)+≡
  procedure :: get_n_pass_default => process_get_n_pass_default
  procedure :: adapt_grids_default => process_adapt_grids_default
  procedure :: adapt_weights_default => process_adapt_weights_default

(Process: procedures)+≡
  function process_get_n_pass_default (process) result (n_pass)

```

29.5.3 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```
<Process: process: TBP>+≡
  procedure :: compute_amplitude => process_compute_amplitude

<Process: procedures>+≡

29.6.1 Generic configuration data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the

variable list.

The number **n_in** is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number **n_components** is the number of components that constitute the current process.

The number **n_terms** is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number **n_mci** is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The **model** pointer identifies the physics model and its parameters. This is a pointer to an external object.

The **rng_factory** component spawns independent random-number generators for use in integration, event generation, and event postprocessing.

Various **parse_node_t** objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the **effective_state** subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The **md5sum** is taken and used to verify the process configuration when re-reading data from file.

```

end if
end subroutine process_config_data_write

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

The model that we import here should be an instance of the global model. If we create the instance outside, we can make it an extension of the basic `model_data_t`. This will allow us to synchronize the variable list with the model. Using a pointer instead of an allocatable, we can guarantee the `target` attribute.

The RNG factory object is imported by moving the allocation.

```

(Process config: process config data: TBP)+≡
  procedure :: init => process_config_data_init

(Process config: procedures)+≡
  subroutine process_config_data_init &
    (config, meta, os_data, qcd, rng_factory, model)
    class(process_config_data_t), intent(out) :: config
    type(process_metadata_t), intent(in) :: meta
    type(os_data_t), intent(in) :: os_data
    type(qcd_t), intent(in) :: qcd
    class(rng_factory_t), intent(inout), allocatable :: rng_factory
    class(model_data_t), intent(inout), pointer :: model
    config%n_in = meta%lib%get_n_in (meta%id)
    config%n_components = size (meta%component_id)
    config%os_data = os_data
    config%qcd = qcd
    call move_alloc (from = rng_factory, to = config%rng_factory)
    config%model_name = model%get_name ()
    config%model => model
    model => null ()
  end subroutine

```

```
end subroutine process_config_data_init
```

Since the captured model is a separate object allocated via a pointer, we need a finalizer.

```
<Process config: process config data: TBP>+≡
  procedure :: final => process_config_data_final

<Process config: procedures>+≡
  subroutine process_config_data_final (config)
    class(process_config_data_t), intent(inout) :: config
    if (associated (config%model)) then
      call config%model%final ()
      deallocate (config%model)
    end if
  end subroutine process_config_data_final
```

Compute the MD5 sum of the configuration data. This encodes, in particular, the model and the expressions for cut, scales, weight, etc. It should not contain the IDs and number of components, etc., since the MD5 sum should be useful for integrating individual components.

This is done only once. If the MD5 sum is nonempty, the calculation is skipped.

```
<Process config: process config data: TBP>+≡
  procedure :: compute_md5sum => process_config_data_compute_md5sum

<Process config: procedures>+≡
  subroutine process_config_data_compute_md5sum (config)
    class(process_config_data_t), intent(inout) :: config
    integer :: u
    if (config%md5sum == "") then
      u = free_unit ()
      open (u, status = "scratch", action = "readwrite")
      call config%write (u, counters = .false., os_data = .false., &
        rng_factory = .false., model = .true., expressions = .true.)
      rewind (u)
      config%md5sum = md5sum (u)
      close (u)
    end if
  end subroutine process_config_data_compute_md5sum

<Process config: process config data: TBP>+≡
  procedure :: get_md5sum => process_config_data_get_md5sum

<Process config: procedures>+≡
  pure function process_config_data_get_md5sum (config) result (md5)
    character(32) :: md5
    class(process_config_data_t), intent(in) :: config
    md5 = config%md5sum
  end function process_config_data_get_md5sum
```

29.6.2 Metadata

This information describes the process and its environment. It is fixed upon initialization.

The `id` string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The `num_id` is meaningful if nonzero. It is used for communication with external programs or file standards which do not support string IDs.

The `run_id` string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The `var_list` is a snapshot of the variable list, taken at the point where the process was initialized.

The `lib` pointer accesses the process library where the process definition and the process driver are located.

The `lib_index` is the index of entry in the process library that corresponds to the current process.

The `component_id` array identifies the individual process components.

The `component_description` is an array of human-readable strings that characterize the process components, for instance `a, b => c, d`.

The `active` mask array marks those components which are active. The others are skipped.

```

29.6.3 Beam configuration

The object `data` holds all details about the initial beam configuration. The allocatable array `sf` holds the structure-function configuration blocks. There are `n_strfun` entries in the structure-function chain (not counting the initial beam object). We maintain `n_channel` independent parameterizations of this chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is `n_sfpar`.

The flag `azimuthal_dependence` tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag `lab_is_cm_frame` is obvious.

```

29.6.4 Process components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components can have different types. In short, `process_component_t` is a wrapper for the actual process variants.

If the `active` flag is false, we should skip this component. This happens if the associated process has vanishing matrix element.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

(Process config: public)+≡
  public :: process_component_t

```

```

<Process config: types>+≡
  type :: process_component_t
    type(process_component_def_t), pointer :: config => null ()
    integer :: index = 0
    logical :: active = .false.
    class(mci_t), allocatable :: mci_template
    integer, dimension(:), allocatable :: i_term
    integer :: i_mci = 0
    class(phs_config_t), allocatable :: phs_config
    character(32) :: md5sum_phs = ""
    integer :: component_type = COMP_DEFAULT
  contains
    <Process config: process component: TBP>
  end type process_component_t

```

Finalizer. The MCI template may (potentially) need a finalizer. The process configuration finalizer may include closing an open scratch file.

```

29.6.5 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with

distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`. In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`. This is the total number of independent entries in the density matrix. For each combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

This type is public only for use in a unit test.

```

(Process config: public)+≡
  public :: process_term_t

(Process config: types)+≡
  type :: process_term_t
    integer :: i_term_global = 0
    integer :: i_component = 0
    integer :: i_term = 0
    integer :: i_sub = 0
    integer :: i_core = 0
    integer :: n_allowed = 0
    type(process_constants_t) :: data
    real(default) :: alpha_s = 0
    integer, dimension(:), allocatable :: flv, hel, col
    type(interaction_t) :: int
    type(interaction_t), pointer :: int_eff => null ()
  contains
    (Process config: process term: TBP)
  end type process_term_t

```

For the output, we skip the process constants and the tables of allowed quantum numbers. Those can also be read off from the interaction object.

```

(Process config: process term: TBP)≡
  procedure :: write => process_term_write

            call it%advance ()
        end do
    end subroutine process_term_write_state_summary

```

Finalizer: the int and potentially int_eff components have a finalizer that we must call.

```

<Process config: process term: TBP>+≡
    procedure :: final => process_term_final

```

```

(Process config: procedures)+≡
  subroutine process_term_final (term)
    class(process_term_t), intent(inout) :: term
    call term%int%final ()
  end subroutine process_term_final

```

Initialize the term. We copy the process constants from the `core` object and set up the `int` hard interaction accordingly.

The `alpha_s` value is useful for writing external event records. This is the constant value which may be overridden by a event-specific running value. If the model does not contain the strong coupling, the value is zero.

The `rearrange` part is commented out; this or something equivalent could become relevant for NLO algorithms.

```

(Process config: process term: TBP)+≡
  procedure :: init => process_term_init

(Process config: procedures)+≡
  subroutine process_term_init &
    (term, i_term_global, i_component, i_term, core, model, &

      pol_beams = use_beam_pol, use_internal_color = use_internal_color)
  end subroutine process_term_init

```

We fetch the process constants which determine the quantum numbers and use those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square

matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

```

29.7 Process call statistics

Very simple object for statistics. Could be moved to a more basic chapter.

```

<process_counter.f90>≡
  <File header>

```

```

module process_counter

```

```

  <Use kinds>
  use io_units

```

```

    <Standard module head>

    <Process counter: public>

    <Process counter: parameters>

    <Process counter: types>

```

```
contains
```

```
    <Process counter: procedures>
```

```
end module process_counter
```

This object can record process calls, categorized by evaluation status. It is a part of the `mci_entry` component below.

```

<Process counter: public>≡
    public :: process_counter_t

<Process counter: types>≡
    type :: process_counter_t
        integer :: total = 0
        integer :: failed_kinematics = 0
        integer :: failed_cuts = 0
        integer :: has_passed = 0
        integer :: evaluated = 0
        integer :: complete = 0
    contains
        <Process counter: process counter: TBP>
    end type process_counter_t

```

Here are the corresponding numeric codes:

```

<Process counter: parameters>≡
    integer, parameter, public :: STAT_UNDEFINED = 0
    integer, parameter, public :: STAT_INITIAL = 1
    integer, parameter, public :: STAT_ACTIVATED = 2
    integer, parameter, public :: STAT_BEAM_MOMENTA = 3
    integer, parameter, public :: STAT_FAILED_KINEMATICS = 4
    integer, parameter, public :: STAT_SEED_KINEMATICS = 5
    integer, parameter, public :: STAT_HARD_KINEMATICS = 6
    integer, parameter, public :: STAT_EFF_KINEMATICS = 7
    integer, parameter, public :: STAT_FAILED_CUTS = 8
    integer, parameter, public :: STAT_PASSED_CUTS = 9
    integer, parameter, public :: STAT_EVALUATED_TRACE = 10
    integer, parameter, public :: STAT_EVENT_COMPLETE = 11

```

Output.

```

<Process counter: process counter: TBP>≡
    procedure :: write => process_counter_write

<Process counter: procedures>≡
    subroutine process_counter_write (object, unit)
        class(process_counter_t), intent(in) :: object
        integer, intent(in), optional :: unit
    end subroutine

```

```

integer :: u
u = given_output_unit (unit)
if (object%total > 0) then
  write (u, "(1x,A)") "Call statistics (current run):"
  write (u, "(3x,A,I0)") "total          = ", object%total
  write (u, "(3x,A,I0)") "failed kin. = ", object%failed_kinematics
  write (u, "(3x,A,I0)") "failed cuts = ", object%failed_cuts
  write (u, "(3x,A,I0)") "passed cuts = ", object%has_passed
  write (u, "(3x,A,I0)") "evaluated   = ", object%evaluated
else
  write (u, "(1x,A)") "Call statistics (current run): [no calls]"
end if
end subroutine process_counter_write

```

Reset. Just enforce default initialization.

```

⟨Process counter: process counter: TBP⟩+=
  procedure :: reset => process_counter_reset

⟨Process counter: procedures⟩+=
  subroutine process_counter_reset (counter)
    class(process_counter_t), intent(out) :: counter
  end subroutine process_counter_reset

```

We record an event according to the lowest status code greater or equal to the actual status. This is actually done by the process instance; the process object just copies the instance counter.

```

⟨Process counter: process counter: TBP⟩+=
  procedure :: record => process_counter_record

⟨Process counter: procedures⟩+=
  subroutine process_counter_record (counter, status)
    class(process_counter_t), intent(inout) :: counter
    integer, intent(in) :: status
    if (status <= STAT_FAILED_KINEMATICS) then
      counter%failed_kinematics = counter%failed_kinematics + 1
    else if (status <= STAT_FAILED_CUTS) then
      counter%failed_cuts = counter%failed_cuts + 1
    else if (status <= STAT_PASSED_CUTS) then
      counter%has_passed = counter%has_passed + 1
    else
      counter%evaluated = counter%evaluated + 1
    end if
    counter%total = counter%total + 1
  end subroutine process_counter_record

```

29.8 Multi-channel integration

```

⟨process_mci.f90⟩≡
  ⟨File header⟩

  module process_mci

```

```

  use phs_base
  use process_counter
  use process_config

<Standard module head>

<Process mci: public>

<Process mci: parameters>

<Process mci: types>

contains

<Process mci: procedures>

end module process_mci

```

29.8.1 Process MCI entry

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly the values that apply to the current pass. Previous values are archived in the `results` object.

The `counter` receives the counter statistics from the associated process instance, for diagnostics.

The `results` object records results, broken down in passes and iterations.

```

Initialize. From the existing configuration, we obtain the number of channels and the number of parameters, separately for the structure-function chain and for the associated process component. We assume that the phase-space object has already been configured.

The allocation of the MCI integrator with the appropriate concrete type is the duty of the process core.

We assume that there is only one component associated with a MCI entry. This restriction should be relaxed.

```

Integrate.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

Generate an event. The instance should be initialized, otherwise event generation is directed by the mci integrator subobject. The integrator instance is contained in a mci_work subobject of the process instance, which simultaneously serves as the sampler object. (We avoid the anti-aliasing rules if we assume that the sampling itself does not involve the integrator instance contained in the process instance.)

Regarding weighted events, we only take events which are valid, which means that they have valid kinematics and have passed cuts. Therefore, we have a rejection loop. For unweighted events, the unweighting routine should already take care of this.

  end function process_mci_entry_get_md5sum

```

29.8.2 MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

```

(Process mci: public)+≡
  public :: mci_work_t

(Process mci: types)+≡
  type :: mci_work_t
    type(process_mci_entry_t), pointer :: config => null ()
    real(default), dimension(:), allocatable :: x
    class(mci_instance_t), pointer :: mci => null ()
    type(process_counter_t) :: counter
    logical :: keep_failed_events = .false.
  contains
    (Process mci: mci work: TBP)
  end type mci_work_t

```

First write configuration data, then the current values.

```

(Process mci: mci work: TBP)≡
  procedure :: write => mci_work_write

(Process mci: procedures)+≡
  subroutine mci_work_write (mci_work, unit, testflag)
    class(mci_work_t), intent(in) :: mci_work
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A,I0,A)") "Active MCI instance #", &
      mci_work%config%i_mci, " ="
    write (u, "(2x)", advance="no")
    do i = 1, mci_work%config%n_par

```

```

        write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
        if (i == mci_work%config%n_par_sf) &
            write (u, "(1x,'|')", advance="no")
    end do
    write (u, *)
    if (associated (mci_work%mci)) then
        call mci_work%mci%write (u, pacify = testflag)
        call mci_work%counter%write (u)
    end if
end subroutine mci_work_write

```

The mci component may require finalization.

```

(Process mci: mci work: TBP)+≡
    procedure :: final => mci_work_final

(Process mci: procedures)+≡
    subroutine mci_work_final (mci_work)
        class(mci_work_t), intent(inout) :: mci_work

29.10 Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

sf_chain is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

`phs` is an instance of the phase space for the elementary process.

The array `f` contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either `sf_chain` or `phs` are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component (‘owned’ by the object) or as a pointer.

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

```

29.11.1 Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The `k.term` object is the instance of the kinematics setup (structure-function chain, phase space, etc.) that applies specifically to this term. In ordinary cases, it consists of straight pointers to the seed kinematics.

The `amp` array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The `int_hard` interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The `isolated` object holds the effective parton state for the elementary interaction. The amplitude entries are computed from `int_hard`.

The `connected` evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The `checked` flag is set once we have applied cuts on this term. The result of this is stored in the `passed` flag. Once the term has passed cuts, we calculate the various scale and weight expressions.

```

For initialization, we make use of defined assignment for the `interaction_t` type. This creates a deep copy.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (`rearrange`) as effective structure-function chain and interaction, respectively.

Finally, we set up the `subevt` component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective con-

nected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

The `rearrange` parts are still commented out; they could become relevant for a NLO algorithm.

Compute the momenta in the hard interactions, one for each term that constitutes this process component. In simple cases this amounts to just copying momenta. In more advanced cases, we may generate distinct sets of momenta from the seed kinematics.

The interactions in the term instances are accessed individually. We may choose to calculate all terms at once together with the seed kinematics, use `component%core_state` for storage, and just fill the interactions here.

```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on

the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

```

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain. (If we have an algorithm that uses rearrangement, it should evaluate `k_term` explicitly.)

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

```

<Instances: term instance: TBP>+≡
  procedure :: compute_eff_kinematics => &
    term_instance_compute_eff_kinematics

<Instances: procedures>+≡
  subroutine term_instance_compute_eff_kinematics (term)
    class(term_instance_t), intent(inout) :: term
    term%checked = .false.
    term%passed = .false.
    call term%isolated%receive_kinematics ()
    call term%connected%receive_kinematics ()
  end subroutine term_instance_compute_eff_kinematics

```

Inverse. Reconstruct the connected state from the momenta in the trace evaluator (which we assume to be set), then reconstruct the isolated state as far as possible. The second part finalizes the momentum configuration, using the incoming seed momenta

```

<Instances: term instance: TBP>+≡
  procedure :: recover_hard_kinematics => &
    term_instance_recover_hard_kinematics

<Instances: procedures>+≡
  subroutine term_instance_recover_hard_kinematics (term)
    class(term_instance_t), intent(inout) :: term
    term%checked = .false.
    term%passed = .false.
    call term%connected%send_kinematics ()
    call term%isolated%send_kinematics ()
  end subroutine term_instance_recover_hard_kinematics

```

Check the term whether it passes cuts and, if successful, evaluate scales and weights. The factorization scale is also given to the term kinematics, enabling structure-function evaluation.

```

<Instances: term instance: TBP>+≡
  procedure :: evaluate_expressions => &
    term_instance_evaluate_expressions

<Instances: procedures>+≡
  subroutine term_instance_evaluate_expressions (term, scale_forced)
    class(term_instance_t), intent(inout) :: term
    real(default), intent(in), allocatable, optional :: scale_forced
    call term%connected%evaluate_expressions (term%passed, &
      term%scale, term%fac_scale, term%ren_scale, term%weight, &
      scale_forced)
    term%checked = .true.
  end subroutine term_instance_evaluate_expressions

```

Evaluate the trace: first evaluate the hard interaction, then the trace evaluator. We use the `evaluate_interaction` method of the process component which generated this term. The `subevt` and `cut` expressions are not yet filled.

The `component` argument is `intent(inout)` because the `compute_amplitude` method may modify the `core_state` workspace object.

else
  n_hel = 1
end if
end subroutine get_numbers
end subroutine term_instance_evaluate_interaction_userdef_loop

```

Evaluate the trace. First evaluate the structure-function chain (i.e., the density matrix of the incoming partons). Do this twice, in case the sf-chain instances within `k_term` and `isolated` differ. Next, evaluate the hard interaction, then compute the convolution with the initial state.

```

<Instances: term instance: TBP>+≡
  procedure :: evaluate_trace => term_instance_evaluate_trace

<Instances: procedures>+≡
  subroutine term_instance_evaluate_trace (term)
    class(term_instance_t), intent(inout) :: term
    call term%k_term%evaluate_sf_chain (term%fac_scale)
    call term%isolated%evaluate_sf_chain (term%fac_scale)
    call term%isolated%evaluate_trace ()
    call term%connected%evaluate_trace ()
  end subroutine term_instance_evaluate_trace

```

Evaluate the extra data that we need for processing the object as a physical event.

```

<Instances: term instance: TBP>+≡
  procedure :: evaluate_event_data => term_instance_evaluate_event_data

<Instances: procedures>+≡
  subroutine term_instance_evaluate_event_data (term)
    class(term_instance_t), intent(inout) :: term
    call term%isolated%evaluate_event_data ()
    call term%connected%evaluate_event_data ()
  end subroutine term_instance_evaluate_event_data

<Instances: term instance: TBP>+≡
  procedure :: set_fac_scale => term_instance_set_fac_scale

<Instances: procedures>+≡
  subroutine term_instance_set_fac_scale (term, fac_scale)
    class(term_instance_t), intent(inout) :: term

```

```

    real(default), intent(in) :: fac_scale
    term%fac_scale = fac_scale
end subroutine term_instance_set_fac_scale

```

Return data that might be useful for external processing. The factorization scale:

```

<Instances: term instance: TBP>+≡
    procedure :: get_fac_scale => term_instance_get_fac_scale

<Instances: procedures>+≡
    function term_instance_get_fac_scale (term) result (fac_scale)
        class(term_instance_t), intent(in) :: term
        real(default) :: fac_scale
        fac_scale = term%fac_scale
    end function term_instance_get_fac_scale

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

<Instances: term instance: TBP>+≡
    procedure :: get_alpha_s => term_instance_get_alpha_s

```

29.11.2 The process instance

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jaco-

bians. These subobjects are public and used for communicating with the multi-channel integrator.

The **process** pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The **evaluation_status** code is used to check the current status. In particular, failure at various stages is recorded there.

The **count** object records process evaluations, broken down according to status.

The **sqme** value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The **weight** value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the **sqme** value times Jacobian weights from the integration, or unity, respectively.

The **i_mci** index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The **sf_chain** subobject is a realization of the beam and structure-function configuration in the **process** object. It is not used for calculation directly but serves as the template for the sf-chain instances that are contained in the **component** objects.

The **component** subobjects determine the state of each component.

The **term** subobjects are workspace for evaluating kinematics, matrix elements, cuts etc.

The **mci_work** subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the **mci_work** array is selected by the **i_mci** index above.

```

<Instances: public>≡
  public :: process_instance_t

<Instances: types>+≡
  type, extends (mci_sampler_t) :: process_instance_t
    type(process_t), pointer :: process => null ()
    integer :: evaluation_status = STAT_UNDEFINED
    real(default) :: sqme = 0
    real(default) :: weight = 0
    real(default) :: excess = 0
    integer :: i_mci = 0
    integer :: selected_channel = 0
    type(sf_chain_t) :: sf_chain
    type(term_instance_t), dimension(:), allocatable :: term

  if (reset_mci) instance%i_mci = 0
end if
instance%selected_channel = 0
instance%evaluation_status = STAT_INITIAL
end subroutine process_instance_reset

```

Integration and event generation

The sampler test should just evaluate the squared matrix element `n_calls` times, discarding the results, and return. This can be done before integration, e.g., for timing estimates.

(Instances: process instance: TBP)+≡

```

procedure :: sampler_test => process_instance_sampler_test

```

(Instances: procedures)+≡

```

subroutine process_instance_sampler_test (instance, i_mci, n_calls)
  class(process_instance_t), intent(inout), target :: instance
  integer, intent(in) :: i_mci
  integer, intent(in) :: n_calls
  integer :: i_mci_work
  i_mci_work = instance%process%get_i_mci_work (i_mci)
  call instance%choose_mci (i_mci_work)
  call instance%reset_counter ()
  call instance%process%sampler_test (instance, n_calls, i_mci_work)
  call instance%process%set_counter_mci_entry (i_mci_work, instance%get_counter ())
end subroutine process_instance_sampler_test

```

Generate a weighted event. We select one of the available MCI integrators by its index `i_mci` and thus generate an event for the associated (group of) process component(s). The arguments exactly correspond to the initializer and finalizer above.

The resulting event is stored in the `process_instance` object, which also holds the workspace of the integrator.

Note: The `process` object contains the random-number state, which changes for each event. Otherwise, all volatile data are inside the `instance` object.

(Instances: process instance: TBP)+≡

```

procedure :: generate_weighted_event => process_instance_generate_weighted_event

```

(Instances: procedures)+≡

```

subroutine process_instance_generate_weighted_event (instance, i_mci)
  class(process_instance_t), intent(inout) :: instance
  integer, intent(in) :: i_mci
  integer :: i_mci_work
  i_mci_work = instance%process%get_i_mci_work (i_mci)
  call instance%choose_mci (i_mci_work)

```

```

        associate (mci_work => instance%mci_work(i_mci_work))
        call instance%process%generate_weighted_event &
            (i_mci_work, mci_work, instance, &
             instance%keep_failed_events ())
        end associate
    end subroutine process_instance_generate_weighted_event

```

<Instances: process instance: TBP>+≡

```

    procedure :: generate_unweighted_event => process_instance_generate_unweighted_event

```

<Instances: procedures>+≡

```

    subroutine process_instance_generate_unweighted_event (instance, i_mci)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_mci
        integer :: i_mci_work
        i_mci_work = instance%process%get_i_mci_work (i_mci)
        call instance%choose_mci (i_mci_work)
        associate (mci_work => instance%mci_work(i_mci_work))
            call instance%process%generate_unweighted_event &
                (i_mci_work, mci_work, instance)
        end associate
    end subroutine process_instance_generate_unweighted_event

```

This replaces the event generation methods for the situation that the process instance object has been filled by other means (i.e., reading and/or recalculating its contents). We just have to fill in missing MCI data, especially the event weight.

<Instances: process instance: TBP>+≡

```

Subroutine of the initialization above: initialize the beam and structure-function chain template. We establish pointers to the configuration data, so `beam.config` must have a `target` attribute.

The resulting chain is not used directly for calculation. It will acquire instances which are stored in the process-component instance objects.

```

<Instances: process instance: TBP>+≡
  procedure :: setup_sf_chain => process_instance_setup_sf_chain

<Instances: procedures>+≡
  subroutine process_instance_setup_sf_chain (instance, config)
    class(process_instance_t), intent(inout) :: instance

    else
      call instance%sf_chain%init (config%data)
    end if
    if (config%sf_trace) then
      call instance%sf_chain%setup_tracing (config%sf_trace_file)
    end if
  end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

<Instances: process instance: TBP>+≡
  procedure :: setup_event_data => process_instance_setup_event_data

<Instances: procedures>+≡
  subroutine process_instance_setup_event_data (instance, model, i_core)

```

Choose a MC parameter set and the corresponding integrator. The choice persists beyond calls of the `reset` method above. This method is automatically called here.

```

<Instances: process instance: TBP>+≡
  procedure :: choose_mci => process_instance_choose_mci

<Instances: procedures>+≡
  subroutine process_instance_choose_mci (instance, i_mci)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    instance%i_mci = i_mci
    call instance%reset ()
  end subroutine process_instance_choose_mci

```

Explicitly set a MC parameter set. Works only if we are in initial state. We assume that the length of the parameter set is correct.

After setting the parameters, activate the components and terms that correspond to the chosen MC parameter set.

```

<Instances: process instance: TBP>+≡
  procedure :: set_mcpair => process_instance_set_mcpair

<Instances: procedures>+≡
  subroutine process_instance_set_mcpair (instance, x)
    class(process_instance_t), intent(inout) :: instance
    real(default), dimension(:), intent(in) :: x
    if (instance%evaluation_status == STAT_INITIAL) then
      associate (mci_work => instance%mci_work(instance%i_mci))
        call mci_work%set (x)
      end associate
      call instance%activate ()
    end if
  end subroutine process_instance_set_mcpair

```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The sf-chain instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```

<Instances: process instance: TBP>+≡
  procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

<Instances: procedures>+≡
  subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%receive_beam_momenta ()
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_receive_beam_momenta

```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```

<Instances: process instance: TBP>+≡
  procedure :: set_beam_momenta => process_instance_set_beam_momenta

<Instances: procedures>+≡
  subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%set_beam_momenta (p)
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_set_beam_momenta

```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```

<Instances: process instance: TBP>+≡
  procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

<Instances: procedures>+≡
  subroutine process_instance_recover_beam_momenta (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    if (.not. instance%process%lab_is_cm_frame ()) then
      if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
        call instance%term(i_term)%return_beam_momenta ()
      end if
    end if
  end subroutine process_instance_recover_beam_momenta

```

Explicitly choose MC integration channel. We assume here that the channel count is identical for all active components.

```

<Instances: process instance: TBP>+≡
  procedure :: select_channel => process_instance_select_channel

```

```

<Instances: procedures>+≡
  subroutine process_instance_select_channel (instance, channel)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    instance%selected_channel = channel
  end subroutine process_instance_select_channel

```

First step of process evaluation: set up seed kinematics. That is, for each active process component, compute a momentum array from the MC input parameters.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Instances: process instance: TBP>+≡
  procedure :: compute_seed_kinematics => &
    process_instance_compute_seed_kinematics

                (instance%mci_work(instance%i_mci), channel, success)
              call instance%transfer_same_kinematics (i_term(j))
              call instance%redo_sf_chains (i_term(j), channel)
            end if
            call instance%term(i_term(j))%evaluate_radiation_kinematics &
              (instance%mci_work(instance%i_mci))
            if (.not. success) exit
          end do
        end if
        if (allocated (i_term)) deallocate (i_term)
      end do
      if (success) then

```

```

        instance%evaluation_status = STAT_SEED_KINEMATICS
    else
        instance%evaluation_status = STAT_FAILED_KINEMATICS
    end if
end if
end if
associate (mci_work => instance%mci_work(instance%i_mci))
    select type (pcm => instance%pcm)
    class is (pcm_instance_nlo_t)
        call pcm%set_x_rad (mci_work%get_x_process ())
    end select
end associate
end subroutine process_instance_compute_seed_kinematics

```

Inverse: recover missing parts of the kinematics from the momentum configuration, which we know for a single term and component. Given a channel, reconstruct the MC parameter set.

```

<Instances: process instance: TBP>+≡
    procedure :: recover_mcpair => process_instance_recover_mcpair
<Instances: procedures>+≡
    subroutine process_instance_recover_mcpair (instance, i_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: i_term
        integer :: channel
        if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
            channel = instance%selected_channel
            if (channel == 0) then
                call msg_bug ("Recover MC parameters: undefined integration channel")
            end if
            call instance%term(i_term)%recover_mcpair &
                (instance%mci_work(instance%i_mci), channel)
        end if
    end subroutine process_instance_recover_mcpair

```

Second step of process evaluation: compute all momenta, for all active components, from the seed kinematics.

```

<Instances: process instance: TBP>+≡
    procedure :: compute_hard_kinematics => &
        process_instance_compute_hard_kinematics
<Instances: procedures>+≡
    subroutine process_instance_compute_hard_kinematics (instance, skip_term)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in), optional :: skip_term
        integer :: i
        if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
            do i = 1, size (instance%term)
                if (instance%term(i)%active) &
                    call instance%term(i)%compute_hard_kinematics (skip_term)
            end do
            instance%evaluation_status = STAT_HARD_KINEMATICS
        end if
    end subroutine process_instance_compute_hard_kinematics

```

Inverse: recover seed kinematics. We know the beam momentum configuration and the outgoing momenta of the effective interaction, for one specific term.

```

<Instances: process instance: TBP>+≡
  procedure :: recover_seed_kinematics => &
    process_instance_recover_seed_kinematics

<Instances: procedures>+≡
  subroutine process_instance_recover_seed_kinematics (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) &
      call instance%term(i_term)%recover_seed_kinematics ()
  end subroutine process_instance_recover_seed_kinematics

```

Third step of process evaluation: compute the effective momentum configurations, for all active terms, from the hard kinematics.

```

<Instances: process instance: TBP>+≡
  procedure :: compute_eff_kinematics => &
    process_instance_compute_eff_kinematics

<Instances: procedures>+≡
  subroutine process_instance_compute_eff_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: i
    if (instance%evaluation_status >= STAT_HARD_KINEMATICS) then
      do i = 1, size (instance%term)
        if (present (skip_term)) then
          if (i == skip_term) cycle
        end if
        if (instance%term(i)%active) then
          call instance%term(i)%compute_eff_kinematics ()
        end if
      end do
      instance%evaluation_status = STAT_EFF_KINEMATICS
    end if
  end subroutine process_instance_compute_eff_kinematics

```

Inverse: recover the hard kinematics from effective kinematics for one term, then compute effective kinematics for the other terms.

```

<Instances: process instance: TBP>+≡
  procedure :: recover_hard_kinematics => &
    process_instance_recover_hard_kinematics

<Instances: procedures>+≡
  subroutine process_instance_recover_hard_kinematics (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    integer :: i
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
      call instance%term(i_term)%recover_hard_kinematics ()
      do i = 1, size (instance%term)
        if (i /= i_term) then
          if (instance%term(i)%active) then

```

```

        call instance%term(i)%compute_eff_kinematics ()
    end if
end if
end do
instance%evaluation_status = STAT_EFF_KINEMATICS
end if
end subroutine process_instance_recover_hard_kinematics

```

Fourth step of process evaluation: check cuts for all terms. Where successful, compute any scales and weights. Otherwise, deactivate the term. If any of the terms has passed, set the state to STAT_PASSED_CUTS.

The argument `scale_forced`, if present, will override the scale calculation in the term expressions.

```

<Instances: process instance: TBP>+≡
    procedure :: evaluate_expressions => &
        process_instance_evaluate_expressions

<Instances: procedures>+≡
    subroutine process_instance_evaluate_expressions (instance, scale_forced)
    class(process_instance_t), intent(inout) :: instance
    real(default), intent(in), allocatable, optional :: scale_forced
    integer :: i
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
        do i = 1, size (instance%term)
            if (instance%term(i)%active) then
                call instance%term(i)%evaluate_expressions (scale_forced)
            end if
        end do
        if (any (instance%term%passed)) then
            instance%evaluation_status = STAT_PASSED_CUTS
        else
            instance%evaluation_status = STAT_FAILED_CUTS
        end if
        do i = 1, size (instance%term)
            if (instance%term(i)%nlo_type == NLO_REAL) call replace_scales (instance%term(i))
        end do
    end if
contains
    subroutine replace_scales (this_term)
    type(term_instance_t), intent(inout) :: this_term
    real(default) :: ren_scale_born, fac_scale_born
    integer :: i_sub
    i_sub = this_term%config%i_sub
    if (this_term%config%i_term_global /= i_sub) then
        ren_scale_born = instance%term(i_sub)%ren_scale
        fac_scale_born = instance%term(i_sub)%fac_scale
        this_term%ren_scale = ren_scale_born
        this_term%fac_scale = fac_scale_born
    end if
    end subroutine replace_scales
end subroutine process_instance_evaluate_expressions

```

Fifth step of process evaluation: fill the parameters for the non-selected ,chan-

nels, that have not been used for seeding. We should do this after evaluating cuts, since we may save some expensive calculations if the phase space point fails the cuts.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Instances: process instance: TBP>+≡
  procedure :: compute_other_channels => &
    process_instance_compute_other_channels

<Instances: procedures>+≡
  subroutine process_instance_compute_other_channels (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: channel, skip_component, i, j
    integer, dimension(:), allocatable :: i_term
    channel = instance%selected_channel
    if (channel == 0) then
      call msg_bug ("Compute other channels: undefined integration channel")
    end if
    if (present (skip_term)) then
      skip_component = instance%term(skip_term)%config%i_component
    else
      skip_component = 0
    end if
    if (instance%evaluation_status >= STAT_PASSED_CUTS) then
      do i = 1, instance%process%get_n_components ()
        if (i == skip_component) cycle
        if (instance%process%component_is_selected (i)) then
          allocate (i_term (size (instance%process%get_component_i_terms (i))))
          i_term = instance%process%get_component_i_terms (i)
          do j = 1, size (i_term)
            call instance%term(i_term(j))%compute_other_channels &
              (instance%mci_work(instance%i_mci), channel)
          end do
        end if
        if (allocated (i_term)) deallocate (i_term)
      end do
    end if
  end subroutine process_instance_compute_other_channels

```

Sixth step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

Final step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

If **weight** is provided, we already know the kinematical event weight (the MCI weight which depends on the kinematics sampling algorithm, but not on the matrix element), so we do not need to take it from the MCI record.

        end if
    end subroutine process_instance_normalize_weight

```

This is a convenience routine that performs the computations of the steps 1 to 5 in a single step. The arguments are the input for `set_mcpair`. After this, the evaluation status should be either `STAT_FAILED_KINEMATICS`, `STAT_FAILED_CUTS` or `STAT_EVALUATED_TRACE`.

Before calling this, we should call `choose_mci`.

```

<Instances: process instance: TBP>+≡
    procedure :: evaluate_sqme => process_instance_evaluate_sqme

<Instances: procedures>+≡
    subroutine process_instance_evaluate_sqme (instance, channel, x)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
    end subroutine process_instance_evaluate_sqme

```

```

    real(default), dimension(:), intent(in) :: x
    call instance%reset ()
    call instance%set_mcpair (x)
    call instance%select_channel (channel)
    call instance%compute_seed_kinematics ()
    call instance%compute_hard_kinematics ()
    call instance%compute_eff_kinematics ()
    call instance%evaluate_expressions ()
    call instance%compute_other_channels ()
    call instance%evaluate_trace ()
end subroutine process_instance_evaluate_sqme

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

```

<Instances: process instance: TBP>+≡
    procedure :: recover => process_instance_recover

<Instances: procedures>+≡
    subroutine process_instance_recover &
        (instance, channel, i_term, update_sqme, scale_forced)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel

    call instance%evaluate_expressions (scale_forced)
    if (update_sqme) call instance%evaluate_trace ()
end subroutine process_instance_recover

```

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the x array, and the f Jacobian array are exposed by the `sampler_t` object.

```

<Instances: process instance: TBP>+≡

```

```

    procedure :: evaluate => process_instance_evaluate
<Instances: procedures>+≡
    subroutine process_instance_evaluate (sampler, c, x_in, val, x, f)
        class(process_instance_t), intent(inout) :: sampler
        integer, intent(in) :: c
        real(default), dimension(:), intent(in) :: x_in
        real(default), intent(out) :: val
        real(default), dimension(:,:), intent(out) :: x
        real(default), dimension(:), intent(out) :: f
        call sampler%evaluate_sqme (c, x_in)
        if (sampler%is_valid ()) call sampler%fetch (val, x, f)
        call sampler%record_call ()
    end subroutine process_instance_evaluate

```

The phase-space point is valid if the event has valid kinematics and has passed the cuts.

```

<Instances: process instance: TBP>+≡
    procedure :: is_valid => process_instance_is_valid
<Instances: procedures>+≡
    function process_instance_is_valid (sampler) result (valid)
        class(process_instance_t), intent(in) :: sampler
        logical :: valid
        valid = sampler%evaluation_status >= STAT_PASSED_CUTS
    end function process_instance_is_valid

```

The `rebuild` method should rebuild the kinematics section out of the `x_in` parameter set. The integrand value `val` should not be computed, but is provided as input.

```

<Instances: process instance: TBP>+≡
    procedure :: rebuild => process_instance_rebuild
<Instances: procedures>+≡
    subroutine process_instance_rebuild (sampler, c, x_in, val, x, f)
        class(process_instance_t), intent(inout) :: sampler
        integer, intent(in) :: c
        real(default), dimension(:), intent(in) :: x_in
        real(default), intent(in) :: val
        real(default), dimension(:,:), intent(out) :: x
        real(default), dimension(:), intent(out) :: f
        call msg_bug ("process_instance_rebuild not implemented yet")
        x = 0
        f = 0
    end subroutine process_instance_rebuild

```

This is another method required by the `sampler_t` base type: fetch the data that are relevant for the MCI record.

```

<Instances: process instance: TBP>+≡
    procedure :: fetch => process_instance_fetch

```

```

<Instances: procedures>+≡
subroutine process_instance_fetch (sampler, val, x, f)
  class(process_instance_t), intent(in) :: sampler
  real(default), intent(out) :: val
  real(default), dimension(:,:), intent(out) :: x
  real(default), dimension(:), intent(out) :: f
  integer, dimension(:), allocatable :: i_terms
  integer :: i, i_term_base, cc
  integer :: n_channel

  val = 0
  associate (process => sampler%process)
    FIND_COMPONENT: do i = 1, process%get_n_components ()
      if (sampler%process%component_is_selected (i)) then
        allocate (i_terms (size (process%get_component_i_terms (i))))
        i_terms = process%get_component_i_terms (i)
        i_term_base = i_terms(1)
        associate (k => sampler%term(i_term_base)%k_term)
          n_channel = k%n_channel
          do cc = 1, n_channel
            call k%get_mcpair (cc, x(:,cc))
          end do
          f = k%f
          val = sampler%sqme * k%phs_factor
        end associate
      if (allocated (i_terms)) deallocate (i_terms)
    exit FIND_COMPONENT
  end if
end do FIND_COMPONENT
end associate
end subroutine process_instance_fetch

```

Initialize and finalize event generation for the specified MCI entry.

```

end subroutine process_instance_final_simulation

```

Accessing the process instance

Once the seed kinematics is complete, we can retrieve the MC input parameters for all channels, not just the seed channel.

Note: We choose the first active component. This makes sense only if the seed kinematics is identical for all active components.

```
<Instances: process instance: TBP>+≡
  procedure :: get_mcpair => process_instance_get_mcpair

<Instances: procedures>+≡
  subroutine process_instance_get_mcpair (instance, channel, x)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    real(default), dimension(:), intent(out) :: x
    integer :: i
    if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
      do i = 1, size (instance%term)
        if (instance%term(i)%active) then
          call instance%term(i)%k_term%get_mcpair (channel, x)
          return
        end if
      end do
      call msg_bug ("Process instance: get_mcpair: no active channels")
    else
      call msg_bug ("Process instance: get_mcpair: no seed kinematics")
    end if
  end subroutine process_instance_get_mcpair
```

Return true if the `sqme` value is known. This also implies that the event is kinematically valid and has passed all cuts.

```
<Instances: process instance: TBP>+≡
  procedure :: has_evaluated_trace => process_instance_has_evaluated_trace

<Instances: procedures>+≡
  function process_instance_has_evaluated_trace (instance) result (flag)
    class(process_instance_t), intent(in) :: instance
    logical :: flag
    flag = instance%evaluation_status >= STAT_EVALUATED_TRACE
  end function process_instance_has_evaluated_trace
```

Return true if the event is complete. In particular, the event must be kinematically valid, passed all cuts, and the event data have been computed.

```
<Instances: process instance: TBP>+≡
  procedure :: is_complete_event => process_instance_is_complete_event

<Instances: procedures>+≡
  function process_instance_is_complete_event (instance) result (flag)
    class(process_instance_t), intent(in) :: instance
    logical :: flag
    flag = instance%evaluation_status >= STAT_EVENT_COMPLETE
  end function process_instance_is_complete_event
```

Select the term for the process instance that will provide the basic event record (used in `evt_trivial_make_particle_set`). It might be necessary to write out additional events corresponding to other terms (done in `evt_nlo`).

```

<Instances: process instance: TBP>+≡

Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

NB: The `recover_beams` option should be used only when the particle set originates from an external event file, and the user has asked for it. It should be switched off when reading from raw event file.

```

<Instances: process instance: TBP>+≡
  procedure :: get_trace => process_instance_get_trace
  procedure :: set_trace => process_instance_set_trace

<Instances: procedures>+≡
  subroutine process_instance_get_trace (instance, pset, i_term)
    class(process_instance_t), intent(in), target :: instance
    type(particle_set_t), intent(out) :: pset
    integer, intent(in) :: i_term
    type(interaction_t), pointer :: int
    logical :: ok
    int => instance%get_trace_int_ptr (i_term)
    call pset%init (ok, int, int, FM_IGNORE_HELICITY, &
      [0._default, 0._default], .false., .true.)
  end subroutine process_instance_get_trace

  subroutine process_instance_set_trace &
    (instance, pset, i_term, recover_beams, check_match)
    class(process_instance_t), intent(inout), target :: instance
    type(particle_set_t), intent(in) :: pset
    integer, intent(in) :: i_term
    logical, intent(in), optional :: recover_beams, check_match
    type(interaction_t), pointer :: int
    integer :: n_in
    int => instance%get_trace_int_ptr (i_term)

Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```

<Processes: execute tests>+≡
  call test (processes_8, "processes_8", &

```

```

        "process evaluation with structure functions", &
        u, results)

Complete events

For the purpose of simplifying further tests, we implement a convenience routine that initializes a process and prepares a single event. This is a wrapup of the test `processes_10`.

The procedure is re-exported by the `processes_ut` module.

```

<Processes: public test auxiliary>≡
    public :: prepare_test_process

<Processes: test auxiliary>≡
    subroutine prepare_test_process (process, process_instance, model)
        type(process_t), intent(out), target :: process
        type(process_instance_t), intent(out), target :: process_instance
        class(model_data_t), intent(in), target :: model
        type(process_library_t), target :: lib
        type(string_t) :: libname
        type(string_t) :: procname
        type(string_t) :: run_id
        type(os_data_t) :: os_data
        class(model_data_t), pointer :: process_model

```

```

type(qcd_t) :: qcd
class(rng_factory_t), allocatable :: rng_factory
class(mci_t), allocatable :: mci_template
class(mci_t), pointer :: mci
class(phs_config_t), allocatable :: phs_config_template
real(default) :: sqrts
libname = "processes_test"
procname = libname
run_id = "run_test"

29.13 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

```
(process_stacks.f90)≡  
  <File header>  
  
  module process_stacks  
  
    <Use strings>  
    use io_units  
    use format_utils, only: write_separator  
    use diagnostics  
    use os_interface  
    use sm_qcd  
    use model_data  
    use rng_base  
    use variables  
    use observables  
    use process_libraries  
    use process  
  
    <Standard module head>  
  
    <Process stacks: public>  
  
    <Process stacks: types>  
  
    contains  
  
    <Process stacks: procedures>  
  
  end module process_stacks
```

29.13.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```
<Process stacks: public>≡  
  public :: process_entry_t  
  
<Process stacks: types>≡  
  type, extends (process_t) :: process_entry_t  
    type(process_entry_t), pointer :: next => null ()
```

```
end type process_entry_t
```

29.13.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

The process stack can be linked to another one. This allows us to work with stacks of local scope.

```
<Process stacks: public>+≡
  public :: process_stack_t

<Process stacks: types>+≡
  type :: process_stack_t
    integer :: n = 0
    type(process_entry_t), pointer :: first => null ()
    type(var_list_t), pointer :: var_list => null ()
    type(process_stack_t), pointer :: next => null ()
  contains
    <Process stacks: process stack: TBP>
  end type process_stack_t
```

Finalize partly: deallocate the process stack and variable list entries, but keep the variable list as an empty object. This way, the variable list links are kept.

```
<Process stacks: process stack: TBP>≡
  procedure :: clear => process_stack_clear

<Process stacks: procedures>≡
  subroutine process_stack_clear (stack)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), pointer :: process
    if (associated (stack%var_list)) then
      call stack%var_list%final ()
    end if
    do while (associated (stack%first))
      process => stack%first
      stack%first => process%next
      call process%final ()
      deallocate (process)
    end do
    stack%n = 0
  end subroutine process_stack_clear
```

Finalizer. Clear and deallocate the variable list.

```
<Process stacks: process stack: TBP>+≡
  procedure :: final => process_stack_final

<Process stacks: procedures>+≡
  subroutine process_stack_final (object)
    class(process_stack_t), intent(inout) :: object
    call object%clear ()
```

```

        if (associated (object%var_list)) then
            deallocate (object%var_list)
        end if
    end subroutine process_stack_final

```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```

(Process stacks: process stack: TBP)+≡
    procedure :: write => process_stack_write

(Process stacks: procedures)+≡
    recursive subroutine process_stack_write (object, unit, pacify)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        logical, intent(in), optional :: pacify
        type(process_entry_t), pointer :: process
        integer :: u
        u = given_output_unit (unit)
        call write_separator (u, 2)
        select case (object%n)
        case (0)
            write (u, "(1x,A)") "Process stack: [empty]"
            call write_separator (u, 2)
        case default
            write (u, "(1x,A)") "Process stack:"
            process => object%first
            do while (associated (process))
                call process%write (.false., u, pacify = pacify)
                process => process%next
            end do
        end select
        if (associated (object%next)) then
            write (u, "(1x,A)") "[Processes from context environment:]"
            call object%next%write (u, pacify)
        end if
    end subroutine process_stack_write

```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```

(Process stacks: process stack: TBP)+≡
    procedure :: write_var_list => process_stack_write_var_list

(Process stacks: procedures)+≡
    subroutine process_stack_write_var_list (object, unit)
        class(process_stack_t), intent(in) :: object
        integer, intent(in), optional :: unit
        if (associated (object%var_list)) then
            call var_list_write (object%var_list, unit)
        end if
    end subroutine process_stack_write_var_list

```

Short output.

```

(Process stacks: process stack: TBP)+≡
    procedure :: show => process_stack_show

```

```

<Process stacks: procedures>+≡
recursive subroutine process_stack_show (object, unit)
  class(process_stack_t), intent(in) :: object
  integer, intent(in), optional :: unit
  type(process_entry_t), pointer :: process
  integer :: u
  u = given_output_unit (unit)
  select case (object%n)
  case (0)
  case default
    process => object%first
    do while (associated (process))
      call process%show (u, verbose=.false.)
      process => process%next
    end do
  end select
  if (associated (object%next)) call object%next%show ()
end subroutine process_stack_show

```

29.13.3 Link

Link the current process stack to a global one.

```

<Process stacks: process stack: TBP>+≡
procedure :: link => process_stack_link

<Process stacks: procedures>+≡
subroutine process_stack_link (local_stack, global_stack)
  class(process_stack_t), intent(inout) :: local_stack
  type(process_stack_t), intent(in), target :: global_stack
  local_stack%next => global_stack
end subroutine process_stack_link

```

Initialize the process variable list and link the main variable list to it.

```

<Process stacks: process stack: TBP>+≡
procedure :: init_var_list => process_stack_init_var_list

<Process stacks: procedures>+≡
subroutine process_stack_init_var_list (stack, var_list)
  class(process_stack_t), intent(inout) :: stack
  type(var_list_t), intent(inout), optional :: var_list
  allocate (stack%var_list)
  if (present (var_list)) call var_list%link (stack%var_list)
end subroutine process_stack_init_var_list

```

Link the process variable list to a global variable list.

```

<Process stacks: process stack: TBP>+≡
procedure :: link_var_list => process_stack_link_var_list

<Process stacks: procedures>+≡
subroutine process_stack_link_var_list (stack, var_list)
  class(process_stack_t), intent(inout) :: stack
  type(var_list_t), intent(in), target :: var_list

```

```

    call stack%var_list%link (var_list)
end subroutine process_stack_link_var_list

```

29.13.4 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```

(Process stacks: process stack: TBP)+≡
  procedure :: push => process_stack_push

(Process stacks: procedures)+≡
  subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    process%next => stack%first
    stack%first => process
    process => null ()
    stack%n = stack%n + 1
  end subroutine process_stack_push

```

Initialize process variables for a given process ID, without setting values.

```

(Process stacks: process stack: TBP)+≡
  procedure :: init_result_vars => process_stack_init_result_vars

(Process stacks: procedures)+≡
  subroutine process_stack_init_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    call var_list_init_num_id (stack%var_list, id)
    call var_list_init_process_results (stack%var_list, id)
  end subroutine process_stack_init_result_vars

```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```

(Process stacks: process stack: TBP)+≡
  procedure :: fill_result_vars => process_stack_fill_result_vars

(Process stacks: procedures)+≡
  subroutine process_stack_fill_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    type(process_t), pointer :: process
    process => stack%get_process_ptr (id)
    if (associated (process)) then
      call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
      if (process%has_integral ()) then
        call var_list_init_process_results (stack%var_list, id, &
          integral = process%get_integral (), &
          error = process%get_error ())
      end if
    end if
  end subroutine process_stack_fill_result_vars

```

```

        end if
    else
        call msg_bug ("process_stack_fill_result_vars: unknown process ID")
    end if
end subroutine process_stack_fill_result_vars

```

29.13.5 Data Access

Tell if a process exists.

```

(Process_stacks: process_stack: TBP)+≡
    procedure :: exists => process_stack_exists

(Process_stacks: procedures)+≡
    function process_stack_exists (stack, id) result (flag)
        class(process_stack_t), intent(in) :: stack
        type(string_t), intent(in) :: id
        logical :: flag
        type(process_t), pointer :: process
        process => stack%get_process_ptr (id)
        flag = associated (process)
    end function process_stack_exists

```

Return a pointer to a process with specific ID. Look also at a linked stack, if necessary.

```

(Process_stacks: process_stack: TBP)+≡
    procedure :: get_process_ptr => process_stack_get_process_ptr

(Process_stacks: procedures)+≡
    recursive function process_stack_get_process_ptr (stack, id) result (ptr)
        class(process_stack_t), intent(in) :: stack
        type(string_t), intent(in) :: id
        type(process_t), pointer :: ptr
        type(process_entry_t), pointer :: entry
        ptr => null ()
        entry => stack%first
        do while (associated (entry))
            if (entry%get_id () == id) then
                ptr => entry%process_t
                return
            end if
            entry => entry%next
        end do
        if (associated (stack%next)) ptr => stack%next%get_process_ptr (id)
    end function process_stack_get_process_ptr

```

29.13.6 Unit tests

Test module, followed by the corresponding implementation module.

```

(process_stacks_ut.f90)≡
    (File header)

```

```

module process_stacks_ut
  use unit_tests
  use process_stacks_util

  <Standard module head>

  <Process stacks: public test>

  contains

  <Process stacks: test driver>

Chapter 30

Matching

```
<matching_base.f90>≡  
  <File header>  
  
  module matching_base  
  
    <Use strings>  
    use diagnostics  
    use sm_qcd  
    use model_data  
    use particles  
    use variables  
    use shower_base  
    use instances, only: process_instance_t  
    use rng_base  
  
    <Standard module head>  
  
    <Matching base: public>  
  
    <Matching base: parameters>  
  
    <Matching base: types>
```

Figure 30.1: Module dependencies in `src/matching`.

```
⟨Matching base: interfaces⟩
```

```
contains
```

```
⟨Matching base: procedures⟩
```

```
end module matching_base
```

30.1 Abstract Matching Type

A matching will need access to the `shower` as well as matrix elements that we currently get over `process_instance`. The `model` is intended for the backup `model_hadrons`.

```
⟨Matching base: public⟩≡
```

```
public :: matching_t
```

```
⟨Matching base: types⟩≡
```

```
type, abstract :: matching_t
  logical :: is_hadron_collision = .false.
  type(qcd_t), pointer :: qcd => null ()
  class(shower_base_t), pointer :: shower => null ()
  type(process_instance_t), pointer :: process_instance => null ()
  class(model_data_t), pointer :: model => null ()
  class(rng_t), allocatable :: rng
  type(string_t) :: process_name
contains
  ⟨Matching base: matching: TBP⟩
end type matching_t
```

```
⟨Matching base: matching: TBP⟩≡
```

```
procedure (matching_init), deferred :: init
```

```
⟨Matching base: interfaces⟩≡
```

```
abstract interface
  subroutine matching_init (matching, var_list, process_name)
  import
  class(matching_t), intent(out) :: matching
  type(var_list_t), intent(in) :: var_list
  type(string_t), intent(in) :: process_name
  end subroutine matching_init
end interface
```

If we use a polymorphic settings type, this boilerplate wouldn't be necessary but then we introduce `select type` statements all over the place.

```
⟨default matching init⟩≡
```

```
type(var_list_t), intent(in) :: var_list
type(string_t), intent(in) :: process_name
call msg_debug (D_MATCHING, "matching_init")
call matching%settings%init (var_list)
matching%process_name = process_name
```

```
⟨Matching base: matching: TBP⟩+≡
```

```
procedure (matching_write), deferred :: write
```

```

30.3 CKKW matching

This module contains the CKKW matching.

The type `ckkw_pseudo_shower_weights_t` gives the (relative) weights for different clusterings of the final particles, as given in Eq. (2.7) of hep-ph/0503281v1. Each particle has a binary labelling (power of 2) (first particle = 1, second particle = 2, third particle = 4, ...). Each recombination therefore corresponds to an integer, that is not a power of 2. For multiple subsequent recombinations, no different weights for different sequences of clustering are stored. It is assumed that the weight of a multiply recombined state is a combination of the states with one fewer recombination and that these states' contributions are proportional to their weights. For a $2 - > n$ event, the weights array thus has the size $2^{(2+n)-1}$. The `weights_by_type` array gives the weights depending on the type of the particle, the first index is the same as for weights, the second index gives the type of the new mother particle:

- 0: uncolored (γ , Z , W , Higgs)
- 1: colored (quark)
- 2: gluon
- 3: squark
- 4: gluino

`alphaS` gives the value for α_s used in the generation of the matrix element. This is needed for the reweighting using the values for a running α_s at the scales of the clusterings.

30.4 POWHEG

This module generates radiation according to the POWHEG Sudakov form factor

$$\Delta^{f_b}(\Phi_n, p_T) = \prod_{\alpha_r \in \{\alpha_r | f_b\}} \Delta_{\alpha_r}^{f_b}(\Phi_n, p_T), \quad (30.1)$$

with

$$\Delta_{\alpha_r}^{f_b}(\Phi_n, p_T) = \exp \left\{ - \left[\int d\Phi_{\text{rad}} \frac{R(\Phi_{n+1})}{B^{f_b}(\Phi_n)} \theta(k_T(\Phi_{n+1}) - p_T) \right]_{\alpha_r}^{\bar{\Phi}_n^{\alpha_r} = \Phi_n} \right\} \quad (30.2)$$

We expect that an underlying Born flavor structure f_b has been generated with a probability proportional to its contribution to the \tilde{B} at the given kinematic point.

We have to solve the equation

$$\frac{\log \Delta^{(U)}(p_T)}{\log \Delta^{(U)}(p_T^{\max})} = \log \Delta^{(U)}(p_T) = \log r_1$$

iteratively for p_T . If the current emission is not accepted, in the next step it is $\log \Delta^{(U)}(p_T^{\max}) = \log r_1$, so that we have to solve the equation

$$\log \Delta^{(U)}(p_T) = \log r_1 + \log r_2$$

using the second random number r_2 .

For massive emitters, the radiation variable ξ is constructed as follows. First,

$$\xi_{\min}(k_T^2) = \frac{\sqrt{k_T^2(k_T^2 z_2^2 + 8\bar{p}^0 q(1 - z_2)) - k_T^2 z_2}}{2q^2(1 - z_2)} \quad (30.7)$$

is computed. Then ξ_1 is computed according to the same equation with $z_2 \leftrightarrow z_1$. Finally, ξ is generated according to

$$\xi = \frac{1}{q^2} \exp \left[\log(\xi_{\min} q^2 - k_T^2) + r \log \frac{\xi_m q^2 - k_T^2}{\xi_{\min} q^2 - k_T^2} + k_T^2 \right], \quad (30.8)$$

where $\xi_m = \min(\xi_{\max}, \xi_1)$.

For each underlying Born f_b , there is a number of radiation regions. A radiation region rr may correspond multiple α_r s. The phase space only depends upon the radiation region kinematics rr and not on the specific α_r . α_r can be picked in the set $\{\alpha_r|f_b, rr\}$ proportional to their R_{α_r} . For now, we simplify things though and just work with the α_r .

The following is valid for one underlying Born.

```

30.4.4 α_s and its reweighting

The main point to ensure here is that the simple fixed-flavor-1-loop expression α_s^{rad} is larger than the more accurate α_s such that we can use a reweighting veto and use α_s^{rad} for the generation of the emission. This can be done by setting

$$\alpha_s^{\text{rad}}(\mu_0) = \alpha_s(\mu_0) \quad (30.13)$$

whereby μ_0^2 is the `scale_to_relate2` that is taken to be $p_{T,\text{min}}^2$.

Chapter 31

Event Implementation

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

event_transforms Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

decays Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

showers Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

tau_decays (not implemented yet) Let τ leptons decay taking full spin correlations into account.

events Combine all pieces to generate full events.

eio_raw Raw I/O for complete events.

31.1 Abstract Event Transforms

⟨Event transforms: procedures⟩

end module event_transforms

31.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified setting that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include `previous` and `next` pointers.

```

(Event transforms: public)≡
  public :: evt_t

(Event transforms: types)≡
  type, abstract :: evt_t
    type(process_t), pointer :: process => null ()
    type(process_instance_t), pointer :: process_instance => null ()
    class(model_data_t), pointer :: model => null ()
    class(rng_t), allocatable :: rng
    integer :: rejection_count = 0
    logical :: particle_set_exists = .false.
    type(particle_set_t) :: particle_set
    class(evt_t), pointer :: previous => null ()
    class(evt_t), pointer :: next => null ()
    real(default) :: weight = 0._default
    logical :: only_weighted_events = .false.
  contains
    (Event transforms: evt: TBP)
  end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

(Event transforms: evt: TBP)≡
  procedure :: final => evt_final
  procedure :: base_final => evt_final

(Event transforms: procedures)≡
  subroutine evt_final (evt)
    class(evt_t), intent(inout) :: evt
    if (allocated (evt%rng)) call evt%rng%final ()
    if (evt%particle_set_exists) &
      call evt%particle_set%final ()
  end subroutine evt_final

```

Print out the type of the evt.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_write_name), deferred :: write_name

(Event transforms: interfaces)≡
  abstract interface
    subroutine evt_write_name (evt, unit)
      import
      class(evt_t), intent(in) :: evt

```

```

        integer, intent(in), optional :: unit

      integer, intent(in) :: i_mci, i_term
    end subroutine evt_prepare_new_event
  end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)
      import
      class(evt_t), intent(inout) :: evt
      real(default), intent(inout) :: probability
    end subroutine evt_generate_weighted
  end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted

(Event transforms: procedures)+≡
  subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set

(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_make_particle_set
  end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

(Event transforms: evt: TBP)+≡
  procedure :: set_particle_set => evt_set_particle_set

(Event transforms: procedures)+≡
  subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
    class(evt_t), intent(inout) :: evt
    type(particle_set_t), intent(in) :: particle_set

```

```

integer, intent(in) :: i_term, i_mci
call evt%prepare_new_event (i_mci, i_term)
evt%particle_set = particle_set
evt%particle_set_exists = .true.
end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. (We need two interactions, one with color summed over, and one with the probability distributed among flows.)

We use the two values from the random number generator for factorizing the state. For testing purposes, we can provide those numbers explicitly.

```

<Event transforms: evt: TBP>+≡
  procedure :: factorize_interactions => evt_factorize_interactions

<Event transforms: procedures>+≡
  subroutine evt_factorize_interactions &
    (evt, int_matrix, int_flows, factorization_mode, keep_correlations, r)
    class(evt_t), intent(inout) :: evt
    type(interaction_t), intent(in), target :: int_matrix, int_flows
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    real(default), dimension(2) :: x
    if (present (r)) then
      if (size (r) == 2) then
        x = r
      else
        call msg_bug ("event factorization: size of r array must be 2")
      end if
    else
      call evt%rng%generate (x)
    end if
    call evt%particle_set%init (evt%particle_set_exists, &
      int_matrix, int_flows, factorization_mode, x, &
      keep_correlations, keep_virtual=.true.)
    evt%particle_set_exists = .true.
  end subroutine evt_factorize_interactions

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

```

<Event transforms: evt: TBP>+≡
  procedure :: tag_incoming => evt_tag_incoming

<Event transforms: procedures>+≡
  subroutine evt_tag_incoming (evt)
    class(evt_t), intent(inout) :: evt
    integer :: i_term, n_in

```

```

integer, dimension(:), allocatable :: beam_index, in_index
n_in = evt%process%get_n_in ()
i_term = 1
allocate (beam_index (n_in))
call evt%process_instance%get_beam_index (i_term, beam_index)
call evt%particle_set%reset_status (beam_index, PRT_BEAM)
allocate (in_index (n_in))
call evt%process_instance%get_in_index (i_term, in_index)
call evt%particle_set%reset_status (in_index, PRT_INCOMING)
end subroutine evt_tag_incoming

```

31.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

<Event transforms: public>+≡
  public :: evt_trivial_t

<Event transforms: types>+≡
  type, extends (evt_t) :: evt_trivial_t
  contains
  <Event transforms: evt trivial: TBP>
  end type evt_trivial_t

<Event transforms: evt trivial: TBP>≡
  procedure :: write_name => evt_trivial_write_name

<Event transforms: procedures>+≡
  subroutine evt_trivial_write_name (evt, unit)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event transform: trivial (hard process)"
  end subroutine evt_trivial_write_name

```

The finalizer is trivial. Some output:

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: write => evt_trivial_write

<Event transforms: procedures>+≡
  subroutine evt_trivial_write (evt, unit, verbose, more_verbose, testflag)
    class(evt_trivial_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, more_verbose, testflag
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    call evt%write_name (u)
    call write_separator (u)
    call evt%base_write (u, testflag = testflag)
  end subroutine evt_trivial_write

```

Nothing to do here:

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: prepare_new_event => evt_trivial_prepare_new_event

(Event transforms: procedures)+≡
  subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
  end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: generate_weighted => evt_trivial_generate_weighted

(Event transforms: procedures)+≡
  subroutine evt_trivial_generate_weighted (evt, probability)
    class(evt_trivial_t), intent(inout) :: evt
    real(default), intent(inout) :: probability
    probability = 1
  end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is.

```

(Event transforms: evt trivial: TBP)+≡
  procedure :: make_particle_set => evt_trivial_make_particle_set

(Event transforms: procedures)+≡
  subroutine evt_trivial_make_particle_set &
    (evt, factorization_mode, keep_correlations, r)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    integer :: i_term
    type(interaction_t), pointer :: int_matrix, int_flows
    if (evt%process_instance%is_complete_event ()) then
      i_term = evt%process_instance%select_i_term ()
      int_matrix => evt%process_instance%get_matrix_int_ptr (i_term)
      int_flows => evt%process_instance%get_flows_int_ptr (i_term)
      call evt%factorize_interactions (int_matrix, int_flows, &
        factorization_mode, keep_correlations, r)
      call evt%tag_incoming ()
    else
      call msg_bug ("Event factorization: event is incomplete")
    end if
  end subroutine evt_trivial_make_particle_set

```

        end if
    end associate
    evt%is_first_event = .false.
end subroutine evt_hadrons_first_event

```

Here we take the particle set from the previous event transform and apply the hadronization. The result is stored in the `evt%hadrons` object. We always return a probability of unity as we don't have the analytic weight of the hadronization. Invalid events have to be discarded by the caller which is why we mark the particle set as invalid.

```

31.4.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

<Decays: types>≡
  type, abstract :: any_config_t
  private
  contains
  <Decays: any config: TBP>
  end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
  procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
  interface

```

```

subroutine any_config_final (object)
  import
  class(any_config_t), intent(inout) :: object
end subroutine any_config_final
end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
  procedure (any_config_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_config_write (object, unit, indent, verbose)
      import
      class(any_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
    end subroutine any_config_write
  end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_config_t
  private
  class(any_config_t), allocatable :: c
end type particle_config_t

```

31.4.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above. This also works around a compiler bug in gfortran.

```

<Decays: types>+≡
  type, abstract :: any_t
  private
  contains
  <Decays: any: TBP>
end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final

<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
      class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface

```

```
end interface
```

The output is also deferred:

```
<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write
<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
      import
      class(any_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
    end subroutine any_write
  end interface
```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```
<Decays: types>+≡
  type :: particle_out_t
  private
    class(any_t), allocatable :: c
  end type particle_out_t
```

31.4.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```
<Decays: types>+≡
  type :: decay_term_config_t
  private
    type(particle_config_t), dimension(:), allocatable :: prt
  contains
    <Decays: decay term config: TBP>
  end type decay_term_config_t
```

Finalizer, recursive.

```
<Decays: decay term config: TBP>≡
  procedure :: final => decay_term_config_final
<Decays: procedures>≡
  recursive subroutine decay_term_config_final (object)
    class(decay_term_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%prt)) then
      do i = 1, size (object%prt)
        if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
      end do
    end if
  end subroutine decay_term_config_final
```

Output, with optional indentation

<Decays: decay term config: TBP>+≡

```
procedure :: write => decay_term_config_write
```

<Decays: procedures>+≡

```
recursive subroutine decay_term_config_write (object, unit, indent, verbose)
  class(decay_term_config_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent
  logical, intent(in), optional :: verbose
  integer :: i, j, u, ind
  logical :: verb
  u = given_output_unit (unit)
  ind = 0; if (present (indent)) ind = indent
  verb = .true.; if (present (verbose)) verb = verbose
  call write_indent (u, ind)
  write (u, "(1x,A)", advance="no") "Final state:"
  do i = 1, size (object%prt)
    select type (prt_config => object%prt(i)%c)
      type is (stable_config_t)
        write (u, "(1x,A)", advance="no") &
          char (prt_config%flv(1)%get_name ())
        do j = 2, size (prt_config%flv)
          write (u, "(':',A)", advance="no") &
            char (prt_config%flv(j)%get_name ())
        end do
      type is (unstable_config_t)
        write (u, "(1x,A)", advance="no") &
          char (prt_config%flv%get_name ())
    end select
  end do
  write (u, *)
  if (verb) then
    do i = 1, size (object%prt)
      call object%prt(i)%c%write (u, ind)
    end do
  end if
end subroutine decay_term_config_write
```

Initialize, given a set of flavors. For each flavor, we must indicate whether the particle is stable. The second index of the flavor array runs over alternatives for each decay product; alternatives are allowed only if the decay product is itself stable.

<Decays: decay term config: TBP>+≡

```
procedure :: init => decay_term_config_init

31.4.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```

<Decays: public>≡

```

```

    public :: decay_root_config_t
  <Decays: types>+≡
    type :: decay_root_config_t
      private
      type(string_t) :: process_id
      type(process_t), pointer :: process => null ()
      class(model_data_t), pointer :: model => null ()
      type(decay_term_config_t), dimension(:), allocatable :: term_config
    contains
      <Decays: decay root config: TBP>
    end type decay_root_config_t

```

The finalizer is recursive since there may be cascade decays.

```

  <Decays: decay root config: TBP>≡
    procedure :: final => decay_root_config_final
  <Decays: procedures>+≡
    recursive subroutine decay_root_config_final (object)
      class(decay_root_config_t), intent(inout) :: object
      integer :: i
      if (allocated (object%term_config)) then
        do i = 1, size (object%term_config)
          call object%term_config(i)%final ()
        end do
      end if
    end subroutine decay_root_config_final

```

The output routine is also recursive, and it contains an adjustable indentation.

```

  <Decays: decay root config: TBP>+≡
    procedure :: write => decay_root_config_write

        class(decay_root_config_t), intent(inout) :: decay
        integer, intent(in) :: i
        type(flavor_t), dimension(:, :), intent(in) :: flv

```

```

logical, dimension(:), intent(in) :: stable
class(model_data_t), intent(in), target :: model
type(process_stack_t), intent(in), optional :: process_stack
call decay%term_config(i)%init (flv, stable, model, process_stack)
end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

For the unstable particles, we have to check whether their masses match between the production and the decay. Fortunately, both versions are available for comparison.

31.4.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```

<Decays: types>+≡
type, abstract :: decay_gen_t
private
type(decay_term_t), dimension(:), allocatable :: term
type(process_instance_t), pointer :: process_instance => null ()
integer :: selected_mci = 0
integer :: selected_term = 0
contains
<Decays: decay gen: TBP>
end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

<Decays: public>+≡
public :: decay_root_t

<Decays: types>+≡
type, extends (decay_gen_t) :: decay_root_t
private
type(decay_root_config_t), pointer :: config => null ()
contains
<Decays: decay root: TBP>
end type decay_root_t

```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```

<Decays: decay gen: TBP>≡
procedure :: base_final => decay_gen_final

<Decays: procedures>+≡
recursive subroutine decay_gen_final (object)
class(decay_gen_t), intent(inout) :: object
integer :: i
if (allocated (object%term)) then

        class(decay_root_t), intent(inout) :: decay_root
        if (decay_root%selected_term > 0) then
            call decay_root%term(decay_root%selected_term)%select_chain ()
        else
            call msg_bug ("Decays: no term selected for parent process")
        end if
    end subroutine decay_root_select_chain

```

Generate a decay tree, i.e., for the selected term in the parent process, recursively generate a decay event for all unstable particles.

Factor out the trace of the connected state of the parent process. This trace should not be taken into account for unweighting the decay chain, since it was already used for unweighting the parent event, or it determines the overall event weight.

```

<Decays: decay root: TBP>+≡
    procedure :: generate => decay_root_generate
<Decays: procedures>+≡
    subroutine decay_root_generate (decay_root)
        class(decay_root_t), intent(inout) :: decay_root
        type(connected_state_t), pointer :: connected_state
        if (decay_root%selected_term > 0) then
            connected_state => decay_root%process_instance%get_connected_state_ptr &
                (decay_root%selected_term)
            call connected_state%normalize_matrix_by_trace ()
            call decay_root%term(decay_root%selected_term)%generate ()
        else
            call msg_bug ("Decays: no term selected for parent process")
        end if
    end subroutine decay_root_generate

```

31.4.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

The flavor component should be identical to the flavor component of the parent particle (`unstable` object).

```

<Decays: types>+≡

```

```

type, extends (decay_root_config_t) :: decay_config_t
  private
  type(flavor_t) :: flv
  real(default) :: weight = 0
  real(default) :: integral = 0
  real(default) :: abs_error = 0
  real(default) :: rel_error = 0
  type(selector_t) :: mci_selector
  contains
  <Decays: decay config: TBP>
end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay config: TBP>≡
  procedure :: write => decay_config_write

<Decays: procedures>+≡
  recursive subroutine decay_config_write (object, unit, indent, verbose)
    class(decay_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,A)") "Decay:"
    call object%write_header (unit, indent)
    call write_indent (u, ind)
    write (u, 2) "branching ratio =", object%weight * 100
    call write_indent (u, ind)
    write (u, 1) "partial width  =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs)    =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel)    =", object%rel_error
1   format (3x,A,ES19.12)
2   format (3x,A,F11.6,1x,'%')
    call object%write_terms (unit, indent, verbose)
  end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should be used instead.

```

<Decays: decay config: TBP>+≡
  procedure :: connect => decay_config_connect

<Decays: procedures>+≡
  recursive subroutine decay_config_connect &
    (decay, process, model, process_stack, process_instance)

```

```

class(decay_config_t), intent(out) :: decay
type(process_t), intent(in), target :: process
class(model_data_t), intent(in), target :: model
type(process_stack_t), intent(in), optional :: process_stack
type(process_instance_t), intent(in), optional, target :: process_instance
real(default), dimension(:), allocatable :: integral_mci
integer :: i, n_mci
call decay%decay_root_config_t%connect (process, model, process_stack)
decay%integral = process%get_integral ()
decay%abs_error = process%get_error ()
if (process%cm_frame ()) then
    call msg_fatal ("Decay process " // char (process%get_id ()) &
        // ": unusable because rest frame is fixed.")
end if
n_mci = process%get_n_mci ()
allocate (integral_mci (n_mci))
do i = 1, n_mci
    integral_mci(i) = process%get_integral_mci (i)
end do
call decay%mci_selector%init (integral_mci)
end subroutine decay_config_connect

```

Set the flavor entry, which repeats the flavor of the parent unstable particle.

```

<Decays: decay config: TBP>+≡
    procedure :: set_flv => decay_config_set_flv

<Decays: procedures>+≡
    subroutine decay_config_set_flv (decay, flv)
        class(decay_config_t), intent(inout) :: decay
        type(flavor_t), intent(in) :: flv
        decay%flv = flv
    end subroutine decay_config_set_flv

```

Compute embedded branchings and the relative error. This method does not apply to the decay root.

```

<Decays: decay config: TBP>+≡
    procedure :: compute => decay_config_compute

<Decays: procedures>+≡
    recursive subroutine decay_config_compute (decay)
        class(decay_config_t), intent(inout) :: decay
        call decay%decay_root_config_t%compute ()
        if (.not. vanishes (decay%integral)) then
            decay%rel_error = decay%abs_error / decay%integral
        else
            decay%rel_error = 0
        end if
    end subroutine decay_config_compute

```

31.4.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it

independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

⟨Decays: types⟩+≡
  type, extends (decay_gen_t) :: decay_t
  private
    type(decay_config_t), pointer :: config => null ()
    class(rng_t), allocatable :: rng
  contains
    ⟨Decays: decay: TBP⟩
  end type decay_t

```

The finalizer is recursive.

```

⟨Decays: decay: TBP⟩≡
  procedure :: final => decay_final

⟨Decays: procedures⟩+≡
  recursive subroutine decay_final (object)
    class(decay_t), intent(inout) :: object
    integer :: i
    call object%base_final ()
    do i = 1, object%config%process%get_n_mci ()
      call object%process_instance%final_simulation (i)
    end do
    call object%process_instance%final ()
    deallocate (object%process_instance)
  end subroutine decay_final

```

Output.

```

⟨Decays: decay: TBP⟩+≡
  procedure :: write => decay_write

⟨Decays: procedures⟩+≡
  recursive subroutine decay_write (object, unit, indent, recursive)
    class(decay_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent, recursive
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call object%config%write (unit, indent, verbose = .false.)
    if (allocated (object%rng)) then
      call object%rng%write (u, ind + 1)
    end if
    call write_indent (u, ind)
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI    = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI    = [undefined]"
    end if
    call write_indent (u, ind)
    if (object%selected_term > 0) then
      write (u, "(3x,A,I0)") "Selected term  = ", object%selected_term
      call object%term(object%selected_term)%write (u, ind + 1)
    end if
  end subroutine decay_write

```

```

else
  write (u, "(3x,A)") "Selected term  = [undefined]"
end if
end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
  procedure :: init => decay_init

<Decays: procedures>+≡
  recursive subroutine decay_init (decay, config)
    class(decay_t), intent(out) :: decay
    type(decay_config_t), intent(in), target :: config
    integer :: i
    call decay%base_init (config%term_config)
    decay%config => config
    allocate (decay%process_instance)
    call decay%process_instance%init (decay%config%process)
    call decay%process_instance%setup_event_data (decay%config%model)
    do i = 1, decay%config%process%get_n_mci ()
      call decay%process_instance%init_simulation (i)
    end do
    call decay%config%process%make_rng (decay%rng)
    call decay%make_term_rng (decay%config%process)
  end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
  procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
  recursive subroutine decay_link_interactions (decay, i_prt, trace)
    class(decay_t), intent(inout) :: decay
    integer, intent(in) :: i_prt
    type(interaction_t), intent(in), target :: trace
    type(interaction_t), pointer :: beam_int
    integer :: n_in, n_vir
    beam_int => decay%process_instance%get_beam_int_ptr ()
    n_in = trace%get_n_in ()
    n_vir = trace%get_n_vir ()
    call beam_int%set_source_link (1, trace, &
      n_in + n_vir + i_prt)
    call decay%link_term_interactions ()
  end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay

MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
  procedure :: select_chain => decay_select_chain

<Decays: procedures>+≡
  recursive subroutine decay_select_chain (decay)
    class(decay_t), intent(inout) :: decay
    real(default) :: x
    integer :: i
    call decay%rng%generate (x)
    decay%selected_mci = decay%config%mci_selector%select (x)
    call decay%process_instance%choose_mci (decay%selected_mci)
    decay%selected_term = decay%process_instance%select_i_term ()
    do i = 1, size (decay%term)
      call decay%term(i)%select_chain ()
    end do
  end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

<Decays: decay: TBP>+≡
  procedure :: generate => decay_generate

<Decays: procedures>+≡
  recursive subroutine decay_generate (decay)
    class(decay_t), intent(inout) :: decay
    type(isolated_state_t), pointer :: isolated_state
    integer :: i
    call decay%process_instance%receive_beam_momenta ()
    call decay%process_instance%generate_unweighted_event (decay%selected_mci)
    if (signal_is_pending ()) return
    call decay%process_instance%evaluate_event_data ()
    isolated_state => &
      decay%process_instance%get_isolated_state_ptr (decay%selected_term)
    call isolated_state%normalize_matrix_by_trace ()
    do i = 1, size (decay%term)
      call decay%term(i)%generate ()
      if (signal_is_pending ()) return
    end do
  end subroutine decay_generate

```

31.4.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```

<Decays: types>+≡
  type, extends (any_config_t) :: stable_config_t

```

```

    private
    type(flavor_t), dimension(:), allocatable :: flv
contains
    <Decays: stable config: TBP>
end type stable_config_t

```

The finalizer is empty:

```

<Decays: stable config: TBP>≡
    procedure :: final => stable_config_final

<Decays: procedures>+≡
    subroutine stable_config_final (object)
        class(stable_config_t), intent(inout) :: object
    end subroutine stable_config_final

```

Output.

```

<Decays: stable config: TBP>+≡
    procedure :: write => stable_config_write

<Decays: procedures>+≡
    recursive subroutine stable_config_write (object, unit, indent, verbose)
        class(stable_config_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        logical, intent(in), optional :: verbose
        integer :: u, i, ind
        u = given_output_unit (unit)
        ind = 0; if (present (indent)) ind = indent
        call write_indent (u, ind)
        write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"
        write (u, "(1x,A)", advance = "no") char (object%flv(1)%get_name ())
        do i = 2, size (object%flv)
            write (u, "(:',A)", advance = "no") &
                char (object%flv(i)%get_name ())
        end do
        write (u, *)
    end subroutine stable_config_write

```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```

<Decays: stable config: TBP>+≡
    procedure :: init => stable_config_init

<Decays: procedures>+≡
    subroutine stable_config_init (config, flv)
        class(stable_config_t), intent(out) :: config
        type(flavor_t), dimension(:), intent(in) :: flv
        integer, dimension (size (flv)) :: pdg
        logical, dimension (size (flv)) :: mask
        integer :: i
        pdg = flv%get_pdg ()
        mask(1) = .true.
        forall (i = 2 : size (pdg))
            mask(i) = all (pdg(i) /= pdg(1:i-1))
        end forall
    end subroutine

```

```

        allocate (config%flv (count (mask)))
        config%flv = pack (flv, mask)
    end subroutine stable_config_init

```

Here is the corresponding object instance. Except for the pointer to the configuration, there is no content.

```

<Decays: types>+≡
    type, extends (any_t) :: stable_t
    private
        type(stable_config_t), pointer :: config => null ()
    contains
        <Decays: stable: TBP>
    end type stable_t

```

The finalizer does nothing.

```

<Decays: stable: TBP>≡
    procedure :: final => stable_final

<Decays: procedures>+≡
    subroutine stable_final (object)
        class(stable_t), intent(inout) :: object
    end subroutine stable_final

```

We can delegate output to the configuration object.

```

<Decays: stable: TBP>+≡
    procedure :: write => stable_write

<Decays: procedures>+≡
    subroutine stable_write (object, unit, indent)
        class(stable_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        call object%config%write (unit, indent)
    end subroutine stable_write

```

Initializer: just assign the configuration.

```

<Decays: stable: TBP>+≡
    procedure :: init => stable_init

<Decays: procedures>+≡
    subroutine stable_init (stable, config)
        class(stable_t), intent(out) :: stable
        type(stable_config_t), intent(in), target :: config
        stable%config => config
    end subroutine stable_init

```

31.4.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: public>+≡
    public :: unstable_config_t

<Decays: types>+≡
    type, extends (any_config_t) :: unstable_config_t
    private
    type(flavor_t) :: flv
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: selector
    type(decay_config_t), dimension(:), allocatable :: decay_config
    contains
    <Decays: unstable config: TBP>
    end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
    procedure :: final => unstable_config_final

<Decays: procedures>+≡
    recursive subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay_config)) then
        do i = 1, size (object%decay_config)
            call object%decay_config(i)%final ()
        end do
    end if
    end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
    procedure :: write => unstable_config_write

<Decays: procedures>+≡
    recursive subroutine unstable_config_write (object, unit, indent, verbose)
    class(unstable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    logical :: verb
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
        char (object%flv%get_name ())
    call write_indent (u, ind)
    write (u, 1) "total width =", object%integral
    call write_indent (u, ind)

```

```

write (u, 1) "error (abs) =", object%abs_error
call write_indent (u, ind)
write (u, 1) "error (rel) =", object%rel_error
1 format (5x,A,ES19.12)
if (verb .and. allocated (object%decay_config)) then
  do i = 1, size (object%decay_config)
    call object%decay_config(i)%write (u, ind + 1)
  end do
end if
end subroutine unstable_config_write

```

Initializer. For the unstable particle, the flavor is unique.

```

<Decays: unstable config: TBP>+≡
  procedure :: init => unstable_config_init

<Decays: procedures>+≡
  subroutine unstable_config_init (unstable, flv, set_decays, model)
    class(unstable_config_t), intent(out) :: unstable
    type(flavor_t), intent(in) :: flv
    logical, intent(in), optional :: set_decays
    class(model_data_t), intent(in), optional, target :: model
    type(string_t), dimension(:), allocatable :: decay
    unstable%flv = flv
    if (present (set_decays)) then
      call unstable%flv%get_decays (decay)
      call unstable%init_decays (decay, model)
    end if
  end subroutine unstable_config_init

```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```

<Decays: unstable config: TBP>+≡
  procedure :: init_decays => unstable_config_init_decays

<Decays: procedures>+≡
  recursive subroutine unstable_config_init_decays &
    (unstable, decay_id, model, process_stack)
    class(unstable_config_t), intent(inout) :: unstable
    type(string_t), dimension(:), intent(in) :: decay_id
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    integer :: i
    allocate (unstable%decay_config (size (decay_id)))
    do i = 1, size (decay_id)
      associate (decay => unstable%decay_config(i))
        if (present (process_stack)) then
          call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
            model, process_stack)
        else
          call decay%init (model, decay_id(i))
        end if
      end associate
      call decay%set_flv (unstable%flv)
    end do
  end subroutine unstable_config_init_decays

```

```

        end associate
    end do
end subroutine unstable_config_init_decays

```

Explicitly connect a specific decay with a process. This is used only in unit tests.

```

<Decays: unstable config: TBP>+≡
    procedure :: connect_decay => unstable_config_connect_decay

<Decays: procedures>+≡
    subroutine unstable_config_connect_decay (unstable, i, process, model)
        class(unstable_config_t), intent(inout) :: unstable
        integer, intent(in) :: i
        type(process_t), intent(in), target :: process
        class(model_data_t), intent(in), target :: model
        associate (decay => unstable%decay_config(i))
            call decay%connect (process, model)
        end associate
    end subroutine unstable_config_connect_decay

```

Compute the total width and branching ratios, initializing the decay selector.

```

<Decays: unstable config: TBP>+≡
    procedure :: compute => unstable_config_compute

<Decays: procedures>+≡
    recursive subroutine unstable_config_compute (unstable)
        class(unstable_config_t), intent(inout) :: unstable
        integer :: i
        do i = 1, size (unstable%decay_config)
            call unstable%decay_config(i)%compute ()
        end do
        unstable%integral = sum (unstable%decay_config%integral)
        if (unstable%integral <= 0) then
            call unstable%write ()
            call msg_fatal ("Decay configuration: computed total width is zero")
        end if
        unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
        unstable%rel_error = unstable%abs_error / unstable%integral
        call unstable%selector%init (unstable%decay_config%integral)
        do i = 1, size (unstable%decay_config)
            unstable%decay_config(i)%weight &
                = unstable%selector%get_weight (i)
        end do
    end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: public>+≡
    public :: unstable_t

<Decays: types>+≡
    type, extends (any_t) :: unstable_t
        private
        type(unstable_config_t), pointer :: config => null ()

```

```

```

31.4.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+≡
  type, extends (connected_state_t) :: decay_chain_entry_t
  private
  integer :: index = 0
  type(decay_config_t), pointer :: config => null ()
  integer :: selected_mci = 0
  integer :: selected_term = 0
  type(decay_chain_entry_t), pointer :: previous => null ()
  end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: public>+≡
    public :: decay_chain_t

<Decays: types>+≡
    type :: decay_chain_t
    private
        type(process_instance_t), pointer :: process_instance => null ()
        integer :: selected_term = 0
        type(evaluator_t) :: correlated_trace
        type(decay_chain_entry_t), pointer :: last => null ()
    contains
        <Decays: decay chain: TBP>
    end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay chain: TBP>≡
    procedure :: final => decay_chain_final

<Decays: procedures>+≡
    subroutine decay_chain_final (object)
        class(decay_chain_t), intent(inout) :: object
        type(decay_chain_entry_t), pointer :: entry
        do while (associated (object%last))
            entry => object%last
            object%last => entry%previous
            call entry%final ()
            deallocate (entry)
        end do
        call object%correlated_trace%final ()
    end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

<Decays: decay chain: TBP>+≡
    procedure :: write => decay_chain_write

<Decays: procedures>+≡
    subroutine decay_chain_write (object, unit)
        class(decay_chain_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)

```

```

call write_separator (u, 2)
write (u, "(1x,A)") "Decay chain:"
call write_entries (object%last)
call write_separator (u, 2)
write (u, "(1x,A)") "Evaluator (correlated trace of the decay chain):"

contains
recursive subroutine write_entries (entry)
  type(decay_chain_entry_t), intent(in), pointer :: entry
  if (associated (entry)) then
    call write_entries (entry%previous)
    call write_separator (u, 2)
    write (u, "(1x,A,I0)") "Decay #", entry%index
    call entry%config%write_header (u)
    write (u, "(3x,A,I0)") "Selected MCI    = ", entry%selected_mci
    write (u, "(3x,A,I0)") "Selected term  = ", entry%selected_term
    call entry%config%term_config(entry%selected_term)%write (u, indent=1)
    call entry%write (u)
  end if
end subroutine write_entries
end subroutine decay_chain_write

```

Build a decay chain, recursively following the selected decays and terms in a decay tree. Before start, we finalize the chain, deleting any previous contents.

```

<Decays: decay chain: TBP>+≡
  procedure :: build => decay_chain_build

<Decays: procedures>+≡
  subroutine decay_chain_build (chain, decay_root)
    class(decay_chain_t), intent(inout), target :: chain
    type(decay_root_t), intent(in) :: decay_root
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    type(interaction_t), pointer :: int_last_decay
    call chain%final ()
    if (decay_root%selected_term > 0) then
      chain%process_instance => decay_root%process_instance
      chain%selected_term = decay_root%selected_term
      call chain%build_term_entries (decay_root%term(decay_root%selected_term))
    end if
    int_last_decay => chain%last%get_matrix_int_ptr ()
    allocate (qn_mask (int_last_decay%get_n_tot ()))
    call qn_mask%init (mask_f = .true., mask_c = .true., mask_h = .true.)
    call chain%correlated_trace%init_qn_sum (int_last_decay, qn_mask)
  end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable particles.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_term_entries (chain, term)

```

```

class(decay_chain_t), intent(inout) :: chain
type(decay_term_t), intent(in) :: term
integer :: i
do i = 1, size (term%particle_out)
  select type (unstable => term%particle_out(i)%c)
  type is (unstable_t)
    if (unstable%selected_decay > 0) then
      call chain%build_decay_entries &
        (unstable%decay(unstable%selected_decay))
    end if
  end select
end do
end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

<Decays: decay chain: TBP>+≡
  procedure :: build_decay_entries => decay_chain_build_decay_entries

<Decays: procedures>+≡
  recursive subroutine decay_chain_build_decay_entries (chain, decay)
    class(decay_chain_t), intent(inout) :: chain
    type(decay_t), intent(in) :: decay
    type(decay_chain_entry_t), pointer :: entry
    type(connected_state_t), pointer :: previous_state
    type(isolated_state_t), pointer :: current_decay
    type(helicity_t) :: hel
    type(quantum_numbers_t) :: qn_filter_conn
    allocate (entry)
    if (associated (chain%last)) then
      entry%previous => chain%last
      entry%index = entry%previous%index + 1
      previous_state => entry%previous%connected_state_t
    else
      entry%index = 1
      previous_state => &
        chain%process_instance%get_connected_state_ptr (chain%selected_term)
    end if
    entry%config => decay%config
    entry%selected_mci = decay%selected_mci
    entry%selected_term = decay%selected_term
  end subroutine

```

```

current_decay => decay%process_instance%get_isolated_state_ptr &
    (decay%selected_term)
call entry%setup_connected_trace &
    (current_decay, previous_state%get_trace_int_ptr (), resonant=.true.)
if (entry%config%flv%has_decay_helicity ()) then
    call hel%init (entry%config%flv%get_decay_helicity ())
    call qn_filter_conn%init (hel)
    call entry%setup_connected_matrix &
        (current_decay, previous_state%get_matrix_int_ptr (), &
        resonant=.true., qn_filter_conn = qn_filter_conn)
    call entry%setup_connected_flows &
        (current_decay, previous_state%get_flows_int_ptr (), &
        resonant=.true., qn_filter_conn = qn_filter_conn)

    call entry%setup_connected_matrix &
        (current_decay, previous_state%get_matrix_int_ptr (), &
        resonant=.true.)
    call entry%setup_connected_flows &
        (current_decay, previous_state%get_flows_int_ptr (), &
        resonant=.true.)
end if
chain%last => entry
call chain%build_term_entries (decay%term(decay%selected_term))
end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

```

⟨Decays: decay chain: TBP⟩+≡
    procedure :: evaluate => decay_chain_evaluate

⟨Decays: procedures⟩+≡
    subroutine decay_chain_evaluate (chain)
        class(decay_chain_t), intent(inout) :: chain

                call entry%evaluate_event_data ()
            end if
        end subroutine evaluate
    end subroutine decay_chain_evaluate

```

Return the probability of a decay chain. This is given as the trace of the density

matrix with intermediate helicity correlations, normalized by the product of the uncorrelated density matrix traces. This works only if an event has been evaluated and the `correlated_trace` evaluator is filled. By definition, this evaluator has only one matrix element, and this must be real.

```

<Decays: decay chain: TBP>+≡
  procedure :: get_probability => decay_chain_get_probability

<Decays: procedures>+≡
  function decay_chain_get_probability (chain) result (x)
    class(decay_chain_t), intent(in) :: chain
    real(default) :: x
    x = real (chain%correlated_trace%get_matrix_element (1))
  end function decay_chain_get_probability

```

31.4.12 Decay as Event Transform

The `evt_decay` object combines decay configuration, decay tree, and chain in a single object, as an implementation of the `evt` (event transform) abstract type.

```

<Decays: public>+≡
  public :: evt_decay_t

<Decays: types>+≡
  type, extends (evt_t) :: evt_decay_t
    private
      type(decay_root_config_t) :: decay_root_config
      type(decay_root_t) :: decay_root
      type(decay_chain_t) :: decay_chain
    contains
      <Decays: evt decay: TBP>
  end type evt_decay_t

<Decays: evt decay: TBP>≡
  procedure :: write_name => evt_decay_write_name

<Decays: procedures>+≡
  subroutine evt_decay_write_name (evt, unit)
    class(evt_decay_t), intent(in) :: evt
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event transform: partonic decays"
  end subroutine evt_decay_write_name

```

Output. We display the currently selected decay tree, which includes configuration data, and the decay chain, i.e., the evaluators.

```

<Decays: evt decay: TBP>+≡
  procedure :: write => evt_decay_write

<Decays: procedures>+≡
  subroutine evt_decay_write (evt, unit, verbose, more_verbose, testflag)
    class(evt_decay_t), intent(in) :: evt
    integer, intent(in), optional :: unit

```

```

logical, intent(in), optional :: verbose, more_verbose, testflag

    call write_separator (u)
    call evt%decay_root%write (u)
    if (verb2) then
        call evt%decay_chain%write (u)
        call evt%decay_root%write_process_instances (u, verb)
    end if
else
    call write_separator (u, 2)
end if
end subroutine evt_decay_write

```

Connect with a process instance and process. This initializes the decay configuration. The process stack is used to look for process objects that implement daughter decays.

When all processes are assigned, configure the decay tree instance, using the decay tree configuration. First obtain the branching ratios, then allocate the decay tree. This is done once for all events.

```

<Decays: evt decay: TBP>+≡
    procedure :: connect => evt_decay_connect

<Decays: procedures>+≡
    subroutine evt_decay_connect (evt, process_instance, model, process_stack)
        class(evt_decay_t), intent(inout), target :: evt
        type(process_instance_t), intent(in), target :: process_instance
        class(model_data_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        call evt%base_connect (process_instance, model)
        call evt%decay_root_config%connect (process_instance%process, &
            model, process_stack, process_instance)
        call evt%decay_root_config%compute ()
        call evt%decay_root%init (evt%decay_root_config, evt%process_instance)
    end subroutine evt_decay_connect

```

Prepare a new event: Select a decay chain and build the corresponding chain object.

```

<Decays: evt decay: TBP>+≡
    procedure :: prepare_new_event => evt_decay_prepare_new_event

<Decays: procedures>+≡
    subroutine evt_decay_prepare_new_event (evt, i_mci, i_term)
        class(evt_decay_t), intent(inout) :: evt
        integer, intent(in) :: i_mci, i_term

```

```

    call evt%reset ()
    evt%decay_root%selected_mci = i_mci
    evt%decay_root%selected_term = i_term
    call evt%decay_root%select_chain ()
    call evt%decay_chain%build (evt%decay_root)
end subroutine evt_decay_prepare_new_event

```

Generate a weighted event and assign the resulting weight (probability). We use a chain initialized by the preceding subroutine, fill it with momenta and evaluate.

```

<Decays: evt decay: TBP>+≡
  procedure :: generate_weighted => evt_decay_generate_weighted

<Decays: procedures>+≡
  subroutine evt_decay_generate_weighted (evt, probability)
    class(evt_decay_t), intent(inout) :: evt
    real(default), intent(inout) :: probability
    call evt%decay_root%generate ()
    if (signal_is_pending ()) return
    call evt%decay_chain%evaluate ()
    probability = evt%decay_chain%get_probability ()
  end subroutine evt_decay_generate_weighted

```

To create a usable event, we have to transform the interaction into a particle set; this requires factorization for the correlated density matrix, according to the factorization mode.

```

<Decays: evt decay: TBP>+≡
  procedure :: make_particle_set => evt_decay_make_particle_set

<Decays: procedures>+≡
  subroutine evt_decay_make_particle_set &

31.5.1 Configuration Parameters

POWHEG_TESTING allows to disable the parton shower for validation and testing of the POWHEG procedure.

⟨Shower: parameters⟩≡

```
logical, parameter :: POWHEG_TESTING = .false.
```

31.5.2 Event Transform

The event transforms can do more than mere showering. Especially, it may reweight showered events to fixed-order matrix elements. The `model_hadrons` is supposed to be the SM variant that contains all hadrons that can be generated in the shower.

```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations is under construction. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid. This procedure directly takes the (MLM) matching into account.

31.6 Fixed Order NLO Events

This section deals with the generation of weighted event samples which take into account next-to-leading order corrections. An approach generating unweighted events is not possible here, because negative weights might occur due to subtraction. Note that the events produced this way are not physical in the sense that they will not keep NLO-accuracy when interfaced to a parton shower. They are rather useful for theoretical consistency checks and a fast estimate of NLO effects.

We generate NLO events in the following way: First, the integration is carried out using the complete divergence-subtracted NLO matrix element. In the subsequent simulation, N -particle kinematics are generated using $\mathcal{B} + \mathcal{V} + \mathcal{C}$ as weight. After that, the program loops over all singular regions and for each of them generates an event with $N + 1$ -particle kinematics. The weight for those events corresponds to the real matrix element \mathcal{R}^α evaluated at the α -region's emitter's phase space point, multiplied with S_α . This procedure is implemented using the `evt_nlo` transform.

```

This event transformation is for the generation of fixed-order NLO events. It takes an event with Born kinematics and creates $N_\alpha + 1$ modified weighted events. The first one has Born kinematics and its weight is the sum of Born, Real and subtraction matrix elements. The other N_α events have a weight which is equal to the real matrix element, evaluated with the phase space corresponding to the emitter of the α -region. All NLO event objects share the same event transformation. For this reason, we save the particle set of the current α -region in the array `particle_set_radiated`. Otherwise it would be unretrievable if the usual particle set of the event object was used.ⓐ

```

The event transform has a variable which counts the number of times it has already been called for one generation point. If `i_evaluation` is zero, this means that `evt_nlo_generate` is called for the first time, so that the generation of an N -particle event is required. In all other cases, emission events are generated. Note that for the first event, the computed weights are added to `probability`, which at this point is equal to $\mathcal{B} + \mathcal{V}$, whereas for all other runs `probability` is replaced. To keep $\langle \sum w_i \rangle = N \times \sigma$ as it is for weighted LO events, we have to multiply by $N_{\text{phs}} + 1$ since the cross section is distributed over the real and Born subevents.

31.7.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The **safety_factor** reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The **sigma** and **n** values, if nontrivial, allow for reweighting the events according to the requested **norm_mode**.

Various **parse_node_t** objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the **event_expr_t** objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

⟨Events: types⟩≡

```

type :: event_config_t
  logical :: unweighted = .false.
  integer :: norm_mode = NORM_UNDEFINED
  integer :: factorization_mode = FM_IGNORE_HELICITY
  logical :: keep_correlations = .false.
  real(default) :: sigma = 1
  integer :: n = 1
  real(default) :: safety_factor = 1
  class(expr_factory_t), allocatable :: ef_selection
  class(expr_factory_t), allocatable :: ef_reweight
  class(expr_factory_t), allocatable :: ef_analysis
contains
  ⟨Events: event config: TBP⟩
end type event_config_t

```

Output.

31.7.2 The event type

This is the concrete implementation of the `generic_event_t` core that is defined above in the `event_base` module. The core manages the main (dressed) particle

set pointer and the current values for weights and sqme. The implementation adds configuration data, expressions, process references, and event transforms.

Each event refers to a single elementary process. This process may be dressed by a shower, a decay chain etc. We maintain pointers to a process instance.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

The `sqme` and `weight` values mirror corresponding values in the `expr` subobject. The idea is that when generating or reading events, the event record is filled first, then the `expr` object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the `expr` subobject. In particular, evaluating the event-selection expression sets the `passed` flag. Furthermore, the `expr` subobject collects data that can be used in the analysis and should be written to file, including copies of `sqme` and `weight`.

31.7.3 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

```

<Events: event: TBP>+≡
    procedure :: basic_init => event_init

<Events: procedures>+≡
    subroutine event_init (event, var_list, n_alt)
        class(event_t), intent(out) :: event
        type(var_list_t), intent(in), optional :: var_list

        logical :: polarized_events
        if (present (n_alt)) then
            call event%base_init (n_alt)
            call event%expr%init (n_alt)
        else
            call event%base_init (0)
        end if
        if (present (var_list)) then
            event%config%unweighted = var_list%get_lval (&
                var_str ("?unweighted"))
            norm_string = var_list%get_sval (&
                var_str ("sample_normalization"))
            event%config%norm_mode = &
                event_normalization_mode (norm_string, event%config%unweighted)
            polarized_events = &
                var_list%get_lval (var_str ("?polarized_events"))
            if (polarized_events) then
                mode_string = &
                    var_list%get_sval (var_str ("polarization_mode"))
                select case (char (mode_string))
                case ("ignore")
                    event%config%factorization_mode = FM_IGNORE_HELICITY
                case ("helicity")
                    event%config%factorization_mode = FM_SELECT_HELICITY
                case ("factorized")
                    event%config%factorization_mode = FM_FACTOR_HELICITY
                case ("correlated")
                    event%config%factorization_mode = FM_CORRELATED_HELICITY

```

```

        case default
            call msg_fatal ("Polarization mode " &
                // char (mode_string) // " is undefined")
        end select
    else
        event%config%factorization_mode = FM_IGNORE_HELICITY
    end if
    if (event%config%unweighted) then
        event%config%safety_factor = var_list%get_rval (&
            var_str ("safety_factor"))
    end if
    else
        event%config%norm_mode = NORM_SIGMA
    end if
    allocate (evt_trivial_t :: event%transform_first)
    event%transform_last => event%transform_first
end subroutine event_init

```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

```

<Events: event: TBP>+≡
    procedure :: set_sigma => event_set_sigma
    procedure :: set_n => event_set_n

<Events: procedures>+≡
    elemental subroutine event_set_sigma (event, sigma)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: sigma
        event%config%sigma = sigma
    end subroutine event_set_sigma

    elemental subroutine event_set_n (event, n)
        class(event_t), intent(inout) :: event
        integer, intent(in) :: n
        event%config%n = n
    end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
    procedure :: import_transform => event_import_transform

<Events: procedures>+≡
    subroutine event_import_transform (event, evt)
        class(event_t), intent(inout) :: event
        class(evt_t), intent(inout), pointer :: evt
        event%transform_last%next => evt
        evt%previous => event%transform_last
        event%transform_last => evt
    end subroutine event_import_transform

```

```

    evt => null ()
end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to `event` subobjects, therefore the `target` attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

<Events: procedures>+≡
  subroutine event_connect (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(string_t) :: id
    integer :: num_id
    class(evt_t), pointer :: evt
    event%process => process_instance%process
    event%instance => process_instance
    id = event%process%get_id ()
    if (id /= "") call event%expr%set_process_id (id)
    num_id = event%process%get_num_id ()
    if (num_id /= 0) call event%expr%set_process_num_id (num_id)
    call event%expr%setup_vars (event%process%get_sqrts ())
    call event%expr%link_var_list (event%process%get_var_list_ptr ())
    call event%process%make_rng (event%rng)
    evt => event%transform_first
    do while (associated (evt))
      call evt%connect (process_instance, model, process_stack)
      evt => evt%next
    end do
  end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
  procedure :: set_selection => event_set_selection
  procedure :: set_reweight => event_set_reweight
  procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡
  subroutine event_set_selection (event, ef_selection)
    class(event_t), intent(inout) :: event
    class(expr_factory_t), intent(in) :: ef_selection

```

```

        allocate (event%config%ef_selection, source = ef_selection)
    end subroutine event_set_selection

    subroutine event_set_reweight (event, ef_reweight)
        class(event_t), intent(inout) :: event
        class(expr_factory_t), intent(in) :: ef_reweight
        allocate (event%config%ef_reweight, source = ef_reweight)
    end subroutine event_set_reweight

    subroutine event_set_analysis (event, ef_analysis)
        class(event_t), intent(inout) :: event
        class(expr_factory_t), intent(in) :: ef_analysis
        allocate (event%config%ef_analysis, source = ef_analysis)
    end subroutine event_set_analysis

```

Create evaluation trees from the parse trees. The `target` attribute is required because the expressions contain pointers to event subobjects.

```

<Events: event: TBP>+≡
    procedure :: setup_expressions => event_setup_expressions

<Events: procedures>+≡
    subroutine event_setup_expressions (event)
        class(event_t), intent(inout), target :: event
        call event%expr%setup_selection (event%config%ef_selection)
        call event%expr%setup_analysis (event%config%ef_analysis)
        call event%expr%setup_reweight (event%config%ef_reweight)
    end subroutine event_setup_expressions

```

31.7.4 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

```

<Events: event: TBP>+≡
    procedure :: evaluate_transforms => event_evaluate_transforms

<Events: procedures>+≡
    subroutine event_evaluate_transforms (event, r)
        class(event_t), intent(inout) :: event

    end subroutine print_transform_name_if_debug
end subroutine event_evaluate_transforms

```

Evaluate the event-related expressions, given a valid `particle_set`. If `update_sqme` is set, we use the process instance for the `sqme_prc` value. The `sqme_ref` value is always taken from the event record.

Note: without the explicit `particle_set` pointer, some gfortran 4.8 version corrupts its memory.

```

            .and. event%sqme_alt_is_known () &
            .and. event%weight_alt_is_known ()
    end if
  end subroutine event_check

```

31.7.7 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we accept the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
  procedure :: generate => event_generate

<Events: procedures>+≡
  subroutine event_generate (event, i_mci, r, i_nlo)
    class(event_t), intent(inout) :: event

```

```

integer, intent(in) :: i_mci
real(default), dimension(:), intent(in), optional :: r
integer, intent(in), optional :: i_nlo
logical :: generate_new = .true.
if (present (i_nlo)) generate_new = (i_nlo == 1)
if (generate_new) call event%reset ()
event%selected_i_mci = i_mci
if (event%config%unweighted) then
  call event%instance%generate_unweighted_event (i_mci)
  if (signal_is_pending ()) return
  call event%instance%evaluate_event_data ()
  call event%instance%normalize_weight ()
else
  if (generate_new) &
    call event%instance%generate_weighted_event (i_mci)
  if (signal_is_pending ()) return

call event%accept_weight_prc ()
call event%evaluate_transforms (r)
if (signal_is_pending ()) return
call event%check ()
end subroutine event_generate

```

Get a copy of the particle set belonging to the hard process.

```

<Events: event: TBP>+≡
  procedure :: get_hard_particle_set => event_get_hard_particle_set

<Events: procedures>+≡
  subroutine event_get_hard_particle_set (event, pset)
    class(event_t), intent(in) :: event
    type(particle_set_t), intent(out) :: pset
    class(evt_t), pointer :: evt
    evt => event%transform_first
    pset = evt%particle_set
  end subroutine event_get_hard_particle_set

```

31.7.8 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
  procedure :: select => event_select

<Events: procedures>+≡
  subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
    if (associated (event%instance)) then
      event%selected_i_mci = i_mci
    end if
  end subroutine event_select

```

```

        event%selected_i_term = i_term
        event%selected_channel = channel
    else
        event%selected_i_mci = 0
        event%selected_i_term = 0
        event%selected_channel = 0
    end if
end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. The event reader may either read in the transformed event separately, or apply all event transforms to the hard particle set to (re)generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
    procedure :: set_hard_particle_set => event_set_hard_particle_set

<Events: procedures>+≡
    subroutine event_set_hard_particle_set (event, particle_set)
        class(event_t), intent(inout) :: event
        type(particle_set_t), intent(in) :: particle_set
        class(evt_t), pointer :: evt
        evt => event%transform_first
        call evt%set_particle_set (particle_set, &
            event%selected_i_mci, event%selected_i_term)
        call event%link_particle_set (evt%particle_set)
        evt => evt%next
        do while (associated (evt))
            call evt%reset ()
            evt => evt%next
        end do
    end subroutine event_set_hard_particle_set

```

Set the α_s value that should be used in a recalculation. This should be called only if we explicitly want to override the QCD setting of the process core.

```

<Events: event: TBP>+≡
    procedure :: set_alpha_qcd_forced => event_set_alpha_qcd_forced

<Events: procedures>+≡
    subroutine event_set_alpha_qcd_forced (event, alpha_qcd)
        class(event_t), intent(inout) :: event
        real(default), intent(in) :: alpha_qcd
        if (allocated (event%alpha_qcd_forced)) then
            event%alpha_qcd_forced = alpha_qcd
        else
            allocate (event%alpha_qcd_forced, source = alpha_qcd)
        end if
    end subroutine event_set_alpha_qcd_forced

```

Analogously, for the common scale. This forces also renormalization and factorization scale.

```

<Events: event: TBP>+=
  procedure :: set_scale_forced => event_set_scale_forced

<Events: procedures>+=
  subroutine event_set_scale_forced (event, scale)
    class(event_t), intent(inout) :: event
    real(default), intent(in) :: scale
    if (allocated (event%scale_forced)) then
      event%scale_forced = scale
    else
      allocate (event%scale_forced, source = scale)
    end if
  end subroutine event_set_scale_forced

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

<Events: event: TBP>+=
  procedure :: recalculate => event_recalculate

<Events: procedures>+=
  subroutine event_recalculate &
    (event, update_sqme, weight_factor, recover_beams)
    class(event_t), intent(inout) :: event

31.8 Raw Event I/O

The raw format is for internal use only. All data are stored unformatted, so they can be efficiently be re-read on the same machine, but not necessarily on another machine.

This module explicitly depends on the `events` module which provides the concrete implementation of `event_base`. The other I/O formats access only the methods that are defined in `event_base`.

```

<eio_raw.f90>≡
  <File header>

  module eio_raw

    <Use kinds>
    <Use strings>
    use io_units
    use diagnostics
    use model_data
    use particles
    use event_base
    use eio_data

```

```

    use eio_base
    use events

    <Standard module head>

    <EIO raw: public>

    <EIO raw: parameters>

    <EIO raw: types>

    contains

    <EIO raw: procedures>

    end module eio_raw

```

31.8.1 File Format Version

This is the current default file version.

```

<EIO raw: parameters>≡
    integer, parameter :: CURRENT_FILE_VERSION = 2

```

The user may change this number; this should force some compatibility mode for reading and writing. In any case, the file version stored in a event file that we read has to match the expected file version.

History of version numbers:

1. Format for WHIZARD 2.2.0 to 2.2.3. No version number stored in the raw file.
2. Format from 2.2.4 on. File contains version number. The file contains the transformed particle set (if applicable) after the hard-process particle set.

31.8.2 Type

Note the file version number. The default may be reset during initialization, which should enforce some compatibility mode.

```

<EIO raw: public>≡
    public :: eio_raw_t

```

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and `sqme`, since these are the values just computed. On input, we store the values as `ref` values. The caller can then decide whether to recompute values and thus obtain distinct `prc` values, or just accept them.

The `passed` flag is not written. This allow us to apply different selection criteria upon rereading.

31.9 Dispatch

An event transform is responsible for dressing a partonic event. Since event transforms are not mutually exclusive but are concatenated, we provide indi-

vidual dispatchers for each of them.

Chapter 32

Integration and Simulation

32.1 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```
<user_files.f90>≡  
<File header>  
  
module user_files  
  
  <Use strings>  
    use io_units  
    use diagnostics  
    use ifiles  
    use analysis  
  
  <Standard module head>  
  
  <User files: public>  
  
  <User files: types>  
  
  <User files: interfaces>  
  
  contains  
  
  <User files: procedures>  
  
end module user_files
```

32.1.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡
```

```

type :: file_t
  private
  type(string_t) :: name
  integer :: unit = -1
  logical :: reading = .false.
  logical :: writing = .false.
  type(file_t), pointer :: prev => null ()
  type(file_t), pointer :: next => null ()
end type file_t

```

The initializer opens the file.

```

<User files: procedures>≡
subroutine file_init (file, name, action, status, position)
  type(file_t), intent(out) :: file
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position
  file%unit = free_unit ()
  file%name = name
  open (unit = file%unit, file = char (file%name), &
        action = action, status = status, position = position)
  select case (action)
  case ("read")
    file%reading = .true.
  case ("write")
    file%writing = .true.
  case ("readwrite")
    file%reading = .true.
    file%writing = .true.
  end select
end subroutine file_init

```

The finalizer closes it.

```

<User files: procedures>+≡
subroutine file_final (file)
  type(file_t), intent(inout) :: file
  close (unit = file%unit)
  file%unit = -1
end subroutine file_final

```

Check if a file is open with correct status.

```

<User files: procedures>+≡
function file_is_open (file, action) result (flag)
  logical :: flag
  type(file_t), intent(in) :: file
  character(*), intent(in) :: action
  select case (action)
  case ("read")
    flag = file%reading
  case ("write")
    flag = file%writing
  case ("readwrite")
    flag = file%reading .and. file%writing
  end select
end function file_is_open

```

```

    case default
        call msg_bug ("Checking file '" // char (file%name) &
            // "' : illegal action specifier")
    end select
end function file_is_open

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the `advancing` option.

```

<User files: procedures>+≡
subroutine file_write_string (file, string, advancing)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: string
    logical, intent(in), optional :: advancing
    if (file%writing) then
        if (present (string)) then
            if (present (advancing)) then
                if (advancing) then
                    write (file%unit, "(A)") char (string)
                else
                    write (file%unit, "(A)", advance="no") char (string)
                end if
            else
                write (file%unit, "(A)") char (string)
            end if
        else
            write (file%unit, *)
        end if
    else
        call msg_error ("Writing to file: File '" // char (file%name) &
            // "' is not open for writing.")
    end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

```

<User files: procedures>+≡
subroutine file_write_ifile (file, ifile)
    type(file_t), intent(in) :: file
    type(ifile_t), intent(in) :: ifile
    type(line_p) :: line
    call line_init (line, ifile)
    do while (line_is_associated (line))
        call file_write_string (file, line_get_string_advance (line))
    end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

```

<User files: procedures>+≡
subroutine file_write_analysis (file, tag)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: tag
    if (file%writing) then
        if (present (tag)) then

```

```

        call analysis_write (tag, unit = file%unit)
    else
        call analysis_write (unit = file%unit)
    end if
else
    call msg_error ("Writing analysis to file: File '" // char (file%name) &
        // "' is not open for writing.")
    end if
end subroutine file_write_analysis

```

32.1.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
    public :: file_list_t

<User files: types>+≡
    type :: file_list_t
        type(file_t), pointer :: first => null ()
        type(file_t), pointer :: last => null ()
    end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
    public :: file_list_final

<User files: procedures>+≡
    subroutine file_list_final (file_list)
        type(file_list_t), intent(inout) :: file_list
        type(file_t), pointer :: current
        do while (associated (file_list%first))
            current => file_list%first
            file_list%first => current%next
            call file_final (current)
            deallocate (current)
        end do
        file_list%last => null ()
    end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```

<User files: procedures>+≡
    function file_list_get_file_ptr (file_list, name) result (current)
        type(file_t), pointer :: current
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        current => file_list%first
        do while (associated (current))
            if (current%name == name) return
            current => current%next
        end do
    end function file_list_get_file_ptr

```

Check if a file is open, public version:

```
<User files: public>+≡
    public :: file_list_is_open

<User files: procedures>+≡
    function file_list_is_open (file_list, name, action) result (flag)
        logical :: flag
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            flag = file_is_open (current, action)
        else
            flag = .false.
        end if
    end function file_list_is_open
```

Append a new file entry, i.e., open this file. Error if it is already open.

```
<User files: public>+≡
    public :: file_list_open

<User files: procedures>+≡
    subroutine file_list_open (file_list, name, action, status, position)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        character(len=*), intent(in) :: action, status, position
        type(file_t), pointer :: current
        if (.not. associated (file_list_get_file_ptr (file_list, name))) then
            allocate (current)
            call msg_message ("Opening file '" // char (name) // "' for output")
            call file_init (current, name, action, status, position)
            if (associated (file_list%last)) then
                file_list%last%next => current
                current%prev => file_list%last
            else
                file_list%first => current
            end if
            file_list%last => current
        else
            call msg_error ("Opening file: File '" // char (name) &
                // "' is already open.")
        end if
    end subroutine file_list_open
```

Delete a file entry, i.e., close this file. Error if it is not open.

```
<User files: public>+≡
    public :: file_list_close

<User files: procedures>+≡
    subroutine file_list_close (file_list, name)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
```

```

type(file_t), pointer :: current
current => file_list_get_file_ptr (file_list, name)
if (associated (current)) then
    if (associated (current%prev)) then
        current%prev%next => current%next
    else
        file_list%first => current%next
    end if
    if (associated (current%next)) then
        current%next%prev => current%prev
    else
        file_list%last => current%prev
    end if
    call msg_message ("Closing file '" // char (name) // "' for output")
    call file_final (current)
    deallocate (current)
else
    call msg_error ("Closing file: File '" // char (name) &
        // "' is not open.")
end if
end subroutine file_list_close

```

Write a string to file. Error if it is not open.

```

<User files: public>+≡
    public :: file_list_write

<User files: interfaces>≡
    interface file_list_write
        module procedure file_list_write_string
        module procedure file_list_write_ifile
    end interface

<User files: procedures>+≡
    subroutine file_list_write_string (file_list, name, string, advancing)
        type(file_list_t), intent(in) :: file_list
        type(string_t), intent(in) :: name
        type(string_t), intent(in), optional :: string
        logical, intent(in), optional :: advancing
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            call file_write_string (current, string, advancing)
        else

    <RT data: types>  
  
    contains  
  
    <RT data: procedures>  
  
  end module rt_data
```

32.2.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn,

is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

32.2.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()
    type(parse_node_t), pointer :: fac_scale_expr => null ()
    type(parse_node_t), pointer :: ren_scale_expr => null ()
    type(parse_node_t), pointer :: weight_expr => null ()
    type(parse_node_t), pointer :: selection_lexpr => null ()
    type(parse_node_t), pointer :: reweight_expr => null ()
    type(parse_node_t), pointer :: analysis_lexpr => null ()
    type(parse_node_p), dimension(:), allocatable :: alt_setup
  contains
    <RT data: rt parse nodes: TBP>
  end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

```

```

<RT data: procedures>≡
subroutine rt_parse_nodes_clear (rt_pn, name)
  class(rt_parse_nodes_t), intent(inout) :: rt_pn
  type(string_t), intent(in) :: name
  select case (char (name))
  case ("cuts")
    rt_pn%cuts_lexpr => null ()
  case ("scale")
    rt_pn%scale_expr => null ()
  case ("factorization_scale")
    rt_pn%fac_scale_expr => null ()
  case ("renormalization_scale")
    rt_pn%ren_scale_expr => null ()
  case ("weight")
    rt_pn%weight_expr => null ()
  case ("selection")
    rt_pn%selection_lexpr => null ()
  case ("reweight")
    rt_pn%reweight_expr => null ()
  case ("analysis")
    rt_pn%analysis_lexpr => null ()
  end select
end subroutine rt_parse_nodes_clear

```

Output for the parse nodes.

```

<RT data: rt parse nodes: TBP>+≡
  procedure :: write => rt_parse_nodes_write

<RT data: procedures>+≡
subroutine rt_parse_nodes_write (object, unit)
  class(rt_parse_nodes_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u, i
  u = given_output_unit (unit)
  call wrt ("Cuts", object%cuts_lexpr)

    write (u, "(1x,A,':')") "Alternative setups"
    do i = 1, size (object%alt_setup)
      call write_separator (u)
    end do
  end if
end subroutine rt_parse_nodes_write

```

```

        call wrt ("Commands", object%alt_setup(i)%ptr)
    end do
end if
contains
subroutine wrt (title, pn)
    character(*), intent(in) :: title
    type(parse_node_t), intent(in), pointer :: pn
    if (associated (pn)) then
        write (u, "(1x,A,':')") title
        call write_separator (u)
        call parse_node_write_rec (pn, u)
    else
        write (u, "(1x,A,':',1x,A)") title, "[undefined]"
    end if
end subroutine wrt
end subroutine rt_parse_nodes_write

```

Screen output for individual components. (This should eventually be more condensed, currently we print the internal representation tree.)

```

<RT data: rt parse nodes: TBP>+≡
    procedure :: show => rt_parse_nodes_show

<RT data: procedures>+≡
subroutine rt_parse_nodes_show (rt_pn, name, unit)
    class(rt_parse_nodes_t), intent(in) :: rt_pn
    type(string_t), intent(in) :: name
    integer, intent(in), optional :: unit
    type(parse_node_t), pointer :: pn
    integer :: u
    u = given_output_unit (unit)
    select case (char (name))

        pn => rt_pn%weight_expr
    case ("selection")
        pn => rt_pn%selection_lexpr
    case ("reweight")
        pn => rt_pn%reweight_expr
    case ("analysis")
        pn => rt_pn%analysis_lexpr
    end select
    if (associated (pn)) then
        write (u, "(A,1x,A,1x,A)") "Expression:", char (name), "(parse tree):"
        call parse_node_write_rec (pn, u)
    else
        write (u, "(A,1x,A,A)") "Expression:", char (name), ": [undefined]"
    end if
end subroutine

```

```
end subroutine rt_parse_nodes_show
```

32.2.3 The data type

This is a big data container which contains everything that is used and modified during the command flow. A local copy of this can be used to temporarily override defaults. The data set is transparent.

```
<RT data: public>≡
  public :: rt_data_t

<RT data: types>+≡
  type :: rt_data_t
    type(lexer_t), pointer :: lexer => null ()
    type(rt_data_t), pointer :: context => null ()
    type(var_list_t) :: var_list
    type(iterations_list_t) :: it_list
    type(os_data_t) :: os_data
    type(model_list_t) :: model_list
    type(model_t), pointer :: model => null ()
    logical :: model_is_copy = .false.
    type(model_t), pointer :: preload_model => null ()
    type(model_t), pointer :: fallback_model => null ()
    type(model_t), pointer :: radiation_model => null ()
    type(prclib_stack_t) :: prclib_stack
    type(process_library_t), pointer :: prclib => null ()
    type(beam_structure_t) :: beam_structure
    type(rt_parse_nodes_t) :: pn
    type(process_stack_t) :: process_stack
    type(string_t), dimension(:), allocatable :: sample_fmt
    class(event_callback_t), allocatable :: event_callback
    type(file_list_t), pointer :: out_files => null ()

```

```

    call global%beam_structure%final_mom ()
end subroutine rt_data_clear_beams

```

32.2.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

```

32.2.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

$\langle RT \text{ data: } rt \text{ data: } TBP \rangle + \equiv$

```

    procedure :: local_init => rt_data_local_init
<RT data: procedures>+≡
    subroutine rt_data_local_init (local, global, env)
        class(rt_data_t), intent(inout), target :: local
        type(rt_data_t), intent(in), target :: global
        integer, intent(in), optional :: env
        local%context => global
        call local%process_stack%link (global%process_stack)
        call local%process_stack%init_var_list (local%var_list)
        call local%process_stack%link_var_list (global%var_list)
        call var_list_append_string &
            (local%var_list, var_str ("$model_name"), var_str (""), &
             intrinsic=.true.)
        call local%init_pointer_variables ()
        local%fallback_model => global%fallback_model
        local%radiation_model => global%radiation_model
        local%os_data = global%os_data
        local%logfile = global%logfile
        call local%model_list%link (global%model_list)
        local%model => global%model
        if (associated (local%model)) then
            call local%model%link_var_list (local%var_list)
        end if
        if (allocated (global%event_callback)) then
            allocate (local%event_callback, source = global%event_callback)
        end if
    end subroutine rt_data_local_init

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
    procedure :: init_pointer_variables => rt_data_init_pointer_variables
<RT data: procedures>+≡
    subroutine rt_data_init_pointer_variables (local)
        class(rt_data_t), intent(inout), target :: local
        logical, target, save :: known = .true.
        call var_list_append_string_ptr &
            (local%var_list, var_str ("%fc"), local%os_data%fc, known, &
             intrinsic=.true.)
        call var_list_append_string_ptr &
            (local%var_list, var_str ("%fcflags"), local%os_data%fcflags, known, &
             intrinsic=.true.)
    end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has `intent(inout)` because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local

environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: activate => rt_data_activate

<RT data: procedures>+≡
  subroutine rt_data_activate (local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), pointer :: global
    global => local%context
    if (associated (global)) then
      local%lexer => global%lexer
      call global%copy_globals (local)
      local%os_data = global%os_data
      local%logfile = global%logfile
      if (associated (global%prclib)) then
        local%prclib => &
          local%prclib_stack%get_library_ptr (global%prclib%get_name ())
      end if
      call local%import_values ()
      call local%process_stack%link (global%process_stack)
      local%it_list = global%it_list
      local%beam_structure = global%beam_structure
      local%pn = global%pn
      if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
      if (allocated (global%sample_fmt)) then
        allocate (local%sample_fmt (size (global%sample_fmt)), &
          source = global%sample_fmt)
      end if
      local%out_files => global%out_files
      local%model => global%model
      local%model_is_copy = .false.
    else if (.not. associated (local%model)) then
      local%model => local%preload_model
      local%model_is_copy = .false.
    end if
    if (associated (local%model)) then
      call local%model%link_var_list (local%var_list)
      call local%var_list%set_string (var_str ("model_name"), &
        local%model%get_name (), is_known = .true.)
    else
      call local%var_list%set_string (var_str ("model_name"), &
        var_str (""), is_known = .false.)
    end if
  end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model

(which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
  procedure :: deactivate => rt_data_deactivate

<RT data: procedures>+≡
  subroutine rt_data_deactivate (local, global, keep_local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), optional, target :: global
    logical, intent(in), optional :: keep_local
    type(string_t) :: local_model, local_scheme
    logical :: same_model, delete
    delete = .true.; if (present (keep_local)) delete = .not. keep_local
    if (present (global)) then
      if (associated (global%model) .and. associated (local%model)) then
        local_model = local%model%get_name ()
        if (global%model%has_schemes ()) then
          local_scheme = local%model%get_scheme ()

            global%model%matches (local_model, local_scheme)
        else
          same_model = global%model%matches (local_model)
        end if
      else
        same_model = .false.
      end if
      if (delete) then
        call local%process_stack%clear ()
        call local%unselect_model ()
        call local%unset_values ()
      else if (associated (local%model)) then
        call local%ensure_model_copy ()
      end if
      if (.not. same_model .and. associated (global%model)) then
        if (global%model%has_schemes ()) then
          call msg_message ("Restoring model '" // &
            char (global%model%get_name ()) // "', scheme '" // &
            char (global%model%get_scheme ()) // "'")
        else
          call msg_message ("Restoring model '" // &
            char (global%model%get_name ()) // "'")
        end if
      end if
      if (associated (global%model)) then
        call global%model%link_var_list (global%var_list)
      end if
      call global%restore_globals (local)
    else
      call local%unselect_model ()
    end if
  end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
  procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
  subroutine rt_data_copy_globals (global, local)
    class(rt_data_t), intent(in) :: global
    class(rt_data_t), intent(inout) :: local
    local%prclib_stack = global%prclib_stack
  end subroutine rt_data_copy_globals

```

This restores global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡
  procedure :: restore_globals => rt_data_restore_globals

<RT data: procedures>+≡
  subroutine rt_data_restore_globals (global, local)
    class(rt_data_t), intent(inout) :: global
    class(rt_data_t), intent(in) :: local
    global%prclib_stack = local%prclib_stack
  end subroutine rt_data_restore_globals

```

32.2.8 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need a finalizer.

```

<RT data: rt data: TBP>+≡
  procedure :: final => rt_data_global_final

<RT data: procedures>+≡
  subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
    call global%model_list%final ()
    call global%var_list%final (follow_link=.false.)
    if (associated (global%out_files)) then
      call file_list_final (global%out_files)
      deallocate (global%out_files)
    end if
  end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: local_final => rt_data_local_final

```

```

<RT data: procedures>+≡
  subroutine rt_data_local_final (local)
    class(rt_data_t), intent(inout) :: local
    call local%process_stack%clear ()
    call local%model_list%final ()
    call local%var_list%final (follow_link=.false.)
  end subroutine rt_data_local_final

```

32.2.9 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
  procedure :: read_model => rt_data_read_model

<RT data: procedures>+≡
  subroutine rt_data_read_model (global, name, model, scheme)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(string_t), intent(in), optional :: scheme
    type(model_t), pointer, intent(out) :: model
    type(string_t) :: filename
    filename = name // ".mdl"
    call global%model_list%read_model &
      (name, filename, global%os_data, model, scheme)
  end subroutine rt_data_read_model

```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```

<RT data: rt data: TBP>+≡
  procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: procedures>+≡
  subroutine rt_data_init_fallback_model (global, name, filename)

```

Return the collision energy as determined by the current beam settings. Without beam setup, this is the `sqrts` variable.

If the value is meaningless for a setup, the function returns zero.

Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data.t`, but this depends on the precision again, so we set them to some dummy values.

```

```

Local Model

Locally modify a model and restore the global one. We need an auxiliary function to determine the status of a model particle:

```

<RT data: test auxiliary>+≡
  function is_stable (pdg, global) result (flag)
    integer, intent(in) :: pdg
    type(rt_data_t), intent(in) :: global
    logical :: flag
    type(flavor_t) :: flv
    call flv%init (pdg, global%model)

```

```

        flag = flv%is_stable ()
    end function is_stable

function is_polarized (pdg, global) result (flag)
    integer, intent(in) :: pdg
    type(rt_data_t), intent(in) :: global
    logical :: flag
    type(flavor_t) :: flv
    call flv%init (pdg, global%model)
    flag = flv%is_polarized ()
end function is_polarized

<RT data: execute tests>+=
    call test (rt_data_6, "rt_data_6", &
        "local model", &
        u, results)

<RT data: test declarations>+=
    public :: rt_data_6

<RT data: tests>+=
    subroutine rt_data_6 (u)

32.3 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

We would like to put this in the `me_methods` folder but it also depends on `gosam` and `openloops`, so it is unclear where to put it.

```
<dispatch_me_methods.f90>≡
  <File header>

  module dispatch_me_methods

    <Use strings>
    use physics_defs, only: BORN
    use diagnostics
    use sm_qcd
    use variables
    use models
    use model_data

    use prc_core_def
    use prc_core
    use prc_test_core
    use prc_template_me
    use prc_test
    use prc_omega
    use prc_user_defined
    use prc_gosam
    use prc_openloops
    use prc_threshold

    <Standard module head>

    <Dispatch me methods: public>

    contains

    <Dispatch me methods: procedures>

  end module dispatch_me_methods
```

32.3.1 Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method` string variable.

Note: `core_def` has `intent(inout)` because gfortran 4.7.1 crashes for `intent(out)`.

```
<Dispatch me methods: public>≡
  public :: dispatch_core_def

<Dispatch me methods: procedures>≡
  subroutine dispatch_core_def (core_def, prt_in, prt_out, &
```

```

                                model, var_list, id, nlo_type)

end subroutine dispatch_core_def

```

32.3.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```

<Dispatch me methods: public>+≡
  public :: dispatch_core

<Dispatch me methods: procedures>+≡
  subroutine dispatch_core (core, core_def, model, &
    helicity_selection, qcd, use_color_factors)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_def_t), intent(in) :: core_def
    class(model_data_t), intent(in), target, optional :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    logical, intent(in), optional :: use_color_factors
    select type (core_def)
    type is (prc_test_def_t)
      allocate (test_t :: core)
    type is (template_me_def_t)
      allocate (prc_template_me_t :: core)
      select type (core)
      type is (prc_template_me_t)
        call core%set_parameters (model)
      end select
    class is (omega_def_t)
      if (.not. allocated (core)) allocate (prc_omega_t :: core)
      select type (core)
      type is (prc_omega_t)
        call core%set_parameters (model, &
          helicity_selection, qcd, use_color_factors)
      end select
    type is (gosam_def_t)
      if (.not. allocated (core)) allocate (prc_gosam_t :: core)
      select type (core)
      type is (prc_gosam_t)
        call core%set_parameters (qcd)
      end select
  end select

```

```

type is (openloops_def_t)
  if (.not. allocated (core)) allocate (prc_openloops_t :: core)
  select type (core)
  type is (prc_openloops_t)
    call core%set_parameters (qcd)
  end select
type is (user_defined_test_def_t)
  if (.not. allocated (core)) allocate (prc_user_defined_test_t :: core)
  select type (core)
  type is (prc_user_defined_test_t)
    call core%set_parameters (qcd, model)
  end select
type is (threshold_def_t)
  if (.not. allocated (core)) allocate (prc_threshold_t :: core)
  select type (core)
  type is (prc_threshold_t)
    !!! Need to wait for Bijan's answer to decide whether prc_threshold
    !!! really does not need color factors
    !!!call core%set_parameters (qcd, use_color_factors, model)
    call core%set_parameters (qcd, model)
  end select
class default
  call msg_bug ("Process core: unexpected process definition type")
end select
end subroutine dispatch_core

```

32.3.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

```

<Dispatch me methods: public>+≡
  public :: dispatch_core_update
  public :: dispatch_core_restore

<Dispatch me methods: procedures>+≡
  subroutine dispatch_core_update &
    (core, model, helicity_selection, qcd, saved_core)

    class(prc_core_t), allocatable, intent(inout) :: core
    class(model_data_t), intent(in), optional, target :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    class(prc_core_t), allocatable, intent(inout), optional :: saved_core

    if (present (saved_core)) then
      allocate (saved_core, source = core)
    end if
    select type (core)
    type is (test_t)

```

```

    type is (prc_omega_t)
        call core%set_parameters (model, helicity_selection, qcd)
        call core%activate_parameters ()
    class is (prc_user_defined_base_t)
        call msg_message ("Updating user defined cores is not implemented yet.")
    class default
        call msg_bug ("Process core update: unexpected process definition type")
    end select
end subroutine dispatch_core_update

subroutine dispatch_core_restore (core, saved_core)

```

32.4 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

```
<process_configurations.f90>≡  
  <File header>  
  
  module process_configurations  
  
    <Use strings>  
    use diagnostics  
    use models  
    use prc_core_def  
    use particle_specifiers  
    use process_libraries  
    use rt_data  
    use variables  
  
    use dispatch_me_methods, only: dispatch_core_def  
    use prc_user_defined, only: user_defined_def_t  
  
    <Standard module head>  
  
    <Process configurations: public>  
  
    <Process configurations: types>  
  
    contains  
  
    <Process configurations: procedures>  
  
  end module process_configurations
```

32.4.1 Data Type

```
<Process configurations: public>≡  
  public :: process_configuration_t  
  
<Process configurations: types>≡  
  type :: process_configuration_t  
    type(process_def_entry_t), pointer :: entry => null ()  
    type(string_t) :: id  
    integer :: num_id = 0  
    contains  
    <Process configurations: process configuration: TBP>  
  end type process_configuration_t
```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

```
<Process configurations: process configuration: TBP>≡
```

```

procedure :: init => process_configuration_init
<Process configurations: procedures>≡
  subroutine process_configuration_init &
    (config, prc_name, n_in, n_components, global)
    class(process_configuration_t), intent(out) :: config
    type(string_t), intent(in) :: prc_name
    integer, intent(in) :: n_in
    integer, intent(in) :: n_components
    type(rt_data_t), intent(in) :: global
    type(model_t), pointer :: model
    logical :: nlo_process
    model => global%model
    config%id = prc_name
    nlo_process = global%nlo_fixed_order
    allocate (config%entry)
    if (global%var_list%is_known (var_str ("process_num_id"))) then
      config%num_id = &
        global%var_list%get_ival (var_str ("process_num_id"))
      call config%entry%init (prc_name, &
        model = model, n_in = n_in, n_components = n_components, &
        num_id = config%num_id, nlo_process = nlo_process)
    else
      call config%entry%init (prc_name, &
        model = model, n_in = n_in, n_components = n_components, &
        nlo_process = nlo_process)
    end if
  end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

```

    <Process configurations: test auxiliary>  
  
    <Process configurations: tests>  
  
  end module process_configurations_uti
```

API: driver for the unit tests below.

```
<Process configurations: public test>≡  
  public :: process_configurations_test
```

```

<Process configurations: test driver>≡
  subroutine process_configurations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Process configurations: execute tests>
  end subroutine process_configurations_test

```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

This is re-exported by the UT module.

```

<Process configurations: public test auxiliary>≡
  public :: prepare_test_library

<Process configurations: test auxiliary>≡

```

32.5 Compilation

This module manages compilation and loading of of process libraries. It is needed as a separate module because integration depends on it.

```
<compilations.f90>≡  
  <File header>  
  
  module compilations  
  
    <Use strings>  
    use io_units  
    use system_defs, only: TAB  
    use diagnostics  
    use os_interface  
    use variables  
    use model_data  
    use process_libraries  
    use prclib_stacks  
    use rt_data  
  
    <Standard module head>  
  
    <Compilations: public>  
  
    <Compilations: types>  
  
    contains  
  
    <Compilations: procedures>  
  
  end module compilations
```

32.5.1 The data type

The compilation item handles the compilation and loading of a single process library.

```
<Compilations: public>≡  
  public :: compilation_item_t  
  
<Compilations: types>≡  
  type :: compilation_item_t  
    private  
    type(string_t) :: libname  
    type(string_t) :: static_external_tag  
    type(process_library_t), pointer :: lib => null ()  
    logical :: recompile_library = .false.  
  contains  
    <Compilations: compilation item: TBP>  
  end type compilation_item_t
```

Initialize:

```
<Compilations: compilation item: TBP>≡  
  procedure :: init => compilation_item_init
```

```

<Compilations: procedures>≡
subroutine compilation_item_init (comp, libname, stack, var_list)
  class(compilation_item_t), intent(out) :: comp
  type(string_t), intent(in) :: libname
  type(prclib_stack_t), intent(inout) :: stack
  type(var_list_t), intent(in) :: var_list
  comp%libname = libname
  comp%lib => stack%get_library_ptr (comp%libname)
  if (.not. associated (comp%lib)) then
    call msg_fatal ("Process library '" // char (comp%libname) &
      // "' has not been declared.")
  end if
  comp%recompile_library = &
    var_list%get_lval (var_str ("?recompile_library"))
end subroutine compilation_item_init

```

Compile the current library. The force flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

```

<Compilations: compilation item: TBP>+≡
  procedure :: compile => compilation_item_compile

<Compilations: procedures>+≡
subroutine compilation_item_compile (comp, model, os_data, force, recompile)
  class(compilation_item_t), intent(inout) :: comp
  class(model_data_t), intent(in), target :: model
  type(os_data_t), intent(in) :: os_data
  logical, intent(in) :: force, recompile
  if (associated (comp%lib)) then
    call msg_message ("Process library '" &
      // char (comp%libname) // "': compiling ...")
    call comp%lib%configure (os_data)
    if (signal_is_pending ()) return
    call comp%lib%compute_md5sum (model)
    call comp%lib%write_makefile (os_data, force)
    if (signal_is_pending ()) return
    if (force) then
      call comp%lib%clean (os_data, distclean = .false.)
      if (signal_is_pending ()) return
    end if
    call comp%lib%write_driver (force)
    if (signal_is_pending ()) return
    if (recompile) then
      call comp%lib%load (os_data, keep_old_source = .true.)
      if (signal_is_pending ()) return
    end if
    call comp%lib%update_status (os_data)
  end if
end subroutine compilation_item_compile

```

Load the current library, just after compiling it.

```

<Compilations: compilation item: TBP>+≡
  procedure :: load => compilation_item_load

```

```

<Compilations: procedures>+≡
  subroutine compilation_item_load (comp, os_data)
    class(compilation_item_t), intent(inout) :: comp
    type(os_data_t), intent(in) :: os_data
    if (associated (comp%lib)) then
      call comp%lib%load (os_data)
    end if
  end subroutine compilation_item_load

```

Message as a separate call:

```

<Compilations: compilation item: TBP>+≡
  procedure :: success => compilation_item_success

<Compilations: procedures>+≡
  subroutine compilation_item_success (comp)
    class(compilation_item_t), intent(in) :: comp
    if (associated (comp%lib)) then
      call msg_message ("Process library '" // char (comp%libname) &
        // "' : ... success.")
    else
      call msg_fatal ("Process library '" // char (comp%libname) &
        // "' : ... failure.")
    end if
  end subroutine compilation_item_success

```

32.5.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
  public :: compile_library

<Compilations: procedures>+≡
  subroutine compile_library (libname, global)
    type(string_t), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
    type(compilation_item_t) :: comp
    logical :: force, recompile
    force = &
      global%var_list%get_lval (var_str ("?rebuild_library"))
    recompile = &
      global%var_list%get_lval (var_str ("?recompile_library"))
    if (associated (global%model)) then
      call comp%init (libname, global%prclib_stack, global%var_list)
      call comp%compile (global%model, global%os_data, force, recompile)
      if (signal_is_pending ()) return
      call comp%load (global%os_data)
      if (signal_is_pending ()) return
    else

```

```

        call msg_fatal ("Process library compilation: " &
            // " model is undefined.")
    end if
    call comp%success ()
end subroutine compile_library

```

32.5.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```

<Compilations: public>+≡
    public :: compilation_t

<Compilations: types>+≡
    type :: compilation_t
        private
        type(string_t) :: exe_name
        type(string_t), dimension(:), allocatable :: lib_name
    contains
        <Compilations: compilation: TBP>
    end type compilation_t

```

Output.

```

<Compilations: compilation: TBP>≡
    procedure :: write => compilation_write

<Compilations: procedures>+≡
    subroutine compilation_write (object, unit)
        class(compilation_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit)
        write (u, "(1x,A)") "Compilation object:"
        write (u, "(3x,3A)") "executable      = '", &
            char (object%exe_name), "'"
        write (u, "(3x,A)", advance="no") "process libraries ="
        do i = 1, size (object%lib_name)
            write (u, "(1x,3A)", advance="no") "'", char (object%lib_name(i)), "'"
        end do
        write (u, *)
    end subroutine compilation_write

```

Initialize: we know the names of the executable and of the libraries.

```

<Compilations: compilation: TBP>+≡
    procedure :: init => compilation_init

<Compilations: procedures>+≡
    subroutine compilation_init (compilation, exe_name, lib_name)
        class(compilation_t), intent(out) :: compilation
        type(string_t), intent(in) :: exe_name
        type(string_t), dimension(:), intent(in) :: lib_name
        compilation%exe_name = exe_name

```

```

        allocate (compilation%lib_name (size (lib_name)))
        compilation%lib_name = lib_name
    end subroutine compilation_init

```

Write the dispatcher subroutine for the compiled libraries. Also write a subroutine which returns the names of the compiled libraries.

<Compilations: compilation: TBP>+≡

```

    procedure :: write_dispatcher => compilation_write_dispatcher

```

<Compilations: procedures>+≡

```

subroutine compilation_write_dispatcher (compilation)

32.6.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

<Integrations: public>≡
    public :: integration_t

<Integrations: types>≡
    type :: integration_t
        private
            type(string_t) :: process_id
            type(string_t) :: run_id
            type(process_t), pointer :: process => null ()
            type(var_list_t), pointer :: model_vars => null ()
            type(qcd_t) :: qcd
            logical :: rebuild_phs = .false.
            logical :: ignore_phs_mismatch = .false.
            logical :: phs_only = .false.
            logical :: process_has_me = .true.
            integer :: n_calls_test = 0
            logical :: vis_history = .true.
            type(string_t) :: history_filename
            type(string_t) :: log_filename
            logical :: combined_integration = .false.
            type(iteration_multipliers_t) :: iteration_multipliers
            type(nlo_settings_t) :: nlo_settings
        contains
            <Integrations: integration: TBP>
    end type integration_t

```

32.6.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied.

```

<Integrations: integration: TBP>≡
    procedure :: create_process => integration_create_process

<Integrations: procedures>≡
    subroutine integration_create_process (intg, process_id, global)
        class(integration_t), intent(out) :: intg

```

```

type(rt_data_t), intent(inout), optional, target :: global
type(string_t), intent(in) :: process_id
type(process_entry_t), pointer :: process_entry
call msg_debug (D_CORE, "integration_create_process")
intg%process_id = process_id
if (present (global)) then
  allocate (process_entry)
  intg%process => process_entry%process_t
  call global%process_stack%push (process_entry)
else
  allocate (process_t :: intg%process)
end if
intg%model_vars => null ()
end subroutine integration_create_process

```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the local stack directly. The intent(inout) attribute for the local data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

(Integrations: integration: TBP)+≡

```

procedure :: init_process => integration_init_process

```

(Integrations: procedures)+≡

```

subroutine integration_init_process (intg, local)
  class(integration_t), intent(inout) :: intg
  type(rt_data_t), intent(inout), target :: local
  type(string_t) :: model_name
  type(model_t), pointer :: model
  class(model_data_t), pointer :: model_instance
  class(rng_factory_t), allocatable :: rng_factory
  call msg_debug (D_CORE, "integration_init_process")
  if (.not. local%prclib%contains (intg%process_id)) then
    call msg_fatal ("Process '" // char (intg%process_id) // "' not found" &
      // " in library '" // char (local%prclib%get_name ()) // "'")
    return
  end if
  intg%run_id = &

32.6.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```
<Integrations: integration: TBP>+≡
  procedure :: evaluate => integration_evaluate

<Integrations: procedures>+≡
  subroutine integration_evaluate &
    (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
    integer :: n_calls, n_it
    logical :: adapt_grids, adapt_weights, final
    n_it = it_list%get_n_it (pass)
    n_calls = it_list%get_n_calls (pass)
    adapt_grids = it_list%adapt_grids (pass)
    adapt_weights = it_list%adapt_weights (pass)
    final = pass == it_list%get_n_pass ()
    call process_instance%integrate ( &
      i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
      final, pacify)
  end subroutine integration_evaluate
```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

```
<Integrations: integration: TBP>+≡
  procedure :: make_iterations_list => integration_make_iterations_list

<Integrations: procedures>+≡
  subroutine integration_make_iterations_list (intg, it_list)
    class(integration_t), intent(in) :: intg
    type(iterations_list_t), intent(out) :: it_list
    integer :: pass, n_pass
    integer, dimension(:), allocatable :: n_it, n_calls
    logical, dimension(:), allocatable :: adapt_grids, adapt_weights
    n_pass = intg%process%get_n_pass_default ()
    allocate (n_it (n_pass), n_calls (n_pass))
    allocate (adapt_grids (n_pass), adapt_weights (n_pass))
    do pass = 1, n_pass
      n_it(pass) = intg%process%get_n_it_default (pass)
      n_calls(pass) = intg%process%get_n_calls_default (pass)
      adapt_grids(pass) = intg%process%adapt_grids_default (pass)
      adapt_weights(pass) = intg%process%adapt_weights_default (pass)
    end do
    call it_list%init (n_it, n_calls, &
      adapt_grids = adapt_grids, adapt_weights = adapt_weights)
  end subroutine integration_make_iterations_list
```

In NLO calculations, the individual components might scale very differently with the number of calls. This especially applies to the real-subtracted component, which usually fluctuates more than the Born and virtual component, making it a bottleneck of the calculation. Thus, the calculation is throttled twice, first by the number of calls for the real component, second by the number of surplus calls of computation-intense virtual matrix elements. Therefore, we want to set a different number of calls for each component, which is done by the subroutine `integration_apply_multipliers`.

    end if
    call process_instance%final ()
end subroutine integration_sampler_test

```

Return the process pointer (needed by simulate):

```

<Integrations: integration: TBP>+≡
    procedure :: get_process_ptr => integration_get_process_ptr

<Integrations: procedures>+≡
    function integration_get_process_ptr (intg) result (ptr)
        class(integration_t), intent(in) :: intg
        type(process_t), pointer :: ptr
        ptr => intg%process
    end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the `global` environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the `process` object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

```

<Integrations: public>+≡
    public :: integrate_process

<Integrations: procedures>+≡
    subroutine integrate_process (process_id, local, global, local_stack, init_only, eff_reset)

```

Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (32.1)$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (32.2)$$

f is the flux of the incoming particles with mass $m = 125 \text{ GeV}$ and energy $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (32.3)$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (32.4)$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (32.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function $f(x) = x$ for both beams. Together with the $1/x_1 x_2$ factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the m_s mass which we set to zero here.

```

Integration with sign change

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`. The weight that is applied changes the sign in half of phase space. The weight is -3 and 1 , respectively, so the total result is equal to the original, but negative sign.

The efficiency should (approximately) become the average of 1 and $1/3$, that is $2/3$.

```

32.7 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```
(event_streams.f90)≡  
  <File header>  
  
  module event_streams  
  
    <Use strings>  
    use io_units  
    use diagnostics  
    use events  
    use eio_data  
    use eio_base  
    use rt_data  
  
    use dispatch_transforms, only: dispatch_eio  
  
    <Standard module head>  
  
    <Event streams: public>  
  
    <Event streams: types>  
  
    contains  
  
    <Event streams: procedures>  
  
  end module event_streams
```

32.7.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡  
  type :: event_stream_entry_t  
    class(eio_t), allocatable :: eio  
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```
<Event streams: public>≡  
  public :: event_stream_array_t  
  
<Event streams: types>+≡  
  type :: event_stream_array_t  
    type(event_stream_entry_t), dimension(:), allocatable :: entry  
    integer :: i_in = 0  
    contains  
    <Event streams: event stream array: TBP>  
  end type event_stream_array_t
```

Output.

```

(Event streams: event stream array: TBP)≡
  procedure :: write => event_stream_array_write

(Event streams: procedures)≡
  subroutine event_stream_array_write (object, unit)
    class(event_stream_array_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Event stream array:"
    if (allocated (object%entry)) then
      select case (size (object%entry))
      case (0)
        write (u, "(3x,A)") "[empty]"
      case default
        do i = 1, size (object%entry)
          if (i == object%i_in) write (u, "(1x,A)") "Input stream:"
          call object%entry(i)%eio%write (u)
        end do
      end select
    else
      write (u, "(3x,A)") "[undefined]"
    end if
  end subroutine event_stream_array_write

```

Finalize all streams.

```

(Event streams: event stream array: TBP)+≡
  procedure :: final => event_stream_array_final

(Event streams: procedures)+≡
  subroutine event_stream_array_final (es_array)
    class(event_stream_array_t), intent(inout) :: es_array
    integer :: i
    do i = 1, size (es_array%entry)
      call es_array%entry(i)%eio%final ()
    end do
  end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

```

(Event streams: event stream array: TBP)+≡
  procedure :: init => event_stream_array_init

```

32.8.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

<Simulations: types>+≡

```

type :: core_safe_t
    class(prc_core_t), allocatable :: core
end type core_safe_t

```

32.8.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration

is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

(Simulations: procedures)+≡

```

subroutine prepare_process &
  (process, process_id, use_process, integrate, local, global)
  type(process_t), pointer, intent(out) :: process
  type(string_t), intent(in) :: process_id
  logical, intent(in) :: use_process, integrate
  type(rt_data_t), intent(inout), target :: local
  type(rt_data_t), intent(inout), optional, target :: global
  if (present (global)) then
    process => global%process_stack%get_process_ptr (process_id)
  else
    process => local%process_stack%get_process_ptr (process_id)
  end if
  if (use_process .and. .not. associated (process)) then
    if (integrate) then
      call msg_message ("Simulate: process '" &
        // char (process_id) // "' needs integration")
    else
      call msg_message ("Simulate: process '" &
        // char (process_id) // "' needs initialization")
    end if
    if (present (global)) then
      call integrate_process (process_id, local, global, &
        init_only = .not. integrate)
    else
      call integrate_process (process_id, local, local_stack=.true., &
        init_only = .not. integrate)
    end if
    if (signal_is_pending ()) return
    process => global%process_stack%get_process_ptr (process_id)
    if (associated (process)) then
      if (integrate) then
        call msg_message ("Simulate: integration done")
        call global%process_stack%fill_result_vars (process_id)
      else
        call msg_message ("Simulate: process initialization done")
      end if
    else

        // char (process_id) // "' could not be initialized: aborting")
    end if
  else if (.not. associated (process)) then
    call msg_message &
      ("Simulate: process '" &
        // char (process_id) // "': enabled for rescan only")
  end if
end subroutine prepare_process

```

32.8.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

For the purpose of NLO events, `entry_t` contains a pointer list to other simulation-entries. This is due to the fact that we have to associate an event for each component of the fixed order simulation, i.e. one N -particle event and N_α $N + 1$ -particle events. However, all entries share the same event transforms.

```

<Simulations: types>+≡
  type, extends (event_t) :: entry_t
  private
    type(string_t) :: process_id
    type(string_t) :: library
    type(string_t) :: run_id

end subroutine entry_copy_entry
```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the **process_instance** pointer. Assign data by looking at the process object and at the environment.

If **n_alt** is set, we prepare for additional alternate sqme and weight entries.

The **compile** flag is only false if we don't need the Whizard process at all, just its definition. In that case, we skip process initialization.

Otherwise, and if the process object is not found initially: if **integrate** is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If **generate** is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the **instance** and **process** pointers of the base type by the **connect** method, so we can reference them later.

32.8.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
    type, extends (entry_t) :: alt_entry_t
    contains
        <Simulations: alt entry: TBP>
    end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the

process and instance.

32.8.7 The simulation type

Each simulation object corresponds to an event sample, identified by the `sample_id`.

The simulation may cover several processes simultaneously. All process-specific data, including the event records, are stored in the `entry` subobjects. The `current` index indicates which record was selected last. `version` is foreseen to contain a tag on the WHIZARD event file version. It can be

```

<Simulations: public>=

Write the current event record. If an explicit index is given, write that event record.

We implement writing to `unit` (event contents / debugging format) and writing to an `eio` event stream (storage). We include a `testflag` in order to suppress numerical noise in the testsuite.

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take `n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the `luminosity` setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the `luminosity`, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

```

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

NB: When reading from file, event transforms can't be applied because the process instance will not be complete. This should be fixed.

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

            call msg_fatal ("Simulation: write event: no process selected")
        end if
    end subroutine simulation_write_event_eio

```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```

  end select
end subroutine simulation_read_event_eio

```

32.8.9 Event Stream Array

Write an event using an array of event I/O streams. The process index must be selected, or the current index must be available.

```

(Simulations: simulation: TBP)+≡
generic :: write_event => write_event_es_array
procedure :: write_event_es_array => simulation_write_event_es_array

(Simulations: procedures)+≡
subroutine simulation_write_event_es_array (object, es_array, passed)
  class(simulation_t), intent(in), target :: object
  class(event_stream_array_t), intent(inout) :: es_array
  logical, intent(in), optional :: passed
  integer :: i_prc, event_index
  integer :: i
  type(entry_t), pointer :: current_entry
  i_prc = object%i_prc
  if (i_prc > 0) then
    event_index = object%counter%total
    current_entry => object%entry(i_prc)%get_first ()
    do i = 1, current_entry%count_nlo_entries ()
      if (i > 1) current_entry => current_entry%get_next ()
      call es_array%output (current_entry%event_t, i_prc, &

```

```

        event_index, passed = passed, pacify = object%pacify)
    end do
else
    call msg_fatal ("Simulation: write event: no process selected")
end if
end subroutine simulation_write_event_es_array

```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

```

Return data that may be useful for writing event files.

Usually we can refer to a previously integrated process, for which we can fetch a process pointer. Occasionally, we don't have this because we're just rescanning an externally generated file without calculation. For that situation, we generate our local beam data object using the current environment, or, in simple cases, just fetch the necessary data from the process definition and environment.

Chapter 33

More Unit Tests

This chapter collects some procedures for testing that can't be provided at the point where the corresponding modules are defined, because they use other modules of a different level.

(We should move them back, collecting the high-level functionality in init/final hooks that we can set at runtime.)

33.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```

```

Processes: scales and such

Initialize a process and process instance, choose a sampling point and fill the process instance, evaluating a given cut configuration.

We use the same trivial process as for the previous test. All momentum and state dependence is trivial, so we just test basic functionality.

```

<Expr tests: execute tests>+≡
  call test (processes_6, "processes_6", &

Chapter 34

Top Level

The top level consists of

commands Defines generic command-list and command objects, and all specific implementations. Each command type provides a specific functionality. Together with the modules that provide expressions and variables, this module defines the Sindarin language.

whizard This module interprets streams of various kind in terms of the command language. It also contains the unit-test feature. We also define the externally visible procedures here, for the **WHIZARD** as a library.

main The driver for **WHIZARD** as a stand-alone program. Contains the command-line interpreter.

whizard_c_interface Alternative top-level procedures, for use in the context of a C-compatible caller program.

34.1 Commands

This module defines the command language of the main input file.

    <Commands: procedures>

end module commands

```

34.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```

<Commands: types>≡
    type, abstract :: command_t
        type(parse_node_t), pointer :: pn => null ()
        class(command_t), pointer :: next => null ()
        type(parse_node_t), pointer :: pn_opt => null ()
        type(command_list_t), pointer :: options => null ()
        type(rt_data_t), pointer :: local => null ()
    contains
        <Commands: command: TBP>
    end type command_t

```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```

<Commands: command: TBP>≡
    procedure :: final => command_final

<Commands: procedures>≡
    recursive subroutine command_final (cmd)
        class(command_t), intent(inout) :: cmd
        if (associated (cmd%options)) then
            call cmd%options%final ()
            deallocate (cmd%options)
            call cmd%local%local_final ()
            deallocate (cmd%local)
        else
            cmd%local => null ()
        end if
    end subroutine command_final

```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

(Commands: procedures)+≡

```

subroutine dispatch_command (command, pn)
  class(command_t), intent(inout), pointer :: command
  type(parse_node_t), intent(in), target :: pn

        call msg_bug ("Command not implemented")
    end select
    command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_write), deferred :: write
⟨Commands: interfaces⟩≡
    abstract interface
        subroutine command_write (cmd, unit, indent)
            import
            class(command_t), intent(in) :: cmd
            integer, intent(in), optional :: unit, indent
        end subroutine command_write
    end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_compile), deferred :: compile
⟨Commands: interfaces⟩+≡
    abstract interface
        subroutine command_compile (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_compile
    end interface

```

Execute a command. This will use and/or modify the runtime data set. If the quit flag is set, the caller should terminate command execution.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_execute), deferred :: execute
⟨Commands: interfaces⟩+≡
    abstract interface
        subroutine command_execute (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_execute
    end interface

```

34.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate

local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```

<Commands: command: TBP>+≡
  procedure :: write_options => command_write_options

<Commands: procedures>+≡
  recursive subroutine command_write_options (cmd, unit, indent)
    class(command_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: ind
    ind = 1; if (present (indent)) ind = indent + 1
    if (associated (cmd%options)) call cmd%options%write (unit, ind)
  end subroutine command_write_options

```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```

<Commands: command: TBP>+≡
  procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
  recursive subroutine command_compile_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%pn_opt)) then
      allocate (cmd%local)
      call cmd%local%local_init (global)
      call global%copy_globals (cmd%local)
      allocate (cmd%options)
      call cmd%options%compile (cmd%pn_opt, cmd%local)
      call global%restore_globals (cmd%local)
      call cmd%local%deactivate ()
    else
      cmd%local => global
    end if
  end subroutine command_compile_options

```

Execute options. First prepare the local environment, then execute the command list.

```

<Commands: command: TBP>+≡
  procedure :: execute_options => cmd_execute_options

<Commands: procedures>+≡
  recursive subroutine cmd_execute_options (cmd, global)
    class(command_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (associated (cmd%options)) then
      call cmd%local%activate ()
      call cmd%options%execute (cmd%local)
    end if
  end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

⟨Commands: command: TBP⟩+≡
    procedure :: reset_options => cmd_reset_options

⟨Commands: procedures⟩+≡
    subroutine cmd_reset_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call cmd%local%deactivate (global)
        end if
    end subroutine cmd_reset_options

```

34.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_model_t
    private
        type(string_t) :: name
        type(string_t) :: scheme
    contains
        ⟨Commands: cmd model: TBP⟩
    end type cmd_model_t

```

Output

```

⟨Commands: cmd model: TBP⟩≡
    procedure :: write => cmd_model_write

⟨Commands: procedures⟩+≡
    subroutine cmd_model_write (cmd, unit, indent)
        class(cmd_model_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,1x,'"',A,'\"') "model =", char (cmd%name)
    end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed. If the model has a scheme argument, take this into account.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

```

⟨Commands: cmd model: TBP⟩+≡
    procedure :: compile => cmd_model_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_model_compile (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd

    end if
  end subroutine cmd_library_execute

```

Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to `O'MEGA`, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for `O'MEGA` matrix elements as Fortran code, `ovm` for `O'MEGA` matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by `WHIZARD`, `template` and `template_unity` for test matrix elements generated by `WHIZARD` as Fortran code similar to the `O'MEGA` code. If the one-loop program (OLP) `GoSam` is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_process_t
  private
  type(string_t) :: id
  integer :: n_in = 0
  type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
  type(parse_node_t), pointer :: pn_out => null ()
  contains
  ⟨Commands: cmd process: TBP⟩

```

```
end type cmd_process_t
```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```
<Commands: cmd process: TBP>≡
  procedure :: write => cmd_process_write

<Commands: procedures>+≡
  subroutine cmd_process_write (cmd, unit, indent)
    class(cmd_process_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)" "process: ", char (cmd%id), " (", &
      size (cmd%pn_pdg_in), " -> X)"
    call cmd%write_options (u, indent)
  end subroutine cmd_process_write
```

Compile. Find and assign the parse nodes.

```
<Commands: cmd process: TBP>+≡
  procedure :: compile => cmd_process_compile

<Commands: procedures>+≡
  subroutine cmd_process_compile (cmd, global)
    class(cmd_process_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_id, pn_in, pn_codes
    integer :: i
    pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_in => parse_node_get_next_ptr (pn_id, 2)
    cmd%pn_out => parse_node_get_next_ptr (pn_in, 2)
    cmd%pn_opt => parse_node_get_next_ptr (cmd%pn_out)
    call cmd%compile_options (global)
    cmd%id = parse_node_get_string (pn_id)
    cmd%n_in = parse_node_get_n_sub (pn_in)
    pn_codes => parse_node_get_sub_ptr (pn_in)
    allocate (cmd%pn_pdg_in (cmd%n_in))
    do i = 1, cmd%n_in
      cmd%pn_pdg_in(i)%ptr => pn_codes
      pn_codes => parse_node_get_next_ptr (pn_codes)
    end do
  end subroutine cmd_process_compile
```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The

user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

```

SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_slha_t
    private
      type(string_t) :: file
      logical :: write_mode = .false.
    contains
      <Commands: cmd slha: TBP>
    end type cmd_slha_t

```

Output.

```

<Commands: cmd slha: TBP>≡
  procedure :: write => cmd_slha_write
<Commands: procedures>+≡
  subroutine cmd_slha_write (cmd, unit, indent)
    class(cmd_slha_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A)") "slha: file name = ", char (cmd%file)
    write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
  end subroutine cmd_slha_write

```

Compile. Read the filename and store it.

```

<Commands: cmd slha: TBP>+≡
  procedure :: compile => cmd_slha_compile
<Commands: procedures>+≡
  subroutine cmd_slha_compile (cmd, global)
    class(cmd_slha_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_key, pn_arg, pn_file
    pn_key => parse_node_get_sub_ptr (cmd%pn)
    pn_arg => parse_node_get_next_ptr (pn_key)
    pn_file => parse_node_get_sub_ptr (pn_arg)
    call cmd%compile_options (global)
    cmd%pn_opt => parse_node_get_next_ptr (pn_arg)
    select case (char (parse_node_get_key (pn_key)))
    case ("read_slha")
      cmd%write_mode = .false.
    case ("write_slha")
      cmd%write_mode = .true.
    case default

    end select
    cmd%file = parse_node_get_string (pn_file)
  end subroutine cmd_slha_compile

```

Execute. Read or write the specified SLHA file. Behind the scenes, this will first read the WHIZARD model file, then read the SLHA file and assign the SLHA parameters as far as determined by `dispatch_slha`. Finally, the global variables are synchronized with the model. This is similar to executing `cmd_model`.

```

Clear values

This command clears the current values of variables or other objects, where this makes sense. It parallels the `show` command. The objects are cleared, but not deleted.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_clear_t
    private
    type(string_t), dimension(:), allocatable :: name
    contains
    <Commands: cmd clear: TBP>
  end type cmd_clear_t
```

Output: list the names of the objects to be cleared.

```
<Commands: cmd clear: TBP>≡
  procedure :: write => cmd_clear_write

<Commands: procedures>+≡
  subroutine cmd_clear_write (cmd, unit, indent)
    class(cmd_clear_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u, i
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)", advance="no") "clear: "
    if (allocated (cmd%name)) then
      do i = 1, size (cmd%name)
        write (u, "(1x,A)", advance="no") char (cmd%name(i))
      end do
      write (u, *)
    else
      write (u, "(5x,A)") "[undefined]"
    end if
  end subroutine cmd_clear_write
```

Compile. Allocate an array which is filled with the names of the objects to be cleared.

Note: there is currently no need to account for options, but we prepare for that possibility.

```

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_expect_t
    private
    type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
    ⟨Commands: cmd expect: TBP⟩
end type cmd_expect_t

```

Simply tell the status.

```

⟨Commands: cmd expect: TBP⟩≡
    procedure :: write => cmd_expect_write

⟨Commands: procedures⟩+≡
    subroutine cmd_expect_write (cmd, unit, indent)

Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

⟨Commands: types⟩+≡
  type :: sentry_expr_t
    type(parse_node_p), dimension(:), allocatable :: expr
    contains
    ⟨Commands: sentry_expr: TBP⟩
  end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

⟨Commands: sentry_expr: TBP⟩≡
  procedure :: compile => sentry_expr_compile

⟨Commands: procedures⟩+≡
  subroutine sentry_expr_compile (sentry, pn)
    class(sentry_expr_t), intent(out) :: sentry
    type(parse_node_t), intent(in), target :: pn
    type(parse_node_t), pointer :: pn_expr, pn_extra
    integer :: n_expr, i
    n_expr = parse_node_get_n_sub (pn)
    allocate (sentry%expr (n_expr))
    if (n_expr > 0) then
      i = 0
      pn_expr => parse_node_get_sub_ptr (pn)
      pn_extra => parse_node_get_next_ptr (pn_expr)
      do i = 1, n_expr
        sentry%expr(i)%ptr => pn_expr
        if (associated (pn_extra)) then
          pn_expr => parse_node_get_sub_ptr (pn_extra, 2)
          pn_extra => parse_node_get_next_ptr (pn_extra)
        end if
      end do
    end if
  end subroutine sentry_expr_compile

```

```

        end if
    end subroutine sentry_expr_compile

```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

(Commands: sentry expr: TBP)+≡

```

    procedure :: evaluate => sentry_expr_evaluate

```

(Commands: procedures)+≡

```

        pn_proc => parse_node_get_sub_ptr (pn_proclist)

```

```

do i = 1, cmd%n_proc
  cmd%process_id(i) = parse_node_get_string (pn_proc)
  call global%process_stack%init_result_vars (cmd%process_id(i))
  pn_proc => parse_node_get_next_ptr (pn_proc)
end do
end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

<Commands: cmd integrate: TBP>+≡
  procedure :: execute => cmd_integrate_execute

<Commands: procedures>+≡
  subroutine cmd_integrate_execute (cmd, global)
    class(cmd_integrate_t), intent(inout) :: cmd

    type(parse_node_t), pointer :: pn_tag
    pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%init (pn_tag, global)
  end subroutine cmd_plot_compile

```

This init routine is separated because it is reused below for graph initialization.

```

⟨Commands: cmd plot: TBP⟩+≡
  procedure :: init => cmd_plot_init

⟨Commands: procedures⟩+≡
  subroutine cmd_plot_init (plot, pn_tag, global)
    class(cmd_plot_t), intent(inout) :: plot
    type(parse_node_t), intent(in), pointer :: pn_tag
    type(rt_data_t), intent(inout), target :: global
    call plot%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      plot%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("plot: name expression not implemented (yet)")
    end select
  end subroutine cmd_plot_init

```

Command execution. This declares the plot and allocates it in the analysis store.

```

⟨Commands: cmd plot: TBP⟩+≡
  procedure :: execute => cmd_plot_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_plot_execute (cmd, global)
    class(cmd_plot_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call drawing_options_init_plot (drawing_options)
    call set_drawing_options (drawing_options, var_list)

    call analysis_init_plot (cmd%id, graph_options, drawing_options)
  end subroutine cmd_plot_execute

```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_graph_t
    private
    type(string_t) :: id
    integer :: n_elements = 0
    type(cmd_plot_t), dimension(:), allocatable :: el
    type(string_t), dimension(:), allocatable :: element_id
  contains
    <Commands: cmd graph: TBP>
  end type cmd_graph_t
```

Output. Just print the ID.

```
<Commands: cmd graph: TBP>≡
  procedure :: write => cmd_graph_write

<Commands: procedures>+≡
  subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)") "graph: ", char (cmd%id), &
      " (", cmd%n_elements, " entries)"
  end subroutine cmd_graph_write
```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```
<Commands: cmd graph: TBP>+≡
  procedure :: compile => cmd_graph_compile

<Commands: procedures>+≡
  subroutine cmd_graph_compile (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
    integer :: i

    pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_tag => parse_node_get_sub_ptr (pn_term)
    cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%compile_options (global)
    select case (char (parse_node_get_rule_key (pn_tag)))
    case ("analysis_id")
      cmd%id = parse_node_get_string (pn_tag)
    case default
      call msg_bug ("graph: name expression not implemented (yet)")
```

```

end select
pn_def => parse_node_get_next_ptr (pn_term, 2)
cmd%n_elements = parse_node_get_n_sub (pn_def)
allocate (cmd%element_id (cmd%n_elements))
allocate (cmd%el (cmd%n_elements))
pn_term => parse_node_get_sub_ptr (pn_def)
pn_tag => parse_node_get_sub_ptr (pn_term)
cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
call cmd%el(1)%init (pn_tag, global)
cmd%element_id(1) = parse_node_get_string (pn_tag)
pn_app => parse_node_get_next_ptr (pn_term)
do i = 2, cmd%n_elements
  pn_term => parse_node_get_sub_ptr (pn_app, 2)
  pn_tag => parse_node_get_sub_ptr (pn_term)
  cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
  call cmd%el(i)%init (pn_tag, global)
  cmd%element_id(i) = parse_node_get_string (pn_tag)
  pn_app => parse_node_get_next_ptr (pn_app)
end do

end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: execute => cmd_graph_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_execute (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(graph_options_t) :: graph_options
    type(drawing_options_t) :: drawing_options
    integer :: i, type

    var_list => cmd%local%get_var_list_ptr ()
    call graph_options_init (graph_options)
    call set_graph_options (graph_options, var_list)
    call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

    do i = 1, cmd%n_elements
      if (associated (cmd%el(i)%options)) then
        call cmd%el(i)%options%execute (cmd%el(i)%local)
      end if
      type = analysis_store_get_object_type (cmd%element_id(i))
      select case (type)
        case (AN_HISTOGRAM)

```

```

        call drawing_options_init_histogram (drawing_options)
    case (AN_PLOT)
        call drawing_options_init_plot (drawing_options)
    end select
    call set_drawing_options (drawing_options, var_list)
    if (associated (cmd%el(i)%options)) then
        call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
    end if
    call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
end do
end subroutine cmd_graph_execute

```

Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
    type :: analysis_id_t
        type(string_t) :: tag
        type(parse_node_t), pointer :: pn_sexpr => null ()
    end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_analysis_t
        private
        type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
        ⟨Commands: cmd analysis: TBP⟩
    end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

⟨Commands: cmd analysis: TBP⟩≡
    procedure :: write => cmd_analysis_write

⟨Commands: procedures⟩+≡
    subroutine cmd_analysis_write (cmd, unit, indent)
        class(cmd_analysis_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)") "analysis: [defined]"
    end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd analysis: TBP⟩+≡
    procedure :: compile => cmd_analysis_compile

```

```

<Commands: procedures>+≡
  subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

<Commands: cmd analysis: TBP>+≡
  procedure :: execute => cmd_analysis_execute

<Commands: procedures>+≡
  subroutine cmd_analysis_execute (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%analysis_lexpr => cmd%pn_lexpr
  end subroutine cmd_analysis_execute

```

Write histograms and plots

The data type encapsulating the command:

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_write_analysis_t
  private
    type(analysis_id_t), dimension(:), allocatable :: id
    type(string_t), dimension(:), allocatable :: tag
  contains
    <Commands: cmd write analysis: TBP>
  end type cmd_write_analysis_t

```

Output. Just the keyword.

```

<Commands: cmd write analysis: TBP>≡
  procedure :: write => cmd_write_analysis_write

<Commands: procedures>+≡
  subroutine cmd_write_analysis_write (cmd, unit, indent)
    class(cmd_write_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "write_analysis"
  end subroutine cmd_write_analysis_write

```

Compile.

```

<Commands: cmd write analysis: TBP>+≡
  procedure :: compile => cmd_write_analysis_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_write_analysis_compile (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
  integer :: n, i
  pn_clause => parse_node_get_sub_ptr (cmd%pn)
  pn_args => parse_node_get_sub_ptr (pn_clause, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
  call cmd%compile_options (global)
  if (associated (pn_args)) then
    n = parse_node_get_n_sub (pn_args)
    allocate (cmd%id (n))
    do i = 1, n
      pn_id => parse_node_get_sub_ptr (pn_args, i)
      if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
        cmd%id(i)%tag = parse_node_get_string (pn_id)
      else
        cmd%id(i)%pn_sexpr => pn_id
      end if
    end do
  else
    allocate (cmd%id (0))
  end if
end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

⟨Commands: parameters⟩+≡
character(*), parameter, public :: &
  DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
character(len=1), dimension(2), parameter, public :: &
  FORBIDDEN_ENDINGS1 = [ "o", "a" ]
character(len=2), dimension(5), parameter, public :: &
  FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "lo", "la" ]
character(len=3), dimension(16), parameter, public :: &
  FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
    "f95", "log", "ltp", "mpx", "olc", "olp", "pdf", "phs", "sin", "tex" ]

```

As this contains a lot of similar code to `cmd.compile.analysis.execute` we outsource the main code to a subroutine.

```

⟨Commands: cmd write analysis: TBP⟩+≡
  procedure :: execute => cmd_write_analysis_execute

⟨Commands: procedures⟩+≡
subroutine cmd_write_analysis_execute (cmd, global)
  class(cmd_write_analysis_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  var_list => cmd%local%get_var_list_ptr ()
  call write_analysis_wrap (var_list, global%out_files, &
    cmd%id, tag = cmd%tag)
end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

(Commands: procedures)+≡

```

subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
  type(var_list_t), intent(inout), target :: var_list
  type(file_list_t), intent(inout), target :: out_files
  type(analysis_id_t), dimension(:), intent(in), target :: id
  type(string_t), dimension(:), allocatable, intent(out) :: tag

      else
        call file_list_write (global%out_files, file, string, advance)
      end if
    end if
  end subroutine cmd_printf_execute

```

Record data

The expression syntax already contains a `record` keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_record_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  ⟨Commands: cmd record: TBP⟩
  end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

⟨Commands: cmd record: TBP⟩≡
  procedure :: write => cmd_record_write

⟨Commands: procedures⟩+≡
  subroutine cmd_record_write (cmd, unit, indent)
    class(cmd_record_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u

```

```

    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "record"
end subroutine cmd_record_write

```

Compile. This is a hack which transforms the `record` command into a `record` expression, which we handle in the `expressions` module.

```

⟨Commands: cmd record: TBP⟩+≡
  procedure :: compile => cmd_record_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_record_compile (cmd, global)
    class(cmd_record_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

```

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

Note: for the integer/real range array, the obvious implementation as a polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are apparently broken.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_scan_t

  type(string_t) :: name
  integer :: n_values = 0
  type(parse_node_p), dimension(:), allocatable :: scan_cmd
  !!! !!! gfortran 4.7.x memory corruption

```

```

    !!! class(range_t), dimension(:), allocatable :: range
    type(range_int_t), dimension(:), allocatable :: range_int
    type(range_real_t), dimension(:), allocatable :: range_real
contains
  <Commands: cmd scan: TBP>
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

```

<Commands: cmd scan: TBP>≡
  procedure :: final => cmd_scan_final

<Commands: procedures>+≡
  recursive subroutine cmd_scan_final (cmd)
    class(cmd_scan_t), intent(inout) :: cmd

    write (u, "(1x,A,1x,A,1x,'(,IO,')')") "scan:", char (cmd%name), &
      cmd%n_values
  end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

```

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of **else if** constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_if_t
    private
    type(parse_node_t), pointer :: pn_if_lexpr => null ()
    type(command_list_t), pointer :: if_body => null ()
    type(cmd_if_t), dimension(:), pointer :: elsif_cmd => null ()
    type(command_list_t), pointer :: else_body => null ()
    contains
    <Commands: cmd if: TBP>
end type cmd_if_t

```

Finalizer. There are no local options, therefore we can simply override the default finalizer.

```

<Commands: cmd if: TBP>≡
    procedure :: final => cmd_if_final

<Commands: procedures>+≡
    recursive subroutine cmd_if_final (cmd)
        class(cmd_if_t), intent(inout) :: cmd
    end subroutine

```

```

integer :: i
if (associated (cmd%if_body)) then
  call command_list_final (cmd%if_body)
  deallocate (cmd%if_body)
end if
if (associated (cmd%elsif_cmd)) then
  do i = 1, size (cmd%elsif_cmd)
    call cmd_if_final (cmd%elsif_cmd(i))
  end do
  deallocate (cmd%elsif_cmd)
end if
if (associated (cmd%else_body)) then
  call command_list_final (cmd%else_body)
  deallocate (cmd%else_body)
end if
end subroutine cmd_if_final

```

Output. Recursively write the command lists.

```

⟨Commands: cmd if: TBP⟩+≡
  procedure :: write => cmd_if_write

⟨Commands: procedures⟩+≡
  subroutine cmd_if_write (cmd, unit, indent)
    class(cmd_if_t), intent(in) :: cmd

        end if
    end subroutine cmd_include_execute

```

Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```

<Commands: types>+≡

```

```

type, extends (command_t) :: cmd_quit_t
private
logical :: has_code = .false.
type(parse_node_t), pointer :: pn_code_expr => null ()
contains
  <Commands: cmd quit: TBP>
end type cmd_quit_t

```

Output.

```

<Commands: cmd quit: TBP>≡
  procedure :: write => cmd_quit_write

<Commands: procedures>+≡
  subroutine cmd_quit_write (cmd, unit, indent)
    class(cmd_quit_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,L1)") "quit: has_code = ", cmd%has_code
  end subroutine cmd_quit_write

```

Compile: allocate a quit object which serves as a placeholder.

```

<Commands: cmd quit: TBP>+≡
  procedure :: compile => cmd_quit_compile

<Commands: procedures>+≡
  subroutine cmd_quit_compile (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_arg
    pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
    if (associated (pn_arg)) then
      cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
      cmd%has_code = .true.
    end if
  end subroutine cmd_quit_compile

```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```

<Commands: cmd quit: TBP>+≡
  procedure :: execute => cmd_quit_execute

<Commands: procedures>+≡
  subroutine cmd_quit_execute (cmd, global)
    class(cmd_quit_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    logical :: is_known
    var_list => global%get_var_list_ptr ()
    if (cmd%has_code) then

```

```

        global%quit_code = eval_int (cmd%pn_code_expr, var_list, &
            is_known=is_known)
    if (.not. is_known) then
        call msg_error ("Undefined return code of quit/exit command")
    end if
end if
global%quit = .true.
end subroutine cmd_quit_execute

```

34.1.6 The command list

The command list holds a list of commands and relevant global data.

```

<Commands: public>+≡
    public :: command_list_t

<Commands: types>+≡
    type :: command_list_t
        ! not private anymore as required by the whizard-c-interface
        class(command_t), pointer :: first => null ()
        class(command_t), pointer :: last => null ()
    contains
        <Commands: command list: TBP>
    end type command_list_t

```

Output.

```

<Commands: command list: TBP>≡
    procedure :: write => command_list_write

<Commands: procedures>+≡
    recursive subroutine command_list_write (cmd_list, unit, indent)
        class(command_list_t), intent(in) :: cmd_list
        integer, intent(in), optional :: unit, indent
        class(command_t), pointer :: cmd
        cmd => cmd_list%first
        do while (associated (cmd))
            call cmd%write (unit, indent)
            cmd => cmd%next
        end do
    end subroutine command_list_write

```

Append a new command to the list and free the original pointer.

```

<Commands: command list: TBP>+≡
    procedure :: append => command_list_append

<Commands: procedures>+≡
    subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
        if (associated (cmd_list%last)) then
            cmd_list%last%next => command
        else
            cmd_list%first => command
        end if
    end subroutine command_list_append

```

```

end if
cmd_list%last => command
command => null ()
end subroutine command_list_append

```

Finalize.

```

<Commands: command list: TBP>+≡
  procedure :: final => command_list_final
<Commands: procedures>+≡
  recursive subroutine command_list_final (cmd_list)
    class(command_list_t), intent(inout) :: cmd_list
    class(command_t), pointer :: command
    do while (associated (cmd_list%first))
      command => cmd_list%first
      cmd_list%first => cmd_list%first%next
      call command%final ()
      deallocate (command)
    end do
    cmd_list%last => null ()
  end subroutine command_list_final

```

34.1.7 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```

<Commands: command list: TBP>+≡
  procedure :: compile => command_list_compile
<Commands: procedures>+≡
  recursive subroutine command_list_compile (cmd_list, pn, global)
    class(command_list_t), intent(inout), target :: cmd_list
    type(parse_node_t), intent(in), target :: pn
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_cmd
    class(command_t), pointer :: command
    integer :: i
    pn_cmd => parse_node_get_sub_ptr (pn)
    do i = 1, parse_node_get_n_sub (pn)
      call dispatch_command (command, pn_cmd)
      call command%compile (global)
      call cmd_list%append (command)
      call terminate_now_if_signal ()
      pn_cmd => parse_node_get_next_ptr (pn_cmd)
    end do
  end subroutine command_list_compile

```

34.1.8 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```

<Commands: command list: TBP>+≡
    procedure :: execute => command_list_execute

<Commands: procedures>+≡
    recursive subroutine command_list_execute (cmd_list, global)
        class(command_list_t), intent(in) :: cmd_list
        type(rt_data_t), intent(inout), target :: global
        class(command_t), pointer :: command
        command => cmd_list%first
        COMMAND_COND: do while (associated (command))
            call command%execute_options (global)
            call command%execute (global)
            call command%reset_options (global)
            call terminate_now_if_signal ()
            if (global%quit) exit COMMAND_COND
            command => command%next
        end do COMMAND_COND
    end subroutine command_list_execute

```

34.1.9 Command list syntax

```

<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

```

For this test, we invent a callback object which simply writes the analysis file, using the standard call for this. Here we rely on the fact that the analysis data are stored as a global entity, otherwise we would have to access them via the event object.

```

<Commands: test auxiliary types>≡
type, extends (event_callback_t) :: event_callback_34_t

```

```

    private
    integer :: u = 0
contains
    procedure :: write => event_callback_34_write
    procedure :: proc => event_callback_34
end type event_callback_34_t

```

The output routine is unused. The actual callback should write the analysis data to the output unit that we have injected into the callback object.

(Commands: test auxiliary)+≡

```

subroutine event_callback_34_write (event_callback, unit)
    class(event_callback_34_t), intent(in) :: event_callback
    integer, intent(in), optional :: unit
end subroutine event_callback_34_write

    save  
  
    contains  
  
    <WHIZARD: procedures>  
  
  end module whizard
```

34.2.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```
<WHIZARD: public>≡  
  public :: whizard_options_t  
  
<WHIZARD: types>≡  
  type :: whizard_options_t  
    type(string_t) :: preload_model  
    type(string_t) :: default_lib  
    type(string_t) :: preload_libraries  
    logical :: rebuild_library = .false.
```

```

        logical :: recompile_library = .false.
        logical :: rebuild_user
        logical :: rebuild_phs = .false.
        logical :: rebuild_grids = .false.
        logical :: rebuild_events = .false.
    end type whizard_options_t

```

34.2.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

<WHIZARD: types> +=
    type, extends (parse_tree_t) :: pt_entry_t
        type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the `last` pointer.

```

<WHIZARD: types> +=
    type :: pt_stack_t
        type(pt_entry_t), pointer :: last => null ()
        contains
            <WHIZARD: pt_stack: TBP>
    end type pt_stack_t

```

The finalizer is called at the very end.

```

<WHIZARD: pt_stack: TBP> =
    procedure :: final => pt_stack_final

<WHIZARD: procedures> =
    subroutine pt_stack_final (pt_stack)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(pt_entry_t), pointer :: current
        do while (associated (pt_stack%last))
            current => pt_stack%last
            pt_stack%last => current%previous
            call parse_tree_final (current%parse_tree_t)
            deallocate (current)
        end do
    end subroutine pt_stack_final

```

Create and push a new entry, keeping the previous ones.

```

<WHIZARD: pt_stack: TBP> +=
    procedure :: push => pt_stack_push

<WHIZARD: procedures> +=
    subroutine pt_stack_push (pt_stack, parse_tree)
        class(pt_stack_t), intent(inout) :: pt_stack
        type(parse_tree_t), intent(out), pointer :: parse_tree
        type(pt_entry_t), pointer :: current

```

```

allocate (current)
parse_tree => current%parse_tree_t
current%previous => pt_stack%last
pt_stack%last => current
end subroutine pt_stack_push

```

34.2.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a `WHIZARD` instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```

<WHIZARD: public>+≡
public :: whizard_t

<WHIZARD: types>+≡
type :: whizard_t
type(whizard_options_t) :: options
type(rt_data_t) :: global
type(pt_stack_t) :: pt_stack
contains
<WHIZARD: whizard: TBP>
end type whizard_t

```

34.2.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>≡
procedure :: init => whizard_init

<WHIZARD: procedures>+≡
subroutine whizard_init (whizard, options, paths, logfile)
class(whizard_t), intent(out), target :: whizard
type(whizard_options_t), intent(in) :: options
type(paths_t), intent(in), optional :: paths
type(string_t), intent(in), optional :: logfile
call init_syntax_tables ()
whizard%options = options
call whizard%global%global_init (paths, logfile)
call whizard%init_rebuild_flags ()
call whizard%preload_model ()
call whizard%preload_library ()
call whizard%global%init_fallback_model &
(var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))

```

```

        call whizard%global%init_radiation_model &
            (var_str ("SM_rad"), var_str ("SM_rad.mdl"))
    end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+=
    procedure :: final => whizard_final

<WHIZARD: procedures>+=
    subroutine whizard_final (whizard)
        class(whizard_t), intent(inout), target :: whizard
        call whizard%global%final ()
        call whizard%pt_stack%final ()
        !!! JRR: WK please check (#529)
        !    call user_code_final ()
        call final_syntax_tables ()
    end subroutine whizard_final

```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

```

<WHIZARD: whizard: TBP>+=
    procedure :: init_rebuild_flags => whizard_init_rebuild_flags

<WHIZARD: procedures>+=
    subroutine whizard_init_rebuild_flags (whizard)
        class(whizard_t), intent(inout), target :: whizard
        associate (var_list => whizard%global%var_list, options => whizard%options)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_library"), options%rebuild_library, &
                    intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?recompile_library"), &
                    options%recompile_library, &
                    intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_phase_space"), options%rebuild_phs, &
                    intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_grids"), options%rebuild_grids, &
                    intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?powheg_rebuild_grids"), options%rebuild_grids, &
                    intrinsic=.true.)
            call var_list_append_log &
                (var_list, var_str ("?rebuild_events"), options%rebuild_events, &
                    intrinsic=.true.)
        end associate
    end subroutine whizard_init_rebuild_flags

```

This procedure preloads a model, if a model name is given.

```

<WHIZARD: whizard: TBP>+=
    procedure :: preload_model => whizard_preload_model

```

```

{WHIZARD: procedures}+=
subroutine whizard_preload_model (whizard)
  class(whizard_t), intent(inout), target :: whizard
  type(string_t) :: model_name
  model_name = whizard%options%preload_model
  if (model_name /= "") then

    allocate (lib_entry)
    call lib_entry%init (whizard%options%default_lib)
    call whizard%global%add_prclib (lib_entry)
    call msg_message ("Preloaded library: " // &
      char (whizard%options%default_lib))
  end if
SCAN_LIBS: do while (libs /= "")
  call split (libs, library_name, " ")
  if (library_name /= "") then
    allocate (lib_entry)
    call lib_entry%init (library_name)
    call whizard%global%add_prclib (lib_entry)
  end if
end do

```

```

        call msg_message ("Preloaded library: " // char (library_name))
    end if
end do SCAN_LIBS
end subroutine whizard_preload_library

```

34.2.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

```

<WHIZARD: public>+≡
    public :: init_syntax_tables
    public :: final_syntax_tables

<WHIZARD: procedures>+≡
    subroutine init_syntax_tables ()
        call syntax_model_file_init ()
        call syntax_phs_forest_init ()
        call syntax_pexpr_init ()
        call syntax_slha_init ()
        call syntax_cmd_list_init ()
    end subroutine init_syntax_tables

    subroutine final_syntax_tables ()
        call syntax_model_file_final ()
        call syntax_phs_forest_final ()
        call syntax_pexpr_final ()
        call syntax_slha_final ()
        call syntax_cmd_list_final ()
    end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
    public :: write_syntax_tables

<WHIZARD: procedures>+≡
    subroutine write_syntax_tables ()
        integer :: unit
        character(*), parameter :: file_model = "whizard.model_file.syntax"
        character(*), parameter :: file_phs = "whizard.phase_space_file.syntax"
        character(*), parameter :: file_pexpr = "whizard.prt_expressions.syntax"
        character(*), parameter :: file_slha = "whizard.slha.syntax"
        character(*), parameter :: file_sindarin = "whizard.sindarin.syntax"
        unit = free_unit ()
        print *, "Writing file '" // file_model // "'"
        open (unit=unit, file=file_model, status="replace", action="write")

```

```

write (unit, "(A)")  VERSION_STRING
write (unit, "(A)")  "Syntax definition file: " // file_model
call syntax_model_file_write (unit)
close (unit)
print *, "Writing file '" // file_phs // "'"

write (unit, "(A)")  "Syntax definition file: " // file_sindarin
call syntax_cmd_list_write (unit)
close (unit)
end subroutine write_syntax_tables

```

34.2.6 Execute command lists

Process commands given on the command line, stored as an `ifile`. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
  procedure :: process_ifile => whizard_process_ifile

<WHIZARD: procedures>+≡
  subroutine whizard_process_ifile (whizard, ifile, quit, quit_code)
    class(whizard_t), intent(inout), target :: whizard
    type(ifile_t), intent(in) :: ifile
    logical, intent(out) :: quit
    integer, intent(out) :: quit_code
    type(lexer_t), target :: lexer
    type(stream_t), target :: stream
    call msg_message ("Reading commands given on the command line")
    call lexer_init_cmd_list (lexer)
    call stream_init (stream, ifile)
    call whizard%process_stream (stream, lexer, quit, quit_code)
    call stream_final (stream)
    call lexer_final (lexer)
  end subroutine whizard_process_ifile

```

Process standard input as a command list. The whole input is read, compiled and executed as a whole.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: process_stdin => whizard_process_stdin
<WHIZARD: procedures>+≡
    subroutine whizard_process_stdin (whizard, quit, quit_code)
        class(whizard_t), intent(inout), target :: whizard
        logical, intent(out) :: quit
        integer, intent(out) :: quit_code
        type(lexer_t), target :: lexer
        type(stream_t), target :: stream
        call msg_message ("Reading commands from standard input")
        call lexer_init_cmd_list (lexer)
        call stream_init (stream, 5)
        call whizard%process_stream (stream, lexer, quit, quit_code)
        call stream_final (stream)
        call lexer_final (lexer)
    end subroutine whizard_process_stdin

```

Process a file as a command list.

```

<WHIZARD: whizard: TBP>+≡
    procedure :: process_file => whizard_process_file
<WHIZARD: procedures>+≡
    subroutine whizard_process_file (whizard, file, quit, quit_code)
        class(whizard_t), intent(inout), target :: whizard
        type(string_t), intent(in) :: file
        logical, intent(out) :: quit
        integer, intent(out) :: quit_code

34.5 Driver program

The main program handles command options, initializes the environment, and runs WHIZARD in a particular mode (interactive, file, standard input).

This is also used in the C interface:

```
<Main: cmdline arg len declaration>≡  
integer, parameter :: CMDLINE_ARG_LEN = 1000
```

The actual main program:

```
<main.f90>≡  
<File header>  
  
program main  
  
<Use strings>  
use unit_tests  
use system_dependencies  
use diagnostics  
use ifiles  
use os_interface  
use whizard  
  
use cmdline_options  
use features  
  
implicit none  
  
<Main: cmdline arg len declaration>

```

34.6.1 Self-tests

For those self-tests, we need some auxiliary routines that provide an environment. The environment depends on things that are not available at the level of the module that we want to test.

Testbed for event I/O

This subroutine prepares a test process with a single event. All objects are allocated via anonymous pointers, because we want to recover the pointers and delete the objects in a separate procedure.

```

<Main: tests>≡
    subroutine prepare_eio_test (event, unweighted, n_alt)
        use variables
        use model_data
        use process, only: process_t
        use instances, only: process_instance_t
        use processes_ut, only: prepare_test_process
        use event_base
        use events

        class(generic_event_t), intent(inout), pointer :: event
        logical, intent(in), optional :: unweighted
        integer, intent(in), optional :: n_alt
        type(model_data_t), pointer :: model

```

```

type(var_list_t) :: var_list
type(process_t), pointer :: proc
type(process_instance_t), pointer :: process_instance

allocate (model)
call model%init_test ()

allocate (proc)
allocate (process_instance)

call prepare_test_process (proc, process_instance, model)
call process_instance%setup_event_data ()

call model%final ()
deallocate (model)

allocate (event_t :: event)
select type (event)
type is (event_t)
  if (present (unweighted)) then
    call var_list_append_log (var_list, &
      var_str ("?unweighted"), unweighted, &
      intrinsic = .true.)
  else
    call var_list_append_log (var_list, &
      var_str ("?unweighted"), .true., &
      intrinsic = .true.)
  end if
  call var_list_append_string (var_list, &
    var_str ("sample_normalization"), &
    var_str ("auto"), intrinsic = .true.)
  call event%basic_init (var_list, n_alt)
  call event%connect (process_instance, proc%get_model_ptr ())
  call var_list%final ()
end select

end subroutine prepare_eio_test

```

Recover those pointers, finalize the objects and deallocate.

(Main: tests)+≡

```

subroutine cleanup_eio_test (event)
  use model_data
  use process, only: process_t
  use instances, only: process_instance_t
  use processes_ut, only: cleanup_test_process
  use event_base
  use events

  class(generic_event_t), intent(inout), pointer :: event
  type(process_t), pointer :: proc
  type(process_instance_t), pointer :: process_instance

  select type (event)
  type is (event_t)

```

```

        proc => event%get_process_ptr ()
        process_instance => event%get_process_instance_ptr ()
        call cleanup_test_process (proc, process_instance)
        deallocate (process_instance)
        deallocate (proc)
        call event%final ()
    end select
    deallocate (event)

end subroutine cleanup_eio_test

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

<Main: use tests>≡
    use eio_base_ut, only: eio_prepare_test
    use eio_base_ut, only: eio_cleanup_test

<Main: prepare testbed>≡
    eio_prepare_test => prepare_eio_test
    eio_cleanup_test => cleanup_eio_test

```

Any Model

This procedure reads any model from file and, optionally, assigns a var-list pointer.

```

<Main: tests>+≡
    subroutine prepare_whizard_model (model, name, vars)
    <Use strings>
        use os_interface
        use model_data
        use var_base
        use models
        class(model_data_t), intent(inout), pointer :: model
        type(string_t), intent(in) :: name
        class(vars_t), pointer, intent(out), optional :: vars
        type(os_data_t) :: os_data
        call syntax_model_file_init ()
        call os_data_init (os_data)
        allocate (model_t :: model)
        select type (model)
        type is (model_t)
            call model%read (name // ".mdl", os_data)
            if (present (vars)) then
                vars => model%get_var_list_ptr ()
            end if
        end select
    end subroutine prepare_whizard_model

```

Cleanup after use. Includes deletion of the model-file syntax.

```

<Main: tests>+≡
    subroutine cleanup_whizard_model (model)
        use model_data
        use models

```

```

class(model_data_t), intent(inout), pointer :: model
call model%final ()
deallocate (model)
call syntax_model_file_final ()
end subroutine cleanup_whizard_model

```

Assign those procedures to appropriate pointers (module variables) in the `model_testbed` module, so they can be called as if they were module procedures.

```

(Main: prepare_testbed)+≡
prepare_model => prepare_whizard_model
cleanup_model => cleanup_whizard_model

```

Fallback model: hadrons

Some event format tests require the hadronic SM implementation, which has to be read from file. We provide the functionality here, so the tests do not depend on model I/O.

```

(Main: tests)+≡
subroutine prepare_fallback_model (model)
use model_data
class(model_data_t), intent(inout), pointer :: model
call prepare_whizard_model (model, var_str ("SM_hadrons"))
end subroutine prepare_fallback_model

```

Assign those procedures to appropriate pointers (module variables) in the `eio_base` module, so they can be called as if they were module procedures.

```

(Main: use_tests)+≡
use eio_base_ut, only: eio_prepare_fallback_model
use eio_base_ut, only: eio_cleanup_fallback_model

(Main: prepare_testbed)+≡
eio_prepare_fallback_model => prepare_fallback_model
eio_cleanup_fallback_model => cleanup_model

```

Access to the test random-number generator

This generator is not normally available for the dispatcher. We assign an additional dispatch routine to the hook in the `dispatch` module which will be checked before the default rule.

```

(Main: use_tests)+≡
use dispatch_rng, only: dispatch_rng_factory_extra
use dispatch_ut, only: dispatch_rng_factory_test

(Main: prepare_testbed)+≡
dispatch_rng_factory_extra => dispatch_rng_factory_test

```

Access to the test structure functions

These are not normally available for the dispatcher. We assign an additional dispatch routine to the hook in the `dispatch` module which will be checked before the default rule.

```

(Main: use_tests)+≡

```

```

    use dispatch_beams, only: dispatch_sf_data_extra
    use dispatch_ut, only: dispatch_sf_data_test
<Main: prepare testbed>+≡
    dispatch_sf_data_extra => dispatch_sf_data_test

```

Procedure for Checking

This is for developers only, but needs a well-defined interface.

```

<Main: tests>+≡
    subroutine whizard_check (check, results)

        type(string_t), intent(in) :: check
        type(test_results_t), intent(inout) :: results
        type(os_data_t) :: os_data
        integer :: u

        call os_data_init (os_data)
        u = free_unit ()
        open (u, file="whizard_check." // char (check) // ".log", &
             action="write", status="replace")
        call msg_message (repeat ('=', 76), 0)
        call msg_message ("Running self-test: " // char (check), 0)
        call msg_message (repeat ('-', 76), 0)
<Main: prepare testbed>
        select case (char (check))
<Main: test cases>
        case ("all")
            <Main: all tests>
        case default
            call msg_fatal ("Self-test '" // char (check) // "' not implemented.")
        end select
        close (u)
    end subroutine whizard_check
